One of the problems of present-day medicine is to dra a just line in the diagnosis of disease between the clinicia and the pathologist, between the hospital ward and th laboratory. It is most desirable that a fair balance shou be maintained, and that there should be rational a sympathetic co-operation. The pathologist has not th first-hand knowledge of disease in the living subject whi is so important. Dead-house appearances represent t late results of disease, not its origin or course. On t other hand, the clinician cannot hope to keep pace wi the rapidly developing and ever-increasing complexity modern pathological technique, though he may aspire understand its methods and appraise its results. His sk in these matters, occasionally exercised, cannot compa with that of the man to whom they are a daily routin In such matters as the examination of the sputum, t Widal test for typhoid fever, or the Wassermann test syphilis, the laboratory can give us inestimable aid. B I would plead that in the last resort diagnosis is t business of the clinician, and that the final test is bedsi experience. While we examine blood, sputum, urin gastric contents, cerebro-spinal fluid, etc., let us not forg to examine the patient. The old physicians who had n even a stethoscope or a clinical thermometer—not mention an ophthalmoscope, laryngoscope, gastrosco sphygmomanometer, polygraph, electro-cardiograph—we often extraordinarily shrewd judges of disease. Ev Hippocrates may still be read with profit, and with chastened sense that after more than 2,000 yea of the triumphant march of medical science he m still be able to teach us something. His first fam aphorism is familiar to us all, but will bear repetiti "Life is short; the art is long; occasion sudden: make experiments dangerous; judgement difficult. Neith is it sufficient that the physician do his office unless patient and his attendants do their duty, and that extern are likewise well ordered." Perhaps his thirteenth aphori is less familiar. It runs as follows: "Old men eas endure fasting, those who are middle-aged not so w young men worse again than they, and children wo of all, especially those who are of a more lively spir These echoes from the great age of Greece still str the ear pleasantly, reminding us that medical insi t is not the exclusive property of the moderns. And the English Hippocrates—Sydenham—is not yet wh obsolete. To come nearer home, Graves on Fevers a Stokes on the Heart may still stimulate our min and make us proud of Irish medicine. Their pathol may need revision, but their clinical insight was ra at fault.

You will remember that the first great aphorism Hippocrates affirms that it is not sufficient for the physic to do his part, that the patient also has a duty to perfo In this matter of early diagnosis we are largely depend upon the intelligence of the public. We cannot ad until we are consulted. We cannot detect the sub premonitions of disease if these are disregarded by patient. I hold it our duty to inculcate a timely wa fulness—quite distinct from fussy anxiety—in mat pertaining to health. And in these matters the consult needs the aid of the general practitioner, who is usu the first to have cognizance of the facts.

Obsta principiis is a very old and, I think, a v excellent medical maxim. The medical practitione is too often in the position of the foolish virgins in

parable—he arrives too late. But the responsibility is not usually his.

I submit these considerations—most of them familiar and obvious—to your judgement, believing, as I do, that in the early recognition of disease and the prompt adoption of remedial measures lies the secret of much of the efficacy of our art.

ACUTE APPENDICITIS AND ACUTE APPENDICULAR OBSTRUCTION.*

[WITH COLOURED PLATE.]

BY D. P. D. WILKIE, CH.M., F.R.C.S.,

ASSISTANT SURGEON, EDINBURGH ROYAL INFIRMARY, AND LEITH HOSPITAL.

MOST medical men are now agreed that for acute appendicular trouble the only safe course is immediate operation. If this be granted, the all-important matter is the accurate diagnosis of such trouble in its early stages. Reliable diagnosis can only be based on a clear understanding of the pathology of the early stages of acute appendicular trouble, and it is as a contribution to this part of the subject that I would lay before you certain facts.

When we find that patients suffering from acute appendicular disease present during the early stages of such trouble symptoms differing widely, the natural presumption is that the morbid processes responsible for such symptoms also differ. The mere fact that all eventually tend toward a dangerous peritoneal infection is not sufficient reason to class them all under the one generic term "appendicitis."

The appendix as part of the intestinal canal is liable to certain pathological changes. From its structure and relations it is specially liable to be the seat of ulceration and inflammation, but as a hollow viscus it is also liable to acute obstruction of its lumen. Now whilst blockage of the lumen of the appendix has been regarded by many pathologists and surgeons as an important contributing factor in the etiology and in determining the course of appendicitis, acute appendicular obstruction as a distinct pathological and clinical entity has not been recognized or given the attention which its importance demands.

Benda,[1] Klauber,[2] and recently Heile have all laid stress on the obstructive factor in appendicitis, but have not clearly differentiated between the two conditions, primary inflammation and primary obstruction, as clinical entities. If we set out by recognizing two definite types of acute disease of the appendix—namely, acute inflammation and acute obstruction—then not only does the understanding and the teaching of the symptomatology of acute appendicular disease become much simplified, but the early diagnosis of such disease becomes inevitably more confident and more correct.

Some years ago, when it was customary for surgeons to have to deal with the secondary effects of acute appendicular trouble, this distinction between inflammation and obstruction was impossible; now, however, we should have to deal with the primary appendicular disease when the distinction is tolerably easy and all-important.

It is difficult to realize and still more difficult to teach that we may have an acute inflammation of an organ without any rise of pulse or temperature, and yet it has been necessary to recognize this in the case of appendicitis.

So far as my observations go they indicate that we never meet with a primary acute inflammation of the appendix without a prompt rise of both pulse and temperature. It is the rule, however, in cases of acute appendicular obstruction to have at the outset no appreciable rise of pulse or temperature, and it is ignorance of these important negative signs which has so often led to fatal delay. We must recognize that if acute appendicitis is a serious condition, acute appendicular obstruction is usually more serious, and is the one in which the call for immediate operation is more clamant.

* The experimental work referred to in this paper was carried out in the laboratory of the Royal College of Physicians, Edinburgh. The expenses of this research were defrayed in part by a grant from the Carnegie Trust.

The essential distinctions between the two conditions may perhaps be best emphasized by two illustrative cases.

CASE I.—*Acute Appendicitis.*

A. H., female, aged 31, had felt out of sorts for two days, and on the evening of the second day she began to have pain in the right side of the abdomen and vomited. She went to bed, and her doctor was called in the same evening. He found her looking flushed but not very ill, with a temperature of 100° F. and pulse of 94. There was some tenderness and rigidity in the right lower quadrant of the abdomen. Hot fomentations were applied, and trional gr.10 given by mouth. Seen early on the following morning, the patient was found to have slept little, was still flushed, temperature 100.5°, pulse 100, whilst the tenderness and rigidity in the right iliac region were more pronounced. Operation was advised, and was carried out in hospital two hours later. Some turbid fluid was found free in the abdomen; a considerably thickened, red, and inflamed appendix was removed, along with an inflamed and adherent portion of omentum. On splitting the appendix its walls were found greatly thickened and oedematous, the mucous lining was turgid, and in two places ulcerated and covered by a layer of muco-pus (see Fig. 1).

CASE II.—*Acute Appendicular Obstruction.*

M. H., male, aged 30, on returning home from a football match was suddenly seized with acute abdominal pain which doubled him up, and he vomited. After lying down for half an hour the pain had almost completely passed off, and he accompanied a friend to the railway station, a mile away. Whilst there he was again seized with acute griping pain, and vomited several times. He came home in a cab and lay down, but the pain continued very severe. At 8 p.m. the doctor was called in. He found the patient suffering acutely from pain in the umbilical region, the abdominal muscles were rigid, more especially on the right side, and there was marked tenderness at a point midway between McBurney's point and the umbilicus; pulse 80, temperature 98°. Heat was applied to the abdomen, and the doctor returned in two hours. The patient had meanwhile had an hour's relief, but was again suffering acute pain; the abdomen was still tender and rigid, whilst the pulse and temperature were normal. A surgeon was called in an hour later, when, as the patient's condition was unchanged, operation was decided on.

The abdomen was opened at 2 a.m.—that is, nine hours after the onset of symptoms. A large distended appendix, green in colour and with a faeculent odour, was delivered through the wound. The proximal half inch of the appendix appeared normal, then there was a slight constriction, and beyond this the organ was three times its normal diameter, tense almost to bursting, and stippled with little yellow areas of focal necrosis on a ground of dark green. The appendix was removed, and the patient did well. On opening the appendix it was found that the distended portion contained faeculent material under great tension, a concretion having become impacted in the constriction, causing an acute obstruction. Apparently the course of events in this case had been that a preceding unrecognized attack of appendicitis had resulted in a constriction, and beyond this a concretion had formed. Then, probably as the result of straining at the football match, some faecal matter had been forced into the appendix beyond the stenosed area, and had been locked up there by the ball valve action of the concretion.

SYMPTOMS OF ACUTE APPENDICULAR OBSTRUCTION.

The first and essential symptom is pain, which as a rule comes on suddenly, is very acute, and is most pronounced in the umbilical region. The pain may be intermittent as in the case cited above, but not infrequently it is constant, though becoming worse at times. Vomiting is usual, but not invariable. Tenderness over the appendix is always present in greater or less degree, and rigidity of the right rectus is usually well marked, though in some cases it may be deceptively slight. The pulse and temperature are of no diagnostic value, for though both may rise within a few hours of the onset of the obstruction, this is not the rule, and when present is usually an indication of a spread of infection through the devitalized wall of the obstructed organ. Obstruction of the appendix does not necessarily produce a reflex paresis of the intestine, and thus the bowels may act even though rapid changes are taking place in the appendicular walls. The distinctive

features of obstruction as contrasted with primary inflammation of the appendix may be briefly stated as the great severity of the pain, the suddenness of its onset, and the absence of disturbance of the pulse and temperature during the initial stages of the malady.

CAUSES OF APPENDICULAR OBSTRUCTION.

The two common causes of acute appendicular obstruction are:

1. Fibrous stenosis of the appendix with plugging of the constriction.
2. Acute kinking of the appendix at a point of abnormal fixation by a band or fold, congenital or acquired.

In the former there has almost certainly been a preceding though possibly unrecognized attack of appendicitis, faecal matter has gained access to the lumen distal to the constriction and the narrowed outlet has become occluded either by inspissated faeces or by a definite hard concretion. A second attack of inflammation in the region of the stricture may rapidly cause occlusion of the lumen at this point and give the composite picture of acute appendicitis and acute appendicular obstruction—undoubtedly a common combination, but by no means an essential one.

Abnormal fixation of the appendix at some point by a band or fold is a very common cause of obstruction. Such a band may be an old inflammatory adhesion the bequest of a preceding attack of appendicitis. In my experience, however, it has more commonly been a congenital fold attached about the middle of the appendix, fixing this part down toward the pelvis. This fold is almost certainly the genito-mesenteric fold described by Douglas Reid.[3] Occasionally the kink is due to a fold tacking some point of the appendix upwards. Some of these folds would appear to be congenital, others, associated with a prolapsed caecum, to be the acquired bands described by Lane as the crystallization of lines of force.

In all these varieties, however, the attack of acute obstruction is probably excited by access of faecal matter to the distal part of the appendix beyond the kink. The slight obstruction at the seat of angulation causes reaction in the distal portion of the appendix and the swelling associated with this rapidly accentuates the kink and renders the obstruction complete.

The access of faecal matter to the lumen of the appendix distal to a stenosis or kink is in all probability frequently determined by strain or other traumatic influence. Kelly[4] noted that trauma, especially indirect injury, was a somewhat frequent cause of acute appendicular trouble where previous disease in the appendix existed. The cases of acute appendicular trouble supervening on an acute intestinal disorder with diarrhoea may be, and almost certainly are, sometimes due to an inflammation in the wall of the caecum, either spreading to or occluding the opening of the appendix, but not infrequently the caecum shows no inflammatory change, and the disease is limited to the appendix. In the latter type of case a concretion is usually found beyond a constriction, and, as Benda has suggested, the probable exciting factor in the attack has been that the enhanced peristalsis of the intestine being shared by the appendix has resulted in the driving of the concretion into the narrowed part, with complete obstruction of the lumen.

RESULTS OF OBSTRUCTION OF THE APPENDIX.

We must now consider the results following a complete obstruction of the lumen of the appendix near its outlet. These can only be ascertained from a study of the combined data of experimental and clinical observation.

Experimental Evidence.—The following experiments were designed to test what was the effect of isolating a portion of bowel such as the appendix, outwith the prima via, under various conditions as regards content. The experiments were carried out on cats, and the terminal portion of the ileum, which contains a large amount of lymphoid tissue in its wall, was used to make an artificial obstructed appendix. The operative procedure was as follows: under ether anaesthesia the abdomen was opened and the caecum and lowest part of the ileum brought out. By means of the thermo-cautery the ileum was divided 5 in. from the ileo-caecal valve, and the cut ends invaginated. Some caecal content was forced through the ileo-caecal valve into the blind lower part of the ileum, which was then cut through with the cautery one inch from the ileo-caecal valve, the cut ends being invaginated. The continuity of the bowel was then established by a lateral anastomosis of the ileum above the upper line of section with the ascending colon. Using such a closed loop of ileum, the following points were then investigated:

Behaviour of:

1. Empty loop—that is, empty except for mucus and bacteria.
2. Loop filled with caecal content (animal on carbohydrate diet).
3. Loop filled with caecal content (animal on rich protein diet.)
4. Loop filled with emulsion of bacteria grown from caecal content.

1. After isolation of an empty loop the animal appears well for a period of days at least, and if killed three days after the operation the loop is found to be slightly enlarged and congested, and to contain mucoid fluid. As a rule the loop gradually distends, the content becomes muco-purulent, and eventually a perforation occurs, but occasionally the bacteria die off, and the animal remains in good health with a mucocele of the loop (Fig. 2).

2. When the loop is filled moderately full with caecal content, the animal having been fed on a carbohydrate diet (porridge), distension occurs more rapidly with fetid faeculo-purulent fluid, and either an empyema of the loop results or a gangrenous patch develops with perforation. The latter course is particularly liable to occur if the loop has been almost completely filled with caecal content or if the animal has been on a carbohydrate diet for only one or two days, the latter fact indicating that probably an alteration in the bacterial flora plays an important contributing rôle.

3. With the loop filled with caecal content in an animal previously fed on a rich protein diet (lights) the changes are much more striking and as a rule the animal is dead within twenty hours. On opening the abdomen *post mortem* the loop is seen to be green and gangrenous (Fig. 4), glued to neighbouring coils of intestine by plastic lymph and giving off a faeculent odour. On opening the loop, foul brown fluid content escapes, and this is found to be strongly alkaline in reaction. In an animal killed before this complete sloughing of the wall has had time to occur gangrene is seen to be most advanced in the Peyer's patches. If the loop be only partially filled with content, the changes are slower in developing, but are practically the same.

4. When the loop is filled with an emulsion of bacteria grown aërobically from caecal content no early changes are seen, and if the animal be killed forty-eight hours later the loop presents an almost normal appearance and shows no signs of inflammation or gangrene.

After observing a long series of such experiments one is profoundly impressed with the rapid morbid changes which ensue when faecal matter is locked up in an isolated portion of the intestinal tract. That complete gangrene of such a segment may occur within sixteen hours without there being any interference with the blood supply of the part is a striking fact, which throws considerable light on those cases in which a completely gangrenous appendix is found without there having been any

appreciable disturbance of pulse or temperature. The importance of anaërobic putrefactive bacteria in such cases has been demonstrated by Heile.

Apparently the two factors determining the degree and the rapidity of the morbid changes in the isolated loop are, first, the amount of faecal matter, and, secondly, its nature as determined by the previous feeding of the animal. If the loop be completely filled with faecal matter at the moment of obstruction, rapid changes, culminating in gangrene, are apt to result no matter what be the nature of the content, though they are more rapid and striking after protein feeding.

When the loop is only partially filled, the changes which follow show more clearly the effects of the nature of the content, those in the protein-fed animals being more of the gangrenous putrefactive type, those in the carbohydrate-fed animals more of the slower empyemic type.

Heile,[5] in his work on experimental appendicitis in the dog, has reached practically the same conclusions. He found that when the appendix in the dog was occluded, the degree and rapidity of the morbid changes which followed were in direct proportion to the amount of faecal matter present. He was also impressed by the importance of the presence of undigested protein and an alkaline reaction in favouring early necrotic changes, and was able to show that autolysis of the lymphoid tissue of the appendix is greatly hastened by an alkaline reaction of the fluid in which it is placed.

Comparable Conditions in Human Appendix.

In a study of the morbid anatomy of the human appendix we can readily distinguish types of appendicular obstruction strictly comparable to the types of morbid change produced experimentally in the artificially obstructed appendix in the cat.

The hydrops cysticus or mucocele of the appendix represents the result of a complete obstruction of a practically empty appendix, the bacteria having died off and allowed of the development of the quiet mucous cyst (Fig. 5).

In empyema of the appendix (Fig. 6) we see the result of an obstruction to the appendicular lumen when a certain amount of faecal matter, probably not rich in protein, was present. As we know, empyema of the appendix may be fairly acute and rapid or subacute and slow in its development, depending almost certainly on the nature of the faecal content, both as regards chemical and bacteriological constitution and the consequent reaction which it induces.

In those cases of rapid distension and gangrene of the appendix which form so large a percentage of the fatal cases we have the replica of the condition of the artificial appendix filled with caecal content after protein feeding (Fig. 7). In such cases the early changes are: distension of the lumen of the appendix, leucocytic infiltration of the wall followed by gangrene first of the lymphoid tissue and then of the remaining structure of the wall, the whole process, which is of a putrefactive nature, occurring in a space of time to be measured by hours.

I would maintain, therefore, that acute obstruction of the appendix is a pathological and clinical entity, a form of intestinal obstruction, presenting always a grave risk to the life of the individual affected, unless immediate surgical measures are taken for its relief, and that it should be distinguished from acute inflammation of the appendix, not because the treatment of the two conditions should differ, but because the obstructive cases demand treatment before the signs of inflammation supervene. When this distinction is borne in mind it is possible in quite a large percentage of cases to foretell before operation what approximately will be the condition of the appendix. I heartily agree with Battle[6] that such diagnosis is not mere guesswork and is both interesting and profitable in that it inevitably tends to more accurate observation and hence to increasingly accurate diagnosis.

INCIDENCE OF ACUTE APPENDICULAR DISEASE.

The above observations may possibly throw some light on the incidence of acute appendicular disease.

Race Incidence.

The remarkable frequency of appendicular disease in its acute and fatal form among Western nations and its comparative rarity among Eastern peoples has attracted considerable attention. Lucas-Championnière,[7] in an analysis of 22,000 patients among Roumanian peasants, found only 1 case of appendicitis. In the cities of Roumania, on the other hand, he found 1 case of appendicitis among every 221 patients. The Roumanian peasants subsist on a diet almost wholly vegetarian, whereas in the cities an animal diet is the rule. Naab[8] found in three hospitals in Asiatic Turkey, staffed by German surgeons, that operations for appendicitis amounted to only 0.1 per cent. of the total major operations. In Constantinople, at the Turkish hospital, staffed by German surgeons, the ratio of appendix operations was 0.3 per cent., whereas at the German hospital in the European quarter of the same city the ratio was 3.3 per cent. Here difference in climatic conditions could be ruled out, the only difference between the two classes of patients being that those admitted to the Turkish hospital subsisted on a diet mainly of fruit and vegetables, those to the German hospital on a mixed diet with a considerable proportion of animal food. In two large hospitals in Hamburg and Berlin the average ratio was 8.5 per cent. of the total major operations. In Germany, also, it has been repeatedly noted that appendicitis is relatively much more frequently met with among town dwellers than among the peasant class, and that its frequency has notably increased in the last few years coincidently with the increased consumption of meat by the working class. Now whilst one must be very careful in drawing conclusions where accurate statistical evidence is so difficult to obtain, I think all will agree that appendicitis among the working classes in this country has increased of late years, that this is not merely due to greater accuracy in diagnosis, and that this increase has been coincident with the rise of wages and the increasing demand for an animal diet among the industrial class.

Sex Incidence.

All statistics on acute appendicular disease agree in showing that such disease is more frequent in the male than in the female sex, the average ratio being 4 to 3. A fact of greater importance, however, and one not usually recognized, is the greater frequence of the severe and, if not promptly treated, fatal type of such disease in the male as compared with the female. On examining the statistics of the Edinburgh Royal Infirmary for the three years from October, 1910, to September, 1913, I found that during this period 1,469 cases of acute appendicular disease were treated in that institution, the mortality being 7.3 per cent. Of this number, 840 (57 per cent.) were males, 629 (43 per cent.) were females. There were 81 deaths among the male cases (9.6 per cent.), and but 26 among the females (4.1 per cent.). It would thus appear that acute appendicular disease is more than twice as fatal in the male as in the female. On examining the records of the fatal cases one was struck by the great frequency of a particular type of case in the males—namely, that with a completely gangrenous and perforated appendix and diffuse peritonitis; in fact, by the number of cases of what I regard as the most acute form of appendicular obstruction. There are two factors which I think may determine the greater frequency of such disease in the male sex: First, the adolescent and young adult male partakes of a diet which is considerably richer in protein than does the female of corresponding age; and, secondly, he is more exposed to strain and injury, such as might determine the entrance of faecal matter to an appendix with a stenosis or kink near its proximal end.

The mild and usually unrecognized attacks of appendicitis which leave merely scarring and fibrosis in the appendix would appear from *post-mortem* statistics to be very frequent in both sexes of all nations. The urgent gangrenous type of acute appendicular disease which my observations indicate to be of the nature of acute appendicular obstruction is a disease of meat-eating nations, and is more frequent in the male sex. If such be the case, then we are justified in the inference that in a bulky and mainly vegetable diet lies the chief safeguard against acute appendicular disease in its most severe and dangerous forms.

Age Incidence.

The comparative rarity of severe appendicular trouble in children during the first few years of life may possibly be explained by the relatively wide and frequently funnel-shaped aperture of the appendix at this period, allowing of the ready entrance and exit of faecal matter. The corresponding, though less marked, rarity of such trouble in old people is accounted for by the pronounced fibrotic changes so commonly seen in senile appendices, changes which, according to Aschoff,[9] represent previous mild attacks of inflammation, and which, as a rule, altogether preclude the entrance of faecal matter. In the intervening ago period, particularly that earlier part of it which might be termed the period of physical activity and dietary indiscretion, the anatomical condition of the appendix predisposes it to acute morbid changes of both inflammatory and obstructive types.

CONCLUSIONS.

1. Two acute pathological processes are met with in the vermiform appendix—acute appendicitis and acute appendicular obstruction.

2. Clinically acute appendicitis is distinguished by the signs of inflammation, there being from the onset a rise in pulse and temperature.

Acute appendicular obstruction gives rise to vomiting, colicky pain, and abdominal tenderness, but at the outset to no appreciable rise in pulse or temperature.

3. The changes occurring in an appendix the lumen of which is completely obstructed depend on the presence or absence of faecal matter within its lumen.

4. In experimental obstruction in an artificial appendix the changes vary greatly according to the nature of the diet of the animal previous to the experiment, rich protein diet being associated with much more rapidly destructive changes than carbohydrate.

5. Undigested protein, putrefactive bacteria, and an alkaline reaction together produce rapid gangrene in the walls of the obstructed organ.

6. The prevalence of the severer forms of acute appendicular disease in Western as contrasted with Eastern peoples is probably to be explained by the animal diet indulged in by the former.

7. On the same lines may be explained the increasing frequency of such disease in large industrial areas and its relative frequency in the male sex.

LEECHES:

EXOTIC LEECHES.

BY A. E. SHIPLEY, Sc.D., F.R.S.,
MASTER OF CHRIST'S COLLEGE, CAMBRIDGE.

Non missura cutem, nisi plena cruoris, hirudo.
HORACE.

THE extension of war into the Near and Far East has brought into action two genera of leeches which were and still are the cause of extreme inconvenience and even of real danger to troops operating in these areas. The enemies of our allies will still insist on fighting on richly stocked leech grounds. For in the new war area, in southern Europe, Asia Minor, Syria, Egypt and the southern lands of Asia, two genera of leeches which are indeed not the friend but the enemy of man, especially of the soldier, abound.

The first of these two is *Limnatis nilotica* (Sav.), and it is from Savigny that I have stolen the picture of this species. It is a leech of considerable size, attaining a length of 8 to 10 cm., and its outline rather slopes to the anterior end. The dorsal surface is brownish-green with six longitudinal stripes, and the ventral surface is dark. It is a fresh-water leech and it occurs from the Atlantic Islands, the Azores and the Canaries—its western limit—all along the northern edge of Africa until it reaches Egypt, Palestine, Syria, Armenia, and Turkestan, where it achieves its uttermost eastern boundary. This leech lives in stagnant water; especially does it congregate in drinking-wells—the wells so often mentioned in the New Testament. In the Talmud (Abōdāh Zārāh, 17*b*) an especial

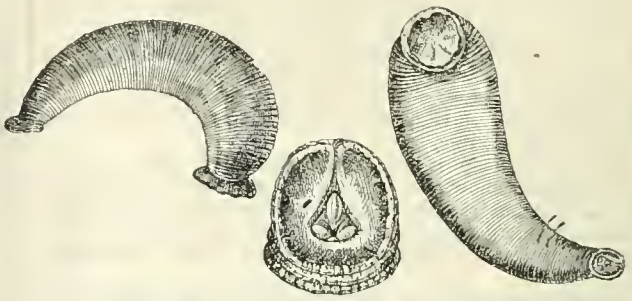

Fig. 1.—*Limnatis nilotica*, side view. Oral sucker, showing characteristic, median, dorsal slit and three teeth; ventral view. (From Savigny.)

warning is given against drinking water from the rivers or wells or pools for fear of swallowing leeches. The Old Testament Jew knew then nearly as much as we know now about these leeches. They were the cause of endless trouble to Napoleon's soldiers in his Egyptian campaign.

I cannot recall that Napoleon talked much about spreading culture,* but he certainly did it. He took on his incursion into Egypt a score of the ablest men of science he could gather from France. He established in Cairo an "Institut" modelled on that of Paris, and his scientific "corps" produced a series of scientific monographs on Egyptian antiquities and on the modern Natural History of Egypt that has not yet been equalled by any other invading force. He freed the serfs in Germany, he codified the laws of France, and these laws were adopted by large parts of Europe; he extended the use of the decimal system. Napoleon had a constructive policy, and was never a consistent apostle of wanton destruction. If he destroyed it was to build up again, and in many instances he "builded better than he knew." He seldom so mistook his enemies as to destroy, to terrify; the "frightfulness," though bad enough in his times, had limits. Napoleon had at least in him the elements of a sane and commonsense psychology. He knew that what was "frightful" to the French was not necessarily "frightful" to the Russian. Amongst the wonderful series of books and monographs on Egypt which described the varying activities of the savants he took in his train, and who, at the confines of the eighteenth and nineteenth century invaded the country of the Pharaohs, none is more remarkable than Savigny's monograph on the "Natural History" of that country. And in this folio the leech *Limnatis nilotica* was for the first time fully described and depicted.

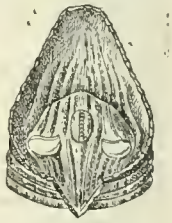

Fig. 2.—Anterior sucker of *Hirudo medicinalis*. This is to compare with the anterior sucker of *Limnatis nilotica*, which has a characteristic dorsal slit.

This particular leech is swallowed by man, by domestic cattle, and doubtlessly by wild animals, with drinking-water. Amongst the medical writers of the Eastern world in classical times who mention leeches there was always, as there was amongst the authors of the Talmud, a great and haunting fear of leeches being swallowed, and these writers mostly wrote from the area where *Limnatis nilotica* still abounds.

According to Mastermar, who has had, as a medical officer in Palestine, a first-hand opportunity of studying this leech, the pest attaches itself to the mouth or throat or larynx during the process of swallowing, and he is convinced that if it be once really swallowed and thus reaches the stomach it is killed and digested.

Limnatis nilotica, unlike *Hirudo medicinalis*, the medicinal leech, is unable to bite through the outer integument of man and is only able to feed when it has access to the softer mucous membrane of the mouth, of

* I wonder if it is any use pointing out that the German word *Kultur* is not the equivalent—as our daily Press take it to be—of the English word "culture," brought into fashion forty years ago by Matthew Arnold. Kultur = civilization. The German word which we associate with "culture" is "Bildung."

the pharynx, or of the larynx and of the other thinner and more vascular internal mucous linings.

In Palestine these pests are particularly common in the region of Galilee and in the district of Lebanon. They are in these and other districts so plentiful in the autumn that almost every mule and almost every horse you come across is bleeding in its mouth or from its nose, for this species of leech is by no means only a human parasite. The natives, who know quite a lot about these pests, generally strain them out of their drinking water by running the water through a piece of muslin or some such sieve when they fill their pitchers. In certain districts these leeches in the local pools or reservoirs are kept in check by a kind of carp, *Capöeta fratercula*.

In the cases which recently came under Mr. Masterman's observation, the leeches were attached to the epiglottis, the nasal cavities, and perhaps most commonly of all to the larynx of their host. When they have been attached to the anterior part of the mouth, or any other easily accessible position, their host or their host's friends naturally remove them, and such cases do not come to the hospital for treatment.

The effect of the presence of this leech, *L. nilotica*, on the human being is to produce constant small haemorrhages from the mouth or nose. This haemorrhage, when the leech is ensconced far within the buccal, the nasal, or the pharyngeal passages of the host, may be prolonged, serious, and even fatal. Two fatal cases Masterman records—one of a man and the other of a young girl—both of whom died of anaemia produced by leeches.

The average patients certainly suffered. There was marked distress, usually accompanied by a complete or partial loss of voice; but all the symptoms disappeared and at once on the removal of the semi-parasite. Sometimes the leeches are attached so closely to the vocal cords that their bodies flopped in and out of the vocal aperture with each act of expiration and inspiration. The hosts of leeches so situated usually suffered from dyspnoea, and at times were hardly able to breathe.

The native treatment is to remove the leech, when accessible, by transfixing it with a sharp thorn, or they dislodge it by touching it with the so-called "nicotine" which accumulates in tobacco-pipes. But nicotine is destroyed at the temperature of a lighted pipe, so whatever the really efficient juice is, it is not nicotine. Still, as long as it is efficient, the native is hardly likely to worry about its chemical composition.

Masterman says that the two means he has found most effective were: (1) Seizing the leech, when accessible, with suitable forceps, or (2) paralysing the leech with cocaine. In the former case the surgeon is materially assisted by spraying the leech with cocaine, which partially paralyses it and puts it out of action. In the latter case, if the spraying of cocaine is not sufficient, Masterman recommends the application of a small piece of cotton-wool dipped in 30 per cent. cocaine solution, which must be brought into actual contact with the leech's body. The effect of the cocaine in contact with the skin of the leech is to paralyse it and to cause it at once to relax its hold. In such a case the leech is occasionally swallowed; but it is more often coughed up and out. Headaches and a tendency to vomit are symptoms associated with the presence of this creature in the human body; the removal of the leech or leeches coincides with the cessation of these symptoms.

In the Further East we come across another species of leech even more injurious to mankind than *Limnatis nilotica*. This Asiatic leech is known as *Haemadipsa zeylanica*, and is one of a considerable number of leeches which have left the water and live on land.

Fig. 3.—The Japanese variety of *Haemadipsa zeylanica*. × 1.

From India and Ceylon, throughout Burma, Cochin China, Formosa to Japan, the Philippines, and the Sunda Island, this terrible, and at certain elevations ubiquitous, pest is spread. It lives upon damp and moist earth. The family to which it belongs is essentially a family which dwells only in the uplands and shuns the hot, low-lying plains. Its members do not occur on the hot, dry, sandy flats. Tennant has described the intolerable nuisance they are in Ceylon. They are in fact of the many visible plagues of tropical Asia and its eastern islands perhaps the worst. Yet few have recorded their dread doings and those few have escaped credence.

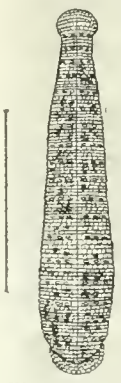

Fig. 4.—*Haemadipsa zeylanica*, seen from above. × 2. (From Blanchard.)

Each specimen of *Haemadipsa zeylanica* is of a clear brown colour with a yellow stripe on each side and with a greenish dorsal stripe. There are five pairs of eyes, of which the first four occupy contiguous rings (Fig. 5); but between the fifth and seventh ring there are two eyeless rings interposed. As in the medicinal leech there are three teeth each serrated like a saw.

In dry weather they miraculously disappear and nobody seems to know quite what becomes of them; but with returning showers they are found again on the soil and on the lower vegetation in enormous profusion. Each leech is about I inch in length and is about as thick as a knitting-needle. But they contract until they attain the diameter of a quill pen or extend their bodies until they have doubled their normal length. They are the most insinuating of creatures and can force their way through the interstices of the tightest laced boot, or between the folds of the most closely wound puttees. Making their sinuous way towards the human skin, they wriggle about under the underclothing until they attain almost any position in the body they wish to take up. Their bite is absolutely painless, and it is usual for the human sufferer to become aware that he has been bitten by these silent and tireless leeches when he notices sundry streams of blood running down his body when he at last has the opportunity of undressing.

Fig. 5.—*Haemadipsa zeylanica*. Head, showing the eyes and the serrations of the jaw. Highly magnified.

Sometimes, as Tennant's figure shows, these land leeches (*H. zeylanica*) rest upon the ground. At other times they ascend the twigs of herbs, grasses, and especially the leaves of the forest undergrowth. Perched upon the ends of growing shoots, leaves and twigs, stretching their quivering bodies into the void, they eagerly watch and wait the approach of some travelling mammal. They

Fig. 6.—*Haemadipsa zeylanica*, land leeches, on the earth. (From Tennant.)

easily "scent" their prey, and on its approach advance upon it with surprising rapidity in semi-circular loops. A whole and vast colony of land leeches is set in motion without a moment's delay, and thus it comes about that the last of a travelling or prospecting party in a land-leech area invariably fares the worst, as these land leeches mobilize and congregate with extraordinary rapidity when once they are warned of the approach of a possible host, but not always in time to engage in numbers the advanced guard.

Horses are driven wild by them, and have poor means of reprisal. They stamp their hooves violently on the ground in the hope of ridding their fetlocks of these tangled masses of bloody tassels. The bare legs of the natives, who carry palanquins, are particularly subject to the bites of these bloodthirsty brutes, as the palanquin-bearer has no free hand to pick them off. Tennant writes that he has actually seen the blood welling over the boots of a European from the innumerable bites of these land leeches, and it is on record that during the march of the troops in Ceylon, when the Kandyans

were in rebellion, many of the Madras sepoys, and their coolies, perished from their innumerable and united attacks. It is also certain that men falling asleep overnight in a Cingalese forest have, so to speak, next morning "woke up dead." These sleepers have succumbed during the night to the repeated attacks of these intolerable and insatiable pests.

Dr. Charles Hose, for many years Resident at Sarawak, has told me that on approaching the edges of woods in Borneo you can hear every leaf rustling, and this is due to the fact that the eager leech, perched on its posterior sucker on the edge of every leaf in the undergrowth, is swaying its body up and down, yearning with an "unutterable yearning," to get at the integument of man or some other mammal.

Landon, who wrote the best book about our adventure into Thibet some ten years ago, entitled *Lhassa* (London, 1905), says of Sikkim:

> The game here is very scanty: the reason is not uninteresting. For dormant or active, visible or invisible, the curse of Sikkim waits for its warm-blooded visitor. The leeches of these lovely valleys have been described again and again by travellers. Unfortunately the description, however true in every particular, has, as a rule, but wrecked the reputation of the chronicler. Englishmen cannot understand these pests of the mountain-side, which appear in March, and exist, like black threads fringing every leaf, till September kills them in myriad millions . . . to remove them a bowl of warm milk at the cow's nose, a little slip-knot, and a quick hand are all that is required. Fourteen or fifteen successively have been thus taken from the nostrils of one unfortunate heifer.

When fully fed, a process which takes some time with *Haemadipsa zeylanica*, the individual leeches drop off; and they can be made to loosen their hold by the application of a solution of salt or weak acid. Attempts to pull them off should be avoided, as parts of the biting apparatus are then often left in the wound, and these may cause inflammation and suppuration.

When winter approaches the leeches die down with extraordinary rapidity, and the species "carry on" over the cold weather period in the form of eggs laid in cocoons on the ground, under leaves or other débris. Hence no land leech ever sees its offspring, and no land leech has ever known a mother's care.

EIGHTY-SECOND ANNUAL MEETING

OF THE

British Medical Association.

Held in Aberdeen on July 29th, 30th, and 31st.

PROCEEDINGS OF SECTIONS.

SECTION OF NEUROLOGY AND PSYCHOLOGICAL MEDICINE.

F. W. MOTT, M.D., F.R.C.P., F.R.S., President.

ON THE IMPORTANCE OF THE UNCONSCIOUS IN PSYCHOPATHOLOGY.

By C. G. JUNG, M.D., LL.D.,

Zürich.

WHEN we speak of a thing as being "unconscious" we must not forget that from the point of view of the functioning of the brain a thing may be unconscious to us in two ways—physiologically or psychologically. I shall only deal with the subject from the latter point of view. So that for our purpose we may define the unconscious as "the sum of all those psychological events which are not apperceived, and so are unconscious."

The unconscious contains all those psychic events which, because of the lack of the necessary intensity of their functioning, are unable to pass the threshold which divides the conscious from the unconscious; so that they remain in effect below the surface of the conscious, and flit by in subliminal phantom forms.

It has been known to psychologists since the time of Leibnitz that the elements, that is to say, the ideas and feelings which go to make up the conscious mind—the so-called conscious content—are of a complex nature, and rest upon far simpler and altogether unconscious elements it is the combination of these which gives the element of consciousness. Leibnitz has already mentioned the *perceptions insensibles*—those vague perceptions which Kant called "shadowy" representations, which could only attain to consciousness in an indirect manner. Later philosophers assigned the first place to the unconscious as the foundation upon which the conscious was built.

But this is not the place to consider the many speculative theories nor the endless philosophical discussions concerning the nature and quality of the unconscious. We must be satisfied with the definition already given, which will prove quite sufficient for our purpose, namely, the conception of the unconscious as the sum of all psychical processes below the threshold of consciousness.

The question of the importance of the unconscious for psychopathology may be briefly put as follows: "In what manner may we expect to find unconscious psychic material behave in cases of psychosis and neurosis?"

In order to get a better grasp of the situation in connexion with mental disorders, we may profitably consider first how unconscious psychic material behaves in the case of normal people, especially trying to visualize what in normal men is apt to be unconscious. To obtain this knowledge we must first get a complete understanding of what is contained in the conscious mind; and then, by a process of elimination, we can expect to find what is contained in the unconscious, for obviously—*per exclusionem*—what is in the conscious cannot be unconscious. For this purpose we examine all activities, interests, passions, cares, and joys, which are conscious to the individual. All that we are thus able to discover becomes, *ipso facto*, of no further moment as a content of the unconscious, and we may then expect to find only those things contained in the unconscious which we have not found in the conscious mind.

Let us take a concrete example: A merchant, who is happily married, father of two children, thorough and painstaking in his business affairs, and at the same time trying in a reasonable degree to improve his position in the world, carries himself with self-respect, is enlightened in religious matters, and even belongs to a society for the discussion of liberal ideas.

What can we reasonably consider to be the content of the unconscious in the case of such an individual?

Considered from the above theoretical standpoint, everything in the personality that is not contained in the conscious mind should be found in the unconscious. Let us agree, then, that this man consciously considers himself to possess all the fine attributes we have just described—no more, no less. Then it must obviously result that he is entirely unaware that a man may be not merely industrious, thorough, and painstaking, but that he may also be careless, indifferent, untrustworthy; for some of these last attributes are the common heritage of mankind and may be found to be an essential component of every character. This worthy merchant forgets that quite recently he allowed several letters to remain unanswered which he could easily have answered at once. He forgets, too, that he failed to bring a book home which his wife has asked him to get at the book store, where she had previously ordered it, although he might easily have made a note of it in his notebook. But such occurrences are common with him. Then there can be no other conclusion reached but that he is also lazy and untrustworthy. He is convinced that he is a thoroughly loyal subject; but for all that he failed to declare his entire income to the assessor, and so, when they raise his taxes, he votes for the Socialists.

He thinks he is an independent thinker, yet a little while back he undertook a big deal on the Stock Exchange, and when he came to enter the details of the transaction in his records he noticed with considerable misgivings that it fell upon a Friday, the 13th of the month. Therefore, he is also superstitious and not a free thinker.

So we are not at all surprised to find here those compensating vices to be an essential content of the unconscious. Obviously, therefore, the reverse is true—namely, that unconscious virtues compensate for conscious deficiencies. The law which ought to follow as the result of such deductions would appear to be quite simple—to wit, the conscious spendthrift is unconsciously a miser; the philanthropist is unconsciously an egoist and misanthrope. But, unfortunately, it is not quite so easy as that, although

there is a basis of truth in this simple rule. For there are essential hereditary dispositions of a latent or manifest nature, which upset the simple rule of compensation, and which vary greatly in individual cases. From entirely different motives a man may, for instance, be a philanthropist, but the manner of his philanthropy depends upon his originally inherited disposition, and the way in which the philanthropic attitude is compensated depends upon his motives. It is not sufficient simply to know that a certain person is philanthropic in order to diagnose an unconscious egoism. For we must also bring to such a diagnosis a careful study of the motives involved.

In the case of normal people the principal function of the unconscious is to effect a compensation and thus produce a balance. All extreme conscious tendencies are softened and toned down through an effective opposite impulse in the unconscious. This compensating agency, as I have tried to show in the case of the merchant, maintains itself through certain unconscious, inconsequent activities, as it were, which Freud has very well described as symptomatic acts (*Symptomhandlungen*).

To Freud we owe thanks also for having called attention to the importance of dreams. For through dreams, also, we are able to learn about this compensating function. There is a beautiful historical example of this in the well-known dream of Nebuchadnezzar in the fourth chapter of the Book of Daniel, where Nebuchadnezzar at the height of his power had a dream which foretold his downfall. He dreamed of a tree which had raised its head even up to heaven and now must fall. This is a dream which obviously compensates the exaggerated feeling of royal power.

Coming now to conditions in which the mental balance is disturbed, we can the more easily see, from what has preceded, wherein lies the importance of the unconscious for psychopathology. Let us consider the question of where and in what manner the unconscious manifests itself in abnormal mental conditions. The way in which the unconscious works is most clearly seen in disturbances of a psychogenic nature, such as hysteria, compulsion neurosis, etc.

We have known for a long time that certain symptoms of these disturbances are produced by unconscious psychic events. Just as clear, but less recognized, are the manifestations of the unconscious in actually insane patients. As the intuitive ideas of normal men do not spring from logical combinations of the conscious mind, so the hallucinations and delusions of the insane arise not out of a conscious but out of unconscious processes.

Formerly, in a more materialistic epoch of psychiatry, we were inclined to believe that all delusions, hallucinations, stereotypic acts, etc., were provoked by morbid processes in the brain cells. Such a theory, however, forgets that delusions, hallucinations, etc., are also to be met with in certain functional disturbances, and not only in the case of functional disturbances but also in the case of normal people. Primitive people may have visions and hear strange voices without having their mental processes at all disturbed. To seek to reduce symptoms of that nature directly to a disease of the brain cells I hold to be superficial and unwarranted. Hallucinations show very plainly how a part of the unconscious content can force itself across the threshold of the conscious. The same is true of a delusion whose appearance is at once strange and unexpected by the patient.

The expression "mental balance" is no mere figure of speech, for its disturbance is a real disturbance of that mental balance which exists more actually between the unconscious and conscious content than has heretofore been recognized or understood. As a matter of fact, it amounts to this—that the normal functioning of the unconscious processes breaks through into the conscious mind in an abnormal manner, and thereby disturbs the adaptation of the individual to his environment.

If we study attentively the history of any such person coming under our observation we shall often find that he has been living for a considerable time in a sort of peculiar individual isolation, more or less shut off from the world of reality. This constrained condition of aloofness may be traced back to certain innate or early acquired peculiarities, which show themselves in the events of his life. For instance, in the histories of those suffering from dementia praecox we often hear such a remark as this: "He was always of a pensive disposition, and much shut up in himself. After his mother died he cut himself off still more from the world, shunning his friends and acquaintances." Or again, we may hear, "Even as a child he devised many peculiar inventions; and later, when he became an engineer, he occupied himself with most ambitious schemes."

Without discussing the matter further it must be plain that a counter-irritant is produced in the unconscious as a compensation to the onesidedness of the conscious attitude. In the former case we may expect to find an increasing pressing forward in the unconscious of a wish for human intercourse, a longing for mother, friends, relations, while in the latter case self-criticism will try to establish a correcting balance. For in the case of normal people a condition never arises so one-sided that the natural corrective tendencies of the unconscious entirely lose their value in the affairs of everyday life. On the other hand, in the case of abnormal people, we find it eminently characteristic that the individual entirely refuses to recognize the compensating influence which arises in the unconscious, and even continues to increase his onesidedness according to the well-known psychological fact that the enemy of the wolf is the wolf-hound, of the negro the mulatto, and that the greatest fanatic is the convert; for I should be a fanatic were I to attack a thing outwardly which inwardly I am obliged to concede as right.

The mentally unbalanced man tries to defend himself against his own unconscious, that is to say, he battles against his own compensating influences. The man already dwelling in a sort of atmosphere of isolation continues to remove himself further and further from the world of reality, and the ambitious engineer strives by increasingly morbid exaggerations of invention to prove the incorrectness of his own compensating powers of self-criticism. As a result of this a condition of excitation is produced, from which results a great lack of harmony between the conscious and unconscious attitudes. The pairs of opposites are torn asunder, the resulting division or strife leads to disaster, for the unconscious soon begins to intrude itself violently upon the conscious processes. Then come odd and peculiar thoughts and moods, and often incipient forms of hallucination, which plainly bear the stamp of the internal conflict.

These corrective impulses or compensations which now break through into the conscious mind should really seem to be the beginning of the healing process, because through them the previously isolated attitude ought apparently to be relieved. But in reality this does not result, for the reason that the unconscious corrective impulses which thus succeed in making themselves apparent to the conscious mind do so in a form that is altogether unacceptable to consciousness.

The isolated individual begins to hear strange voices, which accuse him of murder and all sorts of crimes. These voices drive him to desperation and in the resulting agitation he tries to get into contact with the surrounding *milieu* and does what he formerly had anxiously avoided. The compensation, to be sure, is reached, but to the detriment of the individual.

The pathological inventor, who is unable to profit by his previous failures, still allows himself, by refusing to recognize the value of his own self-criticism, to come to still more absurd designs. He wishes to accomplish the impossible but falls into the absurd. After a while he notices that people talk about him, make unfavourable remarks about him, and even scoff at him. He believes a far-reaching conspiracy exists to frustrate his discoveries and render them objects of ridicule. By this means his unconscious brings about the same results that his self-criticism could have attained, but again only to the detriment of the individual, because the criticism is projected into his surroundings.

An especially typical form of unconscious compensation—to give a further example—is the paranoia of the alcoholic. The alcoholic loses his love for his wife; the unconscious compensation tries to lead him back again to his duty, but it can only partially succeed, for it only causes him to become jealous of his wife as if he still loved her. As we know he can even go so far as to kill his wife and himself merely through jealousy. In other words, his love for his wife has not been entirely lost. It

has simply become subliminal. But from the realm of the unconscious it can now only reappear in the form of jealousy.

Something of a similar nature we see in the case of religious converts. Everyone who turns from Protestantism to Catholicism has, as is well known, the tendency to be somewhat fanatic. His Protestantism is not entirely relinquished, but has merely disappeared into the unconscious, where it is constantly at work as a counter-irritant against the newly acquired Catholicism. Therefore the new convert feels himself constrained to defend the faith he has adopted in a more or less fanatical way. It is exactly the same in the case of the paranoiac, who feels himself constantly constrained to defend himself against all external criticism, because his delusive system is too much threatened from within.

The strange manner in which these compensating influences break through into the conscious mind derives its peculiarities from the fact that they have to struggle against the resistances already existing in the conscious mind, and therefore present themselves to the patient's mind in a thoroughly distorted manner. And secondly, these compensating equivalents are obliged necessarily to present themselves in the language of the unconscious—that is, in material that is of a heterogeneous and subliminal nature. For all that material in the conscious mind which is of no further value and can find no suitable employment becomes subliminal, such as all those forgotten infantile and fantastic creations that have ever entered the heads of men, of which only the legends and myths still remain. For certain reasons which I cannot discuss further, this latter material is frequently found in dementia praecox.

I hope I may have been able to give in this brief contribution, which I feel to be unfortunately incomplete, a glimpse of the situation as it presents itself to me of the importance of the unconscious in psychopathology. It would be impossible in a short discourse to give an adequate idea of all the work that has already been done in this field.

To sum up, I may say that the function of the unconscious in conditions of mental disturbance is essentially a compensation of the content of the conscious mind. But because of the characteristic condition of onesidedness of the conscious striving in all such cases, the compensating correctives are rendered useless. It is, however, inevitable, that these unconscious tendencies break through into the conscious mind, but in adapting themselves to the character of the one-sided conscious aims, it is only possible for them to appear in a distorted and unacceptable form.

The Significance of the Unconscious in Psychopathology.

Dr. Ernest Jones contributed a paper, which in his absence was read by the Honorary Secretary. Dr. Jones considered that there were three different current uses of the term "unconscious." In the first it was regarded as a synonym for "non-mental," and was, therefore, not concerned with psychopathology at all. The second conception of the unconscious was purely philosophical, as developed by such writers as Hartmann, Meyers, Jung, and others; the field of psychopathology was hardly an appropriate one in which to deal with it. The third conception of the unconscious was the scientific one, developed by Freud. He divided those mental processes not accompanied by awareness into two groups, the preconscious and the unconscious proper, and Dr. Jones proposed to use the term in the latter sense. Freud's conception was characterized by the fact that it was a purely inductive one, being built up step by step on the basis of actual experience without the introduction of any speculative hypothesis, philosophical, mystical, or other. As the result of his investigations of actual unconscious mental processes he acquired a gradually increasing knowledge of their nature, content, meaning, origin, and significance, and was therefore able to formulate some general statements. Of these the most important concerned both the origin and the content of the unconscious, and was to the effect that its existence was the result of repression. Unconscious processes were of such a kind as to be incompatible with the conscious ones of the given personality, and were therefore prevented from entering consciousness by the operation of certain actively inhibiting, "repressing" forces. The incompatibility was of a moral order in the widest sense of the word. The processes in question flagrantly conflicted with the moral, social, ethical, modest, or aesthetic standards that obtained in the person's consciousness, and he automatically refused to acknowledge to himself their presence in his mind. In this action of repression only a very small part was played by what might be described as a deliberate conscious pushing of certain thoughts out of the mind; much more extensive was the subconscious keeping apart of the two sets of incompatible mental processes. A second characteristic of the unconscious was its dynamic nature. Unconscious processes were typically conative in kind, and might thus be conveniently, and not inaccurately, described as wishes. These wishes were constantly striving for gratification, imaginary or real, and it was to this striving that the external manifestations of the unconscious were to be ascribed.

Closely allied to the preceding features of the unconscious was the third—its relation to primary instincts—it being the part of the mind that stood nearest to the inborn and original form of these. Commonly it was not realized how extensive was the work performed by the refining influences of education, nor how violent the internal conflict they provoked before finally achieving their aim. Without them the person would remain a selfish, aggressive, immodest, dirty, and cruel animal, inconsiderate of the needs of others, and unmindful of the complicated social and ethical standards that went to make civilized society. The results of this refining process were rarely quite satisfactory; there remained throughout life a buried mass of crude primitive tendencies, always struggling for expression, and towards which the person tended to relapse whenever suitable opportunity offered.

In accord with these features was the infantile nature and origin of the unconscious. The splitting of the mind into conscious and unconscious regions took place in the earliest part of childhood, and the infantile character of the unconscious persisted throughout the whole of life. To be correlated with the infantile nature of the unconscious was the circumstance that it ignored not only moral but also logical standards. It had a logic of its own, but it was one of the emotions and not of the reason. From the usual point of view it would be called illogical. Just as the phantasy could overstep the bounds of time and space, so did the unconscious ignore all reasonable and logical considerations. The sixth attribute of the unconscious was its predominantly sexual character. This might have been expected from the fact that no other primary instinct was subjected to anything like the same intensity of repression. The apparent contradiction between this attribute and the preceding one concerning the infantile nature of the unconscious was resolved when the fallaciousness of the popular belief that dates the sexual instinct from the time of puberty was remembered. Freud and others had produced abundant evidence to show that it was actively operative long before this time, though what was called infantile sexuality differed widely from the adult form, being much more diffuse, tentative, and preliminary in nature. Two of these differences were the close association between infantile sexuality and excretory functions, and the absence of the incest barrier.

These conclusions might be summarized as follows: The unconscious was a region of the mind the content of which was characterized by being repressed, conative, instinctive, infantile, unreasoning, and predominantly sexual. The six attributes, together with others not mentioned, made up a consistent and clearly defined conception of the unconscious formulated on the basis of experience that might at any time be tested.

The significance of the unconscious in psychopathology might be discussed under four headings. In the first place a knowledge of its content and mode of operation furnished a key for the understanding of numerous morbid manifestations that previously seemed bizarre and meaningless; it had given a consistent interpretation of them, and had revealed their coherent and intelligible structure. The reason was that all psychopathological symptoms arose in the unconscious, which was the true seat of the disorder, so that the investigation of it was of cardinal importance for both pathology and therapeutics. In the

second place, this knowledge made clear not only the meaning of the manifestations, but also the causation of them. Normally a great part of the energy pertaining to the repressed trends of the unconscious was diverted ("sublimated") to permissible, social aims. This denoted a partial renouncement of the crude pleasures obtained by indulging in these tendencies, and a replacement of them by other, more or less satisfactory, refined ones. Many persons found it by no means an easy matter to achieve this renouncement, and were in constant danger of relapsing into the old indulgences and gratifications, particularly when the attractions of the more refined aims flagged, as they must whenever the environment became more painful, difficult, or disagreeable. Then the mental interests and energies were apt to "regress" towards older and more primitive modes of functioning. In this regression, however, they were checked by the repressing forces on which the original sublimation depended. In the resulting conflict neither set of forces was entirely successful; on the one hand the repressing forces managed to prevent a complete return to the primitive modes of gratification, while on the other they failed in transforming the energies in question into sublimated activities. A compromise was reached whereby both sets of forces came to expression, though only in a partial and disguised way; these compromise formations were clinically called symptoms, and constituted the various psychopathological maladies. In the third place, the knowledge gained by investigation of the unconscious bridged over the gap between the normal and the abnormal by demonstrating that the same processes went on in both, though the control of the unconscious ones by consciousness was greater in the case of the former. Roughly speaking, insanity presented a picture of the normal unconscious. Last, but not least, was the remarkable aid that this knowledge had yielded for the treatment of psychopathological maladies. Up to the present this had been far greater in the case of the psychoneuroses than in that of the psychoses, but there it had already proved so valuable that the hope was justifiable that further researches might be profitable from this point of view in the case of the latter group also. The mode of action of the treatment, in a word, was that the overcoming, by means of psycho-analysis, of the resistances that were interposed against the making conscious of the repressed unconscious material gave the patient a much greater control over this pathogenic material by establishing a free flow of feeling from the deeper to the superficial layers of the mind, so that the energy of the repressed tendencies could be diverted from the production of symptoms into useful social channels.

DISCUSSION.

Dr. M. D. EDER said that part of the reluctance to accept some of the statements in the literature of psycho-analysis was, he thought, due to the difficulty experienced in describing scenes of warm, actual life. It required a more graphic pen than most possessed to put into words the behaviour of the individual disclosed during analysis. It consisted not only of verbal statements and misstatements, but of a constant and accompanying change of expression. A phonograph which should repeat the exact language, and a cinematograph which should picture the accompanying expressions and movements of the individual, would still leave out the stress laid upon certain words and sentences. Difficult as this kind of sign-language was to embody into reports of cases, it was one of the most important clues to the appreciation of the unconscious. The following example illustrated the symbolic speech and action going on throughout the process of analysis:

A patient, suffering from a minor degree of visual defect, asked early in analysis to be recommended an eye doctor, and was given the name of a well-known London surgeon; a few days later the patient mentioned that he did not think the new glasses suited him as well as the old; very soon he announced with apparent annoyance he had lost the new glasses. His father had, in the meantime, recommended him an oculist to whom he now went, with exactly the same result. Following up this subject it was found that everything to do with eyesight and glasses had presented difficulties. He had first required glasses as a student in Berlin, and a friend of his father had recommended him one of Berlin's best known eye doctors, but the patient had then found the prescribed glasses quite impossible. He had come across some advertising oculist, and it was then that he first found the suitable spectacles which he had continued to use. Fear of blindness was so insistent that although he had only a minor degree of myopia he had learnt the Braile system when a youth, giving the sensible explanation that it was always well to be prepared against all emergencies. Some time later, when the position had cleared up, the glasses obtained from the London surgeon were, he said, found under some letters in his desk. The explanation of this symbolic language was easier to realize than it was to discover. He used his visual defect as a barrier against accommodating himself to any fresh position or outlook; at college, for instance, it served as an excuse for games; in later years it was an equally ready excuse against reading, meeting people, and so on. He was sure that all his difficulties arose from his father's misunderstanding, so he would not see through glasses that came in any way through his father. The hostility towards Dr. Eder was symbolized by the lost glasses; he refused to believe that any enlightenment was to be got through analysis; he preferred to keep up his phantasies. But as the situation developed, and he discovered that he could be helped, he found the glasses, and admitted that they suited him admirably.

This incident could be treated in terms of an incest phantasy—a father complex; the fear of blindness could be understood as a fear resulting from repression of sexual curiosity. This was present also, but was not the main difficulty; his trouble was what the East called the vice of separateness—a refusal to recognize that human beings must stand in some relationship to one another. Leaving aside the expression of the unconscious, there were some statements as to its content made in Dr. Jones's note which it seemed necessary to refute. Dr. Jones stated that certain unconscious mental processes were prevented from entering consciousness by forces of a "moral" order—were imposed upon the individual by the refining influences of education. The primary instincts were to him entirely egocentric and brutal. If this view of the unconscious were to be accepted it must be asked whence was derived the moral forces that obtained in civilization? Whence was the origin of this educational influence? Unless the germ were potential in human beings—unless it were present in the unconscious—how could it be imposed from without? Each individual had to go through a long process of individual education in order to reach the highest, but the possibility of individual reaction to such discipline must be present from the beginning. Each individual, for instance, acquired more or less painfully and more or less perfectly the art of writing, but the potentiality to acquire that art was universally present in man. So it was with the moral endowments of mankind; they were as primary as the egocentric impulses, and formed equally part of the unconscious. Dr. Jones seemed to rate consciousness as too "moral" and the unconscious as too bestial. So far from Jung's view of the unconscious being static, it was charged with movement—indeed, Dr. Jung had given a dynamic value to the concept of the libido. Here was a source of daily conflict, so long as the conscious mind did not deal with the problems passed on to it; set free from these, the unconscious was available for the solution of those of deeper moment. Though recognizing to the full the great importance of sexual instinct, of the infantile sexual life and its repression, Dr. Eder could but think it unreal to leave out of psycho-analysis, or rather out of the presentation of it, much else that dwelt in the unconscious, was dynamically active, and went to make up the whole being.

Dr. CONSTANCE LONG said that in speaking of the unconscious to colleagues it was not unusual to see a shiver pass over them as if something uncanny had been touched—something of which they were dimly aware and not a little afraid. This fear came from the unconscious itself, and was evidence of the bias which existed therein against a view too exclusively scientific. The unconscious, like the Ark of the Covenant among the Philistines, was misunderstood. Freud had brought it forward as a wild beast "waiting its hour to spring." It was not necessary to be altogether grateful for this conception, but it was at any rate arresting—was, moreover, half true. The unconscious, as Dr. Jung had shown, was not only an enemy, but a friend with infinitely delicate perceptions. Freud had provided a technique of precision; the Zürich school had shown that there was another than a reductive side to this science—that there was a constructive side—and that it was not necessary always to look to the lower to explain the higher, nor persistently reduce a personality to its sexual components; it was reasonable, therefore, to pursue this science, which, after

all, was as yet in its infancy. It was clearly time to cease to apply physical treatment to psychical disease. The unconscious, which declared itself so disastrously in insane imaginings and neurotic symptoms, could also be adapted to use as a means of cure. The analysis of dreams and symptomatic acts afforded a way of reaching an understanding of the psychological mechanisms behind this phobia or obsession, and, as Professor McDougall had so aptly said, what was wanted was "not so much explanation as understanding."

Dr. R. H. Steen said that the very fact that the discussion was taking place indicated that the subconscious was at last finding its proper position in psychiatry and neurology. Several factors had interfered, and were interfering, with a more widespread consideration of the subject. The first was the expression "the subconscious mind." When mind was defined as synonymous with consciousness such an expression was of course ridiculous, and the student was apt to turn away from the study in disgust. The facts of life, however, were not bound by definitions, and he did not see why mind should not be defined in such a manner as to include the unconscious, or if this were objected to, the term "psyche" might be used to include both the unconscious and the conscious. The second factor was the confusion in the terminology. Freud wrote of the preconscious (or forconscious) and the unconscious, with two censors, one between the foreconscious and consciousness, and the other between the unconscious and the forconscious. Morton Prince described a co-consciousness and an unconsciousness as subdivisions of the subconscious and so on. In making these criticisms on what were, after all, minor matters, Dr. Steen did not desire to minimize the importance of the subconscious, for the more he studied it the more valuable did he find it. For the proper understanding of the psychoses a knowledge of the subconscious was essential. A beginning had been made by the studies of Jung in dementia praecox, and by Freud and his disciples in paranoia. Among the patients in a mental hospital the bubbling up of subconscious influences to the surface was seen on all sides. The stereotyped movements of the case of dementia praecox would first attract attention. On a neighbouring seat would be seen a patient smiling and talking to himself, enjoying the phantasies fed by his subconsciousness; another patient without warning, quick as lightning, was up and darting for the window. If asked why he did so he said he could not tell, and he spoke the truth, for the reason was in the subconscious. All these things required further study, and the difficulty of the study was increased by the fact that the moment the searchlight of attention was turned on the subconscious it ceased to be subconscious. Still by hypnotism, by the association test, and by other means the subconscious could be tapped and studied. On the other hand, he was not optimistic as to the therapeutic value of the study so far as the psychoses were concerned. He believed that in the greater number of instances the psychoses were caused by toxins of endogenous nature. The study of the subconscious would tell why the symptoms occurred in such and such a form. For example, if a person given chloroform was delirious in the early stages of the administration of the anaesthetic, a study of the subconscious would reveal the reason of the disordered speech and excitement, but the real cause of the delirium was the chloroform. In like manner the study of the subconscious would bring enlightenment as to the meaning of the symptoms in dementia praecox, but the real cause was the toxin underlying the condition. Still, the discovery of new laws of nature might have unexpected results, and for this reason he welcomed the discussion, and thanked Dr. Jung for his most interesting opening remarks.

Dr. Crichton Miller (London) said that when Freud's technique and theories were first brought to his notice he shared with many others a sense of extreme scepticism with regard to both. Then, as he did more psycho-analysis, he realized that the findings that resulted were incontestable, but recognized, first, that the theoretical interpretation put upon the facts by Freud was exceedingly distasteful (especially to one educated in Scotland), and, secondly, that it was only the psycho-analyst who could appreciate the validity of the data, in that the direct observation of the patient's behaviour and reaction to correct and incorrect interpretations was the basic element in their convincing truthfulness. Dr. Jung had offered an interpretation which was intrinsically opposed to Freud's, which seemed more adequate and far more consonant with the general philosophy of life. The average medical man was frightened by the talk of psycho-analysts—they spoke too metaphysically; the technique was too elaborate; the treatment was prolonged. He would appeal for a much more simple thing—namely, a truer psychological outlook in all diagnosis and in all practice. The necessity for careful and adequate physical investigation and treatment was as great as ever, but the unjustifiable attitude was that of obstinately refusing to consider the possibility of a psychic factor and the prolonged and often futile search for a physical cause of disease.

Dr. Alfred T. Schofield was pleased with the unusual courage of Dr. Jung in speaking of the unconscious and not the subconscious, this latter being really a mental territory lying between consciousness and unconsciousness. He had alluded to hysteria, a true affection of the unconscious mind, in contrast to neurasthenia, which was not. In it the ordinary *vis medicatrix naturae* was more or less reversed and acted detrimentally to the body. He asked whether hysteria might not be a mania of the unconscious, just as insanity was a mania of the conscious. That this was so would appear from the treatment in both cases. If in insanity the conscious was disordered while the unconscious remained normal, then the treatment was to help the abnormal by means of the normal. All that appealed to the unconscious was therefore used —no confining walls, no restraints, ordinary food, servants, etc.—and it was these means that were found most effectual by alienists. In hysteria the appeal should be to the conscious mind by means of steady discipline and occupation, rewards and punishments, and education. Dr. Schofield concluded by expressing the highest admiration of Dr. Jung's paper.

SOME CONSIDERATIONS REGARDING INSANITY IN THE HIGHLANDS.

By T. C. Mackenzie, M.D.,
Medical Superintendent, Inverness District Asylum.

(*Abstract.*)

The Inverness Lunacy District is one-third of the total area of Scotland. Its population is, however, sparse and steadily decreasing. There is much intermarriage of relatives. The asylum was opened in 1864, and 212 (158 being transfers) patients were admitted the first year; of these, 3 male patients still survive. The proportion of the insane belonging to the Inverness district has risen from 1.5 in 1864 to 4.1 per 1,000 of the population in 1913. There has been a decrease in the number of patients admitted to the asylum under 30 years of age (due to emigration), and an increase in those of 70 years and upwards. The average annual resident population has grown from 200 in 1865 to 672 in 1914. Boarding out is systematically pushed at Inverness, with the result that this district easily heads the field for Scotland with a percentage of 38. The economical advantage of this is obvious.

With regard to the family history of insanity, accurate accounts were obtained in 226 cases out of 613 admissions for the last four years. These results showed that one-third had had relatives previously in the asylum; one-fourth had relatives who were mentally defective but uncertified; one-eighth had relatives already in the asylum; and in one-ninth of the cases relatives of the patient had already died in the asylum. The comparatively small number of families and individuals within the district is responsible for a relatively high contribution to the total number of cases coming under care and treatment.

In July, 1914, with an asylum population of over 700, there were only 6 cases of general paralysis in the asylum. These are all men who have spent many years of their lives out of the Highlands.

The predominating mental affections in the Highlands are in the order of their frequency: Melancholia, mania, dementia, congenital mental deficiency, epilepsy, and, to a very small extent, general paralysis.

Dr. JOHN MILLS said that in the District Asylum, Ballinasloe (Ireland), similar conditions existed to those described by Dr. Mackenzie. The population was largely Celtic, living in remote and scattered villages. The admission rate to the asylum was affected to the extent of 11 per cent. by returned emigrants, who had broken down under the stress and strain of conditions very different from the simple life to which they had been accustomed. The occurrence of general paralysis was unknown in the native population, but occurred among returned emigrants and ex-soldiers, sailors, and artisans. There was a tendency to a large increase of admissions for the senile period and a lesser increase in the adolescent period. There had been a similar increase in the ratio of insane to 1,000 of the population which in Ireland was higher in the Celtic counties than in the others.

EPILEPSY AND CEREBRAL TUMOUR.

By WILLIAM ALDREN TURNER, M.D., F.R.C.P.Lond.,

Physician to King's College Hospital, and to the National Hospital for the Paralysed and Epileptic, Queen Square, London.

(Abridged.)

It has been recognized for a long time that tumour of the brain may give rise to seizures having features in no respect different from those occurring in the so-called idiopathic or genuine epilepsy. This variety of the disease forms one of the secondary or symptomatic epilepsies.

When epileptic attacks arise coincidently with the general symptoms of a cerebral tumour, or precede their onset by a short time, little difficulty is experienced in forming an opinion of the probable cause of the seizures or of diagnosing the symptomatic character of the epilepsy.

But the type of case to which I wish to call attention in this communication is that form of symptomatic epilepsy which is characterized by the recurrence of fits in all respects resembling those of genuine epilepsy *over long periods of time* before the symptoms or signs of the intracranial tumour, to which the seizures in all probability are due, obtrude themselves.

The diagnosis of epilepsy may be made legitimately in these cases on account of: First, the persistence of the seizures, amounting to no less than sixteen years in one of my cases, without any physical signs of cerebral tumour being apparent; secondly, the generalized character of the attacks; thirdly, the recurrence of the fits, as in ordinary epilepsy; and, lastly, the definite arresting influence on the fits of the bromide salts.

It is difficult to ascertain just what is the frequency of this variety of symptomatic epilepsy. If it were possible to follow throughout the history of most of our epileptic patients, I think it would be conceded that cerebral tumour was probably a more frequent cause of the disease than is at present accepted, more especially of that variety of epilepsy which begins in later adolescence.

It is necessary, however, to state that no case has been included in this series in which the fits had not been present for at least twelve months prior to the detection of the symptoms or signs of intracranial tumour. That is to say, no case has been included in which the diagnosis of epilepsy could not have been made with fair reason, having regard to the character, frequency, and course of the seizures, and the absence of signs of gross disease of the brain.

In the collected cases the disease began between the ages of 21 and 52 years—in no case did the onset of the fits coincide with the period of puberty. Epilepsy from cerebral tumour may be deemed to be a variety of "late" epilepsy, being especially prone to come on during the later years of adolescence or in adult life.

In one case epileptic fits had been recurring for sixteen years before the development of the signs of cerebral tumour, but the average duration of the epilepsy before the obtrusion of the symptoms of organic disease in the remainder was just over four years, with a variation of from two to nine years.

The fits presented all the features which are generally regarded as characteristic of epilepsy—namely, general epileptic fits without warning; general epileptic fits with local warning; general epileptic fits with post-convulsive hemiparesis of the limbs most convulsed; so-called vertiginous attacks with slight general convulsions, twitchings, and tonic spasms of the head and eyes, limbs, or body; the "uncinate" fit, with or without convulsion; psychical attacks—lapses of memory, "spells," and automatism.

As the underlying lesion is of a progressive nature, the fits tend to alter in character as the disease advances. This should be regarded as an important feature in the clinical study of this type of epilepsy, as, in the idiopathic disease, once the general type of fit has been established gross variations are unusual. Thus, in some cases the disease was ushered in by general convulsions recurring at long intervals, which gave place in the later stages to attacks of a more definitely focal or epileptiform type. In another group, in the early stages, attacks having the features either of the "Broca" or the "uncinate" fit were replaced in the later stages by fits with generalized convulsions. In other cases major convulsive seizures gave place to attacks of *le petit mal*, or vice versa.

As regards frequency and time incidence, the seizures correspond to those in the idiopathic disease—that is to say, the fits may recur at intervals of several months, or as often as several in the day. They may come on only during sleep, or only during waking hours, or both; sometimes they occur in series.

Topographical Features.

The cases have been classified into two subgroups according to the situation of the tumour as demonstrated by operation. The exact site and area of the tumour were, in consequence, not accurately defined, but for practical purposes its position was sufficiently ascertained.

(a) Epilepsy and Fronto-parietal Tumour.—In tumours of this region the seizures are of two kinds: First, generalized epileptic convulsions with or without a warning sensation, and secondly, fits of a more definitely focal type.

In the attacks without warning deviation of the head and eyes to one side, with, perhaps, a movement of the whole body in the same direction may be followed by tonic spasm and clonic twitchings of the trunk and limbs. A temporary hemiparesis may be observed in the limbs most convulsed. The constant appearance of a unilateral extensor plantar response is significant. If a warning sensation is described, it may be either motor or sensory, and is referred to the face, hand, or foot on the side opposite to the tumour.

Attacks of a minor or *petit mal* type may also be observed in this group. Thus sensations, vertiginous attacks, dazed feelings, with or without muscular twitchings of the eyelids or face, are described.

The second type of fit occurring with tumour of this region, when the lesion is located on the left side and towards the base, is characterized by sudden temporary aphasia, sometimes associated with general convulsion, at other times more purely epileptiform, and having a facio-linguo-mandibular distribution. This latter type is characteristic of an irritative lesion of Broca's convolution and the adjoining parts. The fit may be followed by a temporary loss of speech. My colleague, Dr. Grainger Stewart, who has also described these attacks, describes the purely motor character of the aphasia, and calls attention to the superficial resemblance which this condition bears to general paralysis of the insane. The term "Broca" fit may well be applied to this type of seizure, as it indicates both the prominent feature of the attack and the locality of the lesion.

In one case of this kind, temporary aphasic seizures, which were present for five years before the development of definite signs of intracranial tumour, were not looked upon as important, until general epileptic convulsions, with loss of consciousness, attracted attention. The latter recurred for some months, and gave way to focal attacks affecting the face, tongue, lower jaw, and sometimes the right arm, without loss of consciousness. During these seizures speech was inhibited, but returned within a short time of the cessation of the fit.

(b) Epilepsy and Temporo-sphenoidal Tumour.—Two types of seizure occur in association with tumours of this region—first, a generalized epileptic attack of either the major or minor variety of idiopathic epilepsy; and, secondly, the "uncinate" fit, long ago described in detail by Hughlings Jackson.

The former type would appear to occur with tumours of the cortex and subcortical white matter of the external part of the lobe; the latter is characteristic of lesion of

the gyrus uncinatus, when it is the seat of an irritative lesion, either primary or encroaching from adjoining parts.

The association of the two types of fit may be met with in the same case. Thus, a warning sensation of flavour or of smell or taste may be followed by general convulsions. In one case general epileptic fits occurring only during sleep were succeeded by others during the day of a warning sensation of a disagreeable taste coming up from the stomach into the mouth.

Just as the "Broca" fit, already mentioned, has features locating the lesion in the left inferior frontal gyrus and adjacent tissues, so the "uncinate" fit is distinguished by outstanding characters which it is perhaps unnecessary to recall in detail here, and locating the lesion on the mesial aspect of the temporo-sphenoidal lobe. It may be mentioned, however, that the symptomatology of the fit refers especially to the digestive system. Warning sensations of smell and flavour—in some cases of a pleasant, in others of a disagreeable kind—may be followed by a "dreamy" state, in which smacking movements of the lips, chewing movements, and sometimes spitting acts, have been observed.

In the later stages these attacks may be accompanied by paraesthesias of one side of the body or by convulsive movements of the limbs on the side opposite to the lesion.

The attacks of minor epilepsy described in tumours of the temporo-sphenoidal lobe, in addition to those already mentioned, are "dreamy" sensations, temporary lapses of memory, and momentary blurrings of consciousness, in which the face changed colour and objects might be dropped from the hands.

Summary.—In the foregoing remarks I have attempted to show briefly that tumours involving the cortex and subcortical white matter of a cerebral hemisphere may give rise to seizures having features characteristic of idiopathic epilepsy. These attacks may precede the onset of the symptoms and signs of intracranial tumour by many years and render the diagnosis of the true cause of the attacks well-nigh impossible. The existence of certain signs, however, favours the presence of an organic lesion; such are a well-defined local warning, the presence of some degree of post-convulsive hemiplegia, inequality of the deep reflexes on the two sides, unilateral abolition or impairment of the abdominal reflexes, and, above all, the development of an extensor plantar response. Eventually more decided evidence of a destroying lesion is shown in hemiplegia, hemianaesthesia, hemianopsia or aphasia, according to the locality of the tumour. When along with such well-marked signs, optic neuritis and the other general symptoms of intracranial new growth are present, there is no longer any doubt that the seizures are symptomatic of a cerebral tumour. It is therefore important in all cases of epilepsy to examine the reflexes and the optic discs from time to time, especially if a decided change occurs in the character of the fits or a new symptom develops.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

THE TREATMENT OF ENTERIC FEVER.

AN experience during the South African war which much impressed me at the time is recalled to my mind by Major Broadbent's advocacy of the use of an icebag suspended near to the patient's abdomen.

In June, 1901, when on the high veldt, I had among my patients about twenty suffering from enteric fever. Our camp had been surrounded and attacked the whole day, so that when night fell there was no opportunity for repitching tents, and one had to leave the men, well wrapped in blankets, out in the open. The night was intensely cold, and it was with forebodings of finding several dead that I went to see them in the morning. None were dead; and to my astonishment the most severe cases showed a wonderful improvement, and the whole picture was in striking contrast with that presented by the same men who had previously been treated in army tents. Delirium and restlessness were quieted, temperatures were lower, tongues and mouths were cleaner and moister. I could only attribute the good effects to the antipyretic action of the cold air respired by the lungs. My cases being quickly removed to a base hospital, I had no opportunity of further adopting this treatment.

Hydrotherapy has claimed good results; is it not possible that the persistent inhalation of cold air might prove more efficient and safer? I venture to suggest that the improvement which Major Broadbent has observed is due more to the cooling effect of the ice upon the air than to the local effect upon the exposed portion of abdomen.

Since that war I have had little experience in the treatment of enteric fever, and I do not know whether cold dry air has been tried in the treatment of this particular disease, or for diseases such as malaria, sprue, etc., which tend to persist in hot countries, and are generally quickly benefited by change to a cooler one,—I am, etc.,

London, E.C. OLIVER BEDDARD, M.D.

Reports of Societies.

ULSTER MEDICAL SOCIETY.

AT a meeting on November 26th, Dr. J. S. MORROW, President, in the chair, Dr. J. A. Milroy and Dr. J. F. Craig, of Bangor, were elected Fellows, and Drs. John Ewing, W. R. Hayden, J. B. Logan, S. McComb, W. Patton, H. L. Greer, G. B. Purce, W. McDermott, Elizabeth Robb, E. McSorley, W. G. Anderson, J. Cathcart, N. C. Graham, E. C. T. Emerson, all of Belfast, were elected members. Dr. CALWELL showed (1) a case of *Tertiary syphilitic affection of face*, with a slight resemblance to a disseminated lupus; owing to the shortage of neo-salvarsan, the patient was put on large doses of iodide and intramuscular injections of mercury, the result being rapid healing; there had been a positive Wassermann reaction. (2) A case of *Pruritus in a neurasthenic*. (3) Early *Lupus erythematosus* treated with CO_2 snow. (4) *Psoriasis in the face* in a girl. (5) *Acute generalized prurigo* in a young child. (6) Photographs of two cases of *Pernicious anaemia*, which showed marked increased and decreased skin pigmentation in patches (melanoderma and leucoderma) instead of the customary lemon tint; of a case of *Fröhling's syndrome* (dystrophia adiposo-genitalis) in a young woman; and of a case of severe *Molluscum contagiosum*. Dr. MCKISACK showed a case of *Acromegaly* in the early stage; improvement had taken place under thyroid gland administration. Mr. A. B. MITCHELL showed: (1) A case of *Solid oedema of the eyelids*, and explained the treatment he had successfully adopted in previous cases of artificial lymphatic channels by means of sterilized thread; (2) a specimen of a *Gall bladder filled with stones* which he had successfully excised; (3) a patient with *Skin grafting of upper eyelid*. Mr. T. S. KIRK sent a specimen of *Ulcerative colitis treated by excision*. Mr. FULLERTON showed a case of *Club-foot treated by tarsectomy*, and explained the *rationale* and method of the operation. Dr. THOMAS HOUSTON showed a number of cases of *Acne treated by vaccines*. He emphasized the necessity of finding the microbes which caused the disease; he did not believe in compound vaccines, as one could not increase either independently; one might desire to increase the acne bacillus, but the staphylococcus would be increased far beyond the proper dose in doing so. Long periods of treatment were sometimes necessary. He thought it better to begin with small doses of one microbe, and increase gradually. Dr. J. C. RANKIN showed a series of cases of *Lupus vulgaris* and of *Rodent ulcer*, showing Lenthal Cheatle's distribution, and remarked on the frequency of lupus of the mucous membrane of the nostril causing stenosis of the tear duct, for which the patient not infrequently went to the ophthalmic hospital. Dr. T. KILLEN (Larne) showed (1) A specimen of *Calcified hydrocele of the tunica vaginalis testis;* (2) *A meningocele*, which he had successfully removed from a child aged three weeks; the child was still alive a year and nine months later, but was showing signs of idiocy.

THE late Dr. William Thomas Fernie, of Richmond, Surrey, author of several books on cooking and herbal remedies, left estate valued at £14,983.

Reviews.

POPULAR FREUDISM.

In his translation of the fourth German edition of Professor FREUD'S *Psychopathology of Everyday Life*,[1] Dr. Brill has given the English reading public a book which will help very considerably in making clear to them both the strength and the weakness of the Freudian system of psychology. Like the *Interpretation of Dreams*, which Dr. Brill has also translated, this work deals with the facts of normal mental life, and its generalizations can therefore be adequately tested by any one trained in the methods of psychological observation and conversant with the special method of psycho-analysis which Freud employs. Briefly stated, the general theory here advocated is that many seemingly accidental slips of speech and pen, bunglings of automatic acts, momentary forgetfulness of certain proper names, and similar "faulty psychic actions" are determined by unconscious psychical motives. To be precisely accurate, a faulty psychic action open to this explanation must fulfil the following conditions: "(*a*) It must not exceed a certain measure, which is firmly established through our estimation, and is designated by the expression 'within normal limits.' (*b*) It must evince the character of a momentary and temporary disturbance. The same action must have been previously performed more correctly, or we must always rely on ourselves to perform it more correctly; if we are corrected by others we must immediately recognize the truth of the correction and the incorrectness of our psychic action. (*c*) If we at all perceive a faulty action we must not perceive in ourselves any motivation of the same, but must attempt to explain it through 'inattention' or attribute it to an 'accident'" (pp. 277, 278).

In such a case as the momentary forgetting of a proper name—a failure well known to most people—Freud would explain the lapse as due to the connexion of this name with an unconscious painful idea or system of ideas. It is the painfulness of the ideas which has brought about their "repression," and to this repression their "unconsciousness" is mainly due. To the obvious objection that many painful memories resist burial in the unconscious in spite of the most vigorous efforts of the conscious personality to get rid of them, Freud replies that this "unwillingness to recall something which may evoke painful feelings," though universally active in mental life, is often "inhibited through other and contrary forces from regularly manifesting itself," which seems to be merely an argument *ad hoc*, and too full of assumption to be anything but sophistical.

Perhaps the weakest part of the book is that in which the author tries to explain slips of speech in terms of unconscious motives striving for expression. Such explanations seem in most cases to be very far-fetched. If, for example, one were to say "whack and blite" in a bungling effort to say black and white, the explanation is patent without having recourse to unconscious motivation. The two words are both in readiness, and run a race, as it were, for enunciation. Or rather, the two alternative orders, "black and white" and "white and black" are both in the fringe of consciousness, and blend during actual enunciation. To make sure that nothing lay behind, the reviewer has observed what free associations occurred in relation to this slip of speech, but completely failed to light on anything suggesting in the remotest degree the working of an unconscious factor. He has applied the method of psycho-analysis to the elucidation of many other faulty psychic actions, and in only a small proportion of cases has he found anything that would bear out this particular view of Freud in the cogent way required by strict science.

The book is indeed, though full of illuminating suggestions for psychology, probably the least convincing of all Freud's writings. It shows that pernicious tendency of the more "popular" psychology of the present day to put possibilities in the place of probabilities. Unconscious motivation is undoubtedly a *vera causa*, but the tendency of Freudians to see it acting everywhere deprives it of the scientific value it would otherwise possess for psychology. The emphasis placed upon determinism is also little more than a quibble. There are very few psychologists at the present day who venture to deny determinism in the mental life. Finally, the Freudian view that forgetting is generally an active process, and is the process requiring explanation rather than that of remembering, seems to be actually false, albeit it approaches to the Bergsonian theory in this respect. The enormous amount of work done on memory by the experimental psychologists bears out the common-sense view that it is memory which needs explanation, not forgetting.

In the translation Dr. Brill has added a number of interesting examples, and is to be congratulated on his rendering of a difficult German text.

[1] *Psychopathology of Everyday Life*. By Professor Dr. Sigmund Freud, LL.D. Authorized English edition, with introduction by A. A. Brill, Ph.B., M.D. London and Leipsic: T. Fisher Unwin. 1914. (Med. 8vo, pp. 348. 12s. 6d. net.)

PROFESSOR BERGSON ON DREAMS.

ENGLISH students of psychology will doubtless welcome the appearance of a translation[2] of the lecture on dreams which was delivered by Professor BERGSON before the Institut Psychologique in March, 1901, and appeared in the *Revue Scientifique* on June 8th of the same year. The theory advanced has several novel features, and certainly seems to cover satisfactorily many of the familiar and universal phenomena of the dream process.

Professor Bergson, it should be remembered, is no believer in the parallelism of mental and cerebral activities; he regards the brain as the organ of attention, by means of which the much wider and deeper activities of the mind are brought to a focus and made subservient to the needs of life. When the brain is inactive or deranged, the mechanism of attention being in abeyance, the mind wanders or "dreams." But the dreaming mind is not to be conceived as isolated from or independent of the body; the vague dramas it weaves are composed of sense-impressions and stored memories, just as are the perceptions of wakeful hours. Experiment has firmly proved the fact, of which every one is more or less aware, that in ordinary perception memory plays a large part; for example, when we read, by no means every letter need actually be seen. We are jumping to conclusions all the time, recognizing words by a letter here and there. So, when we close our eyes and surrender our will to the "disinterested" state called sleep, the ocular spectra or "phosphenes" of changing form and colour which move on a dark background before our inner vision become the prey of thronging memories, and are interpreted in fantastic ways. These visual impressions play, Professor Bergson holds, the main but not the exclusive part as the raw material of dreams. Visceral and tactile sensations contribute, no doubt. Thus the contact of the body with its light clothing, breaking in upon a dream, often suggests that we are abroad in our night attire, or, missing the sensation of the pressure of the ground upon our feet, we fancy that we are flying.

The key to Professor Bergson's theory of dream-perception is his metaphor of innumerable memories packed in the subconscious mind under pressure, like steam in a boiler. On this view the steam would presumably be desire in general, by a modicum of some form of which each of our ideas is to be conceived as energized. During sleep, the safety-valve, that is to say the brain, being out of action, the memories throng forth. It is at any rate a conspicuous feature of dreams that the subject is constantly endeavouring to achieve some absurd or trivial purpose, which inexplicably eludes him time after time.

NOTES ON BOOKS.

THE method of question and answer constitutes an excellent means of conveying instruction, and has been cleverly utilized by Major R. J. BLACKHAM, R.A.M.C., Honorary General Secretary of the Indian Branch, St. John Ambulance Association, for the purpose of enabling members of this useful organization to apprehend clearly the essential facts of first aid and home nursing. *The Indian Catechism of First Aid* and *The Indian Catechism of Home Nursing*[3] which have been drawn up by this officer are companions to manuals of first aid and home nursing also prepared by

[3] *The Indian Catechism of First Aid*. By Major R. J. Blackham, C.I.E., V.H.S., R.A.M.C. Simla: The St. John Ambulance Association, Indian Branch. 1914. (5in. by 7 in., pp. 94. 6 annas.) *The Indian Catechism of Home Nursing*. By Major R. J. Blackham, C.I.E., V.H.S., R.A.M.C. Calcutta: Thacker, Spink, and Co. 1914. (5 in. by 4 in., pp. 173. 12 annas.)

him and noticed in the BRITISH MEDICAL JOURNAL (April 18th, 1914, p. 868, and May 2nd, 1914, p. 972). These catechisms have been composed for the use of pupils and examiners "to enable the ambulance student to test and focus his knowledge" in anticipation of appearing for examination, and to guide examiners regarding the manner and extent of conducting their proceedings in ascertaining the fitness of candidates to be granted certificates of proficiency in these subjects. They are well adapted to these purposes. The subjects are skilfully selected and systematically arranged; the questions clearly put, and answers fully and correctly supplied. A table of contents and general index might have been added with advantage. These or similar catechisms might undoubtedly be usefully employed beyond the limits of the Indian Empire.

The spread of school medical work has influenced others besides the children, and in no class of the community has this change been more evident than in the teaching staff of our schools. They are now athirst for knowledge of the how and why of the defects of their charges and what they can do to prevent them. This leads to much cross-examination of the school doctors by the teachers, and in Dr. HUTT'S *Medical Notes for School Teachers*[4] will be found a most useful and satisfactory means of providing the inquiring teacher with good sound ideas on simple matters hygienical. The book is brief, clear in its diction, sound in its statement, and covers a sufficiently wide ground, both as regards special and general conditions, to make it of real value. By no means least valuable is the last chapter, on the choice of employment for defective children.

There was probably never a time when more care was expended on infant health, and Dr. WALFORD has written in the interests of health workers, but truly his *Handbook for Infant Health Workers*[5] is as fit for the mothers. There are few books of the kind that we have read that are so satisfactory—indeed, we would suggest that the title be made more attractive. It might be "Every Mother's Book," and it would pay the State to present a nicely bound copy to every woman on the day she signs the register in the vestry of the church. Marriage was ordained for a purpose, the service makes that plain, and this little book of 54 pages gives clear and simple advice on the early and fateful days of the infant.

TRYPANOSOMIASIS.

AT a meeting of the Society of Tropical Medicine and Hygiene held on October 21st Sir DAVID BRUCE read a paper on the classification of the African trypanosomes pathogenic to man and domestic animals. He divided the pathogenic trypanosomes into the following groups:

A. GROUP: *Trypanosoma brucei* group.
1. *Trypanosoma brucei.*
2. *Trypanosoma gambiense.*
3. *Trypanosoma evansi.*
4. *Trypanosoma equiperdum.*

B. GROUP: *Trypanosoma pecorum* group.
1. *Trypanosoma pecorum.*
2. *Trypanosoma simiae.*

C. GROUP: *Trypanosoma vivax* group.
1. *Trypanosoma vivax.*
2. *Trypanosoma caprae.*
3. *Trypanosoma uniforme.*

With the exception of *T. evansi* and *T. equiperdum* all these trypanosomes are carried from sick to healthy animals by means of tsetse flies. One of the most interesting features of this new classification is the placing of the second human trypanosome, *T. rhodesiense*, in the *Trypanosoma brucei* group. Sir David Bruce believes that they are one and the same. A full account of all the trypanosomes mentioned in the table is given, and those interested in the subject will find a detailed account in the *Transactions* of the Society of Tropical Medicine and Hygiene, November, 1914, vol. viii, No. 1. In the discussion which followed the paper, much diversity of opinion seemed to exist regarding many of these trypanosomes. Some form of classification is evidently necessary, and such a one as given by Sir David Bruce may help to clear away many of the difficulties which apparently exist in connexion with this subject.

THE RESEARCH SCHEMES OF THE MEDICAL RESEARCH COMMITTEE.

THE following document has been handed to us for publication:

St. Stephen's House, Westminster,
October 30th, 1914.

To the Right Honourable C. F. G. MASTERMAN,
Chairman of the National Health Insurance Joint Committee.

Sir,—On behalf of the Medical Research Committee I beg leave to submit for your approval as Chairman of the Joint Committee further details of the schemes for research which have been prepared by the Committee.

The state of war has closely affected the work of the Committee at many points, and by interference with the plans they had made at an earlier date has greatly delayed the presentation of their schemes for research. In connexion with the war itself the Committee have submitted proposals for work wholly additional to the programme they had contemplated earlier, and an account of this will be given in its place below.

In November, 1913, I submitted the general programme of research proposed by the Committee, and this received your approval after the meeting of the Advisory Council, which was held on the 4th December, 1913.

In the communication dated 30th July, 1914, which was laid before you, and circulated later to the members of the Advisory Council, the Medical Research Committee gave a full account of the progress which had then been made towards the establishment of the centralized part of their general programme of research. In that paper the circumstances of the acquisition of the Mount Vernon Hospital building at Hampstead for use as a Research Institute were explained, together with the alternative proposal, made subsequently to the Committee by the governing body of the Lister Institute, that the Lister Institute itself should become, by gift under trust to the nation, the centre of the National Medical Research organization directed by the Committee. The details of the scheme which the Committee framed for the proposed fusion of their interests with those of the Lister Institute are contained in the Memorandum dated 14th July, 1914, which received your approval, and was circulated to members of the Advisory Council.

By a large majority the governing body of the Lister Institute on July 17th, 1914, recommended the members of the Institute to offer to the nation the whole resources of the Institute as a nucleus towards a National Institute of Medical Research upon the terms settled in the Committee's memorandum. The outbreak of war inevitably postponed the statutory meetings of members of the Institute which are required for the final approval of this recommendation, but the Medical Research Committee hope that within a few days a decision will be reached.

In the event of the members of the Institute supporting by a sufficient majority the recommendation of the governing body, steps would be taken to bring it into effect upon the lines of the memorandum already referred to, and the Committee would arrange for the disposal of the Mount Vernon Hospital. If, on the other hand, the proposals of the governing body are rejected, the Medical Research Committee will proceed to the equipment of the Mount Vernon building as a research institute. Plans for this equipment had been prepared in detail last March, and were deferred in execution only on account of the alternative proposals then made with regard to the Lister Institute.

In accordance with the programme of the Committee approved in last December, the following appointments have been made to the staff:

Bacteriology: Sir Almroth Wright, M.D., F.R.S., assisted by Captain S. R. Douglas, M.R.C.S., L.R.C.P.
Applied Physiology: Leonard Hill, M.B., F.R.S., assisted by Benjamin Moore, D.Sc., F.R.S., and Martin Flack, M.A., M.B.
Bio-chemistry and Pharmacology: H. H. Dale, M.A., M.D., F.R.S., assisted by G. Barger, D.Sc., and A. J. Ewins, D.Sc.
Statistics: John Brownlee, D.Sc., M.D., D.P.H.
Secretary of the Committee: W. M. Fletcher, Sc.D., M.D.

Since their appointment, these members of the staff have been actively engaged in work on behalf of the Committee, and satisfactory arrangements have been made for the temporary provision of laboratory and office accommodation, pending a settlement of the arrangements for the Research Institute.

The Committee have given much time to the preparation of schemes of work to be undertaken at the various centres of medical research in the kingdom. Members of the Committee have severally or together visited nearly all these centres, and have everywhere received the fullest possible assistance from the heads of the laboratories. For the courtesy which has been uniformly shown them the Committee would desire to express their most cordial acknowledgements. From many of the centres of research reports have been received in explanation of the chief needs and opportunities of the several departments.

In the detailed arrangements for inquiries into special problems connected with tuberculosis and other diseases which appear in the schemes given below, they have endeavoured to assign particular parts of these inquiries to particular research centres, choosing the centres either on account of special facilities afforded locally, or with a view to the personal predilections and opportunities indicated to them by the directors at the various centres. Within these schemes the Committee hope to arrange for the effective co-operation of workers engaged upon the same or related problems, and for the regular co-ordination both of the methods employed and the results obtained.

In addition to the grants the Committee desire to recommend in connexion with these schemes, it will be seen that they propose grants also for the support of other investigations not initiated by the Committee, but found to be already contemplated or in progress, which promise to be useful in connexion with the present or future work of the Committee.

It will be readily understood that the outbreak of war has interfered disastrously with the plans for research which the Committee had then prepared. Everywhere the staffs of pathological laboratories have been depleted by the loss of men taken for military or medical duties, and long delay has been necessary for the adjustment of the proposals of the Committee, many of which they have been obliged to recast. In several cases the recommendations now to be made by the Committee must be regarded as contingent upon the requirements of military duties, and some of the proposed work may be delayed for many months. At some of the centres of research, however, the Committee have found that while young workers have gone, senior men find the claims of teaching or of practice much reduced. In such cases, there is a prospect of more time being given to research under present conditions, and consequently some valuable work may be expected where in other circumstances it might have been impracticable.

It will be noticed that partly, but not wholly, as a result of the war, the total recommendations of the Committee, together with the expenditure already authorized for the year, do not reach the whole amount of the Research Fund. A balance of about £10,000 is left unassigned for the present, and this balance, reduced by the demands that will be made upon it for special work needed in connexion with the war, may either be invested in accordance with Regulation 12 (2) and carried forward under Regulation 12 (1) to increase the Research Fund of the next or any succeeding year, or used towards the purchase of the Mount Vernon building.

It seems to the Committee to be desirable that in the present circumstances of war a balance of this kind should be left for expenditure at a later date, when the number of available young workers becomes normal again, or, as is possible for some time after the war, even greater than normal. But, apart altogether from the war, the Committee have not thought it desirable to allow their recommendations to absorb the whole of the research fund for the present year. The Committee has still to gain experience in its work, and it will be able to proceed with greater confidence in many directions when its initial proposals have been tested and developed in practice. Of some of the workers for whom grants are proposed the Committee have necessarily only indirect knowledge, and the recommendations have been made under a sense of caution and reserve. The Committee are confident that, both in regard to grants for personal remuneration and to grants for research expenses, there will be a tendency towards enlargement rather than reduction when grants are to be recommended in a subsequent year.

For similar reasons the Committee have not thought it wise to frame for the present any rigid policy to govern the general or particular conditions under which grants should be recommended. In some directions the right lines of policy will be settled best in the course of time by experience, though upon certain points they desire here to make definite recommendations.

In assigning grants the Committee have in general ascertained that the ordinary equipment of the laboratory will be at the free disposal of the worker, and where no special expenditure is involved in the research work no special grant for expenses will be made.

In the great majority of the grants to be recommended in detail below the Committee have received some estimate of the probable special expenditure to be incurred, but in some cases, and especially where work of a wholly new kind is proposed, trustworthy estimates are not yet obtainable. The Committee think, however, that the total sum required in connexion with all the schemes together can be named with sufficient accuracy, and after careful consideration they consider that this amount may be estimated at £4,500. Within the limits of this sum they propose to receive estimates and sanction special expenditure as it is required.

Apparatus or laboratory fittings of permanent and separate value which have been provided from the Research Fund will be considered to be the property of the nation, and they will revert to the direct control and disposal of the Committee when their use by a particular investigator is ended.

The Committee are strongly of opinion that grants for personal remuneration to a scientific worker should be clearly distinguished from those made to meet laboratory or other expenses. This principle is not always followed in grants made from other sources for scientific work, but after mature consideration the Committee have come to the conclusion that it is a sound principle which should be strictly observed. Without this distinction between personal remuneration and research expenses there may be present an obvious temptation towards the reduction of expenditure, leading not to economy but to unsatisfactory work, and to the omission of adequate control experiments.

In all their recommendations the Committee have assigned a sum for personal remuneration for work, part time or whole time, during a year, and they propose that this payment shall be made in convenient instalments if and so long as the Committee are satisfied that the work is being done in good faith. In general, and especially where younger workers are concerned, the Committee will ask the director of the laboratory to be responsible for the proper discharge of the research duties that have been accepted under him.

It has been the practice of some Government Departments giving grants in aid of scientific research to require that the results shall be published only in the form of a Report to the Head of the Department. In the opinion of the Medical Research Committee this practice is undesirable, and has led to the premature burial in Departmental archives of much valuable scientific work. The Committee propose that liberty shall be given to all the workers aided from the Research Fund who are of such scientific status as to be assigned independent work, to publish their scientific results through the ordinary channels of the technical scientific journals. Those workers who are definitely placed under the direction of a professor or head of a laboratory responsible to the Committee will be free to publish only with the consent of their director.

At the same time the Committee would propose to reserve the right to republish in any form the results of work done under assistance from the Research Fund, and it is hoped that from time to time the issue of reports upon special subjects under investigation will be an important factor in the co-ordination and direction of research which it should be the special aim of the Committee to assist.

With a view to the better co-ordination of research carried out at different centres, the Committee propose to establish subcommittees which may be called "special investigation committees." These would be composed of one or more of the scientific members of the Medical Research Committee, with appropriate members of the staff of the Central Institute and of the directors or workers in the other research centres. The members of it would meet for the discussion of work already done, and

for deciding the lines of attack to be followed by fresh research work. From time to time the investigation committee would prepare a report upon a particular subject in summary of well-established results, both positive and negative, and reports of that kind would have great value.

The Committee hope also to be able to arrange meetings between the workers upon the same or closely related problems, so that methods may be compared and checked, unnecessary repetition of work avoided, and ideas exchanged.

The opportunity which the National Medical Research Fund affords of encouraging and enabling a large number of young men in all parts of the kingdom to carry out definite researches under skilled direction appears to the Committee to give promise of the highest value to the future of medical research in the country. The war has for the time being obscured the prospect, but looking to its end the Committee would hope that in the future, by trial of many workers and by selection of the best, a continual supply of able investigators will be assured, to whom grants on a higher scale may be made.

Young extern workers, engaged for the first time by the Committee and working under supervision in some university or hospital laboratory, will be given to understand that satisfactory work will weigh largely with the Committee in offering them further and more important research work in the future. The Committee think that those who specially distinguish themselves in the work entrusted to them should be promoted to a special *cadre* of extern workers to whom continuous employment and a generous salary should be guaranteed for a term of years.

Under such a process of selection the workers as well as the objects of the Committee would benefit, and future appointments of a more permanent kind, carrying pension rights, might be made from among this higher group of external workers. By this means the Committee might hope to secure that the best of the younger men, who as matters now stand in this country are constantly exposed to the inducement to drift into professional practice soon after their research studentships or fellowships expire, will have the prospect of permanent employment in research work. The scales of pay and pension should not be inferior to those of the public medical services, and it would be better in the interests of research that a few of the best men should be well paid than that a larger number should be paid inadequately and left unpensioned.

Upon the outbreak of war it appeared to the Committee that, with the approval of the Chairman of the Joint Committee, it was their immediate duty to place all the resources at their command at the service of the War Office in connexion with any work of a scientific kind required now by military necessities, or likely to be useful in the future. In consultation with Sir Alfred Keogh, Director-General, who gratefully accepted the offer of the Committee on behalf of the War Office, the Committee have already made some emergency arrangements for research work and for other scientific services related to military hygiene. In a preliminary form these proposals obtained your sanction, and an account of them, not yet complete in detail, is given below, appended to the general research scheme of the Committee.

I beg leave now to ask, on behalf of the Committee, that their scheme for research herewith submitted may receive your approval.—I am, Sir, yours faithfully,

(Signed) MOULTON,
Chairman of the Medical Research Committee.

RESEARCH SCHEMES.

TUBERCULOSIS.

1. *Bacteriological Problems.*—Morphology of bacillus. Cultural investigations. Virulence and attenuation. Mutation of type of bacillus. Chemical influences upon bacilli.
Central Institute.
Edinburgh: Professor Ritchie. Chemical Assistant (whole time), £300
Cambridge: Dr. Stanley Griffith (whole time), £600.
Manchester: Professor Boycott. Assistant (whole time), £250.

2. Presence of bacillus in the blood, Much's granules and Spengler's "splitter forms."
London:—Brompton Hospital: Dr. Inman, £100; Dr. Treadgold (part time), £100. St. Bartholomew's Hospital: Dr. Andrewes; Dr. R. G. Canti (part time), £100. City Road Hospital: Dr. Carnegie Dickson (part time), £100.
Midhurst: Dr. Radcliffe, £100; Dr. Todhunter (part time), £100.

3. (i) Pathology of infection in pulmonary tuberculosis and in tuberculosis of glands, bones, etc.
(ii) Types of bacillus found in the different forms of human tuberculosis in different age-groups.
For these and allied problems it is proposed that at each centre should be one or two whole-time workers, dealing with the pathologico-anatomical side, and with the bacteriological, under the supervision and direction of one of the heads of the laboratory.

(iii) Influence of bovine tuberculosis on human tuberculosis of children and adults.
Dublin: Professor O'Sullivan, £100. Dr. Adrian Stokes (part time), £200.

(iv) Pulmonary tuberculosis of children, its prevalence, mode of infection, relation to other forms of tuberculosis, etc.
London:—London Hospital: Dr. Turnbull and two Assistants, £150. Pathologist (whole time), £250. Bacteriologist, Dr. Rajchman (part time), £300.

(v) Evidence of latent tuberculosis, from a study of glands, etc., in a series of unselected autopsies of children from 0–10 years.
Aberdeen: Professor Shennan, £100. Pathologist (whole time), £300. Bacteriologist (whole time), £300.
Dublin: Professor McWeeney, £100. Pathologist, Dr. W. D. O'Kelly (whole time), £300; assisted by Dr. T. T. O'Farrell (part time), £75.
Edinburgh: Professor Lorrain Smith. Dr. W. Campbell (part time), £100. Dr. Mitchell (part time), £200
Glasgow: Professor Muir. Assistant (whole time), £250.
By conference and arrangement between the supervisors, it is hoped that the co-ordination of the work in the different centres will be effected.

4. Systematization of *post-mortem* records in cases of tuberculosis.
Under discussion by a subcommittee composed of Professor W. Bulloch, Professor Shennan, Dr. Spilsbury, and Professor Turnbull, who will endeavour to arrange for the systematization. Printing, etc., £200.

5. Diagnostic value of radiography in tuberculosis.
(i) Central Institute.
(ii) Manchester: Dr. Bythell (part time), £200.
(iii) London: St. Bartholomew's Hospital: Dr. A. W. Stott (part time), £150; Mr. Dudley Stone (part time), £150.

6. Tuberculin: its preparation and value in diagnosis, prophylaxis and treatment.
Central Institute.
Edinburgh: Professor Lorrain Smith. Dr. James Miller (part time), £100.
Midhurst: Dr. Bardswell. Clerical and visiting assistance for following after-history of cases, £150.

7. *Immunity Problems.*—Complement fixation. Precipitins. Opsonins, etc.
Central Institute.
Belfast: Professor Symmers. Dr. Graham (whole time), £250.
London:—King's College Hospital: Dr. Emery, £150. London Hospital: Dr. Bulloch. Dr. Fildes (part time), £100.
Oxford: Professor Dreyer. Dr. Ward (whole time), £300.
Newcastle-on-Tyne: Professor Hutchens and Assistant, £250
Sheffield: Professor Dean (whole time), £250. Clinical Assistants (part time), £100.
Glasgow: Professor Muir. Assistant (whole time), £250.
Davos Platz:—Queen Alexandra Sanatorium: Pathologist (whole time), £300.

8. Effects of non-specific treatment, as iodoform injection, inhalations, helio-therapy, etc.
Newcastle (Ireland):—King Edward VII Hospital: Dr. Crofton and Assistant, £150; Chemical Assistant, Mr. J. Algar (part time), £150.

9. *Tuberculosis in Relation to Environment and Occupation.*—(i) Statistical relations of tuberculosis to conditions tending to produce ill-health, to be studied (*a*) in Northern industrial districts of England, and (*b*) in some Southern rural districts, and the criterion so obtained to be applied to show whether special circumstances in selected trades or districts specially conduce to tuberculosis and to what extent.
Central Institute: Dr. Brownlee and Assistants.

(ii) Special district inquiry, urban and rural, for study of the influence of environmental and economic conditions.
Dr. Brownlee and Assistants. Medical Officer (whole time), £400. Clerical and travelling expenses, £300.
Bradford: Health Census, directed by Dr. Buchan Contribution to expenses, £200.

(iii) Special trade inquiries.
Dr. Hill and Dr. Moore.

(iv) Hygienic observations in factories, schools, etc.
Central Institute: Dr. Hill and Assistants. Visiting and clerical assistance, £300.

RICKETS.

1. Investigations of the *common deficiency factor* in diets of children who develop rickets. Systematization of hospital dietetic records. Relative efficiencies of curative diets.

Bristol: Work under direction of Professor Walker Hall, £300. Visiting assistance, etc., £75.

Glasgow: Work under direction of Professor Muir and Professor Noel Paton. Statistical investigation and visiting expenses, £250. Chemist (part time), £200. Histologist (whole time), £300. Dr. Renton, surgical assistance, £100. Dr. Findlay, clinical assistance, £100.

London: (i) Dr. Corry Mann (Evelina Hospital), £300; Visitor, etc., £150. (ii) Work under direction of Dr. Garrod and Dr. Still, Great Ormond Street Hospital, £300.

2. Relation of fat metabolism to rickets.

London: Absorption of cholesterol and its distribution in the body in rickets. Dr. J. C. Gardner, £100.

Sheffield: Professor Leathes. Assistant, £200.

3. General metabolism in rickets: Analytic studies.

Leeds: Work directed by Professor Grünbaum and Dr. Dudley. Assistant (whole time), £150.

4. Determination of growth factors, with special reference to rickets.

Cambridge: Worker directed by Professor Hopkins, £200.

Edinburgh: Professor Ritchie. Relation of pituitary and other factors to growth. Dr. Fraser (part time), £200.

London: Dr. E. Mellanby, London Hospital, £100. Chemical Assistant (part time), £150. Dr. Plimmer, Prosector to Zoological Gardens, occasional assistance and expenses, £50. Collection of information from foxhound kennel-masters, £200.

5. Effects of rickets on the incidence and mortality of other diseases.

Central Institute: Dr. Brownlee and Assistants; with co-operation offered by Sir George Newman and his staff.

THE HYGIENIC RELATIONS OF MILK.

1. Monograph and critical review of existing international literature upon the hygienic relations of milk (in extension of the special reports upon parts of the subject already published by the Local Government Board).

Dr. Janet Lane-Claypon (seconded for the purpose by permission of the President of the Local Government Board), with expenses of publication, £400.

The preparation of co-ordinated schemes of work will be deferred until the completion of the general monograph, but the following special inquiries will be begun:

2. Effects of various commercial treatments and methods of sterilization upon nutritive value—(*a*) experimental; (*b*) statistical.

Central Institute.

Manchester: Professor Sheridan Delépine. Expenses of organized inquiry at Manchester, co-ordinated with work at Central Institute, £500.

Birmingham: Professor Leith and Sir Oliver Lodge. Electrical purification of milk: Assistance, £300.

3. *Contamination of Milk.*—Persistence of tuberculous infection in pasture lands.

Reading: Dr. Stenhouse Williams. Assistant (whole time), £200. Laboratory expenses, field rents, etc., £300.

Dublin: Professor O'Sullivan. Bacteriology of Dublin milk supply: Dr. Wigham (part time), £100. Dr. Spiers (part time), £100.

4. The cellular elements of milk in various conditions. (The relations of milk supply to tuberculous infections will be studied also under the tuberculosis scheme, § 3.)

London:—King's College: Professor Howlett and Mr. Revis, £200.

RHEUMATIC INFECTIONS.

1. Bacteriology and morbid histology of rheumatic infections. Study of incidence of rheumatic infections in different parts of the city.

Bristol: Dr. Carey Coombs (part time), £200. Assistant, £150.

2. Study of experimental rheumatic infections supplemented by study of hospital material.

Liverpool: Professor Beattie. Qualified Assistant (whole time), £250.

DISEASES OF THE NERVOUS SYSTEM.

1. Cerebro-spinal fluid in tuberculous meningitis and other diseases. Micro-chemistry of cerebro-spinal fluid.

Cardiff: Dr. A. J. Howell, King Edward VII Hospital, £150.

2. Cerebro-spinal fluid in nervous diseases.

London: Dr. J. G. Greenfield, National Hospital, Queen Square. £200.

3. Application of micro-chemical methods to the study of cerebro-spinal fluid in various conditions.

Cardiff: Dr. R. V. Stanford, City Mental Hospital, £250. Assistant, £150.

4. Certain groups of brain lesions, especially those of speech centres.

London: Professor Mott. Dr. D. F. Sano (whole time), £250.

5. Graphic study of speech with reference to early diagnosis of nervous diseases.

London: Professor Mott. Dr. Scripture (whole time), £250.

THYROID SECRETION.

1. Chemical relations of iodine to the secretion.

London:—Guy's Hospital: Dr. P. P. Laidlaw, £50; assisted by Mr. Finnemore, £50.

2. Iodine in diet and thyroid secretion. Etiological importance of iodine in endemic goitre.

Cardiff: Mr. M. H. Renall, University College of South Wales, £100.

CHRONIC (RHEUMATOID) ARTHRITIS.

The morbid anatomy of chronic arthritis.

Cambridge:—Research Hospital: Dr. Strangeways, £250.

DUST INHALATION AND PULMONARY DISEASE.

1. Investigation of effects produced by dangerous dust (for example, powdered flint) and harmless dust (for example, coal dust) respectively.

Liverpool: Professor Beattie. Assistant, £200.

2. Study of effects produced by dusts in mines and workshops.

Oxford: Under Dr. J. S. Haldane's direction. Dr. A. E. Mavrogordato (whole time), £250. Travelling and other expenses, £150.

3. Chemical and physical inquiries, related to the above.

Stoke-on-Trent: Dr. Mellor, Director of the Pottery School, £100. (Towards the total annual expenses (about £700) of these researches, the Home Office has undertaken to contribute £300.)

ORAL SEPSIS.

Studies of oral sepsis and its relations to other diseases in workers and others.

Cardiff: Dr. Scholberg with Dr. Stevens, £250.

EPIDEMIC INFANTILE DIARRHOEA.

Anaërobic bacteria.

Edinburgh: Dr. Logan (part time), £150.

STATUS LYMPHATICUS.

1. Etiology and distribution of status lymphaticus; collective inquiry undertaken at the request of the Pathological Society.

Cardiff: Professor Emrys-Roberts. Expenses of inquiry, £50. Edinburgh: Dr. McNeill. Expenses of inquiry, £50.

2. Status lymphaticus in relation to infections.

Edinburgh: Dr. McNeill (half time), £200.

DIABETES.

The glycolytic activity of blood in cases of diabetes.

London:—St. Thomas's Hospital: Dr. McLean, £100; Assistant (whole time), £250.

GENERAL PATHOLOGICAL RESEARCHES.

Cardiographic studies.

London:—University College Hospital: Dr. Lewis. Qualified Assistant (part time), £200. Laboratory Assistance, £50.

The biophysics of Brownian movement.

Cardiff: Mr. L. H. Shaxby, £100.

Hypersensitivity in asthma and allied clinical phenomena.

London:—St. Bartholomew's Hospital: Dr. A. E. Stansfield (part time), £200.

Morbid histology of ductless glands.

Cardiff: Mr. T. H. Burlend, £50.

Infections by organisms belonging to the group endomyces.

Cardiff: Professor Emrys-Roberts, £100.

Bacilluria, with special reference to the *coli* group.

Cardiff: Dr. H. Evans, £100.

Epidemic and endemic diphtheria.

Cardiff: Dr. S. J. Ayre, £100.

Lipoid content of organs and its relation to toxins.

Edinburgh: Professor Lorrain Smith. Clinical Assistant, £250.

LOCAL DISTRIBUTION OF RESEARCHES.

England.

Birmingham: Professor Leith and Sir Oliver Lodge—Electrical purification of milk, £300.

Bradford: Health Census of the City. Grant for assistance in study of environmental relations of tuberculosis, £200.

Bristol: Dr. Carey Coombs—Bacteriology and morbid histology of rheumatic infections, etc., £200. Assistant, £150. Dr. Walker Hall—Dietetic factors in rickets, £300. Visiting assistance, etc., £75.

Cambridge: Dr. Stanley Griffith—Virulence and attenuation of tubercle bacillus, etc. (whole time), £600. Dr. Strangeways, Cambridge Research Hospital—Morbid histology of chronic arthritis, etc., £250. Professor Hopkins—Growth factors in relation to rickets, £200.

Leeds: Professor Grünbaum—Analytical studies in the metabolism of rickets: Assistant, £150.

Liverpool: Professor Beattie—(i) Experimental rheumatic infections: Assistant (whole time), £250. (ii) Effects of inhalation of dangerous and non-dangerous dusts: Assistant, £200.

London:—

St. Bartholomew's Hospital: Dr. Stott and Mr. Dudley Stone—Diagnostic value of radiography in tuberculosis, £300. Dr. Canti—Morphology of tubercle bacillus, £100. Dr. Stansfield—Hypersensitivity and asthma, £200.

Brompton Hospital: Dr. Inman—Presence of tubercle bacillus in the blood, etc., £100; assisted by Dr. Tredgold, £100.

Charing Cross Hospital: Professor Mott and Dr. Sano—Brain lesions, £250. Professor Mott and Dr. Scripture—Graphic studies of speech, £250.

City Road Hospital: Dr. Carnegie Dickson—Much's granules, etc., £100.

Evelina Hospital: Dr. Corry Manu—Dietetic factors of rickets, £300. Visiting Assistant, etc., £150.

Great Ormond Street Children's Hospital: Studies of rickets, directed by Dr. Garrod and Dr. Still—Assistants, £300.

Guy's Hospital: Dr. Laidlaw and Mr. Finnemore—Iodine compounds and thyroid secretion, £100.

King's College: Professor Hewlett and Mr. Revis—Cellular elements in milk, £100.

King's College Hospital: Dr. Emery—Immunity problems in tuberculosis, £150.

London Hospital: Dr. Bulloch and Dr. Fildes—Immunity problems in tuberculosis, £100. Dr. Turnbull—Evidence of latent tuberculosis in children, with two assistants, £150; Histological Assistant (whole time), £250; Dr. Rajchman (part time), £300. Dr. Mellanby—Experimental rickets, £250.

National Hospital, Queen Square: Dr. Greenfield—Cerebro-spinal fluid in nervous diseases, £200.

St. George's Hospital; Dr. J. C. Gardner—Cholesterol in rickets, £100.

St. Thomas's Hospital: Dr. H. Maclean—Glycolysis in blood, £100. Assistant (whole time), £250.

University College Hospital: Dr. Lewis—Cardiographic studies, £250.

Zoological Gardens: Dr. Plimmer—Rickets in animals, £50.

Manchester: Profesor Boycott—Chemical influences upon bacilli: Assistant (whole time), £250. Dr. Bythell—Diagnostic value of radiography in tuberculosis, £200. Professor Delépine—Hygienic relations of milk: Organized inquiry, £500.

Midhurst: Dr. Radcliffe—Presence of tubercle bacillus in the blood, £100; Assistant, £100. Dr. Bardswell—After-history of tuberculous cases: Clerical and visiting expenses, £150.

Newcastle-on-Tyne: Professor Hutchens—Immunity problems, £250.

Oxford: Professor Dreyer—Complement fixation and other immunity problems in tuberculosis. Assisted by Dr. Ward (whole time), £300. Dr. J. S. Haldane—Pulmonary effects of inhalation of dusts in mines and workshops. Assisted by Dr. Mavrogordato (whole time), £250. Travelling and other expenses, £150.

Reading: Dr. Stenhouse Williams—Persistence of tuberculous infection of pasture lands, £500.

Sheffield: Professor Dean—Studies of serum reactions. Assistant (whole time), £250. Professor Dean—The Wassermann reaction in tuberculous cases. Assistant (part time), £100. Professor Leathes—Fat metabolism in rickets, £200.

Stoke-on-Trent: Dr. Mellor—Chemical and physical studies of dusts dangerous to pottery workers, £100.

Scotland.

Aberdeen: Professor Shennan—Pulmonary tuberculosis of children, mode of infection, etc. Evidence of latent tuberculosis in children, etc., £100. Pathological Assistant (whole time), £300. Bacteriological Assistant (whole time), £300.

Glasgow: Professor Muir—Immunity problems of tuberculosis. Assistant (whole time), £250. Professor Muir—Types of tubercle bacilli in lesions. Assistant (whole time), £250. Professor Muir and Professor Noel Paton—Studies in rickets. Dr. Findlay—Morbid histology of rickets and experimental rickets, £100. Dr. J. M. Renton—Thymusectomy and experimental rickets, £100. Metabolic studies in rickets: Chemical Assistant (part time), £200; visitors for dietetic inquiries, etc., £250; Histological Assistant (whole time), £300.

Edinburgh: Professor Ritchie—Bacteriological problems of tuberculosis. Assistant (whole time), £300. Dr. Fraser—Determination of factors in experimental rickets (part time), £200. Dr. Logan—Epidemic infantile diarrhoea; anaërobic organisms (part time), £150. Dr. McNeill—Status lymphaticus (part time), £200; collective investigation expenses, £50. Dr. Mitchell—Surgical tuberculosis, etc. (part time), £200. Dr. W. Campbell—Generalized tuberculosis (part time), £100. Dr. J. Miller—Graduated doses of tuberculin (part time), £100. Professor Lorrain Smith—Lipoid content of organs and its relation to toxins. Assistant, £250.

Ireland.

Belfast: Professor Symmers—Immunity problems of tuberculosis. Dr. Graham (whole time), £250.

Dublin: Professor McWeeney—Evidence for latent tuberculosis in children, £100; Dr. W. D. O'Kelly (whole time), £300; Dr. T. T. O'Farrell (part time), £75. Professor O'Sullivan—(i) General blood infection in tuberculosis £100; Dr. Adrian Stokes (part time), £200; (ii) bacteriology of Dublin milk supply—two Assistants, £200. Dr. Crofton—Non-specific treatment of tuberculosis: with Assistant at King Edward VII Sanatorium, Newcastle (part time), £150; assisted by Mr. J. Algar (part time), £150.

Wales.

Cardiff: Professor Emrys-Roberts—Status lymphaticus (with Dr. McNeill of Edinburgh): Expenses at Cardiff, £50. Infections by organisms belonging to the group Endomyces (with Dr. A. J. Howell), £100. Mr. M. H. Renall—Iodine content of thyroid glands under different conditions, £100. Dr. S. J. Ayre—The incidence of diphtheria endemic and epidemic in Llantwit Major, £100. Mr. T. H. Burlend—Morbid histology of ductless glands, £50. Dr. A. J. Howell, King Edward VII Hospital—Cerebro-spinal fluid investigations, £150. Dr. H. Evans, King Edward VII Hospital—Studies of bacilluria with special reference to the *coli* group, £100. Mr. L. H. Shaxby—Biophysics of Brownian movement, £100. Dr. Scholberg, with Dr. Stevens—Oral sepsis, £250. Dr. R. V. Stanford, City Mental Hospital—Pathological studies of cerebro-spinal fluid; applications of microchemical methods, £250. Assistant, £150.

Switzerland.

Davos Platz: Queen Alexandra Sanatorium—Pathologist (whole time), £300.

NATIONAL MEDICAL RESEARCH FUND, 1914.

Summary of Proposed Distribution.

	£	£
Central Institute:		
Part purchase of Mount Vernon Hospital and other expenses		12,005
Repairs at Mount Vernon, wages, and interest on unpaid purchase money	1,656	
Salaries of scientific staff	3,977	
Premiums for pensions	1,100	
Apparatus and chemicals	800	
		7,553
Administration:		
Medical Research Committee and Advisory Council	1,470	
Salaries of secretary, assistant secretary, and chairman's secretary	1,270	
Office expenses	150	
		2,890
Research Schemes:		
Grants recommended above	19,600	
Additional grants for laboratory expenditure ...	4,500	
		24,100
		£46,588

Medical Research Fund (1914) ...	£56,500	
	46,588	
Estimated balance ...	£9,912	

EMERGENCY WORK IN CONNEXION WITH THE WAR.

I. *Inoculation Department, St. Mary's Hospital.*

OWING to the negotiations in connexion with the Lister Institute, the Committee have not yet been able to provide direct opportunities for clinical research by the members of the research staff who have already been appointed and have begun their work. If the proposals with regard to the Lister Institute become effective, at least two years must pass before the hospital offered by Lord Iveagh can be ready and its beds occupied. If the Committee as an alternative return to the Mount Vernon scheme, the proposed fifteen beds would not be available there before the summer of 1915. In the meantime the staff, and especially the bacteriological department under Sir Almroth Wright, will be very heavily handicapped in their work by the absence of beds for research.

The Inoculation Department at St. Mary's Hospital, and with it the clinical facilities which Sir Almroth Wright has at present, would probably have ceased altogether upon his withdrawal to the service of the National Research scheme, but the Committee found that by a reasonable financial arrangement they could secure the use at St. Mary's Hospital of beds for research work by Sir Almroth Wright, or other members of their staff,

for so long as the Committee is without clinical resources of its own. Incidentally, such an arrangement allowed the possibility of Sir Almroth Wright and his assistants maintaining their laboratory work uninterrupted until laboratories under the control of the Committee are ready, and these can hardly be ready now before next Christmas at the earliest.

It was proposed accordingly that the Committee should offer to pay to St. Mary's Hospital, through the Committee of the Inoculation Department, £2,500 for the year from October 1st, 1914, for the use of twenty-five of the beds at present under Sir Almroth Wright. This sum would include the whole of the expenses of the hospital service of all kinds for the beds, full or empty, but the selection and the medical care of the patients would be under the control of the Committee acting through its research staff. It was to be understood that the beds would be available for researches conducted by other members of the staff with the approval of the Committee, but it was expected that the great majority of the beds would be used in connexion with work in the Bacteriological Department.

While these proposals were under consideration war was declared, and the reasons given already for the proposed temporary maintenance by the Committee of the Inoculation Department and Research beds at St. Mary's Hospital, from the point of view of the normal research work which had been contemplated, appeared to the Committee to be greatly strengthened by the outbreak of war and the urgent need for bacteriological work connected with it. The scheme was approved by the Chairman of the Joint Committee, and accepted by the Committee of the Inoculation Department. An option for the extension of the scheme for a second year has been obtained.

Permission was given to Sir Almroth Wright and Captain Douglas to devote the whole of their time to the preparation of vaccines for the use of H.M. Forces, and during the six weeks that followed they were able to furnish the Admiralty and the War Office with 850,000 doses of antityphoid vaccine, and at the same time to supply 350,000 doses of antisepsis vaccine to the Admiralty, the War Office, and the French and Belgian armies. More recently further large quantities of vaccines have been supplied to the War Office. All this work was done at the Inoculation Department of St. Mary's Hospital, where the Committee have undertaken to provide the necessary staff at a cost of £1,000 for the year.

The Committee are providing for a visit to Petrograd by Dr. Freeman, of Sir Almroth Wright's staff, for the purpose of obtaining suitable cultures of cholera from the eastern theatre of war. These will be used for the preparation of vaccines in case of need if the infection is transferred by troops to the western theatre.

Leave of absence was given by the Committee to Sir Almroth Wright and Captain Douglas, in the event of their being required for military duties. Sir Almroth Wright has now been appointed consulting physician to H.M. Forces overseas, with the rank of colonel, and he has already proceeded to France. He hopes to investigate at the theatre of war the existing need for bacteriological investigations, and to return as soon as possible to assist the Committee in making provision for these.

2. Other Schemes Related to the War.

The Mount Vernon Hospital building, which has been standing empty during the consideration of the proposals made to the Committee in regard to the amalgamation with the Lister Institute, was placed, with the approval of the Chairman of the Joint Committee, at the disposal of the War Office, if it should be required, as additional accommodation for the sick and wounded. During the great influx of wounded in October the building was temporarily taken over by the War Office, and it is now being fully occupied and staffed.

The Medical Research Committee, with the permission and cordial co-operation of the Army Council, is making arrangements for the extension of the existing facilities for the proper bacteriological investigation of infected wounds and other pathological work at the chief military hospitals in this country, including the Territorial general hospitals.

The Army Council has also approved of a proposal whereby the whole of the work of dealing with the statistical records of the war will be undertaken by the statistical staff of the Medical Research Committee. The military authorities have expressed their willingness to give all facilities with the view of ensuring that the records shall be made in a uniform manner, and collected under the advice of the staff which will have to handle them. The work of dealing with the records will occupy a considerable amount of time, and will involve a substantial expenditure; but it is hoped that the result will provide complete, well-arranged, and thoroughly reliable statistics.

A more detailed account of these schemes will be submitted at the earliest opportunity.

THE ORIGIN AND DEVELOPMENT OF THE RED CROSS.

(Continued from p. 924.)

JAPAN.

AN account of the organization and resources of the Red Cross Society of Japan was given by Surgeon-General W. G. Macpherson, C.M.G., who was attaché to the Japanese army in the Russo-Japanese war (1904–5).[1] According to this report, the Society had its origin in 1877, during the civil war of Kagoshima, under the name of "Hakuai-sha," or "Society of Benevolence." When the Japanese Government became a signatory to the Geneva Convention in 1886, the name was changed to its present title, "Dai Nihon no Seki-ju ji Sha," or the "Red Cross Society of Japan." In 1894–1895 it assisted during the war with China, and in 1900–1901 during the Boxer troubles. In 1898 it became an Incorporated Society with civil rights, and began to enter into contracts in order to guarantee a personnel for the various establishments which the Society undertakes to provide in time of war or of public calamity. An Imperial Ordinance was passed in December, 1901, authorizing the Society to assist the Army and Naval Medical Services in time of war, and laying down certain rules regarding discipline and control, relative rank of the personnel, and so forth.

The Society began as an influential committee without local branches, and at a time when there were no other benevolent societies formed for aiding sick and wounded in war. The local development of the Society was the work of the Central Committee. The result of this is that the Society is a highly centralized body. The Japanese authorities, however, consider this to be one of the essential features in its utility, because by means of centralized control independent local associations and rival societies do not, and are not, permitted to exist. There is, however, one affiliated association, "The Ladies' Volunteer Nursing Association," which was formed in Tokio in 1887. It is now called the Ladies' Committee of the Red Cross Society, and no one may belong to it who has not first become a member of the Red Cross Society.

Professor Ariga, one of the leading members of the Central Committee, drew up a report showing that the Society had in 1900 over 900,000 members, equal to 1 in every 45 of population. The income during 1903 was 2,965,300 yen, or over £300,000 sterling. In addition to this annual income, which is obtained from members' subscriptions, donations, legacies, etc., the Society possesses a capital sum of 7,371,000 yen (approximately £767,000 sterling), exclusive of buildings and other immovable property.

Membership.

There are three classes of members: (*a*) honorary, (*b*) special, (*c*) regular. The first class is practically confined to the imperial family, and consists of 30 members only. The second class contains over 5,000 members, and is formed of those who have been specially selected by the Standing Council for admission without subscription, or who have made a donation of not less than 200 yen. The regular members form the bulk of the Society. They pay an annual subscription of 3 to 12 yen (6s. to 24s.) for a period of ten years, or a single subscription of 25 yen (50s.). Insignia of membership in the form of a silver medal, worn on the left breast, are granted by

[1] *Journal of the Royal Army Medical Corps*, vol. vi, January-June, 1906, p. 467.

the Emperor, and are allowed to be worn along with other State decorations at public gatherings.

The members of the Ladies' Committee numbered, at the time of Surgeon-General Macpherson's report, 538. They belong to the upper classes of society, and pay a monthly subscription of 20 sen, or 5d., for ten years, or a single donation of 20 yen (40s.).

In addition to membership there is what may be called the personnel of the Society. These form the various groups or detachments, trained by the Society for work in war and public calamities, or held in reserve for that purpose, and paid by the Society for their services.

The organization for war has been carried out on lines laid down by the medical departments of the army and navy. The chief organization consists of what are described as "*Relief Detachments*": These are composed of the following personnel: 2 physicians, 1 apothecary, 1 clerk, 2 chief nursing sisters and male nurses, 20 nursing sisters or male nurses; a total of 28. Each relief detachment is organized to take charge of 100 patients. Their function in war is to replace the sick attendants in the military hospitals of the home territory as these are pushed forward into the area of operations.

At the date of Surgeon-General Macpherson's report the Society had organized 112 "relief detachments" for work in army hospitals, and four for work in naval hospitals. Eighteen of the former are organized with male instead of female nurses; there were two chief male attendants and 20 male nurses. Although the "relief detachments" relieve the army medical establishments gradually in the home territory, they may be moved on to relieve similar establishments in hospitals on the lines of communication as the war progresses. The peace distribution in war is under the control of the Standing Council acting under the orders of the military and naval authorities. For the exercise of proper control in this respect a general administrator of the Red Cross Society is appointed to the Imperial head quarters in Tokio. No representative of the Society has been sent into the field.

"*Transport Columns*" have been organized since the Boxer troubles, and have the following composition: 1 manager, 1 surgeon, 1 clerk, 9 chief male attendants, 3 male attendants, 3 chief stretcher-bearers, 120 stretcher-bearers; total 138. Only three such columns have up till now been organized, but, it is stated, if the experiment proves them to be efficient during the present war, their number can be increased in a few months. The function of the "Transport Columns" is to undertake the transport of serious cases where there are no proper roads for transport by wheeled carriages or other methods. The need of such columns was felt during the operations in China. Each column is organized to carry 30 serious cases, and afford at the same time medical attendance and nursing.

At the date of the report the Society had two *hospital ships*, fitted for the conveyance of 200 sick and wounded, but it was intended to construct two more, each fitted for 100 patients. The establishments are as follows: 1 manager, 4 surgeons, 1 apothecary, 2 clerks, 2 assistant apothecaries, 2 female and 2 male chief nurses, 20 female nurses, 20 male nurses; total, 54. Hospital ship for 100: 1 manager, 3 surgeons, 1 apothecary, 1 clerk, 1 assistant apothecary, 1 chief nurse (female), 1 chief nurse (male), 10 female nurses, 10 male nurses; total, 29. In time of peace the hospital ships are hired out as passenger steamers.

At the beginning of 1906[2] the personnel employed by the Japanese Red Cross Society was as follows:

Directors, 5; chief surgeons, 6; surgeons, 347; pharmaceutists, 168; clerks, 191; assistant pharmaceutists, 6; chief female nurses, 239; chief male nurses, 110; chief stretcher bearers, 3; female nurses, 2,026; male nurses, 643; stretcher bearers, 144; temporarily employed chief female nurses, 9; temporarily employed chief male nurses, 2; temporarily employed female nurses, 607; temporarily employed male nurses, 472; making up 4,978 persons in all.

At a meeting of the Japan Society, a report of which appeared in the BRITISH MEDICAL JOURNAL of January 20th, 1906, Miss Ethel McCaul said the Red Cross Society of Japan was far in advance of all others. On its foundation it was placed immediately under Government, so that in times of peace a million members, with their hospitals, hospital ships, doctors, nurses, stretcher bearers, and lay workers, were equipped and fully trained according to the Japanese army regulations. On the outbreak of war they were available at a few hours' notice. The head quarters are in Tokio, whence the local branches receive all instructions. All governors and mayors throughout Japan are representatives of the societies, and are authorized to hold meetings and develop the work. Members are recruited from every grade and from every part of the empire. In each district a local branch is established, the members subscribing yearly from 6s. to £20.

The Japanese quickly perceived that to make the organization a permanent success they must make it a part of the daily life of the masses. Therefore numerous Red Cross hospitals have been established throughout the country, all of which are used in time of peace as hospitals. These hospitals are free, but in each of them paying patients are admitted to the wards, which in war time are reserved for officers. Some hospital ships built by it were hired out in time of peace as passenger steamers. The sympathy and co-operation of the women of the country is enlisted by the Ladies' Volunteer Nursing Association, which is entirely under the control of the Red Cross. The Association is practically the factory and workroom of the Society, which undertakes to provide the Government with the necessary comforts for the sick and wounded.

The organization is so good that all through the war between Russia and Japan there was not the slightest hitch, and everything required was provided with the promptness and regularity of a business firm. In moving a vote of thanks to Miss McCaul, Professor G. S. Longford described how the Japanese in the late war carefully preserved the personal property of the dead Russian soldiers, and endeavoured in every possible manner to communicate with relatives so that the property might be restored to them. He contrasted this humane procedure with the barbarous ferocity with which the Japanese treated all prisoners of war before 1868, when, at the instigation of a British medical man, Dr. W. Willis, who accompanied a Japanese force operating against some rebels, the authorities commenced to treat wounded soldiers and prisoners with humanity.

In the November number of the *Windsor Magazine* Millicent H. Morrison states that the members of the Japanese Red Cross Society now number one million and a half. In addition to its principal hospital in a suburb of Tokio, which is the pattern of other Red Cross hospitals throughout Japan, the permanent administration offices and stores are in the capital. The storehouses are built round a courtyard in the rear. These include a museum showing the evolution of hospitals and what has been done by other countries in the improvement of all appliances, including uniforms and kitchen equipment, for the benefit of the sick and wounded. The surgical instruments are always kept in condition for immediate use by a small staff. As showing the interest taken by the Imperial family of Japan in Red Cross work, it may be mentioned that every year there is a gathering in the Hibiya Park over against the moat of the palace. This is always attended by one or more of the Imperial household, who receive the banzais of 35,000 or 40,000 people. The late Empress, in a poem, spoke of the Red Cross as

> Universal love
> Overflowing boundaries
> Of Empire,
> Even unto strange lands.
> How glorious this age!

(To be continued.)

[2] BRITISH MEDICAL JOURNAL, January 27th, 1906, p. 210.

ROYAL MEDICAL BENEVOLENT FUND.

AT the last meeting of the committee twenty-eight cases were considered and grants amounting to £278 4s. voted to twenty-six of the applicants. An annuity of £20 was also made to one of the applicants. The following is a summary of the cases relieved:

Widow, aged 55, of M.R.C.S.Eng. who practised in Wiltshire and Devon. Late husband had been helped by the Fund, and on his death in June this year left his widow entirely unprovided for. Sister has helped her a little but cannot continue to do so. One daughter, unable to help. Voted £12 in twelve instalments.

Widow, aged 69, of M.R.C.S.Eng. who practised in London, died in 1913, and left his widow totally unprovided for. Had commenced a boarding house but was seized with aphasia and

unable to carry it on. Made an annuitant of £20 and the Guild to try to get her into a home.

Widow, aged 65, of L.R.C.P.and S.Irel. who practised at Catford and Southend. Too old to work. Lives with a son and his family who cannot afford to keep her. Has an Epsom pension. The case strongly recommended by the Guild visitor. Relieved twice, £18. Voted £12 in twelve instalments.

Daughter, aged 71, of M.D.Lond. who practised in North London. Unable to work owing to defective eyesight. Has recently obtained an annuity from another society. Proposes to apply for the old age pension. Voted £2.

Widow, aged 51, of M.D.Edin. who practised at Newcastle-on-Tyne, has C.M.B. certificate and earned a living by nursing, but fractured her leg some time since, and is making very slow progress. A little help from a married daughter, but not enough to keep her. Voted £12 in twelve instalments.

Widow, aged 55, of M.D.Aberd. who died in 1904 and practised at Balham. Lost the little money left her by husband in assisting her only son, a mining engineer, in South Africa. The venture was a failure, and the son has joined the South African Army. Qualified mental nurse, but finds difficulty in obtaining work on account of age. Voted £10 in two instalments, and referred to the Guild.

Widow, aged 59, of L.S.A.Lond. who practised at Oldham and died in 1898. Youngest son, who has in the past entirely supported her, has joined the army, and up to the present has not had maintenance allowance. Two other children unable to assist. Voted £5 and recommended to apply to the Prince of Wales's Fund.

Son, aged 18, of L.R.C.P. and S.Ed. who is also a recipient of the Fund. Assistance wanted for completion of education as a dentist. The case recommended by the Glasgow branch of the Guild and the current fees wanted £13 13s. The Guild undertook to provide £9 9s. and the Fund £4 4s.

Daughter, aged 55, of M.R.C.S.Eng. who practised at Liverpool. Suffers from asthma and internal trouble and unable to work. Uncle pays rent, but otherwise no income. Previous relief five times, £56. Voted £12 in twelve instalments and referred to the Guild.

Widow, aged 59, of M.R.C.S.Eng. who practised at Liverpool. Has endeavoured to earn a living by nursing, but only earned £19 this year. Age makes it difficult to obtain patients. Relieved five times, £25. Voted £12 in twelve instalments and referred to the Guild.

Widow, aged 56, of L.R.C.P. and S.Edin. who practised at Grantown and died in 1913, and was a recipient of the Fund. Five children, all at school. Endeavours to earn a living by taking in boarders, but cannot make sufficient to support the family. Relieved once, £12. Voted £12 in twelve instalments.

Daughter, aged 63, of F.R.C.S.Eng. who practised at Chester. Acts as housekeeper when able to obtain posts, but has been unsuccessful of late. Relieved twice, £12. Voted £10 in two instalments.

Widow, aged 77, of M.D.Lond. who practised in London, suffers from rheumatic gout in hands and feet. Only income two small annuities. Relieved seven times, £35. Voted £10 in two instalments.

Daughter, aged 48, of M.R.C.S.Glasg. who practised in India and London. Unable to work owing to nervous breakdown. Only income £23 per annum from investments. Relieved once, £5. Voted £5 in one instalment, and referred to Guild to see if they can assist her to have her teeth attended to.

Daughters, ages 62 and 56, of M.R.C.S.Eng. who practised at Bexley Heath. They try to obtain a living by needlework, but so far this year have only earned £6 5s. Only other income £20 from a friend. Previous relief ten times, £154. Voted £20 in twelve instalments.

Widow, aged 67, of L.R.C.P.Edin. who practised at Cardiff. Health very bad. Only income £24 per annum from another charity. Previous relief nine times, £66. Voted £12 in twelve instalments.

Wife, aged 48, of M.R.C.S.Irel. who practised at Chesham, but deserted her in 1905. Three children, the youngest at Epsom and others at school. Health very unsatisfactory and eyesight defective. Only income about £24 per annum. Previous relief, £12. Voted £2, with leave to apply again, and referred to Guild.

Widow, aged 56, of L.R.C.P.Edin. who practised at Langley. Endeavours to earn a living by taking in paying guests, but unsuccessful of late. Lives in own house, but it is mortgaged. Relieved four times, £40. Voted £10 in two instalments.

Daughters, ages 55 and 64 of an M.D. who practised in Cornwall. They both have poor health, but try to earn a living by taking in paying guests, but this year has been very bad. They live in own house. Relieved five times, £82. Voted £18 in twelve instalments.

Widow, aged 76, of M.R.C.S.Eng. who practiced at Holderness. Health very bad. Has six children 30 to 53, but they are unable to assist. Takes in lodgers when she can get them, but too old to do much. Relieved four times, £48. Voted £12 in twelve instalments.

Widow, aged 54, of L.S.A.Lond. who practised at Islington. Practically blind, and her youngest son who practically supported her has joined the army. Her other son married, unable to help. Relieved ten times, £64. Voted £18 in twelve instalments.

Daughter, aged 60, of L.S.A.Lond. who practised at Longton. Is suffering from spinal curvature and internal trouble. Only income £25 per annum and a little help from the Guild. Relieved fourteen times, £152. Voted £18 in twelve instalments.

L.R.C.P.and S.Edin., aged 57, who practised at Old Kilpatrick. Suffering from spastic paralysis and unable to work. Lives with sister, who keeps a boarding-house. One son, aged 18, whom the Fund and Guild are helping to educate as a dentist. Relieved ten times, £120. Voted £12 in twelve instalments.

Widow, aged 63, of M.R.C.S.Eng. who practised at Highgate. Has been ill some months and recently operated on for uterine fibroids, and suffers from rheumatism. Used to earn a living by dressmaking. Relieved once, £12. Voted £12 in twelve instalments.

Daughter, aged 62, of L.R.C.P. and L.S.A.Lond. who practised at Brixton. Unable to earn own living owing to deafness and ill health. Only income a little from sister. Relieved nine times, £104. Voted £12 in twelve instalments.

M.R.C.S.Eng., aged 80, who at one time practised at Great Yarmouth. Advanced age prevents him from working, has an Epsom pension and occasionally obtains an appointment as ship's surgeon. Relieved three times, £36. Voted £12 in twelve instalments.

Contributions may be sent to the Honorary Treasurer, Dr. Samuel West, 11, Chandos Street, Cavendish Square, London, W.

THE CHEMICAL CONSTITUTION OF CERTAIN PROPRIETARY DRUGS.

(*Continued from p. 925.*)

THE contraction *B.P.* with date is used for the *British Pharmacopœia*, and *B.P.C.* is used for the *British Pharmaceutical Codex*, 1911.

Benzosol.

A name applied to guaiacol benzoate, which is said to decompose in the intestine into guaiacol and benzoic acid. The trade name Benzosol indicates the product of Meister, Lucius, and Brüning, Hoechst a/Main, Germany.

Biogen.

This is a name, synonymous with Hopogan, applied to magnesium peroxide. The trade name Biogen indicates the product of Kirchhoff and Neirath, Berlin, N.

Bornyval.

A name applied to borneol isovalerianate, which is also known as hysterol. The trade name Bornyval indicates the product of J. D. Riedel, A.G., Berlin-Britz, Germany.

Boroglyceride.

Boroglycerin of the *B.P.C.* is boric acid in powder 47 parts, glycerine by weight 64 parts. It is prepared by heating at a temperature not exceeding 150 degrees. The trade name Boroglyceride indicates the product of the Kreochyle Co., London.

Borovertin.

A name applied to the triborate of hexamethylenetetramine. It is put forward as a urinary antiseptic and disinfectant. The trade name Borovertin indicates the product of Aktiengesellschaft für Anilin-fabrikation, Berlin.

Bromipin.

This is a name applied to a bromine addition product of sesame oil; it is also known as brominol. The trade name Bromipin indicates the product of Aktiengesellschaft für Anilin-fabrikation, Berlin.

Bromlecithin.

Described as a compound of bromine and lecithin containing 30 per cent. of bromine. The trade name Bromlecithin indicates the product of Aktiengesellschaft für Anilin-fabrikation, Berlin.

Bromocoll.

This is a name given to di-bromo-tannin gelatin. It is put forward for use in epilepsy. The trade name Bromocoll indicates the product of Aktiengesellschaft für Anilin-fabrikation, Berlin.

Bromural.

A name applied to monobromisovaleryl-urea. It is stated to contain 36 per cent. of bromine. The trade name Bromural indicates the product of Knoll and Co., Ludwigshafen on Rhine.

British Medical Journal.

SATURDAY, DECEMBER 5th, 1914.

GERMANS IN CONCENTRATION CAMPS.

At the present time the air is, figuratively speaking, thick with charges and counter-charges of violations of the rules of civilized warfare, breaches of the Geneva Convention, cruelty to prisoners, and inhumanity of all kinds. This is inevitable, and the pity of it is that many of the charges are not unlikely to have some foundation of fact. All these charges will doubtless be investigated in due course; at present the evidence is not complete. In the meantime we feel bound to call attention to a protest made by the Hamburg Medical Association and addressed to the medical profession of Great Britain as to the treatment of "unarmed and innocent Germans who have been held imprisoned for some months in England in the so-called 'concentration camps.'" This document, which is signed by Professor Brauer, Professor Dencke, Professor Nocht, Professor Rumpel, and Professor Simmonds, and others, has special reference to the camp on Newbury Racecourse. It consists for the most part of vague denunciations of England in a style with which the utterances of the prophets of German *Kultur* have recently made us only too familiar. But there are certain definite and specific charges which seem to us to call for inquiry, especially as to the treatment of medical men who are among the prisoners. The appeal has been sent to the British Medical Association, among other bodies in Great Britain, and we feel confident that no difficulty will be placed in the way of accredited representatives of the profession examining the conditions at Newbury Camp, and gathering all the evidence procurable, in the impartial spirit which characterizes a scientific investigation. We are only anxious that the exact truth should be discovered and set forth, and in this wish we venture to think that His Majesty's Government is at one with the profession.

We do not propose to publish the document till the report of such an inquiry has been received, when the whole evidence will be fairly stated. It is sufficient in the meantime to say that the protest of the Hamburg physicians substantially repeats charges which have already been dealt with in the *Times* of October 30th. It was stated by our contemporary that the *Cologne Gazette* had reproduced in the form of a telegram from Hamburg a series of charges made by a certain Herr Emil Selcke, who said he had been arrested with a number of other Germans on his return from Brazil in a Dutch ship, and confined at Newbury. Being over 60 years of age, he was released at the instance of the American Embassy in London. His account of his experiences, as reported in the *Times*, is as follows: "He said that 1,340 Germans were confined in a training stable, eight or ten men lying together on old straw in a horsebox. Each man received two thin blankets and nothing else. There was no furniture and no light, so that at dusk they must all 'creep into their straw.' They had to cook their own food in the open air on a hearth consisting of a ditch and some bricks, on which stood saucepans which had to be used alike for cooking tea and thin soup. The tea was strained through old sacks, and was perfectly dirty. The soup contained a little fat and about a cubic inch of meat for each prisoner. The whole nourishment consisted of a cup of tea and piece of dry bread in the morning, one dish of soup, two potatoes, and a piece of dry bread at noon, and tea and dry bread in the evening. There were no sanitary precautions, and it was only through the energetic action of a number of doctors that 59 prisoners, whom they found to be suffering from a serious infectious disease, were 'shut up in a separate stable.' The names of the doctors are given as Professor Reutlinger, Dr. Steidel, Dr. Oscar Meier, Dr. Christian Johnson, Dr. von Mangelsdorf, Dr. Steinmeier, Dr. Lutz, Dr. Traubmann, and Dr. Oestetter." The *Times* sent a representative to investigate these charges. He reported that, while it was true the men slept in the stables in one part of the compound, the stables were well aired, the straw was clean, and each man was provided with two blankets, a towel, a tin mug, and a knife and fork. Several of them, interrogated without selection, described the charges as all nonsense. They said the cooking was excellent, and everything was clean. There were bathrooms with three baths, all of which were in use. There was a library containing a number of books, with a student of Bonn University as librarian. The names of the doctors given are authentic, but not one of them was ever obliged to intervene in any way whatever. A paper denying Herr Selcke's statements is said to have been signed on behalf of 1,200 prisoners.

Further, Mr. C. P. Anderson and Mr. Chandler Hale, officials connected with the American Embassy in London, were asked to make an independent inquiry into the treatment of Germans interned in the concentration camps. A translation of their report, which was published in the *Cologne Gazette*, was published in the *Times* of November 13th. It is dated October 14th, and it may be pointed out in passing that the Hamburg document is dated November 3rd. The food and the sanitary arrangements were declared to be satisfactory. The following paragraph in the report will serve to show its general tenor: "We spoke without being disturbed to a great many of the inmates of these camps, and any one who wished to address us was allowed to do so. No one complained of ill treatment by the troops on guard or by the commandant. On the contrary, they were spoken of with appreciation, and are liked by the prisoners. Except certain complaints by individuals, who said that they should not have been interned because they should have had immunity as belonging to the 'Red Cross,' the only protests that were made to us turned on matters of personal discomfort, which are unavoidably connected with the status of prisoner." We may add that the charges of ill treatment of the Germans interned at Newbury made in the German press were declared by the British Foreign Office to be "absolutely false."

Herr Selcke's charges naturally excited great indignation in Germany, and "reprisals" were threatened. In the *Times* of November 9th, however, it was announced that the *Cologne Gazette* on November 5th virtually admitted that there was no evidence in support of the charges, and said regard must be had to the favourable report from the American Embassy in London. The German journal proceeded to say: "We, too, consider the demand for reprisals against England, on the principle of reciprocity, to be

thoroughly justified and necessary, but, in order to be able to act effectively, it is necessary that the assertion that the treatment of German prisoners in England is inhuman, shall be definitely and certainly proved. Apart from isolated cases, this has not yet been done."

There for the present we leave the matter. We wish to say nothing that could appear to prejudge the case. But we think that men trained in the scientific weighing of evidence will see from the presentation of the facts that there is a similarity between the statements of the members of the Hamburg Medical Association and those of Herr Selcke so striking as to suggest that his evidence has been accepted by them too hastily. They would help very materially in the proposed inquiry if they would supply any further evidence they can procure in support of the charges which they make, with names and other particulars that could help in the testing of their accuracy.

In conclusion, we need only say that the character of the British profession and, we may add, of the British nation, for humanity stands at least as high as that of the German. If it is shown that the charges, or any of them, are true, we assure the Hamburg Medical Association and the whole German profession that nothing shall be wanting on our part to get any legitimate grievances among interned doctors and other German prisoners redressed and any unnecessary suffering or discomfort prevented.

THE MEDICAL RESEARCH COMMITTEE.

WE are able to print in this issue the full details of the grants in aid of medical research recommended by the Medical Research Committee established to administer the annual revenue accruing from the penny in respect of each insured person (payable out of moneys provided by Parliament) to be applied for the purposes of research. The scheme of the Committee was approved by the Advisory Council on November 17th, and has since been approved by the Minister.

The total amount available for the Medical Research Fund, 1914, is £56,000, of which sum £12,065 has been spent on the purchase of Mount Vernon Hospital, and other expenses, and £7,533 on repairs, equipment, and salary, making a total of nearly £20,000. Administration is estimated to cost nearly £3,000, and the research scheme, including a provision for additional grants for laboratory expenditure, over £24,000. This leaves an estimated balance of nearly £10,000, which, it is expected, will be reduced by the demands for special work needed in connexion with the war. This special work is the extension of existing facilities for bacteriological investigation of infected wounds and other pathological work at the general military hospitals, including Territorial general hospitals, and the organization for the adequate compilation of the medical and surgical statistics of the war, to which reference was made last week.

The publication of the scheme marks an epoch in the history of medical research in this country, for it is the first time that Parliament has granted any adequate sum of money for this purpose. Its previous contributions have been indirect and relatively small in amount. It will be seen that the scheme evolved by the Committee is ambitious in the sense that it covers practically the whole field of medicine, with the exception of cancer and venereal diseases, for which it is considered adequate provision is made by other public inquiries on foot. In consequence of the wide extent of its scheme, the Committee has found it advisable not only to organize inquiries in certain directions, but to subsidize other investigations not initiated by it, but already contemplated or in progress. It has, however, clearly been difficult to draw the line, for it will be seen that among the subjects for which elaborate organization has been made are such matters as tuberculosis, rickets, and rheumatic infections. On inspecting the scheme for tuberculosis, to take an example, it will be observed that the various directions from which the problems that arise can be approached are assigned to various workers in various localities. To meet this difficulty the Research Committee proposes, in order that researches carried out at different centres may be co-ordinated, to establish "special investigation committees" composed of one or more of the scientific members of the Research Committee, of members of the staff of the Central Institute, and of directors or workers in other research centres. It is intended that these committees at their meetings shall discuss the lines of attack to be followed by fresh research work, and prepare reports summarizing well-established results, both positive and negative, in particular subjects. It is also hoped to arrange conferences between the workers upon identical or closely related problems. There is, undoubtedly, the danger in this system of making a closed field of research in particular directions, but it is apparently hoped to obviate this by leaving all workers aided by the Research Fund, who are of such scientific status as to be assigned independent work, at liberty to publish their scientific results through the ordinary channels of the technical and scientific journals. Younger workers definitely under the direction of a professor or head of a laboratory would be free to publish only with the consent of the director—a salutary provision. The Committee also contemplates the publication of reports of work done upon special subjects with assistance from the Research Fund. The Committee is alive to the danger of the premature burial—as it rather oddly calls it—of scientific work in departmental archives, and will therefore, we have no doubt, take care that such official reports as it may issue are well printed in convenient form, with adequate illustrations. The latter point is one which often hampers the due publication of scientific work, for in spite of all the modern mechanical improvements the cost of the reproduction of fine drawings, especially coloured drawings, is a very serious consideration.

The Committee has invariably assigned a sum for personal remuneration for work done during a year, except, so far as we have observed, in the case of directors of laboratories, and will make it a principle to distinguish such personal remuneration from grants made to meet laboratory or other expenses. The Committee admits that it has still to gain experience in its work, and hopes that it may in future be able to proceed with greater confidence; but it believes that there will be a tendency towards enlargement rather than reduction of grants in future years. It has wisely resolved not to lay down a rigid policy to govern the general or particular conditions under which grants should be recommended. The main object it has set before itself, though obscured for the present by the calls made by the war, is to encourage a large number of young men in all parts of the kingdom to carry out definite researches under skilled direction, and finally to select the most competent investigators for grants on a higher scale. The Committee considers that those among the

younger workers who specially distinguish themselves should be promoted to a special *cadre* of extern workers, to whom continuous employment and a generous salary should be guaranteed for a term of years, and further, that from among them appointments of a more permanent kind, carrying pension rights, should be made.

The whole scheme is obviously an experiment, and an experiment on a very large scale, which may work for good or for evil. It is satisfactory, therefore, to know that the Committee itself regards its present scheme as tentative, that it is aware of the pitfalls in its path, and is ready to be taught by experience how best they may be avoided.

THE ROYAL ARMY MEDICAL CORPS.

DURING a debate in the House of Commons on November 26th (p. 984) very warm tributes were paid to the military courage and professional efficiency of the Royal Army Medical Corps. Lord Robert Cecil, who introduced the subject, and who spoke from experience in France, said that of all the corps which had rendered heroic service there was none that had done more heroic service than the Royal Army Medical Corps, whose courage and devotion were absolutely beyond the possibility of praise. Mr. Douglas Hall, who followed, also speaking from experience in France, said that the corps was one of the finest in the British Army. Lord Robert Cecil, however, asked whether it was, numerically, sufficiently strong, and Mr. Hall said that it was working under tremendous difficulties with great skill, but with poor tools. Mr. Tennant, Under Secretary, who replied for the War Office, said that the House would wish to endorse the testimony which Lord Robert Cecil had paid to the wonderful courage shown by the officers and men of the Corps, and added that the War Office could not praise its work too highly, and believed that there was now an ample number of officers and men for the great work that the Corps had to do. The British Medical Association has particular reason to congratulate itself on the high praise that the Corps is earning, for it was due to its persistent efforts through many years against the forces of inertia and prejudice that the recognition of the status of the medical service as one of the technical military corps ranking with other technical corps was due. The excellent results of the policy adopted when the Royal Army Medical Corps was constituted are not confined to the forces in the field. They are seen also at home, both in camps and hospitals. As soon, for example, as the order to prepare the Territorial general hospitals was given the medical officers "available on mobilization" were called up and fell into their proper places, and exercised proper authority without question or delay. We are glad to observe from the statement of its spokesman that the War Office recognizes that the sanitary difficulties must tend to increase as the campaign proceeds, and that precautions are being taken in advance. He stated that members of the Sanitary Committee, recently appointed, had made a tour of inspection of the field of operations, and had reported favourably on the sanitary condition of the actual trenches at the front. At the same time, in his peroration, he said that the dangers of disease became greater, almost day by day, when troops moved to ground recently occupied by the enemy. The means which the British Red Cross Society is taking to deal at Calais with the serious outbreak of typhoid fever among the Belgian troops, which seems to have begun about a fortnight ago, are mentioned elsewhere. The fact that some of the German prisoners arriving in this country from the neighbourhood of Ypres have been found to be suffering from the disease appears to indicate that the region is extensively infected. In these circumstances it is satisfactory to find that the War Office is alive to the situation, and that the military authorities are prepared to be guided by and to act upon the advice of experts in sanitary science.

MORE REPLIES TO THE GERMAN PROFESSORS.

IN the BRITISH MEDICAL JOURNAL of November 28th we quoted the reply of the universities of France to the ninety-three representatives of German universities who appealed to the educated world in defence of what M. Paul Cambon has so well described as "pedantic barbarism." The appeal has not been well received by those to whom it was addressed. Further replies to it have been made by the Paris Académie de Médecine, and the Académie des Sciences. The former body, at its meeting on November 17th, voted the following declaration: "The Académie de Médecine having, to its sorrowful surprise, seen at the bottom of the manifesto recently issued 'by intellectual Germany to the civilized world,' the names of some of its foreign members, feels bound to protest with indignation against the insinuative or lying assertions contained in that document. It holds that denials without proofs cannot invalidate the force of conclusive evidence such as is contained in diplomatic documents, public declarations made before the Reichstag, published inquiries, and the evidence of facts collected everywhere. The systematic crimes of German militarism are the condemnation of the intellectual and social medium which, after erecting them into a doctrine, now strives to excuse or deny them. A man of science could not sign such an apologia without dishonour or culpable blindness." It may be added that a letter addressed to the Academy by Dr. Labrevoit, of Nancy, was ordered to be published in full in its official *Bulletin*. In it he described the bombardment and systematic burning of the village of Gerbéviller on August 24th. The Château had been fitted up as a hospital, and on the top floated the Red Cross flag, which could be seen from a long distance. Yet this building was the first to be destroyed. As the village was burning a German officer whispered to him, "This is vandalism!" Dr. Labrevoit wonders what would be thought of this confession by Behring, Ehrlich, Fischer, Roentgen, and other "intellectuals." The Académie des Sciences has also denounced the "plundering and destruction systematically ordered by the chiefs of the German army, and the massacres of wounded, of women, and of children, committed by troops who call themselves civilized." It expresses the hope that "in reply to a propaganda which knows no scruple the Government will communicate to neutral Powers the results of the inquiries which it has made wherever the enemy has passed, together with the documentary evidence." It points out that "the Latin and Anglo-Saxon civilizations are those which produced during the last three centuries the majority of great creators in the mathematical, physical, and natural sciences, as well as the authors of the principal inventions of the nineteenth century. It protests, therefore, against the pretension of binding the intellectual future of Europe to the future of German science, and against the singular affirmation that the safety of European civilization lies in the victory of German militarism which is at one with German culture. It awaits with confidence the hour which shall deliver human civilization from the scientific barbarism produced by the union of German militarism and culture." To the Universities of America a special appeal—remarkable even among German attempts to influence opinion for its clumsiness and want of tact—was addressed. The American universities were asked to stand by Germany as "they know what German culture means to the world." Apparently they do know too well to express any sympathy with it.

NIETZSCHE THE MISUNDERSTOOD.

IT is a source of unfailing delight to unsuccessful human nature to consider itself misunderstood. The successful man of business has no time to stop and consider whether the world misunderstands him; his every moment is fully occupied in thinking out plans for further advancement in life. Yet, even to him perhaps, when some enterprise has failed, and he is alone in the solitude of his chamber—even to him may come the feeling that he is not yet assessed at his true value—that is, at the value he places upon himself. The struggling artist, on the other hand, has far more time to contemplate the injustice of this world's appraisement; and formerly he was content to pour the vitriol of contempt upon the unsympathetic herd, or to nurse his grievances in loneliness. More recently, however, he has adopted another line of action, and has set himself to produce monstrosities which defy all the conventions in colour and drawing. Having announced these productions to be the acme of art, he and his admirers profess a lofty pity for the misguided creatures whose eyes are not sufficiently opened to understand the "new movement." Not otherwise is it with the followers of the German philosopher Nietzsche. Because mankind has seized upon one of the more obvious corollaries of his teaching, and definitely connected therewith the state of mind in the German which has led to the present war, the admirers of Nietzsche rush forward to tell us that their hero has been misunderstood; that he hated the Prussians and the Prussian brand of culture; that he was an idealist, a hero-worshipper, and, finally, a mystic. All these assertions are doubtless true, but they do not necessarily affect the more popular estimate of the philosopher's writings. It would seem that Nietzsche became obsessed by one idea—an *idée fixe*—to which he gave the name of "Will to Power." To him this became the philosopher's stone, whereby the whole range of human activities could be explained. Shutting his eyes to the possibility of the existence of any other motive in the human mind, he proceeded to build up something which he chose to regard as an entirely new scheme of philosophy, or, at all events, one which the world had forgotten for more than 2,000 years. He tried to impress the world that he had something strange and paradoxical to tell; but the world of multifarious experience refuses to accept his one and only way of progress. Thus Nietzsche has become one of the "misunderstood." Parenthetically it may be suggested that he did not understand himself, for nowhere does he succeed in giving a clear idea of whom he means by his "free spirits," nor what actually are their "virtues"; or else his courage failed him when he came to the description, and, having to admit to himself that the virtues he contemplated would lead to unforeseen results, he preferred to leave them indescribable and undescribed. Thus it follows, of course, that Nietzsche was an idealist—a propounder of ideas impossible of realization. Naturally he was a hero worshipper; hardly a man exists who is not so; but as a mystic he resembled the cuttle-fish, and poured forth a flood of ink to mystify his fellow beings. Some of his generalizations, however, may be regarded as a very useful, if extreme, counterblast to the soppy sentimentality of some modern disciples of what they believe to be democracy; while we may thank him at least for this apophthegm, which should be nailed over every German door: "One does not *hate* as long as one disesteems, but only when one esteems equal or superior."

THE LIGHTS OF LONDON.

IT is interesting to learn that the Home Office has granted permission for a series of photographs and photometric investigations to be made with the object of recording the lighting effects of London under the pall of war. Such records will be of historical value in future years, and more immediately they will serve to guide illuminating engineers who may be called upon to advise the authorities with a view to making the illumination, although diminished, as effective as may be. The present condition of affairs, in which there is evident a lack of uniformity between the various areas, as well as a general patchiness and dangerous sharpness of contrast, show that the order "Lights down" has been carried out with more vigour than science. At the same time, the present lighting of London holds out certain prospective advantages. It was pointed out in the course of a discussion at the meeting of the Illuminating Engineering Society on December 1st that when normal times returned it was improbable that the lighting of London would revert entirely to ante-war conditions. The mass of the people, at whatever cost to their eyesight, have shown a certain fondness for glaring streets, but the experience of the past few months may have reconciled them to a milder illumination, and to the better visual effects obtainable by screened street lamps, although, of course, a permanent screening would be less complete and less amateurish than at present. Another desirable reform may be the final disappearance of excessively bright headlights on motor cars. It has required semi-darkness to bring home the danger of these flares to the authorities. At the same time, the present vogue for paper screens inserted in front of the lenses results only in destroying the value of the headlights for illuminating the roadway. It would be more scientific to screen the lens in such a way as to restrict the rays below the horizontal line. Another advantage is the eclipse—temporary at all events, and possibly permanent—of certain gigantic illuminated signs which hitherto have vulgarized and dazzled the metropolis in about equal proportions.

ON Monday next a discussion will take place at the Medical Society of London on tetanus, with special reference to (*a*) prophylaxis, (*b*) the serum treatment of established tetanus-dosage, and method of administration. The discussion will be introduced by Major D. Embleton, R.A.M.C.(T.), and among others who intend to take part in the discussion are Professor F. W. Andrewes, Dr. John Eyre, Dr. R. B. Blair, and Dr. Carl Browning.

Medical Notes in Parliament.

[FROM OUR LOBBY CORRESPONDENT.]

ON Wednesday, November 25th, the greater part of the sitting of the House was devoted to a discussion of the Government War Obligations Bill and the committee stages of this measure and the Trading with the Enemy Act (Amendment) Bill and with the report stage of the Finance Bill. A number of minor bills passed the second reading and were completed on Thursday, November 26th. Amongst them there was a small measure providing for compensation for disablement for persons other than soldiers and sailors employed abroad in connexion with the war. Another small measure provided for the continuance in benefit on the army and naval funds of soldiers and sailors disabled, on discharge from service, under the usual conditions attaching to sickness and disablement benefit. In order, however, to avoid any competition of the funds with the approved societies, it was further provided that the Insurance Commissioners might require any men remaining on the funds who were not disabled to seek entrance into approved societies.

The sitting of the House on Friday, November 27th, was chiefly occupied by an important statement by the Chancellor of the Exchequer, and at the conclusion of the sitting, before the adjournment, Mr. Churchill made an important statement in connexion with the Navy.

Treatment of the Wounded and Sanitation at the Front.

During the discussion on the third reading of the Consolidated Fund Bill on Thursday, November 26th, some

discussion arose over the arrangements made for the reception and treatment of the wounded during the war.

Tribute to the Work of the R.A.M.C.: The Need for More Medical Officers and Nurses.

The matter was raised in an interesting speech by Lord Robert Cecil, who asked questions with regard to the treatment of the wounded before their arrival at the base hospital. The wounds were inflicted under conditions which lent themselves necessarily to septic poison, and all depended, in the first place, on the way in which they were treated immediately, and in the second place, on the speed with which the wounded man was got to a hospital where he could be treated with the full appliances of science. With regard to treatment up to the time the man left the clearing hospital, he asked whether there were now an ample staff of members of the R.A.M.C. It was quite out of his wish to make any criticism of the work of that corps, for amongst all the corps which had done heroic service to the State there was not, he believed, any that had done more heroic service than the members of the R.A.M.C.; their courage and devotion was absolutely beyond the possibility of praise. All he asked was, Were there enough of them? He also asked whether there were nurses enough in the hospitals? At one time there were not enough nurses. In addition to the value of the high skill which an English trained nurse possessed, the psychical effect of having a woman to attend a wounded man was a very great element in the satisfactory progress of his injury. He asked, further, what was being done to bring the wounded down from the clearing hospitals to the base hospitals with the greatest possible speed. Was every use being made of motor ambulances, and whether, so far as it was possible to control it, the train service was working properly in those respects? Whether, in fact, there was a reasonably short interval between the infliction of the the wound and the treatment of the man at the base hospital. Great as was the heroism of the troops in the field of battle, it was equalled by the heroism in the hospitals, and it seemed to him that the astonishing patience and amazing courage put upon the House a tremendous duty to see that everything was done that could possibly be done to alleviate their sufferings at whatever expense or trouble, so that they might know that the country was not ungrateful for the services they have given.

Transport of Wounded.

Mr. Douglas Hall asked whether horse-drawn ambulances were still being used for bringing troops from the trenches. He thought that motor ambulances could go up further than they did, for in many cases the roads were good up to the trenches. At present a wounded soldier was taken from the trenches to the regimental dressing station, then on one of the horse ambulances to a field dressing station, then to a clearing hospital, then to the rail head, and then from the rail head to the base hospital. All this moving caused pain, and should be made as quickly as possible, and it was desirable to do away with at least one of the transfers. The Royal Army Medical Corps was one of the finest corps in the British army; the men worked under tremendous difficulties with great skill and with poor tools. Sometimes it had been found necessary to enlist men who had no training whatever in conveying and carrying the wounded; they did their best, but a couple of rough navvies could not be expected to know how to lift a man in and out of ambulances carefully; he thought a big reserve of R.A.M.C. orderlies should be formed in time of peace. A great effort ought to be made to get more hospital trains fitted up and to do away with the use of straw. It often happened that hospital trains were delayed for from ten to twenty hours owing to the railways being used for bringing up troops. Why were not the canals and rivers more used? Through the fighting area—Bethune, La Bassée, and Ypres—there was a fine system of canals by which the wounded could be evacuated. Hundreds of barges were lying idle in these rivers and canals, and he asked why the R.A.M.C. did not adopt this ideal form of conveyance? He had himself worked with a Red Cross barge fitted for fifty wounded, with operating tables, beds, and every comfort. It had been used on the Seine, and approved by the highest army authorities, but the scheme had not been developed. A great advantage of water transport was that the wounded man was taken along a road not wanted for troops, for which it was too slow. The big barges were 120 ft. long, 16 ft. wide, and 10 ft. deep. Eight or nine of such barges and the necessary doctors and nurses provided a floating hospital for over 400 wounded. The barges could be towed to the docks or quays at Havre, Calais, or Dunkirk, and wait there until the hospital ships were ready. As it was, if the wounded man had to wait only an hour or two for the hospital ship, he had to be taken out of the train, carried to a hospital, and then conveyed to the hospital ship. He objected to the use of tent hospitals. There were 300 or 400 wounded at Rouen in tents, and he thought that French houses, of which he believed there were plenty, might be requisitioned. He also thought that the sites selected were often unsuitable, in one instance a racecourse. The British Red Cross Society, which was recognized by the Government and had enormous funds at its disposal, did its best, but it had a great number of amateur administrators, and he thought that it would be a good thing if a Government official were appointed, since the Society had now become a part of the army medical scheme. He feared that there had been a good deal of extravagance and waste in the way in which the money has been spent.

Need for Increase of Medical Officers and Nurses.

Sir Frederick Banbury, while not desiring to make any criticism of the R.A.M.C., whose heroism he recognized, said that in some cases men who had not been seriously injured had been passed on without further attention to the base hospital. In one case in which the wounds were slight death ensued, owing to the retention of a piece of cartridge cloth. He thought that such incidents might be prevented by the employment of a larger number of doctors and nurses to be sent as near to the firing line as possible. He also asked that further houses might be taken up for hospitals.

REPLY FOR THE WAR OFFICE.

Mr. Tennant, in replying on behalf of the War Office, said that Lord R. Cecil had asked what were the arrangements for the treatment of the wounded at the front, and whether immediate steps were taken upon a soldier being wounded for his proper and careful treatment. That question could only be answered on the supposition that military exigencies of the case admitted of the men being taken away from the firing line at the moment of injury, and then treated, so that the question of the immediateness or otherwise of the treatment was really a military question, and not a medical one at the moment.

Tribute to the Work of the R.A.M.C.

Lord R. Cecil had borne eloquent testimony to the wonderful courage with which the officers and men of the Royal Army Medical Corps had discharged this duty, a testimony which the House would wish to endorse. The War Office could not praise its work too highly. Therefore there were grounds for hoping that everything possible was done to treat the wounded effectively at the earliest possible moment. He desired to assure the House and the country that the War Office had an ample number of Royal Army Medical Corps, officers and men. The medical and surgical treatment of the troops was in very high and competent hands, as the Royal Army Medical Corps supplied a number of most highly skilled and trained officers, and produced as fine surgeons and doctors as any other branch of the medical and surgical service. In addition, numbers of distinguished members of the medical profession from the civil side were employed and bacteriologists were engaged in endeavouring to solve some very difficult problems.

The Treatment of Wounds.

The wounds are inflicted almost entirely by shrapnel, and the vast majority were of an almost novel type; nothing like them had been seen during the recent history of medical science, and to match them it was necessary to go back to the days of the Crimea. There have been differences of opinion on scientific grounds as to what the treatment of these wounds should be. The aseptic school at the beginning of the war was in the ascendant, but it had been necessary to go back to what was considered a rather antiquated form of treatment by many people; the

antiseptic treatment was being used so much that the War Office was now sending out to every soldier, private as well as officer, fighting, a small amount of iodine for the immediate treatment of wounds when it was possible for the men to do so. A travelling bacteriological laboratory had been established, and also a small laboratory for sanitary purposes. Bacteriologists had been doing work which was bearing great fruit. The R.A.M.C. was working in close connexion with the Lister Institute and the Research Committee of the National Insurance and other institutions.

Clearing Stations.

Mr. Tennant said that when a man was wounded his wound was dressed as near to the firing line as might be, and he was then taken to the clearing station, and from the clearing station to the train which took him to the base. Thus there were three moves and not four. If Mr. Hall had different information from that, it must have been in the early stages of the war. Things did occur in the early stages which did not occur now, and, no doubt, on a tremendous military occasion of the most dangerous and difficult nature which occurred in the early stages of the war, that degree of precision of treatment which could be given in fixed trenches could not be attained. There was an ample number of nurses in the clearing stations. They did not get nearer to the firing line than that. There was also a waiting list. There were in France, roughly speaking—he was not certain of all places—nurses held in reserve. There was an ample supply both of personnel and of materiel. It was not true that there had been a shortage of chloroform so that operations had been performed without it. The statement that the St. John Ambulance Association had appealed for subscriptions for chloroform and other stores was categorically denied by Mr. Arthur Lee, member for Fareham, who had been doing very fine work for the State in inquiring into and reporting upon the treatment of the wounded. Not only were all demands complied with but they were anticipated.

Transport of Wounded.

With regard to the removal of the wounded from one place to another, there were three horse ambulances for every seven motor ambulances. It was necessary to have horse ambulances because there were parts of the country that horses could get over and motors could not because of the mud. Nearly all the horse ambulances were being replaced by motor ambulances from the front to the rear, and the War Office was not prepared to accept more motor ambulances at present, but would be glad to have the offer renewed in a month or two. Hospital trains had been supplied and had been very much improved since the date to which reference had been made, and were very comfortable at present. Three others were being prepared. The War Office was indebted to Lord Michelham and the Red Cross Society for these trains. Tetanus was extremely rare—remarkably rare—in the army at the present time; the use of straw in trains had, he believed, now been abandoned owing to the improvements mentioned. The time that elapsed normally between the clearing hospital and the base hospital varied enormously according to as and when vast numbers of troops and other necessaries were going up. All the railways were in the hands of the French Government, and it was not possible to send over from here officers and men versed in railway service, since the French Government had its own servants there. At the beginning of the war certain officers who had had experience of these matters—for the most part Army Service Corps officers—were accepted by the French Government and were doing excellent work now in endeavouring to expedite the trains, but the difficulty was prodigious, owing to the enormous masses of men and not great train facilities. For the Indian wounded, necessarily detained in England previous to their departure for India, it was hoped in a few days to have 3,000 beds at Brighton. In the meantime they were comfortably housed at Brockenhurst. Everything is being done to insure the comfort of the Indian sick and wounded, for whom everything was specially constructed with a special personnel. Arrangements were being made for the use of mobile hospitals during the winter. He hoped that it might be possible to put in force the suggestion as to barges. He feared that the distressing case mentioned by Sir F. Banbury, of a wounded officer who came home without having had his wound dressed except for the initial dressing after it was inflicted was true, and he could express the hope that with the more perfect organization now in existence there would be no recurrence of such a case. Down to the beginning of November 1,736 wounded had arrived at Boulogne, and the average will be somewhere about 500 or 600 a day. That would give the House and the country an idea of the amount of work which had to be overcome by the medical authorities.

Sanitation.

With regard to sanitation, which the country would consider as important as those with which he had already dealt, he could say that every effort had been made to preserve the health of troops in the field, and so far they had been entirely successful. The sanitary difficulties, of course, increased as the campaign proceeded. An endeavour was now being made to see in advance what the requirements would be and to meet them. Divisional sanitary companies, consisting of sanitary inspectors and men, were being prepared; and on the previous day Sir A. Keogh, the Director-General of the Army Medical Service, saw the members of a sanitary committee whom he had sent out to the front to examine into a phase of the situation which was causing anxiety. That committee had just returned from a tour of inspection, and reported that nothing could exceed the sanitary condition of the actual trenches at the front. That, of course, was where the danger occurred. Every precaution which science and the experience of these gentlemen could suggest had been taken, and the task had been admirably conceived and well carried out. The proof was that there were very few cases of enteric.

Magnitude of the Medical Task.

In conclusion he said: But who is not liable to lie awake at night thinking of the terrible hardships through which our troops have to go and are daily and nightly undergoing in the titanic struggle which is now going on. Our troops have all the horrors which they have before their eyes, with frost bites at night now added; and if the horrors of disease are to be added to all this, then indeed it would be that we were not serving the State in the manner in which the State has a right to expect. We cannot always be certain of these matters, especially as the campaign goes on, and, as I have said, the dangers which confront the troops in the field become greater and greater almost from day to day, particularly when our troops move to the ground which has been recently occupied by the enemy, and where there may be all the horrors of decomposition going on. I feel that the House realizes the task which lies before us. They will know that these are anxious times. I think that members will be glad to know that, so far as this phase of the situation goes, we have been successful. We have been successful through the skill, energy, activity, and scientific knowledge of the Royal Army Medical Corps, under Sir Arthur Sloggett. I should like the House not to withhold the meed of praise where it is due to men like Sir A. Sloggett and Sir Alfred Keogh.

War.

Dental Treatment of Recruits.

In reply to Mr. Boyton, Mr. Tennant said that general officers commanding were already empowered to spend money on any man's teeth to fit him for service. A large number of dental surgeons and dental institutions had patriotically arranged to treat, free of charge, recruits who would otherwise be rejected on account of their teeth, and what had been done in this respect was gladly recognized. Finally, dental surgeons were being appointed to all the larger military stations at home. They would devote their whole time to work with the troops.

Travelling Expenses of Officers Newly Appointed.

Mr. Bennett-Goldney asked whether young officers in the Royal Army Medical Service and other branches of His Majesty's army had been made to pay their own railway fares, as well as other travelling expenses, from their homes to the centres, sometimes over 400 miles distant,

where they had been ordered to join their respective units, and in some cases, after their services had been accepted, from their homes or stations to London or other centres and back in order to keep appointments made for them by the military authorities; and if he would take steps to see that in future travelling warrants were given to such newly-joined young officers so that this additional expense might be borne by the Treasury.—Mr. Baker said that free travelling for officers on first appointment was not admissible under regulations. Any journeys undertaken after joining for duty, authorized by competent military authority and on the public service, were paid for out of public funds.

The Lining of Military Huts.

In reply to Mr. D. Hall, Mr. Tennant said arrangements had been made some time ago for inside lining to be put in the huts occupied by troops at night, for at least some distance from the floors. In exposed situations the whole of the walls would be lined. All efforts had been concentrated, in the first instance, on getting the troops under cover.

Vaccination and Inoculation.

Mr. George Roberts asked the Under Secretary of State for War whether he would cause inquiries to be made of all medical officers in charge of the various camps and barracks throughout the United Kingdom in order to ascertain the extent of sickness and injury to soldiers caused by vaccination and inoculation, and present a report.—Mr. Tennant said that such a report would throw much labour upon the medical department of the army, and hoped he would not be pressed to cast this burden upon officers already overpressed.

In reply to Mr. Chancellor, Mr. Tennant said that he was informed that the death of Corporal Herbert Nichols, 3rd City of London Reserve, was due to pneumonia and not to antityphoid vaccination, but he would cause further inquiries to be made.

School Meals.—In reply to Mr. King, the President of the Board of Education said that inspection of the arrangements for the provision of school meals was undertaken by the medical officers of the Board, assisted by the inspectors of the elementary branch. Under the regulations for distributing the new Grants, one factor to be taken into account in determining the rate of Grant was the economical and efficient administration of the work. No complaints had been received from parents. One or two letters from other sources had drawn attention to the fact that the Act has not been put into operation in certain areas, but nothing was known of outstanding complaints. The average number of children fed in each of the five weeks ending October 31st, 1914, was about 183,000. The corresponding figure for 1913 was about 40,000. Since the end of September the number of children fed each week had decreased from about 195,000 to about 157,000.

Highlands and Islands (Medical Service) Committee.—In reply to Mr. Ainsworth, the Secretary for Scotland stated that the Highland and Islands (Medical Service) Committee had submitted a scheme which was at present under consideration of the Treasury.

Death Certificates.—Mr. King asked the Home Secretary whether his attention had been drawn to the practice, in cases under Section 1 of the Burial Laws Amendment Act, 1880, of requiring that the certificate of registry of death of the person interred should be handed to the burial authority; whether he was aware that the Act imposed no right on the burial authority to demand this, and no duty on the relatives of the deceased to give up the certificate; and whether, in view of the fact that the relatives often required this certificate for other legal purposes or as a record, he would issue instructions to burial authorities not to exceed their rights and cease to demand the handing over of these certificates.—Mr. McKenna said: I believe that it is a common practice for the burial authority to require the production of the registrar's certificate that he has registered or received notice of the death, but it is not limited, as the question appears to suggest, to the special cases in which a body is buried under Section 1 of the Act of 1850. The Registration Act of 1874 requires the certificate, as a general rule, to be delivered to the person who buries or performs the funeral or religious service, and that the only difference made by the Act of 1880 is that in cases under it, in view of the special conditions under which the interment is made, the certificate has to be delivered to the person responsible for the burial. I am advised that it is within the powers of the burial authority under Section 38 of the Burial Act, 1852, to require the production of this document, and as the authority are the responsible authority in regard to interments in their grounds and are also charged with the preparation of the register of burials, the requirement seems to be a reasonable one. The question as to who is entitled ultimately to retain the document is not expressly determined in the Acts, and I have no power to give any instructions in regard to it.

OUR BELGIAN COLLEAGUES AT HOME AND ABROAD.

The British committee was enlarged at the meeting held on November 24th at the offices of the British Medical Association, and since then the names of other adherents have been received, but it will be still further extended and a complete list will be published subsequently. Meanwhile a committee has been formed in Dublin, and comprises the Presidents of the Royal Colleges of Physicians and Surgeons in Ireland, of the University College, Dublin, of the Pharmaceutical Society, and of other representative members of the professions. The honorary secretaries of this committee are Dr. T. Percy Kirkpatrick, Registrar, Royal College of Physicians, and Dr. C. M. Benson, Secretary to the Council of the Royal College of Surgeons of Ireland, to either of whom subscriptions may be sent addressed to the Royal College of Physicians of Ireland, Kildare Street, Dublin. A preliminary list of subscriptions received by the Irish committee is published below, along with the second list of subscriptions received by the Honorary Treasurer of the British fund. Dr. H. A. Des Voeux, 14, Buckingham Gate, London, S.W., to whom cheques crossed "Lloyd's Bank, Limited," should be sent.

The Chairman and Secretary of the British Committee attended the last meeting of the Pharmaceutical Society of Great Britain, when Sir Rickman Godlee made a brief statement of the work so far done by the Committee and of its intentions for the future. Several members of the Council of the Society inquired as to how far any packets of medical material sent over to Belgium could be safeguarded from the enemy in occupation, and it was explained that the packets under dispatch were designed as a tentative measure of relief, and that other packets would follow only if the first consignment reaches its destination in safety. The Council expressed hearty sympathy with the movement, and promised to nominate members to the Committee and give the fund every assistance.

List of Subscriptions (in order of receipt).

INSTRUMENTS.

We have received the following letter from the Master of the Apothecaries' Society, who has undertaken to receive at the Hall of the Society, Blackfriars, E.C., instruments for the use of the Belgian medical profession:

Apothecaries' Hall, Blackfriars, E.C.,
December 1st, 1914.

(To the Editor of the BRITISH MEDICAL JOURNAL.)

SIR,—The appeal for surgical instruments made in your columns on behalf of Belgian doctors has met with a ready response, and I feel sure that the very urgent need for these has only to be more widely known for the Relief Committee to receive a greatly increased number. I ask especially for midwifery instruments, tooth forceps, scalpels, forceps of all descriptions, and scissors.

I enclose a list of those medical men and women who have up to the present given gifts.—I am, Sir, your obedient servant,

MEREDITH TOWNSEND,
Master of the Society of Apothecaries.

Dr. Gardner, Falkirk.
Lieutenant-Colonel Walsh, I.M.S., St. Faith's, Norwich.
Dr. G. Le Scelleur, Jersey.
Dr. A. E. Fiddian, Cardiff.
Dr. John Douglas, Norwood.
A L.S.A.
Miss Iggiesden, Torquay.
Dr. Gregson, Blackburn.
Dr W. Jack, Kendal.
Dr. Eveline Cargill, Cheltenham.
Dr. Campbell, Duns.
Dr. Papillon, Brent Knoll.
Mr. A. E. Tanner, Westminster Hospital, S.W.
Mr. J. B. Lawford, London, W.
Dr. Stormont, Tamworth-in-Arden, Birmingham.
Dr. E. P. Hardey, Hull.
Surgeon-Major R. E. Heath, Eastbourne.
Dr. W. B. Secretan, Reading.
Dr. Hulbert, London, N.
Dr. F. Milnes Blamer, Stafford.
Dr. F. L. Ford, Wimbledon Comi.
Dr. Holden, Sudbury.
Dr. Grierson, Grimsby.
Dr. Hurry, Reading.
Dr. Edith Serjeant, Wolverhampton.
Dr. Ayling, Brixton.
Dr. Evershed, London, W.
Dr. Meredith Townsend, London, W.
Dr. J. W. Bell, London, W.
Dr. Aitchison, Blackburn.
Dr. Exton, Blackburn.
Dr. S. E. Baxter, Wollaston, Wellingborough.
Dr. C. J. Renshaw, Ashton-on-Mersey.
Dr. Herbert Marson, Stafford.
Dr. N. S. Twist, Normanton.
Dr. William Tibbles, Nottingham.
Surgeon-General F. J. Lilly, R.N., Weybridge.
Sir Lauder Brunton, London, W.
Dr. W. T. Scott, Banchory.

BELGIAN DOCTORS AND PHARMACISTS' RELIEF FUND.

SIR,—I earnestly hope that this most deserving fund will receive hearty support from the profession. It has special claims upon some of us. Nearly a thousand practitioners in Great Britain are medical graduates of the University of Brussels, and it is to be hoped that few of these will forget their Belgian fellow graduates in the time of their adversity.

A small contribution from every Doctor of Medicine of the University of Brussels in this country would be of considerable assistance, and could be well afforded by most.

In July, 1899, at the annual dinner of the Brussels Medical Graduates' Association, Dr. Burland of Liverpool being the then President, a complimentary telegram was sent to the King of the Belgians, and a courteous reply received from His Majesty before the festival ended. Surely the good wishes expressed by the representatives of the British practitioners with Brussels degrees to the head of the Belgian State meant something more than mere hollow phrases of courtesy. They were then intended to show the regard of Brussels medical graduates for the university that had conferred their degrees and their respect for the Government and beautiful city, now trodden down by an insolent foe, that had created that university.

Is it, then, too much to ask every Brussels medical graduate in this country to give a donation to this fund, if only to prove that the expressions of their representatives in 1899 to the King of the Belgians were sincere and honest, rather than hollow, meaningless words.—I am, etc.,

MAJOR GREENWOOD, M.D.Brux., LL.B.Lond.

London, N.E., Nov. 27th.

MEDICAL HOSPITALITY FOR BELGIAN MEDICAL REFUGEES.

We are informed that the demand for hospitality for Belgian doctors seems to be diminishing. All offers of such hospitality received by the Medical Secretary of the British Medical Association are placed before Viscount Gladstone, Honorary Treasurer of the War Refugees Committee, who is acting for the committee in this respect. Lord Gladstone states that the medical refugees desire not to leave London or its near vicinity.

THE WAR.

MEDICAL ARRANGEMENTS OF THE BRITISH EXPEDITIONARY FORCE.

[*From a Special Correspondent in Northern France.*]

FRACTURES OF THE THIGH.

In the early stages of the war tetanus and gas gangrene almost monopolized attention, but now, and for some time past, a topic that affords much room for discussion is the treatment of fractures of the thigh. The surgical difficulties in the way of dealing satisfactorily in civil life with a compound fracture of the femur in which an upper or lower fragment has been driven through the skin, and has, perhaps, torn a largish artery or nerve, are considerable, but those involved by the conditions found in fractures now coming under treatment in such large numbers are much greater. The bone, if not hopelessly comminuted for several inches of its length, is commonly split up towards the trochanters or down to the condyles, and even when the external flesh wound is small it commonly communicates with a large irregular cavity thoroughly infected with spore-bearing organisms in all its parts. Frequently also bits of clothing and one or more fragments of shrapnel or shell or a spent rifle bullet lie buried in its interior. The prime necessity, no doubt, is to get these wounds into a reasonably healthy condition, and to eliminate especially the risk of gas gangrene or osteomyelitis or acute septicaemia, but the need of keeping the parts at rest and of attending to the position of the fractured ends of the bones is also great, since to leave a fracture in the upper part of the lower extremity uncontrolled must have a serious effect on the patient's vitality. The need of control is often so compelling that there is a temptation to favour the fracture at the expense of the wound. It was, however, chiefly when working in Paris at a relatively early stage of the war that I noted any tendency to err in this direction. Everywhere now the vital importance of paying minute attention to the wound seems amply recognized, but to combine this with immobilization of the fractured ends is often a very difficult task. Looking back at what I have seen in the course of the last eight weeks, I can recall at least a dozen different methods. I recall, too, that with one or two exceptions, none of their users were particularly enthusiastic as to their merits. As a rule, an appliance which secures real immobility of the fractured ends and due extension is incompatible with frequent re-dressings, and in particular with keeping up a constant watch for pockets, and favouring drainage. In the early stages of a case it is not easy to foresee what course it will take, and at any time the course may change. Another difficulty is that sometimes after the wound has become reduced to a mere sinus, and a large firm callus has locked the broken ends together there is a sudden rise in temperature, and it is found that a fragment now deeply involved in the new bone has become necrosed. At the present time the general inclination seems to be to rest content in the early stages with securing a fair degree of immobility of the bones and deferring definite extension until the wound is relatively clean and its deeper parts obliterated. Consequently suspension appliances and plain long outside splints, like that of Liston, are commonly to be seen in use. The former appear to be comfortable and to allow ready access to the wound, but somewhat to favour the tracking upwards of secretion. The latter keep the parts more steady, perhaps, on the whole, but are not satisfactory if the wound is at the back of the thigh, owing to the amount of movement involved at each dressing. At some hospitals the effect of this is being lessened by applying another Liston to the sound limb and fixing the two together by cross-bars. Liston splints cut with a gap opposite the wound and bridged by a semi-circular bar are also in use. Another useful modification of the double Liston has a facultative hinge at the level of each hip. A further advantage of the double Liston splint is that so far as present experience goes it seems to offer a solution of an administrative problem of considerable importance. In the best of circumstances the treatment of any one of these cases of compound fracture of the thigh must occupy so many months that quite a small percentage of fractured thighs among the wounded would eventually throw a serious strain on the available hospital accommodation at the advanced hospital bases. Consequently it is very desirable to be able to transfer them for final treatment to some place where the pressure on accommodation is less severe so soon as the early difficulties and dangers of each case have been overcome. The few trials so far made indicate that when a double Liston splint is used and the wound has been reduced to a sinus, the case can be transferred by sea to a home hospital without any disturbance of the fracture and with much benefit to the *moral* of the patient. The suspension appliances chiefly in use are of two types. One bears a general resemblance to a Hodgen's splint, and is known as a "Balkan," while the other is simply a bar of bent aluminium running down the front of the limb. Both are attached to the limb by a series of flannel straps, and both are suspended by an overhead beam, fixed to uprights by two or more web or cord bands. If the latter are carefully adjusted, these splints exercise a certain amount of traction on the lower fragment, but less than that of a true Hodgen. So far these suspension appliances have been popular both with patients and surgeons, but the double Liston splints, which are of more recent introduction, seem likely to be much used. With regard to extension, those who have had the longest experience of these cases appear to agree that very little traction suffices in the majority of cases. The bone is usually broken in such a way that no overriding of the ends is possible. They also hold that it is well to be chary in the matter of clearing out fragments of bone when the initial cleansing of the wound is undertaken; if these seem still to possess any fairly firm periosteal attachments, it is better to give them a chance of recovering their full vitality and becoming incorporated in the new bone.

MARLBOROUGH CAMP, BOULOGNE.

The place known alternatively as the Convalescent Camp, Boulogne, or Marlborough Camp, lies on the downs between Boulogne and Wimereux. It is close to the well known column which marks the centre of the site occupied as a vast camp by the French troops just about 110 years ago, when an invasion of England was in question.

The worst thing that can be said about the camp is that its situation is not altogether suitable. It is established on sloping grass land, opposite the partly ruined Jesuit College, and it faces south; but it would not be easy to find a more suitable situation in the immediate neighbourhood of Boulogne, where the soil is a mixture of marl and sand, with a top layer about 18 in. to 2 ft. deep of rather rich loam. What has led to the selection of this site is no doubt the fact that it is near all the hospitals in Boulogne. Le Touquet, which has been suggested as a place for a convalescent camp, is twenty-three miles away and three and a half miles from a railway station. It has sandy soil, which would not hold tent pegs, and there are no suitable houses available there, as all have been taken up for the Westminster Hospital and the Canadian Hospital.

In its application to Marlborough Camp the term "convalescent" is not used in the same sense as in civil life. Of the men sent to it the greater number come from local hospitals, and are supposed to be practically fit for duty either in the fighting line or at a base. The local hospitals send real convalescents home to England. The longest time any man stays in the camp is about six days, the common period a couple of days or so.

The camp was started at the beginning of the fourth week in October, and eventually furnished accommodation for about a thousand men. To house them a sufficient number of marquees were erected. The officers in charge of the camp occupy bell tents, such as those in which soldiers camping out usually live. The marquees were drawn from the stores of various hospital units for whose use permanent buildings had been commandeered. The ground inside each marquee was covered with tarpaulin sufficiently wide and long for about six inches to be curled up against the walls all round. No bed was provided, but, in addition to the tarpaulin "flooring," each man had two blankets and a waterproof ground sheet to protect him from rain and wind and also from damp in the soil itself. This camp was started as a kind of emergency medical

unit; the ambulance trains were arriving with such rapidity that all the real hospital beds had to be reserved for the more serious cases; consequently the cases of very slight injury, as also men suffering from sore feet or minor medical disorders, were sent up to Marlborough Camp.

These observations apply to the camp as it was during the first three weeks of its existence, that is to say, until about a fortnight ago. It was then decided to maintain it as a permanent adjunct to the hospitals at the Boulogne base, and the medical officer in charge set to work on various improvements. As things now are, all the tents actually in use by the men—in fact, all the living tents in camp other than that used as an orderly room and principal medical officer's office—have board as well as tarpaulin floors, the former being raised a few inches from the ground, and a number of coir mattresses made in three sections have been secured. Several hundred have been in use for about seven days and meantime raised bed-boards have been available for other men. About nine days ago a number of iron buckets were obtained, holes were driven through the sides of these, and they serve as braziers. Filled with coke, they are lighted each morning at 7 a.m., and after the first fumes have burnt off one is placed in each marquee. There they remain until 9 p.m., when the camp police visit each marquee and remove each brazier. Two oil lamps are kept burning all night to steady the temperature; each marquee has in its inner roof four openings with an aggregate ventilating area of about 24 sq.ft. Between the lines of marquees paths have been laid out and are being paved with sandstone. A good many of these paths are complete; they communicate with the tents by sidepaths, which end in a strip of brick at the main entrance of each tent. Opposite each tent is a pole, sunk in brickwork; a bucket is placed on the brickwork at night to serve as a urinal, and a lamp on the pole shows its position. At various parts of the camp there are natural channels, and these, when they cut across a path, are being bridged by 4-in. trestles and boards. A good many of these little bridges are already completed. By utilizing these natural channels and digging surface trenches to meet them, the whole camp surface area is gradually being drained. The camp water supply is drawn from the town mains, but is used solely for washing and cooking purposes. The men drink nothing but tea, coffee, and cocoa, except those who frequent the "wet" canteen. This, like the "dry" canteen, is at present housed in a tent, but will, I understand, eventually occupy a hut. The skeletons of several huts have been standing for some days; they are to be used as dining and recreation rooms, as cooking and bath houses, and for other like purposes. The present cook-house is a shanty lying a little below the general level of the camp; it cooks the men's ordinary rations and also supplies beef broth, which is served out about 11 a.m., soup in the afternoon, and cocoa at night. Near the cook-house is an improvised clay-built incinerator, into which all rubbish, including empty tins, is thrown. Each night the tins, which now offer no attraction to flies, are removed and kept in a pile hard by, being eventually removed by a contractor. Close to the incinerator is an arrangement for dealing with kitchen waste water. It consists of a rough filter—built of brushwood, which is burnt each day—placed over a short gulley leading into a 3 ft. deep clay pit. The latter drains into a natural and steep channel leading to the lower drain. There are two latrines below the level of the camp, one being a wooden building with temporary trenches; the other is a canvas structure, which is now being replaced by a second wooden structure, which will be arranged on the ordinary bucket system already employed in the present permanent latrine. The buckets are changed each night by a contractor.

The last feature of the camp which it seems necessary to mention is a bath house; it has been in use for about a fortnight, a free supply of hot water being available all day long. It now has two full-sized baths and is in charge of an attendant. It has a brick floor and wooden walls and roof. It is to be replaced eventually by a large building of the same character, and to be supplemented by the provision of a room in which the men can dry their outer clothes when wet. I am not sure that the officers in charge of this camp will ever succeed in making it look "pretty" so long as the wet weather continues, for it is quite inevitable that the top soil between the tents shall get cut up, the grass being turned into mud. They hope, however, little by little to be able to secure enough broken stone and sand to cover the whole camp area. Meantime they have already secured all the main necessaries of a healthy camp, and it is rather remarkable that they should have succeeded in doing so. The huts are being erected by contractors working under the Royal Engineer department, but the whole of the rest of the work, beyond the laying of the water-pipes, has been, and is being, done by voluntary labour. The officers—an R.A.M.C. captain, a quartermaster drawn from a line regiment, and two temporary R.A.M.C. lieutenants—make the plans, and the non-commissioned officers and men carry them out. The men come and the men go, but the work goes on steadily, if not very rapidly. Camp laying is not really R.A.M.C. work, but the engineers appear to be unable to secure a sufficiency of labour to take this camp in hand, and it is well that an R.A.M.C. officer possessed of a personality likely to secure for him the willing assistance of a large number of voluntary workers should have been ready to step into the breach.

The camp is utilized in the following fashion: A certain number of cases of trifling injury are sent up straight from the casualty department of No. 13 Stationary Hospital, which receives all the "walking" cases brought by the ambulance trains, but the greater number are men discharged from the hospitals. They are inspected on arrival by the junior medical officers, and on the following day by the senior medical officer. The name of each man, besides being booked, is entered on a card record, which is transferred to an "out" card index when the patient is sent away. For camp purposes the whole of the occupants are divided into companies, each of which is submitted to a formal medical inspection three times a week. Meantime those reported sick or known already on their arrival to be in need of treatment, attend at the camp surgery and inspection room.

Theoretically, all the cases are sooner or later divided into five groups: men fit to return to the fighting line, men fit for temporary base duty, men suitable for permanent base duty, men who should be sent home, and men who must go to hospital. The latter are commonly cases which seem to have been discharged prematurely, or to require more active treatment than the camp can supply, but sometimes include cases arising in the camp itself—accidents, sore throats, and the like. The camp also frequently receives batches of men suffering from muscular and other forms of rheumatism—chiefly reservists—but does not keep them. It sends them down to Rouen.

To sum up, it certainly seems to me that the officers in charge of this camp are entitled to very great credit for what they have achieved, and I hardly think that the camp itself is open to much criticism. It is not only a war time camp, but a camp—regarded from an official point of view as a medical dépôt—still in the making.

The tents erected are of two kinds—the double-walled, double-roofed marquees which have been in use in the army as hospital tents for many years, and an entirely new pattern of hospital marquee. This has single walls, but an excellent double roof with eaves (which protect the walls from all but driving rain). The old-fashioned hospital tents mentioned, not being as warm and comfortable as the new ones, are being used as store rooms. They are commonly called four-way marquees; each has four entries, which are not mere openings in the sides, but regular porches. The sides are of canvas, with a double lining; these marquees measure about 36 ft. by 18 ft. The marquees with boarded and tarpaulined floors and braziers alight are distinctly cosy; in most that I inspected there was a big deal table and a number of forms, and even the orderly room, which is not warmed and has only a tarpaulin floor, is decently comfortable.

I believe I have visited practically every marquee and have seen no men who appeared to be ailing. They were all working, or sitting round braziers, or dressing, or shaving. At present, dinner being just over, a lot of them have started football.

PROPHYLAXIS.

A third consulting physician, Sir Bertrand Dawson, has now been attached to the Expeditionary Force, as has also Mr. W. T. Lister, ophthalmic surgeon to the London Hospital. The work of the consulting physicians seems

to be concerned mainly with prophylaxis. Every medical case in which the diagnosis is doubtful is submitted to them, and special watch is kept for cases of enteric fever presenting symptoms which are obscure or slight, and therefore liable to be overlooked. So far there has been very little enteric and no dysentery in the Expeditionary Force.

A number of goatskin coats have been supplied to each division and are allotted to men specially exposed, and it was almost inevitable that these men should have been nicknamed "Teddy bears." Woollen waistcoats are also being served out to the men, but I do not know whether all have received them.

Ambulance Trains.

Ambulance trains have been multiplied, and the best way of disposing the bunks or hammocks has given rise to a great deal of discussion. At first two tiers were fixed in most carriages, but some experts consider this a mistake, inasmuch as it materially reduces the total number of sick and wounded any single train can carry. This is a serious consideration, for, though any number of carriages can be built or converted, only a limited number of ambulance trains can be accommodated on the railway lines. It is thought by the experts to whom I refer that if the bottom berth were placed only an inch or two above floor level and the top berth a few inches higher than at present, there would be enough space for a third or intermediate berth. The carriages converted for use in ambulance trains are, so far as English rolling stock is concerned, chiefly what are known as bicycle vans. Those used by the French (who supply most of the ambulance rolling stock used up to the present by British troops) are either converted luggage vans or the closed trucks in which valuable horses used to travel. Open cattle trucks have never been used either for British or French wounded. A considerable number of ambulance trains are made up solely of compartment carriages, *lit-salons*, sleeping cars and restaurants. These are better than the vans, because the carriages communicate by corridors. They are also fitted with proper air breaks and hot-water pipes. The English rolling stock used for conversion into ambulance trains is rather smaller, I understand, than the French in respect of inside measurements, but has the advantage of being much more solidly and heavily built and of running more smoothly in consequence. In all the ambulance trains the gangways are narrow, but the ambulance men are extraordinarily clever in handling the stretchers. I have often admired their mixture of dexterity, gentleness and strength. Many of these men belong to the St. John Ambulance Corps, and are notably smart and well-disciplined.

The Geneva Convention.

In a recent note regarding the Geneva Convention and the neglect of the Germans to comply with its regulations, mention was made of the fact that the whole personnel of one particular ambulance unit had been charged with pillage. This unit, consisting of fifty-one persons, and including seven German Protestant deaconesses, in addition to three medical officers, fell into the hands of the French on the capture by them of Péronne, and reason was found to examine closely the goods in their possession. These were seen to consist largely of things which no ambulance unit would be expected to bring with it, including Tanagra figures, women's wigs, and opera glasses, while several members had upon them considerable quantities of jewellery which was seen to be of French manufacture. Finally, the suggestion of pillage was emphasized by the finding of a number of parcels containing valuables of different kinds ready for dispatch to different towns in Germany. Consequently, instead of being "respected," the members of this German ambulance unit were sent to Paris and there lodged in different gaols in the same fashion as ordinary civilian prisoners awaiting trial. Over this trial there was some delay, but it eventually took place last week, and after a hearing of three days resulted in most of the prisoners receiving sentences of imprisonment varying between one month and three years. The longest sentences were given to those in unlawful possession of most property, and eleven of the company, including one of the surgeons, were not sentenced at all, as they each had not more than a single piece of stolen property. All the prisoners were duly defended by counsel, and the general plea put forward was to the effect that they had not been guilty of true pillage. In various houses which had already been burned or otherwise destroyed, they had seen things which would be useful to them and had taken them. This excuse was proved to be inconsistent with the nature of many of the stolen goods, and was rendered further untenable by the fact that a good deal of household and body linen found in the possession of the deaconesses obviously came from one particular place of business in the area through which the German forces had passed. This place was known to have been assigned as a billet to a German ambulance unit, and though subsequently destroyed, it was intact when first occupied.

GERMAN, FRENCH, AND BRITISH BULLETS.

Though rifle-bullet wounds have formed a comparatively small part so far during the present war, most of the severe wounds having been caused by shrapnel or fragments of shell, a good deal of interest must attach to them and their manner of production. It has been thought worth while, therefore, to reproduce photographs of the types of bullet used by the German, French, and British, and to add that used originally by the Belgians.

A bullet, which receives its impetus or velocity of translation from the explosion of the powder in the cartridge and its rotation from the rifling of the barrel, is, so soon as it leaves the muzzle, acted upon by two other forces which in combination determine its trajectory or line of flight and its billet. The resistance of the air gradually arrests its flight forward, and gravity brings it to the ground. Gravity is an accelerating force; the rate at which a body falls *in vacuo* increases directly as the square of the time; it falls 16 ft. in the first second, 64 ft. (16 ft. × 4) in the second second, and 144 ft. (16 ft. × 9) in the third second, and so on. The point-blank range of a rifle bullet, therefore, is short, and for distance the muzzle must be raised; the bullet then rises almost immediately after it leaves the muzzle, reaches a culminating point, the distance of which from the muzzle, other things being equal, depends on the elevation, and then begins rapidly to descend. From a point near the muzzle to another point on its descending path its trajectory, when the rifle is sighted for distance, will be higher than a man mounted, and to a point somewhat further on higher than a man on foot. The "danger zones" are within the point-blank area and after the bullet has begun to descend. Taking a mounted man to sit 8½ ft. from the ground and a foot soldier to stand 5 ft. 8 in., the danger zone is obviously rather wider for cavalry than infantry. This is illustrated in the diagram, in which, of course, the height of the trajectory is greatly

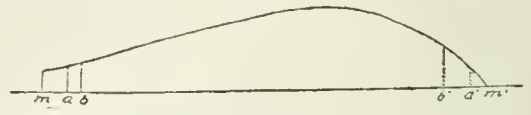

Diagram of trajectory (height much exaggerated). Point-blank danger zone: *m a*, infantry: *m b*, cavalry. Distance danger zone: *a' m'*, infantry; *b' m'*, cavalry.

exaggerated. It follows that the flatter the trajectory the wider the danger zones, and one of the objects in the recent changes in rifles and bullets has been to get a flatter trajectory. The trajectory of the German Spitze bullet is said to be flatter than that of the British.

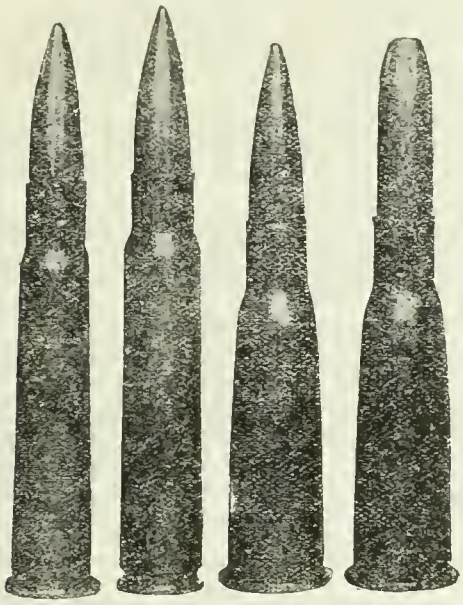
How great the difference may be is shown by the fact mentioned by Stevenson, that whereas the bullet from the Martini-Henry rifle sighted for 1,500 yards rose to 178 ft. above the line of sight, the Lee-Enfield rose to only slightly over 81 ft.

The following table gives particulars of the French, British, and German service rifle ammunition:

Nation.	Name.	Length.	Calibre.	Weight of Bullet.	Velocity (f.s.) at—		
					Muzzle.	500 yds.	1,000 yds.
		in.	in.	grs.			
French ...	Lebel	1.55	.315	198	2,380	1,639	1,141
British ...	Mk. VII	1.28	.303	174	2,420	1,510	1,020
German ...	Spitze	1.105	.311	154.5	2,980	1,780	1,090

Both the German and British bullets consist of a central core of hardened lead with a hard sheath of an alloy of

nickel open at the base. The French bullet is a solid mass of bronze (90 per cent. copper) with a circular groove where the cartridge case is clipped on to it. All the bullets are sharp-nosed, but the German is much sharper-nosed than the



British. German. French. Belgian.

CARTRIDGES WITH BULLETS.

others. The bullet originally used by the Belgians is of the same type as the German or British, but has a flat nose; they are said now to be using French ammunition. The object of the cylindrical form, pointed nose, and more or less sloping shoulder of the modern bullet is to diminish the effect of the resistance of the air. The object of using a nickel

British. German. French. Belgian.

BULLETS.

sheath for leaden bullets was not primarily humanitarian. In a rifle with the high muzzle velocity of the modern weapon a lead bullet would be too soft to take the grooves of the rifling; it would not therefore be given the necessary movement of rotation, and the rifling would quickly be choked by portions of lead torn off from the bullet driven straight through the bore.

Owing to its very pointed shape, the centre of gravity of the German (Spitze) bullet is near its base. A consequence of this, of some surgical importance, is that it has been found[1] by experiment that the resistance it encounters in traversing even soft parts or a layer of cardboard causes it to turn over on its short axis. It was found to begin to turn at once on striking the abdominal wall. In some cases observed in this war the turn over has been so complete that the bullet lies with its point towards the aperture of entrance. Of this Sir John Bland-Sutton quotes an instance in the lecture printed elsewhere in this issue. In consequence of this tendency the German bullet may produce severe wounds even when soft parts only are struck, and, as Surgeon-General Stevenson observes, "Its effects in this matter would therefore appear to be similar to those of an easily 'deformable' bullet."

Dr. EDWARD BIGG writes as follows from the Pinewood Sanatorium, Wokingham:

With reference to the "explosive effect" of small-bore rifle bullets at short range, the following may help to explain the same. The effect of rotation on the bullet in flight (imparted by the rifling) is to deflect its point somewhat downwards, and this position is maintained throughout. At short range, then, the axis of the bullet is not parallel to its trajectory, and the tendency for it to "fall over itself" on meeting with resistance is increased. At longer ranges, when the bullet is on a falling gradient, its axis and trajectory tend to coincide.

Also be it remembered that a ricochet shot may do anything. A ricochet also is more likely to be dangerous at short ranges, the projectile meeting the earth at a much smaller and therefore more effective angle than at long ranges. The angle of exit of such a shot is roughly double the angle of incidence, and the less the angle of incidence the less the probability that the projectile will bury itself.

[1] Fessler, quoted by Stevenson, *Wounds in War*.

ARROWS FROM AEROPLANES.

DUGALD DALGETTY scoffed at the bows and arrows used by the *Children of the Mist*. But as a scientific soldier he would doubtless have been interested by the new form of arrow now discharged from the sky. German surgeons have already gained some experience of arrow wounds inflicted by the Allies. In the Feldaerztliche Beilage of the *Muenchener medizinische Wochenschrift* for September 15th, Dr. J. Volkmann has published a paper, recently read at a special meeting of the Stuttgart Medical Society, devoted to surgical experiences of the war. Soldiers were resting at 5 in the afternoon of September 1st, three companies bivouacking at an interval of about eight paces. Two aeroplanes were circling overhead at a height of about 1,200 to 1,500 metres. Suddenly one of the soldiers felt a stabbing pain in the right foot just above the heel. At first he thought he had been pricked inadvertently by one of his fellows, but this illusion was quickly dispelled when he heard cries of pain all around him. The horses, too, became restive, and two were subsequently found to be wounded. Looking at his foot the soldier found an iron arrow which had penetrated to a depth of 1½ cm. He plucked it out at once. About fifteen of his comrades were also hit, and one of them was pinned to the ground by an arrow which had passed through one foot. The source of these arrows was quickly detected, and cover was taken under wagons. It was subsequently estimated that about fifty arrows had been discharged, and that thus every third arrow had taken effect. The importance of these weapons, particularly when dropped on resting soldiers, is therefore considerable, and the fact that about half the casualties consisted of wounds of the lower limbs, shows how vulnerable the resting soldier is to arrows from above. Apparently the arrows were of two sizes. One shown by Dr. Volkmann was about 10 cm. long and 8 mm. in circumference. It was of steel, its lower third solid, tapering to a sharp point. The upper two-thirds were drawn out to a mere skeleton, composed of four flanges, so that on transverse section this portion of the arrow was star-shaped. Evidently these arrows scatter considerably, for in one case four companies were simultaneously hit. As the weight of this arrow was 16 grams, very many cannot be carried by an aeroplane at the same time. Discussing the casualties in detail, Dr. Volkmann stated that in one case an arrow penetrated both calves, an incision being necessary for its removal. In another case an arrow passed through the sole of the foot just below the Achilles tendon; a haematoma developed at the point of entry. In another wound of the foot, below the ankle, some of the tarsal joints became inflamed. One arrow passed through the scalp without injuring the skull, but another caused instant death by entering the left temple and passing out again by the right coronary suture. One arrow passed though the cheek into the mouth, another passed between the index and middle finger, and a third penetrated one finger. The soldier who was pinned to the ground by an arrow pulled it back, dirty as it was, through the wound. Yet, during the following four days, while he was under Dr. Volkmann's observation, he did well. Treatment

Natura size

consisted of the application of dry dressings with or without a preliminary application of tincture of iodine. On the whole the cases treated with iodine did best; in fact, most of the wounds thus inflicted did well, bones and large blood vessels were seldom hurt, and apparently the only case that proved fatal, in addition to that mentioned above, was one in which the arrow entered at the shoulder and passed through the chest.

The drawing shows an aeroplane arrow which has been placed at our disposal. It consists of two parts, a head and a short flanged shaft. The head measures 5.7 cm. (about 2¼ in.), the total length of the arrow is 11.17 cm. (about 4½ in). Both the head and flanged shaft appear to be constructed of steel, the flange being formed of two flat pieces of metal set at right angles, the ends of the four flanges thus produced being let into the steel head. The diameter of the head is 8.5 mm. (about $\frac{5}{16}$ in.) tapering to a fine point. The weight of the whole arrow is 320.8 grains (about 21 grams).

FROST-BITE.

LIEUTENANT-COLONEL A. B. COTTELL, P.M.O., hospital yacht *Albion*, informs us that many men are now arriving from the front suffering from frost-bite of varying severity. He has, he states, carried more than sixty of them to England from Boulogne, and gives the following account of the symptoms and appearances.

The frost-bite has attacked the toes, and in many cases extended up the metatarsus, the limb being oedematous nearly to the knee. The toes stood wide apart, were extended, and of a purplish-black colour, and in all the severe cases bullae filled with clear gangrene-smelling fluid have formed on the extensor surface. In about 10 per cent. of the cases the glands in the groin were tender but in no case swollen. Some men said they were quite comfortable, and read, ate, and slept peacefully; others complained of pins and needles, and sharp stinging pain; but the majority said that the whole foot seemed heavy as lead, and that there was a dull ache all the time. The treatment adopted has been to dust the affected part with boracic powder, and to keep the foot slightly raised and covered with wool loosely bandaged. The highest temperature recorded was 102° F.; in most the temperature was slightly raised, while in a sixth it remained subnormal throughout. Owing to weather conditions and other circumstances I was able to keep 30 of the cases under my observation for forty-eight hours, during which time all of them showed signs of improvement except one.

G. S., aged 29, of nine years' service, a temperate man, a long distance runner, who had never suffered from chilblains, was in the advanced trenches from November 14th to 19th, during which time it was raining and freezing alternately. His feet felt very cold and numb on November 19th, but owing to the fighting he never took his boots off. On November 20th he could not stand and was carried back; he was seen by a medical officer, temporarily dressed, and sent to Boulogne. He embarked on November 24th. The frost-bite then (11.30 a.m.) included the toes of both feet, extending up the metatarsus; there were bullae the size of filberts on the big toes. The limb had a dull red irregular blush some 5 in. above the ankle, and the legs were oedematous nearly to the knees. The temperature was 100° F., and he complained of dull heavy pain, but there was no headache or definite constitutional disturbance. The temperature rose gradually to 102° F. at 8 p.m.; the pain and oedema had diminished under treatment, which consisted in raising the limb, which was wrapped in cotton-wool to the knees and lightly bandaged. On November 25th the temperature was 99.2° in the morning, and did not rise above 100° all day. The toes and metatarsus got deeper in colour, almost black, and smelt gangrenous. On November 26th the temperature was 99.4° at 8 a.m. The condition showed very little change, and he was sent to Netley Hospital.

The history was much the same in all cases—trench work in saturated boots and sharp frost at night, and dull aching pain in the feet and inability to stand in the morning. I was struck with the frequency with which frost-bite had supervened when men, to keep warm, had put on two pairs of socks and had in doing so restricted the superficial circulation. If the men had had "trench boots"—very large boots made of canvas stuffed with straw to pull on over their boots—much preventable suffering and loss of men in the firing line would have been avoided.

HOME HOSPITALS AND THE WAR.

BRIGHTON.

2ND EASTERN GENERAL HOSPITAL.

THE following two cases are quoted as illustrating the manner in which a bullet will traverse parts or cavities containing important and vital structures without any injury to these structures.

Wound of the Kidney.—A man was struck in the front of the abdomen, the ball passing right through him. The only definite sign of any injury to viscera was haematuria, which lasted five days and then ceased. There was no evidence of any injury to intestine.

Wound of the Neck.—This patient was shot right through the neck, the bullet entering between the scapulae and making its exit by the side of the thyroid cartilage. There was no sign of any injury of the many important vessels and nerves near which it must have passed in its course.

Importance of Dental Defects.

Five men were in a trench when the shelter was struck by a German shell. Three of the men were killed outright, one was wounded, and the fifth was buried completely under the earth. Fortunately for him a plank fell over his chest and protected him from the full weight of the soil. He was dug out by comrades four hours later, just after he had lost consciousness. He very soon recovered, and was back in the trenches fighting. He had unluckily lost his artificial teeth in the accident, and was unable to masticate or digest properly the rather hard food he obtained in the fighting line. As a consequence he began to get thin and ill, and was sent home for the purpose of obtaining fresh teeth. This case, as well as several others which have been admitted, shows the great importance to a soldier in the fighting line of good teeth. There are many cases in the hospital at the present moment invalided home simply on account of dental caries, or for the want of artificial teeth properly to masticate their food.

Complete Loss of Memory.

A man was admitted with no history whatever, and no sign of any injury. He had very complete loss of memory, and he could recollect only his name and regiment. All the rest of his history and life were a total blank. Probably he had had some severe shock.

Flesh Wounds.

There have been very few stab wounds of any kind admitted to the hospital, but one was of a quite exceptional nature. The man was digging in the trenches in the dark, when he was struck in the right upper arm by a comrade with a pickaxe. As it was clear that the wound was contaminated with earth, he was injected with a prophylactic dose of tetanus antitoxin. Many of the cases admitted have already been injected with this serum, in some instances even almost in the firing line.

Extensive flesh wounds have been common, generally made by shrapnel. The method of treatment adopted in a large number of cases is as follows: The wound is cleaned with hydrogen peroxide, and cyanide gauze soaked in chlorinated soda is applied to the wound This, with good food and plenty of fresh air, acts, as a rule, as a charm. In a few days the most extensive foul wound becomes clean and presents quite a different appearance. The following is a typical case.

A man was admitted with a large flesh wound of the back of the left thigh about 12 by 6 in., and another at the back of the right calf nearly as large. Both were suppurating freely and foul, but in a few days, under the treatment detailed above, took on a perfectly healthy appearance, and are making rapid progress.

Tetanus.

Not many cases of tetanus have been met with, so far only three, all following bullet wounds. In all the result was fatal in spite of treatment, which consisted in giving tetanus antitoxin and chloretone. In all cases the incubation period was less than twelve days, and the result seems to agree with what was already fairly generally recognized—namely, that if the disease has an incubation period of less than about twelve days, it is fatal in spite of treatment, whether by antitoxin or other means.

All the men were wounded in the arm, and presented very much the same features—tetanic symptoms such as trismus, rigidity, etc., began within about ten days of being wounded. In one case the patient had had a splint bound on very tightly, and as no facilities were available for dressing him during transport, it was found when the splint was removed three days after application that his arm was gangrenous, and amputation become necessary. Tetanus developed two or three days later. In another of the cases the man had had a previous attack of tetanus ten years previously after a wound received in India.

Fracture of the Jaw.

In one case a bullet passed through the open mouth, just grazing the angle on the left side, taking off a piece of the tongue, and then passing out through the body of the lower jaw on the right side, leaving a large wound here. There was a good deal of suppuration, and the wound was foul. Under treatment it very quickly improved, and the fragments can be kept in quite good position by means of a bandage.

In a second case the bullet passed through the lower jaw and entered the mouth, embedding itself in the tongue, a most unusual place for a bullet to lodge.

In another case the bullet entered by the right cheek, passed through the upper jaw, and then out through the mouth, which must have been open.

Wound of the Brain.

There have been many instances of wounds of the brain, among which are the following:

Depressed Fracture followed by Signs of Cerebral Irritation.—This patient was shot through the head, the bullet causing a gutter wound of the vertex, some inches long. On admission, the wound, which had been stitched up in France, was suppurating, and was opened up, and a fracture of the skull was found to be present. A few days later symptoms of cerebral irritation showed themselves (for example, stupor, slow pulse, slight optic neuritis, irregular fever, etc.). The skull was opened and several large loose fragments of bone were found, one of which had been driven through the dura mater into the brain.

Depressed Fracture of Occiput.—In another case there was a depressed fracture of the occiput, which was opened up. An abscess was found deeply seated in the brain, in which were loose fragments of bone. No trace of a bullet was found, and it is most likely that the fragments of bone were driven into the brain by the force of impact of the bullet, although the latter did not enter the skull.

Secondary Haemorrhage.

The following notes of cases of secondary haemorrhage open up a very important and interesting branch of military surgery:

1. A man was wounded in the knee by a bullet; suppuration ensued in the knee-joint, and in hospital he was suddenly seized with fierce haemorrhage from the popliteal artery. A tourniquet applied at once temporarily checked the bleeding; no other treatment but amputation was available in this case, and the operation was performed at the lower end of the femur.

2. A man had a bullet wound of the shoulder, which caused a compound comminuted fracture of the upper end of the humerus. When in the hospital a large subcutaneous bleeding took place under the pectoral muscles. An incision was made, but a search for the bleeding point was unsuccessful. The subclavian artery was therefore ligatured, but this did not stop the haemorrhage entirely. Bleeding took place on many occasions afterwards, and so weak did the man become that amputation at the shoulder-joint was performed.

3 to 5. In three other cases secondary haemorrhage was met with, but not of so severe a character as the two recorded above. One case was from a wound in the upper part of the thigh, the vessel being the external pudic artery; in another from a wound of the lower part of the thigh, the anastomotica magna being the vessel at fault; in a third case from a wound of the upper arm, the bleeding vessel being a branch of the brachial. In these three cases the treatment consisted in tying the artery at the bleeding point; not much difficulty was experienced in carrying this out.

6. A man was shot through the nose, the bullet cutting right through the palate, passing down the neck, and finally lodging under the sterno-clavicular joint. He was suddenly seized with haemorrhage from the palate about ten days after receiving the wound. This was easily controlled by pressure, but the man, who was in a very exhausted and wasted condition, died a few hours later of asthenia.

7. In this case the wound was in the groin and had perforated the bowel. Faeces passed freely through the opening, and severe bleeding occurred from the circumflex artery. This was treated by tying the vessel in the wound, a quite easy task.

8. As a final example may be quoted a case of wound of the neck, passing directly backwards, comminuting the clavicle in its course. Haemorrhage, of quite slight extent, occurred from the transversalis colli artery, but was readily stopped by slight pressure.

Secondary haemorrhage is not a very common occurrence in civil practice but is of much importance in military surgery. The general principles of treatment advocated by military surgeons are that, if possible, the bleeding vessel should be tied in the wound; but this is not always an easy task owing to the sepsis usually present. If this be impossible in the case of a limb, ligature of the main artery above the wound may in most cases be tried. But if the ligature is successful in arresting the bleeding it may cause gangrene; amputation must then follow. If it does not succeed in checking the bleeding, amputation is also necessary. The case of ligature of the subclavian artery referred to above illustrates this point.

Injury to Nerves.

There have been several cases of concussion of nerves causing loss of sensation and motion. In one instance a shell exploded close to a man without striking him, but the general shock and concussion caused facial paralysis. When the symptoms have cleared up rapidly, as they have in some cases in a few days, there could be no difficulty in the diagnosis, but in those instances in which recovery had not occurred in several weeks, the diagnosis from actual division of the nerve is very difficult. It seems, however, to be good surgery to wait at least two months, or even longer, before attempting any operative treatment, for many of the cases recover, even at as late a period as this.

Eye Injuries.

Not many examples of injury to the eye have been met with. In one instance the outer part of the orbit was shot away; the eyeball was lacerated, and was at once removed. Curiously, the man does not know that his eye has gone. Was it a blind eye? There have been a few cases of traumatic cataract due to the penetration of minute fragments of shrapnel, and also examples of traumatic iritis. One man had a gutter wound of the outer side of the orbit, and the eye on that side became completely blind without any obvious lesion. Was this an example of concussion of the second nerve?

Aneurysm.

Very few cases of aneurysm have been seen. In one there was a traumatic aneurysm of the first part of the axillary artery, and, in a second, of the brachial artery. In both cases the treatment undertaken was the same—namely, to cut down on the aneurysm, and ligature the vessel above and below.

BELFAST.

Some weeks ago the Board of the Royal Victoria Hospital, Belfast, opened three of the wards which, owing to lack of funds, had not been used since the building of the new hospital, for the wounded. Sixty were thus accommodated and put in charge of the surgeons of the hospital, and everything was done for their comfort and speedy recovery. Others were sent to the military hospital and to some of the infirmaries throughout Ulster.

An offer by the Ulster Volunteer Board to provide and equip a hospital of one hundred beds has been accepted by the War Office; the plans are well on the way to completion, and several thousand pounds have been collected to defray expenses. The military authorities have taken over from the Poor Law Board a group of buildings known as "Corry's Buildings," containing 200 beds; these are being changed so as to be suitable for the medical treatment of the Ulster Division. The board of management of the Royal Victoria Hospital has also under consideration a plan for offering 100 beds to the military authorities, so that in the near future several hundred wounded will probably find excellent accommodation and treatment in Belfast, and the sick from the Ulster Division will have similar advantages.

Altogether about 500 beds will be allotted in Belfast, and a large number more will be distributed throughout Ulster.

There is little doubt that if necessary double this number can be got ready without disorganizing the present hospital arrangements in the city.

DUBLIN.

DUBLIN CASTLE AS A MILITARY HOSPITAL.

IT was announced last week that the King had signified to the Lord Lieutenant his approval of a proposal to place Dublin Castle at the disposal of the City of Dublin branch of the British Red Cross Society as an emergency Red Cross hospital for wounded soldiers during the period of the war. The Board of Works is prepared to further the scheme in every way on the same lines as those adopted by the Office of Works in connexion with the conversion of the new Stationery Office in London into a Red Cross hospital. A special committee of medical men has reported favourably on the suitability of the Castle for the purpose, and it has been decided to substitute this scheme for that first recommended, which contemplated erecting emergency pavilions in the grounds adjacent to King George V Hospital. It is estimated that accommodation can be provided for 460 or 480 beds, and that in addition there will be ample room available for the hospital staff and nurses. The City of Dublin Red Cross Society proposes to provide the beds and necessary equipment, and to undertake the management of the hospital. The probable cost of each bed under this scheme will be about £10 instead of the £20 that would have been required under the other. A capitation maintenance grant will be allowed by the military authorities. The Presidents of the Royal Colleges of Physicians and Surgeons and the members of the Dublin hospitals staffs highly approve of the scheme, and have indicated their willingness to co-operate with the resident staff of the proposed Red Cross hospital.

RED CROSS CONVALESCENT HOME.

Temple Hill House (Blackrock, Dublin) was the first convalescent home opened in Ireland under the auspices of the British Red Cross Society; several other districts in Ireland are now contemplating similar co-operation with the military authorities.

Temple Hill House is an ideal gentleman's residence and originally belonged to the first Earl of Clonmel. The grounds are large and well wooded, and the whole place is well sheltered. The home is under the financial supervision of the Joint Committee of the County Dublin branch of the British Red Cross Society and the St. John Ambulance, and is managed and financed by a local committee. There are 20 beds in the home, arranged in four wards. They are supported entirely by private and local subscriptions. The nursing staff, of some thirty ladies, is supplied by the St. John Ambulance City of Dublin Voluntary Aid Detachment, under the supervision of a doctor. The Lady Superintendent and the Quartermaster have temporarily given up their homes and reside at Temple Hill; the other ladies take a fortnight's duty at a time in sections of ten each. Whilst on duty they are subject to the ordinary nursing regulations. The cooking is done by two of these ladies in turn, who hold cooking diplomas; consequently there is absolutely no cost for a nursing staff, the only paid servants in the home being two kitchen-maids. Since the opening of the home, some weeks ago, the beds have been fully occupied, the soldiers, as a rule, remaining there for a fortnight or three weeks.

THE BRITISH RED CROSS SOCIETY.

Typhoid in the Belgian Army.

THE British Red Cross Society received a visit on December 1st from Major H. Stedman, R.A.M.C.(T.F.), stationed at Calais, in order to discuss with him the disquieting situation produced by the outbreak of typhoid fever in the Belgian army. Cases began to be received in batches in Calais about November 20th, and every available house that could be used for isolating them was occupied by November 29th. Major Stedman stated that at a moderate estimate there were between twenty and thirty fresh cases daily, excluding any civilians who might be affected, and that he knew of one case of typhus fever. The Belgian Red Cross Society, owing to the restrictions which the condition of Belgium puts upon its resources, is hardly likely to be able to cope with the emergency of an outbreak of typhoid, and Major Stedman consequently represented to the War Office and the British Red Cross Society the immediate need of a hospital ship fitted for at least 300 beds in order to remove the cases now in Calais, and of a hospital of at least 600 beds in Belgium, preferably near a port. A meeting of the joint committee of the Society and of the Order of St. John was called for the same day, with the result that it was possible to announce on December 2nd that, without definitely deciding on the precise form in which assistance could best be rendered, the committee would make an immediate advance of £10,000 to be expended in Calais under the direction of the Chief Commissioner of the two societies, General Sir Arthur Sloggett.

Sir Frederick Treves has informed us that it is hoped to have a suitable vessel fitted up as a hospital ship within a very short time. The establishment of a special hospital in a public building near Calais would be undertaken immediately, and the accommodation would be increased by the erection of wooden huts. He had already obtained the services of Dr. Cassidy, Physician to St. Thomas's Hospital, as physician to the special hospital. No pathological bacteriologists had been selected here, as suitable men were available on the spot. The Society would be glad, if occasion arose, to make use of the services of Belgian doctors now in London in dealing with the outbreak. As to the source of the epidemic, Sir Frederick thought it to be too early to express a definite opinion. The cases were not indigenous to Calais; they were coming in in batches from that section of the fighting line held by Belgian troops. The cause might be found, therefore, in theconditions of existence in the trenches, and it was not clear what part, if any, the flooding of the country had played.

The King George Hospital.

The King has approved the name of "The King George Hospital" for the new Red Cross hospital now being established in the Government Stationery Office, Waterloo Road, by the joint committee of the British Red Cross Society and the Order of St. John. Over 170 beds have already been endowed. It will be some weeks before any part of the building can be ready for occupation.

The Red Cross Hospital at Netley.

The Red Cross hospital at Netley is now nearly completed. It has the general appearance of a town of grey huts, arranged with great regularity in a meadow behind Netley. The hospital will provide 500 beds (of which about 400 are now available), and is made up of 45 huts disposed as follows; 25 for patients, 9 for nurses, 5 for orderlies, 3 as recreation rooms, and 3 for isolation wards. The staff under Surgeon-Lieutenant-General Sir Warren Crooke-Lawless, C.I.E., consists of 18 medical officers, 65 trained nurses, 20 quartermasters, and 130 N.C.O.'s and men. The huts are of excellent type—light, airy, and well ventilated—and the many difficulties connected with the installation of a sanitary system have been overcome with complete success. Each hut contains 20 beds, and has a well arranged annexe. The meals are cooked in the hospital kitchen, but the rations are supplied from Netley Military Hospital. As each hut has been completed, wounded have been received, and up to the present a considerable number of Indian troops have been under treatment. Special arrangements are made for them. To each of the Indian wards one sister and three orderlies are attached. The sister attends to the general management and to the meals. She directs the nursing, but does not come in actual contact with the patient, the nursing being carried out by orderlies. Two Indian gentlemen attend the hospital regularly, and give their voluntary services as interpreters.

CASUALTIES IN THE MEDICAL SERVICES.

ROYAL NAVY.

WHEN H.M.S. *Bulwark*, a battleship of 15,000 tons, blew up at Sheerness on the morning of November 26th, practically the whole of her complement—between 750

and 800 men—perished with her. Among them were all three of her medical officers.

Fleet Surgeon Percival Kent Nix was educated at Cambridge and at the London Hospital, and took the degrees of M.B. and B.C. at Cambridge in 1896. He attained the rank of Fleet Surgeon on November 10th, 1912, and had been serving on the *Bulwark* since June 4th, 1912.

Surgeon William Miller took the degrees of M.B. and Ch.B. at Glasgow in 1906, and after serving as house-surgeon and house-physician of the Victoria Infirmary, Glasgow, joined the Navy on May 14th, 1909. He was posted to the *Bulwark* on July 29th last.

Surgeon Robert Traill Brotchie was educated at the London Hospital, where he was editor of the *London Hospital Gazette*. He took the diplomas of M.R.C.S. and L.R.C.P.Lond. in 1913, and after serving in the British Red Crescent Hospital in Tripoli during the war between Italy and Turkey, settled in practice at Tarbert, Loch Fyne, Argyllshire, where he was medical officer of health. He joined the Royal Naval Volunteer Reserve on February 12th, 1914, and was called out for the war and posted to the *Bulwark* on July 29th, 1914.

ARMY.

Died of Wounds.

Major Edwin Bedford Steel, R.A.M.C., died on the afternoon of November 23rd, of wounds received that morning at La Clytte. He was educated at Trinity College, Dublin, where he took the degrees of M.B. and B.Ch. in 1893, entered the army as surgeon-lieutenant on January 29th, 1895, became surgeon-captain on January 29th, 1898, and major on October 29th, 1906. He was recently stationed at Netley. He was 43 years of age.

Prisoners, previously reported Missing.

Jackson, Lieutenant J. L., R.A.M.C.
Rose, Captain A. M., R.A.M.C.
Winter, Lieutenant H. G., R.A.M.C.

Missing.

Robertson, Captain H. G., R.A.M.C.

INDIAN MEDICAL SERVICE.

Rejoined.

Lieutenant N. M. Mehta, I.M.S., reported missing after the late battle in East Africa, has rejoined.

DISTINGUISHED SERVICE ORDER.

A NOTICE in the *London Gazette* announces that the King has approved of the appointment of fifty-eight officers to be Companions of the Distinguished Service Order in recognition of their services with the Expeditionary Force. The list contains the names of three officers of the Royal Army Medical Corps as follows:

Captain JAMES STUART DUNNE, R.A.M.C.

During German attack on night of October 31st, near Messines, he established a dressing station just behind the trenches, and was the means of saving many lives, he himself going several times into the trenches to attend to wounded men who could not be moved.

Captain PATRICK SAMPSON, R.A.M.C.

Has shown frequent and conspicuous gallantry throughout the campaign, especially on October 21st and 22nd, attending wounded men under very heavy shell fire.

Captain SIDNEY JOHN STEWARD, R.A.M.C. (Special Reserve).

Went with party of stretcher-bearers across ground swept by rifle and shell fire to Langemark village, and removed eleven wounded men.

NOTES.

PROVISION FOR SICKNESS AMONG THE TROOPS.

AT the request of the War Office, the Metropolitan Asylums Board has agreed to place accommodation at the disposal of the military authorities for the treatment of sickness which may occur amongst the troops or the staffs of military hospitals. The Board will receive a limited number of cases, should any occur, of dysentery; of enteric fever among the nursing staff of the military hospitals in Woolwich; of infectious disease amongst the men of the Public Schools Brigade of the Royal Fusiliers at Epsom (provided the beds are not required by metropolitan patients); and of scarlet fever or diphtheria among the personnel of the Duke of York's Royal Military School. The Board has also informed the War Office that there are generally beds available at seven hospitals, which could be used for cases of enteric fever amongst the troops.

WOMEN'S HOSPITALS.

The response to the appeal of the executive committee of the Scottish Federation of Women's Suffrage Societies for funds to send out a series of hospital units staffed by women doctors and nurses has been generous. The sum actually in hand on November 28th was £6,000, and the money was coming in at the rate or about £1,000 a week. In addition, large quantities of shirts, dressings, and other equipment have been contributed, and Girton and Newnham Colleges had promised to raise £1,500 to equip a complete unit for France. The personnel and equipment of two hospital units are ready. The first will be sent to Servia, and the Admiralty has consented to provide a transport. For the other unit the French Red Cross Society, under which it would work, has provided the Abbey de Royaumont, twelve miles from Chantilly. Mrs. Owen (Merioneth) will act as administrator, and the medical officers are Drs. Deborah Hancock (Birmingham), Berry (London), Ivens (Liverpool), Ross (Paisley), and Ruth Nicolson (London), and for *x*-ray work Dr. Savill (London). In addition, the Scottish Committee is supplying nurses and cooks. At the request of Dr. Depage, the head of the Belgian Red Cross Society, the committee has arranged that the services of Dr. Alice Hutchison, Dr. Sharp, and ten nurses should be placed at the disposal of the hospital in Calais, which is under the patronage of the Queen of the Belgians.

MEDICAL OFFICERS WANTED.

Field Ambulances.

We are asked to state that the 2nd Northumbrian Field Ambulance R.A.M.C.(T.F.) is urgently in need of medical officers for the Reserve Unit. There may be one or two vacancies in the Foreign Service Unit for officers desiring to go abroad. Officers joining for the period of the war only will receive £30 outfit grant, and those joining as ordinary Territorial officers will receive £40. The pay on joining as Lieutenant is 14s. a day, *plus* field allowance of 3s. a day while under canvas.

Applications should be sent to Lieutenant-Colonel D. A. Cameron, Officer Commanding 2nd Northumbrian Field Ambulance R.A.M.C.(T.F.), Bensham, Gateshead.

There is a vacancy for one lieutenant in the South Wales Mounted Brigade Field Ambulance (Reserve Unit) at Hereford, which is under the command of Major Herbert Jones, R.A.M.C.(T.F.), to whom applications should be made at the Barracks, Hereford.

THE strain of warfare is apt to lead to the production of nervous disorder and insanity among soldiers. On the outbreak of the present war, Dr. Vaillard, Médecin-Inspecteur of the French army, suggested that measures should be taken to ascertain the facts and provide a remedy if necessary. Accordingly the Government invited him to study the question in conjunction with Professor Gilbert Ballet. The result of the inquiry convinced them that the amount of insanity caused by the war in the army was inconsiderable. There was a certain number of cases of delirium due to alcoholism in mobilized troops who had celebrated their departure rather too joyously. Almost all recovered quickly and were sent to the front. Then there were cases of slight general paralysis which became aggravated under the influence of the excitement of war. The same may be said of some melancholics. What was chiefly feared was mental disorder among men worn out by the fatigue of the campaign. Such cases, however, were extremely rare. Ballet therefore concludes that, with a few exceptions in which a pre-existing organic taint was always to be found, the war has not produced insanity. It were well, he adds significantly, if the opposite could be said—namely, that insanity has not produced war.

Ireland.

[FROM OUR SPECIAL CORRESPONDENTS.]

TRINITY COLLEGE, DUBLIN, AND THE WAR.

A SPECIAL meeting of the University Senate was held on Friday, November 27th, for the purpose of conferring degrees upon those medical students who had completed their first examination this month and who are desirous of obtaining commissions in the Royal Army Medical Corps. Before conferring the degrees the Vice-Chancellor of the university, Mr. Justice Madden, LL.D., made a statement regarding the part the members of the university are playing in the present international crisis. He dealt especially with the work of the Officers' Training Corps, which is under the command of Major Tate, fellow and tutor of Trinity College and public orator in the University of Dublin. The total number of Trinity College men who have applied for commissions through the head quarters of the corps is 501. Of the 340 members who formed the corps at the beginning of the war practically all are now on active service, and as a result of good recruiting the corps has at the present moment 360 members.

By no class of students has the call of duty been more fully recognized than by students of the School of Physic. Since the war began a large number of young medical graduates have received temporary commissions or joined the reserve list of the officers of the Royal Army Medical Corps. The number of these amounted to 70 at the end of October. Many undergraduate students in medicine in their final year have been granted commissions in the reserve list on probation, but will not be called for active service until they complete their final examinations. We are informed that in addition to these no fewer than 70 students of the School of Physic have enlisted or received commissions in fighting regiments of the army or been appointed probationary surgeons in the Royal Navy.

The number of students who have matriculated in the school in 1914 is above the average, and if it were not for this fact the depleted ranks of the School of Physic would be even more striking than is actually the case.

Scotland.

[FROM OUR SPECIAL CORRESPONDENTS.]

RESIGNATION OF PROFESSOR WYLLIE.

PROFESSOR JOHN WYLLIE'S resignation of the Chair of Medicine in the University of Edinburgh, which was accepted by the Curators of Patronage on November 30th, has been received by his friends (and they are many) with great regret but with little surprise, for his failing health for some time had made it evident that such a step was to be anticipated in the near future. Professor Wyllie has held the appointment of Professor of Medicine since the year 1900, when the death of Sir Thomas Grainger Stewart rendered vacant the chair which had been occupied by Cullen, the Gregorys, Alison, and Laycock; then, after a strenuous contest in which the late Dr. G. A. Gibson was a strong candidate, Wyllie was elected, and, until recently when his health became impaired, has performed all the duties of the office with great acceptance. Many medical men in many parts of the world look back to-day with gratitude to the teaching received from Professor Wyllie in the Medicine classroom in the University and in the wards of the Royal Infirmary. Whilst Wyllie has made many contributions to medical science, there can be no doubt that his outstanding achievement was his book entitled *The Disorders of Speech*, which was published in 1894; it is a classic on the subject with which it deals, and many saw in the degree of LL.D. conferred upon him by his Alma Mater in 1897 a fitting recognition of the worth of the work and the eminence of the author. The Curators have authorized their Secretary, Mr. A. B. Fleming, W.S., 4, Albyn Place, Edinburgh, to receive applications from intending candidates up to January 15th, 1915.

Sydney.

[FROM OUR SPECIAL CORRESPONDENT.]

SIR THOMAS ANDERSON STUART.

THE news that Professor Anderson Stuart, M.D., had received the honour of knighthood was received with great pleasure by the large number of medical students at the Sydney University, as well as by the profession and the public in general. Professor Stuart has been Dean of the Faculty of Medicine for thirty years, and it is largely due to his energy and wonderful organizing powers that the Sydney Medical School has attained to its present important position. He has also been chairman of the Board of Directors of the Royal Prince Alfred Hospital for the last thirteen years, and here again he has done an enormous amount of work in extending and improving the buildings. In addition to these positions he has held others outside those of a strictly professional character, and his work in various directions has been of such a character that the distinction now conferred upon him is recognized as well merited.

THE LATE DR. CRITCHLEY HINDER.

The late Dr. Critchley Hinder was surgeon to the Western Suburbs Hospital, Sydney, for twenty years, and to commemorate his work there the Hospital Committee recently ordered a portrait of the deceased surgeon to be hung in the hospital. The portrait is a basso-relievo, a work of a high order of merit, and shows the full face with singular fidelity.

TREATMENT OF VENEREAL DISEASES.

As a part of the crusade against venereal disease the Minister of Health has approached the boards of the metropolitan hospitals with a view to the establishment of night clinics for venereal diseases. This matter was fully considered at a combined meeting of the honorary medical staffs of all the metropolitan hospitals, and it was agreed to fall in with the proposals. This means that the Government will be called upon to provide the necessary funds and the extra accommodation required to carry on the work.

England and Wales.

[FROM OUR SPECIAL CORRESPONDENTS.]

MANCHESTER AND DISTRICT.

THE CHRISTIE HOSPITAL.

AT the annual meeting of the supporters of the Manchester Christie Hospital for Cancer on November 26th it was reported that the total number of cases treated during the past year was 168, of whom 133 were in-patients and 35 out-patients. Of the in-patients, 67 had been discharged, 47 had died, and 19 remained in the wards. Provision had been made for 61 patients, called "home patients," who were admitted in a late stage of the disease, when there was no hope of cure, simply for the purpose of alleviating their sufferings. Voluntary contributions from patients and their friends had amounted to £191, but the falling off in the income from annual subscriptions had made it necessary for the committee to appeal for additional contributions. A sum of £250 had been placed to the credit of a research fund. The total contributions to the Manchester Radium Fund had been over £31,000.

Professor Wild said that the money for the purchase of radium raised before the war began would provide sufficient radium for the needs of the district for many years. The work of the radiologist had not yet been commenced, as the alterations at the infirmary to provide for the radium department had been much greater than had been anticipated. Many of the cases were too far advanced for any effectual treatment by any quantity of radium, and one of the reasons for the existence of the Christie Hospital was to deal with such cases as well as possible. Other cases who came in the early stage of the disease would not be treated by radium. An intermediate class, however, too far gone for any surgical operation, but not so far gone but that improvement might be made,

d in some cases recovery effected, would be treated by linm, which, though it was not a cure for cancer, was :en of considerable benefit.

Dr. C. Powell White and Dr. W. F. Shaw thought it cessary to warn the public that radium should not be garded as a certain cure, and that the radium treatment is as yet only in the experimental stage.

THE DRUG FUND.

Among the various suggestions made from time to time safeguard the chemists under the Insurance Act, the llowing is noteworthy as perhaps showing the feeling at exists in certain quarters not without influence. Mr. P. Gilmonr, President of the North British Branch of e Pharmaceutical Society, at a meeting of the Manester Rotary Club on November 25th, is reported to have id that if medical benefit is to be anything more than a am, more money will have to be found for it. Under ie present system doctors were giving large quantities of edicines which were of very little value to the patients, id were encouraging malingering. What was called the floating sixpence" for drugs was in Manchester really a ibmerged sixpence. The remedy for the shortage in the ug fund suggested by pharmacists was that the drug bill ould be made the first charge on the medical benefit nd, and that the doctors should only get what was left hen the drug bill had been paid in full. He believed that provision to that effect would have been embodied in the gulations but for the war.

Correspondence.

THE FUTURE OF THE LISTER INSTITUTE.

SIR,—The intervention of Professor Shattock in this ntroversy will command the interest of your readers, id his temperate argument their careful attention. Thus y his letter I am led to offer some reflections which herwise I should not have ventured to publish.

For, to tell the truth, at the Lister meeting I did not, either do I now, feel quite sure that the gathering of outside ersons, however eminent individually, was quite justified in ing beyond advice; that it was quite justified in defeating decision of the governing body—a decision with one exption unanimous—I am not sure. The governing body is timately acquainted with the working of the Institute, s needs, conditions, and prospects; moreover, some of its anagers have a personal stake in its prosperity. We, the tsiders—and here I have some reason to judge others myself—could pretend to no such familiarity, nor any ch stake. Few, if any of us, had frequented the Institute; ost of us, indeed, were surprised to find ourselves invited t only to give counsel but also to vote upon the destiny a corporation of whose inner life we had known so tle. Was there not some danger lest, in our comparative norance of its life and development, we should wander to abstract notions and prepossessions? And if now we e to override the confident decision of the governing dy, our objections should be, not vague forebodings, but efinitely in touch with the facts. Yet even those who ame with the intention of an adverse vote, and confident a the inaccessibility of any such intention to a speech, ust still have desired that their advocates, if only for ppearances sake had been more instructive, had dealt ore in facts and less in rather elderly—"Mid-Victorian" -vaticinations.

Professor Shattock begins his present argument by rankly admitting that "the proposal for confederation mbodies advantages of the highest order." This, he says, "cannot be denied." Thus for the objector he sets a high standard of reply, of weighty, cogent, and practical criticism. As it appears that Professor Shattock was present at the meeting of the Institute, I, who made no notes of the discussion, may presume that his letter contains the main contrary argument; that other contrary reasons may be taken as of secondary importance, and, in view of "advantages of the highest order," negligible. In this I agree. And let us remember that no change, however beneficent, was ever made in any institution but in the face of quite considerable contrary arguments; that all such changes have to be made not on all but on a balance of reasons. Furthermore, governing bodies are not unaffected by the inertia which pertains to all institutions, to all co-operations of men; so that when a governing body speaks for a change the reasons for it are probably overwhelming. What, then, have we of the outer court to advance which so overtops the "promise of advantages of the highest order," and the phenomenon of a revolutionary governing body, that the balance of reasons is for refusal?

It would seem, according to Professor Shattock, and my own recollection of the debate, that the serious objections, however various its expression, may be summed up in one. It is argued that, if confederated with the Medical Research Committee, the "standard and value of the work carried out, if not solely a utilitarian one at the outset, would almost inevitably become so in course of time;" it would, "as a department, come to exist for the purpose of direct public benefit." Let us delete the word "department," which suggests a Government department; such the National Research Committee is not; it is endowed by a department, but with far-reaching and liberal powers. But still even then it is argued that it would be "restricted and even extinguished" (as a disinterested scientific body). This is the apprehension, the abstract notion which is supposed to outweigh "advantages of the highest order."

My mind being unhappily of a material bent, and abhorrent of a vacuum, I find it hard to deal with this kind of speculation. Can we not get nearer to realities? I have in my mind's eye, not a viewless notion but certain solid facts and figures. Let us suppose a sum of about £24,000 a year to be distributed amongst the university and collegiate institutions of the United Kingdom, in accordance with the unfettered requests of the directors of these bodies, and of certain private workers. Whatever we may say about the National Research Committee as a central body, are we to suppose that these many and several institutions throughout the kingdom are bitten by the utilitarian dog? These diverse bodies have, it is true, been visited by the committee, but only to ascertain the wishes and hopes of each and the adequacy of its plant and personnel, in no way whatever to dictate the direction of its own spirit and work. The schemes of such diffused researches were drawn up not before but after the reception of the requests of collegiate and individual investigators, so that the freedom of each and all is at two removes from "departmental" influences, and beyond the reach of the longest official arm.

In respect of the central work of the National Committee, one of the objectors to the confederation gave as his reason that he objected to any central institute, that all funds should be divided between the collegiate and other independent bodies. Well, after a long and patient discussion a scheme providing for some organized work in a central institution has been settled on moderate lines, and has received the approval of almost of all concerned, metropolitan and provincial. Much, indeed, of the functions of such a centre—such as the secretarial, the organizing, the statistical, the bibliographical, and so forth—is to be for the benefit of all workers everywhere, and these functions, at any rate, could not easily be captured by a utilitarian Minister. The research staff will, of course, have that free hand without which, as Professor Shattock will agree, no able scientific staff would accept or retain their offices. If, under special circumstances, a Minister were to invite the Research Committee to attack certain problems—as, for instance, during a great epidemic or a great war, offering at the same time facilities for attacking them—such a proposal, far from being meddlesome, would surely be esteemed and cordially accepted.

Weak as I am in conjectural arguments, to test Professor Shattock's distinction between disinterested and utilitarian researches, let me take a concrete instance. For some years the Home Office has had before it a statement that glass-workers are subject to a peculiar form of cataract. Evidence, medical and lay, was taken without definite result. The Minister decided to allot funds for the inquiry, and to ask for the help of the Royal Society. This I suppose was one of the insidious utilitarian researches for "direct benefit." A committee of the Royal Society undertook the research, and has pursued it quietly without any interference from the Government, and with a perfectly free hand. Now, of this committee Sir William Crookes has pursued laborious investigations at glass-works and in his own laboratory, with the result not only of furthering the special purpose, but also incidentally of discovering certain means not only of

purely scientific interest but probably also of great importance in the arts. Some similar by-results may come out of the physico-physiological side of this research by Messrs. Hill and Hartridge. The truth is that, outside the technical laboratories of some factories, Professor Shattock's distinction between disinterested and utilitarian research is illusory, at any rate in the hands of ardent and competent workers. But no voluntary institute, unaided by public money and encouragement, could or would undertake such labours. Such bodies, to please their subscribers, are too often driven to work for the short, not for the long, run. I can see but one way in which a meddlesome Minister could pervert research. He might say: You have been six months over this job and have done nothing. I give you six months more, and if at the end of this second period you have nothing popular to show I shall cut down your subsidy. But are we to imagine such silly Ministers?

The man in the street now knows all that Professor Shattock urges so well; all about Faraday and electromagnetism, Saul's search for asses and discovery of a kingdom, and so forth. When I pressed one of the most serious objectors to condense his misgivings into something practical, he did not urge this point, but only that members of the House of Commons might be getting up to ask bothering questions. Of course they may. My friend is one of those persons who refuse to see that they are born in a democracy. The times for superior persons to rule *in camera*, or by esoteric methods, are, for good or evil, over. To make progress now we must persuade the public; a slower process, but progress when made is far more solid and permanent. I have seen a good deal of four Government departments, and observed that this new advance by persuasion has wholly altered the official attitude. The older routine, narrowness, and officialism have given way to a breadth of view, to a trust without dictation in men who know their business; thus the services have gained efficiency on a scale far larger than English individualism—excellent ingredient as it is—can possibly achieve. Let us take courage from the National Physical Laboratory at Bushey, which happily combines private munificence and initiative with the scope of national resources; there no whisper of State meddling has been heard. The universities, again, feared the donations of State subsidies, but after experience of them they now admit unanimously that these subsidies are the easiest and most fertile money they receive, and that all their previous apprehensions were bogies.

Professor Shattock admits that an addition of clinical provision for these research institutes would be an inestimable "advantage"; it is not a mere advantage; it is the core of pathology. To set out to investigate disease in the absence of the very thing we are to study is a phantasy which will amaze our children. Without this seed-core of progress a pathological institute must lapse into a backwater. Thus I urge that to combine the Lister and the National Research Institutes would be not a mere addition, but a multiplication of the capacities of both.—I am, etc.,

Cambridge, Nov. 30th. CLIFFORD ALLBUTT.

THE WAR AND TYPHOID FEVER.

SIR,—I venture to criticize one or two of the statements made by Sir William Osler in his extremely interesting and valuable address on "The War and Typhoid Fever," which appeared in your issue of November 28th, because I believe that they may give rise to erroneous ideas. He describes in some detail the symptoms *following* inoculation (the italics here and below are mine), and under the heading "Cases with Untoward Effects, (*b*) General," he writes that symptoms suggestive of enteric, and even enteric itself, may *follow* inoculation. All through this portion of Sir William's address the words "follow" and "sequel" are used, as they are usually used by medical writers, to indicate that (in this particular case) the untoward event was caused by the inoculation.

Now I think that in some of these cases, especially the enteric cases reported by Dr. Walter Broadbent and Professor Boyd and the pneumonia cases, we are hardly justified in concluding that these diseases, although they followed the inoculations, were really due to them, unless we have more evidence before us. I am especially interested in the typhoid cases because at the present ti I have under my care a soldier suffering from typh fever, in whose case it was alleged that the antityph inoculation had given him that disease. Careful inves gation was made, and it was proved that the symptoms the disease were present before the inoculation was ma Yet, had the inoculation been made four or five days lat the attack of typhoid would have *followed* it. T patient, I may add, came from one of the camps n Brighton.

In both Dr. Broadbent's and Professor Boyd's cases t shortness of the interval between the inoculation and t onset of the attack of enteric, compared with the us length of the incubation period of enteric, suggests that t patients had been infected before they were injected.

In respect of the pneumonia cases in the North Midla Division the question of coincidence has to be considere

One other—a minor—point. Sir William states that t inoculation fever has many resemblances to the so-cal serum sickness. There are, however, two very marl differences. The latent period between the injection serum, and the onset of the sickness is rarely less tha week, and is usually nine or ten days; and in serum si ness a rash is almost invariably present.—I am, etc.,

Homerton, N.E., Dec. 1st. E. W. GOODALL

SIR,—In my lecture, which appeared in the JOURNAL last week, I was in error in stating that the Ebe bacillus would probably kill in this year in the Uni States as many as would the German shrapnel and bul in France and Russia. Judging from the recent figure would be nearer the mark to say that it would kill many as would die of wounds in the British force I am, etc.,

Oxford, Dec. 1st. WILLIAM OSLER

THE TREATMENT OF WOUNDS IN THE PRESENT WAR.

SIR,—I should like to add my gratitude to Sir Wat Cheyne for so clearly placing before the profession responsibilities to the wounded. Aseptic surgery s disaster. In peace time the most that can be said aseptic surgery is that it is artistic, but it is a frigh waste of time and clean linen.

Aseptic surgery constitutes a second and more ser danger zone for our *braves*. The results of antise surgery being perfect, why have the tedious detai asepsis?

Assuming the first antiseptic to be carbolic or iod I wish to urge the use of salicylic acid later. My for chief, Lister, regarded salicylic acid as the only antise that would correct fetid feet, in spite of its low solubi I was very short of carbolic, and had to use iodine (10 per cent.), but later I found salicylic acid u successful. I have never seen any wounds so offensiv septic, and at first was in despair. As the salicylic disappears in the wound, I fancy it is dissolved by serum. The sloughs quickly disappear, and bright gr lations cover the wounds, and all odour goes. I w like to note three cases:

1. A shrapnel wound in the perineum, which after b rendered superficial was as bad as anything one imagine, and *B. coli* was present. In three days it w clean granulating sore, and the area odourless.

2. A bayonet wound in the left thigh penetra 9 in. from above. The youth (Zouave) had slain opponent. Bayonet wounds are not seen often by re of their severity. It formed a lacerated wound, the le part contained an abscess, and the limb was purple. pected gas gangrene. After incising in two places I in duced salicylic acid daily on an india-rubber drainage to and it cleared in four or five days. The cellulitis gradu dispersed under boracic fomentations.

3. An abdominal abscess, suprapubic. Here the pus very offensive and so abundant that I laid the man o side for drainage. The wound became rapidly sweet salicylic acid introduced inside, and in time the diminished in quantity.

Every doctor has his own fads, but I certainly comm this one as being very useful. I wish some bacteriol would test its efficacy *in vitro*.—I am, etc.,

London, W., Nov. 28th. ALBERT WILS

SIR,—I should like to direct attention to a valuable preparation which seems to be comparatively unknown, and which seems to me to be admirably suited for use on the battlefield. If crystals of carbolic acid and camphor (equal parts) are ground together in a mortar a fluid is formed which does not produce any discomfort when applied to the skin or mucous membrane. Camphor is an antiseptic and deodorant. It also augments the anaesthetic effect of the acid, but at the same time it prevents it from acting as an escharotic.—I am, etc.,

Glasgow, Nov. 30th. SAMUEL J. CAMERON.

SIR,—The best commentary on Dr. P. R. Cooper's letter is your report of Mr. Charters Symonds's speech at the Medical Society, wherein he says it is agreed for routine practice to wash the wound with some *mild* antiseptic. Mr. Symonds also draws attention to the value of the alcohol in the tincture of iodine, and no doubt, when he has tried petrol, he will agree with Sir Victor Horsley and myself.

If pure carbolic produces no bad results when applied to the trachea by Dr. Cooper, it would seem to be the ideal treatment for all membranes and septic conditions of the pharynx, but apparently his use of it has been only occasional, whereas I have used petrol constantly for swabbing in the early stages of these affections, and invariably with good results and little pain.

I agree with Dr. Cooper that too much emphasis cannot be made with regard to the prevention of evaporation when wounds are treated even by mild drugs.—I am, etc.,

Swansea, Nov. 30th. G. ARBOUR STEPHENS.

SIR,—Having entertained us with his vigorous denunciation of the scheme proposed by Sir R. Godlee, will not Sir Victor Horsley now detail the method he would suggest for the general treatment of wounds in the present war? "Every case," he says, "must be treated on its merits and not by any routine." But the merits of the situation are that practically every wound is infected. Under these circumstances it would seem to be only reasonable to have some sort of routine plan for dealing with this grave risk. Sir Rickman Godlee and Sir Watson Cheyne have detailed one perfectly intelligible plan. If to an eminent surgical authority like Sir Victor Horsley this plan seems fraught with danger, then he surely ought to indicate how he would deal with the situation. This matter is obviously of great importance and interest to medical officers of service battalions, and if Sir Victor's argument is superior there should be no difficulty in appreciating the fact.—I am, etc.,

ERIC D. GAIRDNER, M.B.,
Medical Officer in Charge 5th Royal
Stirling, Nov. 30th. Scots Fusiliers.

SIR,—To prevent any more laughable misunderstandings on this very serious subject, permit me to reply briefly but categorically, and first to Dr. Cooper.

I do not "deprecate the use of such a valuable antiseptic as phenol." On the contrary, I use it almost daily, but on suitable cases and in suitable strengths of solution.

I regret I spoke of his suggestion of November 14th that my "experience of operating under such conditions as must obtain in war, or even in the common accidents of civil life," was limited, as "good-natured banter." It seems Dr. Cooper meant it to be "a sincere compliment." I accept it as such, but, alas! like so many compliments, it is not true, as I showed in my last letter, from my hospital experience. I did not say petrol and alcohol were "antiseptic agents." I said (November 21st, 1914) the former was the "best *cleanser*" and the latter next best.

It did not need any addresses, in my opinion, to suggest that there is an "urgent indication" for prompt and thorough disinfection of wounds, probably septically infected, whether in this war or in civil practice. I am sure all surgeons are agreed on this, and no one but a surgeon unfit to have any responsibility would dream of dealing with these cases by simple asepsis.

It is quite another question what the "thorough disinfection" means. Personally, I use as disinfectants sublimate lotion and hydrogen peroxide 20 volume strength.

I do not consider it justifiable to use a slough-producing escharotic. The condition in which a large number of the wounded arrived in this country would have been prevented if their wounds had been thoroughly irrigated with hydrogen peroxide twice or thrice a day.

As to Mr. Peter Broome Giles's absurdly violent onslaught on my innocent statement of scientific history, all I have to say is: "*Honi soit qui mal y pense.*"—I am, etc.,

London, W., Dec. 1st. VICTOR HORSLEY.

SIR,—I read with interest Sir Watson Cheyne's address on the treatment of wounds. At a big out-patient clinic of which I had charge the routine was to apply crude carbolic acid to fresh cuts and similar injuries. I found the results were more favourable when the acid was left in contact for about two minutes, then removed by swabbing the wound with methylated spirit.—I am, etc.,

Liverpool, Dec. 1st. OLIVER CARLYLE, F.R.C.S.Edin.

AMATEUR WAR NURSES.

SIR,—It is satisfactory to learn from Mr. Edmund Owen's letter that the uniformed ambulance woman will in future exist under the designation of "woman orderly."

Previous to my first letter I had been told on reliable authority that 2,000 dressings a day were being changed by a detachment of untrained women at the front.

Does Dr. Bowhay suggest that a woman whose whole idea of nursing is based upon a short course of lectures is able during one or even two months so-called "hospital training" to acquire sufficient knowledge to dress a wound in accordance with the methods of modern aseptic or antiseptic surgery? Having given ambulance lectures to women for years past, I repeat that, in my opinion, the very slight knowledge expected in examination cannot in any way be compared to the proficiency a hospital nurse must exhibit in order to obtain her certificate. The statement that a trained nurse needs special study to compete with ambulance women is positively ridiculous. Further, I should like to point out to Dr. Bowhay that my letter dealt with nursing, not with cooking.—I am, etc.,

Whitley Bay, Nov. 28th. N. A. EDDLESTONE.

GERMAN SCIENTIFIC PRE-EMINENCE.

SIR,—Out of the horror of this war some modicum of good may come if it leads, at long last, to a revision of the exaggerated estimate that has prevailed so long in this country and in America of the achievements of the Germans in science. To me, who have for so many years been protesting—*vox clamantis in deserto*—against the infatuation of English alienists with German pseudo-science and pseudo-discoveries, it is extremely gratifying to note the change of tone in your leading article of November 28th, and in Dr. Greeley's article in the *Boston Medical and Surgical Journal* of September 10th. A few years ago you published a letter from me protesting against the laudation that you bestowed upon Professor Ziehen for a discovery of his which I had myself discovered and published, along with others, some years before, and which attracted no notice at all when I published them. The example was typical of our attitude towards the Germans and towards ourselves.

Those of us who remember the war of 1870 know that in spite of the ineptitude and divisions of the French higher command, in spite of the deficiencies in the French supply, the Germans on several occasions were within an ace of defeat; but as they were successful, the German army has since been worshipped as the utmost culmination of what is possible in human endeavour; and the admiration bestowed upon it has slopped over on all sides, so that in spite of the plain evidence of our senses, in spite of the fact that in almost every activity of life the Germans have come to this country to learn, we have cultivated a superstition of German pre-eminence in commerce, in machinery, in education, in everything, but especially in science, and more especially in mental science.

Against this superstition I have protested for many years, but my protests have been unheeded. If the Germans had made any discoveries in medicine at all comparable with the discovery of the circulation of the blood, of vaccination, of antisepsis and asepsis, of hormones—all made by Englishmen—if the suffrages of the medical world had identified with German names the discoveries

of Colles's fracture, Pott's fracture, Pott's disease, Bright's disease, Addison's disease, Jacksonian epilepsy, Hutchinson's teeth, or any other of equal importance, there might be some excuse for this superstition; as it is, there is none. But it is especially in mental science that the reputation of the Germans is most exalted and is least deserved. For every philosopher of the first rank that Germany has produced England can show at least three, and in the value of their contributions the comparison is immeasurably in favour of the English. It is absurd to compare the fumbling of Hegel and his disciples in impenetrable fog with the transparent clearness of English philosophy from Hobbes and Locke to Spencer and Mill. It is absurd to compare the logic of Sigwart and Lotze with that of Hamilton and J. S. Mill; and it is absurd to compare the lagomachy of Kraepelin and the filth of Freud with the classical writings of Maudsley and the clinical insight of Clouston. In every branch of mental science the English are immeasurably superior to the Germans.

But let me give the Germans their due. There is one department of activity in which they easily excel all other nations on earth. I do not speak of their skill in espionage, for a spy bureau that will give a handsome reward to a poor boy for information copied out of *Whitaker's Almanack* is not so magnificently competent. No, I refer to their genius for self-advertisement. They have contrived, upon a very slender basis of achievement, to impress themselves upon the world as the most scientific nation on earth. Never was there a greater imposture. Scientific, indeed, they are in one sense—more scientific than any other nation—for, as Dr. Greeley points out, there is a far greater proportion of medical men working at science in Germany than in any other nation; but what have they to show for it all? Less, in proportion to the number of workers, than even Japan, which has so lately entered the field. But in getting themselves accepted at their own valuation they are immeasurably superior to every known example—even to Mr. Bernard Shaw. True, they do not follow his method of beating the big drum with frenzied energy and blowing their own trumpet till their cheeks crack, but they display the same adroitness in foisting upon a gullible world their scientific achievements as their shoddy commercial wares, and the two are of much the same value—made for show and not for endurance—in short, made in Germany.—I am, etc.,

Parkstone, Dorset, Nov. 30th. CHAS. A. MERCIER.

NUTRITION AND MEAT EXTRACTS.

SIR,—Believing that what may be called the multiple body-building theory regarding meat extract had been definitely shattered, it was my intention, when last writing, not to trouble you again with it, but Professor Thompson sends you a third letter,[1] in which he shows so little disposition either to meet my criticisms or admit the illusory character of his doctrine that the facts of the case are obscured, and I feel that, in the interest of prescribers and consumers of meat extract, the following brief summary should be presented to them:

A body-building power of from 10 to 20 times the amount taken was claimed for meat extract as the result of two series of experiments: First, upon 5 dogs,[2] and secondly, upon 2 dogs and 2 human subjects.[3]

If the extract really had such a power, through (as the authors believed) a superior utilization of the other food, an animal previously in metabolic equilibrium upon a particular diet should, when regular additions of extract are made to that diet, show regular increments of weight, and these increments should be from ten to twenty times the quantity so added, for the diet previously sufficient has, according to the theory, become more than sufficient in consequence of its more efficient utilization.

Now, a reference to the figures quoted in my first letter,[4] and to the other abstracts from Professor Thompson's paper, prove:

1. That at the end of several days with extract the animal, as a rule, weighed no more than on the first day—sometimes less.

2. That an increase on the first day of a meat extract period was followed generally by no augmentation of weight on succeeding days, but, on the contrary, a fall usually occurred, notwithstanding successive doses of extract.

3. That after a period without extract the animal sometimes weighed more than after a similar period with extract.

4. That any spasmodic rise in weight which did take place was largely due to water.

This is, I consider, quite sufficient to show that the theory is untenable.—I am, etc.,

Hornsey, N., Nov. 30th. CHARLES E. SOHN.

BELGIAN MEDICAL MEN.

SIR,—Could not the services of these gentlemen be used for medical attendance on their fellow countrymen? In this immediate district we have 18 wounded and invalid Belgian soldiers and about 50 refugees. My knowledge of Flemish is *nil* and of French limited, so that I need an interpreter. My old friend and tutor, Dr. Gee, used to say it was an advantage that he could not understand what his patients said, thus leaving him to find out their ailments. This is true no doubt, but it is a disadvantage not to be able to direct them as to treatment.—I am, etc.,

GEORGE F. SYDENHAM,
M.O.H. South Molton R. District.

Dulverton, Somerset, Nov. 28th.

*** The Medical Act of 1859 provides that any person, not a British subject, having obtained from any foreign university a degree or diploma of Doctor in Medicine, and who shall have passed the regular examinations entitling him to practise medicine in his own country, shall not be prevented from being and acting as the resident physician or medical officer of any hospital established exclusively for the relief of foreigners in sickness, provided always that such person is engaged in no medical practice except as such resident physician or medical officer. The Medical Act of 1886, Part II, permits registration by the General Medical Council of a foreign general practitioner with a recognized diploma, provided that His Majesty in Council is satisfied that the foreign country to which the practitioner belongs affords to the registered medical practitioners of the United Kingdom such privileges of practising in the foreign country as to His Majesty may seem just. The application of the law to the foreign practitioner can only be set in motion at the instance of the Government of the foreign country which desires to establish reciprocity of practice with this country.

Universities and Colleges.

UNIVERSITY OF EDINBURGH.

Privileges to Students in the Services.

THE following privileges have been approved by the Senatus of the University of Edinburgh for students in the Faculty of Medicine who have joined or may join any of His Majesty's services in connexion with the war:

1. Bursaries, scholarships, etc., held by students absent on war service will, unless there are legal difficulties in any particular case, be reserved for the holders until they are able to resume their studies.

2. The period of war service will not be reckoned in calculating the time limit for honours or for scholarships, etc.

3. Students whose attendance on any course is interrupted by the absence on war service may resume and complete their attendance at a subsequent date without additonal fee.

4. The Faculty will do everything to facilitate the completion of the curricula of students who undertake approved service with H.M. Forces. On the conclusion of such service the case of each student will be individually considered, and steps will be taken to grant him any concessions which are consonant with carrying out the regulations of the General Medical Council.

5. Clinical service during the continuance of the war for any period of not more than twelve months in a medical unit of the Army (Regular or Territorial), or in a hospital or detachment of the Red Cross Society, or in any hospital recognized by the naval or military authorities for war purposes, will be accepted by the University as equivalent to the medical and surgical practice in a recognized hospital for an equal period; and, further, a portion of the time so spent, not exceeding six months, may be accepted as equivalent to clinical surgery or clinical medicine at the choice of the candidate.

Notice of war service should in every case be given to the Dean of the Faculty as soon as possible. These or similar arrangements will be in force during the war.

LIEUTENANT J. CROCKET, R.A.M.C., who was killed in action at the battle of the Aisne, left estate valued at £441.

Obituary.

ISAAC BURNEY YEO, M.D., F.R.C.P.,

CONSULTING PHYSICIAN TO KING'S COLLEGE HOSPITAL; EMERITUS PROFESSOR OF MEDICINE, KING'S COLLEGE, LONDON, ETC.

We regret to record the death of Dr. Burney Yeo in London on Friday, November 20th, at the age of 79.

He was born at Stonehouse, Devon, on March 3rd, 1835, and received his early education locally. There, too, he served an apprenticeship of some years to a local practitioner, Dr. James Sheppard, which he always maintained was the most valuable part of his medical education. Entering the Medical Department of King's College, London, at a rather more advanced age than most students, he had a distinguished career, gaining the Senior Medical Scholarship, and qualifying for the gold medal in the M.D. examination of London University. Thereafter he was appointed medical tutor, with residence in King's College, and held for some years this office, which involved the teaching of a variety of subjects, ranging from physiology to logic, to classes of students of varying standing. In 1869 he became assistant physician to King's College Hospital, and subsequently to the Brompton Hospital for Diseases of the Chest. The latter post he held for some ten years only, but maintained his connexion with King's College Hospital, first as assistant physician and afterwards as physician, until his retirement in 1899. At King's College he held successively the chairs of Clinical Therapeutics and of the Principles and Practice of Medicine, and on his ultimate retirement was appointed Emeritus Professor of Medicine. He was for many years physician to the Life Association of Scotland.

ISAAC BURNEY YEO.

Despite his small stature, Burney Yeo was a man of striking appearance — his massive head, strong features, and penetrating eye bespoke a man of intelligence and character, and such he was. Sport of any sort was anathema to him; art, too, was a closed book, as he possessed little or no artistic appreciation. Literature was his main recreation, and had he not adopted the calling of medicine, he might well have gained distinction in the world of letters. He wrote with remarkable facility in simple, terse, and effective language, never straying to right or left from the direct path of his subject matter. He respected the English language, as a Frenchman loves his, and held it to be the duty of every educated man to keep it pure and undefiled. His knowledge of English literature, especially of the drama and biography, was extensive, and his criticisms of what he knew were always acute and pithy. One had to search far afield for a book of the lighter French literature of the last century that he had not read; Dumas, Flaubert, Anatole France, Daudet, and Guy de Maupassant were his constant companions, and the maxims of La Rochefoucauld were often on his tongue. His letters were delightful, full of little details of human and personal interest; they had about them an eighteenth-century aroma which put to shame the illiterate off-scourings of the twentieth century letter writer. His contributions to medical literature are well known. The most widely read is his *Manual of Medical Treatment*, first published in 1893, which still fully maintains its early popularity, and has actually attained a circulation of over 30,000 copies. Two other works from his productive pen, *Food in Health and Disease* and *The Therapeutics of Mineral Springs and Climates*, enjoyed a considerable vogue in their day, and were pioneers of the more serious attention that has been devoted to these subjects by other writers in recent years.

Burney Yeo was not a great teacher just because his heart was not in the work. His house-physicians learnt much from him of those little resources that mean so much to the comfort of the patient, but he had not the patience requisite for the rudimentary teaching of his ward clerks, whom at the end of six months he was apt not to know by sight. As a lecturer he commanded attention because of his personality, his careful and picturesque language, and the sense that he was really master of his subject, tempered, however, by the disappointing impression that he could have given more if he would. As a physician, too, he showed to best advantage rather in his consulting-room than in his hospital wards. His very methods and mental attitude seemed to demand a close personal acquaintance with his patient to afford them full play, and this condition is ill satisfied by the birds of passage of a hospital clinic. He could scarcely be called a skilled physical examiner, and certainly did not possess the *tactus eruditus*. Yet his diagnosis seldom failed of the mark by reason of the meticulous attention he bestowed on the patient's statement of even the most trivial symptoms and circumstances in the course of his illness. He was an empiric in the best sense, in that he carefully pigeon-holed his experiences of success and failure for guidance in the treatment of future patients. His conversation teemed with terse apophthegms drawn from his ripe experience. "The gouty subjects whom I see are those who do too much not those who do too little; the difficulty is to get them to rest." Or, again, "I have never seen the albuminuric who was perfectly healthy," and a thousand more of like kind. His knowledge of the physical and chemical characters of drugs was excellent, and he was a deft and elegant prescriber. He had a profound belief in the efficacy of drugs if skilfully employed, and an equally profound contempt for the fashionable therapeutic nihilism of to-day. He would say, "When I see how medical men use drugs now, I understand their abusing them." An eminent man of letters once said to the writer, "I have consulted many physicians, but Dr. Yeo is the only one who does not habitually contradict himself at successive interviews." The writer himself had offended by forgetting whether a pill of valerianate of zinc was to be taken after or midway between meals. Such a lapse would have been impossible to Yeo, who observed with Aristotelian strictness the how, and the when, and the where of administration. He certainly did obtain better results with drugs than are given to most prescribers, despite the fact that he knew little of modern pharmacological research. If his beliefs did not tally with this he would say, "Even pharmacologists are not immune to error."

It is never easy to estimate the degree of a medical man's success. If it is to be measured by the confidence of a man's patients Yeo was a man of superlative success. His was a most difficult team to drive: statesmen, financiers, men and women of social or literary distinction, leaders of the theatrical profession—just those who are most apt to wander—formed a large part of his patients, and the writer can testify that their wanderings were seldom continued after they had come into Yeo's hands. They felt instinctive confidence in a man whose mind was at their service in the most trifling detail and exhibited no lordly disdain for the subtle phenomena of disturbed function. They found in him, too, a man of the world, an earnest student of this multi-facetted world, able to

transport himself at pleasure into each individual patient's world. They imbibed, too, in large measure the confidence he justly reposed in himself.

In his relations with his colleagues and his profession, Yeo was not at his best. A sensitive but self-assertive man, apt to express his opinions with acerbity, he was bound at times to come in conflict with his professional brethren. The loss was mutual, for Yeo cherished at heart a very sincere regard for the dignity and welfare of the profession to which he belonged; he, in turn, suffered from some measure of professional isolation that served to embitter his outlook and retrospect.

Yeo was married late in life to Miss Winifred Helen Spyers, of Weybridge, who survives him without children. In his bachelor days he was a constant diner out, and made the acquaintance of many interesting people, whose conversation he heartily enjoyed, giving the best of his own to them. His holidays were mostly spent in the quest of health, and in this way he acquired an intimate knowledge of many health resorts and mineral springs. For the last few years of his life he was in feeble health, and slipped entirely out of active practice. His heart failed somewhat rapidly at the last. He was buried in Weybridge Cemetery on November 26th, and on the following day a memorial service was held in the chapel of King's College Hospital. R. C.

JAMES WILKIE SMITH, JUN., M.D., B.S. DUNDEE, RYTON-ON-TYNE.

IT will come as a shock to a great many of our readers to learn of the untimely death of Dr. J. Wilkie Smith, of Ryton-on-Tyne, at the early age of 29.

His father, Dr. James W. Smith, has for many years been closely identified with the work of the British Medical Association, and has filled the highest offices in his area, and has represented the North of England Division on the Council of the Association. His sons likewise were amongst the Association's warmest and unwavering supporters, particularly in the hours of its trial.

Dr. James, as he was known, was a man of splendid physique and a giant's strength; whilst apparently in robust health and overflowing with vitality he was struck down by Death's irresistible hand after an illness of a few hours. To add to the tragedy of it, he had been married but a short three months.

He received his medical education at the College of Medicine, Newcastle-on-Tyne, and graduated M.B., B.S. in 1907. After being house-surgeon to Mr. Rutherford Morison in the Royal Victoria Infirmary, he joined his father and elder brother in the large country practice held by them in the Ryton district. In 1910 he took his doctor's degree, being warmly complimented by the examiners on his thesis.

He shared the family characteristic of enthusiasm for his profession, few operative procedures being too difficult for him to undertake successfully, no technique too elaborate, and no diagnostic measure, whether it entailed microscopic work or the tracing of a blood pressure, too minute to engage his close attention. His thoroughness in his work and invariable kindliness made him more than usually successful in practice. Never indulging in that peculiar form of ingratiation known as "the bedside manner," he was always his natural self—a straight-speaking English gentleman.

The members of the local branch of the St. John Ambulance Association, in which he was a keen officer and energetic instructor, mourn his loss, not only on account of his value to them but also by reason of the affection in which they held him. His popularity may perhaps be best gauged from the fact that the greater part of the five miles' route of the funeral was lined by the villagers amongst whom he did his daily work. There they were—rough miners with tears streaming down their rugged faces, women with heads buried in their aprons, soldiers home on leave standing at the salute. One of the miners expressed the feelings of the mass in saying to the writer: "We feel we have lost our sheet-anchor." Words are inadequate to express our sympathy to his bereaved family, yet to us there seems great comfort in reflecting that

> He has fought the good fight.
> He has kept the faith.

EDGAR JOHN DONBAVAND, L.R.C.P.EDIN., M.R.C.S.ENG.

THE death of Dr. E. J. Donbavand, at the age of 60, which took place at a nursing home in Plymouth on November 23rd, is a severe loss to the medical profession in the Three Towns and district. He was a student of Guy's Hospital, and become M.R.C.S.Eng. in 1876, and L.R.C.P.Edin. in 1880. After practising in Cumberland, Lincoln, and South London, he settled in West Green, North London, where he quickly built up a very large practice.

Overwork caused a breakdown in health and he was advised to retire, but after a prolonged rest he recovered, and in 1903 went to Plymstock, where he entered into partnership with Dr. S. Noy Scott, with whom he had formed a friendship some twenty years before. The country life suited him, and he soon became interested in the local work of the British Medical Association. He was secretary of the Plymouth Division, and spared no pains in advancing and protecting the interests of his professional brethren. The introduction of the Insurance Act threw an enormous amount of work on him, but he devoted himself unsparingly to the demands thus made, and that at a time when his partner was also (as Representative) busily engaged on the same work. In June last, at the annual meeting of the Division, his colleagues marked their great appreciation of his services by presenting him with a handsome cheque and a service of plate, towards which nearly every member of the Division subscribed. His relations with his patients were very cordial; he was unremitting in his attention to them, and in return was highly esteemed by them. As a mark of respect the ringers rang a muffled peal on Sunday, November 29th. Dr. Donbavand was one of the pioneers of the local rifle club, the success of which was largely due to his keenness. He became a good shot, and was nearly always one of the team for local matches. He was a great reader and a fond lover of Nature, and especially of flowers. He spent most of his leisure time in his little garden, and nothing gave him greater pleasure than to send a gift of flowers to some of his "Town" brothers.

For many years he had occasional attacks of gall stone colic, which latterly became so much more frequent and severe that he decided to undergo surgical treatment. The operation proved very difficult and tedious, but he rallied from the immediate effects, and great hopes were formed of his recovery, but on November 22nd he collapsed suddenly, and died on the following day.

He was buried at Highgate Cemetery on December 1st, and the funeral was attended amongst others, by the Medical Secretary of the British Medical Association, on behalf of the Council of the Association.

Dr. Donbavand married about eighteen years ago, but has left no family. His widow has received many proofs of sympathy and of the esteem in which he was held.

WE regret to announce the death of Dr. Angelo Celli, professor of hygiene in the University of Rome. He was born in 1857, and was therefore 57 years of age. When still quite young he was appointed to the chair of hygiene at Palermo, from which, twelve months later, he was transferred to Rome. There he continued to work—teaching, investigating, and promoting social legislation—till last May. To his persevering efforts were largely due the sanitary improvements that have been made in the Campagna, and the organized campaign for the suppression of malaria. His scientific work covered a vast extent of ground, including research on the parasites which cause malaria, on cholera, on pellagra, on cerebro-spinal meningitis, on dysentery, on flies as transmitters of disease, on rabies, and many other subjects. He was an untiring worker in the cause of social reform through the spread of scientific knowledge.

DR. DAVID BRADLEY, of Blackburn, who died recently at the age of 60 after a short illness, was born in co. Derry. He studied medicine at Queen's College, Belfast, and graduated M.D. in the Queen's University in Ireland in 1876. A year later he obtained the degree of M.Ch. and immediately started in practice in partnership with Dr. Jackson at Queensbury, in Yorkshire. After a few years he removed to Hebden Bridge. Whilst there

he took an active interest in the public and political life of the district. He was a prominent Freemason, and assisted in the formation of a lodge at Hebden Bridge. He settled in Blackburn in 1896. He had introduced the St. John Ambulance movement at Hebden Bridge, and maintained his connexion with it at Blackburn. He was also ambulance instructor to the London and North-Western Railway Company in Blackburn, and was held in the highest esteem by the employees. Dr. Bradley was devoted in his attention to his patients, and was especially popular among the poor. He was a member of the Blackburn Division of the British Medical Association and contributed reports of cases to the British Medical Journal. All his life he had taken a keen interest in dogs and canaries, and whilst in Yorkshire figured among the prizewinners at various leading shows. On removing to Blackburn he continued to take a very active interest in the canine world, was an enthusiastic member of the local canine association, and bred St. Bernards, Russian wolf hounds, and Irish terriers.

The news of the death of William Robert Ridley, of Rothbury, Northumberland, at the early age of 33, will be received by his large circle of friends with profound regret. He left England early in September to take charge of a field hospital in Servia, and died on November 3rd from an attack of dysentery, at Krajuevatz Field Hospital. Dr. Ridley graduated M.B., Ch.B.Edin. in 1910, and held appointments in Leith and Sunderland Infirmaries, as well as at the Newcastle-on-Tyne Dispensary. His work was marked by ability and great promise, and being of the most genial and kindly disposition, his friendship was highly esteemed wherever he went. A striking eulogy of his work and high devotion to duty has been received by his parents from the Servian Government, through the Servian Minister in London.

Dr. Alexander W. Woodman Dowding, who died recently, was born at Westbury, Wilts, in 1852. He was educated privately, and in 1872 entered as a student at the London Hospital. He obtained the diploma of L.S.A. in 1875 and that of M.R.C.S. in the following year. He graduated M.B., M.S. at Durham in 1880, proceeding to the M.D. degree in 1882. In 1881 he became a Member of the Edinburgh Royal College of Physicians. He held several appointments at the London Hospital, and was for a time resident clinical assistant at the Borough Asylum, Newcastle-on-Tyne. He was also at one time physician to the Plaistow Dispensary for Women and Children. Later he practised during the winter at Algeciras. He was a member of the Gibraltar Branch of the British Medical Association, of which he was Vice-President. Dr. Dowding was the author of contributions to medical literature on the treatment of whooping-cough and on Algeciras and its climate. He leaves a widow, one son, and one daughter.

Professor August Weismann, who had been professor of zoology in the University of Freiburg since 1867, and whose name is known to all students of biology in association with a well-known theory of heredity, died recently, aged 80.

Dr. Chambige, Senator for the Puy-de-Dôme Department, Vice-President of the General Council, and Mayor of Pont-du-Chateau, died recently. He took his M.D. degree in 1879.

Dr. Jules Gacon, Senator and President of the General Council of L'Allier, Mayor of Donjon, died there on November 22nd after a long illness, aged 67. He had been a member of the Chamber of Deputies for many years, and in 1903 was elected a member of the Senate, in which he retained his seat to the end of his life. He was Vice-president of the Left Democratic group of the Senate.

Dr. T. P. Fraser, West African Medical Staff, who was killed in operations in the Cameroons, left estate valued at £770.

Medical News.

The Chelsea Hospital for Women has received a second donation of £500 from the Drapers' Company to name in perpetuity a bed in the hospital now building.

Sir Frederic Eve, in his Bradshaw lecture before the Royal College of Surgeons of England on Tuesday, December 15th, at 5 p.m., will deal with acute haemorrhagic pancreatitis and the etiology of chronic pancreatitis.

A discussion on preventive inoculation will be opened by Professor G. Sims Woodhead at a meeting of the Royal Sanitary Institute at 90, Buckingham Palace Road, on Tuesday next. The chair will be taken at 7.30 p.m. by Sir Shirley Murphy.

The last number of the *Proceedings* of the Royal Society of Medicine for the session 1913–14 presents a new feature in the form of a supplement, entitled, "New Books." In this supplement it is proposed each month to draw attention to the more important new medical works. It is not proposed either to praise or blame, but merely to analyse and to explain what the authors have attempted to accomplish.

At its meeting on November 3rd, the Paris Academy of Medicine passed a resolution expressing its feeling that it was desirable that, for the duration of the war, Belgian doctors and dentists duly qualified to practise in their own country should be legally authorized to practise in the parts of France and Algeria which are insufficiently supplied with medical and dental practitioners. A similar resolution was passed in regard to pharmacists holding Belgian diplomas.

We received recently from a correspondent some pills which are said to have a wide reputation in a part of the North of England as "female corrective pills." The directions were to take three night and morning. In one case the pills were taken according to directions for five days; on the fifth day haemorrhage occurred, and on the seventh day abortion at the fourth month. A qualitative analysis of the pills shows that they contain no diachylon or other lead compound. The ingredients are: Iron oxide and carbonate with a little sodium sulphate (evidently from a variant of Blaud's pill formula), oil of pennyroyal, vegetable tissue, and a small quantity of a bitter substance which appears to be aloes. Microscopical examination of the vegetable tissue shows a good deal of ginger, cinnamon, and what appears to be canella. There is no evidence of anything else being present.

As already noted in the Journal (December 20th, 1913, p. 1606) an agreement has been made between the London County Council, the London Insurance Committee, and the Metropolitan Asylums Board, that the Asylums Board shall provide the sanatoriums needed for tuberculous persons in London, the capital cost and expenses of maintenance to be borne proportionately by the other two bodies mentioned. Under this arrangement the Asylums Board has now submitted to the Local Government Board plans for the erection of sanatoriums: (1) For 232 women at Hyde Style, near Godalming, estimated cost £42,000; (2) for 168 men at Felbridge, near East Grinstead, estimated cost £30,000; and (3) for 175 men at Ellisfield, near Basingstoke, estimated cost £31,000. In the case of the sanatorium near Godalming the approval of the Local Government Board has already been received.

The usual quarterly meeting of the Medico-Psychological Association of Great Britain and Ireland was held on November 24th at the house of the Medical Society of London under the chairmanship of Dr. David G. Thomson. On the recommendation of the Council a resolution was adopted directing attention to the hardships of the staffs of the Royal Asylums of Scotland, which were not included under the benefits of the Asylum Officers' Superannuation Act. It was resolved to address letters on the subject to the managers of the Royal Asylums, the Scottish Board of Control, and Sir Robert Jardine. It was decided to hold the regular meetings of the association during the continuance of the war, but to abandon the projected visit to Birmingham next February, and to hold a meeting in that month in London. Resolutions of condolence with the families of Dr. Sidney Nelson Crowther, superintendent of the Netherne Asylum, who had enlisted as a motor cyclist, and was killed recently in action, and Dr. Harold Shaw, of the Isle of Wight Asylum, who died after a short illness, were adopted.

Letters, Notes, and Answers.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Office, 429, Strand, W.C., on receipt of proof.

TELEGRAPHIC ADDRESS.—The telegraphic address of the EDITOR of the BRITISH MEDICAL JOURNAL is *Aitiology, Westrand, London.* The telegraphic address of the BRITISH MEDICAL JOURNAL is *Articulate, Westrand, London.*

QUERIES.

IGNORAMUS writes: A patient weaned her last baby two and a half years ago. She now has milk in the breasts, periods are normal, and there is no other sign of pregnancy. Is this usual in the absence of pregnancy?

ABDOMINAL PAIN.

X. Y. Z.—A man aged 40, active, at work all day, who has never had any illness, suffers frequently in the middle of the night from diffused pain over the abdomen, not very acute, lasting about an hour. He has none during daytime. Is it some form of dyspepsia; if so, what is the treatment?

ANSWERS.

POST-SCARLATINAL RHINORRHOEA AND OTORRHOEA.

DR. WILLIAM WILSON (Manchester) writes in reply to "T. W. J.": For rhinorrhoea with skin irritation it is essential not to employ an alkaline douche, for such tends to deposit upon the mucosa and adjacent skin, thereby increasing irritation. The following oily spray should be employed frequently:

Menthol	gr.v
Camphor	gr.iij
Chloretone	gr.v
Liquid paraffin	ad 5j.

The external nares should be gently rubbed with a little compound resorcin or boric acid (half-strength) ointment. Do not forget that the condition may persist from infected adenoids.

Otorrhoea originating after the acute illness has subsided does not assume the virulent form which requires immediate extensive operation. Treatment must be thorough; it is futile to leave the condition to routine syringing by nurses or parents. Fortunately the patient is confined to isolation. Under direct vision by reflected light drops of 10 per cent. hydrogen peroxide must be instilled by means of an ear speculum and allowed to remain in the ear until all effervescence has ceased; then, very gently, a solution of boric acid (warm), one teaspoonful to half a pint of sterile water, should be run (not forced) through the tympanum, the ear being gently and thoroughly dried out by small pledgets of sterile wool. A small drain of sterile gauze (for example, hicyanide) is inserted. As soon as this drain becomes moist the gauze is removed and the ear cleared out by pledgets of wool soaked in mercury biniodide (1 in 2,500) and a drain of gauze replaced. The peroxide and lotion need only be employed twice daily, but the ear must be dried out every time moisture accumulates. Do not overlook infected adenoids. Massage with Siegel's speculum should be commenced when the acute stage has subsided. It will empty the middle ear and also prevent adhesions.

LETTERS, NOTES, ETC.

PRINCE OF WALES'S FUND.

DR. E. ROWLAND FOTHERGILL (Hove) writes: I have received, as a medical practitioner, a printed circular from a firm which sells a proprietary food, asking me to place on my waiting-room table a collecting box for the above fund, the label on which is an advertisement of that food. On inquiry from the subscription subcommittee of the fund, which the firm stated had approved the proposal, I am told "that it is impossible that any collecting scheme such as that promoted by the firm can take place without such aid as theirs." So, shortly, we may expect to receive attractive collecting boxes, bottles, ships, torpedoes, "John Johnsons," etc., advertising backache pills, soothing syrups, "wait and see" tablets, and so on, and be asked to decorate our halls and rooms accordingly. One is sorry to hear the subcommittee can report that thousands of doctors out of kindness of heart have decided to receive these advertisements. I would venture to express a hope that they get themselves out of the trap by scraping off all the advertisement portion of the label.

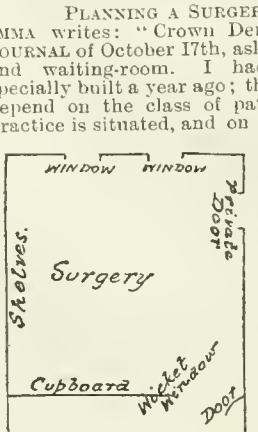
MR. HERBERT TILLEY, F.R.C.S. (London), writes: I presume that many members of our profession, like myself, have had sent to them a tin box for the collection of subscriptions in aid of the National Relief Fund. Upon this box or canister is an advertisement of a food for infants. It seems impossible to regard this otherwise than as a peculiarly ill-timed method of advertisement, and I hope members of our profession will resent it in an appropriate and practical fashion. The box which was sent to me is on my consulting-room table, but the names of the advertisers and their wares have been carefully removed.

ANKYLOSTOMA DUODENALE.

DR. STUART OLIVER (Surgeon-Superintendent, Indian Emigration Service) writes: As an almost incredible proportion of the agricultural population in India is infected with the ankylostome, doubtless many of the Indian contingent are although probably not to an extent sufficient to show in their physical condition. Soil prepared for intensive cultivation especially when moist or wet, would presumably afford very suitable conditions for the preservation of larvae in their encystment stage. I know of only one sure method of dealing with infected faecal matter, and that is by heat. Efficient incinerators are usually not difficult to improvise from material to be obtained on the spot, but plenty of fuel is very necessary.

PLANNING A SURGERY AND WAITING-ROOM.

GAMMA writes: "Crown Derby," in the BRITISH MEDICAL JOURNAL of October 17th, asks for hints in building a surgery and waiting-room. I had a surgery and waiting-room specially built a year ago; the details of such a building will depend on the class of patient, the district in which the practice is situated, and on the size of the practice. I practise in a colliery district; my panel is 800, with clubs and some private practice. I had a temporary wooden surgery erected. The whole building measures 24 ft. by 12 ft. A partition divides the interior into two compartments, each 12 ft. square. I advisedly avoided making the mistake many medical men make of having the waiting-room too small; a waiting-room 12 ft. by 12 ft. will hold a fairly large number of patients. As I do not keep a dispenser I have, near the door leading from the surgery to the waiting-room, a pigeon-hole through which I may give medicine to patients who do not wish consultation. The building stands, so to speak, end-on to the road, and at this end is the entrance door and the window. Over this end I have an awning or canopy, and a seat so that any patients who wish to do so may wait outside, as they often wish to do in a colliery district, or if they have to do so owing to the surgery being crowded. In addition to this public entrance into the waiting-room, I have a private entrance to the consulting-room for my own use, as shown in the sketch. An important matter is the question of light, especially in the consulting-room; there I have two large windows occupying the larger part of the end of the surgery facing the back.



If a dispenser were kept in a large practice, it might be advisable to have the surgery part a little larger, and partition a part off for dispensing.

ALVARENGA PRIZE.

IN a notice as to the Alvarenga Prize, to be awarded by the Philadelphia College of Physicians in July, 1915, which appeared in the JOURNAL of November 21st (p. 908), it was stated that the prize for 1914 had been awarded to Dr. H. B. Sheffield, of New York, for an essay on the fundamental principles involved in the use of bone graft in surgery. Dr. Francis R. Packard, Secretary of the College, from whom the information was received, states that there was an error in the title of Dr. Sheffield's paper, which was "Idiocy and Allied Mental Deficiencies in Infancy and Early Childhood."

"TRANSIENT PARAPLEGIA FROM SHELL EXPLOSIONS."

By T. R. ELLIOTT, M.D., F.R.S.,
LIEUTENANT R.A.M.C.

Among the injuries caused by high shell explosions in the present campaign on the Continent is a form of transient paraplegia, which has already led to mistakes in diagnosis in its early stages, and which will be still more difficult to recognize in the men who are invalided home with only the history that they can give as a guide to a correct opinion.

The chief features of the condition are as follows: Numbness and complete paralysis of the legs are complained of when the injured man receives help from his comrades immediately after the explosion, and yet there is no manifest wound of the body. The arms are generally unaffected, but the legs remain powerless, so that the patient has to be carried from the field on a stretcher. Within a week movement and sensation are returning in the legs, and after the lapse of a fortnight the soldier as a rule can walk about again, though he continues to complain of extreme tenderness in the lumbar region, and aching pains that shoot up the back. There is rarely any trouble with the sphincters. During the paralysis the leg muscles are slightly flaccid, and both the superficial and deep reflexes are depressed, while there is nearly always an area of hyperalgesia encircling the abdomen above or below the level of the umbilicus. The plantar reflex is never extensor.

The slightness of the objective signs and the prominence of the subjective features of pain and tenderness, especially in the lumbar spine, lead naturally to the belief that the paraplegia was functional and the residual tenderness is neurasthenic. That diagnosis is often made, and it is the most likely one to be chosen when the invalided man is first met with in England. In some cases it is undoubtedly correct, for hysterical and neurasthenic breakdowns are frequently met with in men who have been exposed to the shattering effects of the great German shells. An example of this nature is quoted later to illustrate the points of distinction between the true and the functional paraplegia.

A second diagnosis that is tentatively made at times is that of "gassing," which ascribes the weakness to a toxic action of the fumes evolved in the explosion. The bursting of these large shells is accompanied by a dense cloud of dark smoke, which may completely blacken the faces of those who are nearly exposed to it. A crater is formed in the earth 10 ft. to 25 ft. across and from 5 ft. to 10 ft. deep. The soil from this is thrown up more or less in a fine spray, so that it does not crush or bury those standing near to it. But when the shell explodes by the side of a deeply cut trench its commotion drives inwards the sides of the latter, and thus buries alive or crushes the men who were hoping for shelter within it. Death or direct injury may be caused in this way. "Gassing" would be expected to produce unconsciousness, followed by headache, giddiness, and a weakness or peripheral neuritis of general distribution. I have not heard any suggestion made by men returning from the trenches that they have suffered in this way from the German shell fire, and the explanation cannot be applied to the type of injury with which this account deals. The first example quoted is typical of the group:

CASE I.

No. 2047. Reservist, aged 34, in 1st Battalion King's Royal Rifles; a well developed man, who had formerly been army instructor in gymnastics.

October 30th. He was in a narrow trench and sitting, with bent back and legs fully extended, in his "dug out," a small recess excavated under the earth backward from the trench, but not timbered, as a protection against shrapnel. At 8 a.m. a "Black Maria" burst on the trench and covered him up to the chin in heavy, clayish soil. His comrades quickly built up the breach in front of the trench, and then dug him out, some twenty minutes after the explosion. His legs were powerless and numb, and he felt sick but did not vomit. There was no smell of gas about, and he did not feel dizzy or troubled in the head. He had no pain in the small of the back. When darkness came he was removed on a stretcher to the field hospital, and he arrived thence at the base hospital on November 3rd. There had been no difficulty with micturition.

November 4th. Power beginning to return in the legs.

November 6th. Examined. Slight movement in knees, ankles, and toes. Muscles somewhat atonic, and passive movements of the legs caused much pain in the small of the back. Knee-jerks and ankle-jerks were weak, especially on the left side. Both plantars flexor. Left cremasteric reflex weaker than right. Left leg a little more numb than right, but impairment of sensation only slight. Left lower abdominal reflex lost. Band of hyperalgesia over left side of abdomen below umbilicus (eleventh and twelfth thoracic segments), especially to painful pin scratch and to deep pressure. On the right side this hyperalgesia was present to a much less degree. On the back there was slight discoloration of the skin from deep bruising over an area from the eighth thoracic to the second lumbar vertebrae. The spines of the tenth and eleventh thoracic vertebrae were acutely tender when pressed upon, and the pains radiated widely up and down the back.

November 12th. He could move both legs fairly well, but was unable to raise them from the bed with knees extended. The legs could not bear the weight of the body in attempted walking. Reflexes still slightly depressed. Slight hyperalgesia of left side above Poupart's ligament, and an area of slight skin numbness over the front of the thigh below the anterior inferior iliac spine (first lumbar). No localized tenderness over the vertebrae, but only diffuse pain on deep pressure.

It is easy to picture what happened to this soldier. Sitting with bent back in his shelter, he received on his body the violent impact of the mass of earth that was pushed laterally from the crater excavated by the bursting of the shell. The vertebral column was forcibly flexed, its ligaments stretched, and haemorrhages produced in the great muscles of the back. The spinal cord itself received transitory damage at the usual weak spot of greatest bending, near the twelfth thoracic vertebra, and the roots of the cauda equina were probably injured in their passage through the vertebral foramina.

Similar injuries are met with in pit accidents at home, where a fall of stone and earth from the roof may break a man's back or cause only a moderate paraplegia by contusion; and the less severe cases of such injury in the pits are notoriously difficult to distinguish from those of neurasthenic or deliberate simulation.

The next example was of a more severe and fatal nature.

CASE II.

November 1st. Buried beneath earth by the explosion of a "Black Maria." When dug out his legs were numb and powerless.

November 5th. Examined at base hospital. He was too ill to give a connected account of his accident, but he was positive that subsequently to it he had passed no water. Bladder not distended. Legs flaccid and almost completely paralysed. All reflexes obtained, though feebly. Abdomen immobile, slightly tender, and the seat of continual pain. The patient's blanched appearance suggested internal haemorrhage, and consequently the abdomen was opened, but only a little blood-stained fluid was revealed.

November 6th. Died. At autopsy the right clavicle and the symphysis pubis were found to be smashed. The right lung, the right kidney, and the hepatic flexure of the colon were deeply bruised. Complete reflex anuria had resulted from the damage to the kidney. The erector spinae muscles were deeply infiltrated with blood right down to the sacral spines, but there was no actual deformity of the vertebral column, and the spinal cord appeared to be quite normal. The roots of the cauda equina were not examined.

The next example was intermediate in its severity between (1) and (2). An arm was involved in the paralysis as well as the legs, and the eruption of a small crop of herpetic vesicles showed that there was injury, probably a haemorrhage, of the posterior root ganglia of the cauda equina. Yet even in this case there was a strong inclination on the part of those in medical control of the patient to regard the phenomena as chiefly hysterical.

CASE III.

No. 5492. Sergeant in the 20th Hussars.

November 1st. In company with other dismounted cavalrymen he was chasing some Germans with the bayonet over turnip fields that were being pitted in all directions by fire from high explosive shells. This was at 9 a.m. on Sunday morning. He next found himself alone in a small house in a neighbouring village, to which his comrades must have carried him while in a state of unconsciousness. His face was blackened with smoke, and his clothes were covered and filled with soil. The bottom of his haversack had been torn off, which led him to imagine that he had been struck by some missile in the back. There was, however, no wound nor sign of bruising. His left arm was weak, and his legs powerless and numb. After staying in this house some time he was found by a scouting party of English, and at sunset was removed to a field hospital. That night the passage of water caused him pain, but there was no blood in the urine and no haemoptysis.

November 6th. Examined at base hospital. Legs completely paralysed and very numb. Knee-jerk and ankle-jerk obtained

only on right side and with difficulty. Both cremasteric reflexes weak. Pain felt in back on passive movement of legs, which were moderately flaccid. Zone of hyperalgesia around body on both sides just above Poupart's ligament, but most acute on the left side. Lower abdominals weakened on left side. Pain felt in lower part of the abdomen when bladder was full and at the onset of micturition, but no pain in penis. Pain and paresis of left arm but no numbness. Tenderness on pressure over lumbar and cervical vertebral spines. No bruising seen.

November 9th. Arm movements much freer. Can move right toes.

November 12th. Arm fairly powerful, and legs much stronger for movements at all joints. Still has pain with full bladder. Cannot quite stand or walk on legs. Three herpetic blisters on skin of left thigh from 3 to 6 in. above the knee (second or third lumbar segment). Hyperalgesia now only on left side of abdomen above Poupart's ligament. Legs still numb, so that the patient is completely unable to appreciate the position of the joints in passive movements. Movements of wider range still caused severe pain in the small of the back.

The final example is one of hysterical simulation of the true paraplegia, which can be at once recognized by the state of the deep reflexes, and a definite prognosis consequently given of the speedy recovery which will emphasize the distinction between it and the more prolonged results of real injury. Functional disorders of the nervous system are far from rare in the fright caused by a big shell explosion, and they assume very diverse forms. The man may become blind, or deaf, or dumb; he may be seized by a violent and coarse tremor that shakes his body for days; or he may be paralysed with a hemiplegia or paraplegia.

CASE IV.

No. 10348. 2nd Welsh Fusiliers.

November 4th. Was in the trenches when a large shell burst and killed the man next to him. He himself was not covered by soil, but he lost consciousness, according to his own statement, and afterwards was paralysed in the legs.

November 7th. Examined at base hospital. Legs incapable of movement, but not atonic. Deep and superficial reflexes all increased. No definite zone of hyperalgesia on the trunk. Headache and pains in the back of the neck. Hands tremulous.

November 9th. Up and walking about freely. Practically well.

Diagnosis is, therefore, easy in the first or second week after the injury. The *functional* paralysis reveals itself by an increase of tone in the leg muscles and by exaggeration of the knee and ankle jerks, with a tendency to clonic or coarse tremors. Tenderness and pain may be complained of, but they are felt all over the back, and not localized to the area from which spring the nerves that supply the paralysed limbs. *Organic* damage, on the other hand, depresses all the reflexes and lowers the tone of the muscles. There is generally a band of hyperalgesia at the upper limit of the area of numbness, and the back is acutely tender, but only over the corresponding spines. The worst cases may conceivably show change of electrical reaction, and subsequent wasting of muscles, but I have not been able to examine this point. Nor have the men been sufficiently long in France to follow the later history of their recovery.

The evidence is insufficient to determine whether the injury was confined to the spinal nerve roots, or whether it affected the lower segment of the cord itself. The absence of an extensor response and the freedom from paralysis of the bladder suggest that the cord was not injured. In Case III the outbreak of herpetic vesicles on one side made it certain that the posterior root ganglia were injured, and this would be at a level some inches below the corresponding part of the lumbar cord. On the other hand, the band of hyperalgesia around the body tends to support damage of the cord itself. But the lack of symmetry in the interference with function, and the fact that the hyperalgesia persisted much longer on one side than on the other, while it was in Case I associated with a unilateral root area of actual skin numbness, are all in favour of the view that the injury is one of the spinal nerve roots, perhaps as they pass through the foramina rather than while they lie free in the cauda. Damage of this character would explain the escape of the bladder, since its motor and sensory nerves pass by the sheltered second sacral roots.

The pain before micturition, which was complained of by Case III, is of interest in this respect. It was felt vaguely in the lower part of the abdomen as the result of a full bladder—that is, in the region of the hyperalgesic lumbar nerves. There was no pain in the penis, such as would have been expected with hyperalgesia of the sacral nerves. It further shows that the hyperalgesia affects the visceral as well as the ordinary nerves of the trunk.

Lumbar puncture was not made to ascertain whether haemorrhage had occurred around the spinal cord. There was no obvious bleeding either within or without the spinal cord in the single case examined *post mortem*.

However, the distinction between damage of the spinal roots and of the cord itself is one of no great practical importance. The cases recover. But the clinical diagnosis of injury is important, for it is only fair to the injured men that they should not be classed with the neurasthenic or hysterical.

ANTISEPTICS IN WAR.

BY

G. LENTHAL CHEATLE, C.V.O., C.B., F.R.C.S.,

SURGEON, KING'S COLLEGE HOSPITAL; CONSULTING SURGEON, MEDICAL DEPARTMENT R.N., ROYAL NAVAL HOSPITAL, HASLAR.

ALL my experience in South Africa made me confident that wounds ought to receive efficient disinfectant treatment as soon as possible after their infliction and that they should not be treated only by the application of an antiseptic dressing.

That was the conception of Lord Lister, who gave me a supply of double cyanide of zinc and mercury to be used as a powder on the field. I found powder impracticable: wind and rain prevented it from reaching the wounds and its application to the under surfaces of parts was impossible without turning over the patient or limb. Hence I made the powder into a paste by mixing it with 1 in 20 carbolic acid and used it with complete success in many minor fights. The wounds healed beneath a mixture of paste and blood clots were beautiful to see. The surrounding skin was also well treated with the paste and retained its position for days. The dye with which the powder is stained acts as a mordant, and by it the chemicals are more firmly fixed in the tissues.

On my return I placed the paste into the collapsible tubes from which artists squeeze their paints. Although no oil and no fatty substance was inserted into the tubes I am describing, the paste remains to-day of the same consistency as it did fourteen years ago. The tubes have not been altered by the contained chemical.

Personally I am very sorry to see that our troops are being supplied with iodine solution as a disinfectant. Many wounds have arrived in this country in a disgraceful condition after the early application of iodine. I believe that iodine has proved a failure in treating large wounds.

Since being at Haslar I have made perfect—at least from my point of view—a better solution than iodine. It is a mixture of 1 in 20 carbolic acid and 1 in 500 mercury perchloride in absolute alcohol. It is coloured with rosaline. The value of this combination is as follows: 1 in 20 carbolic acid is a solvent of fat as well as a germicide. Mercury perchloride is a most powerful germicide. Rosaline has an important action in being a mordant. Wherever the dye is seen mercury perchloride is present even weeks after application. Alcohol dries sooner than water, it does not macerate the tissues so much, and it appears to encourage greater penetration of the antiseptic. No case has suffered from mercurial or carbolic acid poisoning, although it has been applied frequently and freely to large granulating wounds.

If a solution is to be carried by the soldier, this would be better than a solution of iodine. It is more efficient and absolutely non-irritating, and can be applied safely to the scrotum, eyelid, and other parts liable to show the results of irritants. Pure carbolic acid cannot be applied to skin, and there is every reason to be convinced that, in a wound splashed with mud, the mud and the bacteria it contains are also on the surrounding skin. A friend of mine here blistered his skin with pure carbolic acid, although it was at once washed off with spirit. I have seen cases become infected with *B. pyocyaneus*, although washed with saline solution and hydrogen peroxide. The *B. pyocyaneus* at once disappeared on the application of 1 in 2,000 mercury perchloride, or on the application of the rosaline solution I have described in this article. I do not like the constant application of hydrogen peroxide to wounds; the granulation tissue under its influence becomes anaemic and swollen. It may have its uses in removing blood clot and sloughs, but that is another matter.

COCKROACHES.

BY A. E. SHIPLEY, Sc.D., F.R.S.,
MASTER OF CHRIST'S COLLEGE, CAMBRIDGE.

I.

The Governess: And, perhaps, Mabel, as they are not black and they are not beetles, you will in future call them cockroaches.

Mabel: Certainly, Miss Smith, although they are not cocks and they are not roaches.

ALL this time we have been rather neglecting the navy, partly because it is less interfered with by insect pests than is the sister service, though the common pests of our

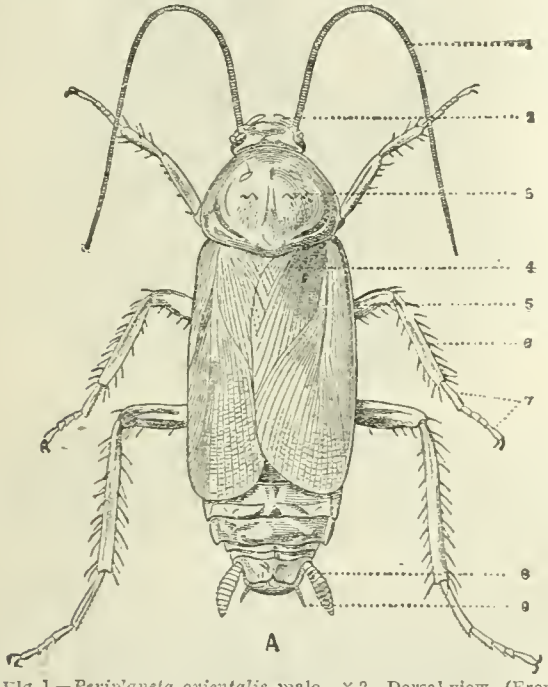


Fig. 1.—*Periplaneta orientalis*, male. × 2. Dorsal view. (From Kükenthal.) 1, Antenna; 2, palp of first maxilla; 3, prothorax; 4, anterior wings; 5, femur of second leg; 6, tibia; 7, tarsus; 8, cerci anales; 9, styles.

poor humanity—the flea, the louse, the bug—are, like the poor, "always with us." Like aeroplanes, insects have captured the air, like motors they have made a respectable show on land, but they have signally failed at sea. They have nothing corresponding to battleships or submarines, and a certain bug, called *Halobates*, alone hoists the insect flag on the ocean, and that only in the warmest waters. But one insect at least causes more trouble to sailors than to soldiers, and that is the cockroach. Like the bed-bug, the cockroach came into England at the end of the sixteenth century, and, like the bed-bug, it came from the East. It seems to have been first introduced into England and Holland by the cross-sea traffic, and from about the end of the sixteenth century the cockroach began gradually to spread throughout the Western world. Like the rat, the bed-bug, and the domestic fly, it has become thoroughly acclimatized to human habitations, and is indeed an associate of man. It is very rarely found living apart from some form or other of human activity.

This insect seems to have been first described in England in Moufet's *Insectorum Theatrum*, 1634, and he speaks of it as living in flour-mills, wine-cellars, etc., in England, and he tells us how Sir Francis Drake took, in 1584, the *San Felipe*, a Spanish East Indiaman, laden with spices and burdened with a great multitude of flying cockroaches on board.

This species is *Periplaneta orientalis*, but there is another and a larger species, which presumably came into England from the West later than its Eastern cousin—*P. americana*—which can frequently be seen in England running about in the cages in our Zoological Gardens; but it is not on exhibition, it is a by-product, and is not counted in the fee for admission to the Gardens.

Latter tells us there are ten species of Blattodea which occur in Britain, but only three of these are indigenous, and these three all belong to the genus *Ectobia*. *Ectobias* are smaller than cockroaches, and do not frequent human habitations, but live in shrubs, under rubbish heaps, etc. Species of *Ectobia* have been known to destroy in one day the whole accumulation of dried, not properly salted, fish in a Lapland village. The remaining species of cockroach are mostly local, and occur sporadically in particular factories, or places where food is stored, but are not very widely spread.

As we have said above, *P. orientalis* is the common English cockroach, *P. americana* occurs especially in zoological gardens and menageries, but a third species, *P. germanica*, sometimes gets established. Mercifully, *P. germanica* does not seem to spread. Neither *P. germanica* nor *P. americana* seem to make much headway against *P. orientalis*, which appears to be predominant over both these other species.

P. germanica is probably most methodical, very thorough, very brave, very faithful—but stupid! If it has any association with its specific name, it illustrates the most striking example in the world's history of the divorce of wisdom from learning. "O Lord! give us understanding," should be the prayer of *P. germanica*.

Miall and Denny tell us that from the first introduction of *P. orientalis* into England it took two centuries before it spread far beyond London. It 1790 Gilbert White speaks of it as "an unusual insect, which he had never observed in his house till lately," and, indeed, at the present moment many English villages are still blissfully ignorant of this particular nuisance.

As Fig. 2 shows, the cockroach is a somewhat slackly put together insect. One might almost call it rather slatternly and loose-jointed—and the latter it certainly is. Its head moves freely on the thorax and the thorax on the abdomen. The successive segments of the latter move very freely on one another. The legs are long and mobile, and so are the antennae with which the animal is ceaselessly testing the ground over which it flits hither and thither in a restless activity.

Cockroaches are very difficult to catch. They practically never walk, but run with a hardly believable rapidity, darting hither and thither in an apparently erratic mode of progression. When caught they are not easily retained, for they have all the slipperiness of a highly-polished billiard-ball. They have great powers of flattening their bodies, and they slip out of one's hand with an amazing

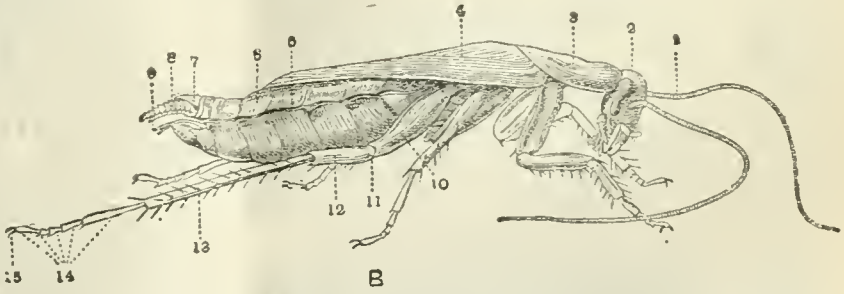

Fig. 2.—*Periplaneta orientalis*, male. × 2. Side view. (From Kükenthal.) 1, Antenna; 2, head; 3, prothorax; 4, anterior wing; 5, soft skin between terga and sterna; 6, sixth abdominal tergum; 7, split portion of tenth abdominal tergum; 8, cerci anales; 9, styles; 10, coxa of third leg; 11, trochanter; 12, femur; 13, tibia; 14, tarsus; 15, claws.

dexterity. Besides their slipperiness they have another weapon, and that is a wholly unpleasant and most intolerable odour, which is due to the secretion of a couple of glands situate on the back of the abdomen. The glands which produce this repellent odour are sunk in the soft membrane which unites the fifth and sixth abdominal segments, and the moment a cockroach is attacked it exudes a sticky, glue-like fluid, which gives out this most unpleasant smell. The fluid is extraordinarily tenacious and difficult to remove from the hand of those who have

touched them. No doubt the cockroach finds safety in this from the attacks of insectivorous animals.

Cockroaches, as has been said, very rarely walk, they nearly always run, and they advance the first and third leg of one side at the same time as the middle leg of the other, pulling themselves forward with their front legs and pushing themselves forward with the hindermost. They are thus constantly poised on a tripod. They occasionally, but not very often, use their wings for flight. When they do so, their anterior wings are stretched out at right angles to the body, and take no active share in beating the air. They act in effect as monoplanes. It is the hinder wings which really do the active flying. After a flight, the hinder wing is shut up something in the manner of a fan.

The flattened-shaped coxae, or thighs, of the leg are adapted for shovelling back débris from beneath the body when the insect is enlarging its habitation. When the cockroach gets into a dusty "milieu" the dust is immediately removed, the hairs on the legs act as clothes brushes and brush every part of the body, whilst the antennae, which attract any dust in the neighbourhood, are repeatedly drawn through the closed mandibles. A cockroach is able to walk on smooth surfaces because it possesses between the joints of the tarsus certain soft, white patches, very velvety, and these give the creature a good hold, and prevent slipping, even on glass.

Cockroaches will eat pretty well everything. They are a great nuisance on board ship, where they are said to gnaw the skin and nibble the toe-nails of sailors. Hardly any animal or vegetable substance is absent from their menu. It is said also that they devour bed-bugs, and that natives on the African shores, troubled by these semi-parasites, will beg cockroaches as a favour from sailors in passing ships.

The mandible (Fig. 3), with its strongly toothed surface, is capable of biting and grinding into fragments a very varied diet. The food is moistened by the secretion of the salivary gland, which is capable of converting starch into the more soluble sugar. The food is further ground up by a series of hard ridges projecting into the inner face of the gizzard (Fig. 4, 7). The secretion of the so-called hepatic caecums is capable of emulsifying fat and rendering proteins soluble. Thus the ordinary food substances are reduced to a condition in which they are capable of diffusing from the lumen of the alimentary canal into the blood which floods the body cavity.

The external movement—one might almost say "the panting"—which is very obvious in the abdomen, the alternately flattening and deepening of this part of the body, is a movement of inspiration and expiration, the air

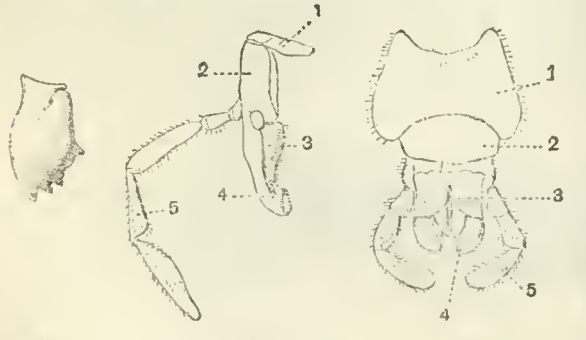

Fig. 3.—Mouth appendages of *Periplaneta*, magnified. A, mandible. B, first maxilla: 1, cardo; 2, stipes; 3, lacinia; 4, galea; 5, palp. being driven into the stigmata and so into the trachea. There is a considerable variation in the number of these pulsations, but the cockroach's heart beats at an average rate of 70 to 80 contractions per minute.

Although cockroaches have fairly developed eyes, they seem to trust more largely to tactile impressions in appreciating their relations to the surrounding world. Their antennae and the palps of their first and second maxillae are constantly touching the surface on which they are resting or moving, and from time to time their antennae wildly wave in the air in a manner which suggests they are smelling out the external circumstances which environ them. The 39,000 sensory "nerve-endings" which are found in the antennae of the male cockroach are almost certainly olfactory in function. At the hinder end of the body the two "cerci" are also sensitive to tactile

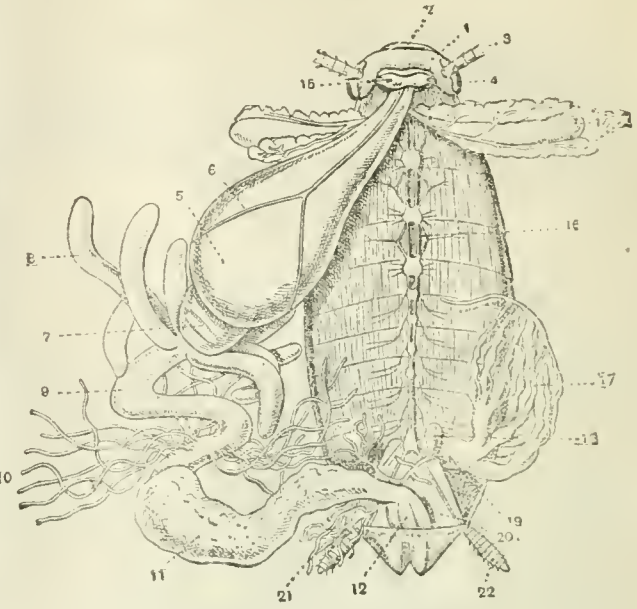

Fig. 4.—A female cockroach, *Periplaneta*, with the dorsal exoskeleton removed, dissected to show the viscera. Magnified about 2. 1, Head; 2, labrum; 3, antenna, cut short; 4, eye; 5, crop; 6, nervous system of crop; 7, gizzard; 8, hepatic caeca; 9, mid-gut or mesenteron; 10, Malpighian tubules; 11, colon; 12, rectum; 13, salivary glands; 14, salivary receptacle; 15, brain; 16, ventral nerve cord with ganglia; 17, ovary; 18, spermatheca; 19, oviduct; 20, genital pouch, in which the egg cocoon is found; 21, collateral glands; 22, anal circus

impressions, and probably act at the hinder end of the cockroach as the antennae act at the forward end. Cockroaches are certainly keenly sensitive to light, and, as every one knows, they shun the light, and when detected in daylight or candle light they make as quickly as they can for some dark hole or crevice in which to hide.

Cockroaches breed during the summer, and their eggs are laid in packets of sixteen in an oval capsule with rounded ends, and with an upper corrugated edge. This cocoon is very like the hand-bag ladies now carry since the dressmakers denied them pockets. There are sixteen ovarian tubes in the female, and each of these deposits one egg in each capsule. The ventral portion of the seventh segment in the female is shaped like the prow of a boat, and it is in this structure that the cocoon, or egg-case, is built up. Each egg is fertilized by a spermatozoon which has been deposited by the male in the spermatheca of the female. The eggs are placed in a double row, eight in each row, facing each other, and as they gradually develop it becomes apparent that the ventral face of one row faces the ventral face of the other row, and that their heads are all directed towards the corrugated ridge. The ripe embryos secrete some fluid, probably saliva, which dissolves the ridge, and it is through this dissolved or softened ridge that they make their way into the outer world.

After birth they are at first quite white but with black eyes, and it has often struck me how surprised they must be when they awake to consciousness and find themselves staring at their brother or sister just opposite, of which they have had hitherto no consciousness.

Young cockroaches are very active, running about and seeking everywhere for any food of a starchy nature. They are, in fact, miniatures of their parents, for a cockroach, like many of the primitive insects, has a direct development, and there are no such stages as caterpillar and pupa in their life-history.

But, like other insects, cockroaches change their skin from time to time, and they lose little time over this ecdysis, for they change it immediately they escape from the cocoon. The second ecdysis is four weeks later, and the third at the end of the first year, and after this time they moult annually. At the seventh moult, when the

animal is now 4 years old, it assumes the form of the perfect insect, and is capable of reproduction. The later moulting falls in the summer time, and so does fertilization and oviposition.

Male cockroaches may be distinguished from the females by their well-developed wings and wing covers. They stand higher on their legs than do the female, whose abdomen often trails upon the ground. In spite of the noxious secretion of their abdominal glands there are creatures who habitually feed on cockroaches—hedgehogs, for instance, are frequently imported into our houses to check these pests. Rats, cats, polecats, frogs, and wasps have been known to eat them, and some few of the digging wasps lay them down in their larders for the use of their progeny.. Some birds will also tackle them. But even the most devoted friend of the cockroach can find little to say in its favour, except that it is currently reported to form the basis of the flavouring of a very popular sauce, but even wild cockroaches will not drag from me which particular sauce that is.

THE INCIPIENT PULMONARY PHTHISIS OF SCHOOL CHILDREN.

By WALKER OVEREND, M.A., M.D.Oxon.,

HUF ASSISTANT IN THE X-RAY DEPARTMENT, ST. BARTHOLOMEW'S HOSPITAL, AND HONORARY RADIOLOGIST TO THE EAST SUSSEX HOSPITAL; LATE PHYSICIAN TO THE PRINCE OF WALES' HOSPITAL, LONDON, N., AND RADCLIFFE FELLOW.

I.

Introduction.

In the present communication the discussion will be mainly limited to the ages between 5 and 15, when the tuberculous process tends to become localized within the ducts and glands of the lymphatic system of the respiratory organs. This is practically the time of school life. During the earlier period of childhood, and particularly the first and second years—that of the first dentition—the conditions differ; the lymphatic system remains embryonic; its channels appear wider, and less able to prevent dissemination into the blood and distant areas.

Fig. 1.—Diagram of the lymphatic glands concerned, modified from Sukiennikow. T.Br, Tracheo-bronchial. B, Bifurcation. H, Hilum, and P, pulmonary glands. Above the tracheo-bronchial group is a tracheo-bronchial chain of glands on each side of the trachea, reaching as high as the thyroid gland.

In other words, children of this age are practically defenceless, and the little resistance they may possess must be ascribed to increased efficiency of the leucocytes, since the opsonic indices are negligible.

The radiological appearances of the healthy infant's chest consist of a few indistinct bronchial streaks, radiating from the hilum towards the periphery. The hilum opacity and its ramifications become more obvious as age advances. Constant irritation of the walls of the lymphatic vessels, by particles, organized or inanimate, leads to a small-cell infiltration and a thickening of perivascular and peribronchial trunks—a process which emphasizes the central and arborescent opacities of the radiogram.

II.

Anatomical and Pathological Considerations.

Bartels[1] divides the glands into four categories: (*a*) Tracheo-bronchial, (*b*) bifurcation, (*c*) hilum, and (*d*) pulmonary glands.

(*a*) *The tracheo-bronchial glands* lie on each side of the thoracic portion of the trachea and on the outside of the extrapulmonary bronchi. They number from five to nine on the right, and from three to four on the left. Normally each is about the size of a large pea. The right glands lie nearer to the margin of the sternum. They receive branches from (*b*) and (*c*), from the posterior mediastinal glands, and from the trachea and bronchi. They send efferents to the broncho-mediastinal trunk on the right, to the thoracic duct on the left, and to the deep cervical glands (supra-clavicular). Since they lie at and above the level of the bifurcation of the trachea, they are situated in the superior and just above the middle mediastinum. In front of the right tracheo-bronchial glands lies the superior vena cava; behind, the right vagus; internally, the trachea; externally, the internal surface of the right lung; below lies the right bronchus, the right pulmonary artery and the terminal bend of the azygos major. The left tracheo-bronchial glands lie behind the ascending arch in front of the left vagus; above is the horizontal arch and left recurrent nerve; externally is the internal surface of the left lung. This group of glands is connected with the lymphatics of the upper and middle lobes of the lung.

(*b*) *The bifurcation glands* are ten to twelve in number and more closely related to the right than to the left bronchus. They lie between the pericardium and left auricle on the one hand, and the oesophagus, aorta, posterior pulmonary plexus and posterior borders of both lungs on the other. They receive ducts from the hilum glands and send branches to the tracheo-bronchial. They are connected with the lymphatics of the middle and lower lobes.

(*c*) *The hilum glands* lie buried in the pulmonary parenchyma at the root of the lung and occupy the angles of the first four divisions of the bronchi. They are in intimate connexion with branches of the pulmonary artery and receive afferent vessels from the pulmonary glands.

(*d*) *The pulmonary glands* lie outside the hilum in the substance of the lung at the divisions of the bronchi. Minute glands are even found just beneath the visceral pleura.

Surface Anatomy.—The trachea bifurcates at the level of the upper border of the fifth dorsal vertebra posteriorly, and about the junction of the manubrium with the sternum anteriorly. The extrapulmonary right bronchus is nearly vertical and reaches to the level of the upper part of the sixth vertebra. It gives one eparterial branch close to the hilum. The left extrapulmonary bronchus ends at the same level as the right. Each hilum is about 1½ inches broad and extends on either side at the level of the vertebral ends of the fifth, sixth, and seventh ribs. Within it are the branches of the bronchi, pulmonary artery and veins, bronchial arteries and veins, lymphatics and lymph glands, nerves and connective tissue. Robinson[2] gives three excellent figures of the mesial surface of the lung with sections of each hilum, showing the arrangement of these structures. The pulmonary artery and veins possess branches corresponding with the bronchi. After the eparterial branch is given off on the right side, the stem sends a ventral branch to the middle lobe. The tracheo-bronchial glands lie at the level of the vertebral ends of the third, fourth, and fifth ribs; the bifurcation at the level of the sixth vertebral extremity, and the fifth spine is dull from this cause and from the proximity of the right pulmonary artery (Ewart[3]). The apices of the upper lobes reach the level of the first rib; the apices of the lower lobes that of the vertebral ends of the fourth rib, but the left lower apex is a little higher (Ewart[3]). In front the middle lobe of the right lung occupies the third and fourth intercostal spaces. In front of the root of the lung lie the anterior pulmonary plexus and the phrenic nerve.

The lymphatics commence in irregular lacunae situated just beneath the walls of the air sacs; and also below the surface of the pleura. They form fine networks around the lobules, the bronchi, and the blood vessels. Superficial collecting trunks arise from the subpleural lobules and deep collecting ducts from the veins, arteries, and bronchi.

These trunks communicate. The lymphatics of the visceral pleura also empty into the superficial collecting vessels. Finally they all reach the hilum. The pressure within the vessels is not more than 15 mm. of mercury, but they possess valves which open only towards the hilum. The subpleural plexus communicates with the pleural cavity by means of stomata, and with the interalveolar lymph vessels. There are numerous adenoid nodules in the deeper parts of the bronchial mucous membrane. With regard to the minute anatomy, the lymphatics of the lung often contain large mononuclear phagocytes conveying carbon particles within their interior. In sections of the lung leucocytes are often visible within the alveoli (Schäfer[5]). Carbon pigment is taken up by these cells in the alveoli and transported through the lymph spaces towards the hilum. Sometimes they are caught on the way and produce proliferation of connective tissue, which may embarrass the lymphatic drainage. The endothelial leucocytes are more important as phagocytes than the polymorphs.[6] They are not transient but *normal* scavengers. Beitzke thinks the pigment phagocytes are sometimes derived from the alveolar epithelium. Probably they remain for some time within the alveolus, at any rate, until they are well loaded with granules. Tubercle bacilli will be incorporated by these cells in a similar manner.

Post mortem the glands exhibit four stages: (1) Inflamed pink; (2) enlarged grey, studded with minute tubercles; (3) caseous, containing a cheesy deposit; and (4) calcareous, containing an accumulation of lime salts, with fibrous matting, due to periadenitis, uniting them to neighbouring glands, nerves, bronchi, and vessels.

III.

Channels of Infection and Dissemination.

The great channel or portal of entry is undoubtedly that of the respiratory tract. Bacilli enter with inspiration, the majority settle on the mucous membrane of the trachea, larger and smaller bronchi, and are usually driven outwards again by the activity of the ciliated epithelium. But some permeate the smallest bronchioles and the alveoli, becoming scattered freely over the periphery, and being transported thence along lymphatic trunks towards the hilum. Dissemination, as a rule, takes place gradatim, from one gland to the next in accordance with Cornet's[7] law of localization. In spite of repeated investigations, undertaken with the idea of repudiation, this law still holds good. Some authorities have even denied the aërogenous origin of anthracosis in the hilum glands. Scepticism could scarcely be more obstinate, since pigment is never found in the mesenteric glands.[8] After the ingestion of tuberculous food, the mesenteric glands may be attacked; after infection of the mouth, throat, and tonsil, the cervical; after abrasion of the limbs, the axillary and inguinal glands may become enlarged if the wound becomes infected with tuberculous material. Mesenteric infection under normal circumstances can only affect the bronchial glands indirectly—that is, by way of the thoracic duct, reaching the lungs through the pulmonary artery (Most and Beitzke[9]). It has been suggested that bacilli may enter the fetus from a tuberculous mother, penetrating the placenta, and pass a *larval* existence within the lymph nodes and the bone-marrow until favourable conditions obtain for future development. This could only be possible in the presence of tuberculous foci within the placenta itself; otherwise, we might relegate infection to the Garden of Eden—an obvious absurdity. Moreover, the newly-born do not react to tuberculin.

The child is really exposed to an infection, which may enter either by the respiratory or by the alimentary channel. Consequently mistaken conclusions are liable to be made as to the manner of infection and dissemination. There appears, however, to be no reason why bacilli should not be arrested within the lymphoid tissue of any one of the terminal bronchioles or in one of the pulmonary glands intervening between the alveoli and the hilum, and there lie dormant until an opportunity arises when they might, if superficial, infect the pleura.

There is much difference of opinion as to the manner in which the bacilli reach the bronchial glands, and as to whether a primary tuberculous affection of the glands really exists. Gohn[10] has made a careful analysis of *post-mortem* investigations in the pulmonary tuberculosis of children, and finds in general one, at times two, primary foci within the lung itself, situated just beneath the pleura. The focus is most frequently found in the upper, anterior, and inner half of the right and left upper lobes; behind, chiefly at the base and apex of the left lower lobe, and apex of the right lower lobe. Sometimes the focus is found on the mesial surface, especially at the right base. According to Gohn the hilum, bifurcation, and tracheobronchial glands are affected secondarily, even although the foci in these situations may be much larger than those within the lung itself. In 1893 Küss described a form of pulmonary tuberculosis in children which he recognized *post mortem* by the occurrence of small subpleural tuberculous foci. The condition might remain stationary for years or become entirely arrested. Gohn is a firm supporter of the aërogenous origin of the pulmonary foci, and can find no trace of retrograde infection. These pulmonary foci, however, are not necessarily primary, since their existence and formation may be due to conduction along other lines of transportation. By direct continuity from a tracheo-bronchial or bifurcation gland an infection—which has entered these structures through the mucous membrane of the trachea—may pass directly to one of the lobes of the lung, and induce the formation of a pulmonary focus. Gohn's investigations afford—by the proof of the very common occurrence of an extensive tuberculous pleurisy, particularly affecting the upper lobes, the hilum, and the base—a third method of dissemination which is well seen in the radiogram of Phyllis P. (Fig. 3), and will be described later. It remains for the radiologist to localize these pulmonary foci where possible, and to corroborate their existence by *post-mortem* control.

When the infection has reached the hilum and established itself within its glands, as well as in the tracheobronchial and bifurcation glands, the bacilli have proved victorious over the leucocytes, and have commenced to multiply. The result is the formation of tuberculous foci within the glands, consisting of epithelioid and giant cells. All the groups of glands appear liable to become involved, but in varying degrees. The tracheo-bronchial and bifurcation glands may be infected directly, that is, without implication of the lung, if the *materies morbi* penetrates the mucosa of the respiratory and alimentary tracts lying immediately adjacent to them (Walsham[11]). The infection may be disseminated by simple continuity from the tracheo-bronchial and bifurcation glands, to the upper and lower lobes, and hilum, and subsequently infiltrate the lung.

There are several possibilities:

1. *Caseation of Glands.*—The glands may caseate, calcify, and becoming surrounded by a fibrous periadenitis, the process may be arrested or completely healed. Several glands may become matted together and form a prominent object within or outside the hilum. In the healthy adult it is quite common to see a few small fibrosed glands at the root of the lung.

2. *Caseous Pneumonia.*—The bacilli may escape through the capsules of the glands and induce a slow infiltration in the middle and lower lobes (caseous pneumonia). Walsham[12] described several instances in children where the disease was found to be confined to the parts of the lung, particularly the middle lobe, in immediate contact with the softened bronchial glands. There is a gland on the right side of the trachea—one of the right tracheobronchial group—which is often found to be caseous (Still).[13] "From this gland the caseous process may pass directly by continuity to the adjacent pleura, forming local adhesions and spreading into the right lung towards the apex." No doubt the infection may spread by continuity from the tracheo-bronchial glands upwards along the chain into the neck, implicating amongst others the deep cervical glands. It has been stated that the thoracic glands may be infected from the abdomen by way of the hepatic and prepericardial glands.[14] But this must be very exceptional.

3. *Irruption into a Bronchus.*—The bacilli may pass from the glands into the walls of the bronchi, particularly behind, where the cartilage is deficient, enter the mucosa, producing small tubercles, which subsequently ulcerate. The currents of air will then aspirate them into adjacent or even distant parts of the lung. "It is not uncommon for one of the diseased glands to perforate a bronchus, and if this occurs beyond the first division of the bronchus

the caseous débris of the gland may be discharged into one lobe only of the lung and set up an acute tuberculous process, sometimes with rapid cavitation throughout the whole of that lobe."[15]

4. *Irruption into a Blood Vessel.*—As a result of periadenitis and the formation of adhesions to an arterial or venous twig bacilli may enter the vessel and induce in the former case a localized miliary tuberculosis in the arterial area of distribution; in the case of the vein a wider dissemination takes place.

5. *Lymphatic Dissemination.*—In the more chronic cases, where resistance is sound, the infection may apparently spread centrifugally along the lymphatic sheaths of the vessels and bronchi to distal parts of the lungs, inducing a thickening and thrombosis in its course. For many years there has been a current belief that a lymphatic tuberculosis may pass along the ducts in a centrifugal direction opposed to the centripetal course of the lymph itself (retrograde flow, retroimpulsion). It has even been asserted that the lymphatic circulation is carried on in a manner not analogous to that of the blood. There is said to be a backward and forward flow of lymph within the chest, and this phenomenon has been invoked in order to explain the facts of dissemination within the lungs. If the flow is of this nature, it can be of little service as an effectual drain. Moreover, the presence of valves is forgotten. When a small lymphatic is blocked, a collateral circulation will be established, just as occurs in the venous system when a vein is thrombosed. It is really unnecessary to assume the existence of a normal retrograde current. It must be of infrequent occurrence, and the facts may be just as well explained by a dissemination along the walls of these vessels. Although the bacilli themselves, being immobile, cannot swim against the stream, the leucocytes containing them possess this power, and they can also creep along the intima and perforate it. Perhaps it is too dogmatically assumed that all the lymphatic striae on the radiogram are produced centrifugally. They may be formed early and in a centripetal direction from the alveolus towards the root. Since blocking of the ingress to the hilum glands would produce an engorgement and stasis in the implicated areas of the lymphatic circulation, even as far back as the alveoli themselves, a repetition of an aërogenous infection would then be more likely to lead to irritation and thickening of the walls (tuberculous lymphangitis). In some middle-aged healthy individuals radiograms show extensive mottling and numerous lymphatic striae, the latter sometimes reaching from the apex to a gland in the hilum (Stürtz). It is quite feasible to regard these as produced centripetally, as well as centrifugally. At the extreme apical end a few obsolete tubercles may be seen. If the affection had spread from the hilum in the reverse direction, and the disease was chronically progressive, why remain at the apex *in statu quo* for a couple of decades?

It is unreasonable, however, to deny the tendency of a hilum infection to extend outwards into the lung. Several methods by which such dissemination may take place have already been described. But it is never possible to exclude the incidence of second or even multiple aërogenous infections. Very many adults possess dense hilum opacities, containing cirrhotic or calcified glands, which must have been originally tuberculous. The infection, therefore, appears to be practically universal and the manner by which it has been acquired is naturally often obscure. Subsequent infections may just as readily occur. A second aërogenous infection might, however, not be so easily transferred to the hilum. If we accept Birch-Hirschfeld's[16] conclusions with regard to the adult—namely, that there exists a particular area, in the upper lobes, of increased danger, produced after puberty by mechanical means, a "summation of bacterial supply" to this region might strain the leucocytic and bactericidal defences, and the nearest subalveolar glands would provide a suitable nidus for development, particularly if the deeper lymphatic channels should be closed. In this manner succeeding aërogenous infections would be more certain to infiltrate the lung. For a time the disease would remain apical, and the sequence would depend on the individual resistance. If there be a coexistent smouldering focus or bacillary residuum within the hilum glands, or if the second infection accidentally should also be carried thither, the old infection would be more likely to burst into flame. It is difficult to see how the principle of centrifugal dissemination can explain the preponderating vulnerability of the apical lobe in adults. There is no anatomical design in the lymphatic system which would explain the fact. Moreover, the additional difficulty remains of determining the priority of an infection. It is possible to decide whether one focus is more advanced than another, but difficult to say which is primary, as the one may progress more quickly. And if we seek for an older lesion by the side of a new one, the search is often successful (Hutinel).[17]

In many instances positive proof can be afforded of the occurrence of second aërogenous infections after puberty. Von Pirquet[18] states "that if an organism has once become infected, it has altered its reactivity towards the tubercle bacillus and its products. It has become allergic. The bacilli can no longer penetrate without hindrance the mucosa and reach the lymphatic glands, but they produce at the portal of entry inflammatory changes which usually heal. This pulmonary form, typical of adults, and found rarely in children, is therefore most probably a reinfection in individuals who have become allergic through a pulmonary infection in childhood." The facts are equally well explained by accepting Birch-Hirschfeld's views and by assuming the existence of stenosis within the lymphatic trunks. Von Pirquet adds, "the interesting statement that no tuberculous child reacts to tuberculin for a definite period—about a week—during an attack of measles and probably also of influenza." During this time the individual is anergic and deficient in necessary antibodies. A mobilization of the bacilli within the hilum takes place leading to an advance. At such a time, both in children and adolescents, a reinoculation may take place at the periphery.

IV.

Clinical Symptoms and Signs.

These are at first obscure, indefinite, and due to a slow and chronic absorption of the products of bacillary metabolism and to the compression exercised upon adjoining structures by enlargement of the glands. The toxaemia induces a delicacy of constitution, a debility, and disinclination for exercise; a loss of appetite and weight, anaemia, and myoidema. Such children are said to "catch cold" easily, and often suffer from "bronchitis."[*] Where there is no apparent cause for feebleness of health, such as adenoids, enlarged tonsils, etc., suspicion should be directed to a possible affection of these glands. There may be swelling of the cervical, axillary, mesenteric and inguinal glands. The statement has been made that blonde children with long dark eyelashes and a blue iris are especially vulnerable.[19] There may be pain, difficult of localization, within the chest on deep inspiration and vigorous exercise (pleuritic?). Some children exhibit scrofulous scars, otorrhoea, rickets, flat-foot, and spinal disease. Many are said to be "threatened with consumption."

Signs of pressure are not obvious in early cases. Cough and congestion of veins over the chest and upper three or four dorsal spines are usually present. The capillary veins over the spine are, without doubt, produced by compression of the superior intercostal veins by enlarged tracheobronchial glands.[20] Lombardi[21] designates this area "the varicose zone of alarm." Tenderness over the dorsal spines,[22] or spinalgia, to firm pressure may be present (first to eighth). Petruschky[23] ascribes it to disturbances of collateral circulation, to periosteal irritation, or to the presence of minute tuberculous foci within the spine. It is probably a referred pain, produced on irritation of the mediastinal nerves by the enlarged tracheo-bronchial and bifurcation glands. Noeggerath and Salle[24] found hyperalgesia in the region of C_3, D_2, and D_3 (Head's zones), and adduce this as a proof of incipient bronchial gland tuberculosis in children. They mapped out the areas by stroking lightly the skin with a smooth metal pencil or a blunt needle. There may also be tenderness on pressure in the interspaces.

Cough is often absent or present only at night. It may be intermittent and paroxysmal, due to pressure on the mucous membrane of the trachea at its bifurcation, or to irritation of twigs in the pulmonary plexuses. The vagi

[*] Are not these attacks due to exacerbations produced by the fluctuating size of the glands, by gradual involvement of neighbouring glands, and by periodical oozing of toxin?

carry both inspiratory and expiratory afferent fibres from the lungs to the medulla (Starling[25]). There is no sputum. There may be dyspnœa and asthmatic attacks at night, the latter produced by irritation of afferent or efferent vagal branches.[26] French[27] thinks the chronic cough in town children may be due to irritation of the right phrenic nerve.

The temperature curve may be normal. It is often subnormal, with occasional fluctuations to 100° in the afternoon or evening. Cornet insists on a two-hour chart. Rest and exercise temperatures are necessary. Night sweats may occur. Pressure on the cardiac branches may induce a slowing of the heart (Dautwitz[28]), but the usual condition is an increased rate, due to irritation of sympathetic fibres.

Physical Signs.

Riviere[29] describes these fully. Briefly they are:

(*a*) *Impairment to light percussion* at one apex, often the right, in front and behind, sometimes dullness over manubrium, the interscapular region, an increased oval interspinous area (Ewart), due to enlargement of tracheo-bronchial glands, and dullness over the fifth and sixth dorsal spines (bifurcation glands).

(*b*) *Auscultatory* changes produced by increased conduction are harshness of breath sounds over apices, with a prolonged expiration and increased vocal resonance; weak inspiration, possibly over the rest of the lung; vertebral bronchophony, with whispering echo on repeating the number 33, as far down as fourth and fifth dorsal spines,[30] or even lower still. Fine crepitations are to be heard occasionally at the apex and within the middle and lower lobes. They may be produced by a condition of slight œdema occurring within the air cells as a result of lymphatic and venous congestion.

V.

Radiological Examination.

Technique.

1. The little patient lies flat on the couch, and perfectly straight (in order to keep the manubrium and spine in the middle line), and the head is turned a little to one side. A small piece of lead is fastened to each nipple and the target is arranged midway between. It is always preferable to radiograph each child in the same way. The tube is of medium hardness (Bauer 6-7) and a moderate current is employed (2-3 milliampères).

On the screen several points are noted:

(*a*) The movements of the diaphragm.
(*b*) The appearances of the apices on deep inspiration and coughing.
(*c*) The hilum opacities.
(*d*) The pulmonary fields, especially the second and third anterior intercostal areas during inspiration.

The screen is then raised 1 to 2 feet above the patient and the hilum again examined for glands.[31] At any selected area, the diaphragm is focussed down. When the screening is finished, with the target in the original position, the diaphragm is opened wide and a radiogram taken on an ordinary plate, making use of a soft tube (6-7 Bauer), a current of 10 milliampères, and an exposure of about 10 seconds. During this time the little patient fixes the chest in deep inspiration.

2. The patient then lies on the face, and similar precautions are again observed. The target is moved upwards to strike a small piece of lead on the fourth dorsal spine, opened out, and a second radiogram is taken as before. This will be a ventro-dorsal view.

3. The patient is then turned into the right oblique or semilateral position, in order that the mediastinum behind the aortic arch may be explored.

4. In cases with pronounced arborization stereoscopic plates are useful.

Examination of the Plate.—1. This shows the central mediastinal shadow, the hilum, and the lung fields. In order to explain the parasternal shadows I have examined several cases of lymphadenoma of the thorax. In Fig. 2, taken from a boy aged 17, the intrathoracic glands are much enlarged. A diffuse homogeneous shadow is seen on each side of the upper mediastinal opacity extending from the vertebral ends of the third to the sixth rib. It is due to the enlargement of the tracheo-

bronchial glands, and may be termed the "tracheo-bronchial" or "superior opacity." It is visible in many cases of pulmonary tuberculosis in children and adults as a fine shadow, outside the sternum, sometimes on both sides, and at times more easily detected in a ventro-dorsal plate. It has been stated by many pathologists that of these three sets of glands those at the bifurcation are the most frequently attacked. They lie on the body of the fifth dorsal, a little more to the right than to the left of the middle line. A shadow just below the level of the vertebral end of the sixth rib, running directly into the hilum and obliterating the narrow isthmus which often intervenes between the hilum and the cardiac opacity, must be produced by congestion of these glands. It may be termed the "intermediate" or "bifurcation opacity." The hilum glands are so commonly affected, on the radiogram, that it makes one doubt the statement of the particular vulnerability of the bifurcation glands, and surmise that in some instances the condition of the hilum glands has been overlooked.

2. *The interspaces*—particularly the first, second, and third—are examined for signs of lymphatic mottling (which is perivascular as well as peribronchial), tuberculous infiltration, and pleurisy. Sometimes these spaces, although becoming more translucent during inspiration, seem, on the screen, to be veiled by a delicate haze or dimness, suggesting either a very close interlacement of lymphatics or a fine uniform but intangible pleuritic shadow. After a focal reaction, the lymphatics as well as the blood vessels would be congested and the interweaving more pronounced.

3. *The hilum* is now carefully observed for signs of swollen, caseous, and calcified glands, the density of the shadows increasing in this order. The hilum opacity lies at the level of the vertebral ends of the fifth, sixth, and seventh ribs. If it is abnormally dark, broad, and contains a large number of circumscribed shadows, these are enlarged and diseased glands. If the hilum is broad, irregular in outline, and uniformly diffuse or cloudy in appearance, the process is active. The branches running to the diaphragm should be carefully followed for signs of tubercles or localized patches of tuberculous broncho-pneumonia.

4. *The sternal ends of the osseous ribs* are examined for signs of calcification, especially the first. In a young subject, if these edges are sharply cut and there is some

calcification of the first rib cartilage, the prognosis is more favourable. At the same time the width of the interspaces on each side is compared. Narrowing of these spaces on one side due to falling in of ribs produces a unilateral drooping of the shoulder. It leads to deficient expansion and weakened breath sounds.

5. *The heart* in older children may suggest cardioptosis (pendulous heart). It is *apparently* smaller than normal in some instances. There may be a convexity on the right side of the heart, due to a dilated right auricle—although this may in some measure be due to the negative pressure within the chest during a fixed inspiration (Walsham).

6. *The pulmonary fields* are to be explored for striae, networks, and small tubercles or tuberculous foci. In itself mottling is a sign of phthisis, but not of activity, since it may be merely evidence of a healed tuberculous lymphangitis. Morton and Owen[32] think that mottling is due to the crossing shadows of thickened lymphatic vessels which are on different levels. The coarser the interlacements are, the more suggestive is the picture of an arrested lesion (Boardman[33]). But the occurrence of

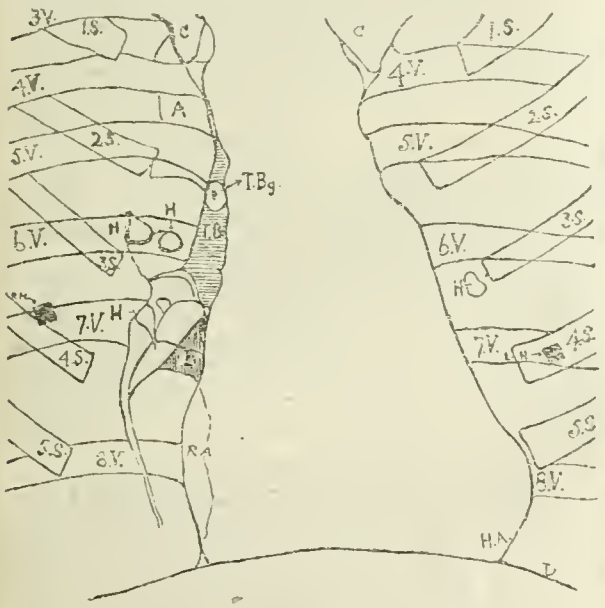

Fig. 3.—Radiogram 2, Phyllis P., aged 10 years.

small pinhead-sized foci standing separately or in conglomerate groups, producing a cloud effect, is diagnostic of activity (Rieder,[34] Morton[35]). If they become fibrosed, the opacities will be denser and more sharply defined.

Interpretation.—Before attempting a diagnosis, the family, the personal, and clinical history, symptoms and physical signs should be examined in order to avoid errors and to command a more reliable prognosis. The radiologist endeavours to make a diagnosis:

1. As to the presence or absence of the disease (von Pirquet's reaction may here assist if it should be negative).
2. As to its activity or latency.
3. If active, as to whether it is open (manifest) or closed.
4. As to the probable direction or otherwise of its dissemination (prognosis).

In cases of difficulty the occurrence of an increased lymphocytosis after the administration of tuberculin may suggest a positive diagnosis as regards activity (Schulz[36]). Or a second or third radiogram may be taken at intervals of a month.

The histories of two cases are now given:

CASE I.

A girl, aged 10 years; family history good; had measles and a septic throat four years ago; has a chronic cough; suffered from pains in chest—pleuritic?—four months ago.

Present Condition.

Cough little but hard; no sputum; no night sweats; no dyspnoea; no palpitation; a well nourished child. Examination reveals diminished expansion of left upper lobe, harsh breath sounds and prolongation of expiration in this locality. At the right apex breath sounds are weak; vocal vibration diminished; dilated capillary veins over the spine. Temperature 97.8° mornings, 98.8°-99.5° evenings; spleen and liver normal; occasional attacks of vomiting; glands not palpable.

Radiological Examination.

Diaphragmatic movements good: both lungs appear dull, but light up well during inspiration, also the apices; increased hilum shadows. On the plate (Fig. 3) increased hilum opacity and arborizations; right tracheo-bronchial opacity containing one visible gland, bifurcation opacity, and gland visible on right; lymphatic mottling within upper interspaces with scattered tuberculous foci. Shadows and strands passing to right diaphragm are dense. Cardioptosis and dilated right auricle. The condition is active.

There is a dimness, radiating from the right tracheo-bronchial shadow, which is due to a fine pleuritic infiltration. Opacities are visible along the lower borders of vertebral ends of fifth and sixth ribs. The inner strands of Stürtz, running upwards and backwards towards the tracheo-bronchial glands, may be produced gradually by a centripetal dissemination from the pleuritic infection intervening between the glands and the striae. We consider that the subpleural foci of Gohn may arise through the medium of the tuberculous pleurisy, which has spread over the visceral pleura from affected tracheo-bronchial

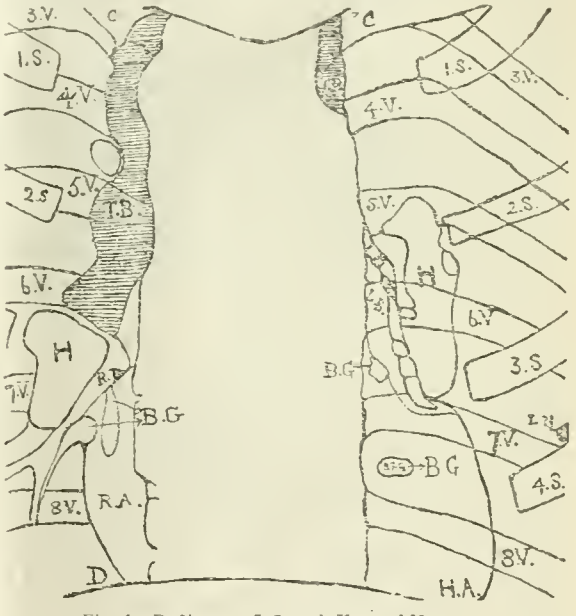

Fig. 4.—Radiogram 3, Joseph Y., aged 12 years.

and bifurcation glands. Such a pleurisy may be ultra-clinical, but none the less effectual as a means for the dissemination of tubercle from paratracheal glands to the substance of the lung.

CASE II.

A boy, aged 12 years. Complains of cough, shortness of breath, and general weakness; has always been delicate.

Present Condition.

Complexion is pale; tonsils enlarged (scraping is negative); glands in axillae, along sterno-mastoids, in anterior and posterior triangles; they are firm and discrete; spleen just palpable; blood count, 4,240,000 red; white 10,800; haemoglobin, 80 per cent.; polymorphs, 53 per cent.; lymphocytes, 47 per cent.; small, 36 per cent.; lymphocytosis; pulse 76–96; respiration 20–24; temperature, morning average 97.6°, evening, 98°. Chest expansion moderate; abdominal respiration increased; percussion note over left upper lobe in front and behind is impaired; breath sounds at apices harsh and expiration prolonged; vocal resonance increased; over the rest of lung the breath sounds are weak and vocal resonance is diminished. The radiogram (Fig. 4) shows massive shadows within the hilum on both sides; a right tracheo-bronchial opacity with a shadow just outside between vertebral ends of fourth and fifth ribs, which may be a pulmonary focus in right upper lobe; a right bifurcation shadow internal to the large right hilum opacity. There is not much mottling and no signs of activity. In the oblique radiogram some of the calcified glands are seen to lie along the left internal mammary vessels; the left axillary glands are also visible. The channel of infection appears to have been from the trachea viâ the tracheo-bronchial and bifurcation glands.

The coexistence of the five conditions:

1. Intermittent sudden cough in the absence of cases of pertussis;
2. Wasting, pallor, and tiredness;

3. A subfebrile temperature, rising occasionally to 100°;
4. The presence of capillary veins and a growth of hair over the upper thoracic spines; and
5. The absence of any obvious disease;

should induce the school medical officer to examine carefully for pulmonary tuberculosis and enlarged bronchial glands. If in doubt the little patient should be sent to the radiologist. The most difficult glands to materialize are the left bifurcation glands.[57] Special contrivances must often be adopted to bring them, as well as the tracheo-bronchial glands, into prominence.

VI.

Treatment.

If there is the slightest doubt, the patient should receive the benefit. All hygienic measures—such as proper diet, graduated exercise, sea air or sanatorium, open-air school or entire freedom from school routine for several months—should be adopted. Virol, red bone marrow, and cod-liver oil are said to increase the bactericidal powers of the blood. Ichthyol[39] (tabloids) and calcium sulphide are believed to hasten the fibrotic changes we desire; iron is useful to tone the erythrocytes, which, according to Spengler, manufacture the immune bodies. With regard to the curative value of the several varieties of tuberculin, the special treatises must be consulted. On the analogy of the cervical glands, the *x* rays may be suggested, making use of a hard tube and of filters, and treating a circular area around the spine of the fourth dorsal vertebra with a third of a pastille dose once a week.

A radiogram should certainly be taken first in order to localize the situation of the affected glands.

In conclusion, my best thanks are due to Dr. Walsham, who provided me with several typical cases and assisted me throughout with valuable advice.

Lieutenant-Colonel Andrew Arthur Macrobin, R.A.M.C., left estate valued at £13,335.

In the *Revue Médicale de la Suisse Romande* there is a note from the President of the Swiss Medical Commission stating that certain members of the medical profession have taken advantage of the absence of doctors called out for service with the army to establish themselves within the area of practice of their absent brethren. The President calls upon all the cantonal medical societies to do whatever lies in their power to safeguard the interests of the mobilized practitioners. He deplores the fact that men capable of such conduct should be found in the ranks of the profession, and expresses regret that there are no means at present available to prevent such action.

THE "ELDERTON" METHOD OF CONTROL IN TESTING THE VALUE OF NEW TUBERCULIN.

By H. BATTY SHAW, M.D., F.R.C.P.,

Physician to the Brompton Hospital for Consumption and Diseases of the Chest, and to University College Hospital.

Professor Sahli has published a criticism[1] of the way in which an endeavour has been made by myself and fellow-workers to arrive at definite conclusions as to the therapeutic value of tuberculin. Such criticism is the main topic of his contribution; but he has also referred to other matters in which we evidently are at variance, and I feel it is due to Professor Sahli that a reply should be made, not only because of the extreme interest of the arguments he puts forward, but also because his point of view is different from the one which, I think, activates practice in this country.

The first duty is to give answers to some of Professor Sahli's remarks: that I have "not the least chronological sense" in reverting "time after time to the experiments of Koch"; that I am wrong in assuming that "no one bases himself now . . . on these far-distant experiments"; that "there is, therefore, a grave injustice" in my "comparison between the quack doctor's lack of criticism and the similar lack which" I assume "in the tuberculin therapist"; that I see "only harmful action in these anaphylactic phenomena"; that my view, "that in anaphylactic phenomena . . . no curative side is to be recognized, should find little approval"; that "the significance of the modern reactionless tuberculin treatment appears to be little recognized" by me.

Professor Sahli does "not think that any thoughtful adherent of tuberculin treatment can nowadays be found to contend that tuberculin produces immunity against tuberculosis." It is an "old argument, which is scarcely used nowadays, that tuberculin treatment is an immunization, and that from the possibility of a protective inoculation against typhoid . . . it might be concluded that such an inoculation must also succeed in the case of tuberculin."

I am sorry that Professor Sahli thinks I have failed in the chronological sense. This is my answer: that I went to the fountain source of Koch's experiments under date of 1890, that I then read Löwenstein's and Römer's articles in Kraus and Levaditi's *Handbuch*, 1908; Cornet's *Die Tuberculose*, 1907; Bandelier and Roepke's *Lehrbuch*, 1908: and Wolff-Eisner's *Handbuch*, 1910, which I had hoped had brought all the experimental work on tuberculin up to that date.

It is my misfortune if I have missed any reference to the experimental proof of the specific cure by means of tuberculin of any animals since the year 1910. At the time of delivering my lecture none of my friends in this country who are following the matter with the greatest acumen knew of any further experimental work supporting Koch's original contention (reiterated by authorities abroad as shown above, and shown by Römer to be wrong) that tuberculin could cure animals of tuberculosis. I submit to Professor Sahli that his charge is not justified, and I fail to find in his own publication any reference to further experimental cure. I am obliged to revert to Koch's experiments, as they are the only ones which it is stated prove the specific curative value of tuberculin. The advocates of the use of tuberculin also revert to these experiments repeatedly as a foundation for their practice.

Now as to the grave injustice done to the tuberculin therapist. As shown in my lecture, all the experimental proof put forward by Koch and reverted to by modern workers is of doubtful value, and Professor Sahli joins me in saying Koch's experiments have never been confirmed. Then I submit that a tuberculin therapist who, in face of the inability to repeat and confirm Koch's experiments, says that he can cure tuberculosis of the lungs or any other organ in human beings by means of tuberculin, lays himself open to the charge of quackery—it makes no difference whether he is a qualified practitioner or not. The injustice so severely commented on by Professor Sahli can only be felt by those who say they "treat" rather than "cure" the disease. My lecture was

in no way meant to be an attack on those who did not use the word "cure." It is common knowledge that some tuberculin therapists use tuberculin to affect the temperature chart, much as many others reduce temperature by using cold baths or antipyretics; but they do not pretend to "cure" by such means. Professor Sahli objects to my seeing only harmful action in anaphylactic phenomena. The answer I would make is that until experiment shows that such anaphylactic phenomena when provoked are curative and not harmful, or that when such small doses of tuberculin are given as to produce no objective or subjective signs of anaphylaxis that cure can be experimentally proved, I am obliged to hold to this statement: Given the development of anaphylactic phenomena, the patient suffers harm varying in degree from the slightest injury to the grave effect produced by Koch and his immediate followers.

I fully admit that I do not recognize the significance of the modern reactionless tuberculin treatment in so far as such treatment effects a cure. It has not been proved in animals because so far it has been impossible to prove it, and I feel that attempts to cure human beings on the same lines are *a priori* bound to be failures too. Without controlled experimental proof, or controlled proof in human beings, I feel that the reactionless dosage with tuberculin is merely doing something to let the patient feel that something is being done—suggestive tinkering, in fact.

So far from condemning the argument that because vaccination against small-pox can, and does, for a time, prevent subsequent attacks of small-pox, and typhoid vaccination can and does prevent for a time the infection by the typhoid organism, it is thinkable that preventive vaccination by means of tuberculin may prevent infection by tubercle bacilli, I am quite open-minded enough to admit the possibility. But admitting such a possibility is quite different from asserting that tuberculin, typhoid vaccine, or small-pox vaccine can cure the diseases, tuberculosis, typhoid, or small-pox, when once these diseases have established themselves.

The reader who cares to peruse the lecture which Professor Sahli attacks, will see that this reply of mine merely reiterates what I have already said. My apology must be that I really have no alternative—that is, if I give any answer at all to Professor Sahli's criticism.

A final point needs discussion, and it is the most important of all. Professor Sahli has thrown up the statistical method, and if I read his criticism aright, his condemnation of my remarks on the points for and against the use of tuberculin as a specific cure is dependent on this fact. In common with other workers in the same field, I feel that until figures are forthcoming which prove, or disprove, the value of tuberculin, I ought not to give up the statistical method. Thanks to Professor Karl Pearson and his pupil, Mr. W. Palin Elderton, I can see that the statistical method shows that the specific cure of tuberculosis by tuberculin is not proven, and that our methods in the past of establishing a cure are at fault. The pernicious and utterly illogical plan of simply treating what we call "suitable cases" without instituting controls is responsible for a large amount of useless clinical work. I fully admit that that is a matter for great regret; energy has simply been turned into the wrong channel, and time and money have been wasted. Dr. Thompson Rigg,[2] Dr. Arthur C. Watkin,[3] and recently Drs. G. V. Stockdale and Ronald Hodson[4] have carried out the treatment of pulmonary tuberculosis by tuberculin under what is a controlled method, the details of which are given in their respective papers.

Professor Sahli does not approve of the scheme, but, as he has abandoned the statistical method, his criticism is hardly to the point. He relies on pontifical assertion; we rely upon convincing our readers by figures. The following table gives an analysis of the cases—84 in number—which were treated by reactionless doses, Dr. Rigg's being omitted because they were treated by reacting doses. The criteria of improvement, etc., was the diminution or increase of râles; all the cases had tubercle bacilli present in the sputum.

It is a matter for regret that the total of 84 cases is so small, but, as was originally pointed out in an earlier paper, the figures are published in the hope that others will follow out the "Elderton" method of control. There

Observer.	Tuberculin or Not.	Afebrile.			Intermittently Febrile.			Febrile.		
		Improved.	Worse.	In statu quo.	Improved.	Worse.	In statu quo.	Improved.	Worse.	In statu quo.
Dr. Watkin ...	Tuberculin	1	0	1	2	4	0	0	0	3
	No tuberculin	0	2	1	3	3	0	0	0	2
Drs. Stockdale and Hodson	Tuberculin	5	1	3	3	11	6	0	0	2
	No tuberculin	2	2	5	7	5	8	0	1	1
Total (84 cases)	Tuberculin	6	1	4	5	15	6	0	0	5
	No tuberculin	2	4	6	10	8	3	0	1	3

(*a*) Of 23 cases which improved, 11 had been treated with tuberculin, 12 had not.
(*b*) Of 29 cases which were worse, 16 had been treated with tuberculin, 13 had not.
(*c*) Of 32 cases which remained *in statu quo*, 15 had been treated with tuberculin, 17 had not.

can be no denial of the fact that, so far as afebrile cases are concerned, the reactionless dosage with tuberculin gives more favourable results than treatment without tuberculin, as far as these cases (23 in number) are concerned. Before complete satisfaction can be given more cases should be tested, and it is most desirable that the numbers should be increased very much—a task which can only be rendered possible in the near future by the sympathetic co-operation of those whose lot it is to have cases under observation.

I sincerely hope that readers will not conclude from the above analysis of 84 cases that my figures prove that it is justifiable to give tuberculin in small reactionless doses. They should, I submit, merely feel that so far as 23 afebrile cases are concerned, 11 of which were treated by reactionless doses, and 12 of which were not, but merely left to what may be called expectant methods, more improved, less got worse, and less remained *in statu quo* with tuberculin treatment than without it. The plan by which the choice of cases to be treated with or without tuberculin has been left to chance, will, when a larger series has been completed, give a true estimate of the value of tuberculin. I frankly confess that I hope tuberculin will be found to be efficacious, but I am told on high authority that many more cases must be studied by the controlled method we have adopted before such favourable verdict as our 23 cases give can be accepted as final.

That the criticism made by Professor Karl Pearson of the methods adopted by medical men to prove the value of tuberculin is bearing still more fruit, is shown in the preliminary report on the treatment of pulmonary tuberculosis with tuberculin at the King Edward VII Sanatorium, Midhurst, by Dr. Noel D. Bardswell (London: H. K. Lewis, 1914), and I cannot do better, in order to encourage others to help in elucidating this most important question on scientific lines, than to ask readers to peruse this volume, which contains salutary remarks by Professor Karl Pearson (pp. 1 to 13), and in the concluding section of which will be seen the following statement by Dr. Bardswell:

> Experience has shown that tuberculin, as at present used, is not a remedial agent which can be depended upon to revolutionize either our sanatorium results or our conception of the outlook for the average consumptive. Tuberculin has not proved itself to be a remedy in the ordinary sense of the term, and no immediate or striking results are to be expected from it, even in the most favourable cases. Even if it be assumed that good effects are produced by tuberculin, they occur almost imperceptibly, the slowness of its action being such that it is often difficult to determine, as regards patients treated under favourable hygienic conditions, how much, if any, of the improvement that takes place is due to its use.

ARTIFICIAL PNEUMOTHORAX.

BY

H. DE CARLE WOODCOCK, M.D.,
LEEDS,
AND
J. A. M. CLARK, M.D.,
LEEDS.

THE suggestions we have to offer as to the value and dangers of artificial pneumothorax are based upon experience gained in over 2,000 operations. Many were done in nursing homes, but by far the greater number in the hospitals at Armley and Killingbeck, to which we are attached. Our cases are of three types:

1. Early cases with localized unilateral disease, characterized by little pleuritic thickening and few constitutional symptoms.
2. Medium cases with more extensive disease, generally bilateral, with more evidence of pleuritic thickening, and with (*a*) slight or (*b*) marked signs of constitutional disturbance.
3. Severe bilateral cases with much constitutional disturbance, offering no hope of cure by ordinary methods of treatment.

Preparation of Patient.

The patient should spend one day in bed before the first operation; more is not needed, except for cases in Class 3. A hypodermic dose of urea hydrochloride (grains 2) and quinine sulphate is given overnight, together with $\frac{1}{6}$ grain of morphine and $\frac{1}{100}$ grain of atropine. Just before the operation the spot selected for puncture is painted with tincture of iodine, and novocain and adrenalin are injected into the site of puncture, the injection being so managed that both the superficial and the deep parts are anaesthetized. Again urea hydrochloride and quinine are administered subcutaneously, since deep injections sometimes cause violent spasm in the intercostal muscles, which should be avoided.

Site of Operation.

With us the site of election for operation is the junction of a mid-axillary line with a line running straight out from the nipple, but this point may have to be abandoned, especially if there is much basal pleuritic thickening. The thickened pleura has to be regarded as a continent shelving into an open pleural sea. We seek, therefore, a resonant spot, preferably in the axillary line, and push the needle in until the manometer shows that it is in the free pleura. Often it may be necessary to forego the local anaesthetic, for novocain must not be given beyond the dose of safety, and therefore cannot be frequently injected at the same operation.

1. *Early Unilateral Cases.*

The operation is easy, though the shock is always severe. Embolism is unlikely, and has never, we think, occurred with us. Patients of this type are not very ill; they are in no urgent dread of a fatal termination to their illness, and they rarely see any imperious need for operation. Extreme nervousness is often shown by patients who have, it may be, received exaggerated accounts of the pain of puncture. At the first introduction of the patient to the operation couch we go through all the steps of preparation, not going beyond the injection of the local anaesthetic. When after four days the patient again presents himself, the process is carried farther, and the special needle (we use Saugman's) is pushed in until oscillation of the manometer shows that it is in the pleural cavity. At the third meeting a small amount of gas is introduced. By this method nitrogen may be injected forthwith; it is not necessary to use air or oxygen. The fear is not of embolism but of shock.

If the oscillation of the manometer is 1 in., the dose given may be 300 c.cm. Should there be any doubt as to the position of the needle, or should the manometer not oscillate freely, then no more than 30 c.cm. should be introduced. The entry of this small amount of gas will not cause embolism, while if the needle is slightly blocked it will push aside the obstruction, on which the oscillations will jump to view. The manometer is the guide.

After the gas has been injected, the patient is made to lie still for half an hour; then, if all is well, he may be sent by ambulance back to the ward.

Some patients suffer from shock even with this careful method. The effects are not necessarily shown on the instant. The operator may be injecting gas into the pleura, encouraged by the smiling comfort of the patient, when suddenly it is seen that all is not right. The drugs used may so have deadened the patient's sensation that he is not mentally aware of his physical distress until a dangerous point is reached. The pulse may quicken and intermit, the patient may become distinctly blue, the respiration may quicken, and pain may suddenly occur and rapidly become excessive. It may be necessary to give morphine to ease the pain; it is at any rate advisable to stop the supply of gas, and also to open the tap of the needle and thus allow the gas to regurgitate, so to speak, from the pleura. The escape of a little gas may at once give ease to the patient and relief to the operator. The severity of the shock in these cases which are unilateral and limited in extent is probably due to the healthy condition of the pleura. It is not thickened; it is not adherent; its nervous mechanism is sensitive, and there is no bar to immediate displacement of the heart. Movement on the part of the patient seems to precipitate the distress. Well do we remember completing a first operation on a girl who thought the whole affair a triviality until we had finished; then she showed acute distress and immediate fear. For a few minutes she was in considerable danger; we had let the gas run in too quickly and had given her too much, and all at once cardiac and respiratory resentment showed itself.

2. *Medium Cases.*

In medium cases, often with bilateral disease and a considerable amount of pleuritic thickening, the shock of needle puncture is not marked. The difficulty is to find the pleural space and the danger is embolism. It may be necessary to try several times before the manometer oscillates; the oscillation is often slight and may even be due to the needle being in loose tissue immediately outside the parietal pleura. Even when the needle reaches the pleural space, it may be in a pocket, and there may be only the possibility of inducing a very partial inflation. The shock, apart from fear, is not great, and the heart is not violently displaced. The thing to be feared is gas embolism.

If an attempt is made to force in gas at any pressure above 3 in. of water, there may be severe local pain, and in an hour surgical emphysema may be recognizable. The occurrence may be guessed at if there is a feeling of constriction in the neck. The necessary precautions are to limit the first introduction of gas to 50 c.cm., and to watch respiratory rather than cardiac movements. If oxygen is to be given at all it should be given in these cases.

Another point is worth mentioning: after four or five injections it is necessary to alter the point of puncture. We take it that a local patch of pleurisy has resulted from the frequency of the trauma. Another trouble in these chronic cases arises from a change in the pleural lining; it becomes haemorrhagic and is apparently turned into something resembling granulation tissue, and the needle may again and again draw blood, as is shown by the reflux into the bulb, which in our instrument is inserted in the line of india-rubber tubing leading from the gas bottle to the needle. There may then be great anxiety lest a vein has been tapped. If the manometer does not show its initial rise, followed by the welcome oscillations, the operation must be stopped. Often when filling the pleural space slowly the gas at a moment rushes in rapidly; this is due to peeling off the softly adherent pleura; the pressure must be lowered or the gas even shut off for a time, or there may be severe pain or even shock.

Haemoptysis of the severest kind allows any risks; nothing else does. In one patient we introduced 1,800 c.cm. of gas at one time; we did it slowly and it took an hour. There was no shock—indeed the patient said he was quite comfortable, and the haemoptysis, which had threatened to be fatal, terminated. There was just an ounce of blood on the morrow, and then no more.

In all cases of severe haemoptysis threatening life, artificial pneumothorax should be thought of. The only contraindication would be such a massive amount of disease that the pressure of a large quantity of gas in the

pleura might lessen the available breathing space until the minimum necessary for life had been passed.

3. *Cases of Very Severe Disease.*

In severe cases with bilateral cavities and much of both lungs affected, the danger of artificial pneumothorax is obvious. The patient has little lung left; he may therefore be suffocated if any of that little is taken away. Still, this is not the last word. In these cases we have many times given the patient the only chance left to him, and in a few instances the result has been good.

The apparatus made at Dr. Woodcock's suggestion by Messrs. Reynolds and Branston, Limited, of Leeds, seems to offer some advantages over the instruments used by most workers, and the plan of it has been approved by a great Continental authority. It is well made and accurate, easily kept clean, and simple in its working. In the latest form of this apparatus a regulator is used, which controls all the pipes by manipulating one indicating needle. This regulator is an invention of Dr. T. D. Lister of London.

EIGHTY-SECOND ANNUAL MEETING

OF THE

British Medical Association.

Held in Aberdeen on July 29th, 30th, and 31st.

PROCEEDINGS OF SECTIONS.

SECTION OF LARYNGOLOGY, RHINOLOGY, AND OTOLOGY.

H. LAMBERT LACK, M.D.Lond., F.R.C.S., President.

*ABSTRACT REPORT.**

PRESIDENT'S INTRODUCTORY REMARKS.

THE President, after welcoming the members, went on to consider the significance of the two subjects which had been selected for general discussion—the treatment of inoperable growths of the nose and throat, and oto-sclerosis in its various aspects. The fact that the former had been chosen was itself an indication that some progress had been made in the direction of alleviation, if not of cure.

Marvellous progress had marked the last year, as was shown by the introduction by Killian of suspension laryngoscopy and by Nagelschmidt of diathermy, which had been found useful not only in malignant disease, but also in intractable lupus of the upper air passages. In conclusion, the President alluded to the use of the intra-tracheal administration of ether as a great step in advance, and to the efforts which were being made by Freeman to provide a rational and successful method of treating hay fever.

DISCUSSION ON THE TREATMENT OF INOPERABLE GROWTHS OF THE THROAT AND NOSE.

OPENING PAPERS.

I.—W. D. HARMER, M.C.Cantab., F.R.C.S.,

Surgeon, Throat Department, St. Bartholomew's Hospital, London.

DIATHERMY.

THE subject of treatment by diathermy had been discussed, Mr. Harmer said, by Nagelschmidt in his *Lehrbuch der Diathermie* (Berlin, 1913). A paper on the treatment was also read by him before the Electro-therapeutical Section of the Royal Society of Medicine in 1910.

The apparatus produced a high frequency current of great power. It had two electrodes, one large which was wrapped in wet cloths and applied to the patient's chest, and the other small which was applied to the growth. The passage of the current produced intense heat at the small electrode only. The instrument must be controlled by a skilled person, and the operator should wear rubber gloves to avoid shocks; the current was not turned on until the small electrode was buried in the growth, and was turned off before the electrode was removed from the tissues; this was necessary in order to avoid sparking; strict aseptic precautions were necessary. A general anaesthetic was required for large growths. Atropin internally and frequent sponging locally were necessary to keep the parts dry. The passage of the current blanched the tissues around the electrode in a few seconds. After a series of punctures had been made the cauterized areas might be removed by forceps or curette and the deeper parts of the growth attacked. Although bleeding did not result from the burning of even vascular growths it was necessary not to remove sloughs too boldly. In large tumours dyspnoea during or subsequent to the operation might require tracheotomy. Too rapid burning was to be avoided as it might lead to dangerous swelling of the neck. More than one sitting was necessary, as a rule.

Mr. Harmer had treated by this method 21 cases of cancer of the tonsil, tongue, palate, pharynx, and larynx. Naevi of the nose and tongue and naso-pharyngeal fibroma had also been successfully dealt with. The subsequent pain was slight, there was rarely any oedema or inflammation, and the patient was able to swallow about forty-eight hours after the operation. Sepsis was less frequent than after cutting operations, and there was no shock. The wounds left healed rapidly, with but trivial scarring. Nearly all the cases he had treated were enormously improved, and in one instance (cancer of the tonsil and tongue) life was prolonged in comfort for about two years. These were striking results in what were cases of very advanced disease. Cases in which the growth had reached the neck or had invaded bone were unsuitable for this treatment.

The advantages over the knife were the rapidity and ease of operation, the absence of haemorrhage, and the sealing up of the vessels and lymphatics by the thermal agent. Mr. Harmer believed that diathermy retarded the subsequent progress of the disease, both in its original site and in the cervical glands. Local recurrence seemed to be less frequent than after a cutting operation. For simple vascular tumours, such as naevi, the results were all that could be desired.

II.—WILLIAM HILL, M.D.,

Surgeon for Diseases of the Throat, Nose, and Ear, St. Mary's Hospital, London.

RADIUM.

RADIUM, Dr. Hill said, was worth trying in inoperable cancer in these regions if an adequate amount were available, if the primary growth were accessible and not too extensive, if metastases were absent, and if the general health was fairly good. When extensive growths were irradiated massive doses of toxins were liberated and might lead to serious complications. In pharyngo-laryngeal cancer radium should not be tried if the growth had invaded the lower air passages or if there was marked glandular involvement.

Sarcomata and endotheliomata reacted better to radium than cancers, but nevertheless some epitheliomas of the nose, throat, and gullet did react well. So well did sarcomata react that accessible sarcomata of the jaw and naso-pharynx might be treated in the first instance with radium and operation postponed until the effect of the radium was manifest. This applied particularly to sarcoma of the tonsil.

As regards the quantity of radium to be used, Finzi held that the equivalent of at least 50 mg. of radium bromide—that is, about 26 mg. of the metal, should be employed. Success might follow the use of smaller quantities, but the necessary increase in the exposure time was inconvenient and even dangerous in cavities like the throat and gullet. Doses as large as 100 to 200 mg., suitably screened, were advantageous in that they permitted a decrease in the time of exposure. There was no reason to believe that the salt itself was more deleterious than the emanation. The great advantage of emanation was that special tubes to suit regions might be employed. Dr. Hill believed that efficient screening was of importance in the case of oesophageal cancer. The needles used by Mr. Pinch,

* A full report has appeared in the *Journal of Laryngology*.

however, in which the screen was thin, might prove to have a wide field of usefulness for embedding in laryngeal and pharyngeal growths. In order to anchor the tube at the selected spot in the œsophagus or elsewhere, Dr. Hill used a flexible silver style. By shifting the style up or down even a moderately long stricture might be thoroughly irradiated. While embedding a tube had its advantages in large or thick growths, it should be avoided if possible, as sepsis was liable to supervene after inserting a tube through a mucosal incision. For this reason embedding, if unavoidable, was best effected through a skin incision if practicable.

Dr. Hill related the history of a number of cases exemplifying the foregoing points, and especially showing the great improvement which followed the use of radium in malignant stricture of the œsophagus. In one such case the patient had had nine applications in four and a half years, and was still alive, with what looked like an ordinary fibrous stricture. Dr. Hill concluded by expressing the opinion that radium therapy was worth trying in epithelioma of the throat, but that diathermy had probably a wider sphere of usefulness in these areas. In the œsophagus the converse was the case.

III.—JOHN MACINTYRE, M.D.,

Surgeon for Diseases of the Throat and Nose, Glasgow Royal Infirmary.

X RAYS.

AFTER defining what was meant by the phrase "inoperable growth," Dr. Macintyre said that in round-celled and other sarcomata some good results followed the use of x rays, and the same was true of epitheliomata of the lip, tongue, nose, and naso-pharynx. The effects were not cure, but arrest or diminution of growth, relief of pain, and arrest of haemorrhage. The nearer to the surface of the body the better were the results. But in the case of the œsophagus and mucous membranes of the respiratory tract the results were not very promising. The use of the x rays might be combined with that of other agents, such as radium and diathermy. Dr. Macintyre concluded with the narration of two cases of sarcoma of the naso-pharynx which had responded favourably to the x rays passed directly through the nose.

DISCUSSION.

Dr. WATSON-WILLIAMS (Bristol) advocated radium for sarcoma rather than carcinoma. In malignant growths of the œsophagus the mere temporary relief and prolongation of life were sufficient excuse for using x rays or radium.

Mr. SOMERVILLE HASTINGS (London) gave from an experience of 16 cases treated by radium the following encouraging synopsis of results: 2 markedly improved, 7 temporarily, and 7 not improved at all. The silver tubes used were 0.3 to 0.8 mm. thick. The dosage was 50 to 200 mg. of radium bromide. The duration of exposure was four to twenty-four hours. This duration was, Mr. Hastings said, an important point, and he described one case in which too long an exposure led to serious sloughing, with adenitis extending to the axilla. In this same case he drew a moral from the fact that the patient had some septic teeth which were not removed before applying radium. For œsophageal growths the radium tube could be fixed in a Symonds's tube.

Dr. H. PEGLER (London) quoted a case in which radium followed by x rays was successful.

Dr. SYME (Glasgow) did not think that the results of radium treatment up to date justified any statement to the laity that there was any successful treatment other than surgical removal.

Dr. LIVINGSTONE (Newcastle) quoted a case of sarcoma of the maxillary antrum treated by radium. The primary growth disappeared and an attendant sinus healed. The patient died of recurrence in the liver.

Mr. JEFFERSON FAULDER (London) advocated experiments with diathermy on the cadaver. It would be regrettable if lay patients, having been told that diathermy cured inoperable cases, should therefore present themselves late in the disease for treatment. Even now cases were not seen sufficiently early. He asked whether Mr. Harmer had found that diathermy caused any such change in the glands of the neck as to make it advisable to remove these first.

Mr. O'MALLEY (London) remarked that sarcomata were amenable, but carcinomata much less so. His experience of diathermy led him to think that this process seemed applicable to growths of any size, and in any situation; there was freedom immediately from haemorrhage, and, remotely, from scarring.

The PRESIDENT recounted sixteen cases treated by diathermy. The process always produced glandular swelling, rendering difficult the removal of glands. The freedom from pain and fever after diathermy operations was remarkable. In his experience both radium and x rays had failed in every case of carcinoma of the throat.

REPLIES.

Mr. HARMER (London) congratulated Dr. Lack on his excellent results with diathermy. Asepsis was of paramount importance. In answer to Dr. Watson-Williams, he expressed the belief that there was no limit to the size of a blood vessel which could be coagulated, but there was the constant danger of secondary haemorrhage when the slough separated. In answer to Mr. Faulder and Dr. Lack, he said that he did not think glands were more difficult to remove after diathermy unless there had been inflammation in the tissues of the neck.

Dr. WILLIAM HILL referred to Dr. Syme's contention that the public should not be lulled into a sense of false security by the pronouncement that it was permissible to use radium and diathermy in the first instance instead of the knife, and thus much valuable time might be lost. Dr. Hill said that there was, as a fact, no such loss of time, because any sarcoma which reacted to radium at all reacted at once, and after diathermy a less extensive operation might suffice. He advised Mr. Hastings to discard the plan of placing the radium tube in a Symonds's funnel. In one case treated by the speaker the loose tube was displaced by post-anaesthetic vomiting. It was necessary to fix the radium tube with a style.

DISCUSSION ON OTO-SCLEROSIS.

MR. J. S. FRASER (Edinburgh), in an opening paper, after marshalling the various known theories as to the causation of oto-sclerosis, favoured the suggestion that the disease was due to a chronic local infection in the muco-periosteum of the tympanum in the region of the anterior margin of the oval window, and showed lantern slides to prove that ostitis vasculosa might follow otitis media. Out of a series of 153 collected cases, 99 were females, and 52 were between 20 and 30 years old. The etiological points in the histories included chiefly pregnancy, anaemia, and rheumatism; and suppurative otitis in only 6 cases. Mr. Fraser had been struck by a peculiar mask-like lack of facial expression in this disease. In 8 cases there was slight neuralgic pain, and in 26 opacity or loss of gloss in the membrane. He had found Gellé's test unreliable. In many normal people he had failed to get any reaction; and if the Eustachian tube was very patent (as was alleged to be frequently the case in oto-sclerosis) the test failed owing to air escaping into the naso-pharynx when the meatal compression was applied, so that the intratympanic pressure was never raised. He regarded the loss of perception by air conduction of the C_2 fork as the most important clinical sign of oto-sclerosis. The sensibility to tickling of the meatus was diminished in every case, and more so on the worse side. There was a close relationship between the degree of deafness and the tone at which Rinne's test became positive; in slight cases the test was negative only with the lower forks; in advanced cases it was negative up to C_{256}. Again, in early cases the upper tone limit approached the normal, whereas in bad cases it might be only 8,000 D.V. The latent period of reaction to caloric stimulation was reduced, suggesting a hypersensibility of the vestibular apparatus in the later stages of oto-sclerosis,

or an alteration in the labyrinthine fluid favouring the production of vestibular nystagmus.

Mr. G. J. JENKINS (London) considered that clinical and experimental evidence showed that there was a change in the labyrinthine fluid. The subject of glandular internal secretions was so complicated that treatment by their extracts must be resorted to by slow degrees only. He had tried opening the perilymphatic space of the external canal, with a resulting improvement in hearing which was brilliant but transitory; in three months the patient's condition was almost as bad as before. Intranasal operations or Eustachian inflation were only justifiable if there were danger of a superaddition of Eustachian deafness. Noisy surroundings undoubtedly increased the symptoms, especially high-pitched noises. Mr. Jenkins's views on instrumental aids may be summarized under three headings: (1) In slight cases the patient was better with no such aid. (2) When the patient could only hear conversation at 2 to 3 feet, an artificial auricle was most useful, and better than electrical instruments. (3) In advanced cases an ear-trumpet should be used.

Dr. W. S. SYME said that in the examination of over 1,100 skulls he had not once found the stapes fixed. After making an opening into the external canal, the usual rapid closing of this opening might perhaps be prevented by implanting a strip of periosteum into it.

Dr. J. MACKENZIE (Inverness) referred to a case which had relapsed despite the constant use of a miniature kinesiphone.

Dr. WATSON-WILLIAMS (Bristol) felt that the absence of gross catarrhal conditions did not necessarily exclude infection as a determining cause; and quoted, in analogy, cases of optic neuritis or atrophy associated with a sphenoidal sinusitis which was quite latent.

AUDITORY RE-EDUCATION.

By F. F. MUECKE, M.B., B.S., F.R.C.S.,
Assistant Surgeon, London Throat Hospital.

MR. MUECKE said that of the 36 cases treated 1 was cured, there was definite improvement in 3, improvement but relapse after treatment in 10, and no change in 22. Two of the "re-education" machines were tested, and the speaker had been associated with a third. The instruments were complicated and ingenious from the electrical and physical standpoint. The objectives aimed at were: (*a*) The production of sound vibration from 80 to 3,500 per second; (*b*) the control of the intensity of the sound; (*c*) regularity in the emission of the sound wave; (*d*) regulation of the waves to each ear separately; (*e*) vibration of the drum by the sound waves and transmitted vibration by the air cushion in the meatus. Each sitting lasted from three to five minutes, and if after fourteen consecutive sittings no improvement occurred the treatment was not continued. The cases tested consisted of old suppurative otitis with large perforations of the membrane or with adhesions and scars, oto-sclerosis, chronic middle-ear catarrh, and various forms of nerve deafness. In patients with old suppurative otitis no benefit was obtained from the treatment. In oto-sclerosis temporary relief of tinnitus was obtained but no improvement in hearing resulted. In early chronic catarrh improvement in hearing or tinnitus was obtained in nearly every case, but no more than what could be got by the use of the Eustachian catheter and less than that which resulted from the use of pneumomassage; relapse was usual. In late chronic catarrh similar findings were reported. In nerve deafness no benefit whatever resulted, showing that "re-educators" were useless when the labyrinth was affected. As a result of his experiments, Mr. Muecke concluded that what little benefit was obtained was referable to the mechanical effect of the vibration. The solitary case of cure was one of neurasthenic deafness.

In conclusion, he expressed the strong opinion that the treatment should not be resorted to until the older and more orthodox methods had proved useless.

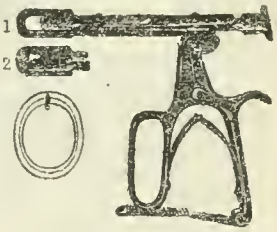
Dr. MACKENZIE BOOTH described a method used by Dr. Maurice, of Paris, of combining diathermy with the use of the "kinesiphone," his instrument for the "re-education" of hearing. Dr. Booth had been using the kinesiphone for five months, and reported that manifest improvement in hearing resulted from its use, but sufficient time had not yet passed to enable him to estimate the permanence of the benefit.

Dr. WILLIAM HILL (London) said Mr. Muecke had, by work on auditory re-education, rendered a signal service, not only to the profession, but also to that section of the lay public who were obsessed with a leaning towards quackery.

THE HAEMOSTATIC TONSIL GUILLOTINE.

By WM. HILL, M.D., and G. J. F. ELPHICK, M.D.,

THE history of tonsil operations was reviewed from the time of Celsus onwards, especially with regard to the methods of avoiding serious haemorrhage. It was urged that, for clearness, the terms "total," "subtotal," and "partial" removal should be used instead of "tonsillotomy" and "tonsillectomy." The various guillotines and guillotine methods resolved themselves into two distinct groups—Physick's method for partial removal, and Whillis's or Sluder's for total removal; the authors gave a clear description of these in detail. The principle of the Elphick haemostatic guillotine was that it possessed two blades. The first was blunt, and crushed the tonsil stump, being held in this closed position by a catch. The coagulation period of the patient's blood having been previously ascertained, the guillotine was left *in situ* for a little longer than this period. The second, sharp blade, working parallel to the first and between it and the luxated tonsil, was then closed to cut off the latter without disturbing the crushed stump. The blood lost hardly amounted to more than a smear in some cases.



1, Crusher open. 2, Crusher closed.

Sir W. MILLIGAN, on the point of nomenclature, said he looked upon a complete enucleation as leaving nothing, in the faucial bed, except the superior pharyngeal constrictor.

Dr. MACKENZIE BOOTH deprecated unnecessary complications in guillotines.

Dr. WATSON-WILLIAMS approved of O'Malley's guillotine, fitted, in addition, with a grasping handle instead of a thumb-sliding blade.

Mr. O'MALLEY claimed that with his guillotine the average loss of blood was only a fraction over 3 drachms. The slot of the frame was filled with lead, into which the blade was driven home; the lead need not necessarily be renewed until after 500 operations. The D-shaped opening gave more space for encompassing the tonsil.

Dr. HILL, in reply, admitted that the haemostatic guillotine was expensive. A simpler and cheaper instrument was contemplated by adding, to the ordinary Mackenzie guillotine an additional blunt blade with a crushing edge.

THE INTRANASAL OPERATIVE TREATMENT OF FRONTAL SINUS SUPPURATION.

By P. WATSON-WILLIAMS, M.D.Lond.,
Lecturer on Diseases of the Nose, Throat, and Ear, University of Bristol.

IN frontal sinus suppuration, whenever operative measures were called for, an efficient intranasal operation was preferable to external operation save when there was bony necrosis

or osteomyelitis, or when ocular or other serious complications were present. After a historical survey of the methods adopted for operating on the frontal sinus through the nose, the clinical anatomy of the fronto-ethmoidal region was described. Stress was laid upon the limitation of operative measures to the outer side of the vertical plate of the middle turbinal, since by keeping in this region the danger of wounding the cribriform plate was avoided. The method of operation followed by Dr. Watson-Williams consisted in clipping away the agger cells and "anti-conchal" ethmoidal cells with suitable forceps as far as the nasal crest. Then the anterior ethmoidal cells lying behind or above the fronto-nasal duct, including the bulla ethmoidalis, were removed, their thick partitions being broken down. Graduated bougies were next passed through the widened fronto-nasal duct into the frontal sinus in order to estimate the width of the duct. The bony boss in the anterior wall of the duct was smoothed down with a suitable raspatory, and after that the anterior end of the middle turbinal was removed. The amount of operative removal of bone varied with each case, but the object to be attained was the formation of a naso-frontal passage sufficiently roomy to drain the sinus freely and to provide for easy lavage. Details of 51 cases operated on in this manner were related.

Sir WILLIAM MILLIGAN doubted whether Dr. Watson-Williams's operation would prove to be devoid of danger in the hands of average operators. He asked whether any comparison had been made between the results obtained by the extra-nasal operation and those obtained by the intra nasal.

Dr. WILLIAM HILL said that he had recently employed Dr. Watson-Williams's bougies in the intra-nasal operation on the frontal sinus, and had found them of great service.

THE DIFFICULTIES AND DANGERS OF EXPLORATORY PUNCTURE OF THE ANTRUM OF HIGHMORE.

By A. BROWN KELLY, M.D., D.Sc.,
Surgeon for Diseases of the Nose and Throat, Victoria Infirmary, Glasgow.

EXPLORATORY puncture of the maxillary antrum was usually made through the outer wall of the nasal cavity under the inferior turbinal. In doing so when the nose was prominent and the anterior wall of the superior maxilla sunken, the puncture should be made further back than usual, otherwise the antral cavity might be traversed by the trocar and cannula, and the tissues of the cheeks infected.

Occlusion of the ostium of the antrum by swelling of its lips or by polypi might prevent perflation of the cavity; the application of cocaine and adrenalin, or the removal of the polypus, might obviate the difficulty. No attempt at forcible perflation should be made, as fatalities had thereby been produced. Even simple puncture and washing out of the antrum had been followed by alarming symptoms, and, indeed, in some rare cases, by death. Cases had been reported in which such disquieting events as apoplexy, transient hemiplegia, abscess of the cheek, hystero-epilepsy, cyanosis and dyspnoea, with or without syncope, had followed this trivial operation. Disturbance of vision affecting the eye corresponding to the antrum which had been washed out, had also been recorded, and this Killian attributed to reflex contraction of the central artery of the retina. The same authority ascribed the occurrence of fatal syncope after puncture of the antrum to vagus irritation. Two cases of fatal air-embolism experienced by Bowen had led that observer to advise that perflation should be avoided, and only washing out practised. Dr. Brown Kelly had himself encountered a case in which air seemed to pass into the jugular vein—fortunately without any harm resulting. It was supposed that the point of the needle had penetrated a vein in the pterygo-maxillary region. The tendency on the part of some authors was to refer these accidents to the action of the local anaesthetic, but Dr. Kelly was strongly of opinion that there was no evidence in favour of this view.

Attention was directed to the similarity of the accidents to those known to attend at times upon puncture of the pleural cavity; in neither instance could it be said that any satisfactory explanation of the occurrences had been given.

Mr. T. JEFFERSON FAULDER, in order to prevent cellulitis, advised that air should be blown through the cannula before any attempt at washing out was made, for if the point of the cannula was lying in the soft tissues instead of in the antrum, then the formation of emphysema—not a serious accident—advertised the error and the patient was saved the risk of the injection of septic fluid into the cellular tissues. He detailed a case in which a patient, after the antrum had been punctured, was seized with epileptiform convulsions which ushered in a fatal illness. In this case the event had probably nothing to do with the puncture, as the patient had previously shown signs of nervous disease. Nothing to account for death was, however, found *post mortem*.

Mr. SOMERVILLE HASTINGS, after experiencing several cases in which collapse had followed puncture of the antrum and perflation, had made it a rule always to move about the cannula after its insertion in order to ensure that its point was in the antrum. He agreed with Dr. Brown Kelly that many of these accidents were due to the trocar traversing the antral cavity.

Dr. OLIVER ST. JOHN GOGARTY recommended the use of strong solutions of cocaine as less liable to absorption from mucous surfaces than weak solutions.

Mr. J. S. FRASER said that he had never seen any of the serious symptoms described by Dr. Brown Kelly; this he attributed to the fact that in Dr. Logan Turner's clinic perflation of the antrum was not practised. After puncture the cavity was at once washed out.

Dr. MACKENZIE BOOTH, in like manner, had never seen any serious sequela follow, and agreed with the last speaker in deprecating the blowing of air into the cavity.

Dr. L. H. PEGLER pointed out, with reference to the theory that ascribed these accidents to vagus irritation, that there was no direct anastomosis between the vagus and the trigeminus. The nerve connexion between the antrum and the heart should more correctly be referred to the sympathetic nerves by way of the carotid plexus.

Dr. WATSON-WILLIAMS drew attention to the advantages of the suction method of exploring the antrum which he had devised. He had used it in hundreds of cases without any untoward results.

LATENT EMPYEMATA OF THE NASAL ACCESSORY SINUSES.

By OLIVER ST. JOHN GOGARTY,
Dublin.

OUT of 300 cases of disease of the maxillary antrum operated upon, 250 were of a chronic nature, and the majority of the patients complained of nothing more definite than "catarrh." The symptoms in the cases detailed by the author were such that without actual puncture and irrigation of the antrum, the existence of disease in that cavity would have been entirely unsuspected. For this reason it was maintained that no examination of the nose was complete without the washing out of the antrum of Highmore on each side. The speaker concluded by making a vigorous protest against the operative injury of the inferior turbinal body, which he believed was followed several years later by the loss of what he called the "air-taste" in the nose.

Mr. J. S. FRASER had never known any harm result from the removal of the anterior end of the inferior turbinal. Indeed, without this step in the operation on the antrum the ventilation and free drainage of the cavity could not be secured.

Dr. J. W. KILLEN held that the removal of the inferior

turbinal was unnecessary if the antro-nasal septum was resected to a low level.

Dr. WATSON-WILLIAMS considered Dr. Gogarty's paper of great value in directing attention to a group of nasal affections which frequently escaped detection.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

SUBCUTANEOUS INJECTION OF OXYGEN IN SEPTIC AMPUTATIONS.

SOME of the most disappointing cases in the present war are the compound fractures. Partly owing to the impossibility of giving early and effective treatment they arrive at a base hospital, or even a more distant centre, very seriously infected. Varying with the nature of the fracture, the size and character of the wounds, and the length of time that has elapsed, there may be merely local sepsis and sloughing, cellulitis far beyond the proximal joints, or extensive gangrene may have already set in. As has so frequently been said in the surgical literature of war, each case must be treated on its merits, but the principle may be laid down that the surgeon's duty is to save as much as possible. It is questionable if it is doing a man a service to disarticulate a limb at the hip or a right arm at the shoulder. It is often worth while giving such a man the chance of a more useful limb by such measures as abundant injections of oxygen both above the apparent limit of infection and deeply into the tissues nearer the wound, and free incisions and drainage.

In any case it may be said with fair confidence—and I appeal to the experience of many others to confirm me—that it is reasonably safe to incise through tissues evidently involved in a process of severe infection, as indicated by obvious signs of comminuted fracture with a black and gaping wound, oedema, and cellulitis. A large injection of several litres of oxygen with Bayeux's instrument into the stump during the operation, or soon after it, will go far to assure a satisfactory result. The flaps can be rapidly formed and very loosely sutured; they need not be left altogether unstitched.

It may be thought that oxygen is not easily obtainable; but since the oxyhydric flame has been so much used in motor and other industries every small town has its cylinders of oxygen. Even if Bayeux's instrument (which accurately measures the amount and regulates the rate of the injection) be not available, a simple system of the oxygen bag adapted to a tube passing through some dilute antiseptic solution can easily be organized.

My points, then, are:

1. Be economical in lopping off limbs.
2. Do not hesitate, in aiming at the preservation of tissue, to cut in deeply infected areas.
3. Drain freely.
4. Inject oxygen abundantly—till there is widespread emphysema. It is not toxic and it will be absorbed in twenty-four hours.

Our experience here as well as in other parts of France make it unnecessary to illustrate these principles by the details of special cases which are of daily occurrence. A recent instance is that of one of our patients now convalescent:

E. C., aged 25, a French soldier of the —— Infantry regiment, wounded in the trenches near Dixmude by an exploding shell which fell a few yards away. Though wounded at 8 a.m. on Saturday, November 21st, it was not till Tuesday morning that he reached the base hospital. In the interval he had been carried on a comrade's back for several kilometres, passed most of one night in a horse ambulance and another in a train. Though he had been dressed several times the shattered fracture of both bones of the leg and the wounds leading to them were very gravely infected, a red blush of cellulitis extending above the knee. I amputated through the knee-joint, pus welling freely from my incision, stitched the flaps loosely together, draining freely and the same day injected about 3 litres of oxygen gas well above the dressing in the upper part of the thigh. Like many other similar cases the wound is healing perfectly.

Malo-les-Bains. A. A. WARDEN, M.D.

A SERIES OF SEVEN THOUSAND ANTITYPHOID INOCULATIONS.

IN view of the attention which is being given to the question of antityphoid inoculation at the present time, both in the medical press and in a certain section of the lay press, the following notes of a series of cases may be of interest. In this communication it is intended to demonstrate not only the utility of the measure in the prevention of the disease, but also to point out how very trivial is the inconvenience caused, and how absolutely devoid of risk the operation is when ordinary precautions against sepsis are taken.

The observations are based on some 7,000 inoculations performed in an alien concentration camp in England where typhoid fever had already broken out, nine cases having occurred at intervals of a few days during the previous three weeks.

Although the sanitary conditions were good and the cases were isolated as they occurred, it was difficult to control with any degree of certainty the further spread of the disease, as prisoners were arriving daily from overseas—in many instances from areas already infected by typhoid. It was all the more striking, therefore, that not a single case of typhoid developed after the inoculations had been carried out.

The average number inoculated daily was about 400, those who had been in closest contact with the patients being done first. The vaccine employed was that prepared at St. Mary's Hospital, and the doses were 500 million and 1,000 million organisms at intervals of ten days. The site of inoculation was for the first injection the forearm and for the second the pectoral region. The usual technique was employed, the skin being painted with tincture of iodine and the needles sterilized either by boiling in water or by hot olive oil—a rapid and most satisfactory method. Inoculation was optional, but it is very satisfactory to note that over 85 per cent. submitted themselves to the first injection and over 60 per cent. had the second.

The reactions after the first injection consisted of a local redness and oedema for the first twenty-four hours, which rapidly subsided. There was no case of high fever and the general reaction was never more than a rise of 1° F. in temperature, with slight malaise. In no single instance was it necessary for the man to give up his ordinary camp duties and working parties carried on light work uninterruptedly. After the second inoculation there was practically no reaction, local or general.

Enteric fever has already broken out in France, and it is of vital importance that everything must be done to check its spread. The value of inoculation has been proved again and again. Is it not unfortunate, then, that the liberty of the press should be abused by the circulation of false reports calculated to influence our soldiers against inoculation, which may result in the loss of thousands of lives and the impairment of our military efficiency? It becomes the duty of every medical man to demonstrate the falsity of these reports, and to use his influence to counteract them.

I wish to thank the commandant of the camp for his permission to publish these notes.

D. GORDON CHEYNE, M.D., D.P.H., R.A.M.C.

A SUBSTITUTE FOR THE WASSERMANN REACTION.

IN the BRITISH MEDICAL JOURNAL for April 5th, 1913, I tried to show, as the result of some research work on surface tension, that syphilis can be treated satisfactorily by the subcutaneous injection of distilled water, and the cases then published have been corroborated by others equally interesting and important, and at the present time there are patients undergoing the treatment successfully at the Union Infirmary, Swansea.

Following up such a successful issue of a treatment arrived at on theoretical considerations, I decided to compare the response of healthy and syphilitic blood to various solutions, including one of ammonium chloride which has the unusual effect of raising the surface tension of distilled water.

In all these experiments it is important to have all the reagents pure and the glasses clean, for otherwise any impurity will negative the rise that ought to take place.

After using various strengths of the solution, I found that one of about 12 per cent. was the most satisfactory.

My method of procedure is as follows: I clean the lobule of the ear with petrol, prick it and draw off in a haemocytometer pipette a sufficiency of blood—that is, up to the 1 mark, and fill up the remainder with a 12 per cent. solution of pure ammonium chloride in distilled water. The blood and solution should be thoroughly mixed, and *at once* a drop should be placed on the slide and examined under the microscope forthwith. Delay in this case, as in all other things, is dangerous, for as soon as evaporation begins to take place the ammonium chloride tends to crystallize out, and the test is worthless.

Examined in this way the red corpuscles show a marked change, for in healthy blood the darker centre tends to contract into an irregular mass, whilst in syphilitic blood the darker centre seems to expand almost to the circumference. The effect is due to the different response to the altered surface tension caused by the presence of the ammonium chloride solution, and to the altered osmotic condition associated therewith.

Naturally there are gradations in the results from complete contraction to the point when doubt arises, and if in doubt use mercury, preferably in the colloidal form, combined with subcutaneous injections of distilled water.

My test takes, at the outside, three minutes, and can be done at a nominal cost by any medical man, whereas the Wassermann is a little more expensive, and outside the powers of the general practitioner.

Swansea. G. ARBOUR STEPHENS, M.D., B.S., B.Sc.Lond.

ON

MEDICAL AND SURGICAL PRACTICE IN HOSPITALS AND ASYLUMS.

THE LONDON HOSPITAL, E.

A CASE OF TUBERCULOUS ANEURYSM OF THE ABDOMINAL AORTA WITH RUPTURE INTO THE DUODENUM.

(By E. A. TOZER, M.B.Lond., M.R.C.S.Eng., L.R.C.P.Lond., late House-Physician to the London Hospital.)

A WELL-BUILT single man of 32, who had been a diver in the Royal Navy for eleven years, was admitted to hospital on September 12th, 1913, fourteen months after he had been invalided out of the service.

History.

Eighteen months before admission there had been a gradual onset of diffuse abdominal pain passing back to the loins. The pain, at first felt only at night, gradually increased in severity until the patient could get no rest by night or day. It was of a throbbing, gnawing character, made worse by recumbency, relieved by sitting up. He improved under medical treatment. Three months before admission there was a recurrence of all the symptoms. There was nothing noteworthy in the previous history or the family history. Venereal disease was denied.

Condition on Admission.

In the abdomen was a visible, expansile, pulsating tumour, about three inches long and two inches wide, situated just above and to the left of the umbilicus, in the course of the abdominal aorta. The pulse was 118 and regular. Both femoral arteries were thickened, and the impulse in them forcible. The radials were synchronous, and the stroke and tension moderate. There was marked pulsation at the sides of the neck. The apex beat of the heart was felt in the fifth space just external to the nipple line, and the impulse was forcible. The second sound was accentuated, especially over the aortic area.

There were no symptoms pointing to derangement of the digestive, respiratory, nervous, or urino-genital systems, and a routine physical examination of these systems showed nothing abnormal. The temperature was 98.8°. The Wassermann reaction, tested independently and on different dates by Dr. P. N. Panton and Dr. P. Fildes, was found to be negative on each occasion.

Laparotomy was performed by Mr. F. S. Kidd on September 16th, 1913. He found a large aneurysm of the abdominal aorta which involved the greater part of the vessel, so that any operative interference with it was not considered practicable.

The patient was subsequently transferred to a medical ward under the care of Dr. Percy Kidd. Rest in bed and the adoption of other medical measures soon considerably relieved the symptoms. The pain would disappear for days at a time, and when present was slight. The pulse decreased in frequency to an average of 88. The apex beat of the heart was in the nipple line. The appetite was good, and the patient felt quite comfortable in bed. On October 12th, 1913, whilst lying quietly in bed, he had sudden profuse haematemesis, followed by collapse and death two hours later.

Post-mortem Examination.

The body was well-nourished and developed. There was a wide-mouthed, saccular aneurysm, measuring 8 cm. by 4 cm., full of laminated clot, on the front of the abdominal aorta, below the orifice of the superior mesenteric artery. The neck of the sac extended above to within 2 cm. of the coeliac axis artery, and below to within 2 cm. of the bifurcation of the aorta. The aorta was extensively scarred and wrinkled in the neighbourhood of the coeliac axis artery, and there were succulent thickenings in the ascending arch of the aorta. The third stage of the duodenum contained a perforated ulcer 4 cm. long, and it was seen that the aortic aneurysm had ruptured at the site of this ulcer. A tongue of clot projected into the ulcer from the aorta.

Caseous tubercles measuring up to 2 cm. in diameter were found in a matted mass of lumbar glands. Smaller tubercles and a few calcareous nodules were found in the coeliac, pancreatic, and iliac glands. Caseous tubercles up to 3.5 cm. in diameter were found in the inguinal, mediastinal, axillary, supra-clavicular and cervical glands.

The lungs showed evidence of tuberculosis in a caseo-calcareous nodule in the apex of the right upper lobe, and a subpleural calcareous nodule at the hilum of the same lobe. Calcareous nodules were found in the right bronchial glands and in the gland at the bifurcation of the bronchi. A moderate degree of alveolar emphysema was present.

The heart showed hypertrophy of the left ventricle, and weighed 11 lb. 2 oz. There was a slight degree of atheroma at the base of the great vessels arising from the aortic arch.

The kidneys showed large areas of focal fibrosis in the interlobar portion of the cortex, and tuberculous endarteritic nodules. The stomach and intestine were filled with blood clot. The testicles showed simple atrophy; there was no fibrosis. Permission was not obtained for an examination of the head.

Microscopic Examination.

(*a*) *Lumbar Lymphatic Gland.*—Sections showed caseous tubercles. Sections stained by two methods for tubercle bacilli showed thin, rod-shaped, acid-fast bacilli with beading.

(*b*) *Abdominal Aorta (above the Aneurysm).*—Sections showed a tuberculous aortitis. The intima was greatly thickened, and mainly composed of collagenous fibres with some wavy fibres of elastic. The lamina was not quite intact. The media was markedly thinned and its elastic fragmented. There was a diffuse fibrosis replacing muscle and elastic, but no wedge-shaped scarring as is seen in syphilitic aortitis. The media was also slightly vascularized, and there was some infiltration by lymphocytes. The adventitia was somewhat thickened and fibrosed. A lymphatic gland in the neighbouring fatty tissues showed tubercles and caseation.

(*c*) *The Aneurysm.*—Sections through the edge showed a similar extreme degree of fibrous intimal thickening. The media was very thin, and also showed fibrous scarring. On following it down the side of the aneurysm, the media was found to be entirely destroyed and replaced by the dense, laminated, fibrous tissue which formed the wall of the aneurysm. At a point proximal to the total destruction of media there was a vascular area with lymphocytic infiltration. On the intimal side of this, projecting into the thrombus, was a nodule of tuberculous granulation tissue containing giant cells. The dense fibrous tissue forming the wall of the aneurysmal sac blended with the adventitial fatty and fibrous tissues. Another section cut from the anterior wall of the aneurysm showed some fibrin clot which was invaded by a granulation tissue containing Langhans's giant cells. This bunch of granulation tissue was seen to be breaking through the remnant of the fibrous wall of the aneurysm. A few shreds of elastic in this fibrous wall indicated the position of the media. In the surrounding fibrous tissues there were large areas of caseation and tuberculous granulation tissue.

(*d*) *Kidney.*—Sections showed tuberculous arteritis with periarterial caseation.

This is the first case of aneurysm of the aorta due to tuberculous changes that has been discovered at the Pathological Institute of the London Hospital.

The *post-mortem* examination and subsequent pathological examinations were carried out by Dr. G. B. Bartlett, the Assistant Director of the Institute.

I wish to express my indebtedness and thanks to those who undertook the various clinical and pathological investigations in this case, to Dr. Percy Kidd for permission to publish it, and to Dr. H. M. Turnbull, the Director of the Pathological Institute, for allowing me access to the pathological report.

Reports of Societies.

ROYAL SOCIETY OF MEDICINE.

Pathological Section.

A MEETING was held in the laboratory of St. Bartholomew's Hospital on December 1st. Dr. LAZARUS-BARLOW read a paper and gave a demonstration touching on his recent work as to the *Effects of radium rays on different kinds of epithelium*, when used in different quantities for varying periods, the total dose, however, always being kept constant. There was a marked difference in activity of the squamous and columnar epithelial cells when submitted to the same dosage. He said radium activity could distinguish better between the various tissue cells than could the ordinary histological methods of examination.

Mr. MACKENZIE WALLIS demonstrated the use of the *Polarimetric method in the detection and estimation of the protective ferments in the blood*. The method of preparation of the various tissue peptones was given. The value of this method as an aid to diagnosis was illustrated by reference to investigation upon the serum of pregnant women in cases of eclampsia and of chorion-epithelioma. The technique of isolating the active principle of the test was described; the results tended to show that such observations were of value not only in simplifying the test but also with reference to improvements of the dialyzation method. The addition of a specially prepared barium sulphate suspension was found sufficient to isolate the active principles, and the actual polarization readings were increased tenfold.

Dr. ANDREWES brought forward a case of *Thyroid metastases in the humerus* of a woman, which histologically differed from other cases recorded in that the histological picture resembled that of exophthalmic goitre and did not contain any colloid. He also showed a case of a growth which he held to be a *True myeloma* which had grown on the periosteum of a humerus at the site of an oblique fracture, which antedated the tumour by some years. This he thought could be explained on the view that at the time of injury some marrow cells had got displaced beneath the periosteum and then took on an independent growth.

Professor S. G. SHATTOCK and Dr. L. S. DUDGEON read a paper entitled, *Wound inoculation in carcinoma, with experiments upon the action of local cytocides as a means of dealing with it*. After referring briefly to the heredity, the infectiousness, and contagiousness of carcinoma, they dealt with autoinoculation and wound infection, and concluded with a detailed account of a series of experiments made upon mice with the object of ascertaining what substances might be of practical use in killing cancer cells accidentally implanted upon the face of a surgical wound. Autoinoculation was an example of autoplastic grafting. There was no evidence that carcinoma ever arose from the transference of cells from one individual to another; that was to say, the disease was not isoplastically engraftable. The transference of the disease to the human subject from the lower animals (heteroplastic grafting) was something of which even the possibility might be ignored. The first record of autoinoculation was that by John Hunter, the specimen illustrating which was in the museum of the Royal College of Surgeons. The patient was a woman, who had a tumour at the verge of the vagina, which, when seen, was about the size of an egg. To quote from the Hunterian MS.:

> But by this time it had contaminated the parts that had been continually in contact with it, which was the back end of the right labium, both externally and internally; with the inside of the left labium, and the angle uniting the two, . . . as the surfaces seemed evidently to have become diseased in consequence of being in contact with the others . . .

The growth was a squamous-celled carcinoma. It was in this position, indeed, that the occurrence of autoinoculation by contact had been most frequently observed. The cells might, however, be transferred to a more distant spot on a free surface, and there reproduce the disease, either on the cutaneous and more often a mucous surface. Transference in the course of the œsophagus, or from the kidney to some lower part of the genito-urinary tract, could be illustrated from clinical and pathological observation. Distant infection of the peritoneum in gastric carcinoma had been fully described and explained by Virchow (*Krankhaften Geschwülste*, lect. iii). The bilateral infection of the ovaries in similar cases, now a well recognized event, might be connected with certain peculiarities in these organs. The surface of the ovary was covered with germinal epithelium. Whether this played a selective and a biologically adjuvant part was worth consideration and experiment; but, setting this aside, the normal rupture of the Graafian follicle exposed the interior in a peculiar way to the access of free carcinoma cells that may happen to lie on the exterior. In plexiform sarcoma (the so-called malignant endothelioma) of the pleura, the complete involvement of both the parietal and pulmonary surfaces was probably largely due to autoinoculation facilitated by the incessant movements of respiration. Nor was the part possibly taken by the stomata of the serous membrane in intercepting such detached cells to be lost sight of, and the fact that the stomata themselves opened into subjacent lymphatic vessels, by the permeation of which further extension would be facilitated. The duplication or triplication of carcinoma of the large intestine received, perhaps, its best explanation as being a result of autoinoculation. The well-known observation of L. Hermann had shown that in normal circumstances shed epithelium constituted an integral part of the intestinal contents. The authors had found that the contents of the normal vermiform appendix not infrequently consisted of a long cylinder of white friable material, which the microscope showed to consist solely of shed columnar epithelium. If the free surface of an ordinary columnar-celled carcinoma of the colon were gently rubbed in the recent state with a cover glass, the smear would be found to contain plaques of well-conditioned carcinoma cells detached by this simple process. It could hardly be doubted that from such a surface during life a shedding of epithelial cells and their displacement by the passage of the firmer intestinal contents was something in constant progress. Had the possibilities for evil which all this implied been realized, not only as a potential cause of distant autoinoculation, but as an explanation of some cases of local recurrence after excision of carcinomatous tumours of the colon? It was a significant fact that whilst duplication of carcinoma of the large intestine (caecum and pelvic colon) was not so very uncommon, no instance was known in which carcinoma of the stomach had been accompanied with one of the colon. The reason might be that any viable cells detached from a gastric carcinoma, supposing that they escaped digestion in the stomach, would not escape tryptic digestion in the small intestine, whilst in the large gut the digestive process was at an end. The grosser forms of cell infection in surgical operations were now unknown amongst surgeons of the higher rank—cases, for instance, of stitch cancer. But in lateral pharyngectomy for carcinoma, when the diseased structures were reached through the side of the neck, and had to be delivered through the wound, the risk of inoculation was not easily avoided. In the removal of carcinomatous organs, again, when the disease had perforated their capsule, the same risk arose. Nor could one fail to perceive that the area around any carcinoma of a mucous membrane, seeing that it might be contaminated with shed and scattered cells, should be sterilized before excision as much against cells as against bacteria, and that the free surface of the neoplasm should be treated in the same way, with the object of preventing the possible implantation of living cells on to the faces of the surgical wound. The authors, before detailing their experiments made with solutions to test their cytocidal powers, referred to their investigations carried out in order to ascertain (1) whether

any antagonism subsisted between tuberculosis and carcinoma; (2) whether a selective anticarcinomatous cytolysin could be raised by the (heterologous) grafting of mouse cancer into the rabbit; and (3) whether the hypertrophied liver of mice suffering from grafted mouse cancer was cytocidal for mouse cancer. In regard to the last, it had been observed at the Imperial Cancer Reseach that in carcinomatous mice the liver underwent hypertrophy. The authors mixed the minced liver with an equal bulk of carcinoma pulp, and after incubation at 37° C. for twenty minutes the material was injected subcutaneously into a series of mice. The result was negative; that was to say, the growth of the grafted material was not inhibited; and it confirmed Dr. Bashford's conclusion to the effect that as the hepatic overgrowth was proportionate to the size of the tumour, and was not inversely to its retrogression, the hypertrophy could not be concerned in hindering growth but promoted it. The attempt of the authors to raise a cytocidal serum was made by the weekly intraperitoneal insertion into the rabbit, of mouse carcinomata (twenty in all); the rabbit was then bled periodically from the ear, and the blood serum used upon mice in which grafted carcinoma had commenced to grow; focal necrosis of the liver occurred in several, but in those which survived no curative effect ensued, and if any necrosis was induced in the tumour it was not of practical avail in stopping its growth. The view that an antagonism existed between tuberculosis and maliguant disease originated with Rokitansky. Their concurrence was not common. The two diseases might be present simultaneously in different organs, or they might coexist in the same, either in different positions, or intermingled at the same spot. The authors had experimentally tested the supposed antagonism, upon mice, but with a negative result. Living tubercle bacilli (of human source) were mixed with the mouse carcinoma pulp, the mixture being then inserted subcutaneously; no hindrance resulted to the growth of the tumours. This experiment was repeated upon another series of mice, and the insertion followed by the subcutaneous injection of Koch's old tuberculin, but no check to the growth of the tumours took place. Concluding with inorganic cytocides, the method of experiment adopted by the authors was to submit the tumour pulp to the action of the solution to be tested—usually for five minutes—to pipette off the fluid, and, after washing the pulp, to inject it subcutaneously into a series of mice. If no tumours grew, the solution was proved to be an efficient cytocide. The following proved to be inefficient:

Distilled water, colloid mercury, colloid selenium, hydrogen peroxide, radium emanation (freshly prepared emanation from the Radium Institute, allowed to act 15 minutes), taurocholate of soda in distilled water (highly lytic for red corpuscles).

The solutions which proved quite efficient were:

Sulphate of zinc, 1 in 240 (2 grains to the ounce); liquor hydrargyri perchloridi, 1 in 500 or 1 in 600 (1 in 1,000 was ineffective); aqueous solution of iodine 2 per cent. or 1 per cent.

Such coagulants as alcohol and carbolic acid would, of course, be cytocides as efficient as mercury perchloride.

SECTION OF OPHTHALMOLOGY.

AT a meeting on December 2nd Sir ANDERSON CRITCHETT showed a patient with *Small optical iridectomies in a case of lamellar cataract.* He described the operation, which was initiated by his father fifty years ago, and narrated cases so treated in which the result was very permanent. Mr. W. H. JESSOP spoke favourably of the procedure, which he had himself carried out with great success, in adults as well as in children. In one case, operated upon twenty-two years ago, the result was as good to-day as at the time. Dr. ANGUS MACGILLIVRAY (Dundee) said he had done the operation described several times. The results by removal of the lens were not so satisfactory in lamellar as in other forms of cataract. Mr. LESLIE PATON showed a case which he regarded as *Mikulicz's disease*, and gave his reasons for the view. Colonel R. H. ELLIOT referred to a case of the disease which he published in *The Ophthalmoscope*, that of a Hindu woman, aged 49. Removal of the lacrymal glands not only improved the appearance, but was followed by subsidence of the other glands. The tissues removed presented a close resemblance to the appearance of round-celled sarcomata. Mr. ROBINSON exhibited a case of *Iridocyclitis*, and Mr. EASON one of *Bilateral temporal hemianopsia*, to illustrate the importance of taking the fields of vision in every case of optic atrophy. The patient became so blind that he had to be led about. His fields had not then been tested. He could make out moving objects and lights on the nasal side only. The onset of blindness within six months was unlike the history of the optic atrophy of tabes, and Mr. Eason thought he might have pituitary tumour. Within a month of taking thyroid there was remarkable improvement of vision. He still took the extract, for if he went long without it he noticed a relapse. The sella turcica was somewhat enlarged. Mr. HAROLD B. GRIMSDALE, in opening a debate on the *Necessity for an exact definition of blindness*, stated that the importance of defining, if possible, the condition of blindness had long exercised the minds of those concerned in the teaching and maintenance of the blind. On the recently appointed Committee on the subject, he was the sole representative of ophthalmic surgery; he had, therefore, invited this section of the Royal Society of Medicine to try and arrive at something like unanimity on the question. Many members of the profession whom he had asked found it impossible to define the status of a blind child otherwise than was done in the Act of 1893—namely, that for educational purposes a child was considered blind who was too blind to read the ordinary school books. Yet all children who did not come into this definition were not fit for the ordinary school—for instance, subjects of high myopia. It was desirable to have some rule for evaluation as a guide in each case. For certain employments a greater acuity was needed than for others. Those having no perception of light were but a small proportion of those ranked among the blind, while among children the proportion was still smaller. The blind persons in the United Kingdom numbered about 27,000, according to the census, but these figures could not be accurate. The ratio of the totally blind to the economically blind was about 1 to 9. The causes of economic blindness in children differed considerably from those in the adult. In the former, the chief trouble was loss of central acuity from corneal conditions; while in adults disease of the optic nerve, with contraction of the visual field, operated chiefly. There was a tendency to make the standard of vision too high, and thus throw a large number of children into the "blind" class. Once labelled "blind" a child was liable to be drafted into a blind workshop. The co-education of the blind and the seeing was one of the most interesting experiments which had been conducted; the blind child was first started in a special school until he had mastered the elements of Braille writing and reading; then he took his place among sighted children in the universal school, and often competed successfully with normal children. Between the "blind" school and the normal school there should be a third school for children who had such visual defect that they could not be taught by the aid of the blackboard. His suggestion was that a distant acuity of $\frac{6}{60}$ should be taken as the highest limit of vision for a blind school child. Those whose vision was better than $\frac{6}{24}$, unless otherwise recommended by a medical man, he would send to an ordinary school. All special schools should be inspected at least once a year, and the vision of each child tested and recorded. After dealing with the question in relation to various trades, Mr. Grimsdale, in conclusion, suggested the appointment of a subcommittee to deal with the question in all its bearings. Mr. ROCKCLIFFE said that during thirty years he had examined and admitted into a blind school large numbers, and his decisions had not been questioned. He divided cases into (*a*) blind, (*b*) partially blind. The latter were those who were able to differentiate fingers at a greater distance than 3 ft. There should be a clear distinction drawn between capacity for ordinary school education and for technical education. A good broad distinction was those who could count fingers at 3 ft. and those who could not. Dr. ANGUS MCGILLIVRAY said that for industrial purposes so-called blind people could be divided into three classes: (1) Totally blind, those who had no perception of light; (2) practically blind, those possessing perception of light, but unable to take part in industrial occupations owing to marked impairment of vision; (3) the partially

blind, whose defect prevented them obtaining employment in ordinary sighted workshops, their vision yet being such as to disqualify them from entrance to a blind institution. Thirty per cent. of the inmates of blind institutions belonged to the category "partially blind." Mr. BISHOP HARMAN contended that there was only one exact definition of blindness, the dictionary one—"want of sight." But the term was used to include many varieties of partial blindness, and for those that definition was sought. Vision was a complex act; acuity, field, mobility, mentality, and effects of difference of lighting, habit, and custom, all took a share in the sensation. It was not possible by any sufficiently simple definition to gather up possible varieties any one of which might constitute partial blindness of serious order. Any attempt to pass a definition of blindness drawn in professional terms, to operate through the Legislature, was doomed to failure, and was liable to be altered out of recognition. He advocated a certification of blindness by two independent and duly approved medical men, who should be required to state their opinion, and the facts upon which that opinion was based; such opinion being subject to the scrutiny of the medical officer of the proper authority. Mr. RICHARDSON CROSS held that if a child's sight was such that it could not attend the ordinary school, some other arrangement for its education must be made. There were blind schools for those nearly blind, and intermediary schools for myopes. Anything brought forward to deal with the infirmity in adults would not influence the good work being done for the children. He thought the registrar would accept two classes. One would embrace those who had no more than perception of light; the other either Snellen's types, or finger-counting, the latter for preference. Any one who could not count fingers at a greater distance than a yard should be regarded as practically blind. Mr. HOLMES SPICER contended that the persons to decide this question should be expert ophthalmologists, not lay members of a county council. The PRESIDENT pointed out how well qualified this section was for giving expert advice on such a matter, which was of the first importance. Miss ROSA FORD showed a case in which *an eyelash pierced the lid border backwards*. Mr. HOLMES SPICER showed a case with *Angioid streaks*.

The PRESIDENT made sympathetic reference to the death on the battlefield of Mr. Angus Macnab, an active member of the Section, and proposed a resolution of sympathy with his family, which was passed.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

AT a meeting on December 4th, Mr. BISHOP HARMAN read a paper on the *Cure of squint*, confining his attention to fixed squints in children. He said that in a school of 1,000 children no less than eighteen were squinters, and that girls were nearly twice as much affected as boys. In 1,400 children seen at a children's clinic on account of poor vision 199 were squinters; the incidence in these cases was from 100 in the years 4 and 5, to 5 in the 14th year. Of these 199 cases 166 were fixed convergent squints, 16 alternating convergent, 8 divergent; the rest were associated with disease of the eyes. He proceeded to trace the evolution of the binocular vision, and the profound effect it had had on the form of man; he maintained that the upright position and "his fair large front" were directly associated with the evolution of vision. The effect on the brain was similar, for the area of visual cortex was incomparably greater in the hunting animals than in the hunted, and greatest of all in man. The balance of the eyes was maintained by the fusion faculty of the brain; if that were poor then squint would ensue even though the eyes were good. Defects of the eyes were adjuvant factors. In not a few cases there was a strongly hereditary tendency to squint. Treatment could be put into three grades:—(1) Balancing the vision of the eyes: First there must be correction of any error of refraction by retinoscopy, next exercise of the vision of the squinting eye. (2) The awakening of the fusion faculty: This had been first attempted by Erasmus Darwin in 1778, and modern practice was of the utmost value in ascertaining the power of the brain to resume control under favourable condition. (3) Operation: The *rationale* of this step lay in the fact that squint of any duration was associated with changes in the tendons, and that these acted as insuperable obstacles to the resumption of brain control. In convergent squint the internus tendon was shortened and thickened, the externus thinned and lengthened. If a true cure was to be effected—that is, the restoration of binocular vision—then, if stages (1) and (2) of the treatment failed to effect a speedy cure, operation should be done before time had stereotyped the vicious effects of the squint. If that time had passed, then they were no more than beauty doctors intent on removing an ugly cast. The advocate of early and regular operation must be prepared to present an operative procedure which was both expeditious and reliable. And in this connexion he showed photographs of the steps of his combined operation for lengthening the contracted tendon and shortening the stretched tendon. He maintained that effects could only be secure when both the affected tendons were adjusted; indeed, it was the only method whereby the full mobility of the eye could be secured without subsequent deformity. His operation for shortening a tendon—"Subconjunctival reefing and advancement"—was performed as follows:

The tendon is not cut or exposed to view. The upper and lower edges are cleared by two button-holes cut through the conjunctiva and capsule. The tendon is freshened by a rasp. Special forceps of simple design are then passed into the button-holes to secure the tendon. The movement of the forceps folds the tendon. The reef is sewn up or advanced, as the case indicates, and then the antagonist is lengthened by a graduated partial tenotomy.

The steps of the reefing advancement are as follows: (1) The eye is secured with an anchor stitch placed at the limbus in the axis of the tendon to be shortened; (2) the position of the tendon is noted, it is pointed out that there are well-defined surface markings and colour differences; (3) the button-holes are cut above and below the tendon close to the canthus; (4) the tendon is lifted and both surfaces rasped with the instrument provided; (5) reefing forceps are applied, adjusted to the extent of the shortening required, and rotated; (6) the reef is sewn up by a double over-and-over stitch; and (7) the reef is advanced by fixing the stitches into the limbus.

Then the antagonist was lengthened by the "jigsaw" operation. The tendon is exposed, secured in "director forceps," which checked bleeding and gave a guide to the incisions. Three cuts were made athwart the tendon, the middle extending two-thirds from one edge, the lateral each one half across from the other edge. The tendon thereon extends lengthwise without loosing its attachments or alignment.

The author showed how the cuts could be varied to secure vertical deviation also. Results: Of the first 100 serial cases, including the early experimental operations, the results obtained after the average interval of nine months were binocular vision 4, straight 36, error less than 3 degrees 22, less than 5 degrees 23 (these make 85 per cent. successes), error 10 degrees (since corrected) 9, over that 4, relapsed six months after operation 1, during severe keratitis 1, and over-correction found six months after operation 1. He had now almost completed the second hundred cases, and the percentages of successes were still higher. One of the advantages of this combined operation was the power for nice regulation of effects. This was of the utmost importance when operation had to be done early to save binocular vision, for at an early age a general anaesthetic was commonly needed, and the operator was entirely dependent on his own judgement and technique.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF MEDICINE.

AT a meeting on November 20th, the President, Dr. J. A. LINDSAY, read an address on the *Threshold of disease*, which was published in the JOURNAL of December 5th (p. 955). After some remarks by the Chairman (Dr. WALTER SMITH) Dr. O'CARROLL said he was not at all sure, when all was said and done, that the early diagnosis of disease had not as many disadvantages as advantages. He thought there might be much to be said for keeping going on as long as possible and try to be guided by nature rather than getting every ill diagnosticated. As to pulmonary tuberculosis, he did not think one should wait until physical signs in the lungs were found before suspecting phthisis and treating the case as such. Dr. DRURY

suggested that in children with rheumatism the diagnosis of the condition of the heart was not the greatest difficulty, but rather to diagnosticate the rheumatism. Dr. MOORHEAD said a distinction should be drawn between the early diagnosis of phthisis on which one would start treatment and the early diagnosis from which statistics might be compiled with fairness. Dr. PARSONS mentioned cases of gastric cancer where there was progressive gain in weight by the patients. The autopsy in one such patient who died of a ruptured heart showed quite extensive cancer of the stomach. Dr. CRAIG also spoke, and Dr. LINDSAY replied.

SECTION OF SURGERY.

AT a meeting on November 13th, the President, Mr. F. CONWAY DWYER, President of the Royal College of Surgeons in Ireland, read an address on *The treatment of perforating gastric and duodenal ulcers*. For many years he had given up the use of lavage, which he believed to be responsible for many untoward results. He removed the septic fluid with large swabs, and relied on pelvic drains for getting rid of any fluid left behind. Although formerly he was of opinion that gastro-enterostomy should be done, if the patient's condition permitted it, in the cases to be detailed he had performed that operation only in one case, and then only because the perforation was so large and the edges so friable that when the rent was sewn up he feared the lumen of the bowel was too much narrowed. Details were given of 12 cases which had been under his care during the past fourteen months. Eight made a complete recovery, 3 did not survive operation more than a few days, and 1 died a fortnight after operation from pneumonia. Mr. H. STOKES showed a case of *Regeneration of ruptured sciatic nerve*. The case was one of arthritis of the hip-joint accompanied by intense pain. Operation was performed for excision of the hip-joint, in the course of which the sciatic nerve was accidentally ruptured. The suturing of the nerve was done about three weeks after the excision. Two and a half years had elapsed since the operation, and the case was shown to demonstrate the amount of regeneration that had taken place. The small loss of sensation now present in the case was most remarkable. Mr. W. C. STEVENSON showed cases treated by *Radium emanation needles*: (1) A case of malignant polypus removed by Mr. Graham about the end of May, 1914. The whole of the anterior wall of the antrum was afterwards removed for recurrence, but the tumour began to grow again. The patient came under Mr. Stevenson's care at the end of June with a large gland on one side and a smaller one on the other, accompanied by considerable proptosis of the eye. He inserted six needles into the gland, and two or three days afterwards six more needles were put in, and left in for about twenty-four hours. When the needles had been inserted four times the tumour showed considerable diminution. A recurrence of the swelling having taken place six weeks after the first application, further needles were applied, and the patient showed the effects of the radiation. He had put on a considerable amount of weight. Although he had to take hypnotics regularly before the treatment, since the radiation was started he was able to do without them. (2) Case not yet treated. Opinion was invited whether it was suitable for surgical interference. He intended to bring the patient forward again after treatment. (3) A case pronounced by Professor McWeeney to be epithelioma of the palate. The ulcer now seen was only about half of its original size. Mr. A. BLAYNEY read a paper on *Intestinal stasis*, discussion on which was postponed.

HARVEIAN SOCIETY OF LONDON.

AT a meeting on November 26th, Dr. H. CRICHTON MILLER opened a discussion on *Drug habit and its treatment by modern methods*. He said the treatment consisted of two stages: (1) The withdrawal of the drug, which could be carried out largely on group lines; (2) the "cure proper," or a reconstruction of the patient's whole mental and nervous dispositions on natural lines. The latter could only follow strictly individual indications. Having spoken of the causes and of the procedures employed in the withdrawal of drugs, he discussed the "cure proper." This was closely related to the etiology. He spoke of the parts played by psycho-analysis and hypnotic suggestion in this part of the treatment. Dr. J. F. WOODS recounted his experiences of the treatment of 25 cases of drug habit. Mr. CAMPBELL WILLIAMS, Dr. R. H. COLE, Mr. ERNEST CLARK, Dr. W. H. WILLCOX, and Dr. J. A. DAVIDSON also took part in the discussion.

Reviews.

PREVENTION OF DENTAL CARIES.

IN the second edition of PICKERILL's *Prevention of Dental Caries and Oral Sepsis*[1] a considerable amount of new material will be found. Of this the part dealing with the anatomy and physiology of mastication is of most interest, since the author concludes that the use of tough food leads to narrowing of the jaws. The note on thyroid insufficiency and dental caries, though, as the author admits, too inconclusive to allow of deductions being drawn from it, yet shows the fallacy of concluding that the sound condition of the teeth was necessarily the result of administration of thyroid extract.

In a new chapter on alimentary secretions considered as a whole, the author claims to show that "what is best for the mouth is best for the remainder of the alimentary tract," "and, further, that from the point of view of initiating and maintaining normal alimentary secretions and peristalsis, the mouth is the most important part of the whole canal." He quotes experiments by Pawlow, Starling, and others, using the "miniature stomach" and pancreatic fistulae, showing that foods which stimulate or fail to stimulate salivary secretions have a similar effect on gastric or pancreatic secretions. He claims that gastric, pancreatic, and biliary secretions, just as salivary secretion, depend to a very large extent on the sensitiveness of a reflex arc of which the glosso-pharyngeal part is common to all. He has experimented on dogs with a miniature stomach and an oesophageal fistula, and finds the digestive power of gastric juice about doubled when the food introduced into the miniature stomach has first been masticated by the dog and passed through the oesophageal fistula—that is, when the glosso-pharyngeal reflex is excited. Rabbits fed on boiled food neutralized with Na_2CO_3 gave remarkable results. Young animals died within six months and only developed to a quarter or a half of the weight of controls. Starch and calcium were excreted in excess in the faeces. The salivary glands were under-developed and polyneuritis supervened. In this connexion he points to the habitual use of alkalis for indigestion, as tooth-powders and in "artificialized foods and drinks." Furring of the tongue he ascribes to viscid saliva following excessive use of alcohol, tobacco, sugar, and salivary depressants such as tea, bread and butter, and alkalis. He holds, further, that the endotoxins of the stagnant material produce a definite effect on the sympathetic system, a stimulation which explains the cold extremities, the pale grey complexion, the headache, the constipation, the anorexia, and the furred tongue of oral sepsis and alimentary toxaemia. There is a vicious circle, beginning with diminished oral stimulation, running through oral and intestinal sepsis, and joining up again at the salivary glands in a further diminished secretion due to action on them of the sympathetic system irritated by toxins. The remedy is a more liberal use of weak organic acids. The author's enthusiasm, perhaps, carries him too far, but he presents an interesting case for his views, and the appeal for clean-tasting food is timely.

In discussing saliva, the action of ptyalin as a cleanser of the mouth in contradistinction to its supposed use as a digester of starch is strongly urged. There was no more undigested starch in the faeces of a rabbit whose salivary glands had been excised than in those of a normal control. The use of ptyalin is to convert insoluble starch granules into sugar, which is washed away, thereby preventing stagnation and sepsis.

The author has given up the view that adenoids are produced by a contracted jaw, and now thinks they are part of a vicious circle. The vicious circle includes a contracted mandible, which Grevers has shown by

[1] *The Prevention of Dental Caries and Oral Sepsis*. By H. P. Pickerill, M.D., Ch.B., M.D.S.Birm., L.D.S Eng. Second edition. London: Baillière, Tindall, and Cox. 1914. (Demy 8vo, pp. 386; 74 figures. 12s. 6d. net.)

numerous measurements is not the case. The author also overlooks the fact that adenoids are a post-nasal and not an intra-nasal condition.

Throughout the book the author's original thesis—the value of weak acids in the prevention of dental caries and oral sepsis—is ably supported, but the claim which has been adduced by others—that stickiness of the food is a more important factor than absence of acidity and sapidity, and is quickly capable of swamping these factors when present—is overlooked.

The whole book makes interesting, often fascinating, reading, and those who possess the first edition will not regret the outlay on the second.

SIR ALMROTH WRIGHT ON PNEUMONIA.

SIR ALMROTH WRIGHT has republished in a book, entitled, *Pharmaco-therapy and Preventive Inoculation applied to Pneumonia, etc.*,[2] the report on his own and his collaborators' researches, directed to the discovery of means to check the ravages of pneumonia among the native labourers employed in the Rand mines, which originally appeared in the *Lancet*. The report is not confined to a bare recital of the investigations in South Africa, since out of 124 pages 26 are devoted to a discussion of the logical methods appropriate to the study of therapeutic problems, and 6 contain a full bibliography of the author's scientific publications. These additions certainly do not detract from the interest of the book.

The general result of Sir Almroth's experience is to suggest that prophylactic inoculations of pneumococcus vaccines are of distinct value. Twenty-four to thirty-six hours' cultures upon glucose blood broth, killed by exposure to a temperature of 55° to 56° C., to which ½ per cent. carbolic was subsequently added, are recommended. A dose of 1,000 million pneumococci, to be repeated after the expiration of four months, is the routine procedure suggested. The *pièces justificatives* of this conclusion are a series of statistical returns derived from mass experiments, in which large numbers of inoculated and uninoculated natives are contrasted. The differences of both incidence and mortality rates between the two groups are considerable in the first two months after inoculation, but subsequently tend to disappear. Sir Almroth justly remarks that the re-establishment of equality does not necessarily mean that, after two or three months, the effect of inoculation has passed away; weeding out of susceptibles, self-immunization, and other factors may have come into operation. The interpretation of these statistics is, however, necessarily difficult, and the reader who desires to form a judgement on the whole problem might do well to supplement his study of Sir Almroth's book with a perusal of Dr. G. D. Maynard's recent report, in which the inoculation returns are examined from a different point of view. We reviewed Dr. Maynard's work in a recent issue (May 30th, p. 1189).

Sir Almroth's discussion of the general principles of immunization on pp. 52–59 is of special interest, and his reasons for insisting upon the view that it is not so much the quantum of vaccine incorporated as the quantum of antigen set free from it in the organism of the patient which is of importance, deserve careful study.

We shall not attempt to criticize Sir Almroth's discussion of scientific methods, which includes a vigorous onslaught upon the statisticians, and evoked at the time of its original publication an equally vigorous reply (Greenwood, *Lancet*, January 18th, 1913). It is hardly necessary to add that the work is composed in the lucid and picturesque style which always characterizes Sir Almroth Wright's publications.

OCCUPATIONAL DISEASES.

To Dr. W. GILMAN THOMPSON[3] belongs the honour of having written the first book on occupational diseases in the United States of America. It is a distinction of which he may well be proud, especially as the work has been well done. The book will serve a useful end. Dealing with the history of occupational diseases in his own country, he points out the backwardness of legislation and how this might be improved. Considering the industrial wealth and the commercial progress of the States, it is astonishing how little America has done in this matter. But the task has been begun, so that within the next few years, having profited by the experience of other countries, she is sure to outstrip them in industrial legislation. It would be advantageous if some classification of occupational diseases could be agreed upon, and also if there could be uniformity in the various States as to penalties imposed for breaking laws. Under the heading of General Pathology and Etiology such subjects are dealt with as tuberculosis and occupation, cancer and occupation, and the influence of sex, age, and exercise. Dr. Gilman Thompson presses, and properly, for the notification of diseases due to occupation.

A review of the book would be incomplete if it failed to take notice of the prevention of these diseases, since it is well known that the author has given considerable attention to prophylaxis. In prophylaxis and industrial hygiene, the kind of work followed, the physique and the home of the workman and his factory environment have all to be considered. The ventilation of factories, for example, is frequently difficult owing to the necessity of excluding outside dust in the manufacture of certain textiles. While, therefore, pleading for the open window, Dr. Thompson maintains that this is not enough to remove toxic gases and fumes. The opening of side and roof windows is always desirable, but the use of electric fans and vertical flues in the walls is necessary also. Too much attention, he thinks, has been paid to the amounts of CO_2 in the air of factories and to hygrometry. Within limits neither of these is a complete test of the fitness of the air for breathing. A chapter is devoted to the hygiene of the workman; details are given as to what he should eat, how he should dress, and the amount of sleep he requires. Rules are given for the cooking of his food. The insertion of these rules, while hardly called for, can do no harm.

Much occupational disease would undoubtedly be prevented if workmen were medically examined before undertaking work. This question was raised some time ago by our own Workmen's Compensation and Insurance Acts, but nothing came of it. No doubt it is difficult to adapt legislation intelligently to the varying needs of rapidly growing industrial enterprises. In some instances it might be well to leave the duty of carrying out of details to factory inspectors; but inspectors vary—they have not all had the same training, nor have they the same experience and method of interpreting the requirements of law. In the United States, as in Great Britain, industrial legislation must be ever changing and ever extended to meet new inventions and new processes of manufacture.

The chapters devoted to toxic metals and their compounds are exhaustive, and cover the ground well. British and other European authorities are freely laid under contribution. The ground covered by the book is extensive. In consequence there is a lack of fullness in the way in which some of the subjects are dealt with, nevertheless in *The Occupational Diseases* Dr. Gilman Thompson has given to the medical profession a book which many will find useful and interesting reading.

NOTES ON BOOKS.

WAR is naturally the dominant note of the Christmas number of *Truth*. The principal literary feature is the Williad, a "potted epic." Jupiter, fearing that the Kaiser's vaulting ambition would lead him to attack Olympus, calls a council of the gods, who decide to defend themselves by a practical application of the maxim *quem Deus perdere vult prius dementat*. Accordingly we are shown Wilhelm of Hohenzollern in the various phases of his madness, as the Super-Statesman, the Super-Amateur, the Super-Bagman, the Super-Hausfrau, the Super-Evangelist, the Super-Nelson, and the Super-Napoleon. Finally he visits Hades where the finger of scorn is pointed at him by Frederick the Great, Blücher, Moltke, Bismarck, and representatives of the true German culture which he has disgraced, and as the involuntary peace-maker among

[2] *On Pharmaco-Therapy and Preventive Inoculation applied to Pneumonia in the African Native. With a Discourse on the Logical Methods which Ought to be Employed in the Evaluation of Therapeutic Agents.* By Sir Almroth E. Wright, M.D., F.R.S. London: Constable and Co. 1914. (Demy 8vo, pp. 133. 4s. 6d. net.)

[3] *The Occupational Diseases: their Causation, Symptoms, Treatment, and Prevention.* By W. Gilman Thompson, M.D. New York and London: D. Appleton and Co. 1914. (Roy. 8vo, pp. 750; 118 figures. 25s. net.)

the nations. The Williad is illustrated by full-page drawings by Mr. Stanger Pritchard, who also contributes a large coloured cartoon showing the horrors of war. Another coloured cartoon by Mr. Roland Hill ("Rip") shows the two Kaisers arraigned in a police court before a bench of neutral sovereigns with the President of the United States in the chair. The whole number is excellent alike in conception and in execution.

The *Medical Directory* for 1915[4] is the seventy-first annual issue of this useful publication. A numerical summary of the medical profession in the British Isles shows a total of 36,656 names. This is an increase of 528 as compared with the number in 1914. The names are arranged in seven sections—London, the Provinces, Wales, Scotland, Ireland, and the Naval, Army and Indian Services. A list of practitioners holding British qualifications resident in other parts of Europe and in North Africa has taken the place of the old section of practitioners resident abroad. This is a saving of space, but we think it will cause a considerable amount of inconvenience. We regard the omission of British practitioners in the Overseas Dominions as particularly unfortunate. There is a separate list of dental practitioners. Mr. W. Oliver Hodges, barrister-at-law, contributes an abstract of the principal laws affecting the medical profession. There are lists of sanatoriums, convalescent institutions, and private asylums which are likely to be useful to the public as well as to the profession. A short account of the principal British and some of the Continental spas and climatic health resorts is given by Mr. Norman Hay Forbes, F.R.C.S.Edin., F.R.S.Edin.

MOTOR AMBULANCE DEVELOPMENTS.

By H. MASSAC BUIST.

THE work of educating the public to some appreciation of the problem of establishing motor ambulance services proceeds apace. It is beginning gradually to be realized, for example, that it is useless subscribing to individual efforts. The collective ambulance organizations officially recognized are receiving a generous response to their appeals for funds, so that there is manifest a tendency to diminish waste of effort. Nevertheless, much remains to be done in this direction, particularly as the old trouble of multiplicity of types of chassis is as pronounced as ever.

NEED FOR STANDARDIZING MOTOR AMBULANCE CHASSIS TYPES.

The fact is, we are learning the business only by degrees and through cumulative experience. To begin with, we had to improvise a motley variety of vehicles. We have now got to the stage when there is at least some attempt to produce ambulance bodies on more or less recognized lines. Now that we have secured large numbers of chassis, however, and that the motor industry has had time to settle down to the new demands created by the war in place of those existing before August, it is time we attacked another basic problem. None of the chassis used for motor ambulances produced in Britain to date have been designed or built for that particular work. We have instead taken one chassis after another of the widest possible variety of types, no one of which was ever designed in the original instance for motor ambulance work. By far the majority of the chassis have been made for pleasure car service. There is little or no similarity between the coachwork accommodation necessary for a motor carriage body and for an ambulance body. This is the prime cause of the difficulty of overhang. Every example that comes to hand, no matter from what company, whether it be an English or a Scottish built vehicle, reveals this same fault; instance the vehicles presented by the King and Queen to the Indian Expeditionary Force. These have the cantilever type of spring, with the driver's seat about midway between the front axle and the mid-length of the rear cantilever springs where those members are attached to the frame of the vehicle. The result is that nearly two-thirds of the ambulance bodywork where the patients are accommodated projects behind the rearmost point at which the cantilever spring is attached to the chassis frame.

ACCOMMODATION OF THE DRIVER.

Unless we are to consider that the prime object in producing motor ambulances is to give an opportunity to motor-car manufacturers to work off chassis which they may have on stock, or to continue making patterns of pleasure-car chassis rather than go to the charges of devising mechanism specially suitable for motor ambulance work, there is, in the light of experience to date, no excuse any longer to continue to accept vehicles schemed on ordinary pleasure or even commercial car lines. In every type of motor ambulance yet produced the driver's seat invariably occupies space that ought to be used for the accommodation of patients. The construction of all the varieties of pleasure-car chassis being employed is such that this is unavoidable, by reason more particularly of the steering column and connexions and of the control levers and pedals.

Yet in the story of the motor car to date we have had experience of something that suggests a line on which chassis might be schemed. I refer to the placing of the driver over the engine, in the manner seen in a large variety of French and German motor omnibuses, and as schemed in the original Wolseley motor omnibus, with the result that for that particular class of service the great advantage of proportionately shorter wheelbase in relation to the number of passengers accommodated was achieved and the great objection of overhang was avoided. If memory serves me right the Austin Company, making a smaller class of chassis intended for private cab work some years ago, also employed this idea of saving space.

Yet earlier in the story of the motor industry we have had examples of putting the engine further back, sometimes midway between the axles. But this has never become commercially practicable, nor does it seem to me to be desirable for motor ambulance chassis, as it would cause heat and undue vibration beneath the patients.

WHY NOT OVER THE MOTOR?

The motor ambulance is a vehicle that is not required to progress at the fast speeds ordinarily needed for touring carriages. There is therefore no inherent objection to placing the driver above the engine, particularly in these days when, if a reasonable price is paid for the vehicle, it can be made so reliable and designed in so accessible a fashion that the engine and kindred details can be got at quite well for such attention as they need.

Therefore in face of the urgent necessity for us to do something to produce a type of chassis that shall really be primarily designed for motor ambulance work, serious consideration must be given to the problem of where the driver is to be accommodated. On all types of motor ambulance produced to date, the driver is in the wrong position for the purpose to be served by the vehicle. The expenditure of money subscribed in future by the public should be controlled on such lines that the motor industry should not be permitted to work off stock chassis. The first and only consideration is the benefit of the wounded. As Lord Kitchener has pointed out, men who have been to the front are very much more valuable to the nation than those who have no experience of war, therefore every additional man whose life is saved and who is restored to health during the campaign is doubly precious to the nation in this time of crisis.

DIFFERENCE BETWEEN PEACE AND WAR CONDITIONS.

Moreover, let us not overlook the fact that a type of motor ambulance which might be most suitable for the average conditions of service obtaining in peace is quite a different sort of vehicle from the one needed in war. In peace, the motor ambulance is called on to deal with cases, as it were, retail; whereas in war it has to deal with them wholesale; in peace the motor ambulance is kept and worked under the most favourable circumstances possible; in war it is neither properly housed nor used under ideal conditions for the mechanism. Therefore the ambulance for war service has to be a vastly sturdier and more powerful vehicle, for it carries greater loads over rougher roads, and every detail of the mechanism must be far more hardy. Indeed, the premium on reliability is incomparably greater for war service than for peace use, because in campaigning the facilities do not obtain for attending to a hundred and one minor details on the stitch in time principle. The car must be hardy, yet it is particularly essential that the machine should embody exceptional degrees of refinement so as to reduce vibration and jarring to the minimum, since this is so essential to the saving of life and suffering.

[4] London: J. and A. Churchill. (15s. net.)

These circumstances practically dictate that the speed of the motor ambulance for active service should be slower than that of the average touring car. We do not want to hurtle the wounded over the roads, bumping and jarring them about, despite the fact that the saving of time between the receipt of an injury and its treatment at the base hospital is one of the prime uses of the motor ambulance. There is to be observed an intelligent compromise between the question of killing your patient in your haste to transport him to a place where he can be treated, and taking a little longer about the business, but depositing him at the destination in a condition in which a serious drain has not been made on his vital forces. Consequently, the most important problem before those concerned with motor ambulance work to-day is that of evolving a special type of chassis.

Problem of Maintenance in the Field.

On the grounds of economy and efficiency there is every reason for following this policy as regards ambulances to be manufactured for future use. At present the wastage and failures in service due to the extraordinarily wide variety of chassis employed represents a margin of at least 50 per cent. that could be avoided by some official action such as that the Government should approve of one special type of motor ambulance chassis designed for that work, and quite unsuitable for touring car or any other use, and issuing that to all manufacturers who are to receive any future orders for motor ambulance vehicles. As various sizes of car may be needed, the scheme of the vehicle might be made in three sizes; though for my part I think two should be the greatest number necessary. This would mean that, no matter from which factory the individual vehicle hailed, and no matter how many had to be sent out to replace losses at the front, the problems of maintenance and of replacing parts damaged in service, and so forth, would be simplified to the extremest possible extent, because it would not matter who the maker of the individual ambulance, any given part needed made by any other maker to the same specification would fit perfectly well as a replacement.

As it is, individual donors of motor cars are only doing half the good that could really be achieved by their generosity, because each will choose the type of chassis for which he has an individual preference when considering the problem of his own private motor car, as instance the numerous six-cylinder chassis that are being offered for work of this sort. While the engine is in its present place and the driver as ordinarily accommodated, there is no gain, but actual loss in using the six-cylinder chassis, because at least half, and usually something like three-fifths, of the frame length of the vehicle is occupied by engine and driver, only the remainder being available for the accommodation of ambulance body work. The engine must occupy the briefest possible over-all length in the chassis frame, and the driver should be accommodated somewhere or other, preferably above the engine, where he will not be using up any part of the frame of the car between the two axles, all which space it is absolutely essential should be placed exclusively at the disposal of the patients.

How to Utilize the Situation.

The longer the campaign progresses the greater the number of motor ambulances we shall need. No mistake could be more absolute than to imagine that we have anything like sufficient vehicles yet. Therefore there is no reason why it should be assumed that we shall have to go through this war with the type of chassis that have been available up to the present. On the contrary, the fact that ever since the outbreak of war some makers have actually been producing types of pleasure car chassis solely for motor ambulance work because they have not enough in stock shows how unenterprising it is to neglect the opportunity thus presented for causing the motor industry to produce a type of vehicle absolutely suitable for ambulance work.

How are we to go about the business? Obviously, the designing staffs of nearly all motor manufacturers are quite capable of evolving very ingenious fresh chassis schemes for the particular purpose in view; but we should only have solved one part of the problem if we allowed each to exploit the special type of motor ambulance chassis he might evolve. Yet to put a check on the use of the wide variety of inventive talent thus available, and, instead, to select some single firm, or even some quite independent designer, for the work would be to miss a hundred and one little practical details, and therefore to produce for the nation's need a chassis inferior to one that might be evolved were there some competition about the business and all the available brains engaged on it.

Employ all our Inventive Talent.

It seems to me that the really practical way to set to work would be for the British Red Cross Society and the St. John Ambulance to agree, in the light of experience in the war to date, as to the power necessary for two classes of ambulance chassis which should be sufficient for the needs. The price at which such chassis should be available, with the understanding that the individual manufacturer would be asked to tender for a minimum of fifty or a hundred machines over a given period, should be indicated by way of assisting the designing department, that they may be able to estimate what materials and degrees of refinement they could embody for the money. All the faults of chassis in service to date should be collected and issued in summary fashion that designers might further learn, not from the experience of an individual vehicle, but from that of all employed, exactly the details of ordinary chassis in use that have failed in service to date.

Individual manufacturers desirous of making motor ambulances should thereupon be required to produce designs within a period of, say, a month, for the designing departments are not ever busy at the moment. The results should be collected and selected. There should then be available an enormous amount of excellent material, and the practical motor engineers of two or three firms should be instructed to embody all the best points in a sort of composite design.

In face of the nature of the work there cannot be a firm in the motor industry of the country that would be so wantonly unpatriotic, as well as unenterprising, as to refuse the services in a consultative capacity of its designers towards so grand a thing for the good of the nation, particularly as there would be a business end to the matter also. When the composite chassis had been schemed, orders should be distributed for them among the manufacturers who had competed and whose work is known to be of a suitable sort.

Problem of Quantity Production.

It may be said that there would be difficulty in placing fifty or a hundred orders with individual firms. But this would not happen if the public were properly educated through the medium of official communications to the general press, pointing out that our present methods are wasteful, and unsatisfactory, and that there is an urgent need for designing special ambulance chassis to accommodate motor ambulance bodies. We must produce special vehicles to standard designs for purposes of future war, and in face of the probable duration of the present war it would be lamentable lack of enterprise on our part to continue merely muddling through as we have perforce had to do to date, but as we need not to an appreciable extent hereafter.

Admittedly even the crudest motor ambulance is a vast advance on the old horse-hauled wagons, which a wounded officer of the North Lancashire Regiment has described from personal suffering as "the wickedest anachronism of all our British war gear—slow, cumbersome, springless, creaking, jolting, with no accommodation in comparison with their size and unwieldiness. They wallow and bump along, an everlasting monument to the inhumanity of their designer." Later in the morning on which his case was being dealt with, there came along "a fleet of motor ambulances, quick, well sprung, and holding twice as many as the old horse wagons. They soon shifted a lot of cases to the railhead."

The point to have in mind, however, is not that any motor ambulance perchance represents a degree of advance, great or little, on the horse-drawn variety, but that such motor ambulances as we have and are at present employing are merely makeshift examples, and in no way comparable with the excellent vehicles which the motor industry of the day has the ability and the resources to

produce, provided the national organizations concerned with the work co-operate on lines which will give the proper direction to the motor industry in general.

Let us have in mind that motor ambulances are needed not only for the British forces, but also for the French and for the Russian, and that the demand for these classes of vehicles must increase to an extraordinary extent, as instance the fact that, starting the campaign with an army of about 186,000 men, the British forces to be in the field by next summer will be increased by anything up to 1,000,000 men. Hence the urgency for ceasing the policy of drift and makeshift, and for substituting one of co-ordination and logical direction in face of the lessons of the war to date.

THE AMBULANCE CONSTRUCTION COMMISSION.

Mr. Henry S. Wellcome, founder of the Bureau of Scientific Research bearing his name, has intimated that the bureau will provide a sum of £2,000 to be distributed in the form of prizes for the best plans and designs of motor ambulances. The functions of the Ambulance Construction Commission, which is being appointed on behalf of the bureau, will be to collect, judge, and report upon such plans, designs, and ideas as may be submitted to it. It is to be of an international character, so that it may obtain information from all sources, even, if it sees fit, from Germany and Austria. The competition will close within six months. This Commission is empowered to arrange for the publication of such designs and particulars as it may approve, or which it may consider meritorious. Apart from the prizes for it, there will be no payments made for plans, designs, inventions and ideas submitted to the Commission. All these are to become public property, so that, when considered advisable, they can be utilized in the cause of humanity. The Commission met last week to discuss such questions as that the design should be for one type of ambulance only; that the specifications submitted by Lieutenant-Colonel James should be accepted, with such alterations as may be necessary; that the last day for the receipt of designs should be June 30th, 1915; that the competition should be open to all nations; and that a subcommittee should be appointed to draw up for the information of competitors a pamphlet embodying the views of the Commission, including the specification of the ambulance required, together with the substance of results already accepted, and to make the necessary arrangements for securing publicity.

THE ORIGIN AND DEVELOPMENT OF THE RED CROSS.

(Continued from p. 965.

GERMANY.

In 1863 Dunant went to Berlin to press his scheme on the attention of the members of the Fifth International Congress of Statistics, which met in that city in September of that year. The fourth section of the Congress was composed of medical officers of the army, who, among other things, discussed the comparative statistics of health and mortality in the civil and military population. Dunant asked for the neutralization of the medical services, a matter which the Geneva Committee had not then considered. His propositions were adopted by the fourth section, and Drs. Boeger and Loeffler, physicians to the King and Queen of Prussia, were charged by these sovereigns with messages of congratulation to Dunant. At its final general meeting the Congress expressed its gratitude to Dunant, and passed a sympathetic resolution. The Crown Prince Frederick, afterwards Emperor, had a long interview with him, and afterwards, at the instance of Queen Augusta, Dunant was presented by Dr. Boeger to General von Roon, Minister for War. The Minister received him with the words, "Ah, ah, you wish, then, to make all our doctors neutral!" As Dunant insisted on the importance of the neutralization of the wounded, the General replied, "We will come to that later." After some minutes of reflection he added, "Of course the neutrality of the doctors and voluntary helpers entails that of the wounded." The cause was won. Von Roon became an enthusiastic supporter of Dunant's scheme, and expressed his approval of a uniform and international flag. Prince Karl of Prussia, brother of the King, promised the co-operation of the Order of St. John of Jerusalem, of which he was Grand Master. It was he who sent Prince Henry XIII of Reuss to represent that powerful hospital association at the Geneva Conference. Count Otto von Stolberg-Wernigerode, later Prince and President of the German Red Cross Societies, who died in 1896, fostered the beginning and promoted the progress of the work in Germany.

From Berlin Dunant went to Dresden, where Baron von Weber and General von Engel procured for him an interview with the King of Saxony. Dunant's account of this interview so well illustrates the combination, simplicity, and steadfastness of purpose characteristic of him that we cannot forbear quoting it:

> Baron von Weber hastened to inform me at the Hôtel de France, where I was staying, that everything was arranged for the audience which was fixed for the following morning, Thursday, October 2nd, 1863, at half-past ten precisely. I went to the Royal Palace. On getting out of the carriage an official of the Palace, who was waiting for me before the entrance gate, took me to a kindly old chamberlain, M. de Gersdorf. The latter, with a quite paternal benevolence, took me by the hand and conducted me across a part of the Castle. We came at last to a little room, very plainly furnished. Before retiring M. Gersdorf said to me, "The King will come in by this door which is in front of you. You will bow three times and wait for him to address you." I followed exactly the instructions of the Chamberlain, conforming to the ceremonial required by etiquette, when His Majesty appeared. With great kindness the King, speaking in French, asked me as to the purpose of my visit. "What can I do for you?" said he. I laid my request before him; then I ended with much earnestness by saying, "Sire, I should be profoundly grateful if Your Majesty deigned to accept the patronage of this work in your states, and if you would be good enough to send a delegate to the conference which will open at Geneva on the 26th of this month." I added that as the result of an interview with the Minister of War at Berlin, I hoped that at that conference the proposal of a general agreement intended to make the wounded soldiers and all those who look after them sacred, would be considered. The King began to smile on seeing my animation, but with an air so kind that I was not intimidated. "I will willingly grant my patronage to so excellent a work," he replied. "But as for sending a delegate, for that I must consult my Chambers." I at once replied with the same respectful animation, "Sire, for a work which is wholly for the sake of humanity, Your Majesty is sure that the Chambers will ratify whatever it may please the King to ordain." The King again smiled. Then, after some questions relative to the project of neutralization, he ended the audience with these precious words: "I will do all I can, for certainly a nation that should not take part in this work of humanity would stand disgraced before the bar of public opinion of Europe."[1]

Dunant that evening wrote to the correspondents he had in most of the capitals of Europe, and soon the various rulers were made acquainted with the result of his interview with King John of Saxony. "Thus," he says, "the cause which I pleaded was won." He attributes the success of his endeavours to get Governments to send delegates to the conference especially to the declaration of the King, none of them wishing to be disgraced before public opinion.

The organization of the German Red Cross Society is described by Professor Antony, of the Val-de-Grâce,[2] and more fully by Surgeon-General W. G. Macpherson.[3] On these articles the following account is based. The German Red Cross Society had in 1905 700,000 members distributed among a hundred local societies, and possessed funds to the total amount of £800,000. There are other bodies, such as the religious orders of the Knights of Malta, St. John, and St. George, intended for rendering voluntary service to the sick and wounded. These bodies are recognized for the purpose because it is understood that they already devote themselves in peace and within the German Empire to the care of the sick and wounded. Under exceptional circumstances permission may be given to others to take part in voluntary aid. Application for such permission has to be made through a high official known as the Imperial Commissioner and Military Inspector of Voluntary Aid, and in the event of approval by the War Office, the society or individuals

[1] *Les Origines de la Croix-Rouge.* Par Ch. F. Haje et J. M. Simon. Stuttgart: Imprimerie de A. Lindhelmer; Amsterdam: Academische Boekhandel, Delsman and Nolthenius. 1903, p. 22 et seq.

[2] *Archives de médecine et de pharmacie militaires*, t. 46, 1905, p. 253 et seq.

[3] *Journal of the Royal Army Medical Corps*, vol. i, July-December, 1903, p. 160 et seq.

concerned are attached to one of the recognized Red Cross territorial societies or to one of the orders of knighthood. Voluntary aid from foreign countries may be accepted under the same conditions, but its sphere of action is confined to the home territory. Finally, it is laid down that voluntary aid will not be permitted to form any independent unit, and its co-operation with the official units is permitted only in so far as it can be dovetailed into the official organization and placed under official control. Otherwise, the regulations state, it will not further but only hamper the administration of the services in aid of the sick and wounded. It must, therefore, submit itself unconditionally to the orders of the military authority and individual representatives of that authority.

In supplementing the regular Army Medical Service, voluntary aid is confined to (*a*) the nursing of sick and wounded; (*b*) the transport of sick and wounded; (*c*) dépôt duties—that is, in stores. This supplementary help must be given in the rear of the fighting force, either in the home territory or on the lines of communication. The employment of voluntary aid in the first line will be permitted only in special emergencies, and with the approval of the Commander-in-Chief. In such emergencies the voluntary aid personnel must be attached to a bearer company or field hospital placed under its commanding officer. It will be seen from this that the organization in the German Red Cross Societies is very elaborate, and that it is in every detail strictly subordinate to the military authorities.

The following is the scheme of work which the regulations lay down as forming the general duties of Voluntary Aid Societies:

(1) The organization of male and female nurses and cooks for duty in military reserve hospitals on the lines of communication and stationary field hospitals. A proportion of the male nurses must be trained as stretcher bearers. (2) Similar organizations of male and female nurses for duty in connexion with the conveyance of sick and wounded from the lines of communication to the reserve hospitals, and also of stretcher bearers in the same sphere. (3) Appointments of individuals trained in merchants' or forwarding agents' offices for the management of voluntary aid dépôts. (4) Collecting and forwarding gifts. (5) Supplementing the military reserve hospitals, either by taking over special branches of hospital management, such as the dieting, laundry work, etc., or by supplying certain portions of equipment such as beds, linen, clothing, kitchen and messing utensils, etc., or by the establishment of special Red Cross Society hospitals; or, finally, by the reception of convalescents into private nursing homes. (6) Supplying information to the relatives regarding the sick and wounded in hospitals, and sharing generally in the duties of the official Central Information Bureau. (7) The establishment of dressing and rest stations at those places along the line of railway where no special provision is made by the regular service. This can only be done with the concurrence of the military director of railways, the committee for sick transport, and the officer commanding the lines of communication. (8) The preparation and equipment of hospital trains out of the Society's own funds, and under its own management and direction. This, however, will only be permitted when the military authorities consider it necessary.

The Prussian voluntary societies rendered great services to the army in the Schleswig-Holstein campaign and in the war with Austria. Under the active direction of Queen Augusta they devoted the years before the Franco-Prussian war to the completion of their organization and the development of their efficiency. In 1870–71 they gave aid to thousands of wounded. Since that time their activity has continued. Besides accumulating large funds and creating great dépôts of sanitary material, they have trained thousands of nurses, sisters, bearers and "samaritans." They supply personnel to work the hospitals, dressing stations, and buffets along the lines of communication, and they place at the disposal of the army numerous transport detachments for the wounded. There are more than 700 of these detachments. Every year, in order to complete their instruction, the detachments of a whole region are gathered together for combined manœuvres. For the purpose of giving practical instruction to the sisters and nurses, the societies also maintain small hospitals, convalescent homes and sanatoriums, and furnish voluntary male Red Cross nurses to the accident stations in the large towns and important factories. The societies of voluntary aid in time of war are an integral part of the medical service, and are under the orders of its chiefs. At their head is an officer with the title of "Imperial Commissioner and Military Inspector of Voluntary Aid." This officer is in constant touch with the Minister for War and the chief medical officer of the army. He sees that their orders are carried out, and transmits the instruction to the delegates and subdelegates at various stations.

In principle their action is limited to the rear of the army and to the home territory. Exceptionally and with the sanction of the General in peace, the societies are allowed to send their transport columns to the front in order to carry away the wounded, and to aid some hospitals with their own material. In such circumstances voluntary detachments are placed under the commanders of medical services and their personnel is subject to the exigencies of military discipline. The chief function of the societies is to form and supply the personnel necessary to the working of the services of evacuation, and to organize numerous war hospitals, dressing stations, and so forth; they receive and distribute voluntary gifts and supply information to the families of the sick and wounded. At home, they assist in the sanitary service of fortresses and auxiliary hospitals.

The Voluntary Aid Associations commence their war duties on reception of the order to mobilize. The Imperial Commissioner proceeds at once on a communication from the War Office to the head quarters of the Commander-in-Chief in the field, in order to undertake the direction of the voluntary aid service with the army. The Territorial delegates get ready as quickly as possible lists showing the personnel and material that is ready for immediate use, along with a statement of the number of persons ready to proceed (1) for duty on the lines of communication with the field army; (2) for general duty with the home garrison; and (3) for duty only in the places where their homes are. The lists are sent to the Imperial Commissioner. The Territorial delegates commence courses of instruction and exercises for the personnel already trained during peace, as well as for those offering their services for the first time. The voluntary aid companies for hospital duties and for duty with sick convoys are equipped and got ready first, and the voluntary gifts and hospital material intended for the army in the field are prepared for dispatch.

According to a table published in the *Journal of the Royal Army Medical Corps* (vol. xi, July-December, 1908, p. 375) the total membership of the German Red Cross Territorial societies was at that time 388,002 persons (94,780 men and 293,222 women). Their funds amounted to £462,350, whilst their revenue was nearly £50,000. There were 53 civilian doctors for the field army, and 460 for an army of occupation. Under the head of "Trained nurses available" were the following: Female helpers 933, voluntary nurses 2,515, of whom 865 were for the field army and 1,650 for the army of occupation; professional male nurses 852, Volunteer Nursing Association 6,988, male nurses 1,255 for field army and 1,092 for army of occupation. There were also 144 unskilled helpers in the Samaritan Society. Under the head of "Field medical units" there is the following: Hospitals to accommodate 11,951; 53 can provide commissariat, etc., of reserve Government hospitals, but 83 only with assistance; 815 sanitary transport columns; 577 rest stations; 518 branches have arranged with families to take in sick and wounded. The total provision is for about 40,000 sick and wounded.

The societies possessed material for three hospital ships and two barges. It had also 147 carriages for hospital trains and 5 for light railways. Besides the Red Cross societies there was the National Society of German Women with 85 parish nursing stations, 69 hospitals, 15 of which were used for the training of Red Cross sisters. In regard to the Knights of St. John and the Teutonic Knights, no statistics were available; but these ancient orders take a practical interest in ambulance work in Germany and Austria.

(To be continued.)

Captain Frank Forrest, killed in action on September 13th, left unsettled estate valued at £1,032.

At a meeting of the Dermatological Section of the Royal Society of Medicine held on November 19th, Dr. Winkelried Williams showed a case of leprosy treated with benefit by a vaccine prepared from the patient's own lesions. Dr. Little had seen improvement take place in a patient treated in a similar manner at St. Mary's Hospital.

THE CHEMICAL CONSTITUTION OF CERTAIN PROPRIETARY DRUGS.

(*Continued from p. 979.*)

THE contraction *B.P.* with date is used for the *British Pharmacopœia*, and *B.P.C.* is used for the *British Pharmaceutical Codex*, 1911.

Camphosan.

This is a name applied to the neutral sanatol ester of camphoric acid or sanatol camphorate. The trade name Camphosan indicates the product of J. D. Riedel A.G., Berlin-Britz, Germany.

Chinosol.

A name given to potassium oxyquinoline sulphonate. It is put forward as an antiseptic and deodorant. The trade name Chinosol indicates the product of Franz Fritsche and Co., Hamburg.

Chinotropine.

A name applied to hexamethylenetetramine quinate. The substance is stated to be of use in the treatment of gout and bacilluria. The trade name Chinotropine indicates the product of E. Schering, Berlin.

Chloralose.

This is a name given to anhydro-glucochloral, which occurs in the *B.P.C.* as Glucochloral. The trade name Chloralose indicates the product of E. Merck, Darmstadt, Germany.

Collargol.

A name given to colloidal silver or soluble silver, which is also known as Argentum Crédé. Collargol is said to contain 85.87 per cent. of silver and a small percentage of albumin, with products of its oxidation. The trade name Collargol indicates the product of Chem. Fabrik von Heyden, Radebeul, near Dresden.

Coryfin.

Defined as the ethylglycollic ester of menthol or menthyl ethylglycollate, and put forward as a succedaneum for menthol in nervous headache, coryza, hoarseness, and pharyngeal irritation. The trade name Coryfin indicates the product of Farbenfabriken vorm Fr. Bayer, Elberfeld, Germany.

Creosal.

Described as a combination of creosote and tannin, sometimes called Tannosal. The trade name Creosal indicates the product of E. Feigel, Mülhausen, Germany.

Creosotal.

This is a name applied to creosote carbonate, which is described in the *B.P.C.* under the latter name. The trade name Creosotal indicates the product of Farbenfabriken vorm Fried. Bayer, Elberfeld, Germany.

Cystopurin.

This is a name adopted for hexamethylenetetramine and sodium acetate. The trade name Cystopurin indicates the product of J. A. von Wülfing, Berlin, S.W.

Dermatol.

A name applied to bismuth subgallate or oxygallate. The trade name Dermatol indicates the product of Meister, Lucius, and Brüning, Hoechst a/Main, Germany.

Diaspirin.

A name given to the succinic acid ester of salicylic acid. It is put forward as an antirheumatic, analgesic, and antipyretic, and is stated to be more strongly diaphoretic than aspirin. The trade name Diaspirin indicates the product of Farbenfabriken vorm Fried. Bayer, Elberfeld, Germany.

Diplosal.

This is a name applied to the salicylic acid ester of salicylic acid, put forward as a substitute for salicylic acid and claimed to be free from untoward effects. The trade name Diplosal indicates the product of Boehringer and Söhne, Mannheim-on-Rhine.

Diuretin.

This is a name applied to theobromine sodio-salicylate, which is official in the *B.P.*, 1914, under the name theobromine and sodium salicylate; it is also described in the *B.P.C.* The trade name Diuretin indicates the product of Knoll and Co., Ludwigshafen-on-Rhine.

Dormiol.

A name given to amylene-chloral or dimethyl-ethyl-carbinol-chloral. It is put forward as a hypnotic. The trade name Dormiol indicates the product of Kalle and Co., Biebrich, Germany.

Duotal.

This is a name applied to guaiacol carbonate, which substance is official under the latter name in the *B.P.*, 1914, and is also described in the *B.P.C.* The trade name Duotal indicates the product of Farbenfabriken vorm Fried. Bayer, Elberfeld, Germany.

Ektogan.

Zinc peroxide is described in the *Codex*, and it is there stated that it is also known under the trade names Ektogan, Dermogen, and Zinc Perhydrol. The trade names Ektogan and Dermogen indicate the products of Kirchhoff and Neirath, Berlin; Zinc Perhydrol that of E. Merck, Darmstadt.

Elarson.

This is a name applied to chlorarsenobehenolate of strontium. It is said to contain 13 per cent. of arsenic and 6 per cent. of chlorine. The trade name Elarson indicates the product of Farbenfabriken vorm Fried. Bayer, Elberfeld, Germany.

Emanosal.

A name given to tablets for the preparation of radio-active, emanation-giving baths, put forward for the treatment of rheumatism, gout and neuralgia. The trade name Emanosal indicates the product of Meister, Lucius, and Brüning, Hoechst a/Main.

Epicarin.

A name applied to beta-oxynaphthyl-ortho-oxy-meta-toluylic acid. It is described as a condensation product of naphthol with cresylic acid, and is put forward as a parasiticide in 5 to 20 per cent. ointment or alcoholic solution. The trade name Epicarin indicates the product of Farbenfabriken vorm. Fried. Bayer, Elberfeld, Germany.

Epinine.

This is a name given to dihydroxyphenylethylmethylamine. Its action is said to be similar to that of adrenalin. The trade name Epinine indicates the product of Burroughs Wellcome and Co.

Estoral.

Described as boric acid menthol ester, or menthyl borate, obtained by the action of boron trichloride on menthol. It is offered for the treatment of nasal catarrh, and a 50 per cent. lactose trituration of it is supplied under the name Estorin. The trade names Estoral and Estorin indicate the products of Zimmer and Co., Frankfort-on-Main, Germany.

Eucodin.

A name applied to codeïn methylbromide. It is offered as a less toxic succedaneum for codeine. The trade name Eucodin indicates the product of J. D. Riedel A.G., Berlin-Britz, Germany.

Eunatrol.

Described as sodium oleate, and put forward as a cholagogue. The trade name Eunatrol indicates the product of Zimmer and Co., Frankfort-on-Main, Germany.

(*To be continued.*)

A BILL is now before the United States Senate providing for the creation of a special division of Mental Hygiene in the Public Health Service. It is said by the *Boston Medical and Surgical Journal* that there is good prospect of its being passed by Congress in the course of the present session, which ends on March 4th, 1915. The duties of the proposed division of Mental Hygiene will be the study and investigation of mental disorders, their causes and prevention. It is believed by the promoters of the bill that with the help of such a division the Government would be enabled to deal more efficiently than it can at present with problems of psychiatry and mental hygiene that may arise in the daily work of the various departments of State, and would also be enabled to do more for the improvement of the treatment of the insane and mentally defective, and for the prevention of mental diseases.

British Medical Journal.

SATURDAY, DECEMBER 12TH, 1914.

THE PROGRESS OF A PEACEFUL CAMPAIGN.

THE concentration of national energy against a visible and tangible foe has for a time overshadowed the steadily progressive campaign against our insidious and elusive enemy the tubercle bacillus, but the provision of means for combating tuberculosis in the various counties proceeds apace. With each succeeding year the medical officers have been able to present reports of work done, or of schemes in progress, which give a comparatively correct impression of the magnitude of the task.

The results achieved vary considerably. Death-rate statistics of pulmonary tuberculosis prove a steady, but not very marked, decline in the mortality per 1,000 in rural districts, but this is not always to be noted in the urban districts and boroughs, although numbers vary considerably from year to year. This is well shown in the report for 1913 presented by Dr. T. Eustace Hill to the Durham County Council.[1] In that county a comprehensive scheme has been formulated for dealing with tuberculous persons, both insured and uninsured. It includes a sanatorium with 240 beds for early cases; hospital accommodation with 160 beds for educational purposes and isolation in various parts of the county; tuberculosis dispensaries, fully equipped for diagnosis and treatment; provision for home visitation and the spread of knowledge by means of lectures and demonstrations. All preventive measures are carried out by co-operation of the local sanitary authorities with the County Insurance Committee. In addition to these, a somewhat new feature has been introduced to deal with cases of surgical tuberculosis in the various hospitals. Many of these cases call for operative interference, and almost all of them for prolonged care. A uniform fee of 3 guineas, payable to the medical officers, and inclusive of a general anaesthetic, has been fixed for all such operations, while a charge of 30s. a week has been established to cover all expenses of maintenance. We understand that the financial arrangement between the Insurance Committee for the County of Durham and the County Council is that the former has entered into a contract with the latter, under which the County Council undertakes responsibility for the treatment of tuberculosis under the Insurance Act. The Insurance Committee has agreed to pay 8d. for each insured person per annum to the County Council, *plus* any unexpended money (that is, from the remaining penny) which may remain over at the end of the year. The sum derivable from this source will probably be quite insufficient to pay for the full scheme, but the County Council considers that with money from the other sources it will probably be able to carry the matter through at a cost to the ratepayers of the county not exceeding £10,000 a year. The probable cost of treatment of surgical tuberculosis in hospitals (other than sanatoriums) is variously estimated at from £6,000 to £8,000 a year, but whatever the sum may be, the County Council accepts responsibility for payment both of the maintenance and surgical operation fees.

These arrangements, and especially the fixation of a uniform fee for operations, are worthy of note. The tendency on the part of the central authorities to utilize the charitable instincts of the medical officers of hospitals has been made very manifest in numerous reports and recommendations that have emanated from Whitehall and Spring Gardens and elsewhere. The services rendered gratuitously to charities supported by voluntary contributions cannot reasonably be expected to extend to State-supported institutions without remuneration, and the example thus set in the County Palatine of Durham may be commended to the authorities of other local areas in which the treatment of surgical tuberculosis has to be undertaken.

Another county report recently issued well illustrates the fact that the organization of a system to deal effectually with a large industrial and agricultural area calls for more than ordinary administrative acumen. Such an area is that of Lanark in Scotland, including as it does the vast industrial population about Glasgow and the mixed community inhabiting the country to the south-east of that city, familiar to all travellers approaching it by the London and North Western and Caledonian Railways. A voluminous report of the scheme that has been developed and of the results that have been obtained, down to the end of the year 1913, has recently been presented to the Local Government Board in Scotland by Dr. John T. Wilson, M.O.H., Administrative Officer of the Tuberculosis Staff.[2]

The aim of the whole scheme is to provide treatment for all forms and stages of the disease and for all classes of the community. For this purpose the area has been divided up into three wards, each fully staffed, with provision for sanatorium, hospital or home treatment, as may be required. Domiciliary visitation has been carried on extensively, and hence the system of tuberculosis dispensaries has only been slightly employed.

A vast amount of statistical information is made available, and a long series of cases is tabulated for detailed examination by any one who has leisure to analyse it. The value of early notification has not yet penetrated into the industrial or bucolic mind in Lanark, and hence a very large proportion of the cases seen come under notice too late. Public education upon this point must of necessity take a long time, but no efforts are spared to keep the subject in the public eye by means of meetings, lectures, and demonstrations. A comparison between the results of home and institutional treatment respectively shows a very marked prepondorance in favour of the latter. The employment of tuberculin, usually of the bovine type, does not appear to have been attended by any brilliant results, and no definite criticisms are offered as to its utility in general.

Dr. Wilson's report as a whole, and the sections relating to individual institutions supplied by his fellow workers, is worthy of a prominent place in the series of publications supplied by medical officers of health in the leading counties. Each of these reports contains a vast amount of practical experience condensed in tabular form, but it would undoubtedly be more useful to the average reader if some uniform system could be adopted whereby comparison could be made between one sanitary area and another in different parts of the United Kingdom.

PATHS OF INFECTION IN ANTERIOR POLIOMYELITIS.

It has been recognized for some years that the minute microbic virus of infantile paralysis, to give its common name to anterior or epidemic poliomyelitis, has a special affinity for nervous tissue. Experiments upon apes have shown that it readily reaches the central nervous system when it is brought into close relation with peripheral nerves—with the sciatic nerve, for example, or the nasal nerves derived from the olfactory lobes of the brain. Flexner and Amoss[1] have recently shown that the virus, when injected into the vitreous humour of the eye, can travel thence to the brain, producing characteristic paralyses in a few days, without apparent injury to the retinal structures.

Other experiments have brought out further interesting points. It has been found that the virus may survive for a considerable period in the interior of the body without producing an infection of the central nervous system; the spleen and bone marrow, but apparently not the kidney, may harbour it thus. Even large quantities of the virus often fail to produce infection of the nervous tissue when administered by intravenous injection; while small or even infinitesimal doses suffice to induce quite constant infection by the intranervous mode of inoculation. There are good reasons for believing that if the virus does make its way from the blood to the brain, it does so by means of the cerebro-spinal fluid; and it may be added that, while it is in this fluid, the virus may be neutralized by intraspinal injections of immune serum. The passage from the blood to the cerebro-spinal fluid takes place by way of the choroid plexus, in which a lymphatic invasion and a widespread infiltration around the vessels are caused by the virus in transit. And it has been proved that an aseptic inflammation of the choroid plexus, such as is caused by an intrathecal injection of horse serum, facilitates and ensures the passage of the poliomyelitic virus through it.

The authors conclude by pointing out that in the main, under natural conditions, it is the upper respiratory mucous membrane that would most often become contaminated with the poliomyelitic virus, and most readily favour its conveyance to the brain. This series of events is determined by the manner in which the virus is thrown off into the air by the patient; by the fact of its presence upon the nasal mucosa even in healthy persons who are in contact with cases of poliomyelitis; and, finally, by the demonstration that it passes, on the whole easily, along the olfactory fibres to the brain, medulla, and spinal cord. This may be regarded as the normal mode of infection in poliomyelitis. But since the virus may reach the brain by way of any nervous channel to which it may gain access, and even, although with great difficulty, from the blood, it is, of course, possible that in exceptional conditions other modes of infection may become effective.

NEW SCHEME OF MEDICAL CERTIFICATION OF INCAPACITY OF INSURED PERSONS FOR WORK.

THE Insurance Commissioners have issued this week a most important Memorandum, 211/I.C., in which the new scheme of uniform certification of insured persons is described. It will be remembered that the form of the certificates to be given to insured persons depends at the present time upon the rules of the various approved societies, and this gave rise to a multiplication of forms and a diversity of requirements that have led to much confusion, legitimate dissatisfaction on the part of the medical profession, and often to hardship to insured persons. The British Medical Association has steadily impressed upon the authorities the necessity for the adoption of some uniform system. As a consequence of the numerous complaints that were made by the approved societies as to the quality of the certification, and by the medical profession as to the anomalies in the present system, the Commissioners have been led to introduce this new system, which will, we believe, be welcomed by the medical profession as a great improvement. But the Memorandum is not merely the announcement of the introduction of a uniform certificate. It deals with many points in connexion with certification of great importance to the profession. We have, for example, a frank recognition by the Commissioners of the impossibility in a certain limited number of cases, of stating the whole truth upon certain certificates; the Memorandum sets out a plan of dealing with such cases, which, while recognizing the delicacy of the position of the medical profession, strives to conserve the interests of the approved societies. We can do no more at the present time than indicate thus briefly the extent and importance of the Memorandum, to which we propose to return at greater length next week. In the meantime, we urge all members of the profession engaged in Insurance Act work, to whom, we understand, it has been sent, to study the Memorandum closely, recognizing that, though it contains some sharp criticisms of the methods adopted by some doctors, it is in great part an attempt to meet grievances which have been put forward on behalf of the medical profession.

A MOTOR THEATRE AMBULANCE FOR THE FRONT.

IN his "Notes and Reflections from the Front," which appeared in the JOURNAL for November 28th, Sir William Collins urged the need of a "field theatre or surgery" as an adaptation of the motor ambulance, with a view to secure the earliest practicable disinfection of wounds with greater care and deliberation than are possible on the open field or in the trenches. This proposal has been in the air for some time, and it is to be hoped will not have to wait, as the motor ambulance did for many years, amid much hostile criticism and more apathetic neglect, before the advantages which it presents are realized and made practicable. Since attention was first called to the matter in the JOURNAL, we have received from the Paragon Thermo-Electric Vehicle Company plans and specifications of an "electric ambulance car," propelled, heated, and lit by auto-generated electricity, which it is claimed can be fitted up as an operating theatre with *x*-ray apparatus ready for use just behind the fighting line. We have also been favoured with copies of *Cooper's Vehicle Journal*, recent issues of which have contained designs of improved motor ambulances for Red Cross work. Here also we find a proposal for transporting *x*-ray apparatus by motor for the purposes of field service. Plans are shown for packing commodiously the dynamo, coil, break, switchboard, etc., tube, and stand into a body mounted on a suitable chassis. We gather, however, that the suggestion here made is for a light-proof tent to be carried in the body and erected on the ground for radiographic work. It would, in our opinion, be infinitely preferable so to utilize the body of the car as to make it serve the purpose of an electrically lit theatre and surgery on the one hand and of a radiographic laboratory on the other. If more space were needed one side of the ambulance could be made to let down and thus afford additional elbow-room. In this connexion attention may also be called to a valuable and suggestive paper which appeared in the *British Journal of Surgery*, vol. i, No. 1, 1913, by Mr. G. H. Colt, F.R.C.S.,

assistant surgeon to the Royal Infirmary, Aberdeen, describing "a portable operating theatre." Mr. Colt's mechanical knowledge has enabled him to devise a singularly compact theatre with fixed operating table and all needful apparatus fitted into a car body of 9 ft. 6 in. by 5 ft. by 7 ft. high. In this case electricity is supplied by a double set of accumulators connected with a dynamo worked from the engine, and the warming is effected by superheated steam. We understand that Messrs. Dennis Bros., who are supplying the motor ambulances to the London County Council, have prepared a complete drawing and specification based on Mr. Colt's suggestion, and that this has been before the War Office for several months. It is really high time that these valuable life-saving and suffering-avoiding proposals took practical shape. It requires the co-operation of the surgeon, the radiographer, the electrician, and the engineer. A little cross-fertilization of the sciences in this case is sadly needed, and it should not be difficult of attainment. When we reflect on the years of persistent advocacy by ourselves and others, against official and obscurantist opposition, to establish the superiority of the motor ambulance, while to-day "the multitude make virtue of the truth they then denied," we cannot but regret the leisurely handling of such questions as these, and marvel at the potency of the *vis inertiae*.

TREATMENT OF RUSSIAN INVALIDS IN GERMANY AND AUSTRIA.

M. CLEMENCEAU'S paper, *L'Homme Enchaîné*, of November 15th, published a protest of Moscow doctors, dated November 3rd, addressed to the whole world, against the treatment of Russian invalids who happened to be in Germany and Austria at the time of the declaration of war. The following passages may be quoted: "What was not our indignation and our terror when we learnt the deplorable state in which our patients in Germany and in Austria found themselves, and to what ill treatment they were subjected? . . . We had sent thousands of patients to the watering places of Germany and Austria in the firm conviction that we were placing them in the safe hands of enlightened doctors, and that our patients would be relieved of their physical and moral sufferings by the science and delicate attention of these practitioners. Never should we have supposed that a time would come when the oath of these doctors and their feeling of professional duty would lose all value. This, nevertheless, is what happened at the time of the declaration of war. Our patients who were surprised by the war when in Germany and in Austria, found themselves in the most deplorable bodily and moral condition. Many of them have died. Their relations and friends in Russia have suffered scarcely less. Our duty as physicians compels us to raise our voice in defence of our patients. The German physicians must answer plainly and tell us if they have taken the necessary measures to relieve the lot of Russian patients, and if these invalids have found the protection due to them in painful circumstances. We await their answer, and demand that they shall insist on the necessary steps being taken to allow Russian patients left in Germany and in Austria, without exception of age or sex, to return to Russia." The address is signed Dr. Maikoff, Moscow, rue Tverskafa, Ruelle Blagovechtchenskj, numero 6. There were complaints some time ago as to the treatment of British invalids detained at German and Austrian watering places, and in at least one particularly pitiable case the intervention of a person very near the All-Highest was invoked. The only answer was that "war is war." From later statements we get the impression that British invalids have been more humanely treated and some have been allowed to return home. But this mitigation of barbarism, dictated as it doubtless is by motives of policy, comes too late. We venture to predict that it will be long before British invalids care to face a German "cure" again.

CARE OF THE FEEBLE-MINDED.

IT was mainly owing to the long and persistent work done by the National Association for the Feeble-minded in stirring up public opinion, culminating in the introduction in Parliament in 1912 of a private bill dealing with the control of feeble-minded persons, that the beginnings were made which issued in the Mental Deficiency Act of 1913. The bill, both in its preliminary stages and after it was placed on the Statute Book, naturally called for exceptional work by the association and its committees. During 1913 Lady Frederick Brudenell Bruce, who had been its president for eleven years, died, and the association has been fortunate in securing the support of H.R.H. Princess Christian in that office. It is interesting to learn from the report for that year that the association, by its own homes and those federated with it, supplied accommodation for no fewer than 3,000 mentally defective persons. The importance of this will be appreciated when it is recollected that there are very large numbers of cases for which the local authorities under the new Act are not called upon to provide, and for the first few years, and especially under the existing abnormal circumstances, they are not likely to go much beyond what is required of them—namely, to provide for defectives who have become criminals, inebriates, the mothers of illegitimate children from workhouse maternity wards, or neglected, abandoned or cruelly treated. It is common knowledge that the local authorities are in great difficulties to find the accommodation necessary for these cases. An important result of the Act to the association has been the division of its work and the transference of the care of mentally defective children living outside institutions to the State-aided scheme formed under Section 48 of the Act—the Central Association for the Mentally Defective—in the initiation of which the National Association took the leading part. The National Association itself can get no share of the Government grant, and it is much to be hoped that its work may not suffer from the loss of the necessary subscriptions. The report contains besides much matter of internal interest to its members and a brief bibliography, compiled by Dr. Shuttleworth, of recent publications in this field.

AN AMERICAN DEPARTMENT OF PUBLIC HEALTH.

A SCHEME for the establishment of a National Department of Health under the United States Federal Government, with a secretary who should be a member of the President's Cabinet, has for years been advocated by the medical profession in America. A bill by which this proposal should be made law has, however, according to the *Boston Medical and Surgical Journal*, twice been defeated by interests which opposed the so-called "doctors' trust." At the annual meeting of the American Medical Association last summer the subject was again discussed, and a resolution embodying fifteen reasons for the adoption of such a measure was passed. Besides ordinary provisions for sanitary protection the resolution included the need of establishing a central organization of such dignity and importance that health departments of States and cities would seek co-operation and pay heed to its advice, and that should influence health authorities, State and municipal, to enact reform legislation in respect of health matters. The National Department would further study the conditions and causes of disease occurring in different parts of the United States; consolidate and co-ordinate the many separate Government bureaus now engaged in health work, and draw up a model scheme of sanitary legislation for the assistance of State and municipal officers. Our contemporary refers to an article in the *Southern Medical Journal* urging the expediency of developing the existing United States Public Health Service into such a department, and the appointment of Dr. William C. Gorgas, Surgeon-General of the United States Army, as its first secretary. But the project does not seem to be destined

to be fulfilled, at any rate in the near future. According to the *Journal of the American Medical Association* of October 10th, President Woodrow Wilson recently issued a legislative programme for the remainder of his period of office. In this he has not included a bill for the creation of a National Department of Health.

THE CORNISH RIVIERA.

THE war must necessarily interfere to a considerable extent with the facilities of travel to health resorts in the South of Europe. Many, therefore, who are in the habit of wintering abroad will be glad to learn that they can get most of the advantages offered by the Riviera without going further from home than the Delectable Duchy of Cornwall. The Great Western Railway has issued a useful and interesting guide-book to the Cornish Riviera. Within easy reach of London, the Midlands, and the North, it has great attractions not only for the invalid but for the sportsman, the artist, and the antiquarian. The booklet contains all information likely to be of use to those who may wish to take refuge in Cornwall or South Devon from the bleakness of winter in other parts of England, and is excellently illustrated.

NEWBURY CONCENTRATION CAMP.

IT was officially announced on December 9th that the Newbury Concentration Camp is to be closed forthwith. Reference to complaints as to the treatment of the interned aliens there was made in the BRITISH MEDICAL JOURNAL of December 5th. These complaints have been proved to be unfounded. The Prime Minister recently paid a visit to the camp, and made inquiries. The open compound is said to have been closed for a fortnight, the prisoners having been transferred to hulks on the South Coast.

THE MEDICAL SERVICES OF THE ARMY.

WE understand that the waiting list of medical men who have offered their services to the War Office has been reduced considerably by recent demands made on it, and that at present not more than about 500 can be said to be available. The age limit is 40, but in special cases medical men may be taken beyond that age.

SIR FREDERIC EVE, whose period of thirty years' service as surgeon and assistant surgeon to the London Hospital terminated last week, has been elected Consulting Surgeon to the Hospital.

OUR BELGIAN COLLEAGUES AT HOME AND ABROAD.

AT the meeting of the Provisional Committee on November 24th, the Chairman of the Council of the British Medical Association said that in order to bring the appeal before the members of the profession generally, it would be sent to the Divisions and Branches of the Association in the United Kingdom. In a circular letter issued by the Medical Secretary on November 28th to the Honorary Secretaries of Divisions and Branches in the United Kingdom, it was stated that the officers of the Association fully realized that the claims on the profession at the present time are very great, but that they believed that this special appeal to doctors and pharmacists on behalf of the Belgian doctors and pharmacists was one to which nearly every member of the two professions would be glad to respond according to his means. It is understood that the Pharmaceutical Society of Great Britain is making a similar appeal through its local branches. It is known that already several Divisions of the British Medical Association have arranged to call meetings, and to appoint committees to raise subscriptions, and at a meeting of the Northamptonshire Division on December 1st it was decided to send a circular to all members of the profession in the area.

The following additional subscriptions have been received by the honorary treasurer; this list does not include any additional subscriptions received by the Irish Committee:

LIST OF SUBSCRIPTIONS (IN ORDER OF RECEIPT).

Third List.

Subscriptions should be sent to Dr. H. A. Des Voeux, 14, Buckingham Gate, London, S.W., and should be made payable to the Belgian Doctors' and Pharmacists' Relief Fund, and crossed "Lloyd's Bank, Ltd." Subscriptions by members of the profession in Ireland may be sent to Dr. T. Percy Kirkpatrick or Dr. C. M. Benson at the Royal College of Physicians of Ireland, Kildare Street, Dublin.

Among those who have recently joined the general committee are the Presidents of the Royal College of Physicians of Edinburgh and of the Royal Faculty of Physicians and Surgeons of Glasgow.

INSTRUMENTS.

The Master of the Society of Apothecaries acknowledges the receipt of surgical instruments, etc., kindly contributed by the following gentlemen since the publication of the last list:

Dr. R. Arderne Wilson, Guernsey.
Dr. W. Horton Date, Barnstaple.
Dr. Pollock, Tiverton.
Dr. W. Habgood, Sutton.
Dr. Leishman, Slough.
Mr. James Watson, Norwich.
Dr. W. H. P. Sheehy, Totteridge.
Dr. J. B. Berry, Keighley.
Dr. P. C. Maitland.
Dr. J. E. Thomas, Bangor.
Dr. G. A. Pirie, Dundee.
Dr. H. A. Des Voeux, London.
Dr. W. J. Harnett, Barnet.
Dr. Leon, Torquay.
Dr. C. J. W. Dixon, Hawick, N.B.
Dr. E. Smallwood, West Norwood.
Dr. A. J. Ballantyne, Glasgow.
C. W. J.

THE WAR.

MEDICAL ARRANGEMENTS OF THE BRITISH EXPEDITIONARY FORCE.

From a Special Correspondent in Northern France.

Enteric Fever.

The extent to which the British troops have suffered either from typhoid or paratyphoid fever has so far been notably small, but it is not certain whether it will be possible to make the same observation a couple of months hence. The favourable points in a forecast are that most of the men sent out during the past six weeks have undergone prophylactic inoculation and that a considerable proportion of the original Expeditionary Force had likewise been submitted to the same precautionary measure; that the general sanitation of the army is conducted on very sound principles and by a very active-minded lot of men; that extreme care is taken to secure that any water served out for drinking purposes shall be free from harmful germs; that there is no dust; that there are no flies, and that for the most part all ranks appreciate the value of hygiene and are prepared to comply with its rules so far as circumstances render this possible. Unfavourable points are that circumstances might arise which would render use of untested water almost inevitable; that it is quite impossible for either men or officers to keep their hands, clothes, or general belongings free from mud and muddy water, and that this mud may be infected with typhoid and paratyphoid organisms. It seems indubitable that some of the trenches at present occupied by the Germans and others occupied by the Belgians and French are infected, and military considerations might render it at any time necessary to move British troops into these same trenches.

Evidence of the condition of the trenches is afforded by the existing state of affairs both at Calais and at Dunkerque. In regard to Calais, a good deal seems already to have been heard in England, but I have seen no statement in regard to Dunkerque. At Calais there is certainly need for activity, but the position is hardly as grave as might be supposed from what has appeared in some of the newspapers. Down to the end of last week the total number of cases did not exceed 150, and the time during which this number accumulated was not ten days, but very much longer. The earliest cases were observed nearly four weeks ago, the patients being the men of one particular battery, which had been fighting near Nieuport; a large proportion of the others belong to Belgian regiments which for some time were unable to leave the trenches; it was impossible to provision them, and they consequently drank unboiled trench water.

Much more serious in some respects is a corresponding outbreak which seems to have begun somewhat earlier among the French troops fighting in much the same area. It was a somewhat sudden outbreak, the men attacked belonging to certain regiments which had only just arrived from quite another part of France. This is much the more important outbreak of the two, partly because in any consideration of either of these outbreaks it should be borne in mind that neither of the towns in question can itself be regarded as an infected area. We owe the presence of cases of typhoid fever in this region to the system adopted in evacuating the sick and wounded on the line between Nieuport and Ypres. The railways subserving this line converge more or less on Dunkerque, and consequently this town is used as a sort of clearing-house for the sick and wounded from the extreme left of the allied line; a certain number are also brought in by sick convoys. In whatever way they arrive, they are all examined at a kind of casualty department established at the station. Occasionally there is a stray British case amongst them, but, practically speaking, the sick and wounded arriving at this town are always either Belgians or French troops, or German prisoners. The Belgian sick and wounded are almost invariably sent straight on to Calais, while all German prisoners, as also the great majority of all the French wounded, are put on board hospital ships for transport to Cherbourg. The remainder of the cases, which consist of wounded men whose condition is grave, or of cases recognized as typhoid fever, are detained at Dunkerque, the wounded being distributed amongst hospitals in the town itself, and the cases of typhoid fever sent to special hospitals established at three small towns within easy reach. There is also a fourth hospital at a considerable distance from Dunkerque and not very far from the British lines, which is in the nature of a large clearing hospital, and has recently, I understand, been utilized for the reception of obvious cases of typhoid fever arising in the trenches in its neighbourhood.

Hospitals for Troops from India.

There are at present three hospitals in the Belgian area devoted to the reception of sick and wounded men belonging to the Indian Expeditionary Force, in addition to a convalescent dépôt, and a fourth is being prepared at Hardelot. Two of these are general hospitals, and the third a stationary hospital. Of the two general hospitals, one recently established at Wimereux, and not yet complete, is for white troops from India as distinct from regiments and units formed of natives; the other two hospitals, both intended solely for native troops, are established in buildings on the edge of the downs above Boulogne. They lie close together, and the general hospital—the larger of the two—has not yet got its full complement of wards and beds. It seems, in fact, not improbable that it will never be fitted up as a real general hospital, and that, so far as circumstances permit, the new hospital at Hardelot will be utilized in preference to both these institutions. The situation of the buildings at Boulogne is rather exposed, and the buildings themselves, though the best available when it was found necessary to make special arrangements for the Indian troops at this base, are not at all easy to render comfortable. The new Indian hospital at Hardelot, on the other hand, is housed in a modern first-class hotel of large size. It is, in fact, considered that when this hospital is ready its occupants will be more happily situated in point of environment than those of any other building utilized in like fashion within the area of the Boulogne hospital base. The convalescent dépôt for Indians at Boulogne lies in a field alongside the two hospitals on the downs that have just been mentioned. It is formed of an array of hospital marquees, but has few occupants. Though this convalescent dépôt is intended for the temporary reception of Indians who have been discharged from hospital as fit again for service in the trenches, it is, I understand, thought better that it should not be used to any large extent until the marquees have been replaced by huts.

Marlborough Camp, Boulogne.

In my previous note regarding the convalescent dépôt, sometimes called Marlborough Camp, Boulogne, I omitted to mention that every morning a number of nurses attend to do any dressings that may chance to be required. This is sometimes the case despite the fact that the majority of all the occupants of this camp are men who have been discharged from one or other of the local hospitals as requiring nothing further in the way of formal treatment. The balance, as has already been mentioned, are the slightly wounded or footsore men brought down by the ambulance trains but not deemed on examination at the casualty department on the quay to require for their recovery more than a few simple dressings or a little rest. These are mainly the men who furnish work for the nurses, though at times, of course, a case requiring dressing may arrive in the camp itself. The men are never idle if the weather is in the least degree decent, and are frequently engaged as volunteer path builders, and other like jobs, in which small cuts and abrasions are liable to occur. They also play football vigorously. During the past ten days the path building and drain digging have made distinct progress, despite the atrocious weather conditions and the fact that all stone used has to be brought from a ruined building which lies some distance away, but serves as a very useful quarry. There are also more skeleton huts to be seen, and to some of them galvanized iron sides are beginning to be fitted. This part of the equipment of the camp is in the hands of civilian contractors, but is making very slow progress, owing to the difficulty of securing labour. The same circumstance is interfering with the subsoil drainage of the general site. The domestic arrangements of the camp are being perfected more rapidly. A camp book-lending

library has been started, and the Y.M.C.A. has provided a second recreation tent and dry canteen. One of the huts is to be devoted to recreation purposes and the rest to—dining-rooms, messes for non-commissioned officers, guard-rooms, bath houses, and the like, and there is a suggestion that the whole of the marquees should be replaced by huts. The new pattern hospital marquees—the four-way tents—which alone are used for sleeping purposes by the men, are warmer and more cosy than huts, and probably quite as capable of standing up against tornados of wind and rain. Those now in place have been tested to the full during the recent bad weather, and withstood windstorms which were whirling into the air paraffin cans and the like. The general appearance of the camp and the ease in running about it must entirely depend on the extent to which it proves possible to cover the whole camp area with broken stone and gravel. It is impossible that this can be done quickly, even if at all, and meantime the camp must look an unattractive place of abode. From a practical point of view, however, it seems to meet the needs of the situation, and an examination of its admission and discharge records suggests that it is in nowise an unhealthy place of residence. Taking, for instance, the last 353 discharges, it appears that 315 were marked as fit for duty either in the firing line or at a base, and 38 as requiring hospital treatment. The stay of the whole 353 men discharged ranged between thirty-six hours and six days, and of the 38 who were sent to hospital only 5 were suffering from conditions which could have been acquired in camp. The 5 men in question were respectively marked tonsillitis, diarrhœa, and pyrexia of uncertain origin (two cases). The diseases for which the remaining 33 men were sent to hospital were orchitis (1), tapeworm (1), scabies (6), impetigo (4), hernia (3), rheumatism (6), wounds (1), frost-bite (2), and haemorrhoids (9). The men suffering from rheumatism and frost-bite arrived in camp in this condition and were forthwith sent out for formal hospital treatment elsewhere. These figures make it clear that about 90 per cent. of the men sent to this camp from the hospitals must be practically fit for duty on their arrival (a view which is supported by their general appearance and the fashion in which they get through their time) and that there is no ground for assuming that among the habitual population of the camp there is any ill-health due to the nature of their environment. The total accommodation of the camp is 1,000, and the average (but daily changing) population during the first six days, 550.

At Calais the hospital accommodation suffices, I understand, for actually existing needs; it would, however, be overtaxed if the stream of cases continued—relatively small though this is at present—and in any case it is considered to be a mistake to bring cases of enteric fever down to Calais at all. Consequently the Belgian authorities propose that special accommodation for cases of enteric shall be provided at La Panne, a place on the sea coast within the Belgian frontier, and within easy reach of the Belgian fighting line. They also desire to arrange for the detention or observation of suspicious cases at a place in the same neighbourhood. From a professional point of view these Belgian authorities seemed to me exceptionally well informed, up-to-date, and active-minded men, and that to enable them to grapple successfully with the situation all that was necessary was a certain amount of monetary assistance. I left Calais, in short, with a strong impression to the effect that probably the best course for the British Red Cross Society to adopt would be to restrict its efforts to assisting the Belgians by placing a certain amount of money at their disposition and leaving them to disburse it according to their own lights. Incidentally, I heard at Calais that Vincent's antityphoid serum had been used in the treatment of a considerable number of cases, and that the experience thereby gained had caused it to be regarded as of much value.

MEDICAL ASPECTS OF SEVERE TRAUMA IN WAR.

[BY A CORRESPONDENT.]

By the above title I wish to imply that a severe wound or severe exposure, or even severe psychic trauma, are of interest from the reaction produced in the injured individual. Such cases are seen by medical men at times unfavourable for the making of any but mental notes, and even what is actually before the eyes is not easily judged of in a quite dispassionate spirit—especially on a first campaign. These facts notwithstanding, it is hoped that the following notes may be of interest.

Wounds and Prolonged Exposure.

At the battle of the Aisne, in particular, we met with a not inconsiderable number of cases in which the wounded had remained where they fell for periods up to as much as three or four days. In a few cases it was even more. These cases when brought to the dressing station were found to be only partially conscious of the nature of their surroundings. After a short time, and particularly after a hot drink or subsequently to a dose of rum, they regained consciousness sufficiently to appreciate what was being done for them, but spoke little or not at all, and were terrible examples of "dumb misery." There was a distinct tendency to muscular immobility, and this was, I believe, due to the fact that they had been very cold for a long time. The odour arising from these cases was quite characteristic, but I was not able to be certain as to its origin. It was certainly not due to incontinence of faeces, but may have been due to urine. Any wound present was septic, and the edges adhered to the clothing. In cases other than head injuries—and even in some of them—the whole picture often changed with great rapidity to one of comparative well-being and contentment within a short time of their coming under treatment. But it must be mentioned that some of these cases had probably laid unconscious for some time and were just recovering consciousness when picked up and brought to us. Except in cases of head injury or of severe injury to the legs, the wounded man manages to crawl to his lines; but even amongst the former classes the sudden and gratifying recovery from a condition of mental and physical stupor was obvious to all.

Amongst really severe cases of head injury—that is, with hernia cerebri and comminution opposite the wound of entry, of which class of case I once saw five in one day—recovery of consciousness was not usual. The following are notes on some of these cases, which I can now call to mind:

(*a*) Two men who exhibited the same type of involuntary movement—namely, the placing of the right hand in the right trousers pocket within a few minutes of its being taken out again. Opposite side of brain no doubt injured; rigidity and paresis of right side.

(*b*) A German, said to be showing the action of the arm in working a machine gun—namely, a circular movement of right arm. I doubt the machine gun hypothesis.

(*c*) A German with continual flexion and extension movements of the right leg. None of the above regained consciousness. The last lived four days after admission.

(*d*) A German, admitted unconscious but who regained enough consciousness to speak to another and to take food. He also died.

(*e*) A German, who actually walked in with the support of an unwounded comrade. (It is noteworthy that they walked to our lines and not to their own.)

(*f*) A German, who remained out about three days calling out to the English to help him. Eventually, at great risk, our men brought him in. In addition to a severe head injury he had both arms broken, but did well, at least until he passed out of our hands.

(*g*) Several cases brought in unconscious who died within twenty-four hours, having shown no sign of recovery. Many of these showed continuous motor agitation, and required mechanical restraint.

All the above had practically the same injury—namely, a wound of entry from which was extruding cerebral substance, often only in very small amount and no wound of exit, but palpable comminution of the skull in a position remote from the entry wound. Most of them had been lying out for one or two days at least. I heard of but did not see one man, a German, who was out in sight of our trenches for some days, and was supposed to be dead. One day he took off all his clothes and staggered in our direction. He lived some days in a state of acute mania.

Insanity and Psychic Trauma.

Considering the stress of conditions at the front, it is wonderful that there were not more cases of insanity; I saw only two, both at the Aisne.

(*a*) A man who had distinguished himself by his bravery. He was brought to the dressing station by two men, and was

then oblivious of the nature of his surroundings, mildly agitated and speaking or muttering continuously. He called to mind the appearance of those who suffer from auditory hallucinations, and these may have been present. He was not violent. I do not recollect whether or no he refused food.

(*b*) A man who had the aspect of profound melancholy which distinguishes most cases of melancholia. He was similarly devoid of initiative, but quiet and gave no trouble. It was not possible in the circumstances to inquire if these cases were hereditarily predisposed to insanity.

Terror (like the unreasoning terror of a child frightened by the dark) was not often seen. It is not the same as "funk," and I would call attention to the following differences: Terror is not abated for some time after reaching a place of safety; it is an unreasoning process, and it is produced by some sudden and unexpected happening. Funk abates in a place of safety unless there is a prospect of having to return to one of danger (terror continues even if the man have a wound which will certainly prevent any further service). Funk is essentially a reasoning process, and in fact depends largely on imagination for its full development, and it has no necessary relation to anything that has happened recently and suddenly. But a man suffering from funk is the mere prone to terror. Of the latter I can give two examples:

(*a*) A certain regiment newly out from home came almost direct to the firing line, and was immediately attacked in force. Ignorance of the ground and of the whole conditions of this warfare were probably largely to blame for the failure of the defence. Many men were wounded and were brought to us. A certain number of these showed what I describe as "terror." They showed a tendency to faint, which was allayed by an assurance that there was no need for them to do so. More than one, if not supported, would have fallen to the floor. They could give no coherent account of what had been happening. They looked at their wounds with a solicitude out of all proportion to their severity or else with an aloofness and curiosity which might have made one think the wounds belonged to someone else. One man stated that he was wounded in the leg, and was enormously excited about it, but on examination no sign of any wound here or anywhere else was discovered. He may, of course, have been hit by some piece of stone or material thrown up by a shell. In the case of officers an exaggerated solicitude for their kit and its safety sometimes took the place of any anxiety about their still undressed wounds—this had reference to articles of kit which they had not brought with them, and which in the nature of things could not be sent for until the more immediate business of attending to the wounded had been seen to. What I have here called "terror" seems to be a sort of temporary insanity—a pathological state.

(*b*) A shell fell and burst amongst a column of men marching in fours along a road which was comparatively safe that is, by comparison with the trenches to which they were going. They had all been in action before. Some eight men were killed or wounded, and one of these—an officer—had three wounds, one of considerable severity. He was extremely agitated, and was only with difficulty persuaded to submit quietly to the necessary dressings; he spoke and called out continuously, but could give no account of what had happened (he was possibly not in a position to know). He proved very quickly susceptible to the influence of morphine. He died from his injuries a few days later.

Possibly cases of "hysterical paralysis," deafness, etc., should be mentioned here, although I am unable to agree with the term "hysterical" as applied to them. They tend to recover gradually without any such treatment as given to hysterical patients. I can only call to mind at all definitely one such case. A physically splendid man was wounded in the shoulder by a shrapnel bullet (apparently). There was no wound of exit, and there was no sign of the bullet. The wound was not deep, and it is probable that the bullet had not stayed in the body. Both legs were paralysed—that is, he was unable to move them. Time did not allow of any prolonged examination, but in the absence of any rigidity or pain in the spine there was no reason to hypothecate a spinal injury. The case was not followed. Deafness and blindness were also met with in other patients, but the writer did not examine any such cases.

Fortitude.

Terror is one of the most distressing phenomena with which the medical man has to deal in war—at least this is my experience—but it has to balance it many examples of extraordinary fortitude. Some cases may be cited:

(*a*) A young officer applied personally to me to ask me to look at his back. This was in the evening, and the officer stated that he had felt a blow "which nearly knocked him off his horse" during the afternoon, and "supposed that he ought to have a dressing on or something of that sort." I had not made any sort of local examination until then. On examination he had a wound over the spine of one of his lower lumbar vertebrae, but no bullet was obvious. There was not unnaturally some impaired mobility. It was the writer's practice to urge all wounded men to "go down"—that is, to leave the firing line for a few days at least—this with a view to avoiding sepsis. This officer refused to do anything of the sort. He is one example of many in all ranks.

(*b*) A private of the Black Watch, who remarked after being wounded for a second time, "This is the second time they've got me, but I'm coming back." I cannot reproduce the Scottish accent or the emphasis on the last words.

(*c*) A man who had a rifle bullet sticking into his ligamentum muchae, but who refused to take any notice of the same. It is true that he was preoccupied to some extent with another injury, but it is remarkable that the severe blow which he must have felt had made no more impression.

It may be noted that a rifle wound is felt as a severe blow, and not as a sharp pain. It is often only the sight of blood which assures the wounded man that he has been hit by a projectile, although the shock of the blow is felt at once. It is possible that during a charge or other strenuous military operation the soldier may be entirely unconscious of a wound, but I was never able to ascertain that this had been the case, although more than one stated that they had "carried on" for a time after being wounded.

(*d*) An officer who, after being wounded—that is, after feeling that he had been hit—retired with his men to the trenches, led another advance from them and retired again. Then, struck with the amount of blood which he saw he was losing, he refrained from going on with a further advance and left the trenches to walk back. After a short time he was overcome, partly from loss of blood and partly from shock, and fell into or sat in a ditch, where he was found by a wounded fellow officer later. The wound was through the palm of the hand from side to side.

(*e*) A man who was brought to the ambulance on a stretcher, and who stated that he had walked a mile before finding the stretcher bearers. He demanded immediate amputation of his arm and a cigarette. His wounds were very severe. He had a large omental hernia in the upper part of the abdomen, the right arm was hanging by a portion of the deltoid, the nerves and vessels; the bone was shattered. There were also wounds in each thigh and in the left hand. None of these was trivial. He lived thirty-six hours.

(*f*) An officer who, although wounded through both knee-joints, showed no sign of pain until the dressings were concluded. He realized that he was not likely ever to be fit for service again, and asked the medical officer attending him whether any part of his kit would be of any use as he would not want it again. The only sign he made that he was in pain was to acknowledge that it was "pretty bad" in reply to a direct question.

I can say without any hesitation that such cases as the above are the rule—the fortitude of the wounded man is amazing. In all fairness one must add that this fortitude is also shown by our enemies.

It is requested that the above notes may be read merely as some reflections on what one medical man has seen during some three months at the front. They are founded on none but mental notes, and it is difficult even to say whether the facts here related were necessarily those which impressed the particular case on one's mind. It may have been that one's mind was especially ready at different times to take a gloomy or bright view of all that was happening, and that contemporaneous incidents were coloured in this way. The stress involved by a rush of work in conditions far from ideal, by the appalling volume of noise, and by the necessity of keeping oneself alive to the importance of every side of one's work creates an atmosphere quite foreign to that which produces the best scientific work and the most accurate observations.

SURGICAL EXPERIENCES OF THE PRESENT WAR.

DISCUSSION AT THE MEDICAL SOCIETY OF LONDON.

TETANUS.

In continuation of the discussion on surgical experiences of the present war, the subject of tetanus was debated at a meeting on December 7th, with Sir JOHN BLAND SUTTON, President, in the chair.

The Micro-organism.

Major D. EMBLETON, R.A.M.C.(T.) said that there were two features of the bacillus of tetanus which must be clearly remembered: (1) The spore, and (2) the fact that the micro-organism was a strict anaërobe. In order to produce the disease by inoculating a clean spore—that

is, one which had been washed clean from its toxin—it was necessary to inoculate at the same time some lactic acid or some other organisms, or to produce considerable trauma—all processes which lowered the vitality of the tissue or killed it locally. He quoted experiments to show that for the development of the disease dead autolyzing tissue was of more importance than the exclusion of oxygen. The bacillus of tetanus was said to occur at the site of the inoculation and in the nearest lymph glands only, but in his opinion it was practically certain that the bacilli migrated rapidly by way of the lymphatics to the thoracic duct, and thus entered the blood stream and became disseminated throughout the body. It was thus possible that toxin might be liberated from many points in the body as well as from the original focus, and this might account for the frequency with which the first spasms started at a distance from the original lesion. It had recently been stated before the society that if a wound was swabbed out with pure carbolic acid tetanus and sepsis would be practically abolished. Against this assertion might be raised the following points: (1) 1 in 20 carbolic acid was the most efficient germicidal dilution of phenol; pure carbolic acid was no more potent than it. (2) 1 in 20 carbolic acid took fifteen hours to kill tetanus spores, and the disease was caused by spores. (3) It damaged the tissues, and these would subsequently undergo autolysis. (4) Kanthack used broth having a strength of 1 in 20 carbolic acid to isolate and cultivate the tetanus bacillus. (5) Dr. Thiele and he (Major Embleton) had shown that carbolic acid, either pure or in a 1 in 20 solution, swabbed on to a wound artificially produced in a guinea-pig and infected with spore-bearing organisms, would not protect the animal even when applied two minutes after the infection had been produced, the bacteria even in this short time having migrated beyond the range of the antiseptic. To sum up, pure carbolic appeared to be of little value in the prevention of tetanus, and in fact by damaging the tissues seemed dangerous. The same argument applied to other strong antiseptics. The fact that the tetanus bacilli had only been demonstrated in the wound and the nearest lymph gland showed that the blood could deal with the organisms if it could gain free access to them. This suggested that no substance likely to damage the tissues should be used, and that free access of blood to the part should be ensured, either by hot baths, fomentations, or Bier's treatment.

Prophylactic and Therapeutic Use of Antitetanic Serum.

Major Embleton considered that the value of antitetanic serum for prophylactic purposes had been definitely established, both experimentally on animals and also from statistics in the case of man. It was probable that nearly every wound received by our troops operating in the highly manured districts of France and Belgium was infected with tetanus spores, but only a relatively small number of cases of tetanus occurred. Although theoretically every wound should be treated with serum this was practically impossible. It had been suggested that this treatment should be reserved for shrapnel wounds; this would include most of the cases which ultimately developed tetanus, but the probability of tetanus arising depended on the extent of laceration and not on the nature of the projectile. It was impossible to lay down rules as to the prophylactic dose. Ideally, at the time of operation a sufficient dose of antitetanic serum should be circulating in the patient's system. It seemed probable that 5,000 units some three hours before the operation sufficed.

He then considered the treatment of established tetanus. Seeing that the nervous system was being severely poisoned by the tetanus toxin, hypnotics being only palliative measures, should, he said, be withheld unless there was urgent need for them. Those which seemed to have given the best results were chloral and bromide, chloretone, and, for rapid action, paraldehyde and ether suspended in saline and administered intravenously. It had been proved experimentally that the administration of antitetanic serum in established tetanus was of value. The intraneural method of injection had been advocated under the impression that the serum would neutralize the toxin and prevent its passing to the central nervous system, but non-diffusible substances like serum did not pass up the axis cylinders but by the perineural lymphatics. The routes of the toxin and the antitoxin were thus different. Intrathecal inoculation of the serum had been recommended on the assumption that the antitoxin could by this means get into rapid and intimate contact with the toxin in the nerve cells. There was no evidence that non diffusible substances such as serum could penetrate to any depth into the nerve tissue when injected either into the subarachnoid space or into the lateral ventricle. Experimental evidence was to the contrary. Roux had obtained very satisfactory results by intracerebral injection of the serum into the frontal lobes, but non-diffusible substances when injected into the brain either leaked back along the track of the needle or remained localized at the point of inoculation. The amount of serum that could be inoculated without producing serious damage was exceedingly small. It was possible that Roux's successes might be ascribed to the relief of tension followed by a pouring out of fresh fluid, as in meningitis. The intravenous route had the danger that it might produce acute anaphylactic symptoms or death in a person primarily hypersensitive to the horse serum or one who had previously been inoculated with an antiserum prepared from the horse.

The subcutaneous route was undoubtedly the safest, since the absorption was slower, and serious anaphylaxis was less likely to occur. Absorption was sufficiently rapid for the purposes of treatment, and very large quantities could be used. The object of administering antitetanic serum was to (1) destroy the circulating toxins, (2) promote phagocytosis of the bacilli, (3) destroy the toxin already causing symptoms. Immediately after the first symptoms appeared 10,000 units should be inoculated, and subsequently 3,000 units every two hours, until the symptoms abated. The injections should not, however, be continued beyond the third day.

Selection of Cases for Serum Treatment.

Professor F. W. Andrewes pointed out that the tetanus bacillus was not an inhabitant of soil as such, but of the animal dung with which cultivated soil was mixed. The risk of tetanus was that of deep implantation, in wounds, of cultivated soil or other matter polluted with the dung of horses or cattle. In any given wound this risk might be roughly estimated by the evidence of such contamination, either on clinical or bacteriological grounds. The bacteriological test on which he was disposed to place chief reliance was the presence of anaërobic bacilli in the wound discharges. A smear of the pus, stained by the Gram-fuchsin method, was commonly a sufficient clue to their presence. Unless an unlimited supply of antitoxin was at hand, it was necessary to exercise some selection of cases in the administration of tetanus antitoxin as a prophylactic. He considered the presence of large Gram-positive bacilli resembling *B. aërogenes capsulatus* a good indication for a prophylactic dose of serum. The evidence went to show that 500 U.S.A. units was an adequate prophylactic dose in ordinary cases, since it was known to be enough to protect a horse; 1,000 units might be safer in a severe and very foul wound, or one in which a considerable time had elapsed since its infliction. He considered it right to give serum in a suspicious wound, even though two or three weeks had elapsed since the infliction of the injury. As regards the treatment of declared disease, Professor Andrewes expressed himself in favour, on theoretical grounds, of amputation or free excision of the wound where this was possible. The route of administration of antitoxin which he advocated was the intrathecal one, as being better than the subcutaneous or intravenous routes and safer than the intracerebral. Statistics showed clearly that, when given, antitoxin should be given in large doses—15,000 or 20,000 U.S.A. units, repeated if necessary. As an adjuvant to keeping up a high concentration of antitoxin in the central nervous system, large doses should also be given subcutaneously. More, however, could not be expected from antitoxin than that it should turn the scale in doubtful cases. In the use of sedatives for the palliation of pain and other symptoms, it must be remembered that death was often due to respiratory complications, and that such drugs as morphine might, in some circumstances, be dangerous.

Dr. JOHN EYRE said that he was in accord with what Professor Andrewes had said with regard to the value of finding Gram-positive organisms resembling *B. aërogenes capsulatus* in the discharge from an infected wound, but he had met with several cases of tetanus in which they were not found. Inoculation of a mouse caused tetanus after two or three days. It was clear, therefore, that the decision as to treatment must depend mainly upon the surgical aspect of the case. Badly lacerated, contused, or deeply incised wounds were those which should be chosen for prophylactic treatment against tetanus. Referring to treatment with carbolic acid, he pointed out that the spore was not the entity which gave rise to the toxin, but the bacillus, which was very susceptible to the influence of carbolic acid. The site of production of the toxin should, in his opinion, be dealt with as soon as possible. With regard to the prophylactic dose, 500 units probably afforded good protection if they could be used immediately. The amount required, however, increased rapidly with delay, and at the end of twenty-four hours from infection twenty or thirty times as much was needed. The serum conferred immunity for about a week, and at the end of that time a second dose was necessary. When tetanus had become established, it was well, on theoretical grounds, to get rid of the site of manufacture of the toxin; in experimental work infection did not remain localized to the focus of inoculation. He thought that intracerebral injections, in view of the grave lesions produced, should only be used as a last resort, though they sometimes seemed to turn the scale. The intrathecal route was the most important and efficient. In his own experience cases treated thus had usually recovered, whilst those only receiving subcutaneous injections had usually died. The cerebro-spinal fluid was often under considerable pressure and ran freely away, so that a considerable dose of serum could be given. Intravenous inoculation acted quickly and subcutaneous slowly, but the latter kept up a persistent dosage. He advised that all three methods should be employed simultaneously.

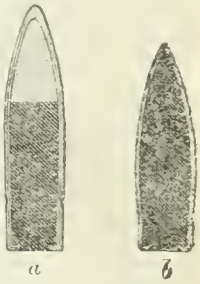
Results of Treatment.

Lieutenant R. B. BLAIR, R.A.M.C., said that he had treated 17 cases of tetanus at the Herbert Hospital, Woolwich; 6 had died, 9 recovered, and 2 were still under treatment; 10 of the cases were very acute. The wounds were mostly severe and all very dirty. They were generally gunshot wounds, not shrapnel. In 4, prophylactic doses of serum had been given before the patient had been admitted to the hospital; 3 of these had died, and it would seem that the doses given were too small, and not given early enough. He thought that unless the patients were seen within two days, 4,000 units should be given intraspinously. The treatment employed at the hospital for the cases of established tetanus was intrathecal injection of 4,000 units daily. No difficulty had been experienced using a light anaesthesia. The cerebro-spinal fluid was under very great pressure; it was allowed to run until it began to drop slowly, and then the serum was injected, the volume introduced being less than that which ran away. The hypnotics used were morphine, chloral, and bromide (60 grains of each two or three times in the twenty-four hours), and chloretone (40 grains in two ounces of olive oil, two or three times daily, per rectum). When the chloretone was retained it relieved the spasms for several hours, but it was often expelled. Stimulants might be necessary if exhaustion appeared. It was seldom necessary to amputate the limb during the attack of tetanus; all but one of the few cases in which this had been done succumbed. The total quantity of serum given varied greatly, 62,000 units being the maximum amount which had been employed.

Dr. CARL BROWNING said that one point was clear, that the amount of serum required grew enormously with the lapse of time from infection. Consequently the earliest symptoms of tetanus must be carefully watched for. The danger of anaphylaxis might probably be avoided by the previous injection of dilute solution of antitoxin, and an antianaphylaxis thus produced. The blood pressure could be used as an indication of the amount of serum to be injected intrathecally. If there was a fall of blood pressure in an average adult of 40 cm. of mercury the limit of dosage had been reached.

GERMAN AND BRITISH BULLETS.

WE published last week photographs of British, French German, and Belgian bullets, and of the bullets in their cartridge cases; we now give sections of the British and German bullets, for which we are indebted to Sir John Bland-Sutton. The German bullet has a solid core of hardened lead and a sheath of ferro-nickel. The British has a cupro-nickel sheath; its core consists of two parts, as seen in the drawing of the section, the front portion being an alloy of aluminium 90 per cent., zinc 10 per cent., or pure aluminium, and the rear portion an alloy of 98 per cent. lead, 2 per cent. antimony, in an envelope of 80 per cent. copper and 20 per cent. nickel. A shallow cannelure is formed near the base, into which the case is secured by three indents. The diameter of the bullet at the base is 0.311 in. and its length 1.28 in. The portion of the bullet which enters the case is coated with beeswax. The weight of the British bullet (Mark VII) is 174 grains, and of the German bullet 154.5 grains. In both bullets, as will be seen, the nickel sheath is open at the base, through which it is filled



a *b*

a, Section of British bullet (Mark VII), showing aluminium front of core. *b*, Section of German bullet (Spitze). The British bullet is natural size (1.28 in.); the length of the German bullet in the drawing is slightly shorter than the standard size, which is 1.105 in.

In the JOURNAL of October 31st (p. 762) we mentioned that M. Tuffier, surgeon to the Beaujon Hospital in Paris, who was commissioned by the French Minister of War to inspect the medical arrangements of the French army, had, in a report to the Académie de Médecine, stated that although a large number of cases had been shown to him in various hospitals in which large wounds of exit were supposed to be evidence of the use of explosive (that is to say, expanding) bullets, he had not satisfied himself that this was in fact true in any case. He believed that all the instances could be explained by a normal bullet having struck a bone, and concluded that, in order to establish the existence of the use of a prohibited projectile, it would be necessary to find it in a bandolier or in the magazine of a rifle in use. M. Tuffier, in a communication to the Académie de Médecine on November 24th, stated that when recently making an inspection in the neighbourhood of Arras he had seen among men brought from the trenches wounds in which the shape of the orifice of the wound of entry and the conical form of the wound produced in the tissues was difficult to account for if an undeformed bullet had been used. In one case seen by Dr. Potherat, chief surgeon of one of the ambulances of the tenth French army, he had found a bullet undeformed, but embedded in the hand with the point still protruding from the skin; as was pointed out last week, however, there is experimental evidence that the German bullet may turn over on encountering even so slight an obstruction as a layer of cardboard, but M. Tuffier says that cartridge cases have been found on German soldiers in which the bullet had been reversed and pushed in again, so that the flat base was in front. A bullet so treated would, no doubt, act as a deformed or expanding bullet. M. Tuffier says that such reversed bullets are used only for short distances, as when the trenches are near together, and that the manœuvre no doubt diminishes the accuracy of fire. The German bullet, M. Tuffier said, is easily removed from the cartridge case by putting the point into the end of the muzzle and pulling lightly. The portion of the German bullet contained within the cartridge case is shorter than in the British, has a less defined neck, and there appear to be no indents in the case.

HOME HOSPITALS AND THE WAR.

2ND LONDON GENERAL HOSPITAL.

LIEUTENANT-COLONEL EUSTACE M. CALLENDER, the Commanding Officer of the 2nd London General Hospital (St. Mark's College, Chelsea), considers that it is now possible to estimate roughly the extent to which the results of wounds would be of a permanent character. The hospital had dealt to date with about 5,000 men,

including those at present under treatment, and only 106 amongst soldiers of more than six months' standing had been invalided out of the service. No record was kept of a further considerable number, principally Territorials, invalided out with less than six months' service. It was impossible to say what proportion of recoveries would return to the front, for in many cases it had still to be seen what degree of recovery to injuries of the nerves would be attained. In a number of cases of severe compound fracture of the limbs, where comminution had been considerable, there remained, after the wounds had healed, injuries to nerves, causing paralysis of various kinds, according to the nerve involved. In some cases operations had been performed to free nerves that had been caught in a big scar, or to suture nerves seriously damaged. Down to this week there had only been ten deaths at the hospital, although the condition of a great many patients might have been thought hopeless. There had only been four or five amputations since the hospital opened. In many cases in which amputation seemed indicated the operation was delayed as long as possible, and ultimately was found to be unnecessary. A considerable time, however, was necessary to obtain recovery in bad cases of compound comminuted fractures. In the case of a man admitted eight weeks ago with bad compound fractures of the thigh, the wounds being in a septic condition, there was as yet little or no sign of union, but eventually, in similar cases, fairly good union had been obtained.

The number of cases of sickness was small; no more cases of enteric fever had been received from the front, but two cases had come from the Home Forces. Amongst the men admitted from France were many cases of rheumatism of the legs and sciatica, and a very considerable number had frost-bitten feet. The feet were considerably swollen, and generally had the appearance of being scalded without blistering; but here and there were small ulcers, almost like the perforated ulcers of tabes dorsalis. In some cases the feet were almost black and shrivelled, as if mummified. So far there had been no gangrene or loss of toes. When first admitted the men said the feet felt dead, and had no sensation, but as recovery began there was a great deal of pain, variously described as aching and burning. It lasted for many days. Where the symptoms were those of constant burning, the most successful treatment appeared to be to apply lead lotions and evaporating lotions, but the more usual method was to apply hot boracic fomentations.

From the Home Forces two or three cases of perforated gastric ulcer had been received, and were doing quite well. Several operations had been performed for acute appendicitis, and all the patients were recovering. In one young man in the Home Forces, admitted with fever, and obviously very ill, the symptoms were found to be due to acute disease of the middle ear and thrombosis of the lateral sinus. After an operation he lived for some days, during which he had repeated rigors. A *post-mortem* examination showed that the patient had acute septic endocarditis and pus in one pleural cavity. He was suffering really from pyaemia, and the case was chiefly interesting because the symptoms made it extremely difficult to diagnose.

One case of tetanus was removed recently from a hospital train arriving at Chelsea. The man was very ill, and antitoxin was administered — 1,500 units subcutaneously. As he did not improve he was given 3,000 units intravenously. Finally, 1,500 units were administered into the spinal canal, and the patient is now recovering.

By the addition of further sections the hospital now contains 900 beds. The sections are established at St. Thomas's Hospital, the Great Northern Hospital, the Victoria Hospital, and a convalescent establishment at Richmond with 40 beds. Latterly the wounded reaching the hospital have not been in such a serious condition, many having been already in hospital in France for two or three weeks. On the morning of Monday, December 7th, a trainload of wounded arrived consisting of men who were in the fighting line on the previous Thursday.

This trainload of 110 men, 30 being cot cases, arrived at 12.8, and the last patient was in bed by 12.30.

1st Southern General Hospital, Birmingham.

The Hospital and Section Hospitals.

The 1st Southern General Hospital, which has been mobilized in the new buildings of the university at Edgbaston, and which originally consisted of 520 beds, has been expanded. At the present time there are 630 beds in use, and in another ten days, when further sanitary arrangements have been completed, there will be 800 available. This is the total number of beds the university building will hold. This is probably the largest number of beds in one building for a temporary hospital. All the various administrative offices, rooms for the resident medical staff, operating theatres, *x*-ray rooms, out-patient department, dispensary, dining rooms for patients and staff, kitchens, recreation room for patients, and a canteen, are in different parts of the same building. The barracks are in a detached building, and the sisters' quarters are in the Women's Hospital of the university, which is about 300 yards away. The whole hospital is lighted and heated by means of a large power station in the university grounds. There is plenty of room to expand the hospital further by placing temporary buildings in the various quadrangles or at either end of the building.

Many of the wards are very large, and the ventilation is extremely good in all of them. A very large number of operations have been performed for hernia, varicocele, varicose veins, etc., and in every case healing has been by first intention. All who work in the hospital remark upon the excellent results that have been obtained. The hospital is situated in a very healthy but rather exposed spot, over 500 ft. above sea level, and on the edge of a plateau. The wind is extremely keen up there, and often very boisterous. This is considered to be an objection to the establishment of open-air wards.

A large number of section hospitals are attached to the 1st Southern General Hospital, and all of these are excellently staffed with medical officers and one or more trained nurses. There are between 600 and 700 patients at the present time in the section hospitals, all of them transferred from the central hospital. The administrative staff is responsible for all the soldiers in the section hospitals.

It is reported that over 2,600 patients have been treated in the hospital, and at the time of writing there are nearly 600 patients. There are also a large number of out-patients who attend daily at 9 a.m.

Transport of Sick and Wounded.

The hospital is about three miles from the centre of the city, and the ambulance trains travel by the Midland Railway to Selly Oak Station, which is under a mile from the hospital. Owing to the shortness of the distance, the wounded can be got to the hospital by means of less transport, as more than one journey can be made. The train is unloaded by the R.A.M.C.(T.) men of the hospital in a siding in a goods station, so that the traffic of the main line is not held up. The transport from the station has been entirely arranged by the staff of the hospital. The police and the city health authorities lend all their ambulances, numbering about fifteen. The proprietors of Heath's Garage have converted two cars into ambulances. Mr. Tailby has constructed an ambulance to attach behind a motor car; it has only two wheels, being on the trailer principle, and carries two stretchers. It is most useful, very simple in design, and can be made for less than £25. The ambulance is attached to the car by means of a drop-pin which fastens into an iron cross-bar fixed on the back of the car. Any car could be fitted to take this ambulance. The car with the ambulance behind is found quite easy to drive, and only very little more room is required when steering round corners. The sitting-up patients are taken to the hospital in motor omnibuses, which the Tramway Committee supply, charging a small fare, and also in motor cars which are very kindly lent by people in the neighbourhood. The secretary of the Automobile Association has organized quite a fleet of cars, which does a large amount of transport work not only of patients to the hospital but also for taking them away again to the section hospital. The work these cars do is very valuable, and without their help, which is offered any time of the night or day, the transport of this large number of patients to and from the hospital would be an impossibility.

Tetanus.

Five cases of tetanus have occurred, and of these two died; in one of them pneumonia was the determining factor. Three had an incubation period of under twelve days and one recovered; in the other two who recovered the incubation period was longer. In addition to the usual hypnotics and special nursing, the chief treatment adopted was the administration of large amounts of antitetanic serum intrathecally and intravenously.

Medical Cases.

There have been a large number of very interesting and curious bullet and shrapnel wounds, and about six cases of traumatic aneurysm. The last two batches of patients from the Expeditionary Force have shown a large increase in the number of medical cases; they included also a considerable number of cases of frost-bite and so-called "trench rheumatism."

BRITISH RED CROSS WORK.

Inspection of Red Cross Hospitals in France.

SIR FREDERICK TREVES left London for France this week on a tour of inspection of the hospitals under the direction of the joint committee of the Order of St. John and the British Red Cross Society. His object will be to learn whether excessive work is being thrown on any of the hospitals, so that they need more help, and whether any need to be weeded out as having served the purpose for which they were established. In the meantime, Mr. Edmund Owen is working in the personnel department of the two societies at Pall Mall. The pressure upon the Red Cross organization is much lessened by the circumstance that the fighting line is so near the French ports. It is found more convenient to bring the wounded to England direct than to draft them in any large numbers into hospitals in France. There have been instances of men who were wounded at six o'clock on one morning being in a hospital in England the next morning. The Red Cross work at points on the lines of communication is thus greatly lessened.

The King George Hospital.

Progress is somewhat slow in the adaptation of the new buildings of the Government Stationery Office near Waterloo Station to serve as the King George Hospital. The reason is that the sanitary provision has to be much extended and bathrooms added before the premises will be suited for hospital purposes. As the building is of concrete, work on alterations to the fabric is necessarily slow. Arrangements are being made, however, by Sir Rowland Bailey and others, so that as soon as the wards are ready there will be no delay in equipping them. Thanks to the generosity of the public, every one of the 1,650 beds which the hospital will contain has been endowed. Appeals will soon be issued for the provision of *x*-ray installations and for the decoration of the day rooms. The following are the members of the consulting staff of the hospital.

Sir Thomas Barlow, Bart., K.C.V.O., President of the Royal College of Physicians; Dr. Mitchell Bruce, Consulting Physician to Charing Cross Hospital: Sir Watson Cheyne, Bart., President of the Royal College of Surgeons; Sir Bertrand Dawson, K.C.V.O., Physician to London Hospital; Sir H. Bryan Donkin, Consulting Physician to Westminster Hospital; Sir Dyce Duckworth, Bart., Consulting Physician to St. Bartholomew's Hospital; Sir Rickman Godlee, Bart., Consulting Surgeon to University College Hospital; Sir James Goodhart, Bart., Consulting Physician to Guy's Hospital; Mr. J. Warrington Haward, Consulting Surgeon to St. George's Hospital; Sir Henry Morris, Bart., Consulting Surgeon to Middlesex Hospital; Mr. Edmund Owen, Consulting Surgeon to St. Mary's Hospital; Sir Seymour Sharkey, Consulting Physician to St. Thomas's Hospital.

The list of visiting physicians and surgeons who have generously undertaken the charge of the soldiers in the wards will be published shortly.

Typhoid in the Belgian Army.

Very little information has reached the head quarters of the British Red Cross Society this week with regard to the outbreak of typhoid in the Belgian army, but information has reached London that to a large extent isolation is to be provided by means of barges converted into small floating hospitals and moored in the tideway. An ample supply of suitable barges is available. The fact that the Order of St. John and the Red Cross Society was able to place £10,000 at the disposal of those responsible for dealing with the outbreak has enabled immediate steps to be taken.

The Chloroform Supply.

Statements have appeared in the lay press that owing to a shortage of chloroform operations have had to be performed upon wounded soldiers without the use of an anaesthetic. The result of the circulation of these rumours has been the receipt by the Red Cross Society of many offers of liberal financial assistance towards providing a supply of chloroform. There is, however, no foundation for the statements, and the public may rest assured that our soldiers are being deprived of none of the benefits of modern science in this or any other respect.

CASUALTIES IN THE MEDICAL SERVICES.

ARMY.

Killed.

Two officers of the Indian Medical Service, serving with the Expeditionary Force in Flanders, were reported as killed, in the casualty lists published on December 4th—Major P. P. Atal and Captain K. I. Singh. It is ten years since the Indian Medical Service lost a member killed in action, the last being Captain F. Syme, who fell in the small force annihilated on April 15th, 1903, at Gumburin, in Somaliland. Though Indians have served in the Indian Medical Service, and have served with credit and success, for just half a century, this is the first occasion on which an Indian member of the service has fallen in action.

Major Pundit Piaraylal Atal, I.M.S., was born on August 2nd, 1872, educated at Bart's, took the M.R.C.S. and L.R.C.P.Lond. in 1898, and after acting as house-physician and junior house-surgeon to the Clayton Hospital, Wakefield, entered the army as lieutenant on January 28th, 1899, becoming captain on January 28th, 1902, and major on January 28th, 1911. He was medical officer of the 129th Baluchis. He served in the China war of 1900, and received the medal.

Captain Kanwar Indarjit Singh, I.M.S., was the son of Sir Haman Singh, K.C.S.I., and was born on December 27th, 1883. He was educated at Cambridge and at King's College Hospital, London, and took the M.B. and B.C. at Cambridge in 1911, the M.R.C.P.Lond. in 1912. He entered as lieutenant on January 29th, 1911, and became captain on April 23rd, 1914. He was medical officer of the 57th Rifles (Wilde's Rifles).

Wounded.

Paterson, Major T. G. F., I.M.S. (Persian Gulf).

Prisoners.

Edmunds, Captain C. T., R.A.M.C.
Garland, Captain F. J., R.A.M.C.
Middleton, Captain E. M., R.A.M.C.
Pollard, Captain A. M., R.A.M.C.
Robertson, Captain H. G., R.A.M.C. (previously reported missing).

NOTES.

DISTINGUISHED SERVICE ORDER.

THE KING has approved of the appointment of twenty additional officers to be Companions of the Distinguished Service Order in recognition of their services with the Expeditionary Force. The list contains the names of three officers of the Royal Army Medical Corps, as follows:

Lieutenant HENRY BELDINGFIELD, M.B., R.A.M.C.:
For coolness and daring in repeatedly superintending removal of wounded from the firing line under heavy fire.

Major SIDNEY GEORGE BUTLER, R.A.M.C.:
At Missy, on September 15th. For coolness and courage in continuing all day to collect wounded under severe shell fire.

Captain MALCOLM LECKIE, R.A.M.C. (deceased):
For gallant conduct and exceptional devotion to duty in attending to the wounded at Frameries, where he was himself wounded.

Dispatches.

Royal Navy.

Appended to the dispatch from Major-General A. Paris, commanding the Royal Naval Division, with reference to the operations around Antwerp, from October 3rd to October 9th, the name of the following medical officer appears in the list of those mentioned for good services:

Fleet Surgeon E. J. Finch, R.N.

Army.

The following additions to the list of medical officers mentioned in Sir John French's dispatches of September 17th and October 8th, dealing with the operations of the Expeditionary Force from August 28th to October 8th, were published in the *London Gazette* of December 4th:

Colonel S. Westcott, Staff R.A.M.C.

Lieutenant H. Beddingfield, R.A.M.C.

Students in Medical Units of the Territorial Force.

Dr. Henry Hick (New Romney) writes: It may interest others, as much as it did me, to know that the War Office letter, dated November 28th, states that "it has been decided that any students who have joined medical units of the Territorial Forces, and wish to immediately resume their studies, shall be released from service."

Croix Rouge Française.

Dr. James Donelan has been appointed medical referee to the Committee of the French Red Cross in London to act in respect of the acceptance of medical men for service in France. The offices of the Committee are at 25, Knightsbridge, London, S.W.

Medical Officers Wanted.

North Midland Mounted Brigade Field Ambulance.

We are asked to state that the North Midland Mounted Brigade Field Ambulance are in urgent need of four medical officers in the reserve unit. The pay as lieutenant is 14s. per diem, with 2s. for food allowance and 3s. for billeting expenses when necessary; £30 allowed for uniform and £7 10s. for field equipment. Applications should be made to the officer commanding reserve unit, North Midland Mounted Brigade Field Ambulance, R.A.M.C.(T.F.), The Drill Hall, Nineveh Road, Handsworth, Birmingham.

South-Eastern Mounted Brigade Reserve Field Ambulance.

Major Hamilton, R.A.M.C., Officer Commanding South-Eastern Mounted Brigade Reserve Field Ambulance, requires four medical officers to complete his Staff. He will be glad to hear from medical men wishing to take up commissions during the war. This Reserve has now been formed, and is at present stationed at the Cricket Ground, Canterbury.

2nd East Anglian (Reserve) Field Ambulance.

There are still a few vacancies for medical officers in the Reserve Unit, 2nd East Anglian Field Ambulance. Pay and allowances as for officers of the Regular R.A.M.C. Applications should be made at once to Colonel Blake Marson, 2nd East Anglian Field Ambulance, 148, Broadway, Peterborough.

England and Wales.

[*FROM OUR SPECIAL CORRESPONDENTS.*]

LIVERPOOL AND DISTRICT.

Belgian Doctors.

The Liverpool Medical Institution, at the meeting on December 3rd, considered the question of forming a Belgian Doctors' Relief Fund. The president, Dr. E. W. Hope, introduced the subject in fitting terms, and it was unanimously resolved to appoint a committee to promote this beneficent scheme. It is earnestly hoped that the medical men in Liverpool and district will show their practical sympathy in alleviating this sad distress, so little looked for or deserved by their Belgian professional brethren.

The Liverpool Panel Committee.

Aqua was recently the subject of discussion, as the chemists who dispense under the Insurance Act used *Aqua destillata*, which added ½d. to the dispensing fee. It would appear that *aqua*, as such, is not official in the *British Pharmacopoeia*. However, as the water supply of Liverpool and its environs is above reproach and exceedingly potable, the committee decided that *aqua* when prescribed should be the *aqua fontis*—tap water. *Aqua destillata* should only be employed when expressly indicated or when the nature of the medicament required its use from a chemical standpoint.

The Liverpool Medical Committee.

Like many medical committees under the Insurance Act, the Liverpool Medical Committee in 1913 prepared a formulary not by any means as large as those of other medical committees, but sufficiently compendious to be of practical service to the panel practitioner. As Bootle is contiguous to Liverpool it was decided to bring the formularies of both county boroughs into harmony, so that the title of the medicine prescribed should not only be the same, but contain the same medicaments and identical proportions. The Committee, not unmindful of the interests of insured persons, passed a resolution that those engaged in public institutions should not be deprived of free choice of and free access to a doctor, that nothing should interfere with that confidential secrecy in their dealings with their medical attendant, and that no practitioner on the panel should allow the records of his patients to pass out of his personal control.

Liverpool Merchants' Base Hospital at the Front.

Liverpool is once more to be congratulated upon the munificence of its citizens. Lord Derby recently presided at a meeting of leading commercial men at which Dr. Haden Guest delivered an address. It would appear that £13,000 will be necessary for capital outlay, and the maintenance will amount to a monthly charge of £1,500. It is gratifying to note that the amount subscribed up to November 28th is over £20,892. The Committee, which has charge of the medical arrangements, has appointed Lieutenant-Colonel Nathan Raw, M.D., senior physician, and Mr. T. C. Litler Jones, senior surgeon to the base hospital. Other medical appointments will follow in due course. Motor ambulances were generously placed at the disposal of the Committee, who, however, found that the control of such vehicles is wholly vested in the War Office, and consequently could not be reserved for the sole use of the Liverpool Base Hospital. The Committee had therefore to decline regretfully such gifts, which need not go astray as the Red Cross Society would thankfully accept them. All the funds will be entirely administered in Liverpool, and it is earnestly hoped that the citizens will keep these so replenished that the Liverpool Merchants' Base Hospital will be an enduring memorial of the noble efforts of its citizens to assuage the sufferings of the wounded in this great war.

MANCHESTER AND DISTRICT.

Disabled Soldiers and Approved Societies.

At a meeting of the Trade Union Approved Societies' Association, held in Manchester on December 1st, a question of great importance to approved societies was raised—namely, the question of the payment of sickness and disablement benefit to returned soldiers and sailors from the war. The association represents about half a million insured persons, and the Committee stated that it viewed with the greatest concern the fact that insured soldiers and sailors discharged from active service who had been incapacitated in the war would be entitled to claim sickness and disablement benefit from their approved societies. This meant that a large number of their members who had been the "best lives" would be returned to their societies as "bad lives," many requiring probably disablement benefit for the rest of their lives. This was an extra liability never contemplated by the actuaries in estimating the cost of State sickness and disablement benefits, and it would have the most serious effect on their funds. The association therefore suggested that the soldiers and sailors incapacitated during active service should be a charge on the military and naval authorities until they recovered from such incapacity, and that health insurance benefits should not be taken into account when arriving at a decision as to pensions and allowances to be paid in respect of illness or disablement arising out of active service. The association was anxious to see the very best treatment given to soldiers and sailors, but thought that insured persons through their societies should not be called upon to bear a liability which the whole nation ought to accept. The association was quite prepared to administer the benefits in these cases for the Government, provided that the Government would guarantee that the increased

amounts paid out were repaid to the societies by the Treasury.

The question is also of great importance to the panel practitioners. The panel funds are at present being considerably lessened by the temporary withdrawal of insured persons who are on active service; when they return and are discharged from the services, they will require from the panel doctors an enormous extra amount of medical attendance which would never have been necessary but for the war, and it is felt in many quarters that though the medical profession has shown its readiness and in fact its eagerness to render freely its services during the war, it deserves equal consideration with approved societies in the circumstances alluded to above.

LONDON.

District Nursing Council.

A Central Council for District Nursing in London was formally constituted at a conference which was opened by Mr. Herbert Samuel, President of the Local Government Board, who was accompanied by Mr. Herbert Lewis, M.P., Parliamentary Secretary. Mr. Samuel said that his department, among many other duties, had to perform the functions of a ministry of health, and consequently took a keen interest in the organization of an adequate nursing service. Though the war had greatly increased the demand for nurses, the requirements of the civil population had to be met. Ultimately he hoped that the war would assist the work, for it had brought home to the population the importance of the nursing service, and the dignity and value of the nurses' work. On behalf of the Government he expressed an earnest hope for the success of the movement. Sir William, J. Collins, K.C.V.O., was elected chairman, and Dr. Christopher Addison, M.P., Vice-Chairman of the Council. Sir William Collins, in taking the chair, said that he understood that it was desired not to supersede or supplant existing organizations, but to supplement, support, and perhaps subsidize the benevolent operations of voluntary agencies. It was resolved that the Executive Committee should consist of twenty-five members, of whom twenty-three were appointed at the meeting. The committee was instructed to obtain full information as to existing provision for district nursing and to take steps to promote an adequate and efficient service.

Scotland.

[FROM OUR SPECIAL CORRESPONDENTS.]

Scottish Medical Service Emergency Committee.

A meeting of the Committee was held at the Royal College of Physicians of Edinburgh on December 5th. The Presidents of the Royal Colleges of Physicians and Surgeons, and of the Royal Faculty of Physicians and Surgeons of Glasgow, the Deans of the Faculties of Medicine of Glasgow and Edinburgh Universities, and Dr. Ashley Mackintosh, representing the Dean of the Faculty of Medicine of Aberdeen University, Drs. J. C. McVail, J. R. Currie, J. Stevens, and Norman Walker (Convener) were present.

The Convener reported that there had been numerous applications to the Committee for assistance in procuring locumtenents, and many offers of service from practitioners retired or temporarily unemployed. Though it had not been possible to provide direct supply in all cases, the influence of the Committee had been of considerable value in promoting arrangements for the carrying on of the work of the men on service, while the recommendation of the Committee that five guineas should be the maximum fee charged to men serving with the colours had apparently been loyally accepted. From several communications he had received it was evident that the financial arrangements between the men called out and their neighbours who were doing their work were not always satisfactory; and, indeed, in many cases no arrangements at all had been made. It was remitted to a subcommittee to consider whether it would be advisable to issue a series of model arrangements suitable to different varieties of practice to help in averting difficulties which might arise and to advise on any cases of immediate difficulty brought under the notice of the convener.

It being evident that more men would before long be called out, the Committee decided to make a fresh appeal for assistance to medical men and women who were in a position to help. A suggestion that the convener should address a meeting, or meetings, on the work of the Committee was approved.

The Royal Faculty of Physicians and Surgeons.

At the monthly meeting of the Royal Faculty of Physicians and Surgeons of Glasgow on December 7th, the following were admitted to the Fellowship, both *in absentiâ*: Major Robert James Blackham, R.A.M.C., C.I.E., L.R.C.P.E., L.F.P.S.G., L.R.C.S.E., D.P.H., Simla, India, and Harry Cecil Darling, M.B.Lond., F.R.C.S.Eng., North Sidney.

The president reported his attendance at a meeting of the Scottish Medical Emergency Committee, and intimated that Dr. Norman Walker had arranged to address a meeting of practitioners in Glasgow within the Faculty on the difficulties which had arisen, and will present themselves still more in the future owing to the large number of medical men on active service both at home and abroad.

The President of the Royal Faculty, Dr. John Barlow, F.R.C.S., has been posted to the Scottish Command, joining the 4th Scottish General Hospital with the rank of Lieutenant-Colonel R.A.M.C.(T.). Major Thomas Forrest, F.R.F.P.S., has been posted Senior Medical Officer, Gailes Command, to the Glasgow Battalion of the Highland Light Infantry.

Ireland.

[FROM OUR SPECIAL CORRESPONDENTS.]

The Belfast Municipal Sanatorium at Whiteabbey.

The Belfast Corporation and the Poor Law guardians recently completed the arrangements for the transference of what was formerly the Poor Law consumptive sanatorium at Whiteabbey to the municipal authorities. Under the Poor Law Board the patients were under the medical care of Dr. Robert Hall and Dr. J. C. Rankin as visiting physicians; and there were two resident medical officers. The Local Government Board recommended the City Council to appoint one resident medical superintendent; this appointment has been made, Dr. Hans Gilliland being elected out of eight candidates at a salary of £500 per annum, with personal board and residence. The position of Dr. Hall and of Dr. Rankin is not yet settled. Dr. Hall qualified twenty-eight years ago, and, as far as one medical officer could, was the originator and developer of the first Poor Law consumptive sanatorium in Ireland; under the Poor Law Board he undoubtedly brought this sanatorium to its present state of perfection, and he has proved one of the most competent and most advanced officers of the board. Dr. Rankin's connexion is much more recent. Dr. Gilliland qualified in 1912, and has devoted his time to the study of tuberculosis. He has been resident medical officer at the Royal Victoria Hospital for Consumption at Craigleith. Considerable feeling has been shown in the public press and in medical circles as to the qualifications and ages of the other candidates, which have not been made public. It is hoped that the advantage of the abilities and large experience of the present two visiting physicians may be retained, at any rate for a few years, in the active service of the town.

Scarlatina in Belfast.

Considerable discussion took place at the last monthly meeting of the City Council on the increasing prevalence of scarlatina. This is the fifth year in succession in which an epidemic has occurred. The public, which pay so heavily for the public health department, did not grudge the cost of building one of the finest fever hospitals and spends large sums for its upkeep, is clamouring for an explanation. This was not forthcoming at the meeting. Discordant opinions of sanitary authorities were freely quoted; schools are being examined, and everything that can be done is apparently being done, and yet, as one

member said, no other city had suffered from an epidemic of scarlatina for five years in succession.

Students' Union, R.C.S.I.

The inaugural meeting of the Students' Union of the Royal College of Surgeons in Ireland was held on December 3rd in the hall of the College, when the President, Mr. F. Conway Dwyer, presided over a large attendance, which included a number of members of the Officers' Training Corps. Mr. Thomas E. Gordon, F.R.C.S.I., delivered an inaugural address, in the course of which he reviewed the events which preceded the war. He discussed some of the problems of military surgery and said that he need not urge his hearers to prepare themselves to join their fellow-students at the seat of war, for of the present class 75 had in one capacity or another given their services to the country, and already there were serving with the army 400 former students of the Royal College of Surgeons. Major-General Friend, in proposing a vote of thanks to the lecturer, said that, in addition to the splendid record of the Royal College of Surgeons, Trinity College had furnished 500 men.

Dublin University Biological Association.

At the opening meeting of the fortieth session of the Dublin University Biological Association, the biological medal was presented to Mr. James S. Robinson, the Bennett medal to Mr. Arthur Chance, the Cunningham medal to Mr. E. D. M'Crae, and the Purser medal to Mr. R. W. Fearon. The President-elect, Dr. Joseph T. Wigham, delivered an address upon the influence of science on modern medicine. In the discussion which followed it was stated that 130 members of the association were at present serving with the colours.

Correspondence.

ACCOMMODATION FOR TROOPS.

Sir,—The large number of men who have recently been called up for training in all parts of the country has placed the War Office in a difficult position as regards their accommodation.

I imagine that at present there are few under canvas, and that they are either billeted on the civil population or housed in temporary or permanent buildings more or less adapted for the purpose.

In addition to the housing question, it is necessary to have space for training, and therefore large towns would naturally be avoided; but there must be some military camps which have some features in common with the one in which I am interested—namely, Guernsey.

At the beginning of the war we suddenly and without warning had 1,500 men sent over here for training. They came from Staffordshire and were mostly dwellers in towns; indeed, many of them had never been near the sea before. I believe work had been slack with them, and they were badly clothed, as a rule, and looked as if sea air and good food would work wonders with them.

The authorities here did their very best to receive them properly; that must be fully acknowledged. Yet their lot has been an unenviable one, although they have borne the hardships and inconveniences they suffered with a cheerfulness that is beyond all praise. They were crowded into unsuitable tents; no latrines, ablution benches, or clothes were available for them, their food and the cooking left much to be desired, and wet and rough weather severely tried them.

The condition of affairs slowly improved, but, as was inevitable, many men became verminous and suffered from their uncleanly surroundings, without having any chance to help themselves. Indeed, the contrast with the treatment of the men of the North Staffordshire Regiment and the well-fed and well-housed men of the Royal Guernsey Militia was most marked.

It will probably be said that such conditions are unfortunately by no means unusual, and need not be mentioned in your columns, but there is a moral to be drawn from them, and this is my excuse for asking you to publish my letter. In my opinion the community did not do its duty to these men, and the reason probably was the "business as usual" attitude of the general public, who require that a great war must be successfully waged, but that they must not be inconvenienced by it.

We are told—and we know it is true—that the success of our army in this almost pan-European war must depend upon its being reinforced at the earliest possible moment by hastily trained troops, and that the comparatively few valiant men who draw the sword and are bearing the burden of the many, are in danger of being overwhelmed by force of numbers and exhaustion at the fighting line. We must clearly, then, sacrifice everything to the necessity of making our new army as efficient as we can at the earliest possible date. It is impossible for men, badly housed, clothed, and fed, and verminous to be at their best, and some of these disabilities might have been avoided. Here we have well built modern schools, with good lighting, ventilation, floors, and latrines. With but little alteration the latrines would serve for troops, and would be ample for the purpose; cooking arrangements, gas or other, could be provided, the heating apparatus could be modified, so as to provide hot water for portable baths of a cheap description and for washing clothes, and by watering the floors with a solution of cresol the appearance of vermin could have been prevented. These unselfish men who are serving their country would have been living under conditions of comparative comfort, which would be the more valuable as the days shorten, and would be quickly able to prepare for the stern ordeal of active service, and take their place in the fighting line. The authorities would have been able to provide without undue haste, which means loss of efficiency, for the accommodation of these men and those who must follow after them.

What is the other side of the question, and what is its value compared with that of the interests of the nation, vital as they are? Children would have been kept away from school for a few months, but this could easily be dealt with by raising the age of school attendance for a limited period. What is that when we are in the throes of the greatest war the world has ever known? I hope there will be many men placed in a similar position to myself who will share my opinions, and will realize that if it is late in the day, it is not too late to help the men of the new army in their efforts to become efficient soldiers of the King.—I am, etc.,

Hy. Draper Bishop,
Guernsey, Dec. 6th. M.O.H., States of Guernsey.

CONCUSSION OF THE SPINAL CORD.

Sir,—I have been much interested in reading accounts of surgical experiences in the war to notice the effects which simple "concussion," uncomplicated by gross lesion, appears to have had upon both spinal cord and peripheral nerves. Mr. D'Arcy Power, for instance, in the Journal of November 28th, p. 238, says that "the most interesting injuries to the nervous system and nerves were those to which the non-committal name of 'concussion' must for the present be applied. They had to be distinguished from laceration, haemorrhage, compression, and other tangible conditions by the fact that no gross lesion was presented by examination during life."

Some years ago, in an endeavour to disentangle "concussion of the spinal cord" from "concussion of the spine"—an elusive term which was the parent of much faulty diagnosis and spinal malingering—I made a scrutiny of, and brought together, all the cases up to the time recorded both in civil and military surgery, and was able, as I believe, to establish the exceeding rarity of concussion symptoms apart from gross discoverable lesion of the spinal column or the contents thereof. A singularly small number, not more than three or four, of unequivocal concussion was to be found, and I wrote: "It should, however, be especially noted that these cases occurred in military practice, and it is not inconceivable that a blow inflicted on a small area with the prodigious momentum of a bullet may be more likely to cause structural damage to the spinal cord or other contents of the spine by concussion than is any other injury which befalls the vertebral column." Anatomical facts, moreover, warranted the surmise that the symptoms of simple concussion were most likely to be met with, if anywhere, after blows upon the lowermost regions of the spinal column, where the nervous elements pretty nearly fill the spinal canal, akin to the condition of things pertaining to the skull and brain.

The opening chapter of *Injuries of the Spine and Spinal Cord* (second edition, 1895) is upon "Concussion of the Spinal Cord," where the whole subject is fully dealt with, and I venture to bring it to the notice of those now interested in the subject, or who may meet with cases in military practice, in the hope that such cases, if any, may be published in full detail, so that this important and difficult subject may be further elucidated.—I am, etc.,

December 1st. HERBERT W. PAGE.

RADIOGRAPHY IN THE DIAGNOSIS OF BULLET WOUNDS.

SIR,—In Sir John Bland-Sutton's exceedingly interestingly clinical lecture on the value of radiography in the diagnosis of bullet wounds, published in the JOURNAL of December 5th, reference is made to the care which is necessary in the interpretation of radiograms, especially when it is desired to determine the relation of a retained bullet to a bone. A case is recorded and figured in which "it required several plates to determine accurately whether the bullet was lying at the back of or in front of the bone" (the femur), and in which operation showed that it was "firmly embedded in the condyle near the adductor tubercle."

My object in referring to this matter is to insist upon the great value of the stereoscopic method in this as in so many other circumstances.

By this means, and with the expenditure of only two plates, the surgeon may have the great assistance of actually seeing that the bullet is *in* a bone, before he proceeds to an operation, if such be undertaken.

I may well illustrate the value of this method by referring to a case in which the omission to employ it nearly resulted in a fruitless search. A shrapnel bullet had been carefully localized in the upper part of the thigh and was believed to be lying behind the femur. For a while it could not be found until a little patch of swollen periosteum over the base of the great trochanter attracted attention and led to the discovery of the bullet in the bone at a depth of about a third of an inch beneath the surface.

The examination of a sufficient number of plates taken in various planes will, no doubt, eventually give the information required, but surely the stereoscopic method is the most conclusive. The value of the method in determining the exact relation of a bullet to the ribs is particularly striking.—I am, etc.,

Royal Naval Hospital, Plymouth, Dec. 8th. RAYMOND JOHNSON.

THE TREATMENT OF WOUNDS IN THE PRESENT WAR.

SIR,—So convinced am I of the absolute necessity of some simple common-sense precaution against all the horrors and dangers of sepsis, and so fatally true is it here that "prevention is better than cure," that I think every soldier at the front should be taught how, and provided with the means, to disinfect his own wounds, or at least that the men at the front should be able to do this for each other on the spot. Having had considerable experience of teaching all classes of people "first aid," and of explaining to them the principles and essentials of antisepsis, I feel quite certain that it would be no difficult or impossible task to instruct our soldiers in the objects of surgical cleanliness and in a simple method of wound disinfection, and I am satisfied that our men are sufficiently intelligent and sufficiently alive to the importance of the matter clearly to understand and carry out this teaching in practice.

As to the means to be employed, I have a simple practical suggestion to make which will meet the case, better at any rate, I think, than the carbolic suppositories suggested by Sir Watson Cheyne. I send you a sample of a little apparatus I have made. A hollow wooden shell or tube,* open at one end and closed at the other (such as is used for conveying tubes of vaccine, etc.), is fitted with a cork at its rounded opening. This cork should project slightly, so as to admit of ready removal. Into the centre of the lower, or narrower end of the cork a piece of thick aluminium wire is fixed, several inches long (the size may be varied according to the size of the container). The free end of the wire may be twisted, or bent upon itself so as to give a secure hold to the pledget of wool or gauze which is wound on to it; the pledget is then soaked in pure liquid phenol, placed in its container, securely corked, and the whole wrapped in paper or in a thin cardboard case. It need take up very little room, and should form an essential part of the first field dressing that every soldier carries upon him at the front. I should suggest that as soon as possible after the infliction of, say, a shrapnel wound the man himself, if able, or one of his companions, in the absence of any medical man, should, after arresting haemorrhage by the application of a tourniquet, etc., swab the wound as thoroughly as possible, using, if necessary, a number of these swabs; any foreign particles, unless ingrained, could at the same time be removed by brushing them off with the swab; the wound should then be covered with an antiseptic (for example, double cyanide) dressing, and bandaged firmly in position until the patient can be removed to the rear hospital for more thorough surgical cleansing and treatment. Bullet wounds should also have their edges swabbed before the antiseptic dressing is applied. (In severe wounds the shocked condition of the patient would make the application of the phenol almost painless, and in no case does the pain of the application last long, and it then acts anaesthetically.)

I do not suggest that this method is ideal, but I submit that it is simple, inexpensive, and worthy of trial, and I would ask the authorities to provide large quantities of these "protected swabs" for immediate use at the front. Their cost will be but trifling, and they will, in my opinion, if properly used, save endless suffering and loss.—I am, etc.,

Bowdon, Nov. 21st. P. R. COOPER, M.D. and B.Sc.Lond., F.R.C.S.Eng.

*To prevent evaporation this can be lined with a thin coating of paraffin, which is simply done by pouring in melted paraffin (melting point, 120° F.), and after allowing to stand a few seconds, pouring it out again so as to leave a thin film, which, on cooling, forms a damp-proof lining.

THE PREVENTION OF TETANUS.

SIR,—In reference to Dr. Stuart Oliver's letter (November 28th, p. 949), it is true that the use of quinine hypodermically and intramuscularly has been considerably restricted during the last two or three years, because tetanus was noticed occasionally to supervene, but such cases were attributed chiefly to the action of quinine stimulating latent spores into activity, and not to an infection through contaminated needle or faulty technique.

This question was investigated by Lieutenant-Colonel Sir David Semple when he was director of the Central Research Institute, Kasauli. The results of his experiments and his conclusions were embodied in a report published by the Government of India in 1911; and I believe it is entirely due to Sir David Semple's investigations that quinine is no longer given hypodermically as a routine practice in malarious countries.

The following extracts from the report are particularly interesting just now:

> At first sight it would seem impossible, when given a sterile syringe, sterile quinine solution, and sterile skin at the site of inoculation, to produce tetanus, and so it would be except for the fact that there are people who harbour in their bodies tetanus spores, which may lie dormant, either in a recently healed up wound or abrasion, or possibly in a old healed-up injury long forgotten. There are also many healthy individuals who harbour tetanus germs in their intestinal tracts. . . .
>
> In a latent tetanus spore infection there are many more conditions, in addition to the hypodermic injection of quinine, which would favour the growth of spores. . . . It has long been known that in campaigns where soldiers are subjected to great fatigue, coupled with extremes of heat and cold, many cases of tetanus occur. Here the depressing influences of fatigue, in conjunction with great heat or great cold, would diminish the resistance in those who harboured infection. . . .
>
> We know that hypodermic injections of morphine, cocaine, strychnine, or digitalin are rarely (if ever) followed by tetanus. I cannot remember ever hearing of a case of morphine injection giving rise to tetanus, and I am sure it is a method of treatment more generally adopted than quinine injections.

With an experience of more than twenty years in Assam, I also cannot call to mind a case of tetanus arising from a morphine injection, and I trust our wounded soldiers will not be denied this means of relief and benefit; due precautions for sterilizing needle, skin, etc., being taken.

Dr. Oliver's suggestion that the needles should be of some non-corrosible metal will commend itself to all who have used them, and they are cheaper in the long run. Steel needles are an abomination: they rust, the bore gets choked, and they are apt to break in use, especially if they have been sterilized by being passed through a flame.—I am, etc.,

Bath, Nov. 30th. E. WELLS WITHAM, Surgeon-Captain (ret.), Assam Valley Light Horse.

BRITISH IN GERMAN CONCENTRATION CAMPS.

SIR,—I was much interested in the leader, "Germans in Concentration Camps," which appeared in your issue of December 5th.

I have myself recently returned after three months' interment in Germany, and can personally vouch for the malicious efforts now being made by the German press (inspired?) to stir up popular feeling against the British. My own experience of a "lager" (concentration camp) at Linden, Hanover, may be of interest to your readers.

This lager was an old disused percussion cap factory—dirty, damp, and dilapidated. In it were men, women, and children; one child was born there. The men were of British, Belgian, French, and Russian nationalities; the women and children were, I believe, all Belgian. On arrival we had to give up all knives, razors, pocket scissors, and sharp instruments of every kind; also pipes, tobacco, matches, and all forms of smoking material; likewise all money had to be deposited with the authorities.

Each man was served with one coarse blanket, a bundle of wheat straw, a small enamelled basin, and an iron spoon; this was our complete outfit. Our beds were made by spreading the straw on the cement floor of one of the outbuildings assigned to us, care being taken to avoid drips from the roof, rat-holes, and suchlike inconveniences.

Roughly one-third of the place was assigned to the women and children and two-thirds to the men, the only common ground being a path, between the male and female side, on which fathers could meet their wives and children and pace up and down to pass the long weary hours.

As for sanitary arrangements there were none. The old privies of the factory had never been cleaned out, and were as full of filth as to be almost unusable. The only water supply was a fire hydrant at one end of the common path. There was no heating apparatus of any kind.

Food was both scarce and coarse. In the morning between 7 and 7.30 we had to line up in front of a central building—which served as an administration block—and wait for bread to be served out. Each one received a chunk (about 4 oz.) of coarse brown bread (*Graubrod*), then we proceeded in batches to receive a large ladleful of very weak "coffee," without milk or sugar, the receptacle being our enamelled basin. For dinner we had lentil, pea, or bean soup with a few potatoes and another vegetable mashed in it. Occasionally there were fragments of meat, liver, lung, or heart in the "soup." Supper, at 6 p.m., consisted of bread only. Women and children all had the same fare.

Truly we lived the "simple life," and for this "kultured" treatment 1 mark (1s.) a day was docked off the sum of money which we had been compelled to deposit with the authorities on entering.

The only redeeming feature was that we were allowed to have visitors occasionally, who brought us white bread, butter, sugar, and sometimes jam or other dainty.

I have recently had post-cards from friends who were with me at the Linden lager, and who are now interned on the racecourse at Ruhleben, near Spandau, and they state that the conditions there are certainly an improvement on those which obtained at Linden.—I am, etc.,

JAMES J. PATERSON, M.D.Lond., D.P.H.,
M.O.H. East Berks United Sanitary Districts.

Guildhall, Maidenhead, Dec. 7th.

THE RESEARCH SCHEMES OF THE MEDICAL RESEARCH COMMITTEE.

SIR,—In the research schemes of the Medical Research Committee published in your issue of December 5th no recognition is given to the study of heredity. While so much is being spent on the study of environmental conditions it is a pity that nothing can be spared for the study of innate constitutional or diathetic factors. The splendid work on hereditary diseases of the eye carried out by the late Mr. Nettleship is just as much a part of medical research as an investigation into the characters of the tubercle bacillus.

Professor Bateson and his co-workers have shown that the analytic study of genetic constitution is of the utmost importance in the understanding of life in all its forms, and man is no exception.

In a national and comprehensive scheme of medical research, this aspect in all its bearings, individual as well as social, should not be overlooked.—I am, etc.,

Warrington, Dec. 16th. J. S. MANSON.

POPULAR FREUDISM.

SIR,—In the review of an English translation of Freud's *Psychopathology of Everyday Life*, published in the JOURNAL of December 5th, it is said that in this book the "strength and the weakness" of the Freudian system of psychology are made clear. But the reviewer shows up the "weakness," and says nothing about the "strength." Nothing is here for wonder—*De non apparentibus et de non existentibus eadem est ratio*. The general theory advocated in the book is that many seemingly accidental slips of speech and pen, etc., are determined by "unconscious" psychical motives. The reviewer especially condemns Freud's explanation of the momentary forgetting of a proper name—a failure common to most people, and very frequent in those of advanced years—as "too full of assumption to be anything but sophistical." Now Freud's explanation is that the temporarily forgotten name is connected with an unconscious painful idea or system of ideas! To argue against such a statement as this is surely unnecessary, its absurdity being patent to all who think about it for a moment, quite apart from the further question as to whether the words *unconscious painful idea* have any meaning whatever.

Surely the time has at last come when all psychologists, psychiatrics, and medical societies should join with Dr. Mercier in ceasing to regard this modern and alien jargon about the "unconscious" as matter for serious consideration, and follow the better course of killing the abounding nonsense of the Freudian "Philosophy" by ridicule, or by letting it perish, at least in this country, from neglect of cultivation. At present it plays the part of a virulent pathogenic microbe in the wells whence psychiatrists drink.—I am, etc.,

December 8th. H. B. D.

EPSOM COLLEGE.

SIR,—Will you allow me to call the attention of your readers to the educational and pecuniary advantages offered by Epsom College to the sons of medical men? These are briefly described in the advertisement which appears on p. 59 of the BRITISH MEDICAL JOURNAL of December 5th; but I should like in this letter to emphasize the facts that this year ten boys out of thirteen passed the whole of the First Examination for Medical Degrees of the University of London, and that eighteen boys out of twenty-three passed the Matriculation Examination of the same university, six of them gaining a first class.

May I also take this opportunity to remind those of your readers who are not already subscribers to the Royal Medical Foundation attached to Epsom College that this Foundation provides gratuitously an education of the highest class, together with maintenance, clothing, and pocket money, for fifty necessitous sons of medical men, and gives pensions of £30 each to fifty aged members or widows of members of our profession in reduced circumstances.

It is necessary to procure a sum of about £4,500 a year in voluntary contributions to enable the continuance of these benefits to the medical profession; and as the numerous calls in connexion with the war are causing the withdrawal of some and the curtailment of other annual subscriptions, I trust that numerous fresh contributors will be forthcoming to assist and encourage the council at a particularly anxious time.—I am, etc.,

HENRY MORRIS,
London, W., Nov. 24th. Honorary Treasurer.

DR. C. E. SHERRINGTON, F.R.S., professor of physiology at Oxford, has been appointed Fullerian professor of physiology at the Royal Institution, London, for a term of three years from January next. During the session which begins after Christmas, Dr. H. G. Plimmer will give three lectures on modern theories and methods in medicine. The Friday evening meetings will begin on January 22nd, when Sir James Dewar will give a discourse on problems of hydrogen and the rare gases. Other Friday evening discourses will be given by Dr. Dugald Clerk, Professor A. W. Crossley, Dr. William S. Bruce, Professor E. B. Poulton, Rev. A. L. Cortie, Sir Rickman John Godlee, Professor G. H. Bryan, and Professor Sir J. J. Thomson.

Obituary.

THE LATE CAPTAIN R. S. RANKEN, V.C.

By the courtesy of his father, the Rev. Henry Ranken, minister of the parish of Irvine, Ayrshire, we reproduce a portrait of Captain Henry Sherwood Ranken, R.A.M.C., on whom the Victoria Cross was conferred for his bravery in tending the wounded in the trenches under rifle and shrapnel fire at Hantvesnes on September 19th and on September 20th, and continuing to attend the wounded after his thigh and leg had been shattered. Captain Ranken, who graduated M.B., Ch.B. in the University of Glasgow in 1905, entered the Royal Army Medical Corps in 1909, and to the brief account of his scientific work already published we may add the following particulars. In 1910 Captain Ranken was appointed by the Tropical Diseases Committee of the Royal Society to be an assistant to Mr. Plimmer in certain researches he had undertaken on the experimental treatment of trypanosomiasis. In November of that year a paper on this subject by Mr. Plimmer, Major W. B. Fry, and Captain Ranken was published by the Royal Society (*Proc. Roy. Soc.*, vol. 83 B.). It was principally concerned with the treatment of trypanosomiasis by the intravenous injection of precipitated metallic antimony, and owing to Captain Ranken's skill this method of treatment was made possible and safe in animals.

CAPTAIN R. S. RANKEN, V.C.
[Photograph by Brinkley and Son, Glasgow.]

Having convinced himself of the possibilities of this method Captain Ranken accepted an appointment in the Sudan Sleeping Sickness Commission and went out to the Yei camp in the Lado enclave in the autumn of 1911. He there carried out this method of treatment on a large number of cases of sleeping sickness, and discovered that the same treatment was effective also for yaws. The results of the work he did there during the first year were published by the Royal Society (A Preliminary Report on the Treatment of Human Trypanosomiasis and Yaws with Metallic Antimony, *Proc. Roy. Soc.*, vol. 86 B.) in February, 1913. He came back from his second year in the Lado in the summer of this year, and unfortunately he had not completed his second report when he was required at the front, where he so bravely died. He was to have gone out to the Lado again last month, and he hoped, after three years there, that he would have been able to have brought his work on the treatment of trypanosomiasis to a practical conclusion. During leave at home in 1913 he was not idle, but worked with Mr. Plimmer again and with Major Fry, with whom he wrote a paper on the subject of the granules extruded from trypanosomes, which was published by the Royal Society (*Proc. Roy. Soc.*, vol. 86 B.). His work, although none of it is finished, was of the best, and by his death research in these subjects is deprived of one of its best workers. He was extremely careful and accurate in his observations, and most patient in his work. He had withal excellent fingers for the delicate technique his microscopic and experimental work demanded. He was, Mr. Plimmer tells us, a delightful colleague and a loyal friend.

HERBERT TAYLOR, M.B.LOND.,
KENNINGTON.

THE friends of Herbert Taylor—and they were many—will have heard of his death with the deepest regret. He was born on August 4th, 1850, being the third son of Dr. David Taylor of Kennington Park Road, who for many years practised in that part of South London. He was educated at Epsom College, where he gained many prizes, and in 1867 the entrance scholarship from that school to St. Bartholomew's Hospital. After taking the degree of M.B.Lond. and the diploma of M.R.C.S. in 1872, he held the posts of ophthalmic house-surgeon, resident obstetric assistant, and house-physician at the hospital. After leaving the hospital he joined his father in practice, and led a busy life of work till his death on December 2nd. He was a member of the British Medical Association, and represented the Lambeth Division on the Metropolitan Counties Branch Council for several years.

It is not too much to say that Herbert Taylor was beloved by all who knew him. His bright, cheery manner, his hatred of shams, and his affectionate nature gave him a host of friends in his student days, and his kindness and gentle care for his patients will make his loss very greatly felt in South London. Herbert Taylor was very musical and had a beautiful voice. Nothing pleased him more than to get a few friends together for a musical evening.

A severe illness a few years ago made a great demand on his strength, and it is doubtful whether he ever quite recovered it. On the Sunday before he died he was able to make his Communion, but in the evening did not feel well, and in spite of all the devoted care of his brother, Frederick Taylor of Guy's, he passed with a gentle sigh beyond the veil in the early hours of Wednesday morning.

He married in 1834 Gertrude Louisa, youngest daughter of Mr. Charles D. Carter, F.R.C.S., of Pewsey, Wilts, and leaves four sons, two serving their King and country in the navy and army, one is in the Colonial Medical Service, and one is a master at Clifton College.

Medico-Legal.

ALLEGED MISREPRESENTATIONS BY A MEDICAL PRACTITIONER. VERDICT FOR DEFENDANT.

ON December 1st Mr. Justice Bray, sitting with a special jury, heard a singular case in which Mr. Gilbert Fox Allom, an electrical engineer, sought to recover damages from Dr. Alexander Cuffe of Tadworth, Surrey, for alleged misrepresentations.

Mr. Colam, K.C., and Mr. Szlumper (instructed by Messrs. Baxter and Co.) appeared for the plaintiff; Mr. McCall, K.C., and Mr. Neilson (instructed by Messrs. Le Brasseur and Oakley, solicitors to the London and Counties Medical Protection Society) appeared for the defendant.

It appeared, according to the report in the *Daily Telegraph*, that in 1911 the defendant, who was the plaintiff's family doctor, advised him to go away for his health. In 1912 the plaintiff went abroad on the advice of a specialist, and when he returned to England, the relations between him and his wife became strained. In 1913 she commenced separation proceedings, and the defendant gave certain information to her solicitors. He was subpoenaed by both sides. The defendant was requested by the wife's solicitors to break to her husband (the plaintiff) the news that he was going to give evidence to the effect that the plaintiff was suffering from a form of epilepsy. This the defendant did, saying that he had formed an opinion which was confirmed by Dr. Fawcett and Dr. Verling-Brown. It was alleged that in making this communication the defendant exceeded his instructions, and that he so acted in order to use his influence to prevent the plaintiff from fighting his wife's petition, and to terrify him into settling the case.

The plaintiff, in giving evidence, said that what was told him was a great shock, and the result was that the suit with his wife was settled. He was so upset that he was totally unfit to fight the action. Cross-examined by Mr. McCall, he said that he had known the defendant since 1907 and down to January 15th, 1912, had every confidence in his skill and care. He fully appreciated that he was charging the defendant, in whom he had had all this confidence, with false and fraudulent representation. Asked whether he could suggest any motive for the defendant telling him lies in order to deceive him, he said it was not for him to suggest any motive. In reply to the Judge, he said that the defendant might have been anxious to see his wife

come through the case successfully. He admitted that neither in his letter to the defendant nor in the pleadings had any such motive been suggested.

Dr. Fawcett, in giving evidence, said he had found no trace of minor epilepsy, but that a brother practitioner might have formed an honest opinion that the plaintiff had minor epilepsy.

Dr. Verling-Brown also gave evidence for the plaintiff.

The defendant, in giving evidence, said that when he first saw the plaintiff in 1908 he had collapsed in a fit on the floor of his bathroom. Subsequent examination of the plaintiff (in 1911) confirmed the view that he was epileptic, and when witness had interviews with Dr. Fawcett he considered that Dr. Fawcett agreed with him. When he informed the plaintiff of this, at the request of the solicitor, the plaintiff thanked him.

Mrs. Constance Allom, in giving evidence, said that the defendant had shown her Dr. Fawcett's letters, and that the defendant had no interest in her success in the suit with her husband.

Dr. H. C. Thompson and Dr. Woodwark having given evidence for the defendant,

The jury intimated that in their opinion there was no case of fraud.

His Lordship: I think I should have held that there was no evidence, but I thought it would save the possibility of appeal to let the jury give a verdict.

Mr. McCall: It is much more satisfactory to the defendant that the jury should have given a verdict.

Judgement was then given for the defendant with costs.

The Services.

ARMY PENSIONS TO THE FAMILIES OF OFFICERS.

THE following are the rates of pensions and gratuities allowable to the families of officers (under the rank of colonel) of the Regular Army, the Special Reserve of Officers, and the Territorial Force, and to the families of officers holding *only* temporary commissions for the purposes of the present war.

Widows and Children.

CLASS A. Families of Officers killed in action or dying of wounds received in action within seven years after having been wounded.					CLASS B. Families of Officers dying from disease caused by fatigue, privation, or exposure incident to active operations in the field or from wounds or injuries sustained on duty (not in action) within seven years after removal from duty for the disease or injury.	
Rank of Officer—that is, permanent rank, unless the Officer holds *only* temporary rank.	Pension to Widow (during widowhood). Yearly.	Compassionate Allowance for each child (Sons till 18, Daughters, unmarried, till 21). Yearly.	Gratuity in addition to pension, etc.		Pension to Widow (during Widowhood). (No gratuity is payable in these cases).	Compassionate Allowance for each Child (Sons till 18, Daughters, unmarried, till 21)
			Widow	Each Child.	Yearly.	Yearly.
	£	£	£	£ s. d.	£	£ s. d.
Lieut.-Col.	180	24	450	150 0 0	135	20 0 0
Major ...	140	21	300	100 0 0	105	17 10 0
Captain ..	100	18	250	83 6 8	75	15 0 0
Lieut. ...	80	15	140	46 13 4	60	12 10 0
2nd Lieut.	80	15	100	33 6 8	60	12 10 0

Motherless Children.—Twice the above rates of compassionate allowance may be granted to motherless children. If an officer (Class A) leaves a *daughter only* (unmarried and under 21) she may be granted, in lieu of the above rates, a special allowance varying from £40 to £90 a year, according to rank. These awards are in addition to the gratuity.

Mothers.—If an officer (Class A) leaves neither a widow nor legitimate child, his mother, if a widow without other pension or adequate provision, may be granted a special pension varying from £40 to £90 a year, according to rank, provided that she had been mainly dependent on the officer.

Sisters.—If an officer (Class A) leaves neither widow, legitimate child, parent, nor brother, a similar pension may be granted to his sister or sisters, jointly, if unmarried, subject to the above proviso.

Applications.—All applications for the grant of pensions, as above, should be addressed to the Secretary, War Office, Whitehall, S.W.

ROYAL NAVY MEDICAL SERVICE.

Report on the Examination of Candidates for Entry as Acting Surgeons, R.N.

THE medical department of the Admiralty requests us to state that the marks shown against Surgeon F. C. Hunot, on page 952 of the BRITISH MEDICAL JOURNAL of November 28th, are those obtained by him at the Entrance Examination only, when he took first place, he having been prevented by illness from attending the Greenwich course and from competing at the subsequent examinations.

Universities and Colleges.

UNIVERSITY OF LONDON.

MEETING OF THE SENATE.

A MEETING of the Senate was held on November 18th.

The War.

It was resolved:

1. That military service during the war be counted as equivalent to not more than two terms of a course of study in military science for internal students in any one of the three years over which such course of study would ordinarily extend.
2. That, in the session 1914-15, in the case of an internal student entering for an examination of the university, 120 hours of military training in the University of London contingent of the Officers' Training Corps, duly certified by the Commanding Officer be counted as equivalent to 25 per cent. of the hours of attendance prescribed for the student's course of study in that session.
3. That, during the continuance of the war only, the Second Examination for Medical Degrees, Part I, be held in December as well as in March and July.

Recognition of Teachers.

The following were recognized as teachers in the subjects and at the institutions indicated:

Guy's Hospital.—Mr. Patrick P. Laidlaw (Pharmacology) during the absence of Dr. Clark on military service.

London School of Tropical Medicine.—Dr. G. C. Low (Tropical Medicine).

Royal London Ophthalmic Hospital.—Mr. R. F. Moore (Ophthalmology).

General Physiology and the Intermediate Examination in Science.

The regulations for the intermediate examination in science for internal students were amended by the substitution of the words "120 hours" for the words "160 hours" at the end of section (2) of the curriculum in general physiology on p. 231 of the Red Book, 1914-15.

Second Examination for Medical Degrees and B.Sc. Honours in Chemistry.

The regulations for the B.Sc. honours examination for internal students were amended by the insertion of the words "Chemistry or" after the words "B.Sc. (Honours) in" in line 3 of the last paragraph on p. 256 of the Red Book, 1914-15; and the regulations in the Faculty of Medicine were amended by the addition of the words "Chemistry or" before the word "Physiology" in the fourth line of the third paragraph on p. 190 of the Red Book, 1914-15. It was resolved also that candidates who have passed the second examination for medical degrees, Part II, should be admissible after an interval of not less than one year to the B.Sc. Honours examination in chemistry for external students without having passed the intermediate examination in science.

B.Sc. Honours Examination in Physiology.

The regulations for the B.Sc. (Honours) Examination in Physiology for internal students was amended by the insertion of the following paragraph on p. 268 of the Red Book, 1914-15, before the words "Subsidiary Subjects":

No Honours course in this subject will be allowed to run concurrently with a course for the Final M.B., B.S. Examination.

Appointment of Examiners.

The following appointments to examinerships have been made: Dr. W. G. Ridewood, as staff examiner in biology for the first examination for medical degrees for internal and external students in December, 1914, in place of Mr. T. G. Hill, absent on military duty. Dr. M. S. Pembrey to be internal examiner in physiology in the second examination for medical degrees, part ii, for internal and external students in March and July, 1915, in place of the late Mr. C. F. Myers-Ward. Dr. S. P. Phillips (Medicine) and Professor A. Carless (Surgery) to act as examiners at the M.D. and M.S. examinations for internal and external students in December, 1914, in place of Dr. H. D. Rolleston (Medicine) and Mr. F. F. Burghard (Surgery) respectively, who are absent on military duty.

The Reitlinger Prize.

The Paul Philip Reitlinger Prize, offered this year for an essay embodying the result of research work on a medical subject, has been awarded to Alfred Hope Gosse, M.A., M.B.Camb., M.R.C.P., London Hospital Medical College, for an essay on The Heart in Acute Rheumatism, with Special Reference to Graphic Methods of Investigation. The prize, this year of the value of £40, was founded with funds given to the university by Mr. Albert Reitlinger in memory of his son, a student of

St. George's Hospital Medical School, who died on December 3rd, 1911. Next year the prize will be offered for the best essay on the economic condition of the people of England in 1815 in comparison with the present day.

UNIVERSITY OF SHEFFIELD.

THE Council of the University has appointed Mr. William MacAdam, M.A., M.D., B.Sc.Glas., D.P.H.Camb., to be demonstrator in public health; and Mr. T. Chetwood, M.D.Lond., D.P.H.Oxon, to be lecturer on hygiene in the training department.

UNIVERSITY OF DUBLIN.

SCHOOL OF PHYSIC, TRINITY COLLEGE.

THE following candidates have been approved at the examinations indicated:

INTERMEDIATE MEDICAL (*Part I, Anatomy and Institutes of Medicine*).—J. R. Brennan, P. Rocks, J. G. Bird, H. J. Rice, P. H. S. Smith, D. S. Prentice, Marie A. Hadden, W. F. Wicht, H. Brill, T. H. R. McKiernan, P. A. Hall, Rita Henry, Millicent Hamilton-Johnstone, R. W. Pritchard. (*Part II, Anatomy and Physiology*).—T. P. Chapman, C. L. McDonogh, J. B. Taylor, L. Blumberg, E. Lipman.

FINAL (*Part I, Materia Medica, Medical Jurisprudence, and Hygiene and Pathology*).—Esther V. Adderley, C. H. Commerford, J. H. C. Walker, F. Healy, G. F. Brady, M. McG. Russell, G. W. Doran, T. E. B. Beatty, W. Hunt, J. A. C. Kidd, †T. W. Sweetman, †L. Murphy, §J. E. Jameson.

† Medical Jurisprudence and Hygiene, Pathology.
‡ Medical Jurisprudence and Hygiene, Materia Medica.
§ Materia Medica, Pathology. ‖ Pathology (completing examination).

FINAL (*Part II, Surgery*).—F. Harris, G. B. Hadden, E. P. H. Vickery, G. A. Hoffman, F. A. Lumley, E. L. F. Nash, D. S. Martin, E. G. Fish, Hilda M. Marsh, E. Robinson. *Medicine*: E. A. Lumley, F. Harris, W. J. Ronan, E. P. H. Vickery, B. C. O. Sheridan, F. A. L'Estrange, A. G. Varian, R. A. Anderson, G. B. Hadden, Kathleen D. Wallace, J. P. Quinn, R. W. Chapman, F. R. Dougan, D. S. Martin, T. J. L. Thompson. *Midwifery*: *I. W. Corkey, E. D. T. Hayes, E. W. Craig, R. W. Shegog, Violet M. Deale, E. J. McSwiney, H. Mitchell, D. C. Pim, Geraldine Murphy, Hilda M. Marsh, G. Stanton, H. Daniel, C. C. Albertyn, E. Mannix, A. W. P. Todd, S. W. Fisher, F. J. O. King, M. B. King, D. H. Hall, C. McL. West, J. H. C. Walker, A. W. D. Magee, A. C. Bateman, G. Joughin, A. J. Horne, D. S. Martin.

* High marks.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

A COMITIA was held on Thursday, December 3rd, Sir Thomas Barlow, Bart., K.C.V.O., the President, being in the chair.

Narcotic Drugs.

A letter was read from the Foreign Office, dated November 4th, thanking the College for its communication concerning the sale of narcotic drugs.

Belgian Doctors' and Pharmacists' Relief Fund.

The Treasurer (Sir Dyce Duckworth) announced that the Finance Committee had recommended that the sum of 50 guineas should be presented to the Belgian Doctors' and Pharmacists' Relief Fund. The recommendation was adopted.

Early Clinical Thermometers.

A gift by Dr. J. E. Squire of two old clinical thermometers in use up to 1870, which had belonged to his father, Dr. William Squire, was accepted with thanks.

Election of Censor.

Dr. Newton Pitt was elected a Censor in the place of Sir Wilmot Herringham, M.D., resigned, owing to his absence with the army abroad.

New Regulations for the Weber-Parkes Prize.

Hitherto the Weber-Parkes Prize has been awarded triennially to the writer of the best essay upon some determined subject connected with the etiology, prevention, pathology, or treatment of tuberculosis. A silver medal has been awarded to the holder of the prize, and a similar medal, distinguished as the second medal, to the essayist who came next in order of merit. New regulations were adopted by the college, providing that the prize shall be awarded triennially for the best work already done in connexion with the etiology, prevention, pathology, or treatment of tuberculosis. A silver medal will still be awarded to the holder of the prize, but the second medal will not be continued.

Recognition of School.

A report was received and adopted from the Committee of Management, dated November 17th, recommending that the Newcastle-on-Tyne Royal Grammar School should be added to the list of institutions recognized by the Examining Board in England for instruction in chemistry and physics.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

Diploma of Fellow.

THE following candidates were approved at the First Professional Examination:

J. Adhya, Marian N. Bostock, L. S. Debenham, S. G. Dunn, B. T. Edye, A. N. Hooper, J. B. Hume, Helen Ingleby, H. G. V. Mence, A. E. Moore, S. D. Rhind, F. O. Shah, J. R. White, D. Whyte, G. S. Wilson.

Medical News.

THE Mayor of Lyons suggests the creation of institutions in which soldiers rendered incapable of resuming their old trades in consequence of amputations should be taught new occupations suitable to their condition.

MR. P. JENNER VERRALL, M.B., B.C.Cantab., F.R.C.S., has been appointed medical officer to Epsom College, in succession to Mr. W. W. Coltart, L.R.C.P., M.R.C.S., who has resigned the position after holding it for twenty-eight years.

THE total number of medical students in Switzerland during the summer semester of 1914 was 2,705. They were distributed among the several universities as follows: Bâle, 327, of whom 20 were women; Berne, 617, of whom 69 were women; Geneva, 879, of whom 223 were women; Lausanne, 316, of whom 70 were women; Zürich, 566, of whom 74 were women.

THE British Fire Prevention Committee, which has already issued 4,712 copies of its poster "Fire Warnings" to military hospitals and 4,355 to 474 Red Cross hospitals, offers to send copies to any hospital taking in wounded, or any refugee home or hostel not yet supplied. Application should be made to the Registrar of the British Fire Prevention Committee, 8, Waterloo Place, London, S.W., stating the character of the building and the number of beds.

THE National Council of Trained Nurses of Great Britain and Ireland has transmitted to the Secretary of State for War a resolution recording its disapproval of the present organization of the nursing of the sick and wounded soldiers in military auxiliary hospitals at home and abroad, and protesting against the dangerous interference of untrained and unskilled women, who have been placed in positions of responsibility for which they are not qualified.

WE are sorry to learn that the Notts County Council, which has in contemplation the appointment of a whole-time tuberculosis medical officer to have charge of the tuberculosis dispensaries and the general arrangements for the provision of tuberculosis treatment in the county, intends to offer a salary of only £450 to that officer. Even if offered in ordinary circumstances such a salary (which is substantially below the minimum of £500 now almost universally recognized in respect of responsible work of the kind) would, in our opinion, be inadequate. At a time like the present it is practically certain that the suggested salary cannot attract candidates fitted, by experience and ability such as would secure cordial co-operation with the members of the local medical profession, for such a post, and in our opinion the county council would, in the interests of the community, do well to reconsider its decision.

MAJOR LEONARD DARWIN presided over the December afternoon meeting of the Eugenics Education Society on December 3rd, when Professor J. L. Myres gave a lecture on the rise and fall of the ancient world. Eugenics in the modern sense of the word was, he said, a very recent branch of knowledge, although ever since practical politics had existed the question had been debated as to what kind of man made the best citizen and how this type might be obtained. This was especially true of the Greeks: the Oriental peoples valued population precisely as they did area, for its quantity rather than for its quality. Though little definite knowledge was obtainable it was possible to trace certain great rises and falls in the population of the ancient world. They were largely due to geographical rather than to political causes. Thus, a succession of bad seasons would lead the inhabitants of the high mountainous regions to emigrate in large numbers to the more fertile lowlands, with the result that one area would be almost denuded whilst another was overcrowded. There was every reason to believe that at certain periods the ancients, like ourselves, were confronted with the problem of over-population. Indeed, Hesiod went so far as to speak of the Trojan war with approval as a means of ridding the earth of its surplus population. Constant wars, of course, acted as a corrective to the natural tendency to increase and multiply, and the problem was also partly solved by colonization. Even this outlet, however, was not always available, for in the sixth century B.C. Greek colonization came to a standstill owing to the fact that all the available sites were already occupied. It was then that the Greek politicians began to preach a policy of restriction, whilst the Greek philosophers anticipated modern eugenists by endeavouring to teach the wisdom of substituting quality for quantity in the birth-rate of the country.

Letters, Notes, and Answers.

☞ *Queries, answers, and communications relating to subjects to which special departments of the* BRITISH MEDICAL JOURNAL *are devoted will be found under their respective headings.*

QUERIES.

THE OCULO-CARDIAC REFLEX.

ATROPOS asks as to the oculo-cardiac reflex of Aschner, whether it is of any practical use in diagnosis, and how is the test performed?

We have referred the question to Dr. Leonard J. Kidd (London), who writes: If an assistant be available, put the patient in the dorsal decubitus, with the head well supported. The physician then compresses the eyeball by the pulp of the index finger, gently at first and then progressively more strongly: after progression has continued for some seconds, the assistant counts the pulse for at least fifteen seconds, and during this time strong compression is kept up. Then compress the left globe, and finally both globes simultaneously. If no assistant be available, the patient lies on his side, and the physician's left finger compresses the globe, while his right feels the pulse. The oculo-cardiac reflex is the slowing of the cardiac rhythm; in 70 per cent. of normal persons this is produced almost immediately by ocular compression. A slowing of from five to thirteen beats a minute is a normal O.C.R.; one of thirteen to fifty or more an exaggerated O.C.R.; one of five to one a diminished O.C.R.; if ocular compression give cardiac acceleration the O.C.R. is "inverted." The diagnostic value of the O.C.R. cannot be usefully stated briefly. If "Atropos" will consult (1) a leading article on the subject in the BRITISH MEDICAL JOURNAL of April 25th, 1914, p. 929, and (2) the exhaustive review by Vernet and Petzetakis in the *Gazette des Hôpitaux* for May 2nd, 1914, p. 837, he will be able to form his own conclusions on that question.

EMPLOYMENT OF SENIOR STUDENTS IN HOSPITALS.

G. P. N. writes: Owing to the impossibility of obtaining house-surgeons, senior students are being employed in the hospital to which I am attached. One of the duties of the senior student allotted to one of my colleagues consists in giving anaesthetics on my operation day. What is my position? Am I covering an unqualified assistant, and in case of accident should I be liable to censure by the coroner?

The notice of the General Medical Council with regard to the employment of unqualified persons as assistants or otherwise does "not apply so as to restrict the proper training and instruction of bona fide medical students as pupils, or the legitimate employment of dressers, midwives, dispensers, and surgery attendants, under the immediate personal supervision of registered medical practitioners." We think that the position described comes within this proviso, and believe that in present circumstances it would in practice be so regarded. The whole of the responsibility would rest upon the medical practitioner employing the student. The views of coroners' juries can never be foretold. At one provincial hospital where large numbers of wounded have been treated a similar difficulty has been met by practitioners in the town, but not on the staff of the hospital, volunteering their services as anaesthetists on specified days.

ANSWERS.

MUSHROOMS AND URTICARIA.

VASO-MOTOR.—Mushrooms are well known as a cause of urticaria, and Dr. W. H. Willcox informs us that he has met with such cases. He has, however, not encountered cases of urticaria following the eating of chestnuts, though it is quite possible that in a susceptible person urticaria might follow their consumption. It is unlikely that severe cases would occur from chestnuts.

LETTERS, NOTES, ETC.

HEALTH RESORTS.

DR. J. F. HOLLAND, British Consul at St. Moritz, states that the Engadine will be open to visitors this winter and that St. Moritz already has a fair number of its old patrons. He states that the journey out can be made by Paris, Lyons, Culoz, and Geneva with sleeping cars. From the *Davoser Blaetter* it appears that in the middle of November this was not the case, and that it was necessary to sleep in Paris and Zurich. Travelling facilities to Arosa will be as convenient or inconvenient as to Davos or St. Moritz. Probably the majority of English people will prefer to winter in this country at some of the numerous health resorts which it possesses.

REFORM OF VITAL STATISTICS.

DR. J. REID (London, W.C.) writes: At page 788 of the BRITISH MEDICAL JOURNAL of November 7th occurs the remarkable statement, "of course the 'neuritis' cases are really deaths due to alcohol." I wonder what the teetotalers certified as suffering from neuritis—often backed by experts—would think if they read the sweeping statement? Again, hiccough is laughed at as a cause of death. Does Sir Victor Horsley ever consider the number of different causes of death in a case of cerebellar disease? The immediate cause of death is demanded by some coroners—for example, congestion of lungs, failure of heart, etc. Surely, Sir Victor has oftener than once found the appearances on the *post-mortem* table puzzling, and the reason why a person should die and others live in worse pathological circumstances. I believe I have heard of a case of uncomplicated hiccough proving fatal. Sir Victor should know that attempts may or may not be crowned with success or failure.

PATENT MEDICINES AND THE PRESS.

MR. HENRY SEWILL (Earlswood Common) writes: I trust that full acknowledgement may be made of the obligation under which medical law reformers have been placed by the article in the *New Statesman* of October 31st. The article occupies two full pages. It forms a most lucid and complete epitome of the Select Committee's reports, and strongly insists upon the need for immediate drastic legislation. The keynote is struck in one of the opening sentences. It affirms "that there has never been issued a Government publication containing so damning an exposure of commercial fraud, shameless exploitation, and legislative muddle; but for reasons of which the war is not the only one, it has received very little notice from the press." The *New Statesman* must be now included in the small minority of papers, led by the *Spectator*, that keep their pages clean and are not afraid to denounce the abuses named in the quoted sentence. In their editorial columns all the papers assume the rôle of censors of morals, guardians of the popular welfare, and protectors of the national honour, whilst the proprietors and managers seem guided by the cult of degraded commercialism. The papers did not need the report of the Select Committee; they have all long ago been made fully aware of the fraudulent, cruel, and murderous character of quackery in every form, and yet the majority go on making money or amassing wealth from this foully-tainted source. It forms a scandal of the first magnitude, and since the attitude of the vast majority of papers forms the greatest obstacles to medical law reform, some means which the Association might devise ought, I submit, to be adopted at once to deal with it.

CONSULTING SURGEONS TO THE FORCES.

DR. W. J. MCCARDIE (Birmingham) writes: I understand that some time ago seven consulting surgeons to the forces were appointed at high, or comparatively high, salaries, and that all but one were London men. If this be so, it is distinctly unfair that the provincial, Scottish, Irish, and Welsh surgeons should not have had an equal opportunity of holding these appointments. The profession, I have no doubt, would like to know the names and rank of the consulting surgeons, their salaries and duties, and also the authority by whom they were appointed.

The consulting surgeons so far appointed by the War Office are Sir Anthony Bowlby, C.M.G., Mr. G. H. Makins, C.B., Mr. F. F. Burghard, Sir Berkeley Moynihan, and Mr. W. T. Lister, F.R.C.S. (consulting ophthalmic surgeon), all serving with the Expeditionary Force in France: Sir Arbuthnot Lane, Aldershot Command; Sir Frederic Eve, Eastern Command; Mr. James Swain, Southern Command; Sir Charles B. Ball and Sir Thomas Myles, Irish Command. The consulting physicians with the Expeditionary Force are Sir Wilmot Herringham, Sir John Rose Bradford, K.C.M.G., Sir Almroth Wright, and Sir Bertrand Dawson, K.C.V.O. The consulting officers serving abroad hold the rank and receive the pay and allowances of a colonel, those at home those of lieutenant-colonel. The pay of a medical officer holding the rank of colonel is £2 5s. a day with allowances, that of a lieutenant-colonel £1 10s. a day; the field allowances are 7s. 6d. and 6s. respectively.

THE WORK OF THE "CLEARING HOSPITALS" DURING THE PAST SIX WEEKS.

BY

COLONEL SIR ANTHONY BOWLBY, C.M.G.,

SURGEON-IN-ORDINARY TO THE KING; SENIOR SURGEON TO ST. BARTHOLOMEW'S HOSPITAL; CONSULTING SURGEON TO THE EXPEDITIONARY FORCE.

It is nearly three months since I joined our army in France. I spent most of the first fortnight in Rouen, where were two excellent general hospitals, and where I had a very interesting experience.

Two months ago the British army moved from the Aisne to the North of France, and I was then invited to go up with the general head quarters and found myself acting as consulting surgeon to the "clearing" hospitals behind the firing line.

It is already well known that we occupy the line from near Ypres to La Bassée, a distance of some thirty to forty miles, and the northern part of this is hilly and undulating, while south of Bailleul the country is very flat and marshy along the river and canal of the Lys.

This town is some miles from each end of our line, and we have had "clearing" hospitals at the towns at each end, and in three other centres between.

THE FUNCTIONS OF A CLEARING HOSPITAL.

For the sake of those who are not yet familiar with army nomenclature, I will premise that a "clearing" hospital is placed conveniently near to the field ambulances of the different corps, and that the wounded are sent into it as soon as possible after being injured, and after their first field dressing. In actual practice this generally means that the men wounded during the night-fighting are brought in in the morning, and those wounded in the day may either be got in during the afternoon, or else it may be necessary to wait till darkness permits of their being brought in safely.

A "clearing" hospital is essentially a "mobile unit," and must be able to move with the army at the shortest notice. Consequently, it is not equipped like a "general" hospital, for it has no tents or huts, and it has stretchers instead of beds, and no such luxuries as *x* rays and a pathological outfit. It consists really only of a staff with a sufficient amount of surgical and medical equipment for emergencies, and is in future to be called a "casualty clearing station." But, although these are the normal conditions, we were very fortunate in that we found some excellent buildings in this town and in the neighbouring ones, and we occupied school houses, hospitals, lycées, and colleges, many of which had a few excellent beds and bedding, and two of which had sisters of charity as nurses, and operating theatres. What is very striking is that these small towns have far more commodious buildings than would be found in any similar places in Great Britain.

We arrived at this town one afternoon and were informed that fighting had taken place that day 14 miles away, and that there were 450 casualties to be sent for. There were 50 motor ambulances ready; suitable buildings were found for a clearing hospital staff to occupy, and preparations were at once made to house, feed, and attend surgically on the wounded.

It must be realized that a clearing hospital is supposed to be staffed and equipped for 200 patients, but warfare and necessity know no laws, and sufficient accommodation was at once found in a derelict college and in a jute factory, and all night the staff laboured hard and got through their work splendidly. But this was only the beginning of a month of unprecedented difficulties, all of which have been surmounted in the same spirit of prompt decision and energetic action which characterized this first incident.

As the divisions came up and moved into line other hospitals were started, and very soon the fight known as the "battle of the Lys" or the "battle of Ypres" developed along the whole front. But the pressure of the fighting would be at one part of the line one day, and at another point another time, and it was therefore my duty to go to the place which was the most busy, and either to stay there or else to go on to some other hospital as might be required.

It is quite impossible really to describe the scene at a clearing hospital when the fighting was at its height, but I will try to give some idea of it. Picture a large open space surrounded by buildings. Into this there drives a motor ambulance. The tail curtains are opened and reveal four "lying-down cases" on stretchers. These latter are swiftly and carefully slid out, and carried into a large receiving room 30 or 40 ft. long. Another ambulance draws up with six or eight men who are "sitting-up" cases, and these are helped out and walk into the receiving room. The clothes of the patients are all thick with mud. Ambulance follows ambulance, for the field ambulances at the front have been filled up during the night, and there has been heavy fighting again at daybreak—a common hour for attacks—and thus it has happened that on many days from 500 to 1,000 or more wounded have arrived at a single clearing hospital in a single twenty-four hours.

And now look inside the receiving room. Here are half a dozen or more surgeons, often some dressers who are medical students, and a score or two of well-trained and very efficient orderlies. Men with simple flesh wounds are sitting on the benches round the room while the surgeons look at their wounds, and perhaps decide that a simple dressing is all that is required; the skin is painted with iodine, the wound is washed with an antiseptic, a dressing is put on by the orderly, and the patient goes off to another room for rest and food.

In another patient the arm bones are fractured, and splints have to be applied before the wound is dressed. In another case there is a bad smash of the thigh or the leg bones, and an anaesthetic is required and given, while the clothes are cut off, the wound washed out with an antiseptic, and splints and dressings applied.

Here is a man in whom it is only too evident that the limb is hopelessly smashed, so the patient is put into the ambulance and sent round to a neighbouring building where a surgeon is in waiting ready to amputate, so the work of dressing the wounded is not interrupted by an amputation. But, in addition to the dressing of wounds, you will see that one surgeon is detailed to inject every man with antitetanic serum, and you will notice that all the men are given hot soup or milk, or perhaps stimulants, while they wait their turns to see the surgeon.

And so on some days for hour after hour, and for most of both day and night, the same scene is enacted with constant variations of detail. But consider for a moment what forethought has been necessary for such a condition to be successfully dealt with. Picture what stores of dressings and bandages are required to dress many hundred wounded men day after day at each of several hospitals, and remember that it has all to come from England and has all to be got to railhead in quantities greater than have ever been required in any previous war. Think of all the stretchers and blankets and a score of other requisites without which the whole thing would be a failure; then realize that we have never once run out of chloroform, dressings, or any single thing, with the sole exception that for some days, after using 30,000 doses, we had not quite enough tetanus antitoxin.

But you must next appreciate that the hospital is only a "clearing hospital" or "station," and in its turn it must be promptly cleared of all cases that can be moved, so as to be ready for next day's wounded. Therefore, ambulance trains must be ready daily to remove their hundreds to Boulogne or Rouen, or to hospital ships waiting to go to England. You might, at first thought, consider that there should be no difficulty about these trains, but there is a great one. The first duty of every general is to defeat the enemy, and trains for troops, and guns, and horses, and stores are the very first consideration, and Red Cross trains must wait their turn.

Remember that we are in the country of our ally, and the trains on the railways are all French, and under French management. We must take what they can afford to give us, and it is not in our power to provide facilities or engines, or engine-drivers, etc. So it comes about that the train question is a most difficult one; yet it is another of those difficulties that has been completely overcome by the energy and foresight of those in charge.

THE WOUNDS.

And now a few words about the wounds themselves. In the first place, a certain number of the men are obviously dying, and this is specially true of wounds of the brain. In such cases there is little to do, and most of the patients are happily unconscious. But all patients with cranial wounds who are not too ill are operated upon subsequently. Wounds of the face are sometimes horrible. Many of these patients die, partly from shock and haemorrhage and partly from loss of blood and difficulty of swallowing.

Thoracic and Abdominal.

Chest wounds are tolerably common, for, now that the range is shorter and often very short indeed, many more men are wounded by rifle bullets.

There is always in lung injuries some dyspnoea at first, and the difficulty of breathing may be very great. Most men are relieved if given morphine and allowed to rest in a half-sitting position, and in twenty-four hours or less they get more comfortable. As a whole they do well, in spite of haemothorax, and wounds near the apex do better than those in the middle of the chest. Many of the latter are fatal from injury to a large vessel or to the heart. In all of these chest wounds operations are to be avoided.

The abdomen is to a great extent protected in the trenches, and abdominal wounds are not as relatively common as they were in South Africa. They have, however, been more common in the recent fighting, and I have seen, I suppose, between fifty and sixty. The conclusions of recent wars are confirmed—namely, that they should not as a rule be operated upon. The minority of those I have seen have recovered, although some of them have had such rigidity and vomiting as to make one feel sure of some peritonitis. Wounds through the upper part of the abdomen do better than those below the umbilicus, and bullets through the liver do not generally do much harm, although I have seen severe vomiting follow haemorrhage into the peritoneum, and have seen fatalities from bleeding.

We have established a general custom of keeping all patients with thoracic and abdominal wounds in the clearing hospitals for several days before allowing them to go to Boulogne, and I feel sure the quieter they are kept the better they do. I like to see them kept in the clearing hospital for at least five or six days if possible.

Extremities.

Wounds of the extremities vary immensely, of course, and while in some cases there are only small flesh wounds, in others, where the limb is not absolutely smashed by a shell fragment, the bones are powdered and the muscles extruded through huge rents in the skin. Many of the worst of them are due to shells, but by no means all.

The fighting has been practically hand to hand in and around the trenches, and huge lacerated wounds of exit, with or without fractures, are quite common and very numerous when bullets have been fired at such close quarters. Many such wounds are thought to be due to "explosive bullets" or to shells, but the explosive effect of bullets fired at very short ranges are unfortunately only too common in reality and are well known to all who have any experience of gunshot wounds.

Blood Vessels.

Injuries of blood vessels have in many cases caused gangrene without causing serious bleeding, and have often necessitated amputations. My very strong impression is that this is a much more common event with the present German pointed bullet than with the old blunt Mauser bullet of the South African war, and I am sure that the new bullet inflicts much more injury on the soft tissues than the older one. On the other hand, aneurysms and arterio-venous aneurysms, which were of frequent occurrence in South Africa, are relatively rare. I can only recall having seen six of all kinds amongst many thousand wounded. They may, perhaps, develop later.

Wound Infections.

Tetanus is probably not so common as on the Aisne, partly, perhaps, because we are on different ground and also because of the preventive inoculation. It is quite a mistake to suppose that it does not occur in bullet wounds but only complicates shell injuries. I have seen it in both, and I have seen it in slight bullet wounds as well as in serious ones. It has been treated by carbolic acid injections, by magnesium sulphate, by antitoxin, and by chloral and potassium bromide; but early acute cases almost always die whatever treatment is adopted, and a good many more chronic cases recover.

True "hospital gangrene," or "sloughing phagedaena," I have neither seen nor heard of in any hospital in France. On the other hand, the "spreading gas gangrene" or "malignant oedema" has attacked, as a rough guess, perhaps a half per cent. of the recent wounds of all the armies. Mr. Sidney Rowland has proved that it is due to one or other of a group of anaërobic spore-bearing organisms, and, as he and I have already written a report on it, I will not further describe it. It is, however, very noticeable that, in all the cases we have seen, it complicated wounds of the extremities only. The wounds of the head and neck, of the thorax and the abdomen, were all free from it. I take this to mean that it occurs especially in those injuries of limbs which are followed by much interference with the circulation due to swelling and stasis, and by oedema and blood extravasation, all of which also tend to produce sepsis, and which are all rare in wounds of the trunk and head, where the circulation is not materially affected. Consequently I believe that gangrene is to be prevented to some extent, at least, by avoiding all constricting bandages, which lead to congestion and oedema, and by opening up and washing with antiseptics wounds which seem to require it, so as to relieve tension and permit the removal of dirt, bone débris, and clothing, and all such wounds require the most free draining, and of course no such wounds are to be sutured.

There is also no doubt that if dressings are allowed to stay on too long, so that they dry and cork up the discharge, gangrene is specially likely to occur. Frequent dressings are therefore most necessary, and this is specially the case in shell wounds, where the contusions and lacerations of the tissues are far more extensive than can be seen, and are in no way limited to the obviously wounded area. The muscles and fasciae far away from the wound may subsequently slough from the mere traumatism, and in such dead tissues the spreading gangrene is specially likely to start.

True pyaemia I have never seen, and I have not heard of its occurrence in the base hospitals either, and wounds as a whole, though they have usually suppurated, have done well, when one considers the very wide-reaching and destructive effects of modern bullets and shells, the mud-covered clothes of the soldiers, and the difficulty or impossibility of helping the wounded at once when under heavy fire. The soil of a richly manured agricultural country, which is also very thickly populated, is a very different matter from the sun-dried South African veldt. The one is full of septic organisms, the other is practically sterile. When many hours, or even days, have elapsed, it is evident that in such cases as these antiseptic treatment comes all too late to prevent suppuration.

As regards wounds by bayonets, I can only say I have seen but three, and I have seen none caused by sword or lance. I am also not aware that I have seen a wound caused by a revolver bullet.

THE WOUNDED.

I cannot close these notes of the clearing stations without a word as to the demeanour of the patients. Nothing could be more admirable than the *sang-froid* and cheeriness of men and officers alike. Many of them were cold, wet, and hungry. All of them had more or less pain. Some of them had suffered exceedingly during their transit from the front, some of them were faint from loss of blood. A few were obviously dying. Yet no one really grumbled or made querulous complaints. At the most they asked for something to drink or for some one to move them to a more comfortable position. Many of them were so tired that, in spite of pain, they went to sleep on their stretchers, but, unless they were too tired, they were cheerful and grateful to those who helped them. Their spirit was not broken by their misfortune, and they were still as steady and self-reliant as when they endured the shell fire in the trench or advanced to a counter attack. "The men are splendid," said Sir Redvers Buller fifteen years ago, and this is still true to-day.

PERMANGANATES IN SLOUGHING AND TETANUS-INFECTED WOUNDS.

BY

LIEUT.-COL. SIR LEONARD ROGERS, K.C.I.E., M.D., F.R.C.P., B.S., F.R.C.S., I.M.S.,

PROFESSOR OF PATHOLOGY, CALCUTTA.

THE prevalence of sloughing wounds, and those infected with tetanus and gas-forming anaërobic organisms, among the wounded in the war, appears to make it advisable to record my experience of the value of permanganate solutions in the first two conditions, and to suggest the possibility of their usefulness in the third.

Permanganates in Sloughing Tropical Ulcers.

In 1909, in a paper read before the Assam Branch of the British Medical Association, but not published, I described a form of spreading sloughing ulcer, known locally as Naga sore, which was causing so much loss of labour on tea estates that the Tea Association sent some cases to Calcutta for me to investigate. A fusiform bacillus, which would not grow on ordinary culture media, was found to be present in enormous numbers and to extend deeply into the tissues. Under ordinary antiseptics the ulcers continued to spread rapidly, and, thinking the organism might be anaërobic, I decided to try the effect of the oxidizing agents potassium permanganate and hydrogen peroxide. The results were most striking. A sloughing ulcer 2 in. in diameter, which had doubled in size within a week under mild antiseptic fomentations, within two days of the frequent application of a 1 per cent. solution of potassium permanganate in the form of cold compresses, presented a healthy red granulating surface; after two more days it had commenced to heal around the whole circumference, and proceeded rapidly to complete repair. In a second case a 10 per cent. solution of hydrogen peroxide cleaned up the ulcer quickly, although less rapidly than the far cheaper permanganate. I subsequently received reports from two Assam medical men that they had empirically come to the conclusion that strong solutions of potassium permanganate, 1 to 4 per cent., had a remarkable effect in cleaning up this form of sloughing tropical ulcer.

Cancrum Oris.

This is a common and very fatal complication of kala-azar, and most difficult to control in those emaciated and exhausted subjects with greatly reduced number of phagocytes. For several years past I have treated this gangrenous condition with very frequent washing with a dark purple solution of potassium permanganate (about 1 in 500), together with swabbing the ulcerated surface with a 1 per cent. solution two or three times a day. In several cases this treatment has stopped the sloughing of the tissues, and complete healing has followed, while in more than one patient recovery from kala-azar has ensued. A simple remedy which can control such a very septic condition as cancrum oris is worthy of trial in any form of sloughing wound.

Bedsores.

Encouraged by the success of permanganate in sloughing tropical ulcer, I soon after tried it in the case of a most extensive and deeply sloughing bedsore right across the sacrum, occurring in a remarkable case of streptococcal pneumonia and septicaemia, who had got over the lung inflammation, but was slowly sinking, apparently through septic absorption from the sloughing sacral ulcer. Several layers of lint soaked in 1 per cent. solution of potassium permanganate, and covered with waterproof material, were placed under the bedsore and changed every four hours, with the result that the ulcer rapidly cleaned up, and began to heal, and the man ultimately left hospital cured. In another case of a severe bedsore in a bad case of typhoid in an obese subject, an equally favourable result was obtained by this treatment after other means had failed. It is sometimes necessary to change the cold compresses every two hours to get the best results.

Suppurative Onychia.

Purulent inflammation around the finger-nails is sometimes a very troublesome affection in the tropics. In two cases, after a variety of antiseptic applications, during several weeks, had completely failed to control the infection, the application of a strong solution of permanganate, until it was no longer decolourized on coming into contact with the discharge squeezed out from around the nail, completely cleared up the condition within three or four days.

Secondary Infection of Liver Abscess Pus.

Although amoebic liver abscesses are nearly always sterile as regards bacteria when first opened, in a damp hot climate the profuse discharge almost invariably becomes infected with a variety of organisms, and is often foul smelling. By irrigating the cavity with a solution of 1 in 500 potassium permanganate, until it returns unchanged in colour, I have repeatedly seen the discharge become sweet and greatly reduced in amount, much to the benefit of the patient.

Explanation of the Above Results.

Potassium permanganate is not usually looked on as a very powerful antiseptic, although very strong solutions do possess considerable bactericidal properties. We must therefore look for some other explanation of the results above recorded than the effect of this salt in destroying pathogenic bacteria. I believe that its most important action is its power of oxidizing, and rendering harmless, the toxins produced by bacteria, which produce a negative chemiotaxis, and thus prevent the phagocytic polynuclear leucocytes from dealing with the invading organisms. When their toxins are destroyed by the permanganate they no longer repel the phagocytes, which can now protect the system against their invasion in a manner which non-oxidizing antiseptics fail to allow.

Another advantage permanganates possess is that their oxidizing powers can be exerted by strengths which are too weak to injure the tissues themselves, and, by continuing their application until the solution is no longer decolourized, we can be certain that their full effect in destroying any easily oxidized substances, such as toxins are, has been obtained. I have already recorded experiments demonstrating the action of permanganates in destroying the toxins of the cholera and dysentery bacilli, and the successful application of this knowledge in the treatment of these diseases.

Permanganates in the Prevention of Tetanus and other Infections due to Anaërobic Organisms.

It may further be worth recalling at the present time that several years ago I recorded in this JOURNAL (1905, vol. ii, p. 1290) some experiments illustrating the action of permanganates in preventing the infection of wounds by the tetanus bacillus. Five out of six rats, under the skin of whose backs a small quantity of Calcutta street dust had been inserted, died of tetanus; but of six more in which a crystal of potassium permanganate was added to the dust, only one succumbed to the disease. In a second series of animals multiple incised wounds were made in the thigh down to the muscles, and some street dust rubbed in. Of six controls four died of tetanus and one of staphylococcus septicaemia. In three other rats the wounds were washed with a strong permanganate solution half an hour, and in another three one hour, after infection with the same dust. In all six animals treated with permanganate the wounds healed rapidly without any sloughing or tetanus infection.

It is well established that if tetanus spores are thoroughly washed, so as completely to deprive them of their toxins, they may be injected with impunity into a susceptible animal, as the phagocytes can destroy the toxin-free organisms. The destruction of the toxins by an oxidizing agent, such as permanganate, would appear from the above experiments to have a similar effect.

It is not unlikely that permanganates may similarly be able to deprive virulent septic organisms of their powers of infection, but I have never been able to find time to test this experimentally.

The infections with gas-producing organisms, which are being reported among the wounded, are probably due to anaërobic bacilli. Permanganate irrigations may very possibly prevent such infections as well as that of tetanus. Antitetanus serum is certainly an effective prophylactic against tetanus, and has been successfully used in dust

infected wounds in Calcutta. It should never be omitted when available, but under war conditions it may often not be at hand when required.

Conclusion.

In view of the experiences recorded in this note the use of strong permanganate solutions, not less than 1 in 500, for irrigating all dust and earth infected wounds appears to me to be well worthy of trial in the field. The crystals are so easily carried, and the solutions so harmless, that this simple plan could be easily carried out at the dressing stations in the case of all wounds in which any sloughing or suppuration has already commenced, or into which dust or earth is likely to have penetrated, with good hope of lessening the number of cases of tetanus, septic and anaërobic bacillary infections.

IODINE AS AN ANTISEPTIC IN JOINT INJURIES.

BY A. GASCOIGNE WILDEY,
DEPUTY SURGEON-GENERAL, ROYAL NAVAL HOSPITAL, HASLAR.

THE accompanying case of severe lacerated wound exposing the knee-joint following an aseptic course after treatment by no other antiseptic than iodine is of special interest at the moment when the claims of the more caustic applications are being advocated:

S. McD., aged 30, shipwright, employed in Portsmouth Dockyard, while at work on November 18th, 1914, in the upper part of an ammunition hoist in a battleship under construction, fell with the staging to the bottom of the hoist, a distance of 40 ft., striking his right leg on some angle-iron. He suffered a severe lacerated wound rupturing the ligamentum patellae and the anterior capsule, widely exposing the interior of the knee-joint. He was with difficulty removed from the bottom of the hoist and received first aid in the dockyard. He was admitted to hospital at 11 p.m., about four hours after the accident.

Condition on Admission.

He was suffering from shock and collapse from haemorrhage. The pulse was 120. The interior of the right knee-joint was exposed by a lacerated wound forming a V-shaped flap, the point 5 in. below lower border of patella, the wings extending to either side of the joint. Part of the tubercle of the tibia was torn away and attached to the patellar ligament which was badly damaged. The anterior part of the capsule of the joint was torn through and was ragged. The crucial ligaments were intact. The joint was full of clot and the whole wound begrimed with oily dirt. There had been considerable haemorrhage and a tourniquet was on the limb.

Operation.

An operation was performed immediately under open ether anaesthesia. Intravenous saline was given at the same time. The wound was protected and the skin of the whole limb was shaved and shampooed with ether soap, cleaned with spirit biniodide (1 in 1,000), dried and sprayed with iodine 2 per cent. in alcohol. A very thorough toilet was performed. The edges of the skin wound were pared about ⅛ in. all round. The gauze protection was removed from the wound, and all clots and dirt washed out of the joint by irrigation with normal saline solution. All badly soiled and damaged tissue, including the greater part of the patellar ligament, was cut away, and the joint thoroughly swilled with iodine solution, a gloved finger puddling the solution into all the synovial pockets. The iodine was immediately washed out with saline and the process repeated. The remains of the patellar ligament were sewn to the remains of the periosteum and deep fascia about the tubercle of the tibia with iodized catgut. The capsule was not completely closed. The skin was sutured with a special form of mattress stitch of silkworm gut. To allow for oozing of serum the extremities of the wound were not completely closed, but artificial drainage was not employed. The closed wound was sprayed with iodine and covered with sterile gauze and cotton-wool, and the limb placed in a back splint with side protection.

Progress.

The subsequent course was that of an aseptic operation on the joint. There was slight rise of temperature for the first forty-eight hours, after which it fell rapidly to normal; there was some slight oozing for the first day. Pain and constitutional disturbance in this case were less than occurred in a case of excision of semilunar cartilage performed on the same day after long preparation and under the strictest aseptic precautions. The wound has been sprayed with iodine daily, and has healed by first intention except at one corner where drainage was allowed. On the fourteenth day after the accident there was no pain, no effusion, and passive movements were commenced. The patient was sitting in a chair with the leg on a back splint.

The routine described above—that is to say, thorough skin toilet, paring of every particle of soiled and badly damaged tissue, swilling with iodine 2 per cent. in alcohol and with saline alternately, closure of the wounds by piling up the skin edges with mattress sutures to ensure complete coaptation, and the avoidance of artificial drainage—has been employed in all cases of lacerated wounds and compound fractures, and wounds of joints treated by me in the naval hospitals of Chatham, Plymouth, and Haslar during a period of four years. No other antiseptic than iodine is used in contact with the wounds. The results have been most gratifying. Sepsis has been extremely rare, and when it has occurred has invariably originated in the skin wound and never in the depths of the wound. The mattress sutures employed reduce the chances of infection by the skin wound. Every effort is made to secure rapid healing of the skin. Every particle of damaged skin is removed, plastic manœuvres being sometimes necessary to secure easy coaptation. A loose stitch or two permits free drainage of serum, and these gaps are closed as soon as possible. It is a great safeguard to spray the wound daily with iodine.

The case here recorded is the severest test to which I have subjected this method of treatment by iodine. If the repair of the ligamentum patellae proves efficient there is every prospect of a perfect functional result. Would such a functional result be likely after an application of pure carbolic?

While recording the almost uniform success of the iodine treatment without drainage in my experience, it is only fair to say that the cases admitted into the naval hospitals have generally received their injuries in ships or dockyard workshops, where they are not likely to be infected by very virulent organisms; also, we receive the patients very shortly after the occurrence of the injuries, and not infrequently iodine has been immediately applied to the wounds on giving first aid.

It will be noted that I have referred to "spraying" iodine. Iodine applied by means of an ordinary continuous bellows spray-producer is a most handy, efficient, and economical method. By this means the expenditure of iodine in this and other naval hospitals has been reduced to one-tenth of the amount formerly used when the solution was applied with swabs and brushes. A spray-producer with hook attachment, by which it can be fastened to the belt or coat, should prove useful for ambulance work in the field.

A SIMPLE FORM OF PORTABLE DRESSING STERILIZER.

BY CHARLES W. CATHCART, F.R.C.S.,
SENIOR SURGEON, ROYAL INFIRMARY, EDINBURGH.

As there is much need at the present time for surgical equipment which combines simplicity of construction, and therefore moderate cost, with efficiency I think it right to publish an account of an improved form of the sterilizer for dressings which I introduced a good many years ago. The appliance was originally devised for sterilizing steel instruments with steam without rusting them, and for this purpose I introduced the method of controlling the direction of the current of steam by means of a three-way stopcock inside the sterilizer.[1]

This device enabled me to give effect to a suggestion made to me at the time by Professor John Haldane, of Oxford, which was to heat the instruments before the steam came in contact with them and thus avoid condensation of moisture on their surface.

Shortly afterwards, however, the method of boiling instruments in a weak solution of alkali was introduced, and as this was a better method I adopted it for instruments and applied the sterilizer to the sterilizing of dressings.[2] For this purpose it has proved relatively better adapted than it was for instruments. The control of the direction of the steam by means of the internal stopcock with the pipes leading from it has two advantages—it enables one to finish the dressings practically dry, and it makes it possible with a very simple mechanism to introduce the steam into the inner chamber at the point or points most suitable for rapidly permeating

the dressings. A change recently made in the shape of the sterilizer is dependent on the shape of the simplified "drum," which now takes the form of a cube instead of a cylinder. Other details of improvement are chiefly concerned with the question of portability.

By adopting the cubical form for the "drum" or "kettle" I am able to dispense with the complication of sliding shutters, which were an essential feature of most drums previously used. The cubical box, which now forms the drum, is open at two opposite sides, which, for the sake of distinction, we may call ends; one constitutes the top, the other, provided with a false bottom of open-wire work, forms the bottom. Each of these open ends has a detachable cover, which fits equally well upon the open ends or the closed sides of the cube. During sterilization the covers are placed on the sides of the drum, leaving the top and bottom ends completely free for the current of steam to pass through the dressings. When the steaming is finished the covers are replaced in position, and the drum is lifted about by rings at the side.

The sterilizer, now also made cubical, retains as its essential feature the control of the direction of the current of steam by means of a stopcock which, with the exception of the handle, is enclosed within the outer chamber. The steam generated in the outer chamber, when so directed by the stopcock, is first of all led by means of a pipe from the stopcock into the open air. This allows the dressings to be heated. Afterwards, by a turn of the stopcock, the steam is directed through

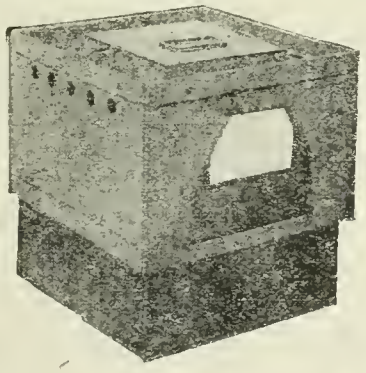


Fig. 1.—Sterilizer packed ready to be placed in its wooden travelling case.

another pipe to the floor of the inner chamber where the open bottom of the drum stands. A single opening in the centre has been found sufficient for the present 9½ in. cubical drum, but to allow of even more rapid permeation as well as of enlargement in the size of the drum the steam will be admitted by several openings in future. The present size of drum was made to have the same cubic capacity as the smaller size of cylindrical drum in common use. In rising up through the dressings to escape at the lid above, the steam drives all the air before it, and maintains a through current as long as the surgeon wishes. After sterilization is finished, the steam is again directed into the open air for fifteen or twenty minutes longer, and the lid of the sterilizer is lifted off. This gets rid of most of the steam. During this drying process, and afterwards, the dressings are protected from contamination by being wrapped, previous to sterilization, in a closely-woven fluffy cloth, such as flannelette about 6d. a yard, or by there being at the top and bottom of the drum a large pad of Gamgee tissue between them and the outer air.

Owing to the kindness of Dr. McGowan, of the Royal College of Physicians Laboratory, Edinburgh, who conducted the bacteriological inquiry, I find that sporing cultures of anthrax laid in the centre of the drum filled with dressings are killed after half an hour's steaming.

In working out the details of this improved drum and sterilizer I have received much assistance from Mr. Spence, the manager of Messrs. Stewart and Co.'s tinplate factory, Edinburgh. He has devised a stand on which the sterilizer can be placed when being heated by a Primus stove, and which, when reversed, fits over the top of the sterilizer as a protection when packed for travelling. The stand is bolted together without solder, and therefore cannot be loosened by the action of heat. He has also invented a simple method of introducing the steam by as many apertures as one wishes through the floor of the sterilizing chamber, and in many other ways has made valuable suggestions.

The sterilizer can be boiled equally well on a gas ring, a kitchen fire, a camp fire in the open air, or a Primus paraffin stove; but for a movable hospital the latter will probably be found the most convenient.

A simple form of water gauge is provided, and consists of an open groove of tin furnished with a handle. A piece of brown paper is slipped into the groove, and when there is any doubt as to the quantity of water in the outer chamber the screw tap is undone, and the tin groove with its brown paper is inserted to the bottom. The discoloration of the brown paper at once shows the level of the water. Marks on the tin groove indicate the number of ounces in the boiler (outer chamber) at the maximum, medium, and minimum levels. The ordinary form of water gauge, which involves a piece of glass tubing, is liable to be broken, and was therefore not employed.

The cubicle drum is well suited to nesting. A second slightly smaller drum fits inside the chief drum, and the Primus stove fits inside the inner one. A third drum could be added if required, and it would still be large enough to contain the Primus stove.

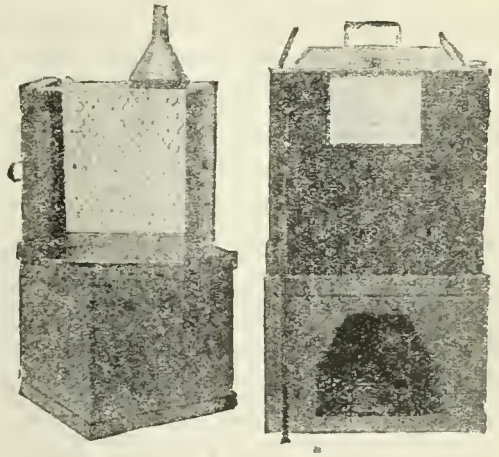

Fig. 2.—Sterilizer unpacked, with its contents displayed.

My first patterns were made entirely of tin. Made of this metal they would, with careful treatment, last for several years. With the view, however, of ensuring greater durability the sterilizer itself is now made of copper, while the stand, drums, and other fittings are of tin.

In order to have an independent opinion as to the efficiency of the sterilizer in its present form I sent one to Professor Woodhead. After having tested it and submitted it to Colonel Griffiths, the officer commanding the 1st Eastern General Hospital at Cambridge, he writes as follows: "We consider the sterilizer, with its various improvements, as being a really practical, economical, and efficient sterilizer for surgical dressings and instruments."

It is quite a simple matter to make larger sizes of this sterilizer. One to hold two drums side by side was frequently made when the cylindrical pattern of drum was used. One of these is now being made. The inner chamber will measure 21½ in. long, 11 in. broad, and 11 in. deep. It will hold two cubical drums with 10½-in. sides, and the steam will enter by four apertures beneath each of them. When packed for travelling this sterilizer can hold eight drums, that is, two of each of the following sizes of cube: 10½, 9½, 8½, and 7½ in. respectively, besides two Primus stoves. An advantage of ranging the drums side by side instead of above one another, as is usually done, is that an enlarged heating surface is available for the enlarged boiler.

The accompanying illustrations show the cubical sterilizer (1) when packed for transport, (2) when its contents are taken out and displayed. In the latter case the lower drum is shown closed as it would be after sterilization, while the upper one is shown with its covers fitted on to its sides, and laid on its side to make evident how free a passage is left for the steam during sterilization. The

card of instructions for use is shown in its fitting just below the stopcock.

During the war Messrs. Stewart and Co., 6, Gilmore Place, Edinburgh, are prepared to sell the instrument with fittings at the cost of production. At the present market price of metal the cubical copper sterilizer will, on this basis, cost 28s. 6d., while the tin stand will be 2s. 6d., the drums 3s. each, and the filler and water gauge 6d. each. The Primus stoves are sold at 8s. 9d., and will be sent at that price with the sterilizer, if required. Particulars as to cost and any other information required will be furnished by Messrs. Stewart and Co.

EIGHTY-SECOND ANNUAL MEETING
OF THE
British Medical Association.

Held in Aberdeen on July 29th, 30th, and 31st.

PROCEEDINGS OF SECTIONS.

SECTION OF TROPICAL MEDICINE.

Professor W. J. R. SIMPSON, C.M.G., M.D., President.

DISCUSSION ON KALA-AZAR OR PARASITIC SPLENOMEGALY AND ALLIED INFECTIONS.

OPENING PAPER.

By Fleet Surgeon P. W. BASSETT-SMITH, C.B., R.N., M.R.C.P.

LEISHMANIASIS, which is the term used to cover all forms of disease dependent etiologically on the presence of the peculiar protozoal organisms known variously as *Leishmania donovani*, *L. infantum*, and *L. tropica*, may be divided clinically into two main groups. First, those in which the diffusion of the parasites is widespread in the body and in which the constitutional symptoms are very severe; and, secondly, those where the parasite causes a very local and superficial infection with practically no constitutional symptoms. I wish chiefly to speak of the former, though the local disease, especially as found in South America, is becoming more and more important.

Geographical Distribution.

The early history of kala-azar, meaning the black disease, as the condition was then called, was mainly centred in a small area in the Gangetic district of India, proceeding in an epidemic form to the foot-hills of the Himalayas, devastating the tea plantations in Assam and the villages in that region. The course of the epidemic has been very fully described by Rogers, and several Governmental Commissions were instituted to determine the cause and prevention. After the cause had been discovered in 1903 by Leishman and Donovan, many cases were found in other parts of India, particularly in the Madras Presidency, where Donovan and Patton have so continuously worked, showing that many of the irregular fevers known previously as non-malarial remittents were really kala-azar.

The extension of the disease eastward, probably through Tibet into China, is now definitely recognized, the most infected region being in the north-eastern part between the Yangtse and Peiho rivers. Cochran has shown the disease to be practically restricted to the north of the Yangtse river in the provinces of Chili, Shantung, Kiangsu, and part of Honan and Hupi. To the west India is linked up with Southern Europe by way of Arabia, Persia, and the Caucasus. Endemic centres appear to be present in Central Africa, Abyssinia, along the Blue Nile, and by the Sudan to Egypt, in which regions it has probably existed a long time.

In 1905 Pianise found Leishmania parasites in Southern Italy. Throughout the whole of the Mediterranean area that form of the disease known as infantile kala-azar has been proved to be prevalent—in Tripoli, Tunis, Algeria, the east coast of Spain, Southern Italy, Sicily, Greece, Southern Russia, Portugal, and Egypt, and in most of the islands, Malta, Crete, etc. Laveran and Nicolle at the International Medical Congress, 1904, in a masterly paper, have described this form most fully.

We thus see that over a wide subtropical and tropical region of the Eastern hemisphere cases are to be found, but, as stated by Laveran, in these endemic zones the amount of sickness due to this cause is very incompletely known, many cases being erroneously diagnosed as malaria and other conditions giving rise to enlargement of the spleen. In the Western hemisphere, one case of the constitutional disease has been reported from Brazil, in a man who had not been out of the country for over twenty years.

Etiology.

The formidable character of the disease, with its high mortality, renders its prevention one of the most important problems of tropical medicine, especially as year by year the number of Europeans affected is steadily increasing. This, in the naval and military services, gives rise to anxiety to those in medical charge of bodies of men in the endemic areas.

From a morphological standpoint there appears to be no distinguishing character which can differentiate the parasite as found in China, India, or the Mediterranean. In man it is mainly an intracellular organism, chiefly affecting the endothelial cells, in which the parasites multiply, as many as 200 being found by Leishman in a single cell. The swollen cell is destroyed, but first tends to block up the lumen of the vessel and thus gives rise to pathological changes in the organ affected; from the ruptured cells some of the free bodies may be carried in the plasma and are found in the peripheral blood, but they are generally taken up by the polynuclear leucocytes, more rarely by the mononuclear cells, and very occasionally found in the eosinophiles. The frequency of their appearance in the peripheral blood appears to vary very greatly in different endemic areas; for instance, in Madras the percentage of positive findings is very high, as demonstrated by Patton and Donovan, but in other parts they can only be demonstrated in the later stages of the disease, their presence then being an indication of serious prognosis. It is, however, probable that with more accurate methods they will be found with greater frequency.

The examination of films is a very laborious procedure, but by cultivation of the blood on suitable media the possibility of showing that the bodies are really present when not detected in films has been demonstrated by Mayer and Werner and by Wenyon.

When studying the etiology, the amount of infection of the peripheral blood must determine the probability of bugs, fleas, and other arthropods acting as carriers of the infection. As shown by Patton, the frequency of the organism in the peripheral blood in the Madras cases points to the conclusion that the infection there is very severe, and that the rôle of the bed-bug (*C. rotundatus*) as a carrier is more likely, especially as he has so frequently demonstrated the flagellate stage of the organism in their intestinal tract. There are no doubt many controlling factors which may influence their doing so, as temperature, moisture, and the number of infected carriers biting a non-immune; also, as Patton has shown, the ingestion of a second feed of blood within a limited time tends to cause the destruction of the growing organism in the gut.

In a recent paper by Rogers and Dodds, the transmission of the disease by a non-flying insect carrier is ably put forward, and the evidence of house infection in Assam is very strong. On the estate of Rangamata, where new coolie lines were provided only a short distance away from the old ones, no case occurred in the 150 healthy coolies transferred to them, yet of the 50 who went on living in the old lines 16 per cent. died and others became quickly infected.

During the last sixteen years in which these preventive measures have been taken they have been uniformly successful. In a labour force of 7,000 workers the disease has been stamped out, where before it had caused a mortality of 207 per thousand.

Whether the bed-bug is the true carrier is not definitely certain, but in this district there appears much in favour of the hypothesis. Many observations have been made with other blood-sucking insects in India, and though

Herpetomonas forms like those of the Leishman body have been found in mosquitos, the evidence of their acting as carriers is very slight.

We have seen that in most cases during some period of the disease the infecting organism is present in the peripheral blood, sometimes in considerable abundance: this indicates transference by blood-sucking arthropods, yet it is known that the organism is not uncommon in the intestinal mucous membrane, where it gives rise to ulceration, and that the bodies have been found by Critien in the faeces. It is therefore possible that they may be the source of infection—namely, that infection may take place directly from the sick to the healthy. All modern research, however, indicates that the organism has an extra-corporeal phase, no matter by what means it escapes from the body.

Another important factor to ascertain is whether in the endemic areas other vertebrates are subject to the parasites on whom it is non-pathogenic or only slightly, so that these animals act as reservoirs of infection. In India none have, so far, been demonstrated, but in the Mediterranean area it has been shown by Nicolle, Basile, and others that the native dogs are not infrequently the hosts of similar parasites, and it is generally believed that the dog and human infections are similar, for they occur in the same endemic areas, the pathological lesions are the same, the parasites cannot be distinguished from one another, and they can be cultivated on the same media, and by experiment the dog is shown to be susceptible to the human strain. The method of conveyance of the organism from dog to dog and from dog to man, by means of fleas, is strongly supported by Lemaire, Sergent, Basile, and Spagnolio, but is controverted by Wenyon and others, though not disproved.

The evidence is sufficiently strong in certain areas to make those in charge of the public health regard dogs with suspicion, and to require the destruction of all unhealthy and ownerless animals. At Hydra, Lignos found 16 per cent. of the dogs infected; in Tunis the proportion was much less, 1.8 per cent.; in Algiers 7 were found infected out of 279 examined. To obtain anything like reliable results, the examination of the liver is not sufficient, the spleen, and bone marrow must be also examined and cultures made, otherwise many infected animals may not be recognised, for, as described by Wenyon, out of 46 dogs in which liver puncture proved to be negative he found the bodies present *post mortem* in the spleen in 6.

In Turkestan, where leishmaniasis is common Yakimoff found 22 out of 76 dogs infected, or 28.9 per cent. (In examining dogs canine piroplasmosis must be remembered, and errors from this cause avoided.) Basile describes two types of the disease in dogs, a chronic form of long duration and an acute condition. There is no doubt that dogs are able to be experimentally infected with the Indian virus, yet apparently never naturally—so different from the Mediterranean area; this immunity of the dogs there may be due to differences of the transmitting host, as suggested by Wenyon, namely, one that is not in the habit of feeding on dogs.

The presence of flagellate parasites in the gut of numbers of insects—fleas, bugs, etc.—which are normal to them renders it very difficult, without definite transmission experiments, to say whether those found in them after ingesting blood of kala-azar patients are of any pathogenic importance or not; in particular, those found by Basile in fleas are looked upon by some of his critics as the normal *Herpetomonas* forms common to this insect.

Wenyon summarizes the relationship of the various Leishmania-like bodies found in man, animals, and arthropods in the following words: "It is most probably correct that all the blood-inhabiting flagellates of the trypanosome group were originally parasites of the insect's gut alone, but some have adapted themselves to develop in warm-blooded mammals. When this has occurred the insect may become infected either by feeding on the blood of an infected vertebrate or by eating the faeces of an already infected insect."

The Indian, Chinese, African, and Mediterranean forms are probably identical. Laveran, in reviewing the characters of the Indian and Mediterranean forms, believes that the diseases are the same, for the differences of age, culture, and infectivity to animals have gradually broken down—the chief characters on which the separation of the species were founded. With the Indian virus Row has caused both local and general infections in monkeys and white mice, and Donovan has inoculated a young dog, while Patton has infected four monkeys, four dogs, one jackal, and white rats. Cultures from India were, at the Pasteur Institute, inoculated successfully into monkeys and dogs, as was also done with the Mediterranean virus. There is, therefore, no advantage in retaining more than one name for the infecting parasite causing the generalized infection, either in the Far East, India, Africa, the Mediterranean, or America, and the original name (*Leishmania donovani*) should be retained.

Pathology and Treatment

Clinically the term *Leishmania infantum* is misleading, for though in the Mediterranean infants suffer most, yet the disease is not restricted to them, which fact was brought prominently forward a short time ago at the Royal Society of Medicine, when a typically affected child from Calcutta, aged 5, the offspring of a father who had recently died from the disease, was shown almost at the same time as a man aged 29 who had contracted the disease in Malta. To this last case I would like time to draw attention. A young man with good previous health was landed at Malta, and was employed on the rifle range there for about six months; three dogs were constantly in attendance at the camp, and one of them became thin and unhealthy. During the following year the patient remained fairly well, except for some shortness of breath after exertion, but fourteen months after leaving the rifle range he was admitted to hospital for anaemia and boils. On examination in March, 1913, he showed considerable emaciation of the limbs, with a big belly. The spleen was very large and hard, the liver less so; the blood showed a marked leucopenia and a decrease of the red cells. Leishman bodies were found on splenic puncture. Since that time he has been under my care, and I obtained the bodies three times from the liver but not on the fourth puncture, and twice since from the spleen. During the whole time he has received twice a week intramuscular injections of atoxyl (3 to 5 grains) and also an autogenous vaccine of his own flagellates.

After four and a half months' treatment no bodies were found by liver puncture, either by smears or cultural methods, but they were still present in the spleen; after twelve months, though they were found in small numbers in smears from the spleen, no growth could be obtained in the cultures. Have we had here a gradual destruction of the parasites in a heavily infected case, the remaining ones in the spleen not having sufficient vitality to grow in suitable media (the media had been recently prepared and other strains of Leishmania grew well in it)? Was this due to the continuous action of the atoxyl? Since the last splenic puncture weekly attempts to grow the organism from the peripheral blood have failed. This is the laboratory picture; the clinical course is less satisfactory. The enlargement of the liver and spleen remain much the same, the anaemia and leucopenia is very marked, but the decrease in the red cells points to a further extension of the infection to the bone marrow. He has maintained his weight except during periods of pyrexia, and is as strong as on admittance. This long course—almost three years—since contracting the disease in Malta is, I feel sure, due to the treatment he has received, and possibly a cure may be effected. The following table gives a summary of the blood counts:*

Total and Relative Blood Counts.

Date.	Red Cells.	White Cells.	Polynuclear.	Mononuclear.	Lymphocytes.	Eosinophiles.
1913.						
May 21 ...	4,000,000	3,400	54.0 %	10.0 %	35.5 %	2.5 %
July 16 ...	3,200,000	2,500	41.6 %	8.0 %	50.0 %	0.4 %
1914.						
Jan. 21 ...	3,500,000	3,600	42.5 %	6.0 %	40.0 %	1.5 %
March 21...	2,800,000	3,300	48.0 %	11.0 %	40.0 %	1.0 %
May 14 ...	2,500,000	3,500	44.5 %	8.0 %	46.5 %	1.0 %
June 14 ...	2,620,000	2,800	40.0 %	9.0 %	50.0 %	1.0 %

* This patient has now been discharged from hospital, has regained his former weight. His blood picture is almost normal, and spleen is very much smaller, and there has been no fever for three months.

A noticeable feature in these cases with marked cachexia is the low systolic blood pressure and extreme dicrotism of the pulse, due probably to the deficient quantity of blood in the vessels and the want of tonicity of the muscular coats of the arteries.

In the Mediterranean area recovery at times takes place with or without specific treatment, more particularly in the older cases, but Caronia states that in his experience arsenic in some form is certainly helpful, and Quilichini describes a complete recovery of a severe case treated with hectine and Robin's iodine injections. Other cases have been cured by inducing or acquiring a secondary septic infection producing a marked leucocytosis; unfortunately more frequently the development of such septic infections carries off the patient.

Injections of salvarsan and neo-salvarsan do not appear to have been attended with any marked success, and the injection of large doses of quinine, as recommended by Muir, are also of doubtful benefit. In Burdwan, where Muir describes the disease as being very common and so successfully treated with quinine injections, Mackie found that the splenomegaly was very prevalent, but of 58 selected cases as probable kala-azar, in only 39 per cent. were the bodies found on spleen puncture; he therefore concludes that a large proportion were malarial and not true kala-azar.

For diagnosis various other methods have lately been employed with success. Cochran removes a superficial lymph gland, smears being made from this. Serological tests are made either by complemental fixation, as recommended by Caronia, or an anaphylactic reaction by Ascoli.

Infections by Leishmania tropica.

The local condition produced by this parasite has received a great variety of names, of which the best known is Oriental sore—a term which does not now cover its geographical distribution. In Persia almost every one becomes infected, but the constitutional form never follows. The specific character of the disease is definitely recognized by the inhabitants there, as they frequently inoculate themselves to prevent contracting the sores in conspicuous parts, and they do not regard it as a dangerous disease. In most areas where these sores are common dogs are very frequently affected, usually on the nose. In both man and animals the infecting parasite is very similar to the *L. donovani*, being culturable in the same media, giving rise to the flagellate forms. Experimentally, when inoculated into animals it gives rise to local infections, but if given in large doses intraperitoneally or intrahepatically it has occasionally multiplied and caused generalized infections. Besides being found in India, Persia, Arabia, and the eastern part of the Mediterranean, other endemic areas are Southern Italy and Sicily (where it is very common), Northern Africa, and the Sudan. Wagon has also described cases from Nigeria. In the Sudan non-ulcerating forms like keloids have been described by Archibald—a condition which is now known to be not uncommon in other areas. There is first a papule, followed by a chronic nodule, which desquamates on the surface but does not necessarily break down.

In tropical America a great number of cases have been described under the term Forest Leishmaniasis or Forest Yaws and Espundia. According to Brumpt, the disease in Brazil may be either benign in character, like Oriental sore, or in about 10 per cent. it is a much more serious condition, affecting the mucous membranes of the mouth, pharynx and nose. Brumpt in his investigations believes that the most likely insects that transmit the disease are species of *Tabanidae*, which are very common in the endemic areas and are persistent biters, but no definite proof was obtained.

Minett has also shown this dermal form of Leishmaniasis to be common in British Guiana. In Peru a disease called "Uta," which was formerly supposed to be a form of syphilis, leprosy, or tubercle, and is very common, has been proved by Strong and others to be due to Leishmania parasites, which have, without sufficient reason, been called *Leishmania peruviana* by Velez. These parasites go through the same flagellate stages on culture media as the oriental form, and can be inoculated into dogs, which appear to be naturally infected in the endemic areas.

In Central America, at the Ancon Hospital, Panama, five cases of dermal infections, one with implication of the mucous membranes, have been described; it is therefore similar to the South American form.

The infection of the mucous membrane, which is such a marked feature of the American cases, is not limited to them, for La Cava and Pulverinti have described similar conditions in Southern Italy and Sicily in four cases. This indicates that the diseases are the same, though probably influenced by local conditions in their clinical manifestations.

DISCUSSION.

Professor GABBI (Rome) read a short communication on the transmission of kala-azar, relating certain experiments he himself had performed, the results of which were contradictory to Basile's; this investigator had asserted the disease to be transmitted by the flea (*Ceratophyllus fasciatus*). Non-infected puppies were brought by Gabbi from Modena and remained for several months in the company of an infected bitch who reared them, but on being killed and thoroughly examined they were found to be free from disease. Subsequently in a village in Calabria Professor Gabbi found a naturally infected dog; the fleas were collected from the animal and placed on two younger specimens which by splenic, hepatic, and bone-marrow puncture had been proved free from infection; sixty-two days after experiment commenced the two experimental dogs were killed and were found free from infection. This experiment fully bore out similar ones instigated by Wenyon in Malta.

Dr. D. E. ANDERSON (London) said that "Uta," the naso-pharyngeal leishmaniasis of Peru, at the time of his visit to that country had been held to be a form of tertiary syphilis.

Dr. P. H. BAHR (London) drew attention to the remarkable absence of both canine and human leishmaniasis in Ceylon, a country so closely related both geographically and zoologically to Southern India. The nasal ulceration sometimes termed "gangosa," which was common in certain portions of that island, he considered to be a form of tertiary yaws as it was only encountered in those districts where that disease was extremely prevalent.

Professor FERGUSON (Cairo) referred to an interesting form of splenomegaly which was extremely common in Cairo, and in which, despite the most rigorous examination both during life and after death, no Leishman-Donovan bodies had been found in recent years. Injection of material into puppies and monkeys had likewise given negative results. These cases had been termed Banti's disease, but he did not consider this to be correct. It was a curious fact that while kala-azar was absent, as far as could be at present ascertained, from Egypt, cutaneous leishmaniasis was common enough in the Nile Valley. The sores were often 12 to 14 cm. in diameter, and were at first papillated, but with the advent of sepsis the protozoön parasites disappeared, and could only be ultimately discovered at the depth of about 1 cm. in the growing margin of the sore. Another form was encountered in which the epidermis remained intact, though it was raised and had a glistening appearance.

Dr. G. A. WILLIAMSON (Aberdeen) said that his experience in Cyprus tallied with that of Professor Ferguson in Egypt.

Professor FERGUSON, in answer to Dr. Bahr, affirmed that twenty-five good results had followed splenectomy in the twenty-five cases of non-febrile tropical splenomegaly in which this operation had been performed.

Captain MARSHALL, R.A.M.C. (London), remarked on the fitful disappearance of the Leishmania in fatal cases of kala-azar; cases which recovered showed a persistent high eosinophilia. All experiments with insect intermediaries, including lice, which he had instituted had so far proved negative. He had never encountered dermal leishmaniasis in Abyssinia.

Professor GABBI (Rome) said that he had seen cases such as described by Professor Ferguson in Sicily. The clinical history was to a certain extent similar to that of kala-azar, but the cases were certainly not examples of Banti's disease, with which he was familiar, as he had formerly acted as assistant to Banti himself. From his experiments and researches he had come to the conclusion that the virus in the disease under discussion was ultramicroscopic. Regarding splenic puncture, it needed to be repeated several times before a positive opinion could be expressed; bone marrow puncture was preferable, and wherever possible should be performed as well. In some of his fatal cases also the parasites disappeared before death. He had seen but one case of kala-azar in Tripoli. In his opinion the *Leishmania tropica* and *donovani* were not identical. The biological properties of the parasites differed; the former never produced flagellate forms in the human body, though the latter had been found to do so. He considered that Patton's experiments on the transmission of *L. donovani* by *Cimex rotundatus* required repetition before being accepted.

Fleet Surgeon P. W. BASSETT-SMITH, in replying to the discussion, remarked that though evidence of the exact mode of transmission of kala-azar to man still remained to be determined, it was essential that prophylactic measures be immediately instituted so as to guard our soldiers and sailors from naturally infected animals, especially dogs.

IS EMETIN SUFFICIENT TO BRING ABOUT A RADICAL CURE IN AMOEBIASIS?

By LLEWELLYN PHILLIPS, M.A., M.D., B.C., F.R.C.P., F.R.C.S.,
Professor of Medicine in the Egyptian Government Medical School; Senior Physician, Kasr el Aini Hospital, Cairo.

IT is now quite unnecessary to describe the good results obtained with emetin by injection in amoebiasis, but in many cases they are not permanent. The patient may go on well for some time, then some indiscretion perhaps may bring about a return of symptoms. Thus, early in 1913, I treated an Englishman for dysentery with emetin, and after a few injections he was apparently cured, but in a few months the dysentery recurred, to be cured again by a few injections. Other similar cases have been published by Orticoni, Allain, and others.

It is true, in my experience, that most cases of hepatitis and cases of amoebic abscess in the lung treated by emetin or ipecacuanha have been completely cured, and this is borne out by Chauffard, who says he has not seen relapses of hepatic amoebiasis after emetin treatment, except in a case reported by Tuffier. I have seen such a case, however. It was that of an old man whom I saw with a liver abscess in 1904, cured by operation; this was followed by acute hepatitis in 1912, cured quickly by emetin; only a few doses were necessary, and owing to the pain of the injections he was unwilling to continue them. In 1913 he had another attack of hepatitis, which also yielded to treatment, but not so readily. Then, again, I published a case of amoebic abscess of the brain, which occurred some months after the cure of a liver abscess by operation secondary to dysentery. Had prolonged treatment been adopted in this case, the abscess might never have occurred and a life have been saved.

This tendency to relapse after apparent cure brings amoebiasis into line with other protozoal diseases and diseases caused by animal parasites, such as malaria, syphilis, and trypanosomiasis, which may quickly and readily react to drug treatment, but which require a prolonged course to fully eradicate the parasite, if ever, and cure the disease.

Recent investigations by Walker, Kuenen, Wenyon, and many others have all shown that in acute dysentery and in hepatitis the *Entamoeba histolytica* is found in the amoebic stage, the amoeba as such, being demonstrable in the tissues; this amoebic or active stage is very vulnerable and quickly dies when the faeces are passed. Further, Vedder conclusively showed—and his results were fully confirmed and adopted by Rogers (whom we must all congratulate on the honour just conferred on him in recognition of his valuable work)—that emetin in a dilution of 1 in 10,000 within a few minutes killed the active stage of the *Entamoeba histolytica*, having no action on the non-parasitic *Entamoeba coli*.

This explains the rapid action of emetin, especially in cases of hepatitis. But unfortunately, as the patient recovers, the cystic form (*tetragena* stage) appears in the faeces, and may persist indefinitely and give rise to fresh relapses, the *minuta* stage appearing in conjunction with it and when loose diarrhoeal motions are being passed. Walker and Sellards found that the infection persisted in their artificially infected cases for as long as two years and four months in one case, and he was then still passing cysts in large numbers.

It has been further discovered that whereas emetin will remove and kill the active amoebic stage very quickly, it has no effect on the *minuta* or *tetragena* stages, hence the patient remains a carrier, and therefore a danger to others, and is liable himself to further complications or relapses. The problem, therefore, is to find some other means of killing the cysts. It might be thought that emetin given by mouth, or ipecacuanha so given, might exert a direct action on the parasite; but the experiments already quoted and clinical experience show that this is not so, nor is rectal administration any more efficacious, besides being at times painful.

We must therefore seek some other drug or drugs which will destroy the encysted *tetragena* stage. I consider that it is advisable to continue emetin hypodermically for a time, either in separate courses, or by mouth in the form of keratin-coated pills, or ipecacuanha combined with tannin. Personally, when possible I give a first course of injections of half a grain night and morning for three or four days, then half a grain daily for another seven or six days, making ten in all, this being followed by its oral administration for some time longer—the treatment to be repeated from time to time. By this means any fresh invasion of the tissues may be stopped and cicatrization assisted.

Quinine is often used in the treatment of amoebiasis, for solutions of 1 in 20,000 will kill amoebae, and I use it largely as enemata in a solution of 1 in 1,000. The good general effects may be caused by its absorption, for cinchonism can occur after an enema. But it is no more efficacious against cysts than is emetin. As you know, it has often been used for injection into a liver abscess cavity. Ujihara has employed quinine by mouth combined with tannin to delay its absorption in the upper bowel.

Tannin enemata 1 per cent. I frequently use, and copper sulphate 1 in 1,000, for the treatment of chronic dysentery, but they do not completely get rid of the parasite, nor apparently do silver salts.

Kuenen observed that when calomel is mixed with faeces containing the encysted form, after three hours half the cysts are found to be dead, and we know that calomel is sometimes very useful in chronic dysentery; its continued use might effect a permanent cure.

Ujihara finds that thymol in doses of 3.00 grams and male fern in doses of 7.00 grams will also kill off cysts; one or other of these drugs should be tried, preferably the thymol, as I have found male fern to be a dangerous drug if given repeatedly.

I suggest, therefore, the following line of treatment: The administration of emetin hypodermically for at least ten days or longer if the state of the patient demands it, followed by the oral administration of the drug. This is to be followed by subsequent courses at increasing intervals, as is the practice with syphilis or malaria, and in the intervals courses of calomel combined with thymol; if this is not sufficient, some other intestinal parasiticide should be tried. No man should be considered cured until after several examinations no cysts of *Entamoeba histolytica* are to be found in the faeces. Further, all carriers, even though they may never have had dysenteric or other symptoms, are to be considered as cases of amoebiasis, and treated as such.

Salvarsan and neo-salvarsan have been employed for the treatment of dysentery and excellent results have been obtained; arsenic has been detected in the stools after its use. But the experimenters have unfortunately not recorded if the cysts were destroyed. I always administer at the same time salines to aid in the expulsion of the parasites.

Reports of Societies.

ROYAL SOCIETY OF MEDICINE.

Clinical Section.

At a meeting on December 11th Dr. Alexander Morison showed a case of *Precordial thoracostomy for heart disease*. The patient was a boy aged 16, who suffered from tachycardia, irregular action of the heart, and breathlessness. A mitral systolic murmur was present and the area of cardiac dullness much increased. Forcible heaving of the left ribs and cartilages in the precordial region was noticed; 4½ in. and 5½ in. of the fifth and sixth ribs and cartilages respectively had been removed. There were no pericardial adhesions. The object of the operation was to relieve the enlarged heart of the labour of raising the chest wall. Dr. A. F. Hertz showed a case of *Cardiac achalasia* (so-called cardio-spasm). The term "achalasia" denoted want of relaxation, and was used to replace the word "spasm," which was incorrect for the following reasons: (1) Hypertrophy of the cardia was never observed after death, even after many years; (2) the mercury tube passed without any sense of obstruction through the cardia; (3) the mercury tube could be withdrawn without difficulty. In this case the patient was a woman, aged 36, showing characteristic symptoms, and by radiography dilatation of the whole oesophagus. Dr. A. F. Hertz and Mr. C. H. Fagge contributed notes of a case of *Spontaneous gastro-enterostomy*, with subsequent perforation and recovery after operation, in a woman aged 48. An opening had formed between the stomach and jejunum, and through this the greater part of the stomach contents passed.

Laryngological Section.

At a meeting on December 4th Sir StClair Thomson demonstrated a case of *Early malignant disease of the larynx*, shown at the last meeting, and referred to some details of the operation of laryngo-fissure which he had performed under chloroform after a preliminary injection of eudrenine. He had injected 10 to 15 minims of cocaine solution into the trachea before making the opening, thus abolishing the spasm of the glottis. No Hahn's tube was used, as he had found that an ordinary tracheotomy tube was sufficient for such cases. He referred to the difficulty in removing the whole of the disease, especially from the arytenoid and subglottic regions, and showed sections from the case. As it was evident that some of the growth had not been removed, he performed a second operation ten days after the first, and the patient made an excellent recovery. The case was discussed by Dr. William Hill, Dr. Dan McKenzie, Mr. Herbert Tilley, Dr. Dundas Grant, Dr. Jobson Horne, and Dr. Stuart Low. Sir StClair Thomson replied. Sir William Milligan showed three *Foreign bodies removed from the bronchi*. Mr. Herbert Tilley said that the results of radiography in these cases were often unreliable, and drew attention to the value of instantaneous photography. Sir StClair Thomson, Dr. D. R. Paterson, and Dr. Irwin Moore agreed that as soon as the object had been grasped it was advisable to withdraw the bronchoscope and forceps together, rather than to attempt to bring the body through the tube. Sir William Milligan said that in young children it was advisable to perform tracheotomy, so that a wider tube and shorter forceps could be used. Dr. William Hill referred to the value of combined x rays and bronchoscopy in operations of this kind. Sir William Milligan showed a case of *Angio-fibroma arising in the maxillary antrum*. He said that, although the microscopical section demonstrated tissue that appeared to be innocent, the case was clinically malignant. Dr. William Hill, Mr. Herbert Tilley, and Dr. Dundas Grant said such cases could often be cured by radium. Mr. Herbert Tilley showed a *Choanal polypus* with an ulcer on its posterior surface the size of a shilling, the latter leading to some difficulty in diagnosis until the growth had been removed. In many such cases there was no recurrence, but if the polypus reappeared twice it was essential to open the antrum. Dr. G. Elphick showed a patient with a *Retropharyngeal swelling*, in whom the Wassermann reaction was positive. It was agreed that the disease was probably syphilitic. Dr. C. W. M. Hope showed a patient from whom he had removed a *Tuberculoma of the nasal septum*. Sir StClair Thomson had seen a similar case in which the disease lasted for seventeen years, during which time it spread from the nose to the pharynx, later to the larynx, and finally to the lungs. Dr. Dan McKenzie showed some *Soft metal tubes for insertion into the nose after submucous resection of the nasal septum*, which greatly relieved the discomfort caused by nasal obstruction. Dr. H. Clayton Fox showed a case of *Malignant disease of the tonsil and pillars of the fauces*, which in its first stages appeared to be a simple tonsillitis with abscess. Later the growth appeared and was microscopically papilloma, though the case was probably malignant. Dr. H. Pegler showed a superior maxilla from an aged female with an *Abnormal malar antrum* behind the true maxillary cavity.

BRADFORD MEDICO-CHIRURGICAL SOCIETY.

At a meeting on November 17th Dr. Eurich read short notes on three unusual cases of *Bacillus coli infection*. The first was that of a workman who was supposed to have strained himself whilst lifting a heavy weight. Shortly afterwards double orchitis set in, which could not be accounted for in the ordinary way. Bacteriological examination of the urine revealed *Bacillus coli* in great abundance. The second case was that of a clergyman, aged 58, with swelling of both testicles, with a history of a knock two years previously; since then he had had periodic attacks of orchitis. Bacteriological examination of the urine revealed enormous numbers of *Bacillus coli*. The third case was that of a lady, aged 45, who on December 13th, 1913, had what appeared to be a slight conjunctivitis of one eye. Four days later there was some iritis. After ten days' treatment her condition improved, but on January 23rd she had a relapse, with slight irritation of the bladder. On February 16th *Bacillus coli* was discovered in the urine, and a vaccine prepared. In a fortnight recovery was complete. Mr. Goyder read a paper on the *Treatment of infantile and other forms of paralysis in general practice*. The treatment was based on the principle enunciated many years ago by Hugh Owen Thomas, and rediscovered by Mr. Robert Jones of Liverpool. The first rule was to fix the limb in such a position that the paretic muscles were relaxed. Operations such as tenotomy might be required for this purpose. Plaster-of-Paris splints might be used, or, better, the much lighter celluloid splints. Walking should be encouraged with the patient in the splints. Even after many years of paralysis the improvement was often astonishing. No operation for tendon grafting should be undertaken until many months after the application of the splints. If as soon as possible after the initial attack such splints were applied, since the paretic muscles never became overstretched, recovery from paralysis, if it were going to take place at all, was certainly hastened. This principle could be applied to nearly all forms of paralysis, irrespective of their cause—for instance, wrist-drop from lead, or musculo-spinal injury, or Erb's obstetrical paralysis. In Little's disease the element of spasm was also present, but much good could be done if the child had any intelligence, by simple fixation in the over-corrected position for some months after simple tenotomy of the adductors or tendo Achillis according to the region affected. In many cases no tenotomy was required. More complicated procedures should be reserved for cases in which simpler ones had proved insufficient. Hence, apart from operation, much could be done by the general practitioner, especially in the early stages of infantile palsy.

LIVERPOOL MEDICAL INSTITUTION.

Mr. C. P. Newbolt read a paper on *Appendicitis in the elderly*. He reported three cases, and emphasized the fact that appendicitis occurred in persons over 60 more commonly than was generally recognized, and also that perforation not infrequently took place without causing any serious initial symptoms. Mr. A. A. Bradburne read a paper on *Bilateral optic neuritis due to sphenoidal sinusitis* in which the left sixth nerve was involved. The vision of the left eye was somewhat impaired with severe occipital pain. Spontaneous discharge of pus from

sphenoidal sinus was followed by gradual improvement. Total absence of any trouble in the nose pointed to sinus infection. Captain C. THURSTAN HOLLAND read a paper on the *X-ray treatment of the wounded* at Fazakerley Hospital, fully illustrated by lantern slides. There were numerous lantern slides showing the destruction of bone and the character of the injuries produced by bullets and pieces of shell. The PRESIDENT opened the discussion. Dr. BARCLAY described the instrument which he had devised to facilitate rapid estimation of the depth of foreign bodies and deprecated indiscriminate removal of bullets. Dr. ORAM described another method based on the series of curves. Captain ARTHUR EVANS referred to his experiences in the Boer war, and compared them with those at Fazakerley base hospital. He was strongly in favour, when removing the bullet from the fleshy parts, of making a free incision in order to save the muscles as much as possible. The muscles should be separated rather than cut across. The bullet of to-day made a much more serious wound than the bullet of the Boer war. Attention was drawn by the PRESIDENT to the Belgian Doctors' Relief Fund, and a Committee was formed to work with that of the Royal College of Physicians.

Reviews.

INSANITY AND OTHER MENTAL DISEASES.

WHEN the first edition of this book[1] was published, twelve years ago, it was recognized by many thoughtful beginners in the study of insanity, as well as by some older men scientifically or professionally interested in the subject, as a work which, before all others, gave a clear account of what insanity consists in and made a serious effort to establish a logically sound and useful classification of instances of insanity as met with in practice. On grounds such as these the book on its first appearance was confidently recommended to students in this JOURNAL. This larger edition, owing to much new matter and to the great amount of careful thought that has been bestowed on its revision throughout, will, we believe, gain the attention it deserves from all students, teachers and practitioners, as the most comprehensive, well reasoned, and instructive review of the whole subject of insanity—from its foundation upwards—that has as yet been produced in any country. There is no other book which lays such a sure foundation for this study in the consideration of normal mind and conduct, or builds upon this foundation a scheme of the disorders of mind and conduct among which insanity must find its true place.

Although the first edition, intended primarily for the use of medical students as an introduction to the study of insanity, has been largely used as a textbook in several universities and some other medical schools both here and in America, its real originality and importance have not been adequately recognized. Before its appearance, even the best textbooks on insanity, though unquestionably of high clinical value and replete with evidence of practical knowledge, consisted largely in descriptions of cases arranged under a few more or less conventional and ill-defined headings, involving much cross-division and consequently disconcerting confusion in the minds of those desirous of forming clear conceptions of the subject of their study. There was little or no reference to the normal processes of which insanity is the disorder, and the very definition of insanity was usually given up as a hopeless task. Since the publication of Dr. MERCIER'S book, however, and since his teaching in lectures and monographs on insanity have become more widely known, most works on the subject have contained some account of the normal processes of mind, and no longer give prominence to the description of individual cases. And the two-fold causation of insanity in hereditary tendency on the one hand, and "stress" on the other, first explicitly insisted on by Mercier, is now generally accepted, although without due recognition of its originality.

In this new edition the author has expanded and emphasized his teaching that the description, or analysis of insanity into disorders of conduct and mind, is the key to the comprehension of insanity. Notwithstanding the fact that disorders of conduct play far the largest part among those symptoms of insanity which raise the question whether a given person is insane or not, and the further fact that many persons are certified insane on the evidence only of disordered conduct, most writers on insanity either implicitly or explicitly regard insanity as disorder of mind alone. We cannot but think that a careful study of Part I of this book must succeed in convincing all intelligent readers of both the truth and the importance of this fundamental part of Dr. Mercier's teaching. They will thus understand that insanity and unsoundness of mind are not the same thing, as they are generally assumed to be both by Law and Medicine; that there are many disorders of mind that are not insane—a fact which is rendered prominent in the title of this book; and that there is much disorder in insanity that is not disorder of mind.

Dr. Mercier supplies the student in this book with an exposition of psychology that is exactly suited to his needs. The chapter on mind, indeed, would alone distinguish this work as furnishing by far the best basis for the alienist's study of mental pathology and psychiatry, which is already held to necessitate a knowledge of the normal constitution of mind.

The second part of the book—on the forms, types, and kinds of insanity—cannot be adequately dealt with within the limits of this review, but we would note especially the distinction between "symptoms" and "disease" as of great importance, extending far beyond the application of this distinction to insanity. Dr. Mercier has here supplied a model for a future scheme of nomenclature of diseases and death certification which would be far superior in clearness and accuracy to any previous attempts in this direction. As an outcome of the distinction he makes, it is shown that insanity may be either a disease or a symptom, and that the failure to grasp this has hitherto rendered any acceptable classification of insanity well-nigh impossible. He submits a classification which has the welcome qualification of being at once clear, logical, and comprehensive. We think that he justifies the claim made in the preface that in his classification there is no inclusion of anything that is not insanity; that insanity is distinguished from everything else, including unsoundness of mind; and that there is no attempt to divide any class on several principles at once, and consequently no cross-division.

Many points made in this edition are new, and some others have not as yet been fully appreciated. With respect to these, we can but refer to a few: for example, to the author's Preface; to the remarks concerning the equivocal use of the term "melancholia" on p. 127; to the use and import of the term "anoia" as denoting the defect of mind and conduct that constitutes insanity (pp. 158–164); and to "sequelar" insanity as distinguished from "symptomatic" (p. 236).

There are but a few places in which we call in doubt the author's teaching. He gives, in our opinion, too little weight to hallucinations, both of sight and hearing, as premonitions of insanity; and is scarcely justified in his assertion of the great frequency with which an attack of delirium tremens is brought about by cutting off, and cured by administering, alcohol. There are, we think, many attacks of delirium tremens that begin when the patient is drinking up to his full amount, and many that are cured by greatly reducing, or entirely and even suddenly cutting off, the alcoholic supply. We are also inclined to differ from Dr. Mercier anent his "Index," which is "expurgatory" of indices altogether. We *have* read the book, and have not "rejoiced greatly" over the absence of an index when writing this review.

What strikes us most forcibly after reading this book is that the definition of insanity, the description of its true nature, and the construction of a water-tight classification, taken all together, raise the study of insanity to the level of a science—of a systematized scheme of knowledge. Hitherto it has been treated of in unorganized fragments supplying isolated, though often important and instructive, information; but leaving the subject as a whole in a stage of chaos, and the student's mind in a high degree of

[1] *A Textbook of Insanity and other Mental Diseases.* By Charles Arthur Mercier, M.D., F.R.C.P., F.R.C.S., etc. Second edition, enlarged and entirely rewritten. London: George Allen and Unwin, Ltd. 1914. (Pp. xx, 348. 7s. 6d. net.)

confusion. And this criticism is especially applicable to certain foreign works on insanity, in which novelty of terminology has been mistaken for originality of thought, and has caused them to be accorded an undue authority as manuals of instruction.

BELGIUM.

King Albert's Book[2] was published on December 16th by Messrs. Hodder and Stoughton for the proprietors of the *Daily Telegraph*, the *Daily Sketch*, and the *Glasgow Herald*, to accomplish, in the words of Lord Kitchener, the "twofold object of bearing further testimony to our admiration of the courage and devotion to duty shown by King Albert and his army, and of securing material help and comforts for the Belgians who have suffered so terribly at the hands of an invading enemy." The preface, written by the editor, Mr. Hall Caine, is dated Christmas, 1914, and the book will be a seasonable gift, for the text is well printed and the illustrations admirably reproduced. It contains contributions from statesmen, sailors, soldiers, poets, artists, men of letters and men of science in the neutral countries—the United States, Italy, Spain, Portugal, Holland, Denmark, Sweden, Norway, Poland; and also in the allied countries—France, Russia, and Japan, as well as in Canada and India. There are five or six articles from members of the medical profession, but among men of science we may perhaps refer especially to Sir William Ramsay's declaration that "every scientific man who is not a Teuton (and I hope and trust many who are of German race) deplores the barbarity, incredible if it were not true, with which Belgium has been treated. We had hoped that the universality of the spread of science, both pure, and applied to industry, would have made it impossible for any nation to revert to barbarism, and to destroy what it has taken so many centuries to create. The scientific achievements of the Belgians have always stood on the highest plane; to quote only two instances, taken from my own subject, the name of Stas, in pure science, and of Solvay, in applied science, are among the most illustrious in their particular spheres, which the world has ever produced." The volume concludes with a short note of thanks by Macterlinck, and perhaps the spirit of the book and the motive with which it will be preserved are best expressed by his translator, Mr. Alfred Sutro, when he writes, "Her cities are laid waste now, and her people scattered—but her people will return and rebuild the cities, and the enemy will be dust. The day will come when the war will be far distant, a thing of the past, remote, forgotten—but never, while men endure, or heroism counts, will it be forgotten what the Belgians did for Liberty's sake, and for the sake of Albert their King."

In *Fighting in Flanders*[3] Mr. E. ALEXANDER POWELL gives an account of what he saw as correspondent of the *New York World* during the period between the flight of the Belgian Government from Brussels and the fall of Antwerp. The author is a practised journalist of the most modern school; he knows the value of condensation: he can draw a vivid picture, but he lets it tell its own tale. Therefore we believe that the book, slight and informal though it be, will prove itself to possess permanent historical interest. One of the most curious chapters contains an account of the journey of Mr. Powell and his companion photographer to dine with the Commander of the Ninth German army, "composed of the very flower of the German empire, including the magnificent troops of the Imperial Guard." It was, we think, published in a London newspaper at the time, but well bears repetition. Mr. Powell was impressed with the completeness of the organization—down to cobblers working in boot-mending wagons, pedicurists who examined and treated the feet of the men, and hair-cutters with clipping machines which were used on any man whose hair an inspecting officer at a cross roads considered too long. He seems to have been less impressed by General von Boehn's denials and explanations of German atrocities. The story of the fall of Antwerp, as told by Mr. Powell, is not a story of which Englishmen can feel proud, but it is not tinged by any partiality for the Germans, for he tells us that when he left Antwerp he was as pro-Belgian as though he had been born under the red black and yellow banner, for he had "seen a country, one of the loveliest and most peaceable in Europe, invaded by a ruthless and brutal soldiery," and its people "resourceful, unafraid, and fighting, fighting, fighting." It is a book to read now, and a book to keep for the future, when German professors may be expected to take up General von Boehn's parable, trusting to the shortness of human memory.

NOTES ON BOOKS.

DIARIES.

THE enterprise of the publishers of diaries shows no diminution on account of the war. Messrs. John Walker and Co. make a special feature of loose-leaf pocket diaries, which can be increased or diminished in bulk as the user's convenience requires; the leaves are retained in position by rings at the back, which can be easily opened by pulling a slide. They also make many other forms of pocket diaries in various shapes and sizes. The paper is good, and the workmanship throughout of a high quality.

Messrs. Cassell and Co. make many varieties of diaries, but are specially strong in desk diaries of various sizes, ranging from large foolscap forms to small octavo. Pocket diaries are also produced in various convenient forms. The diaries continue the name and traditions of Letts's diaries, so well known to many past generations.

Messrs. T. J. and J. Smith have sent us specimens of quarto half-hourly appointment books, which can be obtained either with or without interleaved blotting paper. The books are provided with an index.

Messrs. Hazell, Watson, and Viney have issued *Smith's Physicians' and Surgeons' Visiting List* for 1915, being the sixty-ninth year. It is strongly bound, and has been specially designed to meet the needs of general practitioners, to many of whom its merits are already well known.

PREPARATIONS AND APPLIANCES.

Maple Sugar and Syrup.

WE have received from the Canadian Maple Products Company, Limited (1, Endell Street, London, W.C.), samples of maple sugar and maple syrup, which they are selling under the "Pride of Canada" brand. These articles, made by concentration of the sap of the sugar maple, enjoy considerable popularity in Canada; their distinctive character lies in the flavour, which is due to non-saccharine constituents of the sap which remain in the product. The sample of maple sugar submitted is in the form of a brown cake, or tablet, breaking with a short crystalline fracture, and sufficiently pleasing to the palate to be eaten as a sweetmeat without further preparation. The syrup is brownish-red in colour, and a good deal thinner than ordinary "golden syrup." Our analyses gave the following results:

	Maple Sugar. Per Cent.	Maple Syrup. Per Cent.
Cane sugar	77.8 ...	60.4
Reducing sugar, calculated as glucose	7.8 ...	1.7
Acidity, calculated as malic acid	0.13 ...	0.08
Ash	0.9 ...	0.6
Water	8.3 ...	33.7
Undetermined matters ...	5.07 ...	3.52

There appears to be every reason to regard these products as a very wholesome form of saccharine food.

A Carpenter's Brace for Bone Plating.

Mr. W. SAMPSON HANDLEY (London) has designed an instrument which combines a brace with a Sherman's screw-holding screwdriver. The screws used have a drill end so that the previous use of a drill is unnecessary, and have either a coarse or a fine thread. Mr. Handley finds the coarse-threaded wood screw preferable, as there is less likelihood of overdriving it, so causing it to lose its grip. The instrument is new only as a combination and not in its separate parts. Its use is found to simplify the technique and shorten the duration of bone-plating operations. In favourable circumstances it will enable the operator to plate a fractured femur in an adult in less than half an hour.

THE DEPARTMENTAL COMMITTEE ON SICKNESS CLAIMS UNDER THE NATIONAL INSURANCE ACT.

THE report of the Departmental Committee on Sickness Benefit Claims under the National Insurance Act, which has been presented to Parliament, deals with matters of such great importance to the medical profession and is so likely to be regarded as a basis for future legislation seriously affecting the profession, that no excuse is needed for giving a somewhat lengthy summary and at the same time a suggestion that all members of the profession who are now or may be in the future engaged in working the Insurance Act would be well advised to procure a copy of the report and study it in detail.[1]

The Committee was appointed in August, 1913, by Mr. Masterman as Chairman of the Commissioners, with the reference "to inquire into and report upon the alleged excessive claims upon, and allowances by, approved societies in England in respect of sickness benefit and any special circumstances which may cause any such claims or allowances." Sir Claude Schuster was appointed Chairman of the Committee, which consisted of fourteen members, three of whom were women, and was representative of the Commissioners, the approved societies, and the medical profession. With the exception of a week at Christmas and two weeks at Easter, the Committee sat continuously on two days of each week and examined 94 witnesses, whose evidence fills three volumes apart from the report itself. Of the witnesses, 52 represented 49 approved societies of different types from all parts of the country, with a total membership of 6,900,000 insured persons. Out of 26 medical witnesses, 20 were panel practitioners, while the British Medical Association, the Association of Registered Medical Women, and Sir Thomas Barlow as representing the Royal College of Physicians, consented to nominate representative witnesses. Insurance Committees were represented by nine witnesses, and several other persons were heard as having made a special study of the principles of sickness insurance. The Committee was not expected to undertake any actuarial investigation, but merely to examine into the actual working of the insurance machine as exemplified in the action of its several parts, taking into account the interests, often somewhat conflicting, of insured persons, doctors, and approved societies. The report, with attached memoranda, fills 94 folio pages, and is dated July 24th, 1914, but has only recently been issued.

The reference to the Committee related solely to sickness benefit, but disablement benefit was regarded as merely a continuation of sickness benefit, and medical and maternity benefits are so closely related that they were practically to a very large extent included in the investigation. The number of approved societies actually operating in England is given as 1,891, ranging from the great centralized societies and affiliated orders with hundreds of thousands of members down to small village clubs with not over a hundred members, and with every conceivable type of organization. A brief survey is given of the relations between the societies and their doctors in the past, and evidence was given that as a rule the societies had seldom thought of questioning their doctors' certificates. At the same time, it is pointed out that the medical certificate, though in law and theory it is not the sole evidence available to establish incapacity for work, was in practice always regarded as the chief evidence to be relied on. This was at a time when there were far more intimate relations existing between societies and their specially appointed doctors. But under the Insurance Act the old intimate relationship between societies and doctors exists to a far less extent, and this has had, it is stated, a considerable effect in modifying the value set upon medical certificates.

Much evidence was given as to the extent of double insurance, that is, insurance both under the Insurance Act and as members of voluntary societies, and numerous cases are mentioned in which insured persons, when incapable of work, received as sickness benefit sums considerably in excess of their normal wages when working. Some of the witnesses urged that double insurance showed a spirit of thrift and prudence which would be generally opposed to attempts to exploit the sickness funds, that expenses were greater in sickness than in health, and that though doubly insured persons might remain longer on the funds they were thereby enabled to avoid a second illness by getting completely cured from the first, so that in this way the total effect on the funds was not so bad as generally thought. In the Insurance Bill as originally drafted there was a provision for reducing the amount payable from the National Insurance Funds in such cases, so that it would be impossible for a man's income to be more when sick than when well, but this provision was rejected by the Legislature. The Committee states very distinctly that it considers over-insurance offers to some persons a temptation to declare on the funds unnecessarily and to remain on longer than they otherwise would. But the only suggestion is that societies, when they find evidence of over-insurance, should encourage the adoption of alternative benefits and apply the strictest tests possible through sickness visitors and by communicating with the doctors.

In considering the alleged frequency of cases in which there is unwillingness to bring the period of incapacity to an end, the report says:

> Even in recording this fact, it must be stated also that the main feeling in the mind of any one examining the operation of the Act, is one of wonder that it should proceed as smoothly as it does. Practically all the witnesses, medical and lay, repudiate the idea that any appreciable amount of fraud exists. Falling short of deliberate fraud, however, there is a considerable body of evidence, both from representatives of approved societies and of the medical profession, of an unwillingness to bring the period of incapacity to an end, and of the difficulty in getting an insured person who has once declared on the funds to declare off.

Numerous witnesses spoke of the difficulty in the supervision of married women while receiving sick pay. A tendency was often noticed to remain on the sick funds in order to do housework and often a disposition to make use of the sickness benefit while out of employment, and a certain amount of evidence of an intention to get the most out of the Act. Many of the medical witnesses spoke of the tendency to claim for trivial complaints and to remain on the funds longer than was necessary, but the difficulty that faced the doctors was the practical impossibility of fixing an exact day when incapacity for work ended. On considering the whole evidence on these points, the Committee concludes:

> It would be idle and extravagant to base upon such experience as we have before us a general charge of malingering or of greed against the insured population generally.

Evidence was also given to show that there is in fact far more sickness than was expected when the Act came into operation, and that among women, and especially those employed in the lower-paid industries, the real amount of illness is enormously greater than was ever imagined, even after allowing for the fact that in a sense the Act had to treat a large arrears of sickness which had hitherto gone untreated. It was pointed out, however, that when such sickness had been treated for a time the average amount of sickness might be expected to show some decrease. Some of the medical witnesses expressed a fear that a valetudinarian habit of mind might be induced through over-attention to health and disease, and in support of this it was repeatedly stated that an enormous number of the persons who consult panel practitioners are only suffering from the most trivial complaints. The Committee suggests that to avoid claims in such cases it is essential that the insured should recognize that the insurance is a mutual one, and that fraud or laxity of one may result in the impoverishment of all, that the old friendly society spirit of mutual self-help and good fellowship did much to lessen the sickness claims, and that if this gives place to a mere business idea, or a feeling that through the intervention of the State the funds are now a bottomless purse, it will lead to ruin.

[1] To be purchased through any bookseller or direct from Wyman and Sons, London, H.M. Stationery Office, Edinburgh, or F. Pousonby, Dublin. [Cd. 7687.] Price 9d. The Minutes of Evidence are printed separately in three volumes as follows: Vol. i, Minutes from October 15th, 1913, to December 18th, 1913, as [Cd. 7688], price 3s. 7d.; vol. ii, Minutes from December 31st, 1913, to March 5th, 1914, as [Cd. 7689], price 4s.; vol. iii, Minutes from March 11th, 1914, to May 22nd, 1914, as [Cd. 7690], price 3s. 4d. The Index to the Minutes of Evidence is printed separately as [Cd. 7691], price 10d.

A large quantity of statistics as to the cost for sickness benefit in the various societies was given. The actuarial estimates were, of course, based on averages for the whole country on the unavoidable assumption that each society would have average lives exposed to average sickness risks through their employments and environment. A process of segregation was, however, inevitable, with the result that some lodges and clubs have a large proportion of the best lives living under the best conditions, while others have a great preponderance of members engaged in unhealthy occupations and living in the worst possible conditions. On this account it was only to be expected that some societies and branches would show a low rate of sickness, while others would have an almost ruinous amount of claims. In the Foresters the cost for sickness benefit was about 2.75d. a member a week, taking men and women together. In the Manchester Unity of Oddfellows it was 1.96d. for men and 1.95d. for women; in the Druids 3.06d. for men and 2.97d. for women; in the Sons of Temperance 2.11d. for men and 1.95d. for women. Wide variations occurred, however, in the separate lodges of these societies—for example, at Barnsley the men in the Sons of Temperance cost 4.25d. per week, while in Birmingham the cost was only 1.65d. When separate trade groups were taken the variations were still more marked, and especially was this the case among women workers. To take a single example out of many given, the half-yearly cost for women (domestics and mixed occupations) in one district was 2s. 9d., but in another district 8s. 2d. The Committee found it necessary to be on its guard against assuming that the healthiness or unhealthiness of a place or trade was the only or even the chief factor in deciding the amount of the claims for sickness benefit, as other important factors had to be taken into account—for example, local conventions as to the degree of illness necessary to claim benefit, idiosyncrasies of local medical practitioners, and, perhaps most of all, the type or adequacy of the organization of the local approved societies. The common-sense view is expressed that the most efficient administration could only be obtained when there is a happy combination of centralized control with a certain amount of local independence.

A considerable amount of evidence was given to show the great value of the society sick visitors when properly employed, and though some complaints came from medical witnesses of undue interference by sick visitors with the work of the doctors, there was much evidence to show that the profession would welcome the assistance of properly trained and discreet sick visitors.

A considerable portion of the report deals with the question of excessive sickness claims viewed in relation with the work of medical practitioners under the Act. The sections dealing with this are well deserving of the attention of the whole profession, and the report itself ought to be carefully read by all practitioners who are willing to see themselves as others see them. It is recognized throughout that the successful working of the Act cannot be hoped for unless the medical profession stands in relations of sympathy and understanding with the machinery of the Act. The medical evidence as to the proportion that exists between the number of persons treated and the number to whom certificates for sickness benefit were given, varies enormously. In one area, where the bulk of the patients were teachers, journalists, and superior servants, only 2 per cent. of those receiving treatment applied for sickness benefit. In an industrial area the proportion rose to 32 per cent., and in a large number of estimates it varied from 25 per cent. to 35 per cent., and in some areas it reached 53 per cent. for men and 66 per cent. for women. The correct interpretation of the term, "incapacity for work," has caused the greatest embarrassment to both doctors and approved societies. To interpret this strictly and literally as meaning "incapable of any kind of work whatever," is evidently regarded by the Committee as somewhat absurd, for we read that "under such an interpretation it would be difficult for any one, apart from the completely paralysed and the unconscious, to establish a claim for sickness benefit." Before the Insurance Act came into operation the friendly societies had used terms which simply meant "unable to follow the usual occupation," and the Committee believe that the natural instinct of the doctors would have been to regard this as sufficient to entitle to the benefit, but questions raised by societies in particular cases had produced a state of doubt among medical men. The Committee calls attention to the fact that the finances of the Act were based on the experience of the Manchester Unity, which before the Act paid sickness benefit when a member was unable to follow his usual occupation, and it is suggested that such a meaning is "more in consonance with the intention of the Legislature in passing the Act than the adoption of the strict and literal interpretation of the clause."

At the same time it was evident that such an interpretation could not be taken as of universal application, especially in cases of prolonged incapacity. For example, an engine-driver may be for ever unable to resume his usual occupation if he has minor epilepsy, but it does not follow that he should be for ever on the sick funds, because he may be quite capable of finding another occupation, and in such a case some time limit might, it is thought, reasonably be placed on the payment of sickness or disablement benefit. Taking everything into consideration, the Committee therefore recommends that "it should be provided by statute that sickness benefit should be payable when an insured person is incapacitated by disease or bodily or mental disablement from following his usual occupation," but a person who, without ever regaining his ability to follow his previous occupation, becomes able after a time to follow some other occupation which is reasonably open to a person of his training and education, should become disentitled to sickness or disablement benefit, and this should apply especially in the case of women.

(To be continued.)

THE ORIGIN AND DEVELOPMENT OF THE RED CROSS.

(Continued from p. 1031.)

AUSTRIA.

In 1863 Dunant, after his visits to Berlin and Paris, went to Vienna, where M. Steiger, Minister Plenipotentiary of the Helvetic Confederation, presented him to the Archduke Rénier, the Emperor being absent. Dunant says:

> After a long explanation, and when I had mentioned my idea of the neutralization of the victims of the war and those who helped them, as well as that of a universal flag of humanity, His Imperial Highness deigned to say three times in French these words of approval, with a convinced and cordial expression, "What a magnificent idea!"

This was a great encouragement for Dunant. He insisted particularly on the expediency of there being one flag for all countries. He pointed out that all nations had indeed a flag for their ambulances, but the colours differed, being white in Austria, red in France, yellow in Spain, black or green elsewhere. The soldiers of opposing armies knew only the colours of their own ambulances. This confusion would be prevented by a uniform flag for the ambulances of all armies. The Archduke promised Dunant that Austria would be represented at the Conference, and accordingly Dr. Unger, Staff Surgeon of the Austrian Army, was sent to Geneva.

Major C. E. Pollock, in an address delivered to the officers of the 2nd London Division, Territorial Force, on November 20th, 1913,[1] stated that in the Austrian army medical organization voluntary aid societies fulfil a number of duties. Thus the Teutonic Order furnishes 5 ambulance wagons for the divisional medical unit; the same order provides the equipment for 4 field hospitals of 200 beds each, the personnel is furnished by the Landwehr; each hospital has a wounded transport column attached to it. The Austrian Red Cross Society provides 33 wounded transport columns, with a total of 648 wagons; the War Office finds the personnel from the Landwehr. This Society also provides a number of field medical dépôts, with supplies to replenish field medical units, and has two field hospitals of 200 beds each. In addition it is prepared to accommodate some 4,000 officers and 23,000 men in

[1] A Comparison of Foreign Army Medical Methods with those of the British Army, with special reference to the Territorial Force. *Journal of the Royal Army Medical Corps*, January to June, 1914, p. 35 et seq.

hospitals and convalescent homes in Austria. It also provides all the first field dressings for the entire army.

The following account of the resources of the Austrian Red Cross Society is taken from a speech by Surgeon-General Ritter von Uriel, late Director-General Austrian Army Medical Service, published in *Das Rote Kreuz*, No. 1, 1912 :[2]

	£
I. War funds (£417,870)—	
(*a*) Central Red Cross Society	147,610
(*b*) Austrian Patriotic Society	42,040
(*c*) Other affiliated Societies	100,570
(*d*) Branches of the Society	127,650
II. Funds allocated for special purposes ...	140,685
III. Peace funds	24,010
IV. Value of equipment, stores, etc. ...	72,000
V. Value of buildings	81,260

The total capital in cash and property belonging to the Red Cross and affiliated societies amounted to £735,825. About two-thirds of this total has been provided by members' subscriptions and the interest on investments. Of the remaining one-third more than half has been derived from the proceeds of lotteries; about a quarter belongs to the Austrian Patriotic Society, and the balance has been derived from Government subventions, gifts, legacies, etc. The war funds shown in Section I constitute a reserve for war purposes. The £147,610 belonging to the Central Committee of the Red Cross Society is intended to cover expenditure in rendering assistance to the Army Medical Service at the front and on the lines of communication, and for expenses in connexion with the Central Information Bureau. The sums shown in the other three subdivisions would be expended in the home territory in the provision of hospital accommodation, convalescent homes, rest stations, etc.

The funds in Section II are mainly allocated for the provision of pensions to soldiers incapacitated by war, to widows and orphans of soldiers who die or are killed in war. Of the values shown in Sections IV and V, 2 per cent. per annum is written off for depreciation. In addition to this £13,260 was struck off, that sum representing the cost of first field dressings which had become obsolete, and of first field dressings which the Red Cross Society supplied free of charge to the army. The Society's head quarters cost £12,250, and the dépôt for transport vehicles £12,720.

Dr. Richter (*Das Rote Kreuz*, No. 8, 1913, p. 168), gives the following account of the preparations made by voluntary aid societies for war:[3]

The Austrian Red Cross Society has in store a large quantity of medical and surgical material, among which may be mentioned 1,400,000 first field dressings for the army. It has also 35 medical store wagons with all the contents complete, and 3 mobile field medical store dépôts packed in 50 covered vehicles to replace material expended by field medical units.

For the transport of wounded the Society has 500 ambulance wagons and 4,000 field stretchers. It has also 84 medical carts with complete equipment for mountain warfare. Two complete field hospitals have been provided for use with the fighting troops; the personnel is supplied from the Landwehr. Three hospital ships can be fitted out by the Society at short notice. Recently Voluntary Aid Detachments, consisting of two doctors, four to six male attendants, and thirty female nurses have been organized to reinforce immobilized field medical units.

In the home territory the Society has 39 reserve hospitals, 19 hospitals for slight cases, and 25 convalescent homes; together these afford accommodation for 317 officers and 9,400 men. In addition beds have been promised in civil hospitals for 249 officers and 1,943 men, and in private nursing homes for 4,170 officers and 12,183 men. Thus the Society can find accommodation for a total of 4,736 officers and 23,526 men. The railway rest stations, 50 of which have been prepared, can accommodate for one night 50 officers and 5,064 men. A large sum of money has also been set aside to assist invalids and widows and children of men injured in war, and to institute an information bureau for wounded and prisoners. To combat epidemics sixteen mobile field laboratories have been organized with a specially trained staff. The Sovereign Maltese Order has prepared twelve hospital trains. The Teutonic Order has a large number of ambulance wagons, and also four fully equipped reserve mobile field hospitals.

During the present war hospital trains have been organized for the transport of the wounded. These trains, organized by the Order of Malta, have special wagons in which operations can be performed. At all the important stations on the line of route local committees offer refreshments to the wounded and give them cigars, cigarettes, and flowers. The organization of aid to the wounded in all the provinces is said to be excellent, and wounded prisoners of war are treated by the people with the same care as Austrian wounded. Members of the imperial family are at the head of all the humanitarian and military organizations in Vienna and Budapest. The Archduchess Maria Theresa, mother of the murdered Archduke Francis Ferdinand, works in the hospital as a Red Cross Sister. The Archduchess, daughter of the Commander-in-Chief, the Archduke Frederick, before the war did work as a nurse; she is now in a base hospital in Galicia.

HUNGARY.

We take the following account of the Hungarian Red Cross from the *Boston Medical and Surgical Journal* of October 8th, where it is quoted without any indication of its source:

"The Hungarian Red Cross Society, whose aim has always been to keep itself in constant readiness to take the field, issued shortly before the war broke out a circular in which it was stated that in the event of war Hungary would probably find herself responsible for 100,000 wounded and 250,000 sick soldiers, many of whom would be Hungarian subjects. The circular further stated that it had been estimated that, in addition to those of the military nurses, the services of some 7,000 civilian nurses would be required to meet this sudden demand; and since the number exceeded the total number of trained nurses throughout the whole of Hungary, it was obvious that it could not be recruited from the ranks of the nursing profession alone. Even when the country was at war the work in the general hospitals would have to be carried on as usual, and if, as was quite likely an epidemic broke out, would become considerably heavier. It was therefore a matter of necessity to obtain the assistance and co-operation of all women who were willing to offer their services as nurses in time of war. The response to this appeal was both prompt and gratifying. In almost every town in Hungary courses of lectures were at once organized, and held in the wards of the local hospitals, and at the conclusion of each course the candidates were examined in the presence of a delegate of the Red Cross Society and other civil and military authorities."

The total membership of the Red Cross Societies is stated to be 100,000, while the total amount of funds in their possession was estimated in 1908 at £494,915.

(To be continued.)

MOTOR NOTES FOR MEDICAL MEN.

By H. MASSAC BUIST.

MOTOR SHOWROOM WEEK.

THIS is the season of the year when, in times of peace, a concerted effort is made by the motor industry to introduce to the notice of the public at Olympia, Kensington, novel features embodied in chassis and coachwork for the succeeding year. For about eight weeks after the outbreak of war the Society of Motor Manufacturers and Traders made no definite announcement, but in the result it was fain to decide that the pleasure carriage show, planned for this month at Kensington, should be abandoned—a decision which was immediately followed by one also to abandon the light car show, planned to follow it in the same building, at an interval of ten days. Nevertheless, manufacturers and concessionaires have been busy making an effort to have a showroom show, as they are styling it, this week. They are taking the opportunity to display their new cars in their showrooms about London. From the point of view of the public, this is by no means as convenient a method as the centralization scheme, possible

[2] Abstract in the *Journal of the Royal Army Medical Corps*, July to December, 1912, p. 138.
[3] Abstracted in the *Journal of the Royal Army Medical Corps*, January to June, 1914, p. 479.

only by employing a large public building for the purpose of a collective display.

All things considered, it is somewhat remarkable that at a time like this so much should be done in the way of incorporating new features, and particularly sound improvements, in motor chassis as is being done by the industry. Ordinarily, in times of stress like the present, manufacturers are content merely to go on reproducing their models as they have been making them in the past season, awaiting the advent of a revival in trade before changing the machines in any respect. It is indeed a sign that there is no appreciable amount of stock on hand that manufacturers can now come forward with new features incorporated in their chassis.

THE 1915 TENDENCIES.

From a general consideration of the material brought forward, it would appear that only a minority are continuing to make their cars as before, and that a slight majority are incorporating fresh features in them. In broad terms, the movement for providing still better value for money continues. This, however, is not all. Last year some of the most costly and luxurious chassis, such as do not fall to be considered by the average medical man, were fitted with mechanical engine-starting devices; whereas this year there is no little evidence to the effect that the middle-powered, medium-sized car of moderate price is now furnished with some form of mechanical engine-starter. Instance in this connexion the enterprise of the Napier Company in furnishing an electric engine-starting apparatus to the four-cylinder 16 to 22 horse-power chassis having the longer of the two wheel-bases supplied.

In nearly all cases, too, these engine-starting devices are supplied at the inclusive price of the chassis, and it need hardly be added that wherever they are supplied electric lighting apparatus is also a standard fitting. Very few chassis are now marketed that have not electric lighting equipment furnished as standard; but the same remark does not apply concerning the mechanical engine-starting movement, about which much has yet to be learnt. It will be a year or two before no manufacturer will think of putting a car on the market that has such a thing as a starting handle. In the case of light cars, of course, the little engines are so easy to spin round that it may well be questioned whether it is in any case worth while going to the trouble of fitting an engine-starter. It adds to weight, and, no matter how perfected the apparatus may be, it necessarily involves complication. That, of course, is a thing always to be avoided, not only on grounds of cost, but because the more there is on a car the more are the chances of something going wrong multiplied.

The ideal car would be a vehicle with as few parts as possible, whereas the whole tendency of motor development up to the moment has been constantly to multiply the number of parts that go to build up a complete motor vehicle in the most modern sense. The motor engineer himself has displayed remarkable ingenuity in gradually simplifying each part of a chassis. But every time he succeeds in eliminating some part his ingenuity, or that of his colleagues, immediately devises some other luxurious fitting of a more or less complicated character, which promptly becomes semi-essential, or at least such a vogue that none will do without it, whereby anything from three to a dozen extra parts are added to the equipment for the one that has been eliminated from some other portion of it.

Nevertheless, there is not the call this year to sound a warning note to the medical man against using a car with a mechanical engine-starter, such as it was necessary to utter twelve months ago. In the interval a great deal has been learnt not only by the manufacturers of such specialities, but also by the firms that fit them as standard. It should be understood that half the troubles that arise in dealing with novelties come not necessarily from any fault of design, but from lack of knowledge of exactly the materials of which to manufacture every minor part of them, and, even more often, from lack of sufficient experience in the actual manner of fitting and applying them to the chassis.

LARGER DIAMETER BRAKES.

A welcome sign is that this year very considerable attention has been given to brakes, in which connexion mention must be made, for example, of the 12 to 16 h.p. Sunbeam car, which is marketed with hand brakes on the rear wheels of what we at present call extraordinarily wide diameter, though in a season or two we may be sure that this feature will become quite ordinary.

The value of having a brake of wide diameter is that you are able to "finish off" your braking very much better. Thus if the diameter of the brake is small, but the width of the brake surfaces is proportionately considerable, it is possible to reduce the speed of the car from very fast travel to comparatively slow travel with ease, but the final action of braking is weak, because the rubbing surfaces begin to travel past each other quite slowly as the vehicle's speed dies away. The object of having a wide diameter brake is that when the vehicle begins to travel slowly, nevertheless the friction surfaces are passing by each other at a very much faster speed than when the diameter is small. By this means the large diameter brake completes the action of bringing a car to a standstill very much more efficiently than a brake of small diameter.

These points have been arrived at in two different ways in two hemispheres. In the New World, where efficient braking is needed by reason of the very treacherous, ill-graded, and poor surfaces that have to be traversed, the Cadillac Company had the happy idea some years ago of sending some of its experts with three cars to the Rocky Mountains for several months, where they experimented with all sorts of brakes and learnt the principle that it was necessary to make them of much larger diameter and more ample surface than had been the practice previously. In Europe we have arrived at the same conclusion by quite another method of procedure. Many leading firms, such as Peugeot in France, Sunbeam in England, and the like, use racing as a means of developing the efficiency of their machines. In connexion with racing they learnt the necessity for having very much more efficient brakes than were used on touring cars. Efficiency was reached in the cases of such firms as have been instanced by making brakes of proportionately very large diameter.

THE PRINCIPLES EMPLOYED.

In the original notion the use of the wide break was merely to slow the car from a very high rate of travel to what is proportionately a slow rate, as, for example, when negotiating corners. But it was found that when these cars were not being raced this style of brake also enabled the machine to be brought to a standstill very much better. The designers thereupon began to realize that what had originally been considered a special feature suitable for racing only was really an essential need of private car equipment.

It should be understood that these large diameter brakes do not necessitate the use of appreciably more material or weight of metal than is employed on the medium-sized type of back-wheel brake hitherto used. The alteration is almost entirely in the designing. In some cases the total of the friction surface area is no larger than in that of brakes of small or medium diameter, the superiority of action being achieved merely by the greater rate of travel of the friction surface. If the latest Sunbeam brakes be compared with any of the hitherto ordinary sort, it will be found that there is a surprising difference in the way in which the braking can be "finished off" without imposing any extra strain on the tyres. Of course at need and in emergency the bigger diameter brake gives stronger control. But to use this carelessly is necessarily to wear out tyres at a greater rate. All that the average user, and especially the medical man with an eye to service with economy, needs is a brake the action of which will not become less and less efficient as the speed of the car dies down, but which can "finish off" the action of braking and bring the car to a standstill, because it can be made to absorb the momentum of the machine as well when it is travelling quite slowly as the medium diameter brake can while the car is travelling proportionately fast.

INCREASING USE OF CANTILEVER SPRINGS.

In the matter of suspension it is to be observed that the movement in favour of using the cantilever spring—otherwise a half-elliptic member, the mid-length of which is

attached not to the axle but to the frame of the car, and the rearmost extremity of which is attached to the axle of the machine—is coming into increased popularity. Thus the Napier firm, which this year is making only two classes of pleasure car—the 30 to 35 h.p. six-cylinder model, and the 16 to 22 h.p. four-cylinder model—uses the cantilever spring. The four-cylinder model, by the way, is made in some variety of types, in that the Colonial Napier for overseas service is a highly specialized product, strikingly distinct from the 16 to 22 h.p. machines for home use.

THE CHEMICAL CONSTITUTION OF CERTAIN PROPRIETARY DRUGS.

(*Continued from p. 1032.*)

THE contraction *B.P.* with date is used for the *British Pharmacopoeia*, and *B.P.C.* is used for the *British Pharmaceutical Codex*, 1911.

Euporphin.

A name applied to apomorphine bromomethylate. It is offered as a substitute for apomorphine hydrochloride, and is claimed to give more permanent solutions than the latter salt. The trade name Euporphin indicates the product of J. D. Riedel A.G., Berlin-Britz, Germany.

Euquinine.

Euquinine or euchinin is a name given to quinine ethylcarbonate, under which name the substance is described in the *B.P.C.* It is put forward as a complete substitute for ordinary quinine, free from taste and less apt to produce cinchonism and other disturbances. The trade name Euquinine indicates the product of Zimmer and Co., Frankfort-on-Main, Germany.

Euscopol.

A name given to optically inactive scopolamine hydrobromide. Scopolamine hydrobromide is given in the *B.P.* as a synonym of hyoscine hydrobromide, but nothing is said about its optical activity. According to the *B.P.C.*, it is a mixture of the hydrobromides of the laevo-rotatory and inactive stereo-isomeric varieties of the alkaloid. The trade name Euscopol indicates the product of J. D. Riedel A.G., Berlin-Britz, Germany.

Eustenin.

A name applied to theobromine-sodium sodio-iodide. It is put forward for the treatment of arterio-sclerosis, angina pectoris, and aortic aneurysm. The trade name Eustenin indicates the product of Zimmer and Co., Frankfort-on-Main, Germany.

Exalgin.

This is a name applied to methylacetanilide, under which name it is described in the *B.P.C.* The trade name Exalgin indicates the product of McKesson and Robbins, New York.

Ferratin.

This is a name applied to a synthetic ferric acid albuminate containing about 6 per cent. of iron. It is also known as ferralbumin. Ferratin is the chief constituent of ferratose, a liquor containing 3 per cent. of iron. Arsenferratose is an elixir of arsenated ferratin. The trade names Ferratin, Ferratose, and Arsenferratose indicate the products of C. F. Boehringer and Soehne, Mannheim, Germany.

Ferripyrine and Ferropyrine.

Described as ferric-chloride-antipyrine, a compound containing about 64 per cent. of antipyrin and 36 per cent. of ferric chloride. The trade name Ferripyrine indicates the product of Meister, Lucius, and Brüning, Hoechst a/Main, Germany.

Ferropyrine is stated to have the same composition as ferripyrine. The trade name Ferropyrine indicates the product of Knoll and Co., Ludwigshafen-on-Rhine.

Fibrolysin.

A name applied to thiosinamine sodio-salicylate. Thiosinamine is described in the *B.P.C.*, where it is stated that its use was advocated by Hebra as an injection for the removal of scar tissue; thiosinamine-sodium salicylate, a double salt, is more soluble in water than thiosinamine and is used in sterilized solutions for similar purposes. The trade name Fibrolysin indicates the product of E. Merck, Darmstadt.

Formidine.

This is a name applied to methylene-iodo-disalicylic acid an iodized derivative of salicylic acid and formaldehyde. The trade name Formidine indicates the product of Parke, Davis, and Co., Detroit, Mich.

Formitrol.

A name applied to pastilles yielding formaldehyde when dissolved. The trade name Formitrol indicates the product of A. Wander, Ltd., London.

Glutol.

This is defined as glutoform or formaldehyde gelatin, and is put forward to be used pure as a wound antiseptic; it is said to liberate formaldehyde on contact with the wound secretions. The trade name Glutol indicates the product of E. Schering, Berlin.

Glycosal.

This is a name for salicylic acid glycerin ester, also known as glycerin salicylate. It is put forward for use internally in place of sodium salicylate, and externally as a paint in articular rheumatism. The trade name Glycosal indicates the product of E. Merck, Darmstadt.

Gujasanol.

This is a name given to guaiacol-diethylglycocoll hydrochloride. It is put forward mainly for the treatment of tuberculosis. The trade name Gujasanol indicates the product of Meister, Lucius, and Brüning, Hoechst a/Main, Germany.

Gynoval.

Defined as the isoborneol ester of isovaleric acid, and offered as a substitute for the customary valerian preparations. The trade name Gynoval indicates the product of Farbenfabriken vorm Fried. Bayer, Elberfeld, Germany.

(*To be continued.*)

CAPTAIN THOMAS SCATCHARD, R.A.M.C., who was killed in action on September 8th, left estate valued at £1,190.

ACCORDING to the New York *Medical Record*, an examination of the male members of the freshman class of Indiana University, recently made by the physical director, Dr. F. P. Holland, revealed the fact that about 17 per cent. of the students were physically defective, the chief faults being flat chests and pes varus. Of the female students less than 11 per cent. were defective.

THE report of the Bureau of Health shows that during the first quarter of 1914 the health conditions of the Philippine Islands were very much better than at any time during the past ten years. The death-rate of Manila for March was 20.39 per 1,000, which is the lowest on record, and compared with the rate of 40.23 per 1,000 for March, 1904. Cholera gradually decreased, but 14 cases of plague and 10 deaths occurred. Sixty-seven rats, dead of plague, were found in one building in which human cases occurred. Owing to lack of funds, it is not possible to stamp out the disease among rats. Occasional cases of human plague are likely to appear. A severe outbreak of small-pox occurred in the province of Samar, where the vaccinations had probably not been efficient. In the climate of the Philippines vaccine remains potent only for about one week after it leaves the ice, and there are many regions in Samar in which it is impossible to deliver vaccine in a potent condition. The principal causes of death were tuberculosis (pulmonary), beri-beri, and acute bronchitis. Appended to the report is a series of interesting tables dealing with vital statistics, showing that Dr. Heiser, Director of Health, and his assistants devote much time and trouble in their endeavour to improve the public health of the Philippine Islands.

British Medical Journal.

SATURDAY, DECEMBER 19TH, 1914.

CLINICAL WORK WITH THE EXPEDITIONARY FORCE.

WE have been able to publish in this and our last issue papers dealing with some of the surgical and medical problems raised by this war, written by members of the consulting staff with the Expeditionary Force.

There are at present four consulting physicians with the Expeditionary Force; they have the rank of Colonel in the Army Medical Service, and attached to each is a junior officer, or more than one. In this way Dr. T. R. Elliott, F.R.S., Assistant Physician to University College Hospital, is associated with Sir John Rose Bradford, and to Dr. Elliott we were indebted last week for an extremely interesting and helpful description of transient paraplegia, due to the effect of the enormous German shells with their massive charges of high explosives. The cases, in which the precise nature and severity of the lesions vary, have given rise to difficulties in diagnosis and prognosis, and on both these heads Dr. Elliott affords information which, we have no doubt, will be helpful to the staffs of military hospitals at home. The paralysis he describes at once follows the bursting of a large shell in the near vicinity of the patient. It involves immediate numbness and complete paralysis of the legs, while the arms are generally unaffected and the sphincters are not impaired in their activity. The reflexes, both superficial and deep, are lessened, and perhaps unequal on the two sides—a point of great importance in distinguishing these cases from those of hysterical paraplegia, where the reflexes are exaggerated and there is a tendency to the occurrence of clonic or coarse tremors. In the cases described by Dr. Elliott great improvement takes place in a week or a fortnight, and the patient is able to walk about again, but a great deal of pain is felt in the loin and back, and there is generally a girdle of hyperalgesia round the body above or below the level of the umbilicus. In the severer instances it seems probable that the muscles and ligaments of the back and vertebral column are directly injured or overstretched, with the result that the spinal cord itself receives transitory damage and the roots of the spinal nerves are injured as they issue from the vertebral foramina. In some instances it may be impossible to say whether it is the nerve roots that are injured or the cord itself, but the distinction is one of no great practical importance. If there is organic damage the reflexes and the tone of the muscles are lowered, and the patient complains of pain and tenderness in the injured region of the back, and in the area supplied by the nerves arising therefrom, rather than of pain and tenderness all over the back. These points should suffice to prevent the wrongful diagnosis of hysteria or neurasthenia from being made. As Mr. Herbert Page pointed out in his letter (p. 1046), the war appears to furnish ample opportunity and material for clearing up the pathology and diagnosis of the obscure and hitherto largely medico-legal disease known as "concussion of the spine."

This week Sir Anthony Bowlby, who was one of the first of the five consulting surgeons appointed to serve with the Expeditionary Force in France, gives a very graphic description of the work of the clearing hospitals, in future to be called "casualty clearing stations," for they are not in the ordinary sense of the word hospitals, although when convenient they may be established in buildings. Sir Anthony says that he finds it impossible really to describe the scene when the fighting was at its height, but we are inclined to think that the description he gives will survive as a sketch not unworthy to be set beside Zola's famous picture in *La Débâcle* of the similar hospital at Sedan. He gives also some interesting provisional conclusions to which he has come with regard to the treatment of wounds of the thorax and abdomen, and as to spreading gas gangrene. Incidentally he makes an observation which is perhaps not in accord with the opinion prevalent among the staffs of the military hospitals in this country when he says that the present German pointed bullet inflicts much more injury to the soft tissues than the old blunt Mauser bullet of the South African war.

In recent issues we have been able also to publish a series of notes written on the spot by a correspondent who enjoys special facilities for observation. Many of these notes deal with administrative matters, but they have also raised several interesting clinical questions which are proving worthy of further investigation and discussion.

THE NEW SYSTEM OF MEDICAL CERTIFICATION.

ALL panel practitioners and officials of Insurance Committees and approved societies ought by now to have received a copy of the Memorandum (211/I.C.) issued by the Insurance Commissioners dealing with the new system of medical certification for insured persons which is to come into operation on January 1st, 1915, throughout England, Scotland, and Wales. As intimated in the JOURNAL in a brief note last week, the system is in great part an attempt to meet grievances which have been put forward on behalf of the profession, and to replace the present multiplicity of forms of certificates by a uniform system. It is clear, too, that in framing the system the Commissioners have been guided very largely by the report of the Departmental Committee on Sickness Claims, some of the recommendations of that Committee being adopted almost in their entirety. As the Memorandum, with the rules for certification, will be in the hands of all practitioners, it is unnecessary to enter into any detailed description of the system, but some comments on its chief features may not be out of place, especially in the light of the further Circular (A.S. 156) on the "supervision of claims for sickness and disablement benefit," which has been issued to approved societies during the last week.

The outstanding feature of the new system is that in future all certificates for sickness or disablement benefit are required to be given on the forms that will be supplied to each practitioner by the Insurance Committee of his area, the approved societies being compelled to adopt these forms to the exclusion of all their present forms. This uniform system is to be embodied in the agreements of panel doctors with the Insurance Committees for the coming year, and in a note to Circular (A.S. 156) the Commissioners further

state that "insured persons who have made their own arrangements for medical benefit under Section 15 (3) of the Act of 1911 and those receiving treatment through an approved institution under Section 15 (4) of the Act, will also be furnished by their doctors with certificates in the standard forms." At the same time the societies are clearly told by the Commissioners that the panel doctors "cannot be required, and societies should not attempt in any case to induce them, to do any of the following things: (1) To furnish certificates in any other form or on any other occasions than those required by the Medical Certification Rules; (2) to furnish certificates on any particular day of the week; (3) to ante-date or post-date certificates, that is, to append to their signature on the certificate any date other than that on which they sign it."

That the introduction of some uniform certificate had become necessary and was greatly desired by the profession can hardly be doubted, but it is necessary to point out that the special forms now imposed will entail far more clerical work on the doctors. Up to the present the continuation certificates of the majority of the societies with the largest number of members have simply required the doctor's initials and the date, but in future every weekly certificate will have to be fully entered up with the patient's name, full diagnosis, full signature, date of signing, and at times with "other remarks by the doctor," such as his instructions to the patient to remain in bed and so on, these "other remarks" being optional and for the guidance of the society's sick visitors. The object of all this weekly repetition is, of course, to ensure more careful consideration on each occasion, but while it entails extra work in every case and on each occasion, and will tend to make the careful practitioner still more careful, it is doubtful whether, if there be any tendency to carelessness, it can be prevented in this way. There will, too, be the risk that in some cases the societies may receive a different diagnosis in succeeding weeks, because the patient has developed new symptoms which may be of the nature of sequelae of the initial attack. Thus a case might be certified successively as influenza, bronchitis, bronchial catarrh, or dyspepsia, etc., according to the most prominent symptoms at the time when the certificate was given. Something of this sort is evidently anticipated by the Commissioners (Memorandum, Section 51), and we can imagine that societies that have hitherto drawn up statistics of the different diseases that have led to claims on the sickness fund will find themselves in considerable difficulties on this account.

Attention is drawn to the fact that in a case of incapacity for work, the first and intermediate certificates need only be given when the patient asks for them, but the final certificate must be given when the doctor considers the patient fit for work, whether a request is made for it or not. This is clearly imperative. During incapacity the certificates will generally be required every week, but if the doctor considers that the patient may be able to resume work before the end of the week then running, he may name on the certificate a particular day on which the patient must call on him without waiting for the end of the week, in order to receive his declaring-off note. On the face of it, this is an excellent provision to prevent the very prevalent custom of "having the week out" which has led to a considerable drain on the societies' funds, and if strictly carried out by the doctors, as it certainly ought to be, it will prevent the still worse trick, which some patients have resorted to, of not going to see the doctor for ten days or a fortnight and then coolly going and saying that they think they are now ready to declare off.

As a rule all certificates must be dated and signed on the day when the patient is seen. This rule may, however, be modified in certain events—for example, in rural areas which have been specially approved for this purpose by the Commissioners. When a declaring-off certificate is being contemplated for a patient who resides more than two miles from the doctor's residence in one of these approved areas, a special (blue) certificate may be used, which states in effect that though the patient was examined on the date named on the certificate, the practitioner was of opinion that the patient would not be able to resume work until a future date, which must not be more than three days after the date of examination. This will often prevent the need of an extra visit for the mere purpose of giving the final certificate, and so far it is good; but there can hardly be any doubt that this arrangement will often be desired by the rural patients simply to enable them to "have the week out," and practitioners will incur just as much odium if they refuse this as they now incur when they insist on signing-off a patient in the middle of the week, and it is doubtful whether the remedy by its mere suggestiveness may not aggravate the complaint in the rural areas. The safeguard of the doctor is, however, the strict rules laid down for him, under which, as he can easily show his patient, he has no option in the matter.

The suggestions to societies that weekly certificates should not be required for certain chronic cases, and the arrangements about certificates for patients who are allowed to go away for a short holiday to recuperate after a severe illness, and for patients who are receiving hospital treatment, were much needed, and appear to meet the requirements fairly well. The fact that when a patient during incapacity is receiving his full wages from his employer and is thus not claiming sickness benefit, certificates are nevertheless still required for other purposes under the Act, such as calculating arrears, has certainly not been appreciated in the past by a large number of the insured or by many panel doctors. Though the doctor can only be compelled to furnish such certificates when specially requested by the patient, we have little doubt that as an act of grace and in the interests of their patients, most practitioners will be ready to remind their patients that if certificates are not sent in, certain penalties may be incurred even though sickness benefit is not being claimed.

An important part of the new system is intended to meet those classes of cases in which practitioners up to the present have undoubtedly refused to state the real nature of the disease on a certificate which is handed to the patient personally and has to pass through the hands of officials of societies—cases, for example, such as certain forms of heart disease, cancer, and incipient insanity, where it would be prejudicial to the patient to know the exact character of his disease, or certain diseases of women and cases of congenital syphilis, where unjustifiable distress or injury would be caused by giving the information to other parties. In all such cases the Commissioners are satisfied that the rule that the cause of incapacity must be stated precisely on the certificate cannot be enforced. In these circumstances the doctor on the certificate handed to the patient may describe the disease in less precise terms than his knowledge would enable him to use, but undertakes to send to the society on the same day a notice, on a form

supplied, informing the society that he has given such a certificate, and also to send to the Government referee, or, if there be none, to the Commissioners, on a form supplied, a precise statement of the true nature of the disease, and his reasons for not stating it on his certificate. In this way no one except the Commissioners need know the real nature of the disease, and the Commissioners will only communicate to the society such information as they think right. To this procedure the objection will certainly be made that while, in a certificate handed to a patient personally, there can be no breach of professional confidence, seeing that the patient is at liberty to use or not use the certificate as he thinks fit, apart from possible legal objections that might arise, it would be a breach of professional confidence to communicate the true nature of the disease even to the Commissioners, without the express consent of the patient. In certain cases, of which gynaecological cases may be quoted as examples, the point could no doubt be discussed with the patient, but in others obviously this course could not be followed without rousing the patient's suspicions and defeating the whole object of the concealment. This being so, in actual practice every practitioner must use his own discretion as to how he carries out the provision in question. In all such cases the lesser of two evils that would arise would be the cloud of suspicion cast round the patient in the minds of the officials of the society, who, not being fully told the nature of the disease, would often imagine the worst. The position will undoubtedly be difficult if either the society or the Commissioners are not satisfied with the certificate of the doctor that the patient is incapable of work through no fault of his own, but the Commissioners having made an attempt to meet an undoubted difficulty, and there being no other solution suggested, it seems incumbent on the profession to give this experiment a fair trial.

There is one other point that must be mentioned, namely, the almost undue insistence which the Commissioners lay, not only in the Memorandum but in the circular to societies, on the fact, which we do not dispute for a moment, that a medical certificate is only one part of the proof that an insured person is entitled to sickness benefit through incapacity for work. No one can deny the value of the work of the sick visitors if properly done, and the Commissioners distinctly warn societies against allowing their sick visitors to interfere in any way with the functions of the doctors. If this warning be heeded no difficulty need arise, seeing that with a proper understanding between the doctors and the societies the sick visitors may be of the greatest assistance in detecting malingerers. But, presupposing, of course, that a patient has fulfilled his legal obligations as regards contributions, arrears, and such matters, it will be a matter for the greatest regret if the societies show the least inclination to belittle the paramount importance of the medical certificate in deciding on an insured person's fitness to receive sickness or disablement benefit. The risk to which we have referred will be avoided if all members of the profession are equally scrupulous in observing to the letter the requirements which must be fulfilled if the new system is to work efficiently. It seems to be a distinct move in the right direction, and this, we believe, will be the view of the large majority of members of the medical profession who are engaged in working the Act.

Numerous other points in the Memorandum will probably present themselves when the system has been in operation for a time, but in spite of the difficulties that are so obvious at present, on the whole it must be acknowledged that it shows a clear desire on the part of the Commissioners to deal with difficult matters in a way that shall be fair to all concerned—patients, societies, and doctors alike.

ANTITYPHOID INOCULATION.

CIVILIAN members of the medical profession throughout the country have already given proof of a desire to aid their brethren serving in the military forces of the Crown in the performance of the duties devolving upon them during the present crisis, and we venture to think that they may usefully second the efforts of officers in the Royal Army Medical Corps to combat the attacks on the employment of prophylactic inoculation against typhoid which we have reason to know are being vigorously carried on.

Medical men who have not had personal experience of the controversial methods employed in connexion with such subjects are in danger of both underrating and overrating the calibre of their opponents. On the one hand, the perusal of idle vapourings imputing the lowest personal motives to members of the medical profession, or of assertions affording evidence of the grossest ignorance of facts within the knowledge of all third-year medical students on the part of their authors, generates a feeling of contemptuous confidence, and may lead the professional man to forget that his opponents are often sufficiently expert in the detection of real or apparent inconsistencies in and omissions from statistical evidence. On the other hand, there is a danger of forgetting that evidence, the value of which would be instantly grasped by a scientifically trained intellect, may seem, even to an intelligent and candid layman, either very mysterious or irrelevant.

To apply these principles to the case before us, we would remark that what the average recruit requires is evidence that inoculated men placed under the same conditions as uninoculated men do in fact suffer less from enteric fever, and, further, evidence that the process of inoculation does not itself entail dangers commensurate with those it prevents. It is very important to provide him with data which are substantially and formally complete, and to be prepared to meet the objections with which he may have been furnished by interested or fanatical opponents. To illustrate this point, we think that a comparison between the incidence of typhoid upon inoculated troops in one year and that upon inoculated troops at a much earlier period is both unsatisfactory and unnecessary. It is unsatisfactory, because the medical man using the argument is not in the least likely to be able to meet the stock objection that improved "sanitation" is responsible for the result he desires to attribute to inoculation; it is unnecessary, because reliable evidence not subject to the stock criticism is available. Such evidence is provided in the report of the War Office Antityphoid Committee. We noticed the findings of this Committee in our issue of October 3rd (p. 597), but it will be convenient, for the reason mentioned, to deal more explicitly with the statistical data contained in it.

To begin with, can we take the responsibility of informing the recruit that the conditions of the inoculated and uninoculated men in these returns were strictly comparable? The following statement can be made. The test units were drawn from all arms of the service; neither commissioned officers, women nor children were included in the returns, while the technique of inoculation and of confirming the

diagnosis of enteric was carefully standardized and as nearly as possible uniform.

Two objections, and two only, are likely to be made to the general conditions of the experiment. The first is that non-commissioned officers were not excluded from the returns, and that they are likely to be older than privates and more ready to submit to inoculation. We have no evidence that the latter assertion is correct, and, with regard to the former, it is certain that in a short service army such as ours the postulated difference in mean age is too small to introduce any sensible error in the statistics.

The second criticism is that the inoculated men were not taken at random but volunteered, and that their relative immunity from disease was not due to the inoculation but to their being more careful in their habits of life, willingness to submit to inoculation being a proof of greater natural forethought. The reply to this objection, which seems formidable on paper, is that the etiology of typhoid fever is such that no precautions an individual soldier living under the service conditions of the test units could adopt would sensibly diminish his risk of infection. Food contaminated by a "carrier" prior to distribution creates a danger only to be countered by the soldier who sterilizes every mouthful of his rations before consumption, and we make bold to say that no such soldier ever has existed, or ever will exist. The use of water from forbidden supplies would only raise a serious difficulty in active campaigning—a factor which did not complicate the Committee's returns. It may be said that typhoid stands at almost the opposite end of the series headed by venereal disease. In the former, personal prophylaxis (apart, of course, from inoculation) can be of small avail to the soldier; in the latter he can, if he chooses, almost entirely avoid the possibility of infection. We have no doubt that the cogency of these arguments can be made clear to the average recruit and the objection completely refuted.

These preliminary difficulties having been removed, we may pass to the actual statistics. They show that among 10,378 inoculated men 56 cases of typhoid occurred, or 5.4 per 1,000, and among 8,936 uninoculated, 272 cases, or 30.4 per 1,000. The numbers are considerable, and the difference so marked that no one needs to be told that the probability of the difference being due to "chance" is infinitesimal. What special objections can be raised to invalidate the obvious inference? The first is, that the proportion of inoculated men notably increased after arrival at the foreign station, so that some of the 10,378 inoculated men were possibly uninoculated during part of their period of exposure to risk. To meet this objection, let us assume that the cases of typhoid should be allotted entirely to the men actually inoculated or uninoculated at the time of arrival in the first foreign station. That is to say, we assume that the 56 cases of typhoid in inoculated men should be placed to the credit of the 6,815 who were inoculated at the time of arrival and the 272 among uninoculated to the 11,668 who were uninoculated at the same period; this arrangement yields rates per *mille* of 8.2 and 23.3 respectively. Even so the difference is substantial, but in making this arrangement we have enormously over-estimated the probable force of the objection, since in many of the units the great rise in the number of inoculated men actually took place shortly after arrival at the foreign station, so that those stated to be inoculated at the time of the last report were really in that condition during practically the whole period of exposure.

The next criticism is that several of the units never returned any cases of typhoid fever, and that, if these regiments consisted mainly of inoculated men, the case in favour of inoculation is bolstered up by numbers of persons never really exposed to risk. It will be noted that the latter supposition involves a *petitio principii*, since it might be retorted that freedom from disease was due not to absence of risk but to presence of acquired immunity. We can, however, allow for it by confining our comparison to those units in which at least ten cases of typhoid occurred. If we do so, we find that 46 cases were found among 3,387 inoculated men and 227 among 2,656 uninoculated men, rates of 13.6 and 85.5 respectively.

The final criticism is that the exclusion of cases of paratyphoid fever was unjustifiable and was practised with the object of showing a lessened rate of typhoid fever among the inoculated as compared with the uninoculated. We must apologize to scientific readers for the necessity of refuting this argument, but it is gravely adduced in a pamphlet entitled *The "Cooked" Statistics Concerning Antityphoid Inoculation Used During the Recruiting for the Great War, 1914*, emanating from the British Union for the Abolition of Vivisection. Numerous clear accounts of the essential differences between organisms of the paratyphoid group and the *Bacillus typhosus* are available, one of the most convenient being that contained in Kolle and Hetsch's *Lehrbuch*.[1] We think that most laymen would have no difficulty in following an argument arranged on the following lines. In the first place, the clinical diagnosis of typhoid has always been subject to error; even a member of the British Union for the Abolition of Vivisection could hardly contend that the distinction between pneumonia and typhoid is "a pure statistical trick," for so expert a physician as Sir William Osler has told how he has "brought such a case before the class one week as typical pneumonia and a fortnight later shown the same case as undoubtedly one of typhoid fever."[2] It should be pointed out that the diagnosis of typhoid fever is usually rendered precise by the agglutination test and that in performing this test in cases clinically similar to typhoid the discovery was made that another group of diseases occurred, due to organisms culturally different from the typhoid bacillus and frequently responsible for clinically dissimilar conditions. The fact may be emphasized that these discoveries were due to workers neither interested in nor concerned with the employment of antityphoid vaccines. The work of Achard and Bensaude in 1896 and of Schottmüller in 1900 and 1901—that is, before antityphoid inoculation on a large scale had become a practicable measure—should be mentioned. In this way it ought to be easy to demonstrate that the assertion of the British Union for the Abolition of Vivisection is a mere example of either crass ignorance or wilful falsification, alternatives which indeed cover the majority of such statements with respect to scientific problems.

We think we have exhausted the criticisms to which the data provided by the Antityphoid Committee are subject, and we are strongly of opinion that members of the profession engaged in educational work would be well advised to confine their statistical arguments to this field. We do not deny that the experience of other countries and observers affords strong *prima facie* confirmation of these results, but

[1] Kolle and Hetsch, *Die experimentelle Bakteriologie und die Infektionskrankheiten*, vol. i, pp. 281–296.
[2] Osler's *Principles and Practice of Medicine*, eighth edition, p. 37.

we feel at the same time that it might be difficult, without much more familiarity with details than can readily be obtained, to rebut arguments of the type noticed above. It is a capital error to overstate a fundamentally strong case.

We now turn to the alleged danger of the inoculation in itself. Major Russell, of the United States Army Medical Service, reported, in 1912, the results of twenty thousand inoculations—that is, the experience of 6,690 men each vaccinated three times.[3] Out of this number only 223 men were even excused from duty—a rate of about 1 in 90. The degree of reaction varies, and it is only prudent to observe the precautions recommended by the Antityphoid Committee. The first is that the inoculation should be made in the afternoon, so that the man has the benefit of rest in bed; the second is that undue muscular fatigue should be avoided on the following day, even though the man himself feels perfectly well; and the third is to avoid alcohol in any form for at least twenty-four hours following inoculation. When these simple precautions are observed, the Committee states that "in nine cases out of ten the symptoms, both general and local, are trivial, and in twenty-four to forty-eight hours the inoculated man is quite himself again except perhaps for a slight tenderness at the site of inoculation, which may last for a day or two longer." Arrangements should always be made for the men to be excused by the commanding officer from drill and heavy fatigues for one or two days after inoculation.

If a man is told that inoculation will diminish his chance of contracting typhoid to something between a fifth and a third of that appertaining to his non-inoculated comrades, while the price he has to pay is measured by a probability of at most about one in ten of being moderately indisposed, the dreadful tales of strong men cut off in their prime by the machinations of the vaccinists—a phantom army blessed with the reproductive powers of Falstaff's men in buckram—are likely to be received with the contempt they deserve. We have incidentally referred to the utterances of the British Union for the Abolition of Vivisection, and we think it is only just to express our gratitude to that society for stating that medical men who advocate the use of antityphoid inoculations do so on pecuniary grounds. Thus, they remark that the performance of a process, facetiously termed by them "statistical examination," "would not suit Sir Almroth Wright, and, if pursued, might reduce to infinitesimal proportions the sale of his precious quackery, of which he has had the good fortune to supply 1½ million of doses recently for the soldiers of the British army." When the recruit learns that the most ardent supporters of inoculation are the officers of the Royal Army Medical Corps, that its practice throws upon them considerable work and responsibility, and that they derive therefrom no more pecuniary advantage than he does himself, he will know what to think of the British Union for the Abolition of Vivisection.

We have no doubt that if the facts above set forth are brought to the notice of men serving or about to serve with the colours, the consequence will be to popularize still further the practice of antityphoid inoculation, and to inflict another crushing defeat upon the ignorant and malicious obscurantists represented by the British Union for the Abolition of Vivisection.

DR. E. F. BASHFORD has, on account of the state of his health, resigned his position as General Superintendent of the Imperial Cancer Research Fund.

EPSOM COLLEGE.

IN the BRITISH MEDICAL JOURNAL last week Sir Henry Morris, the Honorary Treasurer of Epsom College, made an appeal on behalf of the Royal Medical Foundation, which, like all other institutions of the kind, is feeling the financial pressure caused by the war. The benefits of the Epsom Foundation are, or should be, well known to every member of the profession. The school provides gratuitously an education of the highest class, with maintenance, clothing, and pocket money, for fifty sons of medical men with whom the battle of life has, for one reason or another, gone ill. It does for them what the oldest and most famous of our English public schools were intended to do for a larger class. In some of these the stream of charity has been diverted into channels certainly not foreseen by the pious founder. Although Epsom as a school has far outgrown the dreams of those to whom it owes its existence, the benefits of its endowments are strictly applied to the purpose for which they were intended. In addition to the foundationers, the school has accommodation for 250 boys. The excellent quality of the education given at Epsom is shown by the fact, mentioned by Sir Henry Morris, that this year 10 boys out of 13 passed the whole of the First Examination for medical degrees at the London University, while 18 out of 23 passed the Matriculation Examination, 6 of them in the first class. But it is important that it should be understood that, though science has a prominent place in its teaching, the classical and other intellectual training given at Epsom is of the same kind as that of the older public schools. It fits a boy for any sphere in life, and it fosters in him the spirit of citizenship, as is proved by the fact mentioned in the JOURNAL not long ago, that more than 200 old Epsomians are serving their country with the forces in the present war. Although Epsom cannot claim the venerable traditions that cluster around Eton and Winchester, it has already sent forth not a few who have written their names in the roll of honour of our "rough island story." Another part of the work of the Royal Medical Foundation is the payment of pensions to members of the medical profession in need of such help or to their widows. The Foundation has, therefore, a special claim not only on the benevolence of the profession, but of the public which benefits so largely by the ill-paid work of doctors. At this time, particularly when so many young practitioners have thrown up their prospects in civil life to help the sick and wounded, it is to be hoped that Sir Henry Morris's appeal will receive the widest and most generous response.

GERMAN DRUG DIFFICULTIES.

THOUGH Germany is the home of the synthetic drug, her supply of natural drugs is largely dependent on foreign produce. She is, therefore, faced with serious difficulties in this respect if the war is protracted. These difficulties are discussed in the *Muenchener medizinische Wochenschrift* for September 29th, by W. Straub, who states that the importation of drugs through neutral countries cannot be relied on, as they have already prohibited the export of the most important drugs. It is practically certain that the German army is supplied with drugs for a long time to come; and the Belgian supplies constitute a further source on which the German writer dwells complacently. The wants of the public are less likely to be met satisfactorily if the war continues for more than a year. As Germany's synthetic drugs are no longer exported, their supply should be more than sufficient, and in many cases they can be used in place of imported natural drugs. There is no lack of raw material, such as benzene, nitric acid, and chlorine, from which so many of the synthetic drugs are prepared. The writer gives a list of drugs which may be expected to fail in the near future. Aloes, he points out, comes from South Africa, and is so highly valued by the pill-consuming (*sic*) English that this aperient is sure to be kept back. As a substitute

or aloes, alder buckthorn bark (frangula) is suggested, as well as the synthetic drugs istizin and phenolphthalein. Balsam of Peru, being most useful in war as a dressing, should be reserved for this purpose and should not be prescribed in scabies, for which styrax should be used. There are also many synthetic balsams, such as peruscabin and pernol, which may be used as substitutes, though their value is doubtful. As for quinine, though the principal clearing-house of cinchona bark is Amsterdam, most of the quinine factories are in Germany, so a sufficient store of quinine and its derivatives should be available. Cocaine, too, is principally imported through Amsterdam. A shortage of this drug would not be serious, as there are sufficient quantities of eucaine, novocain, and alypin, not to mention the insoluble anaesthetic powders, anaesthesin and ortheform. Caffeine can be prepared synthetically from uric acid, and the supply should therefore be unlimited. The same remark applies to theobromin, diuretin, and theocin. Large stocks of simaruba bark have been accumulated, and the host of antigonorrhoeal drugs is so great that cubebs, which is obtained from the Dutch colonies, can be dispensed with. For kousso, which comes from Abyssinia, male fern, it is said, may be used, while the same substitutes may be given for senna as for aloes. Hydrastis root can be replaced by the synthetic hydrastinin. Though iodine is largely imported, its extensive industrial use should assure a supply more than sufficient for medicinal purposes, and the same consideration is said to apply to castor oil, which comes from India and Italy, though the purity of this drug, as supplied for industrial purposes, is questionable. Another valuable aperient, with the loss of which the Fatherland is threatened, is rhubarb root, which comes from China. The supply of morphine hydrochloride, and of all the other derivatives of opium, threatens to run short, for in every neutral country the export of this group of drugs is prohibited. Though developments in the Balkans may release large quantities of opium stored in Asia Minor, Germany cannot definitely count on this source, and should, therefore, limit the use of morphine to the relief of pain. In this respect morphine and codeine are indispensable, but as hypnotics they can be replaced by the synthetic drugs, veronal, etc. Physostigmine, though it comes from Africa, should not run short, as its uses are much limited and only high dilutions are required. The same considerations hold good for pilocarpine. The suspension of the import of ipecacuanha from Brazil may become serious if dysentery breaks out in Germany. In bacterial dysentery bolus alba, Straub suggests, might be given as a substitute internally, its action being supplemented by 0.5 per cent. enemata of sodium salicylate; bolus alba is the term used in the German Pharmacopoeia for kaolin. In amoebic dysentery, quinine enemata might, it is suggested, be given. As the santonin used in Germany is said to be made from flowers grown in Southern Russia, it may in the future be necessary to resort to chenopodium anthelminthicum (American wormseed) in the treatment of ascarides. Of ergot, which is imported chiefly from Spain and Russia, it is said that its action is uncertain, as is also that of the new synthetic drug, nteramin, which is said to be equivalent to certain elements of ergot. Unfortunately, the action of uterine drugs prepared from the pituitary body is not identical with that of ergot. Strophanthus, though an imported drug, should not run short for a long time, as the factories in which it is refined are chiefly German, and large stocks are in hand. Still, should this drug be used up, a satisfactory substitute could be found in the lately introduced drug, cymarin.

A HISTORICAL MILITARY MEDICAL EXHIBITION.

THERE is, perhaps, no branch of medicine which shows more clearly the advance of science than the care of the wounded in time of war, and the contrast between modern field surgery and nursing and the rough and ready methods in vogue less than a century ago is demonstrated in a very striking manner in the special exhibit of objects connected with naval and military surgery now on view at the Wellcome Historical Medical Museum in Wigmore Street. This interesting section, which was opened on December 14th, includes every variety of object connected with the medical equipment of an army in the field; and many of the exhibits should appeal almost as strongly to the student of history as to the student of medicine. A case in point is a couple of modest boxes which formed the travelling pharmacopoeias of Lord Nelson and the Duke of Wellington, and a bulky medicine chest belonging to an Italian army surgeon of the seventeenth century, a few of whose vast array of bottles still hold the remnants of once-powerful drugs. Close by is a large collection of amputation saws and knives, which illustrate the gradual change in the shape of these instruments, whilst in another case may be seen the evolution of the tourniquet, and a third contains a number of antique bandage winders, one of which, beautifully carved in ivory, was evidently intended to be carried at the nurse's waist. A set of field dressings, such as were used during the Crimean and Boer wars, are exhibited side by side with a telephone probe for locating bullets, whilst another section shows a number of formidable looking instruments once employed in extracting them. Near at hand are cases of surgical instruments used on the fields of Vittoria, Waterloo, and other battles of the Peninsula. Another interesting section is composed of models of improvised stretchers used by the Japanese army during the Russo-Japanese campaign. These afford good proof of the extraordinary ingenuity and fertility of invention in the face of difficulties on the part of our allies. A quantity of autograph letters of Miss Nightingale, Baron Larrey, and others, are also on view, the most remarkable being one written by George Washington to his dentist, in which the champion of American independence arranges for the payment for a set of false teeth, a cast of which is displayed near by. A large collection of portraits and pictures is included in the exhibition, which should prove a popular feature of the museum for some time to come.

THE ROYAL EARLSWOOD INSTITUTION FOR MENTAL DEFECTIVES.

THE "Report 1914" of the institution at Earlswood recently issued was presented at the annual general court, held on April 30th, 1914. It gives an account of the proceedings of the "past year," and contains the report of the medical superintendent (dated March, 1914) with the statistical tables for the year 1913. The board of management, after referring with gratitude to a much needed generous bequest, expresses anxiety as to the future of the charity under the operation of the Mental Deficiency Act. Reference is made to certain alterations in the certification of patients as "irksome and objectionable to the friends of cases" as compared with the simpler method in use under the Idiots Act, now repealed. In consequence of the fact that under the new Act the mental defectives of the poorer classes will be provided for by the local authorities, the board looks forward to Earlswood ministering in future more especially to the needs of the middle classes who are relatively poor and unable to pay the charges for private treatment. It is pointed out that, subject to a modified election, admission may be obtained at a minimum contribution on the part of friends of 15 guineas a year. Consequent on altered conditions under the new Act, it was proposed to alter the name of the society to the "Royal Earlswood Institution for Mental Defectives," and it was announced at the general court that His Majesty the King had sanctioned this alteration in title. The report of the medical superintendent (Dr. Charles Caldecott) for the year 1913 states that 49 patients (39 male and 10 female) had been admitted. 35 cases

(26 male and 9 female) had been discharged, and 20 cases (14 male and 6 female) had died, leaving in the asylum on December 31st, 1913, 490 patients (338 male and 152 female), as compared with 496 on January 1st, 1913. The average number resident during the year was 489, and the percentage death-rate calculated on this was 4.09. Of the deaths 8 were due to measles (108 cases), a serious epidemic of which occurred in the early part of the year; 4 deaths only are attributed to tuberculous disease. We note that three patients died aged 60 years and upwards, and that in the table of patients resident no fewer than 20 are recorded as having attained 65 years and upwards. This should be borne in mind in comparing the death-rate of Earlswood with that of similar institutions where the average age of the inmates is lower. In conclusion the medical superintendent emphasizes the appeal of the board for the continued charitable support of the benevolent public by stating that under the operation of the Mental-Deficiency Act the voluntary charitable institutions "will not receive the slightest financial support from the State or the rates," and that "the necessity for their existence will, in all probability, be greater than ever, and consequently there will really be a demand for increased, rather than diminished, charitable support in the future." It is now nearly seventy years since the benevolent work carried on at Earlswood was inaugurated on a charitable basis by the efforts of the Rev. Dr. Andrew Read, and its success, both from a social and scientific standpoint, are well set forth in an appreciative communication recently received by the Board from Sir James Crichton-Browne, in the course of which he wrote: "Earlswood remains to-day, as it has always been, in all senses, the premier institution in this country for the care and education of the weak-minded. It first awakened interest in the work, and drew to it sympathetic support; and it has pursued the work with ever-growing success to this hour. . . . Making no exaggerated pretensions, it has done a signal public service; has carried consolation into many afflicted homes, and made multitudes of useless beings—mere cumberers of the ground—capable in some degree of contributing to their own support. Earlswood is eminently deserving of generous aid. It is, I know, under wise scientific guidance, and should lead the way in that campaign against mental defect which is now being vigorously undertaken."

CEREBRO-SPINAL FLUID.

DR. LOUIS H. WEED has published an essay[1] on the cerebro-spinal fluid, the first section of which deals with the theories of drainage of cerebro-spinal fluid and contains an analysis of the methods of investigation. After giving a complete and interesting account of previous researches, he details his own experiments and concludes that the observations of previous investigators have in fairly definite fashion established the fact that cerebro-spinal fluid escapes chiefly by way of the venous system, and to a lesser extent along lymphatic pathways. There is as yet no agreement as to the exact pathway of escape. The injection methods of past investigators have been such that any deductions made from them are open to adverse criticism. Dr. Weed has introduced a new method by the intravital injection of the cerebro-spinal spaces with true solutions and the subsequent precipitation of the chemical body *in situ* which enables him satisfactorily to study the manner of escape of the cerebro-spinal fluid from the subarachnoid spaces. The solutions he used were of potassium ferrocyanide and iron ammonia citrate. The second section deals with the pathways of escape from the subarachnoid spaces, with particular reference to the arachnoid villi. After discussing fully observations previously recorded, he concludes that the chief method of return of cerebro-spinal fluid to the general circulation is by a process of filtration through arachnoid villi into the great venous sinuses. He admits the possibility of an accessory but relatively unimportant drainage of the fluid into the lymphatic system. He found no evidence of the escape of cerebro-spinal fluid into cerebral veins or capillaries. But in the next section he gives definite support, by his observations of an intramedullary canalicular system, to the view which Mott advanced; moreover, he agrees with him when he asserts that the cerebro-spinal fluid "undoubtedly possesses an active function in maintaining the metabolic exchange and elimination of the nerve cells." He observes that nervous tissue lacks entirely a lymphatic system; it would appear that its place is taken by the perineuronal, pericapillary, and perivascular systems with the contained fluid, and that this fluid is poured into the subarachnoid space, where it mixes with the fluid of the choroid plexus. He concludes that the cerebro-spinal fluid is derived from two sources—the choroid plexus in the cerebral ventricles and the perivascular system of the nervous tissues. He has been able, by injection of the ferrocyanide solution into the subarachnoid space and subsequent precipitation, to show the particles of Prussian blue in the ganglion cells and in the perineuronal, pericapillary, and perivascular spaces. This valuable monograph is illustrated by five excellent plates.

[1] *Studies on Cerebro-spinal Fluid.* By Louis H. Weed. (From the Laboratory of Surgical Research, Harvard Medical School.) The *Journal of Medical Research*, vol. xxxi, No. 1. (New series, vol. xxvi, No. 1.) September, 1914. (Pp. 21-117.)

TUBERCULOUS GLANDS IN THE NECK.

AFTER considerable experience of the various conservative methods of treating tuberculous glands of the neck, the surgical clinic at Utrecht has arrived at a plan of which an account is given by H. Verploegh and C. L. W. Reis.[1] Naturally the treatment varies somewhat according to the number of glands involved, the stage to which the disease has advanced and the degree of extraglandular reaction, but it may be divided into two main methods, injection and radiation, with excision as an occasional auxiliary expedient later in the treatment. The case *par excellence* for injection is the large solitary infected gland with or without caseation. A needle is pushed into the gland through the nearest part of the skin, and as a rule this will decide whether caseation has occurred or not. Through it is then injected either camphorated thymol or a gum-oil mixture. The use of camphorated naphthol recommended by Calot is considered to be too dangerous. The former consists of thymol 30 parts, camphor 60 parts, and sulphuric ether to 100 parts, and the dose injected varies from a few drops up to 1 c.cm.; the early injections usually cause some pain. The gum-oil is composed of ol. eajuputi 10 (or 20 or 33) parts, and sterile ol. sesami to 100; it is given in doses varying from 0.5 c.cm. of the 10 per cent. solution to 1 c.cm. of the 33 per cent. or even higher; it is painless. The effect of these injections is to produce a breaking down of the gland, the content of which becomes at first gelatinous, then thin, yellowish, and purulent, and finally serous and bloodstained, before the gland is completely absorbed and converted into a knot of connective tissue. The difficulty is to control the rate at which the breaking down occurs. As a rule, more than one injection is necessary to bring it about, and occasionally in simple hypertrophied glands sclerosis occurs without any breaking down. But sometimes it proceeds very rapidly, and unless care is taken a fistula may be formed, which requires scraping. Commonly, however, the results are entirely satisfactory. Radiation is more suited to the case in which a mass of glands in varying degrees of enlargement is involved. The apparatus is arranged to deliver in about forty minutes a dose producing reddening; half this amount is given at one sitting, at least a week being allowed to elapse before another dose is given. The

[1] *Nederlands Tijdschrift voor Geneeskunde*, 1914, No. 16.

first injection is followed by a general reaction resembling the tuberculin reaction; but this becomes less and less after subsequent sittings. Locally the effect depends on the state of the glands. A simple hypertrophied gland at first enlarges and becomes hard, while an extensively caseated gland swells very little and contracts very slowly. A gland with small areas of caseation swells markedly, and may break down, great care being required to prevent it breaking through the skin. At the same time a marked improvement occurs in the periglandular tissues, the glands becoming free and movable as they diminish in size. A neck, even very extensively enlarged, may be brought back to normal size in a few months. Combination of the radiation and injection methods may frequently be employed with advantage; and if operation is eventually undertaken to expedite the final clearing up, it is a much smaller affair, and the condition is not liable to recur.

DAY NURSERIES.

THE term "day nursery" contains for many of us pleasant recollections of early youth, and it is said that the institution of afternoon tea originated there. The term has not lost its earlier meaning, but its connotation has been extended, so that the Board of Education has now decided that the time has come when Day Nurseries should receive some assistance from the State. It has recently issued regulations under which it will make grants, and in a covering memorandum—after observing that many of the ailments from which children suffer when they enter school are attributable to the absence of adequate care during their earliest years—it points out that this lack of care arises from various causes. The mother may be ignorant of the simple laws of health, or the conditions of employment or other circumstances may lead to her being absent from home during a large portion of the day; unable herself to take proper care of her child, she may find it impossible to secure proper care by other persons. The day nurseries which are eligible for recognition by the Board are those which provide primarily for infants and young children under 3 years of age; though the Board will not object to the admission of children over that age, it is not prepared to recognize day nurseries intended primarily for older children. The person in charge of the home will be a matron, not necessarily a trained nurse, but one who has had practical experience in the training and care of small children. She must have at least one understudy, and usually two or three probationers or other assistants will be considered necessary. Every child must be seen by a responsible person daily on arrival; every day nursery must have a medical officer who will visit it at regular and frequent intervals, and whose services will be available at other times in case of emergency. The matron will watch the state of the children daily in order to deal promptly with any cases of illness or possible cases of infectious disease, and in this respect will act under the general supervision of the medical officer. A day nursery must make adequate provision for the suitable feeding of the children, and arrangements must be made for allowing them to sleep under healthy conditions, so far as possible in the open air. When necessary the children must be provided with special clothes to wear in the nursery while their ordinary clothes are disinfected. Further, each nursery should as a rule include two apartments—one for infants and one for young children—baths, a kitchen and larder, and accommodation for the staff. It should also have a playing ground, and the medical officer of health of the district should be consulted as to the accommodation to be provided and the maximum number of children to be admitted. Pains are to be taken to secure that only those children are admitted for whom adequate care cannot be provided in their homes by reason of the unavoidable absence of the mother. The matron will be required to keep a register giving information as to the home circumstances of the child, and a note as to the extent to which the children have suffered from measles or other forms of epidemic disease. The grant will be based on the number of attendances, and applications should be supported by an assurance that the medical officer of health is satisfied with the work. It is recommended that every endeavour should be taken to keep in close touch with the local education authority and the sanitary authority. The first grant will be based on the work during the year ending March 31st, 1914, and will be paid not later than March 31st, 1915.

WE regret to have to announce that Dr. Albert Van Gehuchten, Professor of Neurology in the University of Louvain, who has recently been residing and working at Cambridge, died on December 9th after a short illness. We hope to give next week some account of Professor Van Gehuchten's valuable contributions to the physiology and pathology of the nervous system.

OUR BELGIAN COLLEAGUES AT HOME AND ABROAD.

GENERAL COMMITTEE.

AT a meeting of the Executive Committee on December 10th it was announced that the following nominations had been made to the General Committee by the Pharmaceutical Society of Great Britain: Mr. Edmund White, President of the Pharmaceutical Society of Great Britain; Mr. J. H. Cuff, Mr. W. H. Gibson, Mr. R. L. Gifford, Mr. A. Hagon, Mr. P. F. Rowsell, Mr. G. E. Pearson (Messrs. Burroughs, Wellcome and Co.), Mr. F. P. Sargeant, Mr. W. S. Glyn-Jones, M.P., Mr. J. C. Umney, Mr. D. Gilmour, Mr. J. C. Gilmour, Mr. W. L. Currie, Mr. T. Guthrie, and Mr. J. Rutherford Hill. It was also announced that Mr. Lynn Thomas, C.B., and Professor E. W. Hope of Liverpool had been added to the General Committee. At the same meeting, Mr. E. T. Neathercoat, Vice-President of the Pharmaceutical Society of Great Britain, was elected a member and Mr. W. J. Uglow Woolcock, Secretary and Registrar of the Pharmaceutical Society, was associated with Dr. Squire Sprigge as joint honorary secretary. The Committee also received promises of co-operation from universities, provincial centres, and individual medical men and pharmacists.

The following subscriptions to the fund have been received by the Honorary Treasurer, Dr. H. A. Des Voeux, up to Tuesday evening, December 15th, in addition to subscriptions, amounting to £1,444, previously acknowledged:

By a clerical error the addition of the letter "k" was made to the name of Dr. Mary Acworth in the list published last week.

Subscriptions should be sent to Dr. H. A. Des Voeux, 14, Buckingham Gate, London, S.W., and should be made payable to the Belgian Doctors' and Pharmacists' Relief Fund, and crossed "Lloyd's Bank Limited."

SCOTLAND.

The first meeting of the Edinburgh Obstetrical Society for the session was held on December 9th, the President, Sir HALLIDAY CROOM, in the chair.

The President of the Royal College of Physicians, the President of the Royal College of Surgeons, and a large number of Fellows of the Society and of other members of the profession in the city and neighbourhood were present.

The PRESIDENT in a brief speech introduced Professor JACOBS, of Brussels, who gave a thrilling and appalling account of the state of Belgium, and more particularly of the sufferings of the medical profession there. He pointed out that the Belgian medical men are sharing to the full in the general distress. A strong sense of duty is alone keeping many of them in districts which have been absolutely devastated by the Germans, and before these men there stand many months during which they know that they will have to suffer, whilst giving all their services to their country. Professor Jacobs mentioned numerous instances of suffering which he personally knew about. Many doctors, for example, had to work as navvies in order to gain a few coppers for a livelihood. Others had to sell such few and meagre belongings as were left to them. Many he knew who had not even seen bread for a fortnight, and who had to sleep on a little straw on the bare ground. Several of his own colleagues were so reduced that their very clothes and boots were falling to pieces. One professor of Louvain University had with his wife subsisted for three days on wayside herbs. Another he found looking for his wife and family whom he had not seen or heard of for six days. One Belgian professor was shot after having had his ears cut off and his eyes put out, and the German soldiers then carried his head round the town on the end of a lance! Professor Jacobs then related a few instances of German "Kultur." One example may be stated here. Three weeks before the war broke out he operated on a lady near Namur. In the beginning of August she was convalescent. A day or two after the outbreak of hostilities she was, before the eyes of her husband, violated by seven German soldiers, as a result of which she died two days later.

Sir A. R. SIMPSON moved a hearty vote of thanks to Professor Jacobs. Germany was trying not to conquer but to murder and obliterate Belgium, and the nation that attempted such a crime must perish. The Germans had no word of their own for culture; they did not know the real meaning of it, and they had given the word a debased significance for all time. Germany's methods were the end of all true culture. He believed that ever since 1870 Germany had steadily deteriorated through pride and material success. She would have to learn to serve before she could ever hope to be able to rule.

Sir JAMES AFFLECK seconded the motion in a few words, and assured Professor Jacobs of the hearty sympathy of the meeting.

The PRESIDENT, in conveying the thanks of the meeting to Professor Jacobs, was able to inform him that a sum of well over £100 had been promised by those present, which they hoped he would accept and administer for the medical profession in Belgium.

Scottish Committee.

The Presidents of the Royal Colleges of Physicians and Surgeons of Edinburgh and of the Royal Faculty of Physicians and Surgeons of Glasgow announce that steps are being taken for the formation of a Scottish Committee in connexion with the Belgian Doctors' and Pharmacists' Relief Fund. The Presidents state that according to recent information in their possession the condition of the Belgian doctors and pharmacists is deplorable and their need very great.

IRELAND.

We are informed that in Belfast the Ulster Medical Society and the Ulster Branch of the British Medical Association are making arrangements to draw the attention of their members to the movement.

The first list of subscriptions received by the Irish Committee contained the following names in addition to those in the preliminary list published in the BRITISH MEDICAL JOURNAL of December 5th, p. 987:

LIEUTENANT-COLONEL CHARLES DALTON, R.A.M.C., who died from wounds on September 18th, left estate valued at £4,412 3s. 2d.

THE New York Health Department, in its *Weekly Bulletin*, gives tables showing the department's work in venereal diseases during the second quarter of 1914, and calls attention to the fact that approximately three-fifths of the cases of syphilis reported are reported through the results obtained in its serological laboratory. The number of specimens sent to the laboratory, it is stated, is steadily increasing, showing that this diagnostic aid is appreciated by medical practitioners.

THE WAR.

MEDICAL ARRANGEMENTS OF THE BRITISH EXPEDITIONARY FORCE.

[From a Special Correspondent in Northern France.]

HOSPITALS AND CHLOROFORM.

I UNDERSTAND that the stories to the effect that, owing to a shortage of chloroform, operations are being performed in British Red Cross and British army hospitals without the preliminary establishment of anaesthesia have already been authoritatively denied in the public press at home, but it may be worth while to say that I have often seen anaesthetics used when nothing beyond wound dressing and quite small surgical procedures have been in question. Anaesthesia has been induced in these cases because the patients were quite broken down in respect of their nerve power and capacity for self-control. Some of these patients are officers who have been subjected for weeks not only to the hardships of life in the fighting line but also to the strain of great responsibility. I merely mention these cases and the use of anaesthetics in connexion with them by way of illustrating the fact that in the British war hospitals in France there is no lack of chloroform. There is, indeed, no lack of anything. Supplies of all kinds are ample. I believe, too, that, so far as anaesthetics are concerned, the same statement would be made in regard to the hospitals under French control. One acquaintance told me a week or two ago that he had brought out a few days previously from England a large quantity of chloroform, and offered it to an institution—a French Red Cross hospital—which, though it had plenty of work, was situated a long way from any supply centre. The offer was declined on the ground that the hospital already had more chloroform than could conveniently be stored. Another acquaintance, living in a town in which four or five French Red Cross hospitals are established, told me a couple of days ago that he had received from England for distribution several consignments of chloroform, but nowhere did he find it to be specially required. I also learn on inquiry at the shops of various chemists in the quite moderate-sized town from which I am writing that they have plenty of chloroform on sale, and have no difficulty in obtaining fresh supplies from the manufacturers when they require them. In view of these facts, it appears clear that if there be any basis whatever for stories of shortage of chloroform, it is to be found in the maladministration of some small private hospital enterprises in France. There are hundreds of these in existence, and some of them have been started by persons who have no knowledge of hospital administration whatever. They have brought to their self-imposed task nothing but enthusiasm and a few thousand francs collected amongst their friends, and it is not difficult to believe that at times they allow themselves to run short not only of chloroform but of many other necessaries. The amount of control that the various French Red Cross societies, under whose aegis they work, are able to exercise over them is very small. Now that the first difficulties created by the outbreak of the war have been overcome, the fact that the existence of these small institutions—excellently staffed sometimes, from a surgical point of view, but often inadequately equipped—is not always an unmixed blessing, is beginning to be recognized. A cry, in fact, for the abolition of a good many of them was raised in Paris some weeks ago, but whether any practical steps towards this end have yet been taken I am unable to state.

RED CROSS HOSPITALS.

It seems sometimes to be assumed in England that Calais and Dunkirk are British hospital bases. This is not the case; neither of them is occupied by the British forces, and our own Army Medical Service exercises no control over the medical arrangements existing therein. It occasionally happens that a British soldier gets included in a batch of French or Belgian wounded, and is taken to one of these towns for treatment, and since these towns are not far removed from the British lines, insanitary conditions in them, or rather the existence of a considerable amount of epidemic disease, might complicate matters for our own army authorities. These towns have, however, a direct interest for the British public owing to the fact that there

are established within them an aggregate of about ten voluntary hospitals of British origin. For the most part they are working under the nominal control of the French or Belgian authorities, but at one time and another nearly all of them have received more or less extensive assistance from or through the British Red Cross Society itself, and still require it. Moreover, the ambulance work connected with those at Dunkirk is under the direct control of this Society.

Of the two hospitals at Calais, one is concerned with the special arrangements proposed for the benefit of the Belgians suffering from typhoid fever. I am unable to describe it more precisely, for at the time of my last visit to Calais it was not complete. The other hospital has been at work for some weeks. It owes its foundation, I understand, to a subscription got up in the Baltic Exchange in London, and is fortunate in having its nursing arrangements in the hands of a lady who, at the time of her appointment, had only recently returned from a long tour of corresponding work in the Balkans. This hospital, which ranks as a British Red Cross institution, shares the Sophie Berthelot School—a very large building—with a French Red Cross hospital, and can accommodate 80 or 90 Belgian wounded. A third extemporized institution in the town should also be mentioned, though except for the fact that most of its nurses have been supplied by the British Red Cross Society, I do not know that it can be regarded as in any wise British. This is the Jeanne d'Arc Hospital. It is under the control of Professor Depage, whose chief assistant is Dr. J. van de Velde, and is doing some very admirable surgical work.

Of the seven hospitals in Dunkirk, much the largest is that known as the Duchess of Sutherland's Hospital. It has about 70 beds, and, under the very active control of Millicent Duchess of Sutherland herself, has been leading a useful if somewhat ambulatory existence almost since the beginning of the war. Another—and one of the youngest—is supported by the Quaker community, and is apparently very well organized. A third, which represents Edinburgh and the Border towns, has a very strong staff, but seems to be badly off for funds—a malady from which most of the hospitals in Dunkirk appear to suffer. As they are all quite small institutions, and with one exception are all housed in rather flimsy buildings of the summer residence order, it is possible that their common object would be better attained if a process of amalgamation were carried out. That object is the benefit of the French wounded, and its desirability is not in the least diminished by the fact that the principle on which the French medical authorities are working is that of evacuating to his own territorial area every wounded man who can possibly be moved. It might be well if the small committee which represents them with the French authorities, besides bringing about one or more amalgamations, were strengthened by the inclusion of a larger French official element.

The voluntary hospitals at British bases, such as Boulogne, Rouen, Paris, and Havre, are in a different position; they all work under the general authority of Sir Arthur Sloggett in his double capacity of Director-General of the Army Medical Service (overseas) and of Chief Commissioner of the British Red Cross Society and St. John Ambulance Association. As the operations of the British Red Cross Society in France now extend over so wide a field and it is obvious that they will have to be continued for a very long period, it seems to be thought best that general administrative control should be placed in the hands of someone accustomed to the management of large commercial undertakings. The gentleman selected for the position, with the approval of Sir Arthur Sloggett and of the War Office, is Sir Courtauld Thomson, who is well known as the capable business manager of more than one important commercial concern.

General Progress.

The latest addition to the list of consultants attached to the Expeditionary Force is Sir Berkeley Moynihan, of Leeds, who, after a short stay at Boulogne, proceeded south to act as surgical consultant to the hospitals in the Rouen area.

Owing to the fact that the fighting has been much less severe during the past week or two than previously, the number of wounded men reaching the various bases has fallen. Cases of tetanus and gas gangrene have become comparatively rare. Some points of practice arising out of the special character of the injuries seen in this war seem to have been settled, provisionally at least, so far as general principles are concerned, but both the consultants and the ordinary staff are, of course, still learners and must so remain for probably at least six months longer. Not until some such interval has elapsed will real knowledge of the final results of the various treatments adopted begin to accumulate in respect of cases deemed initially satisfactory. Meantime, however, it is certain that in the surgery of twentieth-century warfare marked progress has occurred. Seemingly every one now has shaken off the shackles of aseptic surgery. The French were at first perhaps a little disposed to confound conservative surgery with non-intervention. It will be interesting to learn how the German surgeons and their patients fared. Judging from one thing and another, I fancy they, too, made some errors at the beginning. The application of gypsum bandages to cases in which tumefaction was bound to occur was one of them. I saw, too, early in the war instances of what seemed exceedingly crude surgery among some batches of wounded men who had been under treatment in the German lines. This applied particularly, perhaps, to amputations, but it is possible that all these were cases in which it was considered that the right initial course was to remove the limb as low down and as rapidly as possible, and to defer covering the end of the bone until a later date. Fortunately for our own wounded, the principles and value of antiseptic surgery have always been impressed upon the minds of officers of the Royal Army Medical Corps by those whose task it has been to give instruction on the special conditions of military surgery; but in the French army medical schools, as also in French civilian hospitals, the fervour with which the principles of aseptic surgery were held is illustrated in a paper published a few weeks ago by a fairly well-known French surgeon. Writing on the subject of military surgery, the author, after referring to differences of opinion as to how often it was legitimate to change dressings, boldly declared himself as in favour of changing them not a given number of times each week, but as often as they began to smell.

GERMAN EXPERIENCES.

Treatment of Wounds.

The lack of unanimity among English surgeons as to the best treatment of wounds in war is also to be observed in the utterances of German military surgeons. Surgeon-General O. von Angerer,[1] who acted as a volunteer surgeon in the war of 1870, holds conservative views on the treatment of bullet wounds which involve no injury to important structures. When the wounds of entry and exit in such cases are small, he treats them as if they were uninfected, though the bullet has of course penetrated the clothing and skin of the patient. He admits that germs are carried into the body under these conditions, but considers their existence of no importance so long as they are left strictly alone. In other words, he thinks the danger of sepsis begins only when the surgeon interferes. The routine he favours in such cases is the application of tincture of iodine and the plugging of the wound with iodoform gauze. He removes this plug before applying a sterile, dry dressing. He is not in favour of using gutta-percha sheeting between the wound and the dressing, as the moisture retained under these conditions facilitates the growth of germs. He is also against the use of collodion and similar preparations, which many surgeons advocate in the hope that the germs on the skin will be fixed there. Exploration of the track of the wound with a probe or finger, laying open the wounds of entry and exit as well as the track of the bullet, disinfection of this track with injections of antiseptics, and the insertion of a drain are, he considers, not only superfluous, but actually harmful measures, when the wound is simple. He contents himself with bandaging the part affected, and expresses the opinion that antiseptic solutions do not kill the germs in a wound, but merely stimulate it to more active secretion. So much

[1] Feldärztliche Beilage, No. I, *Muench. med. Woch.*

for simple, uncomplicated wounds. When, however, the wounds of entry and exit are large, and nerves and large blood vessels are injured, the track of the wound must, he says, be explored and opened, and crushed tissues, which may form a nidus for germs, must be removed. Blood vessels must be ligatured, nerves sutured, and foreign bodies removed, the operation being completed by irrigation with physiological saline solution, and light plugging of the wound with iodoform gauze. But though he advocates the removal of a foreign body in a much lacerated wound, which must in any case be freely opened to remove necrotic tissue, he deprecates the relentless search for bullets which some surgeons indulge in, on the supposition that a retained foreign body implies suppuration sooner or later.

In his discussion of the treatment of wounds of bones and various organs, von Angerer again expresses a preference for conservative methods. Even if a bone has been splintered as well as perforated by a bullet, he advises conservative treatment with plaster-of-Paris splints, provided the wounds of entry and exit are small, and the track of the wound has not been severely lacerated. Abdominal wounds should, he says, also be treated in a conservative spirit; and it may often be advisable to abstain from laparotomy even in cases in which, in times of peace, there would be no doubt as to the necessity for an operation. He upholds this view in the face of the acknowledged fact that the modern bullet is apt to wound the intestines sideways, and thus inflict severe injuries. Bullet wounds of the chest and skull are, he says, also often best left alone. When a wound has become infected he advocates free incisions, plugging with tampons, irrigation with hydrogen peroxide, and frequent change of dressings. Bier's hyperaemia treatment is, he says, admirable in such cases, as it helps to irrigate the wound and dilute the toxins in it; but expert knowledge of this treatment is necessary. Treatment of suppurating wounds for two hours, once or twice a day, in a hot-air bath is also advocated, but von Angerer has nothing good to say of the antiferment treatment of suppurating wounds. He is an ardent supporter of scrupulous cleanliness among surgeons. Though he recommends the routine use of rubber gloves by both the surgeon and his attendants, he insists on exhaustive disinfection of the hands as well. For this purpose he uses a soap containing 80 per cent. of alcohol, which has been shown to kill staphylococci, streptococci, the colon bacillus and that of diphtheria within half a minute. He rubs this soap well into his hands till it has become dry, and then rinses them in sterilized water.

Dr. Linkenheld[2] is not satisfied merely with painting the skin with tincture of iodine, because in the course of the operation it disappears, leaving the skin unprotected. He therefore fixes the iodine with a coating of varnish, containing 1 part of turpentine to 50 parts each of colophony (resin) and ether. He strengthens this with a single layer of muslin. Apparently it is no more difficult to remove than ordinary sticking plaster. To the objection that this procedure complicates matters, he replies that it may be simplified by mixing the tincture of iodine with the varnish beforehand. He has never found the skin injured by this application, but when other ingredients, such as mastic or chloroform, have been added, the skin has suffered. He never washes the skin with soap and warm water before an operation, as this measure is not effective, and predisposes the skin to dermatitis if tincture of iodine is subsequently applied. He therefore cleans the skin by rubbing it with cotton-wool, slightly moistened with benzine. He sterilizes his hands with iodine and alcohol, and then puts on rubber gloves. As a substitute for these he sometimes wears cotton gloves soaked in alcohol, which he also finds useful for hardening the skin of his hands.

Tetanus and its Treatment.

In the German medical press the most suitable methods for combating tetanus have, as might be expected, been receiving much attention of late. The remedies to which most attention is devoted are antitetanic serum and magnesium sulphate. Both are, on the whole, admitted to be efficacious in a certain number of cases, but neither can be regarded as wholly reliable and satisfactory.[3]

Dr. Ludwig Kirchmayr of Vienna has published a critical analysis of statistics of tetanus treated with or without antitetanic serum. His conclusions are favourable to the serum treatment although the statistical evidence is somewhat meagre. The difficulties of estimating its value by statistics are, he recognizes, much enhanced by the capricious variations in the disease. The incubation period may be long or short, the temperature and pulse may from the outset be practically normal or alarmingly altered, and the virulence of the disease may be much affected by the locality in which it occurs. Thus in Italy, for example, the mortality from tetanus hardly exceeds 20 per cent., even in the absence of specific treatment. The arguments of the statistician are therefore apt to be unusually misleading in this disease, and the experience of the clinician in severe cases carefully observed and recorded, is most valuable. In this connexion Dr. Kirchmayr gives details of a case which, by virtue of its severity, before antitetanic serum was given, illustrates its effectiveness under certain conditions. The patient was a man, aged 55, whose head was severely wounded by the wheel of a cart as he lay in the road. This accident occurred on July 22nd. On July 26th the muscles of the jaws began to twitch, and on the following day he could no longer open his mouth. The temperature was 38.6° C. (101.5° F.), and the pulse 86. The wound in the scalp was freely opened, and some thick frothy pus was squeezed out. Dry antitetanic serum was carefully distributed over the whole wound, and in its immediate neighbourhead intra- and sub-cutaneous injections, each containing 20 c.cm. of fluid antitetanic serum, were administered; 30 c.cm. were at the same time injected into a vein. During the next two days two intravenous injections were given. At the end of this period all the most serious symptoms had vanished, but some rigidity of the muscles of the jaws and facial paralysis persisted for some time longer. The total dose of Paltauf's antitetanic serum given in this case was—150 units applied to the wound itself, 100 units injected into the skin, and 650 units injected into veins. The outstanding features of this case are the shortness of the incubation period, the severity of the symptoms, and the high temperature. Dr. Kirchmayr holds that statistical evidence supports the conclusion to be drawn from this case that antitetanic serum is valuable even after the disease has been well established. He doubts whether any great part of the antitetanic serum is conveyed from the site of injection along the nerves, and prefers intravenous injections to all other methods.

The treatment of tetanus with injections of magnesium sulphate is based on the investigations of Meltzer and Auer, who found that magnesium sulphate and chloride, when injected in animals subcutaneously in the proportion of 1.5 gram to the kilo of body weight, produce deep sleep with muscular relaxation and abolition of all the reflexes except the conjunctival and trigeminal. Dr. A. Falk[4] has reported some severe cases of tetanus in which the subcutaneous injections of magnesium sulphate were strikingly successful. He states that the intralumbal administration of the drug was first attempted by Kocher's assistant, Dr. Pellavel, who treated 5 severe cases of tetanus in this manner during the recent Turco-Bulgarian war. Two of the patients recovered, although the disease was advanced and the patients were extremely exhausted when the injections were given. Dr. Falk prefers subcutaneous injections on account of their greater simplicity, and he finds they rapidly banish pain and ensure sleep. He reports 3 cases of tetanus neonatorum of which 2 appear to have been severe. The treatment was continued for a fortnight, three injections being given every twenty-four hours. The amount of magnesium sulphate given every twenty-four hours was determined by the severity of the symptoms from day to day, and ranged from 0.45 to 4 grams. The larger doses were dangerous, alarming symptoms, including apnoea of twenty minutes' duration, being observed after the treatment had been carried out for ten days. Possibly the drug has a cumulative effect when thus given. In both cases presenting signs of magnesium sulphate poisoning, a rapid recovery was effected after 5 c.cm. of a 5 per cent. solution of calcium chloride had been given by intramuscular injection. Poisoning by magnesium sulphate is, apparently, more frequent when the intralumbar route is chosen, and Kocher has advised tracheotomy as a precautionary

[2] Feldärztliche Beilage, No. VI., *Muench. med. Woch.*
[3] Ibid., No. VI.
[4] *Deut. Med. Woch.*, August 27th, 1914.

measure when magnesium sulphate is given in this way. Other precautions include rectal injections of 0.3 to 0.9 gram of chloral, which Dr. Falk found exceedingly useful, and injections of small quantities of physostigmine. Profuse bronchorrhœa following the injections of magnesium sulphate can, he says, be checked by injections of atropine. Serious symptoms following the injection of magnesium sulphate are, however, in his experience, practically limited to young children, and adults and adolescents tolerate fairly large subcutaneous injections. Intravenous injections, even of small quantities of the drug, are rapidly fatal. There is still some uncertainty as to the most suitable dosage. Mielke gives from 0.5 to 0.7 gram a day for every kilo of body weight in a child between 5 and 6 years old. Stadler gives 8 to 20 grams a day to adults. The strength of the solution has varied from 10 to 40 per cent., and Stadler has found the latter strength the least irritating. He has experimented with these injections on himself, and has found it advisable to relieve the pain they cause by giving chloral, omnopon or morphine beforehand. The magnesium sulphate may cause some dysphagia, necessitating light and frequent meals.

Some interesting pathological notes on tetanus have been published by Professor Aschoff,[5] who has been conducting a series of necropsies at Metz. In the course of four weeks he supervised 251 necropsies, including 28 cases of dysentery and 23 of typhoid fever. The latter were characterized by severe intestinal hæmorrhage and perforation, caused, no doubt, by the severity of the disease in subjects already physically exhausted. There were 25 deaths from tetanus and 19 from sepsis. Professor Aschoff associates the frequency of cases of tetanus in this war with the preponderating part played by artillery. Of 133 cases of wounds inflicted in battle, 23 were caused by fragments of shells. Of these, again, 13 showed wounds of the muscles, and all developed tetanus. On the other hand, wounds of the bones, cranium, and pleura were not complicated by tetanus. He argues from this that even if the tetanus bacillus can produce toxins in serous cavities, absorption of the toxin from these cavities does not occur. Further, it is not, he thinks, frayed clothing, carried into a wound by fragments of shell, but freshly ploughed-up earth, which is responsible for the development of tetanus. Professor Aschoff adds that the German projectiles, as a rule, cause greater damage than the French, as the former, when striking bones, break up and expose the leaden core.

HOME HOSPITALS AND THE WAR.

ST. BARTHOLOMEW'S HOSPITAL.

THE whole of the east wing of St. Bartholomew's Hospital was placed at the disposal of the War Office on September 1st, and now forms a section of the 1st London (City of London) General Hospital, with head quarters at St. Gabriel's College, Camberwell. The General Hospital contains 520 beds, while the section at St. Bartholomew's has 180 beds, and there have passed through it already 127 wounded Belgians and about 400 British soldiers.

This series of cases has enabled some idea to be formed as to the types of wounds being sent from the front to general hospitals in Great Britain; percentages have been worked out and injuries have been classified. The distribution of wounds has been found to be approximately as follows: 71 per cent. are in the extremities, upper and lower limbs being about equally affected; head and neck wounds, 10.6; thorax, 8.2; back, 5.3; abdomen and pelvis, 4.8. That wounds of the abdomen and pelvis should show such a small percentage is attributed to the fact that bad cases of this type of injury are only sent over in small numbers, being generally retained in hospitals at the military base.

Wounds have been classified under two heads—non-perforating and perforating. The non-perforating wounds are generally markedly lacerated and usually very septic. They have been produced in the majority of cases by round shrapnel bullets and fragments of shell casing. These wounds have certain marked characteristics which enable them to be grouped under five headings as follows:

1. Superficial or "brush-burn" wounds, where the bullet just scrapes off the superficial tissues.
2. A deeper wound, the "trough" wound. This is a very characteristic wound, often seen on a finger, and inflicted while the finger grips the trigger. These wounds are troublesome, and take a long time to heal.
3. A much deeper lacerated wound is the broad "pit" wound.
4. A penetrating wound, the narrow "pit" wound; and
5. The "total" wound, in which the part is blown away, as when a foot or forearm is entirely removed by the missile.

The greater number of the non-perforating wounds fall into one of these five classes, and it has been found convenient to use the descriptive names given in referring to each type of injury in the course of hospital work.

Perforating wounds are usually caused by the sharp-nosed bullet. In many cases the bullets have done practically no harm beyond the small wound of entrance and exit; one soldier who was sent to St. Bartholomew's was struck by a bullet which entered just in front of the right tragus and escaped over the left malar bone. No symptoms whatever, except some immediate bleeding from the nose, have followed. The bullet probably passed through both antra, although evidence of this is not obtainable by skiagram. Several instances have been observed of a similar passage through the thoracic cavity, and consequently a lung, with only slight haemoptysis. In one case in which stereoscopic skiagrams showed the missile to be in the root of the right lung no untoward symptoms have manifested themselves. Sometimes the sharp-nosed bullet remains in other and deep tissues, causing in many cases little inconvenience, provided there is no sepsis.

In addition to gunshot and shrapnel wounds, cases have been admitted of frost-bite, appendicitis, and fractures from accident. Only two cases of enteric fever have been seen; both were infected probably ten days before admission. One had been wounded and the other was sent home "sick." Cases of frost-bite have been characterized chiefly by swelling and pain rather than sloughing or gangrene. They have been treated by careful cleansing and drying of the skin with methylated spirit, particularly between the toes, with subsequent dusting of the parts with a powder consisting of equal parts of boracic acid, zinc oxide and starch, and then lightly covering the whole foot with sterile wool. One case of tetanus has supervened after admission to the hospital; it was very acute and death occurred within twenty-four hours, in spite of treatment. Several patients have suffered from a rise of temperature and malaise, believed to be the result of injections of antitetanic serum given before they left France.

THE INDIAN SOLDIERS' FUND.

THE LADY HARDINGE HOSPITAL.

WE fear that the Indian Soldiers' Fund has been encountering a good many difficulties and disappointments in the fulfilment of its beneficent mission. Its general idea was to make the Indian soldiers feel that in coming to Europe to help the Empire in this great crisis they were coming among friends anxious to provide them with those smaller attentions and comforts by which a host seeks to express the welcome he extends to a guest. The British War Office is responsible for the supply of clothing and food and other necessaries, and also for the treatment of the sick and wounded, but there are comforts for the men at the front and special advantages in hospitals and convalescent homes which private benevolence can with advantage supply without casting any reflection on the official organization.

We mentioned a month ago that a hut hospital for 500 beds was about to be established in Brockenhurst Park, and indicated the staff which the Indian Soldiers' Fund was providing. This hospital, which will be known as the Lady Hardinge Hospital, has been pushed on as rapidly as possible and will, we understand, be available at a very early date. It was mentioned also that a general hospital had been established by the War Office in two hotels at Forest Gate, and Balmer Lawn, near Brockenhurst. These, however, we understand, turned out to be buildings unsuitable for the purpose and the men were removed to temporary quarters elsewhere, pending the

completion of the Lady Hardinge Hospital in Brockenhurst Park, and the establishment of hospitals at Brighton. Sir John Hewett, the Chairman of the Executive Committee of the Fund, stated at a recent meeting that provision would be made at Brighton for over 3,000 sick and wounded from the Indian contingent. There will be, in fact, four hospitals under one centralized administration; the Pavilion and Dome will afford accommodation for 600, schools in the neighbourhood for as many more, while the workhouse and infirmary will afford room for two hospitals of 1,000 each. As soon as the arrangements at Brighton are sufficiently advanced the Indian wounded in the Royal Victoria Hospital, Netley, and the Red Cross Hospital adjoining it, to the number of over 1,000, will be removed to Brighton.

Sir Walter Lawrence, who was private secretary to Lord Curzon when Viceroy of India, and afterwards a member of the Council of India, has been appointed to take over the general superintendence of the Indian wounded both in France and in England, and the Indian Soldiers' Fund has accepted his suggestion that the more serious cases which would suffer by travelling should be sent to the Fund's hospital at Brockenhurst Park, which is only a few miles from Southampton. With the assistance of Sir Havelock Charles the Fund has obtained the services of a number of retired Indian medical officers, and through the help of the St. John Ambulance Association an adequate supply of nurses speaking Hindustani. It has also obtained from the same body thirty British orderlies, and through Mr. Mallet and Colonel Baker has been promised the services, should they be needed, of some young Indian students who have been formed into an ambulance corps. The authorities in India are supplying a number of Indian orderlies and menial servants for the hospital. Pending the opening of the hospital at Brockenhurst Park, the Fund has placed at the disposal of the medical officer in charge of the hospitals at Brighton all its medical officers, with the exception of Colonel Perry and Colonel Meyer, who are engaged in arranging for the equipment of Lady Hardinge's hospital at Brockenhurst Park.

Among other arrangements which the Fund is making, one has reference to the supply of good milk, which is an essential article of diet in hospitals for Indians. The Fund has also received an offer from the planters of the West Indies to send large supplies of fruit, especially bananas and apples.

It is believed that the difficulties which recently seemed to stand in the way of the Fund carrying out its plan of having its own motor lorries to carry comforts to the commands and units in the field are in a fair way to be overcome, and Sir James Willcocks has expressed his sympathy and promised his co-operation in carrying out the Fund's plans for the benefit of the Indian soldiers at the front. Sir John Hewett also announced that an appeal made in Dundee had met with a very generous response, and that within the first fortnight the Fund benefited to the extent of nearly £3,500.

As our correspondent in France mentioned last week, the principal general hospital in France for Indian troops is being established at Hardelot. At present the projects for establishing a hospital in Egypt, probably at Alexandria, are in suspense, although it is realized that circumstances may ultimately lead to the survival of the proposal.

BRITISH RED CROSS WORK.

The Stores Organization.

As in the case of other departments the pressure upon the stores and transport branch has considerably diminished since the middle of November. The military stores in France are well stocked, and can supply hospitals abroad with all scheduled requirements, so that the British Red Cross Society has been able to concentrate upon the supply of its own hospitals and the furnishing of articles not included in the War Office schedules. It has been freely admitted by the heads of the Army Medical Department that the aid given by the Red Cross Society during the period of pressure was invaluable, and it is realized that periods of severe stress may again arise. It has been arranged, with the approval of the Director-General of the Army Medical Service, that as long as the present conditions continue the Red Cross Society will limit its supplies to its own hospitals, the ambulance trains (comforts and garments only), the rest stations, ambulance ships (garments only), and will supply military hospitals abroad with comforts and garments not included in the army schedule. If an emergency arises, the Society will send over stores of all kinds as quickly as possible. During periods of calm the stores department will steadily prepare for times of pressure, and have considerable quantities of stores ready packed for dispatch.

The Netley Red Cross Hospital.

Plans have been prepared for an extension of the British Red Cross Hospital at Netley to provide 200 more beds (made possible by the generosity of Lord Iveagh), and it is hoped that the additional beds will be available by the end of January. More than half the wounded at present in the hospital consist of Indian troops.

British Hospital at Wimereux.

Sir Henry Norman reports that the British hospital at Wimereux, near Boulogne, has been opened at the Hotel Bellevue. It has its own private fleet of six motor ambulances, a motor lorry, and two cars. The military medical officer in command is Lieutenant-Colonel Copeland, R.A.M.C., the chief surgeon Major H. M. W. Gray, R.A.M.C.(T.F.), the assistant surgeons Dr. A. H. Rabagliati and Mr. Wm. Pearson, the physician Lieutenant-Colonel A. H. Lister, R.A.M.C.(T.F.), and the radiographer Mr. P. Lake-Hope. The hospital has 102 beds, and during its first month has treated 484 cases.

Voluntary Hospitals in France.

The War Office has announced that no further voluntary hospitals are required at present for the British Expeditionary Force in France, and that any voluntary hospitals at present on the Continent, or which may at some future time proceed to the Continent, will work as base hospitals only and will not be allowed to proceed further.

Help for Servia and Montenegro.

The British Red Cross Society has already sent a considerable quantity of medical stores and a Red Cross unit to Serbia. Requests are now being received for further help in this direction for Montenegro as well as for Serbia. The question of the extent of the aid that can be afforded to these countries is now under consideration.

CASUALTIES IN THE MEDICAL SERVICES.

ARMY.

THE official lists of casualties published since our last issue contain the names of the following officers of the Royal Army Medical Corps.

Died of Wounds.

In the announcement of the grant of D.S.O. to Captain Malcolm Leckie, R.A.M.C., in the *London Gazette* of December 9th, it was stated that Captain Leckie was dead. His name appeared in the casualty lists long ago, as wounded, but his death had not previously been reported. He was educated at Guy's Hospital, took the diplomas of M.R.C.S., and L.R.C.P.Lond. in 1907, and entered the army as Lieutenant on February 4th, 1908, becoming Captain on August 4th, 1911. He was recently attached to the Egyptian army.

Wounded.

Charnock, Lieutenant J. P., R.A.M.C.
Osburn, Captain A. C., R.A.M.C.
Stack, Captain G. H., R.A.M.C.

Prisoners, previously reported Missing.

Hayman, Lieutenant J. R., R.A.M.C.
Hepper, Lieutenant J. E., R.A.M.C.
Russell, Lieutenant W. A., R.A.M.C.
Thompson, Major A. G., R.A.M.C.

NOTES.

WAR HOSPITAL SUPPLY DÉPÔT AT IPSWICH.

THE War Hospital Supply Dépôt at Ipswich is the outcome of a meeting called by the Mayoress and Deputy

Mayoress on the outbreak of the war. A committee was formed, and offers of help came from all sides. The workers have the use of an empty house, in which bandages and other surgical dressings are made in large quantities. There is a great demand for pinewood sawdust dressings, as recommended by Mr. Charles W. Cathcart of Edinburgh in the BRITISH MEDICAL JOURNAL of October 17th, 1914, p. 661. Garments for the wounded are made or altered in large quantities; old linen is made into sheets or used for padding splints. The following consignment, which was sent to Limoges in October, may be taken as representing the contents of a typical consignment sent abroad in response to requests: 35 nightshirts, 33 dayshirts, 15 pairs bedsocks, 68 pillowcases, bundles of old linen, 10 nightingales, 528 bandages, 900 swabs, 22 many-tailed bandages, 58 splints, 58 sheets, rolls of iodoform lint and cotton wool, 6 Gamgee pneumonia jackets, 30 bed jackets, rolls of gauze sublimate and carbolic. Crates have also been sent to Brussels, Calais, Dunkirk, Servia, Antwerp, Dieppe, St. Malo, Rouen, British East Africa, and to various regiments, battleships, an ambulance train, and to military and naval hospitals. The Ipswich dépôt has undertaken to keep the Moka Hospital, St. Malo, of which Mr. James F. C. Hossack, of Ipswich, is in charge, supplied with dressings and as far as possible with drugs. Although the dépôt was started independently of any society, it co-operates with the St. John Ambulance Association and with the British Red Cross Society. All who have helped or are helping in this admirable work may be congratulated on the success of their philanthropic labours.

MARLBOROUGH CAMP, BOULOGNE.

Lieutenant R. H. GREEN, Quartermaster, R.A.M.C. (Boulogne, France), writes: Referring to the article in the BRITISH MEDICAL JOURNAL of December 5th, on the above camp, which mentions the camp staff as partly comprising a "quartermaster drawn from a line regiment," I think it is only fair to the R.A.M.C. to explain some facts apparently not known to your special correspondent when writing.

The camp mentioned was originally pitched by R.A.M.C. N.C.O.'s and men, under the direct supervision of a R.A.M.C. quartermaster. Not only that, but the camp was organized and commanded for the first fortnight by him, during the heaviest pressure period on the medical department at Boulogne. Nearly 1,200 men (lighter cases of sick and wounded) passed through the camp before the present staff arrived from St. Nazaire to take charge. The staff originally consisted of the quartermaster (commanding), two temporary lieutenants, and about twenty N.C.O.'s and men, all R.A.M.C., who were temporarily detached from No. 13 Stationary Hospital for the purpose, under arrangements made by the Assistant Director of Medical Services, Boulogne.

The Boulogne Base authorities expressed entire satisfaction with all the camp arrangements during that very strenuous period of late in October and early in November.

Many R.A.M.C. Quartermasters, although it may not be generally known, have passed the qualifying examinations in military law, administration, organization, etc., for the rank of captain, and have so fitted themselves for such commands as the one in question from the military point.

MEDICAL OFFICERS WANTED.

2nd South Midland Mounted Brigade (Reserve) Field Ambulance.

We are asked to state that there are vacancies for one or two qualified medical men as officers in the 2nd South Midland Mounted Brigade Field Ambulance, R.A.M.C.(T.) Reserve, Head quarters, Great Missenden, Bucks. Full particulars can be obtained by applying to the Officer Commanding, Great Missenden.

4th (R.) Battalion, The Buffs.

Lieutenant-Colonel E. O. Skey informs us that the 4th (R.) Battalion, The Buffs (East Kent Regiment), is in need of a medical officer. The battalion is now stationed at Sunninghill, and communications may be addressed to Lieutenant-Colonel Skey there.

THE new order issued by the Home Secretary with regard to lights in the metropolitan police district and the city of London prohibits the use of any lights whatever for outside advertising or the illumination of shop-fronts; and requires all vehicles, including cycles and hand-carts, to carry a red light at the rear; the red glass reflectors largely used by cyclists will no longer be considered sufficient.

India.

[FROM OUR SPECIAL CORRESPONDENT.]

INVESTIGATION OF DIABETES.

CIVIL ASSISTANT SURGEON B. K. NARAYANA RAO, B.A., M.R.C.S., D.P.H.Lond., D.O.Oxon., has been posted for preliminary training at the physiological laboratory, Medical College, Madras, before being placed on special duty in connexion with the investigation of diabetes.

THE PAREL BACTERIOLOGICAL LABORATORY.

The Government of Bombay have just published a pamphlet in language as untechnical as possible on the work of the bacteriological laboratory at Parel. The pamphlet contains several useful plates illustrating the work done by the laboratory and is divided into five chapters. The first gives a brief history of the institution; the second deals with the efficacy of antiplague inoculation, how it protects and reduces the chance of an attack from plague and assists recovery. The other chapters deal with the preparation of antiplague vaccine and other activities of the laboratory. Originally started by Mr. Haffkine, the discoverer of antiplague vaccine, the laboratory has grown from a small institution into one of considerable dimensions and of first-rate importance. For ten years it bore the name of the "Plague Research Laboratory," but its present designation indicates more aptly the wider field of investigation over which its activities now extend.

The measures described in the pamphlet are of two kinds—measures of permanent utility and measures of temporary utility. The former are designed to mitigate those habits which bring out the association of rats with men. They include the erection of well-built houses, separation of shops, warehouses, granaries, and stables from human habitations, and the construction of concrete floors and roofs of materials which cannot harbour rats. But as these measures cannot be carried out in their entirety at once, recourse must be had to measures of temporary utility. They include the protection of the people in their homes from rats and other parasites, measures for removing the people from their homes to avoid infection (evacuation), and measures rendering the individual largely immune from attack and death from plague by means of inoculation. Like vaccination against small-pox, inoculation reduces the chances of plague attack, and those who are attacked recover more frequently and more easily.

TOWN PLANNING IN THE PUNJAB.

The Punjab Government has appointed a committee which is now sitting with a view to the preparation and issue of a manual on town planning, designed for the guidance of officers engaged in planning new towns or in extending present towns in the Punjab canal colonies.

WAR PRISONERS IN INDIA.

The Bengal Government announces that 354 of the enemy subjects have been dealt with since the outbreak of war as follows: Handed over to the military, 275, of whom 266 are interned at Ahmednagar, and 9 are temporarily on parole. Eight who exceeded the reservist age or are members of the consular service left India for Venice. Of the remainder, 71 are under civil control, of whom 28 have been sent to Katapahar; 16 persons, having families dependent or over age of 55, are under surveillance in Calcutta; 27 in various districts of the Presidency, mainly missionaries and priests, are under the control of the district magistrate.

LADY HARDINGE MEMORIAL MEDICAL COLLEGE, DELHI.

The offer of Dewan Bahadur Daya Kishan Kaul, C.I.E., Finance Minister, Alwar State, of a gold medal in connexion with the Lady Hardinge Memorial Medical College for Women at Delhi has been approved by the Viceroy. It will be given to the student of the first year who distinguishes herself most in the preliminary scientific subjects. Thirteen girls are receiving instruction in scientific subjects at various lay colleges in anticipation of their joining the Lady Hardinge Medical College as soon as it is ready for opening, and it is hoped that they, as well as other students contemplating entering the college, will

prepare themselves for the examination in connexion with the grant of this medal.

Indian Medical Service Officers and Military Duty.

The following forty-four officers of the Indian Medical Service have reverted to military duty from civil employ: Lieutenant-Colonels Lumsden, Parry, Dawes, Stodart, and Prall; Majors Husband, Fayrer, Harley, Foster, Satisbose, Forrest, Paymaster, Tuke, Betts, Hamilton, Wolley, Beit, Thorneley, Watling, Delany, Ross, Ritchie, Walker, Willmore, Pearson, Wells, Clements, Mell, Greig, Dalziel, and Mackenzie; and Captains Stewart, Drake, Hunter, Barker, Jones, Steel, White, Goil, Watson, Scott, Macrea, Macmillan, and Rutherfoord. This list, and a reference to the *Gazette of India*, will show that altogether over 200 officers of the Indian Medical Service in civil employ have reverted to military duty, thus effectively disposing of the assertions which have appeared in the past as to the impossibility of utilizing these officers in time of war.

Madras Allotments for Medical Buildings.

The Madras Government has ordered the distribution among certain district boards and municipal councils of a sum of Rs.2,31,007 out of the provision of Rs.10 lakhs made in the Civil Budget Estimate for 1914–15 for the construction of medical buildings.

Medical Organization in Bengal.

Two notable advances have recently been made by the Presidency of Bengal tending towards the organization and elevation of the medical profession. By an Act passed by the Legislative Council in April last the Bengal Council of Medical Registration was constituted to fulfil functions relating to the medical profession and to medical education analogous to those performed by the General Council of Medical Education and Registration of the United Kingdom. More recently an order has been issued by the Governor of Bengal in Council establishing a State medical faculty for Bengal—an examining body empowered to grant licences to practise medicine, surgery, and midwifery. The need of some system of distinguishing qualified from unqualified medical practitioners has long been felt in India, and efforts have been made, notably in Bombay, to put the public in possession of a means of discriminating the two classes, and to restrict the performance of important public duties to persons properly educated and publicly proclaimed as qualified. Difficulties exist in India in attaining these purposes; but the law which has now been enacted in Bengal is an important step in that direction, and it is hoped that in time it will be possible to extend its operation throughout the Indian Empire. The members of the Council have been nominated and elected, and may now proceed to carry out the provisions of the Act. The creation of the State medical faculty was rendered necessary by a resolution passed by the University of Calcutta in the year 1906, discontinuing the examination for the Licence in Medicine and Surgery (L.M.S.) and restricting its functions to the granting of degrees (M.B., M.D., and M.C.). It was also felt desirable to adopt measures to grant licences to practise on terms less exacting and difficult than those imposed by the university for obtaining its degrees. The regulations constituting the State Medical Faculty were published in the *Calcutta Gazette*, and have been reproduced in the October number of the *Indian Medical Gazette*. They represent fully the constitution and operations of the faculty, setting forth the requirements as regards education and examination for obtaining the membership or licence (M.S.M.F., and L.S.M.F.). A limited number of Fellows (F.S.M.F.) may be elected *honoris causa* by the governing body, the members of which have already been nominated. The Faculty will work in harmony with the Council of Medical Education, to which is assigned the duty of declaring what institutions are sufficiently provided in respect of teaching staff and appliances to entitle their students to appear for examination for these licences.

Thirteen cases of plague and eleven deaths from the disease were reported in Mauritius during the fortnight ending December 3rd.

Sydney.

[FROM OUR SPECIAL CORRESPONDENT.]

Hospitals Advisory Board.

The first meeting of the Hospitals Advisory Board appointed to assist the Minister of Health in his dealings with the public hospitals was held last month. The Minister of Health, Mr. F. Flowers, presided, and there were present representatives from the Sydney, Royal Prince Alfred, Royal Alexandra Hospitals, Royal Hospital for Women, Royal North Shore Hospital, St. Vincent's, South Sydney, and Lewisham Hospitals, and the Hospice for the Dying.

In the course of his introductory remarks the Chairman said that he did not wish in any way to lessen the powers or the authority already possessed by the various bodies which had executive control over the great hospitals of Sydney. But there were grave problems with which he was confronted from time to time on which the secretaries of the hospitals could afford valuable advice and information, and that without in any way interfering with the loyalty that they owed to the organization with which they were connected. One very important matter was the serious increase in the cost per bed in many of the hospitals: he quoted figures to show that the cost ranged from £56 to £111 per annum. He also referred to the cost of the food and drugs, and suggested that it would be worth while to consider whether by the establishment of a common drug factory and dépôt for supplying all the hospitals a considerable saving could not be effected. He suggested, also, that it might be possible and economical to arrange with the State bakery to supply all the hospitals, and thus to effect a considerable saving.

Mr. Flowers is a pronounced socialist, and a member of a Labour-Socialist Government, and all his public utterances have to be considered from his point of view. It is well known that since the present Government assumed office wages have gone up by leaps and bounds, with proportionate increase in the cost of living. The wages of the hospital porters and attendants have been increased very considerably, and the increased expenditure at the hospitals is to a large extent due to these two factors. At the same time we must agree with Mr. Flowers that some attempt may well be made to reduce the annual expenditure per bed at the large public hospitals in the metropolis.

Mr. Flowers has on several occasions expressed his views on the functions of hospitals, and on the occasion of the opening of two new wards at the Royal North Shore Hospital, he stated that "he did not look upon hospitals as a charitable movement, but as a commercial movement. Every healthy individual in the State is a distinct asset to the State, and in curing those who are not in good health we are doing a good to the State by increasing its assets." On this principle Mr. Flowers considers that the hospitals should all be State institutions, and should be open free to all sick persons, irrespective of their financial position.

The Sydney Dental Hospital.

A complete rearrangement of the management of the Dental Hospital has been arrived at as a result of a conference between Mr. Flowers, the dental board, and representatives of the Sydney University and the Education Department. Mr. Flowers told the conference that the Dental Hospital, mainly through financial embarrassment, had not been able to accomplish the work it had intended to do, and the reconstitution of its management was in no way a reflection on the present committee. He thought that more use should be made of the hospital as a training school for dental students, and to this end suggested the establishment of a chair of dentistry. It was also desirable that the hospital should afford adequate facilities for the treatment of dental defects in school children. Sir Thomas Anderson Stuart agreed that a professor of dentistry was needed, who would devote his whole time to the work and share in the labours of the Dental Hospital. It was agreed that the present twelve members of the Dental Board should remain and that six additional members should be appointed—three to represent the Department of Health and three the Department of Education. The main feature will be a business committee of five, two to be elected by the existing twelve members and

three to be chosen from the new six. Two of the latter three will represent the Department of Health, and one the Department of Education. The Chief Secretary to the Government is to be chairman. This rearrangement amounts practically to a nationalization of this hospital.

Correspondence.

SANITATION IN INDIA.

SIR,—The letter of Colonel W. G. King, C.I.E., which appeared in the BRITISH MEDICAL JOURNAL of September 26th, seems to call for some answer, as the views which he expresses are not those held by a large number, at least, of the officers of the Indian Medical Service.

Colonel King states that the present Director-General of the Indian Medical Service was selected for that position on account of his ability as a physician, and objects to the sanitary department being placed under that branch of the medical profession which is specialized for cure, and also to the post of Director-General of the Indian Medical Service being always filled by a member of the Bengal Service.

The present Director-General, Sir Charles Pardey Lukis, is certainly a distinguished physician. On entry to the service he was first of his term. Ten years after entering he took the M.B. of London (1889), and in 1904 the M.D. After holding important posts in the United Provinces, he was appointed, in 1905, Principal and Professor of Medicine in the Calcutta Medical College, and first physician to the College Hospital, and held that post for five years, till his promotion to his present rank. He was also, before his appointment to a purely medical post, a successful surgeon, and took the F.R.C.S.Eng. in 1890. The principalship of the Medical College is an administrative as well as a professional appointment, and the ability with which he discharged the administrative duties of that post probably had more to do with his selection for the highest medical administrative post in India than purely professional merit. Rightly so, most would think, for administrative ability is the main requisite in the holder of an administrative appointment.

To speak of one branch of the medical profession as being specialized for cure seems also a curious way of putting things. Treatment and cure are the original objects of the whole medical profession, and still remain the duty of the great majority. A branch dealing particularly with preventive medicine, or sanitation, has gradually developed, and to some extent has split off from the general profession. But those who take up this speciality must still qualify in medicine and surgery before entering on their special line.

Colonel King says that the subordination of the Sanitary Commissioner to the Director-General is much as if the chief medical officer of the Local Government Board in England were placed under a physician, and that physician always selected from one county—Middlesex. The comparison of Middlesex in England to Bengal in India is, to say the least of it, hardly fair. Middlesex is one county out of forty in England, and a very small county, though it contains part of London. There are, or were up to 1896, three branches of the Indian Medical Service—the Bengal, Madras, and Bombay "establishments." And the Bengal service has always been of greater strength than the other two put together.

Previous to 1895 the Surgeon-General with the Government of India was head of the Bengal service only, and necessarily a Bengal man. In 1895 this appointment was made that of Director-General, and head of the whole Indian Medical Service of the three Presidencies. Since 1895 five officers have held the post of Director-General. These five, certainly, have all been Bengal men. But there does not appear to be any absolute rule restricting the post to Bengal officers, while the appointments of Surgeon-General of Madras and Bombay are restricted to members of the Madras and Bombay services. In any case all the appointments will be open to the whole service in another twelve years or so, when the last men of the separate services have retired, and only those of the new combined or general service list, started in 1896, remain.

As regards the subjection of the sanitary department to the Director-General, in 1880 the head of the Bengal medical service, formerly known as Surgeon-General, was made Surgeon-General and Sanitary Commissioner with the Government of India. As he was both Surgeon-General and Sanitary Commissioner, there could be no doubt that the sanitary department was under his orders. This state of affairs lasted for twenty-four years, till in 1904 the late Lieutenant-Colonel J. W. T. Leslie was appointed Sanitary Commissioner with the Government of India, and placed in a semi-independent position. When Lieutenant-Colonel Leslie went on furlough in 1911, the Director-General took up the duties of Sanitary Commissioner in addition to his own. Some months later, after Lieutenant-Colonel Leslie's death, a new Sanitary Commissioner was appointed, the present holder of the post.

The statement that the administrative policy of the Sanitary Commissioner must be submitted to the Director-General for his approval is also hardly correct. The Sanitary Commissioner appears to have power to put forward any sanitary policy which recommends itself to him. He must, of course, be prepared to lay before the Government of India reasonable arguments in favour of any sanitary policy which he puts forward, but the same holds good with the head of every department—military, civil, or political. The administration of research is in the hands of a board, on which the Director-General and the Sanitary Commissioner each have a seat and a vote.

This letter is already too long. But in conclusion, it may be stated that the service can have only one head. That head must be, as the name implies, the Director-General. He administers the sanitary department, as he also administers the various provincial medical departments, the political medical department, the gaol department, etc. There is no rule which prevents the holder of the office of Sanitary Commissioner from rising to the higher post of Director-General. But for his premature death the late Sanitary Commissioner might not improbably have done so.—I am, etc.,

November 29th. I.M.S.

TREATMENT OF FRACTURES OF THE THIGH.

SIR,—Your special correspondent, in his interesting letter from Northern France, published on December 5th, emphasizes the difficulty experienced in treating compound fractures of the thigh. He points out that the surgeons find it all but impossible to combine immobility of the fractured ends with easy access to the wounds. Plaster-of-Paris, as advocated by Lange, the Liston, both double and single, and Hodgen's splints and their modifications, do not meet the requirements. In my opinion, there is no support comparable with what is known as a Thomas's knee splint for any fractures of the middle and lower thirds of the thigh, or fractures of the knee and upper tibia. It allows of easy access to the wound without disturbing the fragments, adequate and constant extension, while correct alignment is automatically secured. In addition, a patient can be transported any distance and in any conveyance with the minimum discomfort. Its application requires little special knowledge, as its construction is so simple.

For injuries of the upper third of the thigh, including the hip-joint and pelvis, what I have so often described as the abduction frame secures immobility and easy access to the wound. The splint is carried with the patient on it, is self-contained and transport does not interfere either with extension or alignment. It is adjusted in the following manner: The patient is laid on the abduction frame with natal cleft immediately over the cleft in the splint—this cleft in the splint serving for nursing purposes. Extensions of adhesive plaster having been applied as high as indicated by the injury, the leather groin strap is then fixed around the uninjured limb to the splint, then slight traction is made on extension of this limb to prevent pelvic tilting. Having done this, the degree of traction desired on the injured leg is obtained by pulling on the extensions, the extensions being "made fast" to the iron loop of the splint. The tension is maintained by keeping the groin strap tightly applied.

The general use of these two splints at our base hospitals would be an incalculable boon both to the surgeon and the patient.

The initial cleansing of the wound is most important, and great effort should be made, whatever the antiseptic used, to spend reasonable time over it. Carbolic acid

and iodine are often of great service, but I should prefer hydrogen peroxide as a routine injection to any other. Where shrapnel is embedded near the surface, drainage should be secured by free opening.

I strongly advise surgeons not to remove and destroy loose pieces of bone in comminuted fractures, even when they have no periosteal attachment. It is a practice fraught with danger, leading to non-union and functionless limbs. Loose pieces may be taken from the wound, scrubbed and sterilized, and replaced to reinforce the fracture. I have known them to become attached even in the presence of infection.—I am, etc.,

Liverpool. ROBERT JONES.

PREVENTION OF TYPHOID IN OUR HOME CAMPS.

SIR,—The exclusion of typhoid epidemics from the camps of our Expeditionary Force during the four months of service in the field is a notable event, probably a record in the history of our campaigns—an achievement to be attributed to various factors, but chiefly, no doubt, to the systematic organization of our Army Medical Service, to the ability, vigilance, and devotion of our army medical officers, and to the genius and foresight of those who are responsible for the preparation and direction of the various preventive measures required in order to ensure security from this subtle foe.

Our regular troops have entered into this present war with all the advantages acquired since our last campaign—not merely the protective influence of antityphoid inoculation, but also of all the instruction and knowledge which has been gained from the South African war itself, and more especially from the history of the violent epidemics amongst the Volunteers of the U.S.A. when encamped in their own country during the war with Spain, and finally from Japan's triumphant and unprecedented reduction of typhoid during her war with Russia.

Our army medical officers, we know, have made intimate study of all the hygienic and sanitary measures which have been shown to be necessary for the exclusion of epidemic typhoid from the camp, whilst the combatant officers, and even the rank and file generally, have been well instructed and drilled in the necessary precautions—to such an extent, we hope, that the precautions have become a matter of routine and instinct instead of a matter of compulsion.

With regard, however, to the hundreds of thousands of recruits at present encamped or billeted throughout the United Kingdom, who to a large extent seem to be under the care of civilian medical men, it is difficult to see how they will enjoy the protection of the same precautions unless the medical men and also the combatant officers, as well as the rank and file, are being consistently instructed and drilled in the routine measures required for the maintenance of the best health and the exclusion of infection. Who are the officials responsible for the organization of all the necessary protective measures for the home camps? Will this organization be as complete and thorough as that of the Japanese army in 1904? The public may justly ask to be reassured on these matters.

It may be well to recall the chief preventive measures by means of which, in face of extraordinary difficulties, the Japanese achieved their unparalleled triumph over "the secret foe":

1. Systematic instruction and education in military hygiene and sanitation of medical and combatant officers, and also of the rank and file.
2. Careful inspection, with cleansing and disinfection (if necessary) of all camps and billets previous to occupation.
3. Boiling of all water before drinking (when possible). This implies the provision of means for boiling and strict water discipline.
4. Cleanliness of individuals, with ample provision for baths, and the regular cleansing of camps and billets.
5. Constant daily inspection of cases reported sick, rapid diagnosis by bacteriological methods, separation of suspected cases. All cases with pyrexia or diarrhœa were treated as suspects, and their blood promptly examined.

The importance of all these measures will probably be generally recognized. But the detection of incubating and ambulatory cases of typhoid by bacteriological methods is an additional safeguard the importance of which was first fully realized during the epidemics among the U.S.A. Volunteer encampments, when the Commissioners appointed to inquire into these epidemics came to the conclusion that many of the cases of recorded diarrhœa, "simple continued fever," etc., were in reality cases of typhoid; that they were to a large extent the sources of the epidemics, and that the infection spread from them—from tent to tent, and from man to man within the tent. Those who have not studied this evidence may very easily overlook the great importance of detecting these "first cases," of disinfecting all the various articles with which they may have come into contact, and of separating them from their tent; especially as it is very generally supposed that typhoid is not infectious or contagious, and that the infection is conveyed almost solely by water. These two prevailing ideas have long ago been confuted by close and careful study of the disease. The infection, no doubt, has in a large number of cases been conveyed by water—sometimes by other carriers—and generally speaking the disease is not very "infectious," but it must be remembered that in military camp life the soldiers are frequently in close contact with their neighbours, their clothing, bedding, etc., and that soldiers are of the age most susceptible to typhoid.

They may be regarded as a highly inflammable material in which a spark may readily give rise to a conflagration. Successful preventive inoculation makes them more resistant to flame and prevents the fire from spreading in the individual. At the same time it is not difficult to realize that the exclusion of all sparks by whatever paths they may be conveyed should be provided for by all possible means.

> A little fire is quickly trodden out,
> Which being suffered rivers cannot quench.

The importance and great advantage of immunization by preventive inoculation appear at present to overshadow the measures required for keeping typhoid infection entirely out of the camp.

It has been usual both in civil and military life, from want of prompt detection of the earliest cases, to realize the presence of a typhoid epidemic some two or three weeks after many infections have actually taken place.

If, however, constant and regular examination be made, with the aid of rapid bacteriological methods, of suspected cases in our home camps, we may hope that no explosive outbursts may occur, with consequent long lists of sickness and death.—I am, etc.,

CHRISTOPHER CHILDS, M.D., D.P.H.

Boscarn, Cornwall, Dec. 8th.

SENIOR STUDENTS AND THE WAR.

SIR,—In my presidential address to the General Medical Council on November 24th I expressed the opinion that "the need for efficient physicians and surgeons, in the field and at home, is not less urgent than the need for efficient soldiers and sailors"; and I said that I had "felt it my duty to press this consideration on senior students, who, though they have nearly completed their curriculum, are ready to forego the prospect of early qualification, and to enrol themselves straightway in the combatant forces."

To-day I have received a letter from Surgeon-General Sir Alfred Keogh, which contains the following passage: "I think with you that the senior student is best fulfilling his duty to the country by getting his degree, and then joining the army. The need for young qualified men will become great, and I should regret that the supply should be diminished."

As I daily receive letters from senior students and their parents, who desire guidance in their choice of apparently conflicting duties, I shall be grateful if you will make known the opinion held at the War Office on the subject.—I am, etc.,

DONALD MACALISTER,
President, G.M.C.

Medical Council Office,
299, Oxford Street, London,
December 10th.

THE TREATMENT OF WOUNDS.

SIR,—If a few simple principles are kept in mind the *rationale* of the treatment of these wounds is surely quite simple. The soldier, lying in the trench for considerable periods, has his exposed parts encrusted with a varying thickness of mud; his clothes likewise become saturated with the same material. This mud is derived from a soil

that has been intensively cultivated with animal manure, with which, owing to the exigencies of warfare, is often an admixture of human excrement. It is therefore rich in virulent organisms. Travelling with great velocity through the tissues, the bullet sets up along its track centrifugal currents. As a result, the organisms are driven with considerable force into the surrounding living tissues and lodge there. These tissues are devitalized by the bruising action of the bullet; they therefore lose both their power of phagocytosis and their ability to generate antibodies. The organisms in consequence can readily grow in such a medium.

Assuming these data to be correct, it must follow that in order to kill the organisms it is necessary to kill the tissues which shelter them; pure carbolic acid effects this object. Moreover, by causing a coagulation of the raw tissues to which it is applied, it seals up the open mouths of the torn afferent lymphatics, and so prevents infection of the system.—I am, etc.,

London, W., Dec. 3rd. KENNETH CAMPBELL.

ANTISEPTICS IN WAR.

SIR,—Correspondents have asked me the percentage of rosaline in the antiseptic mixture I advocated in the JOURNAL of December 12th. It is rosaline ½ per cent., carbolic acid 1 in 20, mercury perchloride 1 to 500 absolute alcohol or pure methylated spirit.—I am, etc.,

Haslar, Dec. 14th. G. LENTHAL CHEATLE.

SIR,—I see that in your issue of December 5th Dr. Stephens maintains his championship of petrol in the treatment of wounds, etc., with, as he says, "invariably good results and little pain." Results which one man may consider good may far from satisfy another, while the term "little pain" is entirely relative; and if, as I think it is fair to assume, taking this letter of Dr. Stephens with his previous communication, this summing up of his results with petrol applies to wounds as well as septic pharyngeal conditions, it remains for me to remind him that the case I quoted in the JOURNAL of November 21st is one of which the details are all too familiar to himself. It would be interesting and instructive to know whether Sir Victor Horsley also uses petrol freely, repeatedly, and without anaesthetics in large suppurating cavities.—I am, etc.,

Swansea, Dec. 9th. W. F. BROOK.

THE CAUSE OF HERNIA IN INFANTS.

SIR,—Sir Victor Horsley, in the Sir William Banks Memorial Lecture published in the JOURNAL of October 17th, urges that every hernia should be cured by radical operation as soon as it is discovered, and regards as clearly untrue a statement quoted from a textbook to the effect that "during the first few years of life herniae show a great tendency to undergo spontaneous cure."

In discussing the cause of hernia Sir Victor Horsley makes no mention of a group of factors which tends powerfully to its production in young infants. Although hernia is not rare in strong, muscular, and well-nourished babies, it is nevertheless true that it is much more commonly met with among infants suffering from chronic dyspepsia and malnutrition, marked by abdominal distension, flatulence, and colic. In such cases the accumulation of gas in the coils of intestine is accompanied by a rapid loss of subcutaneous and extraperitoneal fat, while the abdominal musculature becomes stretched, thinned, and atrophied. Finally, the abdominal wall gives at its weakest point—the umbilical cicatrix, the inguinal canal, or the line of junction between the recti muscles.

What part is played in this hernial formation by developmental defect I do not know. Inguinal hernia is certainly more common in premature infants than in children born at full time, but so also are the symptoms of flatulence, colic, and dyspepsia. In Mongolian infants, too, and in cretins, among whom hernia is very common, abdominal distension and atrophy of the abdominal musculature is also the rule. Certain it is that with efficient treatment of the dyspepsia, with the disappearance of the abdominal distension, and the replacement of the thinned and stretched abdominal wall with muscle of good quality, very many, perhaps most, of the hernias present in the first six months of life disappear. In how many cases the aperture remains closed for many years only to give way again in later life I know of no statistics to show, and Sir Victor Horsley does not furnish any. It seems to me highly unlikely that this happens with such regularity as to make it prudent to operate on all cases of infantile hernia without exception.

The essential part of the treatment in these cases is to secure by proper modification of the diet the growth of a satisfactory abdominal wall. No one now imagines that the woollen truss advised by the surgeon is of itself curative. Nevertheless its use is justified, because it helps to reassure anxious parents, who, noticing that the hernia bulges during a painful spasm of colic, are persuaded only with difficulty that the hernia is itself painless. To prescribe the truss without correcting the colic and flatulence is useless. Strangulation of inguinal or umbilical hernia in infancy, although not unknown, is very rare.

The importance of phimosis as a cause of hernia is, I think, very slight, and bronchitis, because of the poorly developed cough, has less effect relatively than in adult life. On the other hand, the part played by infantile dyspepsia and malnutrition is so marked that I do not think the profession will be easily persuaded to abandon its present practice and submit all cases to immediate operation until full play has been allowed to the marvellous power of growth and repair inherent in the abdominal wall in the first year of life. Within a few months of the disappearance of the dyspeptic symptoms the hernia may have gone and a firm muscular wall may have developed.—I am, etc.

London, W., Oct. 25th. H. CHARLES CAMERON.

NUTRITION AND MEAT EXTRACTS.

SIR,—I have read the correspondence on this question with special interest, and I hope you will allow me to call the attention of the whole profession to its importance. It is a long time since Dr. Bright pointed out that dropsy coincided with some change in the kidney, and albuminuria and dropsy have been regarded as due to disease of the kidney. The dropsy of Bright's disease pits on pressure, but there is a dropsy of the skin, lately discovered, which does not pit on pressure. Professor Laycock taught that the dropsy in Bright's disease was a neurosis, from the fact that he had observed that it was not symmetrical in every case. Whether the dropsy that pits on pressure, which may be called oedema although coincident with changes in the kidney is due to kidney disease, is a question not easily answered; but, from my experiments and observations, I am inclined to think that, whatever organic lesions may be discovered in any disease, they are due to failure in function of the nervous system—are, in fact, neuroses.

When on my recommendation a late well-known physician, who carried little or no fat, weighed his food and restricted himself to 12 oz. in the twenty-four hours, he lost 6 lb. in weight, as he observed, "All from the belly;" but I find my weight varies according to the loss by the kidneys and lungs and skin, as well as by the bowels, the loss by the kidney being the chief regulator. It is said that the intestine contains normally 7 lb. weight of food refuse, but with abnormal accumulations that weight will no doubt be exceeded. I do not suppose any one has ever ventured to say what the weight of fluid in the system may be in any disease; but we know that, reduced to ashes, the body weight is very small. I have little doubt that the system may hold 7 lb. of fluid under abnormal conditions, and any food which not only stops elimination of fluid, but causes thirst which makes one drink, is likely to increase body weight, but such increase is dangerous to health. Whatever may be the effect of meat extracts, further experiments and observations will prove that increase of weight generally precedes an illness, and is really more dangerous than loss of weight; and further, that the increase in weight is due largely to retention of fluid in the system generally, although it can only be seen in the skin. In conclusion, I should like to emphasize the fact that what comes out is really of more importance than what goes into the body.—I am, etc.,

Hawick, Scotland, Nov. 14th. JOHN HADDON, M.D.

YELLOW FEVER.

Sir,—On my return from a somewhat prolonged tour in the "bush," a friend of mine has to-day forwarded me your issue of July 18th, pointing out the review you publish (p. 106) of a paper by Dr. J. W. Scott Macfie and myself in the *Yellow Fever Bulletin*, vol. iii, No. 2, April, 1914. With your permission I should like to review your review.

The statement that the general opinion amongst experts at the present day is that these bodies are not parasitic in their nature is not wholly accurate. The question is still *sub judice*, and unbiassed opinion is still divided.

Your reviewer lays great stress on the variations in the forms shown in our coloured plate, making no charitable allowance for the fact that we were finding these bodies *de novo*, not merely describing well-known and easily recognizable parasites. Surely under such conditions it is permissible to make some slight errors, and to include a few bodies which later we might consider to be a different nature.

Writing solely for myself, I admit that I am doubtful of Figs. 1 and 35. Fig. 1 may possibly be a distorted malarial parasite; Fig. 35 I deliver into the hands of your reviewer. But as to the remainder I am afraid I am not so pliable.

Let us consider a simple case—say, *Plasmodium vivax*. There is very great variety in form between the segmented and sporulated schizont, the early ring-form, the parasite of, say, half-growth, and the gametocytes. Further, the careful study of very large numbers of malarial blood-films will lead one to recognize that bodies, perhaps grotesquely distorted, are yet the identical parasites. Therefore, Sir, when your reviewer considers it "rash to say, for example, that the bodies in Figs. (1), 7 and 14 of the coloured plate are the same bodies or in any way similar to those represented in Figs 9 and 10," I beg to utterly disagree with him. When he is even so unkind as to refuse to see any connexion between Figs 20, 25 (and 39), and "the bodies depicted as coming from the human cases," I must really beg him to look at Fig. 13. It is unfortunate that he referred to Fig. 39. Reference to the text, with which he does not appear to be very familiar, would explain its presence in the plate.

I have recently collected a large number of blood-films from cases of piroplasmosis in oxen. One film alone would provide your reviewer with all the forms shown in our plate, with the exception of Figs. 1, 22, and 35. The fact that similar bodies may be found in guinea-pigs at home is surely a singularly weak disproof of our suggestions. Can any sound reason be brought forward why English guinea-pigs should not have them? Because piroplasmata occur in various animals, it in no way follows that they are of similar species, or that any one, expert or other, could differentiate their species purely by the microscope.

Were a new bacillus to be described as the causative agent of some disease, it would hardly be a sound criticism to say that similar bodies—similar, that is, from a microscopical point of view alone—had been found in animals in a country where this disease did not occur. I am aware of no experimental method by which it has been proved that these bodies found in guinea-pigs at home are of similar species to those described by us. If an unwise criticism as regards bacilli, of which much is known, how much the more so as regards piroplasmata!

Your reviewer makes a curious paraphrase of our paper when he states that "... they found bodies similar to those described by Seidelin in the blood of guinea-pigs ... etc." Surely he should make it clear that this was only after experimental inoculation (except in the case of certain dogs), instead of leaving your readers to suppose that we found the animals naturally infected with our parasite (and therefore considered them a carrier of the disease), which is a complete misrepresentation of the facts.

I must apologize, Sir, for the length of my letter, but must refer the ultimate blame to your reviewer.—I am, etc.,

J. E. L. Johnston,
West African Medical Staff.

Medical Research Institute,
Yaba, West Africa,
Sept. 22nd.

POPULAR FREUDISM.

Sir,—In your current number a nameless correspondent, "H. B. D.," proclaims the need of an organized policy of ridicule and neglect in order to kill the Freudian system of psychology. Your readers will not fail to notice the implicit admission that rational argument and open discussion are not to be relied on to this end. And, incidentally, how vivid the glimpse your correspondent affords us of a mind not yet liberated from a belief in prejudice as the court of appeal in matters of science!—I am, etc.,

David Forsyth.

London, W., Dec. 14th.

Sir,—Your correspondent "H. B. D.," in the Journal of December 12th hopes that the time has at last come when "all psychologists, psychiatrists, and medical societies" should cease to regard "this modern and alien jargon about the unconscious as matters for serious consideration." Taking the sentence literally, what is meant is perhaps that "H. B. D." is dissatisfied only with Freud's writings on the "unconscious," but I gather from the tone of the letter that it is the study of the "unconscious" generally that merits his disapproval. If I am right in this assumption, I trust that the psychologists, etc., will do nothing of the kind. There are many writers on the "unconscious," for example, Janet and Morton Prince, to mention two only, and the study of their books cannot be neglected by the student of psychology.—I am, etc.,

R. H. Steen.

City of London Mental Hospital,
near Dartford, Dec. 14th.

Sir,—However undesirable it may be that the complete Freudian system should be established in this country, the danger of such an invasion is not likely to be met by such a letter as that of "H. B. D."

Freud's statement that a forgotten name has a connexion with some painful idea which has been pushed out of consciousness is not patently absurd to every one who thinks about it for a moment. In all the literature which deals with this subject careful proof is given on this point. It is possible that the proof is faulty, it is possible that it is not complete; but it must be met by counter reasoning and not by ridicule, which will certainly not kill it.

The words "unconscious painful idea" have no meaning as they stand in an ordinary English sentence. They have a perfectly definite technical meaning, and they assuredly represent a fact.

Freud's teaching could not have claimed such widespread attention if there was nothing in it at all. It is clear that there is something. It is clear that the German mind has exaggerated the sexual part of the theory. Our duty now is to endeavour to separate the grain from the chaff. I have no doubt that English psychologists will be equal to the task.—I am, etc.,

T. A. Ross.

Ventnor, Dec. 14th.

Universities and Colleges.

UNIVERSITY OF EDINBURGH.

The following candidates have been approved at the examinations indicated:

Final Examination (*Forensic Medicine*).—A. F. Campbell, J. F. M. Campbell, R. P. Cormack, H. J. Davidson, H. F. Ferguson, H. J. Foote, H. C. Fox, Helen M. Gall, A. M. Gosh, Helen G. Hewat, E. Jamieson, T. Janakiramiah, D. H. Jones, N. B. Laughton, A. R. Laurie, P. M. Little, T. J. Lloyd, W. K. M'Intyre, C. F. Maclachlan, J. B. P. M'Laren, E. S. Mellor, O. D. Price, A. Ravunni, C. Russell, W. Shanks, J. W. Simpson, G. H. Sinclair, C. I. Stockley, T. J. W. Sveinbjornsson, A. J. Taylor, G. M. Torrance, A. A. Watson, E. W. Wilbourne, M. E. Willcock, P. H. Young.

Final Examination (*Public Health*).—M. H. Alikhan, A. Aziz, H. J. Bruwer, A. F. Campbell, J. F. M. Campbell, J. E. Chow, A. Clarke, R. P. Cormack, A. J. Ferguson, H. J. Foote, A. M. Gosh, E. B. Israel, E. Jamieson, T. Janakiramiah, F. J. C. Johnstone, D. H. Jones, J. L. Lamond, T. J. Lloyd, W. K. M'Intyre, C. F. Maclachlan, J. B. P. M'Laren, J. Macqueen, P. C. MacRae, W. B. Postlethwaite, P. V. Ramanamurty, J. W. Simpson, G. H. Sinclair, C. J. Stockley, T. J. W. Sveinbjornsson, G. M. Torrance, A. A. Watson, J. D. Whitfield, E. W. Wilbourne, M. E. Willcock, P. H. Young.

Final Examination (*M.B., Ch.B.*).—J. H. Baird, M. Barseghian, E. G. von B Bergh, D. G. Boddie, W. K. Chalmers, U. J. Cherry, W. A. Coats, R. P. Cormack, Georgina E. Davidson, A. M. Duarte, A. J. Ferguson, Agnes R. H. Greig, G. D. Hamilton, H. Jackson, C. W. Lewis, H. Lewis, G. A. G. Macdonald, J. Macqueen, E. S. Mellor, J. J. Molyneux, W. H. Pallett, P. V. Ramanamurty, J. Ritchie, R. C. Rogers, G. M. Scott, C. G. Skinner, L. J. Spence, T. J. W. Sveinbjornsson, P. G. Tuohy, H. M. Vickers, E. L. White, E. W. Wilbourne, A. Wotherspoon.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AN ordinary council was held on December 10th, 1914, when Sir W. Watson Cheyne, Bart., President, was in the chair.

Issue of Diplomas.

Diplomas of Fellowship were granted to the following nine candidates found qualified at the recent examination:

R. N. Geach, D. W. Hume, C. Noon, G. W. Beresford, J. H. Barclay, B. W. Howell, P. G. Doyne, R. M. de Mowbray, and D. Green.

Diplomas of Member were also conferred upon the following:

Mabel K. Bishopp, Hilda G. Johnson, J. H. Parry, and Mary Woods.

Diplomas of the Licence in Dental Surgery were granted to thirty-five candidates found qualified at the recent examinations.

Election of Examiners.

Mr. H. F. Waterhouse was re-elected a member of the Court of Examiners. Dr. C. M. Hinds Howell was elected an examiner in physiology for the second examination of the Conjoint Examining Board.

Annual Meeting of Fellows and Members.

The Council decided that as the matter referred in the resolution adopted at the recent annual meeting of Fellows and Members was very fully considered by the Council so recently as March last, it saw no advantage in reopening the discussion at the present time.

Hunterian Oration.

The Hunterian Oration will be delivered by the President, Sir William Watson Cheyne, on February 15th, 1915. No Hunterian dinner will be held.

War Relief.

A letter, dated November 21st, from the honorary secretaries of the Professional Classes War Relief Council, was read. It stated that the Council had been formed to deal with distress in the professional classes directly due to the war, and that it was decided at the last meeting of the Council to ask the College to nominate a representative to serve on the Council. The President was nominated.

Supply of "Subjects."

A letter was read, dated November 30th, from Professor F. G. Parsons, stating that at the annual general meeting of the licensed teachers of anatomy in London, held on November 26th, it was decided to ask the Council of the Royal College of Surgeons to help in taking further measures with a view to increasing the present supply of "subjects" for dissection, and to suggest a conference between representatives of the Council and the licensed teachers. A committee was appointed to confer with representatives of teachers.

General Medical Council.

A vote of thanks was given to Sir Henry Morris for his services as the representative of the College in the General Medical Council.

ROYAL COLLEGE OF PHYSICIANS IN IRELAND.

THE next triennial award of the Reuben Harvey Memorial Prize will be made on July 1st, 1915. Competitors, who must be either students in one of the Dublin schools of medicine recognized by the medical licensing bodies in Ireland, or graduates or licentiates of those bodies of not more than three years' standing at the time of the award, can choose any subject they please on animal physiology or pathology; but their work must represent original research, and be illustrated by drawings or preparations. The value of the prize is £25. Further particulars will be found in our advertisement columns.

The Services.

GENERAL HOSPITALS (T.F.).

IN reply to several correspondents who have made inquiries, we understand that the pay and allowances to which medical officers serving on the staffs of General Hospitals (T.F.) are entitled are as follows; the rates are daily:

	Pay.	Field Allowance.
Lieutenant-Colonel ...	£1 10 0	... 6s. 0d.
Major	1 3 6	... 4s. 6d.
Captain ...	0 15 6	... 3s. 6d.
Lieutenant ...	0 9 0	... 3s. 0d.

The Administrator is usually a lieutenant-colonel, and draws pay and allowance of that rank *plus* charge pay, for a hospital of over 200 beds, at the rate of 10s. a day. The Registrar is usually a major, and draws the pay and allowance of that rank.

With regard to the medical officers of local hospitals which have undertaken to receive wounded men, or are hospitals affiliated to a Territorial General Hospital, we have not been able to ascertain that any remuneration is paid by the War Office. If the officers of such hospitals were granted commissions, they would no doubt receive the pay of their rank, and any allowances to which they might be shown to be entitled.

Medico-Legal.

ASSUMPTION OF THE NAME OF A REGISTERED PRACTITIONER.

AT the Central Criminal Court, on December 9th, Harold Charles Edward Harrison pleaded guilty to forging death certificates and to committing perjury.

According to a report in the *Daily Telegraph* (December 10th), Mr. Bodkin, who prosecuted, said that the prisoner had pleaded guilty to forging certificates relating to the deaths of three persons. Fourteen such certificates had been produced in the course of the case. It appears that in 1900 the prisoner was summarily convicted of giving a false medical certificate and of using titles to which he was not entitled. In 1901 he was convicted of theft, in 1903 of bigamy, and in 1908 he was sentenced to five years' penal servitude for bigamy and assault. In January, 1914, he became assistant to Dr. Allen of Bethnal Green, having told him that he was Surgeon-Major Harrison engaged at the War Office in examining recruits. Dr. Allen took him on as assistant. In that capacity he attended patients, gave death certificates, and attended inquests, all under the name of Harold Charles Harrison, M.R.C.S., L.R.C.P.—there being a registered practitioner of that name at Lincoln. After he had been with Dr. Allen a few months the prisoner announced the death of General Sir John Richard Harrison, to whom he said he was heir, and he continued to act as assistant, having cards printed "Surgeon-Major Sir Harold Richard Harrison, D.S.O." In July, 1914, the suspicions of Sir Wilmot Herringham, who had been asked to consult with some one who said he was with Dr. Allen, were aroused. Inquiries subsequently made by the Medical Defence Union led to the present charge.

The prisoner, whose real name was stated to be John Cubbin, read a long statement in mitigation of sentence. He said he had studied medicine in Montreal and Vienna.

He was sentenced to three years' penal servitude.

Public Health AND POOR LAW MEDICAL SERVICES.

REFUSE TIPS.

THE standard textbooks on public health make very little reference to the length of time required to render refuse tips inert. If layers of soil are laid at frequent intervals over the refuse nitrification is hastened. The Public Health Acts Amendment Act, 1890 (an adoptive Act), Sec. 25, makes it unlawful to erect a new building on any ground which has been filled up with noxious matter until such time as the matter has become innocuous. "If a building site is artificially made care must be taken to see that the subsoil is free from organic pollution of any kind . . . . Where the subsoil has been excavated for sand or gravel, the place is used frequently as a tip for rubbish of all kinds until the level is raised to a sufficient height to allow of its being used for building purposes. Where 'made soils' of this nature are utilized as building sites, they should be asphalted or covered with a layer of concrete of other impermeable material at least 6 in. thick, and extending from one outside wall to the other" (Notter and Firth in *Theory and Practice of Hygiene*, third edition, p. 422). "Made soils—which result from the filling in with household refuse and other rubbish of low-lying sites or excavations made for the purpose of removing the virgin soil, etc.—should be avoided" (Parkes and Kenwood in *Hygiene and Public Health*, fourth edition, p. 264).

RESPONSIBILITIES OF OWNER AND OCCUPIER.

SANITARY.—Under Section 94 of the Public Health Act, 1875, which deals with the abatement of nuisances, a Local Authority is empowered to call upon the person by whose act, default or sufferance, a nuisance arises or continues, to abate such nuisance. It is often very difficult to decide as between owner and occupier which is to be called on to abate. Where an occupier under the terms of his lease has to carry out internal repairs and the owner external, it would appear equitable in the case mentioned for the occupier to take up the drain which runs under the kitchen floor, and for the owner to lay a new drain outside, properly trapped and ventilated. The occupier to clean out and fill in the disused water tank under the kitchen, and disconnect the overflow from the drain.

THE Lord Mayor of London, in presiding at the annual meeting of the Royal Surgical Aid Society on December 9th, stated that during the past year 42,575 appliances had been distributed, making a total since the foundation of the society of 856,696. In addition, artificial teeth had been supplied to a large number of recruits. A vote of thanks was accorded to Sir Frederick Treves, who had resigned the office of honorary consulting surgeon, which he had held for ten years. The sum of £348 was collected at the meeting.

Obituary.

JAMES EARL MORETON, F.R.C.S.

The death of Dr. Moreton removes a well-known personality from the neighbourhood of Chester. He was born at Minshull Vernon, Cheshire, in 1831, and educated at Dr. Brindley's, Tarvin, in the very house in which he died; at this school he was a somewhat successful rival of the Senior Wrangler of 1853. In the years 1848 and 1849 he was apprenticed to his uncle, Dr. Earl of Tarvin, Chester, who had qualified owing to the fact that he had been in practice before 1815. During his apprenticeship he had been chloroformed as an experiment, the drug having then just been introduced. In October, 1849, he entered St. Thomas's Hospital in the Boro', living in "the College" in Dean Street South. His studies were interrupted by an attack of typhoid fever and a threatening of phthisis. Sir Thomas Boor Crosby was a contemporary and lifelong friend. When in London he became intimately acquainted with Dr. Edw. Westall of Croydon, whose degree of M.D. was conferred on him by the then Archbishop of Canterbury, whose household he attended. Dr. Moreton obtained the diplomas of M.R.C.S. and L.S.A. in 1853, and that of F.R.C.S. in 1865. He was house-surgeon to St. Thomas's Hospital till he became house-surgeon to Chester Infirmary in 1854. In 1856 he was house-surgeon at Stafford Infirmary, and while there had as a pupil the late Mr. Reginald Harrison, F.R.C.S., whose father was Chaplain to the Infirmary. In 1857 Dr. Moreton joined his uncle, Dr. Earl, at Tarvin, and up to 1898 was in practice at that place. When he retired he went to live at Kelsall, but on the death of his wife a few years ago he returned to Tarvin.

He married in 1858 Janet Steel, by whom he had five children—four daughters (two of whom survive him) and one son, who joined him in practice in 1890. His chief recreations were hunting and reading. One of his friends, in a letter of condolence, says: "I don't think I ever knew a man who had a more charming personality or who was beloved by a wider circle of friends."

We regret to announce the death of Dr. Oscar Jennings, which took place suddenly at Ramsgate on November 23rd. He received his professional education at Guy's Hospital, and was admitted M.R.C.S. in 1873. He afterwards studied in Paris, where he graduated M.D. in 1878. For many years he practised in Paris, and won a considerable reputation by his writings on the mechanical treatment of diseases of the spinal cord, and particularly on the treatment of the morphine habit, on which he wrote several monographs. He was an enthusiastic believer in the virtues of cycle exercise, and, we believe, very successfully reduced his own weight by this means. He was the author of a French translation of Gowers's *Diseases of the Spinal Cord*. Dr. Jennings was a member of the Bibliographical Society, of the Société de l'Histoire de la Médecine and of the Société Médico-historique de Paris. He was for some time medical electrician at the Faculty Clinic, Asile St. Anne. Dr. Jennings was for many years the Paris correspondent of the *Lancet*. Of late years he had resided in London.

We regret to have to record the death of Dr. James Simpson, which took place at his residence, Mayola, Cullybackey, County Antrim, on November 27th. Dr. Simpson, who was a son of Mr. Thomas Simpson of Cullybackey, studied medicine at Queen's College, Belfast, and in 1881 graduated M.D. Queen's University, Ireland. He had a distinguished college career, and subsequently settled in Cullybackey, where he acquired an extensive practice and a high reputation as a physician. His personality and his professional knowledge gained him wide popularity and consideration. His genial disposition and thoughtfulness for others endeared him to all who knew him. A man of great strength of character and honesty of purpose, he gained the confidence of his patients, by whom he will ever be remembered. They found in him a personal friend. His health had been a good deal impaired during the last two years, and a fortnight before his death he had a paralytic seizure, from which he did not rally. By his death the community of Cullybackey have sustained a severe loss. He leaves a widow, an aged father, and a married sister to mourn their loss.

Deaths in the Profession Abroad. — Among the members of the medical profession in foreign countries who have recently died are Dr. John Lanson Adams, of New York, one of the most prominent specialists on diseases of the eye, ear, nose, and throat of the United States, aged 54; Dr. L. B. Bangs, professor of genito-urinary surgery at the Post-Graduate Medical School, and at Bellevue Hospital, New York, President of the American Association of Genito-urinary Surgeons in 1895, and editor of the *American Textbook of Genito-urinary Diseases*, aged 72; Dr. Washington Emil Fischel, of St. Louis, who took an important part in the fusion of the St. Louis and Missouri Medical Colleges as the medical department of Washington University, in which he was clinical professor till his death, aged 64; Dr. Theodore W. Fisher, sometime lecturer on mental diseases in the Harvard Medical School, aged 77; Dr. Morris Longstreth, for many years professor of pathology in Jefferson Medical College, New York, aged 68; and Dr. Opie, one of the founders of the College of Physicians and Surgeons of Baltimore, and its Dean from 1872 to 1905, aged 72.

Medical News.

The late Sir Henry Littlejohn, M.D., left personal estate valued at £26,624.

The ordinary annual general meeting of the London Cremation Company, Limited, will be held at 324, Regent Street, W., on Monday, December 21st, at 3 p.m.

At a meeting of the Council of the Lister Institute of Preventive Medicine on December 10th, Sir John Rose Bradford was re-elected a member of the governing body.

The library and offices of the Royal Society of Medicine will be closed for the Christmas holidays from Thursday, December 24th, to Monday, December 28th, both days inclusive.

Dr. C. S. Sherrington, F.R.S., Fullerian Professor of Physiology, will deliver a course of six lectures at the Royal Institution on muscle in the service of nerve, on Tuesdays at 3 p.m., beginning on January 19th.

We are asked to state that owing to the fact that Dr. A. S. Martin, Tuberculosis Officer for the County Borough of Sunderland, has received notice to join the R.A.M.C. at once, it is probable that an officer will be appointed for the time of the war to fill his place. Communications may be addressed to Dr. Henry Renney, M.O.H., Sunderland.

In a lecture on "Self-Expression through Language with Older Children," delivered by Miss Margaret Corner at a meeting of the Child Study Society held on December 3rd, she said that language possessed three elements—the objective, the subjective, and the social. The third element hardly entered into the language of children at all. The child was not incomplete man but a different entity, whose language, like his ideas and emotions, differed from that of the adult, although he was compelled to make use of the same words and expressions. As a general rule, young children could be made to chatter without a trace of self-consciousness on any subject, but an older child experienced difficulty in expressing herself subjectively, and disliked a transition from the objective to the subjective in conversation. In a class composed entirely of girls between the ages of 11 and 15, she had noticed that many of the children experienced acute discomfort when forced to consider and answer questions from the subjcetive point of view, although as the age advanced this characteristic gradually disappeared. This, in many cases, undoubtedly meant that the child was not only incapable of giving verbal expression to her feelings, but was actually unaware of their existence until they were forced upon her attention. Those engaged in the training of children should endeavour to teach them to know themselves, whilst inculcating at the same time the necessary lessons of discipline and self-control.

Letters, Notes, and Answers.

ORIGINAL ARTICLES and LETTERS *forwarded for publication are understood to be offered to the* BRITISH MEDICAL JOURNAL *alone unless the contrary be stated.*

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Office, 429, Strand, W.C., on receipt of proof.

TELEGRAPHIC ADDRESS.—The telegraphic address of the EDITOR of the BRITISH MEDICAL JOURNAL is *Aitiology, Westrand, London.* The telegraphic address of the BRITISH MEDICAL JOURNAL is *Articulate, Westrand, London.*

TELEPHONE (National):—
2631, Gerrard, EDITOR, BRITISH MEDICAL JOURNAL.
2630, Gerrard, BRITISH MEDICAL ASSOCIATION.
2634, Gerrard, MEDICAL SECRETARY.

☞ *Queries, answers, and communications relating to subjects to which special departments of the* BRITISH MEDICAL JOURNAL *are devoted will be found under their respective headings.*

QUERIES.

LICE.

S. asks how fast lice reproduce themselves, and therefore how often blankets, etc., should be stoved.

*** The best answer that can at present be made to this question is contained in Dr. Shipley's article on lice published in the JOURNAL of September 19th, p. 493. Mr. Warburton summarizes the life-cycle of the insects, as indicated by his experiments, as follows:—Incubation period: Eight days to five weeks. From larva to imago: Eleven days. Non-functional mature condition: Four days. Adult life: Male, three weeks; female, four weeks. These figures are based upon laboratory experiments, and under normal conditions the rate may be accelerated. It is clear, however, that, as in the case of many other insects, temperature plays a large part in the rate of propagation. The development of the eggs may be suspended, though they are not killed, during cold weather; the larvae, which are very ravenous, appear to die in a day and a half unless they can obtain food.

DR. STUART OLIVER (Littleham, Bideford) writes: If the woollen singlet or other garment worn next to the skin be dipped, after washing and wringing, in a 5 per cent. solution of boric acid, again wrung out, and then dried, it will be found no longer to harbour the parasites for a considerable time, nor will the sweat become sour and offensive nearly so soon as it would otherwise. One ounce of the acid in solution should, if economically employed, suffice for a couple of garments, size and material, of course, affecting the amount required. If all socks were similarly treated after washing, I feel confident that the number of men off duty from foot troubles would be largely diminished.

ANSWERS.

"ABDOMINAL PAIN."

S. writes, in reply to "X. Y. Z.," who requested suggestions for an abdominal pain, that it may resemble that of the man who had "a migraine in his belly." If so, his remedy might be tried—namely, pot. brom., sod. salicyl. āā gr.xx, taken at the onset, and repeated if required.

MUSHROOMS AND URTICARIA.

C. E. L. writes: I was called to an old gentleman who was suffering from eczema of the legs, which were covered with a very irritable eruption; the next day it assumed much the appearance of measles, but there were no conjunctival symptoms. I found he had eaten some mushrooms two days previously. On the third day he complained of some sore throat; the fauces were oedematous, the uvula swollen, and the conjunctivae congested; there was a slight rise of temperature. All these symptoms abated on the fourth day, and as the eruption was fading distinct "fairy rings" showed, and were the last part of the eruption to disappear. The question of diagnosis was important, as there were children in the house; against measles were the age of the patient (79), the lateness of the conjunctival and faucial symptoms, and the "fairy rings."

LETTERS, NOTES, ETC.

DR. W. M. M. JACKSON (Las Palmas, Grand Canary) writes: As passenger traffic to the Continent may be interfered with this winter and many of the usual health resorts cut off, it may be of interest to your readers to learn that the route to this island is open and quite safe, and that everything here is as usual. There is plenty of accommodation for invalids both at sea level and higher—12 or 1,400 ft. The winter climate is cool, bracing, and moderately dry.

THE HAEMOSTATIC TONSIL GUILLOTINE.

DR. GRAHAM GRANT (London) writes: In your issue of December 12th, p. 1019, there is an interesting description of a double-bladed tonsil guillotine, which is designed for the purpose of checking haemorrhage. Now my tonsil guillotine has not been sharpened for years, and I do not intend to have it sharpened as long as it will do its work. The reason is not far to seek: we have had no cases of troublesome bleeding since it has been blunt.

A PLEA FOR SUPERSTITIONS.

DR. J. C. MCWALTER (Dublin) writes: We are all enchanted with Sir F. Treves's address on "Dogmatism in Medicine," but let us be a little merciful, for we also shall be judged by captious critics. Have we not seen, even in our own days, that when a man got a pain in the right side of his belly the surgeons insisted that the cure was to cut out a bit of the gut? And when a piece of gut was cut out of a great prince without fatality, have we not seen honour, title, and wealth poured on the gut-stitcher? Have we not been taught that it is possible to cure cancer of the breast by cutting it off, when we might as well try to cure a cold in the head by cutting off the nose, or erysipelas by cutting out the first purple patch? Our cure for small-pox is to infect every infant with an allied disease, and we boast of curing the plague by catching rat-fleas. We think that tuberculosis is caused by a microbe, and because a like microbe may be found in milk we hope to cure consumption by murdering cows.

THE DIAGNOSIS OF DEATH.

DR. JOHN J. HANLEY (Motherwell) writes: The importance of being able to diagnosticate death *quickly* must be of superlative importance on the battlefield, and indeed sometimes, though rarely, in civil practice. In the *Presse médicale*, Paris, September 16th, No. 67, pp. 621–624, M. d'Hallain states that the simplest and most practical test for continuing vitality is the instillation of ether into *one* eye. If there is life, the eye reddens. The body should be horizontal when applying this test, and only one eye treated; the other eye is for "control." He claims that the test has never failed him, but advises that it must not be relied on in case of negative findings. Some R.A.M.C. men might try this, and I suggest, in addition, a test on the conjunctiva with adrenalin chloride solution (1 in 5,000), which may prove even more reliable than the ether test, for in severe wounds and injuries of the head it would appear to be more applicable, for obvious reasons.

BENZOL IN BILHARZIA.

DR. WM. ROBERTSON (Durban) writes: I have recently had under treatment for five or six months a case of bilharzia which did not improve on various remedies, such as sulphur, urotropine, male fern, and methylene blue. After the administration of benzol, the ova began to appear black in colour and much shrunken. At times the slide was covered with these, and contained only one or two of normal appearance. Again, there would be some ova less black alongside of the dense black. After the administration of benzol for about fourteen days, all constitutional symptoms disappeared renal colic, pain in back, frequent urination, etc. The urine is now normal in colour, more so than he has seen it for seven years. It still throws down a sediment on boiling. There are no tube casts. The drug is comparatively innocuous. I gave it in doses of ʒj every three hours on sugar. I can offer no explanation of the black colour of the ova unless it is to be attributed to the action of benzol. If ova are treated on a slide with benzol, a faint blackness, like that seen on some ova passed in urine, is soon produced. No intestinal symptoms have been complained of. I have examined faeces twice without finding ova, but this, of course, is not a sufficient test. Lately I have combined thymol with the benzol (thymol 2 grains, benzol ½ drachm) every four hours. The change in the symptoms under the drug has been so rapid and radical that I have ventured to record them thus early.

In a further note, Dr. Robertson, among other observations, remarks that he finds that the very heavy exudate seen on boiling the urine of a fresh case of bilharzia may become a mere haze after brief treatment by thymol and benzol; also that the cystic haemorrhage is unaccompanied by the formation of clots, the urine consequently passing freely. He mentions one case in which the patient, after passing more or less blood for years, passed none whatever for fourteen days when put on thymol-benzol. In another case the patient gained weight rapidly, and improved surprisingly in colour. Treatment by these drugs should be kept up for three or four weeks, and then be intermitted, urinary antiseptics being substituted for a time.

COLOUR VISION AND TESTS FOR COLOUR BLINDNESS.

By C. DEVEREUX MARSHALL, F.R.C.S.,
SURGEON TO THE ROYAL LONDON OPHTHALMIC HOSPITAL.

THERE is scarcely any subject in the domain of medicine and surgery which has been more misrepresented than that of the facts of colour blindness, nor is there any in which such lack of discrimination has been shown with regard to the selection of appropriate tests for its detection.

Many of us know from experience how the methods advocated by Edridge-Green have won all along the line, and that those who have not been so blinded by prejudice as to refuse to examine the facts have been led by the overwhelming weight of evidence to admit that his theory explains the facts, and that his methods are efficient and reliable for the detection of errors of the colour sense. Lately, however, it has been freely stated that many, if not most, scientific men have failed to be convinced and have rejected his ideas as untenable. Such statements have been made without a shadow of proof that such is the case, and in order to show how far it is from the truth I wish to review briefly what some of the most eminent men have said regarding his work. I should like also to point out that what follows represents only a very small fraction of similar evidence, but I have made selections from the writings of those whose names are so well known in science that any statement they make cannot but carry weight, and must be respected by those who are in any way conversant with the position they occupy in the scientific world. It is also hoped that this may serve to stop the dissemination of reports which are so freely handed about and which are so foreign to the facts of the case.

Dr. E. H. Starling, F.R.S., Professor of Physiology in University College, London, writes in his *Principles of Human Physiology* (1912): "It is very difficult, however, to harmonize the facts of colour blindness with either this" (Helmholtz's) "or Hering's hypothesis. It is better to abandon hypotheses altogether and to adopt a purely empirical classification of colour vision as has been done by Edridge-Green. This observer points out truly," etc., and this is followed by a page and a half of the facts pointed out by Edridge-Green.

Dr. Halliburton, F.R.S., Professor of Physiology in King's College, in his *Handbook of Physiology* (1913), writes: "The Edridge-Green lantern is one of the best to employ; in it the intensity and colour of the light, and the order in which the colours are shown can be easily varied. If the colour-blind person is made to examine and report on the colours of a spectrum" (Edridge-Green's method) "or in portions of the spectrum exposed to view, the results obtained are more accurate, but this is not so simple as the lantern test."

Sir Edward Schäfer, F.R.S., Professor of Physiology, University of Edinburgh, in *Experimental Physiology* (1912), writes:

> Testing for colour vision. Edridge-Green's lamp and spectroscope. . . . The best practical method for testing colour vision is by the use of a lamp provided with glasses of different colour, the subject being expected to name the colour which is exhibited. A more accurate method of obtaining spectral colours for testing purposes is the employment of a spectroscope so arranged that only a definite part of the spectrum with a pure spectral colour is visible at one time.

(This is the method of using the Edridge-Green spectrometer.)

Professor Burch, F.R.S., in his *Physiological Optics* (1912), describes Edridge-Green's monochromatic colour patch method, and concludes thus: "The most powerful grating spectroscope may be used in the way described by Edridge-Green and the preceding statements verified." Edridge Green's signal lantern is then described.

Professor Alcock and Dr. Ellison, in their *Experimental Physiology*, write: "Colour Blindness. Examine portions of the spectrum by the method of Edridge-Green." Details are given, and they add: "Examine Holmgren's set of coloured wools and let the student test his neighbour for colour blindness. This test succeeds best if both experimenter and subject are slightly thick-headed."

Professor D. J. Hamilton, F.R.S., of Aberdeen, wrote as follows in his *Textbook of Pathology*:

> Edridge-Green's Theory: All these theories, however, presuppose that the essential defect is in the retina. From what we now know of the visual centre in the brain, it seems quite as likely, if not more so, that the vice is located in the apperceptive centre—that, in fact, colour blindness is essentially a disease of interpretation, not one which is bound up with the mechanism placing the visual centre in communication with the periphery; that it is, in fact, simply a form, and probably a very pure one, of congenital psychical blindness. . . . Edridge-Green in his fascinating work on the subject of colour blindness has taken this view of the matter. His explanation of the colour sense is as follows.

(Then he gives nearly three pages of details).

Lord Rayleigh, in a letter to Dr. Edridge-Green, wrote as follows:

> I think you are entitled to claim credit for having advocated the "lantern" tests at a time when they did not seem necessary to others, and if you like you may quote me as saying so.

Sir William Ramsay, K.C.B., F.R.S., Professor of Chemistry in University College, London, has written to me as follows:

> Very many years ago I came in touch with Dr. Edridge-Green. I have certain peculiarities of vision which he classes as "three-colour." I was, and am, convinced that he is right. Since then I have followed his work more or less; my son and I were examined in Professor Starling's laboratory some years ago, and his tests confirmed our impressions as to our vision. I cannot say that I agree with all that he has published, because I have not followed it all minutely; but I am sure that he is correct in the broad lines on which he interprets colour vision, and that he has got very scant justice from others who have held the field with their preconceived notions; they have, in many cases, come round to his views, which they have adopted without acknowledgement.

Professor A. W. Porter, F.R.S., Assistant Professor of Physics in University College, London, in a letter to the *Lancet*, dated September 27th, 1912, wrote:

> I was present along with Professor Trouton at the test of the case made by Dr. F. W. Edridge-Green, which is described in the *Lancet* of June 22nd, 1912. The examinee passed successfully the official wool test of the Board of Trade, but failed completely when tested with Dr. Edridge-Green's lantern. There is no doubt whatever that the examinee was a very dangerous case, in spite of passing the wool test. This case alone would make it clear that a lantern test is a necessity. But there are lanterns and lanterns, and in my opinion it is exceedingly doubtful whether the new lantern suggested by the recent Departmental Committee has the requisites for effecting a correct discrimination between candidates. To mention one point only—it lacks any possibility of adjusting the luminosity so as to imitate the effects of atmospheric changes. This is the requisite which every lantern must have if it is to discriminate between the safe and the unsafe colour defectives. It is possible to imitate service conditions in this respect with Dr. Edridge-Green's lantern. A lantern which lacks this provision is as useless as the fine weather tests which were made in the open by the Departmental Committee.

At the International Medical Congress at Budapest in 1909 Dr. Edridge-Green read a paper on the theory of vision, by special request, in the two Sections of Ophthalmology and Physiology. Not one word of adverse criticism in either Section was made. (See the remarks in the *Lancet* for 1909, page 1005, and the BRITISH MEDICAL JOURNAL at the time.) The strongest approval of his ideas and methods was expressed. Professor Von Tschermak, Professor of Physiology in Vienna and one of the leading authorities in the world on vision, afterwards wrote to the *Lancet* and supported the theory, pointing out how Edridge-Green's work fitted in with that of other authorities on vision. This letter, which is too long to quote, was written on October 25th, 1909, and published directly afterwards.

Professor C. Timiriazeff of Moscow wrote in 1913 thus: "The chemical hypothesis concerning the functions of the visual purple seems to gain ground. Professor Edridge-Green has succeeded in removing the most formidable obstacle in its way."

It may be remembered that a resolution was passed in the Ophthalmic Section at the Annual Meeting of the British Medical Association held at Brighton last year, condemning the tests at present in use by the Board of Trade. This resolution was passed with one dissentient only, and that gentleman happened to be one of those who was a member of the Departmental Committee who recommended the tests at present in use. It may also be

pointed out that this vote was taken in the middle of the morning, and before an unusually full meeting which was about as representative as any special meeting could be.

Most people will remember the long articles and discussion published in the *Morning Post* early in the present year. A vast amount of evidence was put in supporting the claims made by Edridge-Green, and methods and tests still in use were very freely criticized. None of the facts were disproved, and in fact no one came forward to criticize what was written. Why do not the adherents of the other side appear, and show where the majority are wrong? The answer can be given by any one who will give it a moment's consideration. It is certainly a fact that one unbiassed opinion in favour of a statement is worth twenty of jealous rivals who refuse to give reasons.

Can any one who was present at the meeting of the International Medical Congress in London last year have any doubt as to the favourable reception which Dr. Edridge-Green's paper had? I wonder if any demonstrator at that large meeting got a more enthusiastic reception than did he when he showed some of the most convincing experiments that were ever demonstrated before a large and highly scientific assembly, in which it is perhaps no exaggeration to say that every civilized country in the world was represented.

Only a few months ago a letter was sent to the press, signed by thirty-one of the leading ophthalmic surgeons of the United Kingdom, in which they condemned the method at present in use at the Board of Trade for form vision; they stated that "The wool test for colour blindness is not an efficient test"; and also that "Any lantern used for testing colour blindness should have means for regulating the luminosity of the lights shown." The lantern used by the Board of Trade has no means of regulating the luminosity, simply a means for increasing or diminishing the size of the aperture.

The British Association met in 1912 in Dundee, and a committee was formed to inquire into the subject of colour vision and colour blindness. This committee consisted of the following gentlemen: Professor E. H. Starling (Chairman), Dr. Edridge-Green (Secretary), Professor Leonard Hill, Professor A. W. Porter, Dr. A. D. Waller, and Professor Gotch. The report they drew up stated:

> The inadequacy of the wool test even with additional colours as an efficient test for colour blindness is now established.

They then show from the published statements of the Board of Trade examinations the shocking results of the wool test thus: Out of "105 failures, 55 failed in both wool and lantern test, and 50 in the lantern only. None failed in the wool test only." In a daylight test "the bead test of Edridge-Green is preferable." "The chief difficulty from a practical point of view is the line at which rejection should take place, as there is every grade of transition between total colour blindness and the normal colour sense. If a large number of persons be examined with the Edridge-Green lantern, about 25 per cent. show defects of colour perception. In the majority of cases the defects are slight." Those who know anything about the subject will see how entirely this report backs up the ideas of Edridge-Green, and how thoroughly opposed it is to the theory of Helmholtz on which the wool test is based.

I have heard it stated in the usual loose manner taken by the opposition that Professor Gotch, who unfortunately can no longer be reckoned among the living, was opposed to the ideas of Dr. Edridge-Green. As a matter of fact, he was one of his strong supporters, and although he never published much, there is abundant evidence in existence in his private correspondence to prove this, but I hesitate to quote from this in the circumstances. Unfortunately for the world of science, he died before the report just quoted was brought out, but I have ample proof from some of his colleagues on the committee that had he lived he would have signed it with the others.

Professor von Kries was shown by Dr. Edridge-Green how readily certain colour-blind people were able to do matching tests. He subsequently wrote agreeing with Dr. Edridge-Green's view of this case.

At a meeting of the Paris Ophthalmological Society, held during the present year, Edridge-Green's tests were specially shown by Dr. Sulzer, when not a single adverse criticism was expressed.

Mr. W. M. Beaumont writes in the BRITISH MEDICAL JOURNAL of January 13th, 1912, page 69: "Modern methods of colour vision testing are due to the work of Edridge-Green, and the present-day use of his lantern increases *pari passu* with the disuse of Holmgren's wools."

I am entirely unacquainted with a single person who has been convinced of the truth of the Edridge-Green facts having subsequently changed his opinion and adopted an attitude hostile to his theory and his tests.

At one time it was impossible for him to get a hearing at any scientific meeting, because he brought forward ideas which were altogether hostile to those which were held. Since, however, he has obtained a hearing, the papers which he has communicated to the Royal Society, the Physiological Society, various English and foreign ophthalmological societies, the British Medical Association, the Society of Arts, and many others too numerous to mention, would take up several pages, if only to name their titles. To the mass of this evidence it is impossible to find a single criticism that will hold good. He has challenged the world over and over again to bring forward anything which will disprove his facts or theory, and the result has been that no one has had the power to do so. One has often heard people state that he is wrong. One naturally asks, "In what way?" The answer has never amounted to more than this, though perhaps not expressed in the identical words, "You are wrong because we say you are." "Look at my cases and let me show them to you," says Dr. Edridge-Green. They reply, "We will neither look at your facts nor allow you to show us your cases. You are wrong because we say you are." No better argument than this has ever been adduced against him, and to show that I am not exaggerating let me point out that this very action was taken by the Royal Society Committee and the Departmental Committee appointed by the Board of Trade to investigate the whole subject. On each occasion they refused to allow him to show them a single case or to demonstrate a fact before them. Could a more partial attitude be adopted?

It would not be so bad if the opposition would only act fairly towards him, but this they do not do. Take, for instance, the latest book by Sir William Abney on *Colour Vision* and compare it with his former writings. We find that whereas he was formerly an opponent of Edridge-Green's methods, and a strong supporter of the methods used by the Board of Trade, yet now he recommends almost everything that Edridge-Green has for many years been advocating, and yet never mentions his name from the beginning to the end of the work. Methods which he condemned with the greatest energy a few years ago are now given in such a way that it leaves the impression that he has always advocated them, if not that they were actually introduced by himself. Is this a way which recommends itself to fair dealing with an opponent? The fact of the matter is this: Every one who has looked into the subject has been convinced of the truth and practicability of the methods advocated by Dr. Edridge-Green; his methods have been advocated all over the world; no one has ever arisen who has been able to prove that any fact he has stated is wrong, though there still are those who do not hesitate to use methods to prejudice those unlearned in the matter which are grossly unfair. If they have any criticism to offer why do not they come out in the open and make it, and then give the other side the opportunity of answering? They have scores of times been accused of failing to do so because they know that they could not maintain their position, and this view must be still held until some one can come forward and disprove the facts that are so strongly held and so readily demonstrated to any one who will take the trouble to see such demonstrations. If they will not do this then judgement goes by default, and it must be because they have no answer to give better than they have so often used, namely, that your ideas are wrong because we say they are.

The Royal Society must be held entirely responsible for this state of affairs. It appointed a special committee to do the work which Edridge-Green had been asked to do by the Board of Trade, and after three years' deliberations it recommended the wool test, which even in its improved form allows 50 per cent. of dangerous cases to pass (vide above). The subject is undoubtedly difficult, but if Edridge-Green were able to find out facts which a committee containing such men as Lord Rayleigh, Lord

Kelvin, and Sir George Stokes failed to ascertain, or even recognize when they had been pointed out, the Royal Society should have made some acknowledgement of his work, especially as it utterly discredited him and ruined his career. As I have shown, many have heard of his discredit, but are unaware of the complete change of opinion. I have written this article to show these people exactly how matters stand.

COLECTOMY FOR INTESTINAL STASIS.

BY

A. WILLIAM SHEEN, M.S., F.R.C.S.,

SURGEON, KING EDWARD VII'S HOSPITAL, CARDIFF.

I HAVE done four cases of colectomy for intestinal stasis—one in a man and three in women. Three cases recovered and one died.

History, Symptoms, and Progress after Operation.

CASE I.—W. C., a mason, who had not worked for three months and had done only light and intermittent work for eight years, complained of abdominal pain one hour after meals. He was very constipated, had often gone a week without bowels acting, and was constantly taking castor oil or salts. He had had sickness after nearly every meal, but not lately; he sometimes made himself sick; he had vomited blood (a teacupful) on six or seven occasions. He suffered from distension, flatulence, had got thinner, and was very miserable, said life was not worth living, and felt inclined to finish himself off. He had taken much medicine, and was treated medically in hospital four years ago without relief. He was a thin man, with sallow complexion and dark rings round his eyes; the tongue was coated, the right kidney was movable. There was pain, tenderness, and gurgling over the caecum, tenderness beneath the upper part of the right rectus, and pain in the epigastrium. The urine contained creatin and creatinin in large quantities. A test meal gave total acidity 0.1606 per cent. X-ray photographs of bismuth meals showed great delay, and dropping of the transverse colon so that its centre reached the bottom of the pelvis. After operation, on November 6th, the parietal wound suppurated slightly. The patient got up on November 25th, and on December 11th, five weeks after operation, went home.

CASE II.—A. L., housewife, had been "ailing" many years; suffered from indigestion, and was very constipated. Eight years ago she was fitted with a supporting ring for "womb trouble." The symptoms had been worse for the last four months, and for three months she had passed blood frequently from the bowel, and had grown much thinner. She was a thin, anaemic woman, with lemon-yellow complexion, dark rings beneath the eyes, cold extremities, and a miserable appearance. The lower abdomen was distended, and there was much gurgling of gas; tenderness was most marked in the left iliac region, but was present also over the caecum and pylorus. X-ray photographs of bismuth meals showed, after half an hour, the stomach dropped, so that the greater curvature reached the pelvis, and, after twenty-four hours, large masses in the caecum, with distension of colon and sigmoid. Examination with the sigmoidoscope revealed nothing abnormal. After operation (January 22nd) she at first went on well, but later developed progressive asthenia and cardiac weakness without active symptoms; there was no parietal infection. She died on January 31st, nine days after operation. An examination *post mortem* through the operation wound only showed thin pus in the pelvis and lower abdomen; the bowel wounds were intact.

CASE III.—A. M. S., a married woman, complained that for four or five years she had had pain in the left side of the abdomen, particularly in the lower part. It was worse directly after food; she sometimes vomited, and was only able to take "baby's food." She was very constipated, and passed a quantity of whitish material and "strings" with the motions and at other times. She had had an enema once daily for two years. She was very thin, with a yellow-brown complexion and darkish red areas on the cheeks. There was much tenderness all over the course of the colon, and mucus and shreds in the motions. The sigmoidoscope showed the bowel to be very red. An x-ray photograph of a bismuth meal showed that the transverse colon reached to the pubes. Operation was postponed because after a preparatory enema the patient became dizzy, lost consciousness for two hours, and had great cardiac weakness. It was eventually performed on March 2nd. She did well; no parietal infection occurred, and she left the hospital one month after operation.

CASE IV.—C. A. had been operated on three years earlier for "ulcerated stomach," and had been better until five months ago, when vomiting and pain commenced after food. She had been very constipated for years, and had had three slight attacks of haematemesis. She was a thin woman with a coated tongue and earthy complexion. She vomited frequently after admission, sometimes a little blood. There was tenderness over the caecum and duodenum, a vertical median scar in the epigastrium, and slight oedema of legs. Test meal: Total acidity 0.1752 per cent.; urine, trace of creatin. Mobile right kidney. The case was transferred from a medical ward after prolonged treatment, including morphine frequently. After operation (April 30th) she did well except for slight parietal infection and obstinate cystitis. She left hospital seven weeks after operation.

Details of Operation.

The conditions found in the abdomen and the operative details were substantially the same in all four cases. The preparation, which commenced three days before operation, consisted of enemata, castor oil, clear soup, albumin water, tea, brandy. Case 3 had kerol gr. v thrice daily for a fortnight before operation. Anaesthesia was by scopomorphine and open ether. A continuous submammary saline injection was given throughout the operation. The patient was placed in a partial Trendelenburg position, with the legs over the end of the table. A long vertical incision was made through the inner part of the left rectus. In each case external adhesions were found between colon and parietes and kinking at hepatic and splenic flexures, particularly the hepatic, where the transverse and ascending colon were bound together, ileal kink, dilated duodenum, prolapsed stomach, and transverse colon. In Case 4 (previously operated on) the stomach was adherent to the anterior parietes and the duodenum was most markedly dilated. There were various omental, gall bladder, duodenal, and other adhesions and varying degrees of membrane overspreading the caecum and ascending colon. After separating external and other adhesions, so as to render the colon freely mobile and permit of its being lifted out of the abdomen, it was removed from 8 in. to 9 in. proximal to the ileo-caecal valve to the middle of the pelvic colon; the distal end of the colon was closed and the ileum joined to the colon by an end-to-side anastomosis, taking care that the ileum was not twisted. The hole in the mesentery was carefully closed and an oesophageal tube passed up the rectum and through and about a foot beyond the anastomosis, the operator manipulating the tube and an assistant pumping paraffin in to help its progress. This tube was tied to the anal margin. The parietal wound was closed in layers without drainage, except in Case 3, in which a tube was kept in the abdomen for forty-eight hours.

The dressing throughout was sterilized, frequently changed, hot boracic fomentations. The patient was placed in a marked Fowler's position. The rectal tube drained well in all cases, a few ounces of paraffin being pumped up it every twenty-four hours. It was taken out in seven or eight days. All cases showed some shock after the operation, but it was only marked in Case 2, where the pulse was very weak and rapid from the first.

End Results.

The three cases which recovered were all seen and examined by me on October 5th, 1914, when their condition was as follows:

CASE I (eleven months after operation).—Says he is much better than before the operation, that he can eat practically anything, and that he never vomits. He still feels a weakness in his abdomen and has loose motions, the bowels acting two or four times a day. He has tried two or three times to do his ordinary work, but cannot manage it. He has not got fatter or thinner. On examination he is pale, his eyes are clear, with no dark rings round them. He wears a belt; the recti are slightly separated. There is epigastric tenderness.

CASE III (eight and a half months after operation).—Says she is much better and much fatter; can eat anything now. All her people say how very different she looks. She sometimes has a pain in the back and in the lower abdomen when she walks, and she suffers from palpitation. She takes a tablespoonful of paraffin every morning, and this keeps the bowels regular. She is never sick. On examination she is a fat, healthy looking woman with a good complexion and clear, bright eyes. There is a sound abdominal scar; some tenderness over sigmoid region. She is emphatic in saying that she is better than she has been for many years.

CASE IV (five months after operation).—Much better. Put on a stone in weight after she went home. Her friends say she looks quite different. She is sick at her periods, which are profuse. She takes syrup of figs occasionally for the bowels. She is a healthy looking, well-nourished woman, with bright eyes and clear complexion. There is a strong abdominal scar, with no tenderness.

The operation is a serious one. It requires careful preparation of the patient and careful technique. It should be reserved for cases with marked signs and symptoms of stasis. It contrasts, in my experience, with many cases in which various lesser measures have brought about cure. In all these abdominal cases—which can be grouped under

no short title (unless "stasis" be used), but which present symptoms suggesting trouble now in one region, now in another—it should not be the practice to approach and expose simply the part where the trouble is thought most likely to be, but by a wide incision to investigate the whole of the abdominal contents and to recognize and, as far as possible, remedy the various abnormalities.

The end results, as far as can be judged from these few cases, show that, while great improvement may be expected, a perfect condition of health is not necessarily attained.

AN OPERATION FOR MOVABLE KIDNEY.

By G. S. THOMPSON, F.R.C.S.Eng.,
KIMBERLEY.

In this operation the essential desiderata are (1) a guarantee against recurrence of the undue mobility, and (2) an assurance that the fixation shall be satisfactory, by restoring and maintaining the normal position of the organ.

None of the ordinary operations—extraeapsular, capsular, suture- and tendon-fixation, etc.—can be said to fulfil these essentials. All the usual methods are faulty owing to their uncertainty, whilst their very number suggests that no one is adequate and sure, which is, indeed, true. Hence we may say that so far no good operation has been generally practised for nephroptosis.

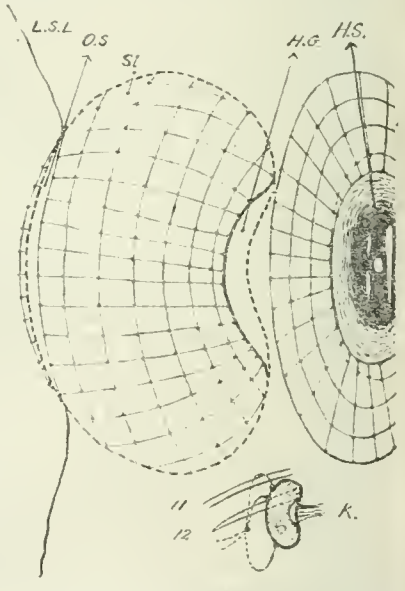
The procedure to be described gives a virtually normal fixation of the organ, and if properly carried out can be relied on almost certainly to ensure a satisfactory and permanent cure. By this method the kidney retains with certainty the position in which it is fixed, and it cannot become displaced again; and, owing to this very fact, care must be taken to see that the correct or proximate position is obtained before anchoring in place. Moreover, although the pathological mobility is corrected by this operation, the normal slight respiratory excursions of the organ are not hindered. One advantage more is that the patient can be got up very much earlier than in the ordinary way—in fact, soon after the wound is healed—namely, by the third week, in contrast with the inevitably prolonged, but not always successful, detention in bed with the other methods.

The principle of this operation is the insertion of the kidney into, and its suspension by, a sling, and the fixation of the latter to the posterior abdominal wall.

The sling consists of a net made from chromicized catgut, or preferably floss silk, the material at present varying according to the predilection of the surgeon, as time alone can show which is to be preferred. These slings are made in various sizes, so that there shall be no difficulty in adapting one to the requirements of the particular case. A gap is left at the hilum 2 in. long by 1 in. broad, so that the border of the net here falls well short of the vessels and duct, and thus no pressure can be exercised on these important structures. The convex border is left open to facilitate the insertion of the kidney into the sling, and at the ends of this opening two free ligatures are left open for the purpose of lacing up the gap, and then using to sling the net to the abdominal wall. The complete sling is thus reniform with a permanent gap at the hilum and a temporary slit along the outer border, the size of the mesh being about $\frac{1}{2}$ cm.

The kidney, having been exposed in the usual way, is inserted through the gap and by the help of the slit into the sling; it is then laced in, but loosely, and when this is completed the ligatures are knotted and thus fixed, the lower ligature ending above opposite the costal groove on the kidney. The lacing should not be tight so that the sling fits the kidney somewhat loosely, in order to allow of the expansion of the organ which is known to occur. It must not be loose enough, however, to permit the net to rotate and impinge by its free inner border on the structures of the hilum, thereby compressing them; and in order to obviate this it is as well to insert one or two fixation sutures so as to include the net and kidney and maintain the proper relative positions of both. The kidney having been invested, the next step is to fix it in position by the free ligatures along the outer border. One is passed external to the normal position of the kidney over the twelfth, or if necessary the eleventh rib, the other through the muscles near the lower end of the viscus, and the two ends tied loosely under the skin; loosely, again, in order that the kidney may be free to move with respiration and adapt itself spontaneously to the exact position, after the patient has been placed in bed with the foot blocked up, should such not have been quite correctly obtained at the time of operation—not always an easy matter to be certain of with the patient in the lateral position. The remaining steps of the operation are as usual.

The netting by its presence will provoke a cellulo-plastic exudation which will surround and infiltrate the meshwork, and in time form by organization a firm adventitious tissue capsule, in addition to the extraneous capsule already present. Probably the former would be sufficient to permanently fix the organ if a slowly absorbable material, as chromic catgut, be used. This seems very likely, but to obviate any possible doubt on this point perhaps it would be better, as suggested, to use floss silk. I say floss silk, and not the ordinary twisted surgical silk, as I think the former smooth material less liable to determine haematogenous bacterial deposit than the rough irritating surface of the latter. In both cases a fibrous tissue capsule will form; with catgut this alone will be permanent, but with silk both will remain. I do not think it likely that floss silk, by its permanent presence, would provoke an excessive formation of fibrous tissue, and thus produce an unyielding covering not altogether desirable in an expansile organ like the kidney; but this might occur with the roughened variety. The only disadvantage of silk in contrast to catgut is the slight tendency of the latter to become the seat of remote haematogenous infection, and give rise to abscess, assuming, of course, the wound heals, as it should, by primary union, and there is no immediate soiling from ungloved hand contamination, as is the rule when such occurs, and not through any imaginary difficulty in sterilizing silk. But the use of floss silk will also tend to obviate this contingency.



L.S.L., Lacing and suspending ligatures; *S.L.*, kidney sling containing kidney (dotted); *O.S.*, outer slit; *H.G.*, hilum gap; *H.S.*, structures of hilum—vessels and duct; *K.*, kidney fixed over twelfth or eleventh rib, triple anchorage by ligatures and pedicle.

When I first developed the above method, in 1909, I used for the posterior base of the sling a reniform plate of thin sheet celluloid, riddled with punch-holes, the remainder of the sling being as above and the netting attached to the border of the plate. When placed in the body this plate soon becomes fixed to the neighbouring parts by infiltration. But I think the elimination of the plate an improvement in technique, and have not mentioned it nor used it latterly.

The first patient operated on, in 1909, is still quite well and free from all her previous troublesome symptoms, whilst the organ still remains quite fixed. The wound healed by primary union, and the patient left the hospital at the end of three weeks.

I think it can be claimed that this operation is an advance on any other, and is sure, quick, rational, simple, as well as satisfactory from the patient's point of view. I consider its merits should cause it to supplant the other faulty and bad procedures which are in vogue at present. A good operation for nephroptosis has long been required, and in the belief that this one meets the case and fulfils all necessary requirements it is submitted with confidence.

COCKROACHES.

By A. E. SHIPLEY, Sc.D., F.R.S.,
MASTER OF CHRIST'S COLLEGE, CAMBRIDGE.

II.

"In Russia the small Asiatic cockroach has everywhere driven before it its greater congener" (*P. germanica*).
DARWIN (*Origin of Species*).

COCKROACHES do a very considerable amount of damage by consuming food supplies. But they do not stop at food supplies; woollen clothing, newspapers—not a great loss—blacking, ink, leather, and even emery paper, are all to their taste, and being of an economical frame of mind they devour their own cast skins and the dead bodies of their relatives. The late Professor Moseley recorded how on one occasion, when on the circumnavigating tour of H.M.S. *Challenger*, a number of cockroaches took up their abode in his cabin and devoured parts of his boots, "nibbling off all the margins of leather projecting beyond the seams on the upper leathers." He further records: "One huge winged cockroach baffled me in my attempts to get rid of him for a long time. I could not discover his retreat. At night he came out and rested on my book-shelf at the foot of my bed, swaying his antennae to and fro, and watching me closely. If I reached out my hand from bed to get a stick, or raised my book to throw it at him, he dropped at once on the deck, and was forthwith out of harm's way. He bothered me much, because, when my light was out, he had a familiar habit of coming to sip the moisture from my face and lips, which was decidedly unpleasant, and awoke me often from a doze. I believe it was with this object that he watched me before I went to sleep. I often had a shot at him with a book or other missile as he sat on the book-shelf, but he always dodged and escaped. His quickness and agility astonished me. At last I triumphed by adopting the advice of Captain Maclear and shooting him with a pellet of paper from my air-gun, a mode of attack for which he was evidently unprepared."

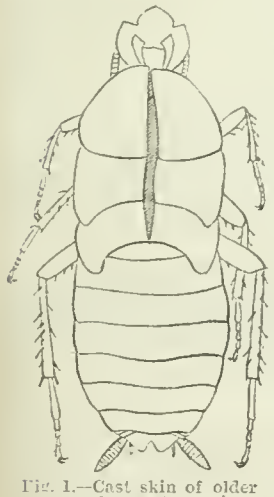


Fig. 1.—Cast skin of older nymph (pupa). × 2½.

It is on record that cargoes of cheeses have been destroyed by cockroaches on ships. Not only do they devour great quantities of each cheese, but these insects defile every one of them with a very tenacious fluid which has a most disgusting smell. This the cockroaches pour out from their stink-glands, making the cheeses of no commercial value.

When a cockroach casts its skin a median longitudinal slit appears on the back of the thorax, and through this slit the insect slowly emerges. With much labour and difficulty it squeezes its body through and pulls one limb after another from its old integument, until at last even the long whip-like antennae are completely withdrawn. Certain portions of its inner anatomy, such as the lining of parts of the breathing tubes, or tracheae, are also left behind. Should the discarded skin not be eaten by the emergent insect, it remains on the floor and might easily be mistaken for a sedentary cockroach but for the fact that live cockroaches never are sedentary.

The incomplete metamorphosis, the generalized character of the nervures of the hind wings, the complete separation of the three thoracic segments (or rather their want of fusion so conspicuous in the higher insects—the flies and the bees), and the undifferentiated condition of the mouth organs, all point to the insect being of a primitive type. But there is no doubt that, whether a primitive insect or not, the cockroach is a very successful one; it is *an arriviste*—as "our lively friend, the Gaul," to quote Mr. Micawber, would say—probably owing to its attaching itself in all cases, and with unvaried devotion, to the habitation of men. Not popular with humanity, it nevertheless ceaselessly extends its domain by slowly yet surely entering into new and hitherto unconquered human habitations. In spite of insect traps and vermin killers, it is extremely difficult to eradicate from a house when once it is well established. It has, in fact, gradually dislodged in most places in Great Britain and Ireland the old domestic

Fig. 2.—Nymph (in last larval stage) escaping from old skin. Magnified.

house-cricket. For in spite of its irritating, and to some people quite maddening, ticking, the "cricket-on-the-hearth" has somehow established itself as a household pet, and one that has won not only our respect but our affection. So curious is our psychology.

"The cockroach has many enemies, and the genus *Sphex* (or *Chlorion*) may be seen hunting about here and there, up and down the roadside and gardens, searching for its favourite prey. It spies out a cockroach, which appears to know intuitively that there is danger at hand, for it shows symptoms of great fright, and seems so confused that it cannot run away. The *Chlorion* pounces upon the insect, clasps it with its mandibles between the head and the corselet, and stabs it in the body with the sting. Then it flies off for a little distance, and awaits the effects of the poison thus introduced; and when the convulsions of the victim have ceased, the clever little insect seizes its stupefied prey, and drags the heavy burden with great efforts to its nest. Usually the opening of the cavity is so narrow that the cockroach cannot be got in, for its legs and wings stick out and prevent its introduction. But the *Chlorion* sets to work and cuts off the legs and the wings, and having thus lessened the difficulty, it strives hard to push the body into the hole, but as this plan usually fails, the hymenopteron enters first of all, seizes the cockroach with its mandibles, and drags it in with all its force. As the integuments of the *Blatta* are more or less soft and flexible, the great insect is at last forced into the gallery, where it never could have been expected to have entered. Such proceedings on the part of the *Chlorion* almost verge upon the domain of reason; and it is difficult to explain them by the notion of that very indefinite quality called instinct, for the manœuvres vary according to circumstances, and there appears to be an intelligent method of overcoming every difficulty."[1]

Apart from animals which eat it, there are a number of parasites which infest it, beginning with the parasitic beetle *Symbius blattarum*, whose wingless females attach themselves to the bodies of the cockroaches and feed upon their tissues. Then occasionally a round-worm, *Filaria rhytiplcurites*, whose sexual stage is passed in the rat, is found in its larval stage in the fat bodies of the cockroach.

Two years ago Dr. C. Conyers Morrell undertook some investigations and observations as to what part, if any,

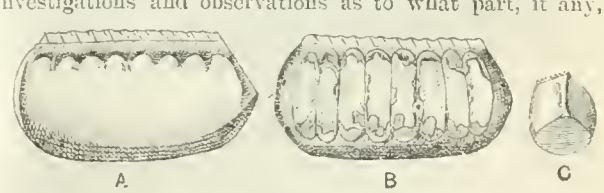

Fig. 3. Egg capsule of *P. orientalis* (magnified). A, External view; B, opened; C, end view.

cockroaches played in the dissemination of pathogenic microbes, his object being, as he says, "first to ascertain what bacilli belonging to the colon group are likely to be conveyed to food and milk by this insect, and secondly to find whether known bacteria and moulds can be transmitted by the faeces." Dr. Conyers Morrell's experiments were conducted on one of the Union-Castle liners sailing to South Africa, and the insects which were investigated

were collected only from the larder or passages adjacent to the kitchens; in no case were they taken from lavatories or from state-rooms. The general condition of the ship, which was almost new, was one of exceptional cleanliness, and thus afforded good conditions for the experiments. Dr. Morrell was of opinion that there was little danger except by contamination from the faeces of the infected insect.

One of his first experiments was to prove that should cockroaches fall into the dough which was being baked for bread the heat of the baking entirely destroyed the bacilli that were in the alimentary canal of the insect. With regard to infection with the colon bacillus he kept an infected insect under the best antiseptic conditions he could compass until it had passed some undigested food. Of this undigested food an emulsion was prepared, and cultures were made from it on bile-salt medium and in litmus-milk. Afterwards special cultures were made in gelatine and peptone solutions. Incubation was conducted in all cases at 37° C., and cultures were made from seventeen specimens. Five of these produced colonies of bacilli on the bile-salt medium, with subculture results as follows: Four produced acidity and clotting of milk, acid and gas in glucose, lactose and saccharose, and production of indol. But the bacilli did not liquefy gelatine, and were Gram-negative. One specimen produced gas in glucose and lactose and liquefied gelatine and coagulated milk. The former in its reaction corresponded with the *Bacillus lactis aërogenes*, the latter with *Bacillus cloacae*. In five cases greenish moulds of the aspergillus variety were found after inoculating litmus-milk.

Cockroaches will devour human sputum with avidity, and are frequently to be found in spittoons (or, as the more delicately minded American calls them, "cuspidors"), and it is interesting to know that after feeding the insects on infected sputum from a tuberculous patient, the tubercle bacilli are found in the faeces within twenty-four hours; two specimens which had been fed on staphylococci showed these pathogenic organisms in their faeces and in the cultures on agar-agar, which were obtained from these dejecta.

I have quoted largely from this important paper, and now propose to quote a good deal more, and thus I append Dr. Conyers Morrell's conclusion of the important experiments he conducted on the Union-Castle liner.

"The foregoing experiments, though insufficient in number to afford a basis for working out percentage results, are, I think, of some value, in that they prove the following facts:

"The common cockroach is able by contamination with its faeces (1) to bring about the souring of milk, (2) to infect food and milk with intestinal bacilli, (3) to transmit the tubercle bacillus, (4) to disseminate pathogenic staphylococci, (5) to transmit from place to place destructive moulds.

"These facts, taken in conjunction with the life-habits of the insect, lead to the conclusion that the cockroach is able to and may possibly play a small part in the dissemination of tuberculosis, and in the transmission of pyogenic organisms; that the insect is in all probability an active agent in the souring of milk kept in kitchens and larders; and that it is undoubtedly a very important factor in the distribution of moulds to food and to numerous other articles, especially when they are kept in dark cupboards and cellars where cockroaches abound. The distribution and numbers of the cockroach are rapidly increasing, and unless preventive measures are adopted the insect is likely in the course of time to become a very troublesome and possibly a very dangerous domestic pest."[2]

THE next Ophthalmological Congress will be held at Oxford on July 15th and 16th, when a discussion on industrial diseases and accidents will be opened by Dr. Frank Shufflebotham. The honorary secretary of the congress is Mr. Bernard Cridland, of Wolverhampton.

THE Georgia State Sanitarium at Milledgeville has been chosen by the United States Government as a station for experimental work on pellagra. The patients will be separated and kept under special treatment—carried out under the charge of two experts of the United States Public Health Service.

A CASE OF TETANUS TREATED BY INJECTIONS OF CARBOLIC ACID.

BY

PURVES STEWART, M.D., F.R.C.P.,

AND

J. T. C. LAING, M.B., C.M.,

THE following case of tetanus appears worthy of record, in view of the fact that the disease, in spite of treatment by antitetanic serum, was steadily advancing. In such cases it may be useful to remember that we have other methods of treatment at our disposal.

The patient, aged 27, was an officer who, on October 27th, sustained several shell wounds—one in the right groin, another in the right knee, a third, more severe, in the right hand. The wound of the hand became septic, and appears to have been the point of entrance of the tetanus infection. The patient came under the care of one of us on October 28th, in the Robert Lindsay hospital for officers.

On November 3rd—that is, seven days after the wounds—tetanic rigidity of the jaw muscles commenced. On the same evening he was given a subcutaneous injection of 1,500 units of antitetanic serum. The rigidity continued to spread, and extended to the abdominal and spinal muscles.

On November 4th 1,500 units of antitetanic serum were injected intrathecally by Mr. Tyrrell Gray. The foot of the bed was subsequently elevated for several hours, in order to assist diffusion upwards of the serum. On November 5th a third dose of 1,500 units was given subcutaneously. The patient was also given full doses of bromide and chloral.

Notwithstanding the foregoing measures his condition became steadily worse, and on November 6th the rigidity of the jaws was extremely marked. The teeth could not be separated more than a quarter of an inch. The facial muscles were rigid, with risus sardonicus. The sterno-mastoids were tonically contracted, also the spinal and abdominal muscles, and slight stimuli produced typical tetanic spasms. The patient perspired profusely; his temperature was normal.

At this stage it was decided to commence treatment by means of carbolic acid. Accordingly 2 c.cm. of a 5 per cent. solution were injected hypodermically into the abdominal wall every two hours. Improvement commenced on the same day. The spasms of the jaws, sterno-mastoids, and facial muscles steadily improved. The tetanic spasms diminished in frequency, and on November 7th he had only one spasm, as compared with twelve on November 5th. The carbolic injections on November 7th were reduced in frequency to four-hourly, but on November 8th, owing to a slight recurrence of tetanic spasms, the injections were again increased to two-hourly for a couple of days. The spasms promptly diminished. From November 9th onwards the patient's convalescence was uninterrupted. The thoracic and abdominal muscles were slower than the other muscles in losing their tonic spasm.

On November 12th a diffuse, red, punctate rash appeared in both flanks, apparently a carbolic rash. The temperature remained normal throughout. The urine, which was examined daily, never showed any pigmentation nor the slightest trace of albuminuria. From November 13th to November 18th the injections were reduced to four-hourly. They were then stopped. The patient was discharged on December 5th, completely cured.

This case exemplifies the efficiency of the carbolic acid treatment of tetanus, originally introduced by Baccelli some fifteen years ago. From a study of the statistics of published cases treated by antitetanic serum, the gross mortality varies from 78.9 per cent. in Permin's 199 cases to 61.8 per cent. in Iron's 225 cases. On the other hand, the statistics of the carbolic acid treatment, as recorded by Baccelli, give a gross mortality of 17.4 per cent. in 190 collected cases. These figures are suggestive, and we consider it of the highest importance that cases of tetanus which may occur amongst our wounded officers and men during the present war should be given the chance of this treatment, which in no way supersedes tetanus antitoxin as a preventive, but appears to have certain advantages as a remedial agent once the disease has actually developed. It appears to us that the value of antitetanic serum lies chiefly in its preventive action.

THE New York Rockefeller Institute for Medical Research will receive £40,000 under the will of Mr. Henry Rutherford, to be applied to the investigation of cancer.

A ROENTGEN RAY ASSOCIATION, intended "to improve the practice and study of roentgenology and to form a closer association among roentgenologists or x-ray experts," has recently been founded in New York. The founders are Drs. George S. Dixon, I. Seth Hirsch, Adoniram Judson Quimby, William A. La Field, and Archibald P. Evans.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

PNEUMONIA FOLLOWING ANTITYPHOID INOCULATION.

In Sir William Osler's address on "The War and Typhoid Fever," accounts are given of two cases in which lobar pneumonia occurred within twenty-four hours of antityphoid inoculation. In the following case the interval was greater.

Private P., aged 25, received the usual first dose at Codford on October 27th. He became feverish on the following day, and was admitted to the 2nd Southern General Hospital, Bristol, on October 30th under my care. He then had a temperature of 103°, a cardiac rate of 108, and a respiration rate of 26. Physical signs were negative. He remained in this condition until the evening of November 1st, when the respiration rate rose to 36, and on the following morning fine crepitations were heard at the base of the left lung. Consolidation was well marked on November 3rd, and the patient began to cough up rusty sputum, which was found by Captain Fortescue-Brickdale to contain pneumococci, streptococci, and Gram-negative rods. The temperature fell by crisis on November 8th after a severe illness.

Lobar pneumonia thus began on the fifth day after inoculation, and in the interval the patient was continuously feverish though without any abnormal symptoms or physical signs.

F. H. EDGEWORTH,
Bristol. Captain R.A.M.C.(T.).

INJURY TO HEART WITHOUT FRACTURE OF RIB.

MR. C., whilst getting into his governess cart, struck his chest against the step iron, owing to the pony moving as he was getting in at the back. He complained of pain in the chest after the accident, and also mentioned it at a board meeting which he attended shortly afterwards; he seems to have forgotten all about it until three days later, when he had a fainting attack, and complained of a very acute pain over the region of the apex of the heart.

When I saw him, late at night, he was suffering intense pain over the apex of the heart; he was very collapsed, the pulse was very irregular and almost imperceptible. Early next morning he was still in great pain. There was a distinct but very localized rub at the apex, and the pain was almost entirely confined to this area; there was also very slight discoloration of the skin at this spot. In a day or two the rub ceased, due to slight effusion of fluid. He had several other severe fainting attacks, and later developed some hydrothorax. He died about two weeks after the accident.

Post-mortem Examination.

There was a fair amount of fluid in the pleural cavities. The pericardium contained some blood-stained fluid. Situated at the apex of the heart was a ragged depression about the size of the tip of the finger; there was a good deal of lymph, especially near the bruised portion, and spreading up over the surface of the right ventricle; the wall of the heart at the bottom of the bruised indented portion was very thin. I examined carefully for any injury to the ribs, and there was no sign of any fracture or partial fracture.

Evidently at the same moment as the apex of the heart came against the inner chest wall the injury must have occurred, the ribs being rather more elastic than usual for a man over 50.

Staple Hill. MAURICE C. BARBER, M.B., M.R.C.S.

ACCORDING to the *Cronica Medico-Quirurgica de la Habana* it is reported that the Mexican National School of Medicine has closed its doors.

THE American Medical Association will hold its next annual meeting at San Francisco in the second week of June, 1915.

GLASGOW ROYAL INFIRMARY.

ACUTE INTESTINAL OBSTRUCTION DUE TO LARGE GALL STONE: REMOVAL OF STONE BY ENTEROTOMY: RECOVERY.

(By JOHN A. C. MACEWEN, M.B., C.M., B.Sc., F.R.F.P.S., Surgeon to the Elder Hospital; Assistant Surgeon, Glasgow Royal Infirmary; Senior Assistant, Regius Professor Surgery, Glasgow University.)

THE patient, a woman of 53, was admitted on August 26th in an almost collapsed condition, with symptoms of acute obstruction. Her condition was such that a history of previous illness was unobtainable, but her friends stated that she had been vomiting very frequently during the previous forty-eight hours, that there was paroxysmal abdominal pain, and that constipation had been absolute in spite of the administration of purgatives. The temperature was 101° F. and the pulse 120.

Vomiting continued, the matter being slightly faecal in character. As the abdominal wall was very fat and the abdomen distended and rigid, no definite information could be obtained by palpation.

In the absence of guiding symptoms an exploratory incision was made in the left iliac region, the presence of carcinoma of the colon in that region being considered probable. A large quantity of glairy fluid, resembling that sometimes found in ovarian cysts, poured out on the peritoneum being opened. As the large intestine was collapsed, the fingers were introduced, and in the region of the umbilicus a hard mass in the bowel was detected. The portion of the bowel was carefully brought down, and with a little difficulty, owing to its size, was brought out through the wound. It was now found that the bowel (ileum) was occupied by a mass about the size of a walnut, which distended the lumen, but was not impacted, it being quite easy to thread the mass from one portion to another. A small longitudinal incision was made, the mass slipped readily out, the bowel was rapidly stitched, the wound packed, and the patient returned to bed.

Notwithstanding the injection of saline solution, and other stimulation, the patient's condition remained critical for some days, but improvement ultimately set in. A noticeable feature was the amount of glairy discharge which came away from the wound, both at the time of operation and for about three weeks thereafter, when it gradually diminished and ultimately ceased.

The stone was of a dark brown colour, friable, laminated, weighed 258 grains, and measured 1½ in. in long diameter, 1¼ in. in short diameter, and 3½ in. in circumference.

The patient's history, obtained after recovery from the operation, was that for some months previous to admission she had vomited about half a pint of yellow bilious matter about once a month, the attacks being accompanied by abdominal pain which sometimes went in sharp spasms through to her back. Two days prior to admission she suffered from an attack of pain in the stomach after a light meal. She took an emetic and vomited, and continued to vomit up to the time of admission.

Remarks.

One would imagine in cases such as this that the passage of a large stone from the gall bladder to the intestine, which presumably occurs by a process of extensive ulceration both of the gall bladder and intestine, would be accompanied by a period of severe illness of considerable duration. Here, however, beyond occasional bilious attacks, the patient felt quite well until a couple of days prior to admission. The period of two days would appear to be too short to cover the process of ulceration of the walls and passage of the stone, and rather to coincide with the obstruction caused by the slow progress of the stone through the intestine.

ROYAL SOCIETY OF MEDICINE.

SECTION OF OBSTETRICS AND GYNAECOLOGY.

At a meeting on December 3rd, Mr. CLIFFORD WHITE showed: (1) An *Ovarian tumour which had been infected with tubercle;* (2) a case of *Interstitial tuberculous salpingitis*, in which tubercle bacilli were found in a small intramural abscess. Dr. MACNAUGHTON-JONES demonstrated a *Myomatous uterus containing large numbers of intramural and submucous growths.* The tumour, which weighed 1 lb. 1 oz., was removed from a patient aged 47. There were three larger intrauterine growths, two in the fundal cavity, and a cervical polypus. Altogether, in this comparatively small-sized tumour, there were from thirty to forty growths, subserous, in the cavity and in the wall. The uterine surface was studded over with them, and its wall was a mass of nuclei. It was noteworthy that the patient sought advice rather for other symptoms than pelvic ones. Only for the past year had she suffered from menorrhagia. Dr. TREVOR B. DAVIES recorded: (1) A case of *Sarcoma of the cervix uteri.* The patient, who was under the care of Dr. T. G. Stevens, was a single woman aged 29. There had been vaginal bleeding for three weeks. The menstrual periods were quite regular. Examination revealed a soft, smooth, rounded, bleeding tumour growing from the anterior lip of the cervix, and filling the upper part of the vagina. The uterine body was normal in size and position. A hysterectomy was performed, the vagina being divided well below the growth. Microscopically, the appearances were those of a spindle-celled sarcoma. (2) A case of *Sarcoma of the broad ligament.* The patient, who was under the care of Mr. Drew, was aged 51, married, and had two children. Menopause one and a half years ago. She complained of pain in the right side of the abdomen running through to the back. In March 1910, Mr. Drew removed an inflamed appendix vermiformis. The appendix-scar was tender, and the right kidney freely mobile. Examination per vaginam showed that to the right of the cervix lay a hard fixed mass the size of a large walnut, which bulged down into the vaginal roof. The uterus was normal in size and position and quite separate from the mass. At the operation a hard swelling the size of a duck's egg was found between the layers of the right broad ligament. It was shelled out with the finger and the broad ligament closed. In less than three weeks another fixed mass was felt in the same position. The tumour was about the size of a Tangerine orange, with a small mass the size of a large cherry projecting from its upper part. Microscopically, the growth was a typical spindle-celled sarcoma composed of large spindle cells arranged in bundles without any fibrous stroma, but with numerous thin-walled blood vessels. Dr. HUBERT ROBERTS showed a case of *Pyometra and cancer of the cervix.* The specimen was removed from a patient aged 62, who had had seven children and two abortions. Menopause seventeen years ago. History of severe haemorrhage three months before admission, and also gushes of putrid fluid accompanied by severe colicky pains. The cervix revealed no ulceration or new growth. The uterine body was enlarged, soft and mobile. During hysterectomy the vagina ruptured and foul material escaped into the pelvis. The lower part of the abdominal wound became infected, but the patient subsequently did well. The specimen showed a tubular solid growth of the whole of the cervix, which extended from the portio vaginalis to the os internum, and was densely hard. The cavity of the uterus was distended with purulent débris. The growth was a squamous-celled epithelioma. Dr. CUTHBERT LOCKYER showed a case of *Double ureter* which simulated a parovarian cyst of the right broad ligament. The specimen was obtained from a patient aged 63, in whom Dr. Routh had noticed an enlarged and tender right kidney for two years previously. Pyonephrosis had been suspected. There was *coli* bacilluria, for which many injections of autogenous vaccine had been given without improvement. A hard, tender, solid lump was felt in the left posterior quadrant of the pelvis. In March, 1914, the patient began to lose blood from the uterus. As the menopause occurred twenty years previously at the age of 43 years, this latter symptom raised the question of malignancy starting in the body of the uterus. At the operation two tumours were found (1) an isolated calcareous myoma adherent to the rectum and to the back of the broad ligament; and (2) above this, and separate from it, a solid tumour of the ovary, which proved to be malignant. The uterus, together with the tumours, were removed. The right broad ligament contained a cystic swelling of the size of an orange. This proved to be a dilated ureter twisted upon itself. In size it corresponded to a distended coil of small intestine. This hydro-ureter was removed; the corresponding kidney was left *in situ*. The contents of the ureter were found after operation to be two calculi (blocking the lower twisted portion) and foul stagnant urine. Six weeks later a perinephric abscess was opened, since when the kidney had given no trouble. The cause of the uterine haemorrhage was two myomatous polypi and endometrial hyperplasia. The uterus was not malignant. Dr. HERBERT SPENCER read a communication on a case of *Extensive cancer of the cervix with pyosalpinx, well seven years after Wertheim's hysterectomy.* The patient was aged 28. The cervix was occupied by a large ulcerated growth as big as a small apple, which distended the vagina. The uterus was fixed by thickening in the left broad ligament and the left sacro-uterine ligament; the thickening was not nodular. Operation was performed at University College Hospital on February 16th, 1907. The cervical growth was first curetted and cauterized, and several protruding masses were cut off with scissors. A solution of formalin (10 per cent.) was then applied. The operation was rendered difficult owing to the presence of bilateral pus tubes, which were adherent to the pelvis and rectum. The separation of the left ureter was also difficult. No glands were removed. A small abdominal drain was used. Urine escaped by the abdominal drainage tube for a few days, and afterwards by the vagina. The patient recovered and left for Canada, where a vesical fistula was found and closed by Dr. Marlow of Toronto. Dr. Spencer examined the patient every year for four years after operation and found no recurrence. In a letter from Canada, dated March 24th, 1914, the patient reported herself as in the best of health. Mr. THOMAS G. STEVENS read a communication on two cases of *Hysterectomy for ante-partum haemorrhage:* (1) Central placenta praevia in a patient, aged 37, twenty-eight weeks advanced in her twelfth pregnancy. She was admitted to Queen Charlotte's Hospital at 1 a.m., having had a severe blood loss the evening before. The os uteri was found to admit two fingers, and the whole lower uterine segment was covered by placenta as far as the finger could reach. A Champetier de Ribes's bag was introduced above the placenta, considerable haemorrhage occurring during the procedure. Subcutaneous saline and morphine, ¼ grain, were given owing to signs of collapse. Seven hours later the bag was expelled, the uterus was in a state of tonic contraction, and the cervix had closed up after allowing the bag to pass. No further haemorrhage occurred. At this point Mr. Stevens saw the patient, and came to the conclusion that hysterectomy without opening the uterus would be the best method of delivery. As the child was already dead, this operation was performed under morphine-atropine open ether anaesthesia, with infiltration of the abdominal wall by urea-quinine hydrochloride. Four pints of saline solution were infused under the breasts during the operation. The operation proved to be very easy, and was practically shockless. The patient made an uninterrupted recovery. (2) External and concealed accidental haemorrhage in a patient, aged 33; about thirty weeks advanced in her ninth pregnancy. She was admitted to Queen Charlotte's Hospital at 4 a.m. with the history of a big haemorrhage at 10 o'clock the previous night. There was no haemorrhage on admission; the pulse was 112 to 120; the patient looked very anaemic, and no placenta could be felt in the lower uterine segment. She was kept quiet in bed, and twelve hours after admission bleeding recommenced. An attempt to introduce a de Ribes's bag failed owing to the rigidly closed internal os. Pituitary extract, ½ c.cm., and a little later morphine, ¼ grain, and 4 pints of saline were given subcutaneously, after which the external bleeding ceased. The pulse, however, was 150, and examination of the uterus resulted in a provisional diagnosis of concealed haemorrhage. As the child was dead, the internal os uteri closed, and the patient in a very serious condition, Mr. Stevens decided to do hysterectomy without opening

the uterus. This was done under morphine-atropine open ether anaesthesia with novocain infiltration of the abdominal wall. The operation was very easy and shockless, the pulse falling from 150 to 134 at the end of the operation. The patient made a good recovery. The reason for the choice of hysterectomy rather than Caesarean section in these two desperate cases was the impossibility of any guarantee that the latter operation could be done without further considerable blood loss. When Mr. Stevens saw the patients there was no possibility of delivery *per vias naturales* without a considerable loss. The actual amount of blood lost during the operation in each case did not amount to 3 oz.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF OBSTETRICS.

AT a meeting on November 27th Dr. SOLOMONS showed a *Sarcoma of the uterus*, removed from a woman aged 47, who had been married sixteen years. She had had four children and one miscarriage, the last child eight years previously, the miscarriage six years previously. She complained for a year of difficulty in walking, with pain and tenderness in the lower abdomen. Menstruation had been irregular for the last six months. On bimanual examination the uterus was found to be enlarged by a tumour on the anterior wall. On opening the abdomen extravasated blood was seen, which exuded from the region of the right cornu. He considered that the case was one of sarcoma, and performed Wertheim's hysterectomy. The glands were not involved. The patient made a good recovery. The specimen was examined by Dr. WIGHAM, who reported that the sarcoma was of the large, mixed-celled variety, which had undergone almost complete necrosis with much haemorrhage into the necrotic tissue. Only in the outlying parts, where the tumour was infiltrating the muscle of the uterus, could its structure be made out. Referring to the fact that sarcoma of the uterus was said to be a disease of early life, Dr. SOLOMONS stated that he had now seen a fair number of cases, and all were about the time of the menopause. Remarks were made by Professor A. SMITH, Dr. GIBBON FITZGIBBON, Dr. ROWLETTE, and the President, Dr. M. J. GIBSON; and Dr. SOLOMONS, in reply, said that on the whole he considered the prognosis comparatively good. Sir WILLIAM SMYLY, in showing a specimen of *Tubal abortion*, said it was chiefly a blood clot, and a little fetus, about three-quarters of an inch long, was to be seen in the middle of it. The capsule of the tumour was formed by the extremity of the Fallopian tube and some blood. The patient came into the Adelaide Hospital on October 28th. She was aged 28, had been married three years, and had one child aged 2. She menstruated regularly up to June, missed that period and the two following ones. On August 10th red discharge set in, and after ten days she got pains in the back, and was supposed to have aborted about August 20th. From that time there was continuous red, bloody discharge from the vagina, and she was sent into hospital to be curetted. On examination, the tumour was found on the right side of the uterus, and attached to it by a pedicle. The peculiarity of the case was the small fetus, three-quarters of an inch long. Supposing the pregnancy to date from May, which would have been five months, that would have been a long time for such a small fetus to have remained preserved. The symptoms were those of ectopic pregnancy, but he considered it more likely that the supposed abortion was really an abortion, and that between that and October she conceived the ectopic pregnancy. The case was discussed by Professor A. SMITH, Dr. SOLOMONS, Dr. GIBBON FITZGIBBON, Dr. MADILL, and the PRESIDENT. Dr. E. H. TWEEDY read short notes on the etiology and treatment of *Toxaemic pregnancy*, based on a case of severe hyperemesis gravidarum. Recovery from a very severe and exhausting attack followed on abstinence from all food and the administration of rectal injections of warm alkaline solutions to the amount of 4 pints in twenty-four hours. The processes which normally took place between food particles and their antibodies were undoubtedly interfered with in pregnancy, and it was reasonable to conclude that this interference was connected with the foreign albumin derived from chorionic villi, which was known to circulate in the blood. He suggested that the efforts to neutralize this foreign albumin caused a diminution in the blood of normal food antibodies. Morning sickness was an effort to eliminate food which had failed to combine with its proper antibody. The extent of this failure was the measure of severity in toxaemia. Clinical evidence was convincing that food, even milk, could induce vomiting or convulsions. Injurious consequences of food were not due to (1) irritation or (2) fermentation, but to absorption following the earliest processes of digestion. Carbohydrates and proteins were equally injurious. When it was once admitted that food could to some extent increase the severity of toxaemia, it was not logical to limit the extent of its deleterious action. Dr. FITZGIBBON, Professor A. SMITH, Dr. SOLOMONS, Dr. MADILL, and the PRESIDENT took part in the discussion.

NORTH OF ENGLAND OBSTETRICAL AND GYNAECOLOGICAL SOCIETY.

AT a meeting held at Sheffield on November 20th Dr. HELLIER (Leeds) exhibited a specimen of *Cystic sarcoma of the uterus* removed from a multipara aged 46, who had noticed a steadily growing lump in her abdomen for fourteen months, until it reached the size of a four months pregnancy. The tumour was removed by supravaginal hysterectomy and was then found to be converted into a multilocular cyst filled with yellowish serous fluid. Dr. GEMMELL (Liverpool) exhibited a specimen of *Fibroids complicating pregnancy*, from a primipara aged 41. It was considered safer for the patient to have the pregnant uterus removed than to wait for Caesarean section. Dr. STOOKES (Liverpool) exhibited a specimen of *Fibroids complicating pregnancy*, from a primipara, aged 30, five months pregnant. The fibroid had undergone cystic degeneration. Mr. W. R. FAVELL (Sheffield) related (1) a case of *Labour obstructed by fibroid*. The patient, a 3-para aged 37, had been in labour for a week, during which time meconium was passed. (2) A case of *Chorion-epithelioma*. The patient was a woman, aged 23, whose only pregnancy ended in a two months abortion in September, 1913. The uterus was removed a year later with mass behind it with a history like ectopic gestation. Later a small bleeding growth in the vagina was removed. The patient was now gaining weight. Mr. MILES H. PHILLIPS (Sheffield) described a case of *Hydrometra* the size of a seven months pregnancy removed from a multipara aged 56, married thirty years. The uterus consisted of a thin-walled cyst lined with columnar cells. The cervix was blocked with fibrous tissue. Mr. W. W. KING (Sheffield) read notes (1) of a case of *Concealed accidental haemorrhage* with haematoma in the broad ligament treated by Caesarean hysterectomy; (2) of *Acute hydramnios* in a 9-para, aged 30, six months pregnant. The symptoms were rapid enlargement of the uterus with great tenderness and abdominal pain. Delivery was followed by severe *post-partum* haemorrhage.

ASSOCIATION OF REGISTERED MEDICAL WOMEN.

AT a meeting, on December 8th, Dr. MABEL PAINE read a paper on *Mucous colitis*, giving an account of the etiology, symptoms, prognosis, and treatment of the disease, and laying stress upon the unsatisfactory results obtained by most methods of treatment. Dr. LAURA VEALE described the Harrogate treatment of mucous colitis as carried out since 1905. In 1906, 4,864 patients had come for treatment, 11,706 in 1910, and nearly 20,000 in 1913. The disease was there looked upon as a secretion neurosis, and the points in the treatment were: (1) To obtain a daily evacuation of the bowels; (2) to remove infective material from the bowel by lavage; (3) to alleviate pain; (4) to improve the general health. Irrigation was carried out by means of a bland fluid, after the bowel had been partially evacuated by means of a blue pill at night, and hot, strong sulphur water taken before breakfast. Sulphur water gave rise to copious watery evacuation, caused no griping pain, and could be comfortably taken for weeks; it improved the appetite, stimulated gastric secretion, and acted as a diuretic. Lavage, using 10 to 40 oz. at a temperature of 96° to 102°, was carried out three times weekly for three to six weeks, and was followed by

a sulphur bath and a douche at 110°. The diet found most suitable in Harrogate was one giving rise to a small and non-irritating residuum; vegetable food was put through a sieve, recooked food was forbidden, fat was reduced to a minimum. Moderate exercise was allowed, and a maximum amount of sleep advised. Drugs were seldom used. Haemorrhoids, if present, often disappeared under the treatment, and no enema rash was ever observed. Patients were advised to repeat the course of treatment two to three times, and they could continue the lavage at home, using sulphur water, sulphaqua tablets, or normal saline solution. The condition commonly recurred in the late autumn and early spring, and often commenced with severe diarrhoea. A starch and opium enema should be given, followed by lavage with sulphur or saline. Thus a bad attack could often be warded off. Frequently pelvic disorders were found in connexion with the condition, and if these could be cured the mucous colitis often disappeared. Dr. BARRIE LAMBERT had found that patients complaining of most pain suffered least from toxaemia, and vice versa; the pain and characteristic sensations were quite genuine and not merely neurotic manifestations. The bowel became fixed in a state of spasm, but the abdomen was not generally tender. Discomfort on palpation was often due to displacement of gas and the sigmoid felt like a tight tube. Cure was rare and relapse usual. Abdominal massage was of great value and the patients usually bore deep massage well; the spasm could be felt to relax, especially after vibratory treatment. But although the patient's condition often improved greatly, the signs of the disease usually persisted. Mrs. FLEMMING, M.D., described cases under her care; one was seen four years ago who had passed blood and mucus for six months. On palpation a swelling resembling a tumour of the transverse colon was detected. Laparotomy was performed and the colon was found to be healthy. Gall stones were present and were dealt with. The patient passed no more blood or mucus at the time, but she quickly relapsed and had had frequent attacks ever since. Dr. JANE WALKER had seen several patients cured at Plombières and Harrogate. Good effects could be obtained by the administration of thyroid and from injections of ichthyol (1 drachm to two pints) into the bowel. Some patients could not stand treatment by irrigation. Dr. DOROTHY HARE had obtained one cure by treatment with antistreptococcic vaccine, the patient having remained well until now (nine months after treatment). One case was associated with threadworms and another with appendicitis, removal of the appendix relieving the condition. Dr. MARY SCHARLIEB said that in India mucous disease in children was common; it was tractable and curable. As in adults, it was accompanied by nervous manifestations, such as night terrors, etc. Dr. LOUISA ALDRICH BLAKE described a case of liver abscess recently under her care at the New Hospital for Women. A married woman, aged 34, complained of diarrhoea, which came on suddenly, and continued for a month. She appeared very ill, pale and thin, like a patient suffering from advanced tuberculous peritonitis or ulceration of the intestine. A ridge resembling rolled-up omentum could be felt; temperature was normal, pulse 128. There was resistance and pain over the right iliac region and through a small incision half a pint of clear fluid was evacuated; there was no evidence of tuberculous disease. Adhesions and the presence of the mass like rolled omentum suggested malignant disease. The following day she had an attack of heart failure, and some hours later vomited a small amount of dark blood. At night a second attack of heart failure caused death. *Post mortem* the large bowel was studded with numerous raised ulcers, typical of amoebic dysentery; the liver was enlarged and on section a single abscess was found containing one pint of pus. The small intestine was normal. The patient had never been abroad. Dr. LESBIA LEPPER showed specimens and slides of the case. The liver abscess was in a necrotic septic condition; cultures from the pus remained sterile. No amoebae were found.

DURING the fortnight ending December 17th, 15 cases of plague and 11 deaths from the disease were reported in Mauritius. Since the first notifications of plague in the island this autumn, 46 cases and 38 deaths have occurred.

Reviews.

A TEXTBOOK OF BACTERIOLOGY.

THE fifth edition of Professor HEWLETT'S *Manual of Bacteriology: Clinical and Applied*[1] is, like its predecessors, a mine of useful information. It must be remembered that the pathogenic varieties form but a small class among bacteria. None the less, our knowledge of the pathogenic bacteria, incomplete as it is, includes so vast a mass of information, and such a series of apparently unrelated and isolated observations, that the writer of a comparatively small textbook is faced with no easy task in the selection and arrangement of the more important facts. To this initial difficulty is added the recurrent necessity of revising what has been written in the light of new discoveries and of incorporating the best authenticated of an ever-increasing mass of new observations. These difficulties must be obvious to all who possess even a rudimentary knowledge of bacteriology. But from the point of view of the practitioner and of the student of medicine, bacteriology is an applied science, and it is from this point of view that the author treats his subject. It has been the author's obvious intention to collect from the vast mass of bacteriological literature those facts which it is important for the medical student to know, and in the arrangement of these facts to lay stress on those which have the most direct bearing on clinical medicine and surgery. In the execution of his scheme Professor Hewlett has undoubtedly succeeded.

The utility of the book is increased by the addition of chapters dealing with various subjects which seem to have come by general usage within the province of the bacteriologist. The sections dealing with the facts and theories commonly included under the term "immunity," and the summaries of recent additions to our knowledge of the more important protozoan and microzoan parasites, are admirably done. There is an excellent chapter on the bacteriological examination of water and milk, and there is a short account of the mode of action of the more important disinfectants. These sections greatly increase the value of the book to medical officers of health and to those preparing for examinations for a diploma in public health.

The author includes a description of practical methods and brief, but sufficient, as far as written instructions can be sufficient, directions on matters of bacteriological technique. The methods described are well selected, and are those which are in actual use at the present day. They do not include an account of methods and illustrations of apparatus which are no longer in common use. The older methods have, no doubt, an historical value, but their inclusion in textbooks of an elementary nature is undesirable from the practical point of view. In a work of this size it would be unreasonable to expect a complete bibliography, but the references given are singularly well chosen and will be found of great use by those who wish to extend their studies. The book is very readable, and the information is given in a very pleasant fashion. The author is to be congratulated on the skill with which he has accomplished a task of no little difficulty.

THERAPEUTICS OF THE CIRCULATION.

THE second edition of Sir LAUDER BRUNTON'S *Therapeutics of the Circulation*[2] differs in many points, both in form and substance, from the first. The matter has been largely rearranged, many new paragraphs added, and the division into chapters instead of lectures adopted, but the salient characteristics remain unaltered. The first six chapters deal with the physiology of the circulation; a couple of paragraphs have been introduced dealing with venous tracings, and short accounts are given of the string galvanometer and the normal electro-cardiogram, but there is no discussion of the results which these two methods of

[2] *Therapeutics of the Circulation.* By Sir Lauder Brunton, Bt., M.D., D.Sc., LL.D.Edin., LL.D.Aberd., F.R.C.P., F.R.S. Second edition. London: J. Murray. 1914. (Fcap. 8vo, pp. 560; 111 figures. 5s. net.)

investigation have yielded in elucidating the mechanism of the various forms of cardiac irregularity. After three chapters on the pathology, symptoms, and diseases of the heart and circulation, the remaining ten are devoted to the treatment of cardiac and circulatory disorders, the mode of action and the various drugs and agents employed. The book is eminently readable and contains a large amount of information, many interesting historical references, and much shrewd advice on therapeutics. The author's own work and experience are brought prominently before the reader, who cannot but feel that the methods of treatment discussed are the outcome of long personal observation.

The medical press has from time to time during the last five or six years published several communications from Dr. ARTHUR GOULSTON on this subject, and he has at length embodied them in a book entitled *Cane Sugar and Heart Disease*.[3] He says that thirteen years ago his attention was directed to the failing hearts of old age, and he came to the undoubtedly correct conclusion that the state of the muscular wall of the heart was the main factor in producing the symptoms which were present. He knew that in the German army sugar was given to soldiers as an emergency ration to be used when considerable muscular exertion would be demanded of the men, and that Alpine climbers found sugar most sustaining. He tried it at first as a forlorn hope, selecting absolutely pure cane sugar for the purpose, and the treatment was so successful that he was induced to give it a continued trial in all cases in which he diagnosed or suspected the existence of myocardial weakness or degeneration. He gives as much as two, four, or six ounces of sugar daily; the whole daily dose is dissolved in hot but not boiling water, and taken at the patient's convenience during the day, or part may be taken in tea, coffee, cocoa, or milk, or with puddings, fruit, or spread upon bread and butter.

He recommends that the patient should begin with a smaller dose and gradually increase the quantity. He considers it essential that the sugar should be cane sugar, which according to Abderhalden is not attacked by the lactic acid ferment of the intestine. He has found very little trouble from gastro-intestinal irritation, but where the taste nauseates he suggests the addition of a little essence of ginger or powdered ginger. He has not found the cure of any use in true angina pectoris. He supports his thesis by relating the histories of twenty patients who have derived benefit from the treatment, a good many not having been under his care but have been communicated to him by other practitioners who have heard or read of the method and have given it a trial. The kinds of sugar which he recommends are "Glebe" granulated cane sugar, brown Barbados and East Indian sugar; he thinks it necessary to avoid beet sugar. As a rule he starts with 2 oz. daily for the first week, increasing the quantity to 3 oz. in the second week, and 4 oz. in the third week, the last dose being maintained unless some special feature in the case suggests an increase in the quantity. He refers to one instance in which 8 oz. were given with "a surprisingly successful result," but he admits that as a rule with these large quantities there is a danger of most distressing vomiting. He does not confine his treatment altogether to cane sugar, using digitalis and "diuretics" as well, but does not specify those he prefers. He condemns the use of alcohol as a beverage with the exception of "Plymouth gin," which may be given well diluted as a diuretic. While the treatment is being pursued it is not desirable to take sharp acids, such as vinegar or lemons or effervescing drinks. The author has not seen any bad effects in rheumatic or gouty subjects, and has never detected sugar in the urine. The number of cases given is small, and the facts are not so fully stated as to make the diagnosis always beyond question, but the result remains that in a number of persons who were suffering from symptoms indicative of heart failure from old age, over-strain, or chronic valvular disease, benefit was derived from the persistent use of sugar in these large quantities. We are sorry to see that the author should write of "Bailey's pill" as if he did not know that this pill is generally ascribed to the celebrated physician and pathologist, Dr. Matthew Baillie. In another place he speaks of Apostoli's treatment for fibroids as "Epistolary treatment," but this is possibly only a poor joke at the expense of the patient.

THE DECLINING BIRTH-RATE.

STUDENTS of the population problem will welcome Miss ETHEL ELDERTON'S important contribution to the literature of the subject.[4] Her work comprises a detailed study of the birth-rates from 1851 to 1906, in all English registration districts north of the Humber, diagrams and statistical constants show the actual changes, potential birth-rates are calculated for comparative purposes, and much information respecting housing and industrial conditions is provided. A special feature of the book, which must have involved an immense amount of labour, is the inclusion of reports received from local residents in several of the districts studied.

The general conclusions drawn from the results of a careful analysis of the data are not particularly novel, but this fact in no way diminishes the value of Miss Elderton's work. She finds that the decline of the birth-rate is far greater than could be accounted for by changes in the age distribution of married women, and that this must be largely attributed to the employment of means to prevent conception or destroy its fruits. Even apart from the direct evidence of local correspondents—which, however graphic, is beyond the reach of cross-examination and may be tinged by personal predilections—there are the highly significant facts that the decline has in most cases been greater in districts where the standard of life has been above the average, and that it is associated with diminishing opportunities for the employment of child labour and increasing discussion and dissemination of means to prevent or terminate pregnancy. A good deal of evidence is adduced to show how widespread is the demand for abortifacients or reputed abortifacients, and the following pungent observations of a working class woman in York are worth quoting:

> Six out of ten working women take something, if it is only paltry stuff . . . One tells another. There's no hawking here; it's all done in secrecy . . . Sometimes they can take a druggist's shop and it does no good . . . the child comes just the same; but it's puny, it's half-starved . . . I knew a child, nine months, only weighed about four pounds; they kept it alive the twelvemonth, then it died. The mother died too . . . She'd been taking all sorts, and she went into a rapid consumption . . . more than half the consumption in our class is due to that and nought else . . . You see its not like the rich folks that can support themselves with all kinds of luxuries and good food when they bring on these mishaps. And they can go to private homes and pay endless . . . Our folk go on taking what weakens them, and they can't make up for it like the rich. One woman said to me, "I'd rather swallow the druggist shop and the man in't than have another kid." She used to boil ten herbs together, I forget the names on 'em now, mixed up with gin and salts . . . and take a glassful every morning after breakfast. It ran her tenpence a pint . . . I mind saying to her: "Whatever is't a boiling?"—nauseous stuff it was. And she told me, and I said, "Thou wants a blooming job to sup that hot . . . If I supped it I should think I was ready for my box!"

Miss Elderton warmly supports the plea of Sir Thomas Oliver which was recently published in our columns (1913, i, p. 1199) for drastic reform and, whatever difference of opinion there may as to the general subject of restricting the size of families, no medical men will dissent from the view that the ease with which abortifacient drugs can be procured by the public is a national disgrace.

With regard to means of preventing conception, although Miss Elderton thinks that police action might be beneficial in the case of shops which also openly display purely pornographic literature—as notoriously happens in hundreds of instances—she is under no illusions as to the difficulty of checking a social habit regarded by many as both moral and desirable. Her remedy is to discover a real statesman who will devise means of rendering healthy children not burdens but welcome possibilities and who will enforce the view that such children are the foundation of national greatness and the price of empire.

In a work of this kind, which aims at a recital of facts

[4] *Report on the English Birth-rate. Part I. England North of the Humber.* By Ethel M. Elderton. London, 1914, pp. 246, with two diagrams and twenty plates. (Eugenics Laboratory Memoirs XIX and XX, published by Dulau and Co. Price 9s. net.)

and their analysis, the writer naturally does not provide a full discussion of the various means by which economic pressure upon large families might be relieved, but she deserves credit for her insistence upon the economic difficulties of the situation as it appears to parents or would-be parents. No wise man underrates the value of emotional stimuli, but he is a foolish one who overlooks the fact that much, perhaps most, of the present restriction is due neither to selfishness nor love of ease, but to the great and ever-increasing difficulty of providing children with an adequate start in life.

Miss Elderton naturally makes wide use of the statistical methods associated with the school to which she belongs; but a liberal supply of diagrams enables a reader unfamiliar with coefficients of regression to follow all her main arguments. The birth-rate is based upon the numbers of married women aged 15 to 55, and compared with potential rates determined by the method devised by Professor Tait and published in Dr. Matthews Duncan's classical work, *Fecundity, Fertility, and Sterility*. Since Newsholme and Stevenson's method of correcting birth-rates is now extensively employed, it would have rendered comparisons slightly more convenient had Miss Elderton also adopted it, but she no doubt had valid reasons for choosing the course actually followed. We unhesitatingly commend her work to the notice of our readers, and congratulate her upon its completion.

NOTES ON BOOKS.

AMONG the many minor discomforts endured by our troops at the front not the least are those arising from their inability to converse with the inhabitants of the countries in which they are fighting. To one entirely ignorant of the elements of French the *Soldiers' English and French Conversation Book*,[6] by Mr. WALTER M. GALLICHAN, should prove a valuable help in the linguistic difficulties which must inevitably occur between people unable to communicate with each other except by signs. The author, with great judgement, has not attempted to deal with grammatical rules, but has confined himself to lists of such words and phrases as are most likely to meet the requirements of a soldier on active service in a foreign country. These are arranged under such headings as "Billeting," "Transport," "Convoy," "Trenches," etc., and at the same time an attempt has been made to give a phonetic rendering of the correct pronunciation of each word. The contents of Mr. Gallichan's useful book should be easily mastered by any one anxious to obtain, within a short space of time, a working knowledge of simple conversational French, whilst the book itself is small and light enough to be carried without inconvenience in the pocket.

[6] *The Soldiers' English and French Conversation Book.* Containing hundreds of useful sentences and words; enabling the British soldier to converse with the French and Be gian allies, with the correct pronunciation of each word. Vocabulary of every-day words. Compiled by Walter M. Gallichan. (T. Werner Laurie, 8, Essex Street, London, W.C. 1914. Pp. 142. 7d. net.)

THE ORIGIN AND DEVELOPMENT OF THE RED CROSS.

(Concluded from p. 1067.)

ITALY.

IN 1864 Italy adopted the Geneva Convention. When the unification of the country was accomplished committees were formed in the principal cities, and they combined to form the Red Cross Association. This society was publicly recognized by law on March 30th, 1882.

The Italian Red Cross was the first, or one of the first, of the National Red Cross societies to become organized in close touch with the military authorities and under their inspection and control.[1]

It takes part in the sanitary service of the army by providing war hospitals organized on the same lines as the field hospitals of the army and by supplying hospital trains and railway station infirmaries. It collects and distributes gifts intended for the army. Moreover, it arranges for the supply of information to those who make inquiries as to the fate of soldiers at the front. The association can recruit its personnel only from those free from liability to military duty, or from the national militia. The President of the Central Committee is appointed by the King upon the recommendation of the Ministers of War and Marine. On mobilization this president is recognized as the sole representative of the association with these Ministers. The commissaries of the association delegated to armies are placed under the orders of the Army Intendant. Each of the twelve army corps districts has a district or regional Red Cross Committee, and each coastguard district has a special sub-committee. The presidents of the district committees are in close touch with the generals commanding the army corps, and under the district committees there are sections, local or communal societies, or committees, which are in touch with the generals commanding the military division. Altogether there are 222 such branches, with eighty-nine ladies' branches. They maintain dépôts in each of the military districts. Should the occasion arise, the association can place at the disposal of the Minister for War eight hospitals of 100 beds, forty-one hospitals of 50 beds, which in need could be raised to 100 beds each, fifty-four mountain ambulances, 244 railway station dispensaries, fifteen hospital trains, two river ambulance boats, two hospital ships, besides eight large dépôts of stores. The personnel are given as much practice as possible, and for this purpose takes part in the autumn army manœuvres. In 1900 it mobilized six war hospitals, one mountain ambulance, and sections of hospital trains (Sicily and Bari). In 1902 the Italian Red Cross Association had 25,000 members, and possessed funds and material to the value of £268,953.

In addition to its other work the Italian Red Cross conducts an organized campaign against malaria. Since 1899 eight of its ambulances have been employed in the most fever-stricken parts of the Campagna. It does similar work in Sicily and in Sardinia. The President of the Italian Red Cross is Count della Somaglia, and its Medical Inspector-General is Professor P. Postempski, of Rome.

The Association of the Italian Knights of the Order of Malta is an independent organization which exists for the same object as the Red Cross Society. It is governed by a committee, the president of which in war time becomes its commander, and represents it with the Minister of War. The commander, with the consent of the Minister, appoints a delegate, who accompanies the army in the field and places himself under the order of the Intendant-General. The personnel wear the Geneva and the Maltese crosses. The association has organized three hospital trains, each accommodating 280 wounded.

SPAIN.

Among the other influential persons whose sympathies with his philanthropic schemes Dunant sought to engage when he was in Berlin in 1863 was the Count de Ripalda, a Spanish senator, who promised to lay his views before the Queen of Spain. Soon afterwards Queen Isabella gave her patronage to the work, and charged the Count de Ripalda to form a permanent committee in Madrid. The Infante Don Sebastian, as Grand Prior of the Order of St. John of Jerusalem, was authorized to give his adhesion in his own name, and in the name of the hospitallers. Surgeon-Major Don Nicasio Landa y Alvarez de Carvalla represented Spain at the Conference of Geneva. By a decree dated July 6th, 1864, Her Catholic Majesty recognized the neutralization of the wounded and of those who worked in helping them.

The Spanish Red Cross Society, which is organized on very similar lines to that of Italy, was recognized in 1864 and in several subsequent official decrees as a civil society. Its relations with the army and navy are governed by the Royal Decree of 1902 and 1903. It has important ambulance groups arranged in brigades and divisions. The personnel are exercised at military and other manœuvres and do much good work in cases of public calamity. In 1898 an auxiliary corps of cyclists was organized by the society for the purpose of bringing aid to the sick and wounded and conveying them to ambulances.[2]

UNITED STATES.

It has already been stated that an independent organization for the aid of the wounded came into existence in America during the Civil War. An account of the work of the Sanitary Commission was given in the JOURNAL of October 10th, p. 633. In the report of a committee "on

[1] The "Rôle of the Red Cross Societies in Peace and in War," by Lieutenant-Colonel (now Surgeon-General) W. G. Macpherson. *Journal of the Royal United Service Institution*, November, 1907.

[2] Macpherson, *Journal of the Royal United Service Institution*, November, 1907.

the organization of the American Branch of the Red Cross Association and its status in connexion with the medical department of the National Guard and U.S. Army" published in the *Proceedings of the Fifth Annual Meeting of the Association of Military Surgeons of the United States held at Buffalo, N.Y., May 21st, 22nd, and 23rd, 1895 (Cincinnati, 1896)*, it is stated that the United States was slow to accept the articles of the Geneva Convention. The Civil War was then raging and the country had its attention fully occupied with its own affairs. Accordingly no delegates were sent to Switzerland. At the second International Convention held in Paris in 1868 the United States was represented by the Rev. Dr. Henry Bellows, Chief of the Sanitary Commission, but no official action was taken on his presentation of the articles to the State Department. In 1870, however, the American Colony in Paris decided to organize an American Red Cross Ambulance, and a Committee, of which Dr. Thomas W. Evans was chairman, was formed to carry the scheme into effect.

In response to a request the United States War Department promptly sent hospital tents to the Paris Committee, but outside of this Governmental contribution nothing was sent from the United States for the equipment of the ambulance. While it was in process of organization the German armies invested Paris, and the ambulance had to be converted into an establishment illustrative of the American field division hospitals as they existed during winter quarters in the army of the Potomac. Dr. Marion Sims was at first in charge, but during the active service of this American field hospital Dr. John Swinburne was its chief. As it was the only hospital under canvas in Paris during the siege it attracted considerable attention.

During the Franco-Prussian war Miss Clara Barton, an American lady who had given her life to labours in the cause of philanthropy, took an active part in the work of the relief associations in the field. Shortly before the outbreak she became acquainted with the history of the Convention of Geneva and the excellent results that had been accomplished under its terms in 1866. Thenceforth she devoted her energies to bring the United States into official brotherhood with the nations that had accepted the treaty, and on her return from Europe she made several efforts to have the articles of the Geneva Convention officially recognized by the United States Government. It was not till March, 1882, that she succeeded.

Up to 1905 the American Red Cross, however, existed as a private organization conducted by a few well meaning individuals. In that year it was reincorporated by Act of Congress.[8] By that Act the American Red Cross is designated as the organization which is authorized to act in matters of relief under the treaty of Geneva. Provision is made for a central committee, the governing body, which is empowered to organize State and territorial associations, which are the branch societies. The Act states that as soon as six branches have been formed the central committee shall consist of six persons appointed by the incorporators, six by the representatives of branch societies, and six by the President of the United States, one of whom shall be designated by him as Chairman, the others coming from the departments of State, War, Navy, Treasury, and Justice. The Act provides, further, that the funds of the association shall be audited by the War Department. Shortly after the Act was passed the Board of Incorporators held its first meeting, and elected as its President the Secretary of War. The Central Committee elected a distinguished and energetic executive committee. A beginning was soon made in organizing branch societies, the committee endeavouring in all cases to secure as organizers representative men and women of the various States and territories. A Board of Consultation composed of the surgeons-general of the army, the navy, and the marine hospital service, was created at the first annual meeting of the Red Cross. In 1907 the branch societies were over thirty in number instead of eighteen as at the first annual meeting, and they had all enlisted the aid of prominent persons in their own localities. At the first annual meeting it was reported that 3,337 members had joined. In December, 1906, these had increased to over 9,000, and there were 133 doctors and 121 nurses registered at the branch societies. An active propaganda is conducted by means of lectures and a quarterly bulletin.

The association has declared official a textbook on first aid, prepared by Major Charles Lynch, of the United States army. The relief columns consist of members of the Red Cross, organized in detachments (twenty-two officers and men), columns (four detachments), and legions (four columns). The entire force is designated a Grand Legion of the Red Cross. A detachment is commanded by an assistant director, a column by a director, and a legion by a director in chief. The two latter must be regularly qualified practitioners in their respective States. The women are organized as a nurse corps auxiliary.

The American Red Cross Association has done excellent work in the relief of sufferers from disasters in various parts of the country—in Michigan during the forest fires of 1881; in South Carolina after the earthquake of 1886 and the tidal wave of 1893; in Texas during the drought of 1886, after cyclones in Mississippi and Illinois, and during the floods of the great river valleys. It is rendering splendid service in the present war without regard to the nationality of belligerents.

Other Countries.

In Belgium, Holland, Switzerland, and, in fact, all the countries of Europe, official recognition and encouragement are given to Red Cross Societies, to induce them to become organized in time of peace on lines that will enable them to dovetail into the army medical organization in war, and thus relieve that service of a considerable amount of anxiety in its responsible function of providing for the care of the sick and wounded.

By Major Charles Lynch, Medical Department and General Staff, United States Army. Published in the *Military Surgeon*, Journal of the Association of Military Surgeons of the United States. Vol. xxi. 1907, p. 397, et seq.

POISONING BY TETRACHLOR-ETHANE.

The results of important investigations by the Medical Department of the Home Office into the toxicity of the vapour of tetrachlor-ethane were given at an inquest held by Mr. C. Luxmoore Drew, Coroner for the Western District of London, in Marylebone, on December 19th. The inquiry had been adjourned owing to unusual circumstances attending the death of a french polisher, named Gilbert Moody, employed at an aeroplane factory at Hendon, Middlesex.

From the preliminary evidence given by fellow-employees it appeared that one of the duties of the deceased in the course of his employment at the Aircraft Company's Works, Hendon, was to help in applying to the parts of aeroplanes a varnish bearing the trade name of Emaillite. The deceased complained at times—as others did—that the smell of the material affected him. The witnesses agreed that the fumes left an unpleasant taste in the mouth, especially noticeable on waking in the morning. The deceased developed jaundice, and attributed it to the vapour from the varnish. He had begun to work at the factory in August, when pressure of work owing to the war caused a large increase in the output of the factory and in the staff. He left about the middle of October, when, according to the manager, he looked very ill. At about this time, also, other workmen developed jaundice. It was noticed by the smell that the vapour from the varnish hung about in invisible clouds, so that one would walk into a patch of it quite a long distance from the place where it was being applied; also that the smell was much less noticeable at higher levels. The building was a large one, without partitions, and the material was applied in one corner of the premises.

Henry Bailey, sales manager to the British Emaillite Company, 30, Regent Street, London, W., said the company had been manufacturing different grades of this material for the last two years. Similar solutions were used in the manufacture of cinematograph films. There had been one other complaint with regard to the material prior to those now made. In July, 1913, the company was told that the varnish affected the eyes of the workmen who applied it, and caused ulcers under the eyelids. Another ingredient was substituted for the one which was supposed produced the condition. This was the first time it had been suggested that the fumes caused jaundice.

Dr. F. W. Andrew, M.O.H. Hendon, said his attention had been drawn to the occurrence of 13 cases of jaundice amongst workers at the aircraft company's factory. Eleven of the men affected had nothing to do with the application of the varnish. In the adjoining parish, and at Finchley, there were cases of jaundice in the schools, and on inquiry he found that the local practitioners had treated 23 cases of jaundice in children. The two outbreaks appeared to be quite distinct.

Dr. W. H. Willcox, physician to St. Mary's Hospital and official analyst to the Home Office, said that on November 5th the deceased attended at his out-patient department for examination. The man was suffering from jaundice, and said he had had it for fourteen days; he had suffered from nausea and sickness in the mornings. His stools had been pale and the urine dark brown in colour. He said he had had no severe abdominal pain, but slight pain in the upper part of the abdomen. The temperature was 99.6° F., and the pulse 96. The liver was enlarged, but there was no sign of anaemia, nor of alcoholic excess, nor of gall bladder disease. Dr. Willcox said that he made a diagnosis of jaundice due to the action of some poison on the liver; he did not see the patient again. On December 4th he was called upon to analyse materials marked, "Dope from Aircraft Works, Hendon." He found it was a compound of cellulose in a mixture of methylated spirit, acetone, benzene and tetrachlor-ethane. He distilled the material, and found that the bulk of the liquid distilled over at between 63° and 80° C. It was volatile, and quickly evaporated, yielding a vapour 1.91 times heavier than air. On visiting the aircraft works he was much struck by the way in which the vapours hung about even at a distance of thirty yards from where the material was being used. This was explained by the fact that heavy vapours only mixed slowly with the air. He decided to make careful animal experiments to determine if any of the constituents of the material were likely to have harmful effects on the liver. White rats were placed on perforated platforms in glass vessels, each containing a different constituent of the material and one the material itself. The rats were kept there for eight hours a day for a week. After being kept in the vapour of the "dope" and of the tetrachlor-ethane the rats became drowsy and remained so after removal for some little time. After an hour or so they fed and became active, but did not gain in weight. In the acetone vapour the animal was drowsy but gained in weight as the week advanced, and became normal at once when removed from the vapour. The same phenomena occurred in regard to the benzene, but in the methylated spirit the animal was not affected. After seven days' treatment the animals were killed, and *post-mortem* examinations were made by Dr. Spilsbury and himself. The rat kept in the tetrachlor-ethane vapour showed marked changes in the liver, signs of fatty degeneration and bile staining. The rat kept in the material itself showed similar liver changes but less marked. In the other rats no changes were present to the naked eye. Dr. Spilsbury made microscopical specimens of the organs. In the rat exposed to tetrachlor-ethane very marked fatty degeneration and cloudy swelling was present in the liver and kidneys. In the rat exposed to the material there was marked degeneration and cloudy swelling exactly similar to the changes produced by the first but not quite so advanced. In the case of rats exposed to acetone, benzene, or methylated spirit no fatty degeneration or cloudy swelling were present; the liver and kidneys were normal. The experiment showed conclusively that tetrachlor-ethane was a powerful liver poison, and that the vapour from the material used at the Aircraft Company's Works was a liver poison because of the tetrachlor-ethane in it. Dr. Willcox recalled the instance in which fatal results followed the use of tetrachloride of carbon at Harrod's Stores in 1909.[1] The substance now under consideration was one of the same series of compounds. He came to the conclusion that the tetrachloride of ethane was a powerful poison, and the experiments on the rats fully confirmed that opinion.

The Coroner: Is the effect in any way influenced by the dosage?

Dr. Willcox: In 1909 I had animals in a known percentage of the vapour of tetrachlor-ethane, and the results showed that the poisonous effects were largely affected by dosage. Poisonous symptoms were caused by a relatively high percentage of vapour in the atmosphere, and the time during which the subject was submitted to the vapour was important. Air containing small traces of the vapour would not be harmful, but air containing appreciable quantities would be harmful, especially if breathed for a long period. Dr. Willcox added, in reply to further questions, that he could not say what percentage would be injurious or safe. If there was not sufficient for the smell to be noticeable the vapour would not be injurious, but he would not go so far as to say that because it could be smelt therefore it was injurious. In the subjects submitted to the vapour there was a remarkable destruction of liver tissue which might be a consequence of preceding fatty degeneration. The liver and gall bladder were reduced in size, and weighed 34¼ oz.; there was a condition of subacute hepatitis. That was the condition also observed in the microscopical specimens. It was a result he would expect from exposure to the vapour for a considerable period, especially if the patient lived for several weeks after exposure. The changes took time, and it would be necessary for a patient to live some time after exposure for them to be manifested.

The Coroner: Would the effects of the vapour be lost after a time if a man were removed from its influence?

Dr. Willcox: Not necessarily. If exposed to a great extent the liver cells might be so changed that they died and fibrous tissue took their place. In this case the healthy liver tissue was replaced by fibrous tissue. If a man were exposed, so as to cause slight fatty degeneration and then removed, he would probably recover.

The Coroner: The effect of a long exposure would be a cirrhosis of the liver?—That would be the sequel.

Are you able to state the cause of death?—Yes. I have no doubt that the cause of death was heart failure, consequent on degeneration of the liver caused by tetrachlor-ethane present in the cellulose varnish, to the vapour of which the deceased was exposed during life.

In further evidence Dr. Willcox said he had investigated the other cases affected at the factory. Certain symptoms were common to all: drowsiness while at work, loss of appetite, nausea, vomiting, headache, a peculiar taste and irritation at the back of the throat, jaundice, with pale stools and high coloured urine, constipation generally, and no anaemia. In a few cases the patients became delirious and severely ill. In one case there was conjunctivitis. There was no ulceration underneath the eyelids. In several cases the symptoms disappeared when the patient was absent from work, but on resuming they returned speedily in an aggravated form. In one case, a very severe one—the patient was very ill at the present time—there was much dropsy of the abdomen (ascites), owing to the shrinkage of the liver. He found several of the workers in the factory suffering from unmistakable signs of the onset of the poisoning. They had loss of appetite, nausea, and a tendency to sleepiness. He had no doubt that the illness could be entirely avoided by proper arrangements at the factory; he did not think the deceased would have met his end in this way if he had not been engaged in this particular work. He could not say if age had any bearing on the incidence of the poisoning, but elderly people appeared to be more severely affected. He was sure this was not a contagious form of jaundice; it was not catarrhal jaundice in the ordinary sense; such a patient was only mildly ill. These patients were severely ill; some were delirious, one or two had a slight rise in temperature and a rapid pulse. The two classes of jaundice could be absolutely dissociated.

In reply to Mr. Osborn (who represented the British Emaillite Company), Dr. Willcox said that if proper precautions were taken to get rid of the vapour it would be quite safe to use the material. Now that the cause of the trouble, and the fact that the vapour was heavier than air, were known, he had no doubt that the matter could be dealt with so as to remove the danger completely. Not only the people who had been using the material had been taken ill but men in other parts of the factory also; these were mild cases.

Dr. T. M. Legge, Medical Inspector of Factories under the Home Office, said the premises at which the deceased worked were originally an omnibus dépôt. It was a large

[1] British Medical Journal, 1909, vol. ii, 243.

open shed without partitions, so that it was all open to the same atmosphere. Natural ventilation was arranged for by three lantern openings in the arches of the gables, and mechanical ventilation was installed on the Plenum system, a high-pressure fan driving into the factory air that had been warmed. The installation was well designed. At the time of his visit he understood that the system had broken down—not for the first time. This system of ventilation, though good in ordinary circumstances, was bad in the absence of localized ventilation by fans drawing the fumes away. There should be an exhaust system of ventilation by fans removing a volume of air near the ground level, behind the spot where the material was applied, and no one should be working in the intervening space. The portion of the building where the material was applied should be separated from the rest of the factory and be supplied with air inlets fixed opposite to the outlets to replace the air that the volume fans removed. These precautions would remove any danger from the fumes, but there might be a danger of a mixture of air and inflammable vapours, such as acetone, benzene, and methylated spirit gave off, forming an explosive compound which might be set alight if sparking were possible from the electric motor driving the fan. The motor would have to be explosion proof, or the connexions of the fan should be placed outside. The Factory Department of the Home Office had power to deal with these matters. He found the sanitary accommodation insufficient for the large influx of workmen since the war began. There were four w.c.'s for 400 men; when he went in the vestibule of the lavatory, quite ten men were waiting, and such interference with the bodily functions would naturally lead to gastric disturbance and predispose to the condition set up by the fumes. He understood that a number of the workers had been affected by gastric disturbance quite apart from jaundice, and a number had left without giving reasons because they found the work disagreed with them. If quick drying of the varnish was aimed at, a better system of ventilation would help that, but he thought one point was the maintenance of a temperature of about 65°, and this might account for a system of exhaust ventilation not having been put in.

The Coroner: Were the people in the factory in a healthy condition?

Dr. Legge: No. Questions addressed to the men and women—there were a few women employed in sewing strips of fabric—brought out evidence of recent gastric attacks, and some of the men looked decidedly run down.

Dr. Legge said he visited the premises of the company manufacturing the material; there was very little smell, and the air seemed fresh. A volume fan was placed in the wall. The men employed there seemed perfectly healthy, but all the mixing was done in closed drums, and the workers were not exposed to vapours except when transferring an ingredient into a revolving mixer. The conditions of manufacture were quite different from those obtaining during the use of the material. He had visited the manufacturers' factory two years previously, when the industry was a new one. He was then told that the substance was narcotic but not toxic, and he could find no evidence of injury among the workers at that time. Subsequently complaint was made of the effects where similar compounds were used and a colleague investigated cases of illness that occurred. He found that one man had been rendered unconscious and that the fumes appeared to produce gastric disturbance, but there was no jaundice. He visited other places where similar compounds were manufactured, but again found no evidence of illness amongst the persons mixing the ingredients. He then visited seven factories where aeroplanes were made. In one he found that a man had declared himself ill from jaundice; he was able to satisfy himself that the man was suffering in exactly the same way. At another factory the work was done largely by young women. He examined a number of them. One had been away this year for jaundice and congestion of the liver; others showed unmistakable evidence of the effects of the material. In some of the factories where women and girls were doing the work, though they had not suffered from jaundice (except in the cases mentioned), the vapour had given them a flushed and rosy appearance. This was cited by the management as evidence of their good health and he mentioned it to prevent misapprehension as to the meaning of the symptom. He had not found in any of the factories so widespread an outbreak of jaundice as had occurred in the one under consideration, but he found very pronounced effects from the material. In most of the other factories the material was of a somewhat different composition; but he believed tetrachlor-ethane must have been present in all. The other vapours would cause headache and some giddiness, but he would not have expected them to cause jaundice. In none of the other factories were the ventilating conditions the same as at the Aircraft Company's premises, where fumes were driven about the whole building; in the other factories the material was applied in a separate portion of the building. In the factory where he found least effect, more attention had been paid to natural ventilation than in any of the others, but not much of the material was used. One of the factories was made exceptionally lofty with the idea of allowing the fumes to escape, in ignorance of the fact that they were heavier than air. He attributed the fact that no cases of illness occurred before September at the Aircraft Company's works to the circumstance that before the war less of the material was used; the men did not get a sufficiently large dose. It had taken six weeks for the symptoms to develop from the period in August when the pressure of work was greatest. If the amount of work had continued normal the ill effects of the vapours might never have become sufficiently pronounced to have been brought to light. In addition to the precautions he had already mentioned as to ventilation and partitioning, Dr. Legge said the workmen should not be allowed to eat their meals in the room where the material was used; this precaution was taken in all the other seven factories he visited. He did not consider it practicable to provide the workers with helmets to which air would be supplied as they worked. If the precautions he had indicated were efficiently carried out, the danger would be removed. Naturally, if some other substance, without toxic effects, could be used in the manufacture of the material, so much the better. He agreed with Dr. Willcox as to the cause of death.

The Coroner: Do you consider this a very dangerous occupation?

Dr. Legge: Very dangerous as carried out in this case and in the others.

Dr. Bernard H. Spilsbury, Pathologist to St. Mary's Hospital, said that since the last sitting of the court he had examined the organs of the deceased and confirmed his previous opinion that the condition of the liver was one of subacute hepatitis. The other organs were generally healthy apart from secondary changes due to the toxic condition. He entirely agreed with the earlier evidence as to the cause of death.

The Coroner, in summing up the evidence, emphasized the importance of the inquiry, and expressed the thanks of the court to the witnesses who had given the benefit of their special knowledge, without which the inquiry could not have been conducted.

In returning a verdict in accordance with the medical testimony, the jury added a rider expressing thanks to Drs. Willcox, Spilsbury, and Legge for their valuable investigations.

ON December 15th the Paris Académie de Médecine held its annual public meeting. M. Magnan, Vice-President, was in the chair, in the room of Dr. C. Périer, the President, who died a day or two before. Among those present were: His Highness the Prince of Monaco; M. Emile Loubet, formerly President of the French Republic; M. and Madame Vallery-Radot, son-in-law and daughter of Pasteur; and MM. Roux and Metchnikoff, as representatives of the Pasteur Institute. After the distribution of the prizes for 1914, the perpetual secretary, Professor Debove, pronounced an *éloge* of Pasteur. By heredity and education, he said, Pasteur was a true patriot, and no one was more pained than he by the events of 1870. Having witnessed useless acts of cruelty committed by the German army, he threw up his doctorate of the University of Bonn. His was not, however, an exclusive patriotism; he used to say, "Science has no country, though men of science have." M. Debove concluded by reading a letter from M. Vallery-Radot offering to the Academy a bust of Pasteur from the chisel of the distinguished sculptor, Dubois.

THE DEPARTMENTAL COMMITTEE ON SICKNESS CLAIMS UNDER THE NATIONAL INSURANCE ACT.

(*Continued from p. 1066.*)

We may now pass to that part of the report of the Departmental Committee on Excessive Sickness Claims which deals with the influence of the action of the panel practitioners.

Certification.

The Committee thinks that some of the doctors, having had no previous experience of friendly society work, "do not correctly apprehend the nature of their task, the value to be placed on their certificates, the relation in which they should stand to the society, or their responsibility to the working of the whole machine," while others, who have acted in the past as friendly society doctors, no longer consider themselves bound to look after the interests of the societies. As the remuneration of a practitioner depends on the number of his panel patients, there is, we are told, "a widespread belief that the fear of offending patients is a motive which induces practitioners to grant certificates for trivial illnesses or continuing certificates after incapacity has in fact ceased," and the evidence of society officials is almost universal that on this account certificates are granted recklessly, and the societies' funds in this way depleted. The medical evidence on this point showed that the desire to be on friendly terms with patients is not necessarily based on pecuniary motives; to doubt the word of patients, and to act as a detective would soon destroy that confidence which is a necessary part of treatment. Nevertheless, several medical witnesses admitted that the fear of losing patients by refusing certificates, even when somewhat unreasonable demands were made, could not fail to influence at any rate some practitioners, as the reputation of being strict would rapidly damage any practitioner who had to compete with others who readily placed patients on the funds. On consideration of the whole evidence, the Committee thought that a large part of the leakage of the funds must be ascribed to this feeling among practitioners. The Committee also expressed the opinion that among a large section of the panel doctors there was an absence of a sense of responsibility to the insurance system. The statement that the doctor's duty is to his patients is regarded as in a sense a platitude, but it is claimed that "regard for the interest of the patient involves a duty to see that the undeserving do not receive benefit to the detriment of the deserving." The report says: "It is impossible to overlook the almost universally expressed opinion of society officials that the action of the doctors with regard to certification and the administration of the Act generally has been unsatisfactory"; but the Committee is still bound to add: "There has been very little evidence of definite acts of deliberate false certification by panel practitioners, and it is necessary to bear in mind that carelessness and indifference on the part even of a comparatively small section of doctors may react unfavourably on the reputation of the whole profession in any area."

A number of the medical witnesses urged that the term "debility" ought to be quite enough for a society with the doctor's certificate that the patient is incapable of work. The Committee points out that this attitude assumes that the doctor is the sole judge as to whether a person shall receive sickness benefit or not, whereas the approved society alone is the judge under the Act, and the medical certificate is only one of several other pieces of evidence. The society has, for example, to consider whether the case comes under the Workmen's Compensation Act or not, and whether the disease is due to personal misconduct. Moreover, the doctor's judgement may be misled by fraudulent patients where the symptoms are purely subjective, and the societies must be in a position to check the certificate partly by their knowledge of their members and partly by investigation through sick visitors, and such checks cannot be applied unless the certificates convey clear and precise information. It is also pointed out that "debility" is not a specific disease and not a diagnosis, but only a state arising out of or accompanying illness which has to be diagnosed, and one of the medical witnesses confessed that "'debility' is always a great refuge for malingering; it is feeble on the part of the doctor to use it." It is admitted that in the early stages of disease exact diagnosis may be impossible, but to continue to use the term "debility" for many weeks "must be attributed either to slackness, incompetence, or what can only be termed 'the perverseness of the practitioner.'" The only cases where the Committee can see some excuse for vague diagnoses being given are:

1. Those in which grave injury might be done by letting the patient know the exact nature of his disease, such as in cancer, some forms of heart disease, and incipient insanity.
2. In diseases peculiar to women where it would be revolting to the patient's feelings that an exact certificate should be handed about among society officials; and
3. In cases of venereal disease.

The last class admittedly presents great difficulties, whether the disease is due to misconduct or not; but it is held that the difficulty cannot be met by the use of synonyms or by euphemisms. If the doctor believes that the disease is due to personal misconduct, it is his duty to certify what he believes. In other cases it is recommended that the doctor should be at liberty to give the patient a vague certificate, but if he does so, he must inform the society that he has purposely given a vague certificate, and at the same time he must send precise information to the referee who, according to a later recommendation, is to be appointed by the Commissioners. The referee should then communicate to the society just such information as he thinks necessary, and the society should also undertake no investigation that would in any way rouse the patient's suspicions. It may here be noted that in the new system of medical certification for 1915 these suggestions of the Committee have been adopted almost in their entirety. With regard to vague certificates arising out of incompetence and slackness of the doctor, the Committee says "there can be little doubt that the slovenliness of mind which shrouds itself in vagueness will generally result in carelessness in other aspects of the practitioner's work."

Great importance is attached to the name of the disease being entered up on the certificate week by week. Many society officials do not like the doctor to alter the diagnosis first given, but the Committee points out that a correct diagnosis may not be possible at first, and it often shows greater care on the part of the doctor to alter his certificate as the true character of the disease shows itself, rather than continue in a mechanical way to initial a continuation sheet.

On a general survey of the facts referring to men's societies, the Committee concludes "that a large part of the excessive payments on account of claims for sickness benefit must be attributed to defects in the administration of the societies and to the carelessness and inaccuracies of the medical profession."

(*To be continued.*)

MOTOR NOTES FOR MEDICAL MEN.

By H. MASSAC BUIST.

Two Notable New Models.

Though there are to be no motor exhibitions in London or Scotland this year, nevertheless the British as well as the American motor industry is well forward with its plans for 1915 patterns of cars.

An American Car.

From America comes an entirely new Willys-Overland model of 15 to 20 h.p., sold complete with a London-built three-quarter coupé for doctor's use at £295, the finish being really excellent; or available as an ordinary five-seater touring car, excellently upholstered, finished in dark green with white lines, with an improved type of ventilating screen, rain-proof hood with side curtains, together with a cover for it, electrical engine starter, electric lighting, detachable rims including a spare, proportionately large-sized tyres, three-quarter elliptic back springs, and twelve months' guarantee, for £198; or as a two-seater with the same equipment for only

£190. The remarkable feature of this car is that it is a vehicle of middle size and power, constructed practically throughout on the latest European lines, including the under-slinging of the lower members of the three-quarter elliptic back springs. The lines are excellent, the slightly sloping bonnet and dash being employed, and there is here no freak designing, all the points having been long and well proved in practice. The substantial nature of the construction is out of the ordinary, as instance the strength of such details as the wings, on which a man can easily sit without injuring them. Little details of finish may be noted, such as the provision of a rail behind the front seats for carrying rugs when not in use, and a leather sheet behind the front seats to prevent the enamelling thereabouts being destroyed by the feet of those occupying the back seats.

It is essentially an owner-driver's car, too, in that it can be started in the coldest weather from the driver's seat without lifting the bonnet, because a special carburettor agitator is furnished in the form of a little knob conveniently situated on the dashboard, on which there are also various stops for controlling alike the engine starter and the different sets of lights. The engine, moreover, is well up to the car, a clever feature of the design of which is that the total weight, with all accessories, has been kept down to approximately a ton. The four cylinders of the motor are cast singly, and are offset in relation to the crankshaft, the bore measurement being 4 in. and the piston travel 4½ in., while the details of construction are particularly praiseworthy, as instance the five bearing crankshaft. The valves have adjustable tappets, while the Schebler adjustable carburettor is standardized. There is nothing about the car that looks cheap, and there is nothing unsubstantial in its design or production. I do not think America has ever sent to this country any cheap car representing such good value for money. This newer model comes with the better guarantee, in that it supplements the 20-25 h.p. Overland type which has been sold in considerable numbers during the last year, and has thoroughly justified itself in the hands of owners. This larger type was reproduced 45,000 times in the manufacturing year that closed this summer, and it is brought forward this year with still better finish and with a number of detail improvements. Therefore the Overland work is not unknown in this country. This year's manufacturing programme aims at the production of a total of no fewer than 75,000 cars between the two types.

A New Light Car.

In quite another direction of motor manufacturing there is a very interesting development in the Swift policy. This is one of the three Coventry firms which between them have made the most notable showing in light car competitions in Great Britain and Ireland during 1915. The other two types are the Singer and the Standard. Those are both four-cylinder machines, but hitherto the Swift has been available only as a two-cylinder type. There is now introduced for the 1915 season, however, a 10 h.p. four-cylinder Swift model with a bore measurement of 63 mm. and a piston travel of 90 mm., giving 1,172 c.cm. engine volume, the vehicle being sold complete with electric-lighting dynamo and accumulators, a fifth detachable wheel and tyre, screen, hood, and all necessary accessories, for an inclusive sum of £200. I had opportunities of studying three examples of this make in service in the Isle of Man in June, before it was possible to make mention of it in public, and it was quite amusing to observe the astonishment that its hill-climbing powers produced among all motorists who chanced to come upon it on the road. The one point for criticism in the two-cylinder Swifts that did so brilliantly in competitions this year was that they took their time about climbing the hills. Therefore those who witnessed the performances of these early examples of the four-cylinder type, which practically gave no outward indication of their being at all different from the two-cylinder variety, could scarcely credit their eyes when they saw them tackling the Manx hills.

The lines of the little car are thoroughly sound and smart, nor is there here anything of an experimental constructional nature; therefore there is every reason to be sure that, with the experience the firm has had in the production of its light car chassis, this new four-cylinder model will continue and even increase the success that has attended the two-cylinder variety. The four cylinders are cast all in one operation, the valves being set Indian file fashion on the one side, with stems and springs enclosed by a readily detachable aluminium cover. The valves are worked by enclosed silent chain drive from crankshaft to camshaft. The electric lighting dynamo is mounted on a table above the magneto, the legs of the table resting on the magneto platform. The dynamo is belt-driven from the front end of the crankshaft, which is fashioned of 3 per cent. nickel steel and carried on three bearings. The pistons are proportionately more than common long, and have each only one ring at the top and one at the bottom. The moving parts of the engine are oiled by force furnished by a geared pump driven from the near end of the camshaft. The natural circulation of the water is relied on for cooling purposes. The gear box furnishes three speeds forward, and the back axle is bevel driven. Altogether this is a most excellently workmanlike job.

A 1915 Tyre Programme.

The tyre firms are also producing new wares for the 1915 season. They are putting these on the market the earlier by reason of the fact that there are no motor shows to furnish occasion for holding them back any longer. In the case of the Dunlop Company—which pioneered the pneumatic tyre industry and whose wares have been gaining consistently in repute, a remark which can be applied to very few tyre concerns—its enterprise is this year supplemented by the introduction of something for which many users have been waiting from this quarter. This firm now supplies 815 by 120 mm. size tyres to fit 105 mm. rims; and 820 by 135 mm. sized tyres to fit 120 mm. rims; in other words, it is now marketing a series of what are ordinarily called over-size tyres, but which may be more accurately described as larger section tyres than those hitherto available for given sizes of rims. It should be understood, moreover, that these Dunlop over-size tyres are distinct from the company's interchangeable sizes, which continue to be available. As cars are made to require tyres of such extraordinary variety of sizes, it may be as well to illustrate what are the sizes of Dunlop tyres common to one and the same rim:

650 × 65 mm. rim takes	650 × 65	and 700 × 80	tyres
700 × 65 mm. ,, ,,	700 × 65	,, 750 × 80	,,
750 × 65 mm. ,, ,,	750 × 65	,, 800 × 80	,,
710 × 90 mm. ,, ,,	700 × 85	,, 700 × 90	,,
760 × 90 mm. ,, ,,	750 × 85	,, 760 × 90	,,
		,, 760 × 100	,,
810 × 90 mm. ,, ,,	800 × 85	,, 810 × 90	,,
		,, 810 × 100	,,
870 × 90 mm. ,, ,,	870 × 90	,, 870 × 100	,,
910 × 90 mm. ,, ,,	910 × 90	,, 910 × 100	,,

American Sizes.

32 × 3½ in. rim takes	32 × 3½	and 33 × 4	tyres
36 × 4½ in. ,, ,,	35 × 4½	,, 37 × 5	,,
36 × 5 in. ,, ,,	36 × 5	,, 37 × 5½	,,

Another news item concerns the most popular form of motoring, in that Dunlop light cars, rubber-studded tyres have been introduced; they are made in the 700 × 80 and the 700 × 85 mm. sizes. The tread of this is of similar design to that of the patented rubber-studded motor-cycle tyre which has given such excellent results.

Professor Wilhelm Erb, the distinguished neurologist of Heidelberg, recently celebrated the fiftieth anniversary of his doctorate.

Dr. W. E. Forsythe reports in the *Journal of the American Medical Association* of November 28th on the health services at Princeton, Cornell, Yale, and Stanford Universities, the Massachusetts Institute of Technology, and at a number of the State universities. The staff usually consists of a university physician, health officer, or medical adviser, with assistants as required, and in most places convenient quarters are provided for examinations, and office treatment can be had. In a number provision is made for bed patients. The expense of the service is provided for, as a rule, by a general student fee. One of his chief conclusions is that a man interested in the subject should be at the head of the work to which he should preferably devote his whole time. He should be given large authority in carrying out the requirements of the service. Besides good office facilities, a laboratory is needed for efficient work.

British Medical Journal.

SATURDAY, DECEMBER 26TH, 1914.

THE RED CROSS.

In this issue a series of articles in which the history of the origin and development of the Red Cross movement is sketched in outline, is brought to a conclusion. By a curious irony of fate the jubilee of the Geneva Convention fell in August of the present year, shortly after the outbreak of the bloodiest war recorded in history. Henri Dunant, the founder of the Red Cross, had been appalled by the amount of human suffering which he witnessed after the battle of Solferino, and he forthwith entered on his philanthropic crusade with a consuming zeal which earned for him the name of the new Peter the Hermit.

Although ostensibly Dunant's purpose was to make war more humane, his deep desire was to make it impossible. He was one of the early advocates of arbitration as a means for the peaceful settlement of disputes between nations. At the meeting of the Social Science Congress held at Plymouth in 1872, he delivered an address on the subject, and a resolution was passed that there should be created in some city to be decided upon a diplomatic permanent committee on which each country should be represented officially. That committee might transform itself into a tribunal of arbitration at the request of countries between which *casus belli* might arise. This idea found material expression in the International Peace Conference held at The Hague in 1899, when sixteen countries signed a convention accepting the proposal of arbitration. To this peace movement the impulse was undoubtedly given by the Geneva Convention.

Although Dunant's attempt to abolish war has failed, his scheme to mitigate its horrors has in large measure been successful. In the light of what the world has witnessed during the past few months it is not a little remarkable that Prussia was one of the first countries in which Red Cross work was efficiently orgauized, whereas Great Britain did scarcely anything for years after signing the Convention, and the United States did even less. Yet it did not need the experiences of the present war to show that in both these countries the sentiment of humanity is far more advanced than in Germany, by whose armies "frightfulness" is deliberately practised as a system in warfare. With us aud the Americans alike the apathy in regard to Red Cross work is an outcome of the feeling of comfortable security—one of the cankers of a long peace—that led us to look upon war as a thing so far outside the scheme of probable events that preparation for it was no part of the serious business of life. We have had a rude awakening from this dream, and already we have learnt to look on the world with unscaled eyes.

One of the lessons of the war is that the Red Cross, if it is to fulfil its mission, must be carefully organized and kept at the highest degree of efficiency in time of peace. It may be added that volunteer aid, if it is not to be a hindrance rather than a help, must be strictly subordinated to the military authorities. It is the nature of these, as of all official bodies, to be unsympathetic to irresponsible enthusiasm, and even sometimes to show a tendency towards irritating obstructiveness. But the first principle of organization is the "orrder, duty an' restraint, obedience, discipline," which McAndrew found in his engines. Without these, goodwill is ineffective, and even expert skill may be worse than useless.

SELECTION AND DISEASE.

In the course of his interesting and scholarly presidential address to the American Medical Association, Dr. Victor C. Vaughan devoted some attention to the riddle whether infectious diseases have benefited the race by the destruction of the unfit, and answered the question with an uncompromising No. This topic is, we suppose, one that mankind will continue to debate until the crack of doom, and disputants are likely to have cause to repeat sadly the lines of Omar Khayyam respecting the upshot of his attendance on the discourses of Doctor and Saint. In one sense the question is trivial and its answer obvious. Those who are "fittest" to survive are those who *do* survive, consequently the survivors of the Black Death were "fitter" than its victims. *Cur quis non prandeat hoc est?* But the real problem is not so trivial as this debating society method would make it.

Dr. Vaughan seems to hold that epidemic diseases are negatively selective, and quotes Boghurst's approval of Diemerbroech's saying that "Plague left the rotten bodies and took the sound." He also adduces certain United States army statistics to the effect that the attack-rate of typhoid was higher among soldiers with a previous good record of health than amongst those who had already figured on the sick list. But, as Dr. Vaughan goes on to point out, since a strong healthy man leading an active life is more likely to be exposed to infection than R. L. Stevenson's "eminent chemist who took his walks abroad in tin shoes and subsisted wholly upon tepid milk," the statistics hardly establish his proposition. It is generally recognized that the fatality of the common endemic-epidemic diseases, such as scarlet fever and diphtheria, diminishes with age down to a certain point. Thus, taking the London returns of deaths and notifications, 1901–10, it is found that the fatality of both scarlet fever and diphtheria diminishes appreciably from the age group 0–1 to the quinquennium 10–15, the values thereafter being irregular partly owing to the smallness of the numbers. It is possible, and has indeed been suggested, that were *any* child shielded from contagion until after the earliest years of life, his chance of passing successfully through an attack of measles, scarlet fever, or diphtheria would be increased. But it is also possible that the diminishing fatality-rate with age is a consequence of selection. It is difficult to believe that those cut off early are in truth the flower of the race, and no one doubts that in such diseases as pneumonia the healthy vigorous man has a better chance of life than the weakling or the drink-sodden.

Dr. Vaughan's contention is not, however, probably intended to be taken literally. He means rather, we should suppose, to protest against the idea that were, say, the zymotics abolished, the loss of their selective action would prejudice racial characters. Perhaps it might be objected that unless the contagium could be permanently excluded, its introduction at rare intervals would be attended by such mortality that, in the long run, little would be gained. In support

of such a contention the famous experience of Fiji with respect to measles might be quoted. But many who cite that case forget that Corney, to whom we owe the best description,[1] attributed much of the mortality not to the peculiar virulence of the disease, but to secondary complications associated with a neglect of sanitary measures impossible in a civilized community under normal circumstances. Indeed, the experience of the Confederate troops in 1866, of the National Army of Paraguay during the Brazilian war, and of the Parisian Garde Mobile during the siege testify to the enhanced mortality of measles associated with unfavourable hygienic conditions.[2]

We do not wish to assert that the dangers of introducing an epidemic disease amongst an "unselected" population are not real, but it may be that some of the dramatic instances do not afford such cogent evidence as has been thought. It has also been urged by selectionists that the most efficient way of safeguarding the public health is to encourage the reproduction of resistant strains—to attend to the soil rather than the seed. This is a suggestion in favour of which much can be said; whether much can be done is another matter. So far as epidemic diseases are concerned, it a little reminds us of the prescription for capturing lions—sift a desert, the sand will pass through and the lions will be retained.

In conclusion, it may perhaps be said that the common causes of disease and death, including the epidemic diseases, do not fall alike upon the weak and strong, that the proportion of weaklings is higher amongst those who perish than amongst those who survive; that there is no evidence to warrant us in concluding that epidemic diseases do, in fact, choose the healthy members of a community provided all composing it live under comparable conditions. But we may not less certainly conclude that any racial advantages so purchased are bought at an exorbitant price, and that to strive for the elimination of these selective agencies is one of the duties of a good citizen. The process of selection is after all not so simple a matter as some would have us believe. Were all the zymotics abolished, there would still be plenty of pitfalls to entangle the feet of the feeble, plenty of selective agencies to encourage the "fit." We do not think those who strive to reduce the prevalence of epidemic disease in our midst need seriously concern themselves with the possibility that they are opposing the principle of national selection of which they are themselves a product.

THE AMERICAN VOLUNTEER AMBULANCE CORPS.

In a "letter to the editor of an American journal" Mr. Henry James gives an interesting account of the work of the American Volunteer Ambulance Corps in France.[3] It was organized by Mr. Richard Norton and is now in active operation at the rear of a considerable part of the longest line of battle known to history. The idea was suggested to him when, early in the war, he saw at the American Hospital at Neuilly scores of cases of French and British wounded whose lives were lost or who would have incurred lifelong disability and suffering through long delay in their removal from the field of battle. In three weeks of his return to London with the object of carrying out the work, he was joined by a number of his countrymen and others possessing cars, who offered them as ambulances already fitted or easily convertible, and volunteered themselves to act as chauffeurs. Other cars were bought with funds rapidly received from friends in America, and a fleet of fifteen ambulances was soon in being. Its services were gladly accepted by the British Red Cross and the St. John Ambulance, and Colonel A. J. Barry co-operated with Mr. Norton in directing the beneficent activities of the corps. "Its function," says Mr. James, "is primarily that of gathering in the wounded and those disabled by illness (though the question is almost always of the former) from the *postes de secours* and the field hospitals, the various nearest points to the front, bestrewn with patient victims, to which a motor car can workably penetrate, and conveying them to the base hospitals, and when necessary the railway stations, from which they may be further directed upon places of care, centres of those possibilities of recovery which the splendid recent extension of surgical and medical science causes more and more to preponderate." Mr. James vividly contrasts the celerity and comfort of cars with the slow, often interrupted, progress of trains in the transport of the wounded. The number of men to be carried away, however, leads necessarily to overcrowding of the cars; this can be remedied only by the provision of more cars. Mr. James pays a warm tribute to the admirable spirit of devotion, "of really passionate work," which animates the members of the corps; and he finds "a positive added beauty in the fact that the unpaid chauffeur, the wise amateur driver and ready lifter, helper, healer, and as far as may be consoler, is apt to be a university man and acquainted with other pursuits." "One gets," he adds, "the sense that the labour, with its multiplied incidents and opportunities, is just unlimitedly inspiring to the keen spirit or the sympathetic soul, the recruit with energies and resources on hand that plead with him for the beauty of the vivid and palpable social result." Mr. James gives some striking examples of the work of the corps in bringing away wounded and in helping women and children to escape from places threatened by advancing Germans. The presence of doctors with the squad has been the means of saving very many lives; from this fact he draws the moral that the "very ideal for the general case is the not so quite inconceivable volunteer who should be an ardent and gallant and not otherwise too much preoccupied young doctor with the possession of a car and the ability to drive it, above all the ability to offer it, as his crowning attribute." What Mr. James has learnt of the work of the corps multiplies for the hopeful mind "the possibilities and felicities of equipped good will." The work is by no means free from danger, for, Mr. James says, "The Germans . . . are noted as taking the view that the insignia of the Red Cross, with the implication of the precarious freight it covers, are in all circumstances a good mark for their shots, a view characteristic of their belligerent system at large." This testimony from a neutral should be noted at a time when the German press, in what Mr. Winston Churchill has well called its "frenzy of hatred," is making the wildest charges against this country of "murdering" prisoners and similar fictions. The British army and nation owe a deep debt of gratitude to their American friends who are working with such practical sympathy for the relief of the sick and wounded. We hope that Mr. James's eloquent appeal for help in the form of cars, capable chauffeurs, or money, will meet with a generous response. Donations in this country will be received by Mr. George F. Read, Honorary Treasurer, care of Messrs. Brown, Shipley and Co., 123, Pall Mall, S.W.

LOUVAIN AND ITS LIBRARY.

PROBABLY no one of the many atrocities perpetrated by the Germans in this war has made such an impression on the minds of educated people throughout the world as the wanton destruction of Louvain. A short sketch of the history of the university is given by Dr. John G. Vance in

[1] Corney, *Trans. Epidem. Soc.* (N. S.), 1883, iii, 76.
[2] Hirsch, *Geog. and Hist. Pathology*, i, 167.
[3] Macmillan and Co., Ltd., London. 1914. Price 1d.

the *British Review* for November, while a longer account, with special reference to the medical faculty by Dr. John Bethune Stein, of New York, appears in the *Medical Record* of November 14th. The university was founded by Pope Martin V in a Bull dated December 9th, 1425, establishing all the usual faculties with the exception of theology. In view of the large part given to theology in the university when it was born anew in the nineteenth century, this exception is remarkable. The early history of the medical faculty is obscure, and the documents concerning it probably perished in the flames kindled by the torches of German *Kultur*. It is known, however, that the first professor of the medical faculty was Jean van den Eele, a graduate of Cologne, who was also the first rector of the university. He held that office in 1427, 1431, and 1437. Dr. Stein gives a list of forty-one members of the medical faculty, each of whom was rector of the university; it extends from 1427 to 1788. In the list appears the name of Jan Wesalia or Vesale, who taught medicine from 1429 till 1472, and was Rector in 1430, 1433, and 1438. He was an ancestor of the great reformer of anatomy, Andreas Vesalius. Less than twenty years after the foundation of the university Pope Eugenius IV, learning that the medical professors of Louvain were neglecting the sound doctrine of Hippocrates and Galen, and taking Avicenna and Rhazes as their masters, founded in 1443 two new chairs in the medical faculty to which priests were appointed. They were canons of St. Pierre, an ancient church destroyed by the Germans. St. Pierre was interesting to doctors on account of its connexion with the early history of medicine in Belgium. Among its treasures was a famous triptych, painted by Dierick Bondts in 1468; this represented the martyrdom of St. Erasmus, whose speciality as a patron was intestinal disease. It might, perhaps, have been described as an early example of abdominal surgery, for it showed the bishop with an incision in his abdomen, from which the intestines were being drawn out and wound upon a crank by two men. The first medical graduate was Jan Stockelpot, a priest who was a professor in the faculty of arts. The degree of doctor of medicine was conferred on him in 1433, and in 1445 he became a professor in ordinary. The university suffered severely during the forty-three years of war in Belgium in the sixteenth century, and in 1580 Pope Gregory XIII, hearing that there were no funds for the payment of the professors' salaries, sent a large sum to be divided among them. In the early part of the seventeenth century the degree of doctor of medicine had become so expensive a luxury that the students addressed a petition to the Archduke Albert and his consort Isabella asking for various reforms, and particularly to be relieved of the expenses entailed by the elaborate ceremonial and the banquets customary on the occasion. This led to an "act of investigation," the outcome of which was the establishment of four chairs in the medical faculty instead of two, the duties of each professor being clearly defined. By the treaty of Aix-la-Chapelle, October 18th, 1748, Belgium passed under the sway of the Empress Maria Theresa of Austria. She tried to raise the standard of medical education, but foreign rule did not prove favourable to this aim. Joseph II reformed the university in so drastic a fashion that in 1788 it virtually died under the operation. The medical department was reinstated in 1790, but the university was suppressed by the French Revolutionary Government in 1797. It was revived by the Belgian bishops as a Catholic university in 1834. In that year the number of students was 86; it grew steadily till within the last year it was 3,000. With regard to the library, which was said to have been burnt by the Germans, it has recently been stated by M. Henri Bergson, the distinguished philosopher, in a communication to the Académie des Sciences Morales et Politiques, that he has good reasons to believe that it was pillaged before the building was burnt. Since then the *Temps* has published a letter from M. Ossip Lourié, a well-known journalist and man of letters, in which he tells a story which seems to lend confirmation to M. Bergson's statement: "In the month of August, 1913," he writes, "I met among the mountains of Switzerland two Germans, one of them a professor of physiology, the other of linguistics. The latter constantly spoke to me of the new Royal Library of Berlin, which he said was 'capable of containing five million volumes.' On my remarking that it would take a long time to fill it, my interlocutor replied very seriously, 'That will be very easy after a war.'" The meaning of this utterance is now too clear. The Germans say they make war to spread their culture among those who live in darkness. It is remarkable that as a means to this end they should steal the books of the "uncultured."

FOOD AND COOKING.

THE National Food Reform Association has published a small book with the title *Facts for Patriots*, urging that it is above all necessary at the present time that the people should learn to apply those principles of nutrition which the association has been endeavouring, with perhaps some amount of exaggeration, to instil into the public mind. As is well known, the association, under the direction of Mr. Eustace Miles, urges the adoption of a lacto-vegetarian diet, on the ground not only of its high nutritive value but of its economy. As we have often pointed out, there is a popular objection to many articles of food merely because they are cheap. The inquiry undertaken not long ago into the use of oatmeal in a large number of households, showed that the percentage in which this valuable food was employed was in inverse proportion to the rental of the houses, and even in Edinburgh the labour members of the town council protested against the action of the Education Committee in providing porridge for the free breakfast given to the children attending elementary schools. We may share the regret of the association that such valuable foods as cheese and oatmeal are neglected to a large extent, but it will take much spade work to uproot the prejudice existing against them. The value of pulses and lentils is exaggerated; their relative difficulty of digestion and assimilation was proved by Professor McCay in his interesting investigations of the metabolism of Bengalese; he showed that no less than 25 per cent. of the total nitrogen of the food was contained in the faeces, and he attributed this to the use of dhal (pulse), which he holds responsible for most of the bowel complaints so prevalent amongst these people. Undoubtedly the Food Reform Association is right in complaining of the abuse of tea, for it is no exaggeration to say that tea is now drunk four or five times a day, or with every meal, by large numbers of the poorer classes, and it is abused also in our own houses by servants. Sir James Crichton-Browne, in a recently published interview, speaks of tea as "one of the saviours of mankind," for he believes its use has to a large extent superseded that of alcohol. There is a good deal of truth in this, but stewed tea is at the present time responsible for a large amount of indigestion, nervousness, sleeplessness, and other troubles. Not only is there in this country an enormous amount of ignorance of food values, but also great neglect of cookery and inability or unwillingness to provide appetizing dishes from food materials which are happily so abundant and so cheap. Instead of attempting to induce the people to eliminate animal food from their dietary, it would be more practical to teach them the proper use of the cheaper kinds of animal food and how to cook it so that with a considerable addition of all those articles which the Food Reform Association rightly advocates, dishes could be made which would possess the sapidity which meat undoubtedly confers. This quality is perhaps too highly appreciated, but it cannot be ignored. The Food Reform Association has done good work in demonstrating the value of vegetable

foods, but we have often heard complaints that the dishes sold at restaurants where its principles are carried out fail to please from the want of the sort of flavour that the popular palate seems to crave.

FAT-EMBOLISM.

IT has, of course, been common knowledge for fifty years that fat droplets may appear in the capillaries of the lung as a sequel to fracture or other injury of the bony skeleton. There is, however, a prevailing impression that the phenomenon is met with only in pathological conditions where the bone-marrow is obviously affected. In more than one textbook of forensic medicine, for example, statements may be found to the effect that its occurrence in the presence of fracture is conclusive evidence that the fracture took place during life. This does not appear to be strictly true. Nicolai[1] examined both lungs in 57 autopsies on cases in which there was no reason to suspect osteomyelitis, fracture, trauma, or other skeletal injury, and in as many as 8 he found quite considerable amounts of fat in the lung capillaries. He examined frozen sections, stained with Sudan III, one from each lung, and took as positive only those in which the fat occurred as elongated droplets or strings, like plugs, definitely within the vessel wall. His criterion was thus stricter than that adopted by others, such as Flournoy or Scriba, who have also stated that they found fat in the lungs in all sorts of diseases; he excluded cases in which the fat was seen only as small isolated droplets or globules. Nicolai further gives an account of a case of fat-embolism after fracture which presented most of the classical features originally described by von Recklinghausen. Death occurred on the third day after the injury, and the examination revealed remarkable quantities of fat in the capillaries and small vessels of the general circulation—namely, in the white matter of the brain, in the kidney, heart, subcutaneous tissues, and elsewhere. It has been asserted that these large quantities of fat outside the pulmonary circulation occur only in cases in which the foramen ovale is patent, but in this instance the foramen was closed, and the fat must have passed through the lungs with very little delay.

RADIUM IN THE TREATMENT OF CANCER.

THE Columbia University has recently issued the first annual report of the George Crocker Special Research Fund for the investigation of the nature and cure of cancer. It indicates the general lines on which research has been conducted under the director, Professor Francis C. Wood, since the laboratory was opened in December, 1913. The working staff consists of a director with five assistants. From a summary of the report published in the New York *Medical Record* of December 5th, we gather that a special study has been made of the action of radium and x rays on tumour and normal tissues growing in culture media. The results show such discrepancies that the director insists on the necessity of great caution in drawing any conclusions, and deprecates hasty generalizations as to the sensitiveness or lack of sensitiveness of tissues to the action of these agents. A large series of experiments has been made with the object of testing the action of radium on primary tumours in mice, which are said to correspond very closely with tumours in man. The results have not shown that radium has any great therapeutic effect on such growths. Radium has also been used on a considerable scale on patients in hospitals, and it is hoped in this way to collect data on which an accurate judgement as to its therapeutic value may be based. Investigations with certain colloidal silver preparations, highly vaunted in Germany as well as in the United States as of great value in the treatment of malignant disease, have shown, according to Professor Wood, that these substances have no effect on cancer either in man or in animals.

BATH.

ALTHOUGH British health resorts need not fear comparison with Continental spas in respect of the advantages and amenities they offer to invalids and other visitors, they have not hitherto shown as much enterprise as many German and Austrian, and some French and Italian health resorts in bringing their excellencies to the notice of the medical profession and of the public. The closure of so much of the Continent this autumn afforded an opportunity of which very little use seems to have been made. Apparently, however, the need for publicity is coming home to some British spas, and Bath has recently issued a well illustrated handbook in which the merits of Bath waters in gouty and rheumatic affections, in neuritis, in some skin diseases, and in certain disorders of the digestive system are mentioned. The recent analysis by Sir William Ramsay is given, and the results of his estimation of the amount of radium and radium emanation in the waters are shown. Bath possesses a very complete installation for giving baths in various forms, and for hydrotherapeutic treatment generally. Its sheltered situation renders it a very suitable place for residence in winter, and it is not a dear place to live in. The surrounding country is beautiful, and contains many interesting old towns and villages such as Bradford-on-Avon, Glastonbury, and Castle Combe. The hot springs are the property of the corporation, which has established a visitors' inquiry office, where full particulars may be obtained on personal application, or by letter addressed to Mr. John Hatton, director of the baths. The corporation has also recently issued a leaflet in French addressed to Belgian and French visitors.

WE regret to have to announce the death, on December 22nd, of Sir Robert M. Simon, who in May last resigned the position of physician to the General Hospital, Birmingham, after having served the hospital for thirty-five years.

OUR BELGIAN COLLEAGUES AT HOME AND ABROAD.

MEETING OF THE HAMPSTEAD DIVISION.

A MEETING of the medical profession in Hampstead, called by the local Division of the British Medical Association, was held in the hall of the Blind School, Swiss Cottage, on December 18th in furtherance of the objects of the fund for the relief of doctors and chemists in Belgium. The Chairman of the Division (Dr. COODE ADAMS) presided. Letters of apology for absence were received from Dr. S. Squire Sprigge, Professor Starling, and Dr. Ford Anderson.

Sir RICKMAN GODLEE explained that the objects of the fund were the assistance of doctors and chemists, either in Belgium or amongst the refugees in this country. In Belgium the doctors and chemists were in an extremely unfortunate position, because their premises contained material useful to the invaders and consequently were pillaged. It had not been thought desirable at present to send money into Belgium. The gifts of subscribers, therefore, would take the form at first of packages made up of articles which would help a small number of doctors and chemists to begin work again. Fifty boxes, each of the the value of £5, had been prepared, and if these reached those for whom they were intended further supplies would be sent. There were about 4,000 doctors in Belgium, and probably 2,000 would require assistance. It was not thought practicable to single out doctors and

chemists for special gifts of food; they must share in that respect with the general population. It was difficult to discover how many Belgian doctors were in this country, but probably there were not more than 200. A certain amount had been spent already in relieving their immediate necessities. As to raising funds for these purposes, the profession in Dublin took early action, and on December 15th had collected £680; Scotland had also taken action, and in England £1,888 had already been subscribed. Help was promised from America, and it was hoped to secure a share in an enormous contribution of £20,000,000 by Mr. Rockefeller towards the relief of distress in Belgium. An appeal had been issued for a supply of surgical instruments, which though not perhaps of the latest pattern, might be serviceable to their Belgian colleagues. He had spent an interesting time examining some of the instruments sent in response to this appeal. Some dated back to very hoary antiquity, but there were a large number of very useful knives and forceps, and midwifery forceps. When the Committee heard that the supplies of drugs had arrived safely it proposed to send out the instruments. To reinstate the doctors and chemists of Belgium was a large task which might take a considerable time to complete, and it was necessary to appeal most urgently to the medical profession and those whom its members could influence.

Dr. D. G. PIDCOCK moved, and Dr. G. E. SHUTTLEWORTH seconded, the following resolution:

> That a fund be established entitled "The Belgian Medical Relief Fund," and that the trustees be the Chairman and Vice-Chairman of the Hampstead Division of the British Medical Association.

This was carried, and the proceedings concluded.

THE BRUSSELS MEDICAL GRADUATES' ASSOCIATION.

Dr. MAJOR GREENWOOD, Treasurer, Brussels Medical Graduates' Association (243, Hackney Road, N.E.), writes: At a recent meeting of the Council of the Brussels Medical Graduates' Association it was resolved to send out a circular to all British practitioners with Belgian medical degrees, specially asking support for this fund.

It was hoped that they would be willing to assist the association in getting together a considerable sum that might be presented to the above mentioned fund in the name of Belgian medical graduates generally.

The appeal has been fairly successful, but the Council desires that at least a hundred guineas should be collected before the contributions are handed over, and this amount has not yet been quite gained. May I ask, through your columns, any Belgian medical graduate, whom our circular may not have reached, or who has not already subscribed to the fund, for a small subscription for the above purpose?

Dr. F. HOWARD HUMPHRIS, President, Brussels Medical Graduates' Association (8, West Chapel Street, Mayfair, W.), writes: An appeal in money is being made for those Belgian doctors who are refugees in this country, and this has met already with generous response.

There are many, however, who would doubtless prefer to find a home in the family of an English medical man where they could give such services as lie in their power. Up and down the country thousands of homes have already been given to destitute Belgians, and I feel that there must be many medical men in this country who would in this way like to repay something of the debt of gratitude which they owe to Belgium.

There are about 140 Belgian doctors at present in England, the majority of whom are in very straitened circumstances, and I feel that it only needs an appeal through your columns to the 30,000 British practitioners to call forth a ready response in the form of an offer such as I indicate.

I shall be pleased to deal with any correspondence relating to this matter and put any offers before the Committee of Belgian Medical Men in London, who are endeavouring to arrange some *modus vivendi* for their compatriots.

THE BRITISH COMMITTEE.

The British Committee has appointed a subcommittee to inquire into cases in this country in which immediate relief is sought, and if deemed necessary the regular action in this direction of the British Government will be supplemented. The Pharmaceutical Society of Great Britain has already been able to help Belgian pharmacists who are refugees, many of whom are in very distressing circumstances.

The first consignment of parcels of medical materials has been prepared by Messrs. Burroughs, Wellcome and Co., Ltd., for distribution through Mr. H. Hoover, 3, London Wall Buildings, E.C., chairman of the Commission for Relief in Belgium. So soon as the licence of the British Government to export is obtained the parcels will be sent, in accordance with the request of the Belgian Committee represented here by Professor Jacobs, to M. Delacre, a well-known pharmacist in Brussels, who has been requested to report the results of the distribution of the first consignment as soon as possible to the British Committee.

The following subscriptions to the Fund have been received by Dr. Des Voeux up to Tuesday morning, December 22nd, in addition to subscriptions amounting to £1,888 previously acknowledged:

Fifth List.

	£	s.	d.
Mr. E. Warters ...	2	2	0
Sir John W. Byers ...	2	2	0
Dr. Clifford Beale ...	5	5	0
Dr. T. W. McDowall	5	5	0
Mr. F. Manser ...	2	2	0
Mr. G. L. Latour ...	1	1	0

Dr. Hugh Playfair ...	3	3	0
Dr. W. B. Russell ...	1	1	0
Dr. G. Victor Miller	1	1	0
Dr. Arthur C. Black	3	3	0
Dr. W. Townsend Storrs	1	0	0
Mr. F. Ashley Rogers	2	2	0

Subscriptions should be sent to Dr. H. A. Des Voeux, 14, Buckingham Gate, London, S.W., and should be made payable to the Belgian Doctors' and Pharmacists' Relief Fund, and crossed "Lloyd's Bank Limited."

INSTRUMENTS.

The Master of the Society of Apothecaries begs to acknowledge with thanks the receipt of surgical instruments, etc., kindly contributed by the following donors since the publication of the last list:

Lieut.-Col. C. J. McCartie, I.M.S., Kingston, co Dublin.
Dr. Evers, Faversham.
Anonymous, Clifton Down.
Messrs. Maw, Son, and Sons, London.
Dr. Darley Wynne, Clonmel.
Dr. F. W. Monsell, Lydney.
Colonel Joubert de la Ferté, Weybridge.
Dr. J. Ross Steen, Ilford.
Dr. R. Murdoch Matheson, Edinburgh.
Dr. Aldersmith, Horsham.
Dr. E. A. Milner, Lancaster.

THE Royal Dental Hospital (Leicester Square) has received a donation of £1,000 from Mr. Somerset Beaumont.

THE WAR.

MEDICAL ARRANGEMENTS OF THE BRITISH EXPEDITIONARY FORCE.

[From a Special Correspondent in Northern France.]

RAIN IN THE TRENCHES.

SAVE for one fine day, rain—and often heavy rain—has for over a month only ceased to fall when its place has been taken by sleet or when a tornado of wind has swept it upwards from the earth. On days when these conditions have prevailed I have passed some hours within earshot of the firing line, picnicking, so to speak, in the open in a flattish country, whose rain-sodden fields are intersected by deep ditches and whose horizon is cut by sparse clumps of trees, small woods, and an occasional distant church spire or factory chimney. It was positive luxury to be able to escape direct impact of wind and rain by crouching at the bottom of a ditch, and a chunk of tinned beef and a slice of dry bread seemed a meal for Lucullus. I marvelled then that our men should be able to withstand these conditions day after day, maintaining meanwhile their fighting qualities, despite artillery and rifle fire and the sight of comrades killed and wounded. I marvel still to some extent, but I find that in my own case the absolute change from the protected existence of a city dweller to a semi-savage life has not been followed by ill effects. This, which is the general experience, suggests that possibly an individual's preoccupations and mental attitude towards his environment have more effect on his physical condition than one is at first disposed to admit, even in these days of psycho-therapy. This reflection, added to the knowledge that the great majority of our troops are men in the very prime of life, makes their general bearing, their vigour, good spirits, courage and endurance, and the comparative infrequency of medical disorders amongst them, seem the less remarkable. It is true that there are many cases of rheumatism. It would be strange indeed if this were not so.

At the best of times the life of the men at the front is not one of comfort; the existence of those who are for the time being in billets, that is to say, in any cottages or houses that may be available, is rough, and when their short turn of rest is over and they have moved into the trenches they are never really dry or warm or comfortable until the time for their next relief arrives. This may be in three days, a week, or a fortnight, the duration of a turn of trench duties varying with the activity of the operations and the number of troops that may be available at the moment. Once in the trenches a man's life is divided between hours on and off duty; commonly the rule is two hours "on" and four hours "off," but all depends on the number of men in charge of the particular trench and the activity of the enemy. Often the periods are one hour on and one hour off, and the "off" is liable to disappear altogether. A man on duty stands quite still at his assigned position, he rests his rifle on the deck—the level of the upper ground—and fires it as often as he thinks necessary. Sometimes only his head and shoulders are exposed, at others his whole body from the waist upwards. In either case he leans against a wet, muddy wall, and often stands in six or more inches of water. A man off duty, if the trenches are of recent construction, can merely huddle himself together and rest under protection of its sides, but if it is a completed trench he lives in a cave dug out of one of its sides and protected from the inrush of water by a wall of clay or mud. Sometimes he has a waterproof sheet; the general atmosphere is muggy and damp, and he knows that any moment a "Jack Johnson" may strike the ground over his cave and bury him prematurely.

CLOTHING AND FOOD.

When vast numbers of men are living in such conditions it is not remarkable that there should be a good many cases of rheumatism, especially among the older individuals. Among counteracting forces are the facts that despite all difficulties the men are almost invariably supplied with a large amount of good food and that they are warmly clad. Each man wears a woollen jersey, a pair of woollen drawers, a flannel shirt, a cardigan jacket, a cloth tunic, and a thick cloth overcoat. Putties embrace his legs from the knee downwards, and under them are usually two pairs of long woollen socks, and on his feet a pair of very strong well-made boots. His regulation cap he commonly discards, for the time being at any rate, in favour of a knitted helmet or other light headgear. He often, and indeed usually, has also a pair of mittens, and men known as "Teddy Bears"—that is, men wearing short fur coats of goatskin—are rapidly ceasing to attract attention, owing to these coats being served out in increasing quantity. They are made with the hair on the outer side—a method which has led to some criticism. A coat with the hair turned inside would certainly be warmer, but one with the hair outside keeps a man drier. Possibly the authorities consider that since in Western Europe rain is quite as common a feature of the winter as dry cold, it is best to compromise between preservation of the body temperature and its protection from external damp. Neither can be obtained in the highest degree by one and the same garment. I also understand that at some billeting stations arrangements have been made for supplying the men with hot baths when they come out of the trenches, and I am informed that in some of the older trenches it has been found possible to introduce charcoal braziers. Each of these factors counts no doubt for something in keeping down the prevalence of rheumatism and other disorders commonly ascribed to cold and damp.

FROSTBITE.

The stream of cases of frostbite from the front has for the moment almost ceased, but the number of men incapacitated, temporarily or permanently, from this cause has been sufficiently large to be of some importance I should imagine from a military point of view. The temperature so far has never been really low; in fact, there has never been more than a few degrees of frost for a limited number of hours, mainly at night. In all probability the actual temperature of the air at any given moment is only one of several factors in the production of the condition to which the term "frostbite" has been applied, and I understand that all the cases hitherto noted have been limited to the feet. Apart from actual frost, the factors in question appear to be the soaking of the men's boots and socks either in freezing water or a mixture of mud and slushy snow, the absence of any local output of muscle heat owing to the fact that the men are standing still, and some tightness of their boots owing to the men putting on two or three pairs of socks which are thick even when dry, and thicker still when wet. With their legs thus chilled in advance and the whole local circulation already reduced to a very low ebb, it is comprehensible that here and there in superficial areas it should be arrested for a time altogether. The usual history of these cases is that a man who has just got into his dug-out after standing for an hour or more with his rifle on the deck, has seen his way to a good rest and consequently has taken off his boots. On doing this he has noticed nothing the matter with his feet, but subsequently has found that they have become so swollen that, apart from any question of pain, to get his boots on again is quite impossible. The cases as seen at the advanced base hospitals within twelve hours or so of their occurrence vary very considerably. Only a minor proportion resemble classical cases of frostbite; the larger number bear a greater resemblance to huge chilblains of sudden onset and so acute a character that they are already disposed to "break," as one used to say in one's school days. Many suggestions are being mooted for prevention of these cases of frostbite. I understand that the experts believe that the situation, military and medical, would best be met by providing the men with larger boots. There seems, however, to be some probability that a large number of "Arctic boots" will be served out. These, which are of American origin, have leather soles and thick felt uppers reaching to the knee, and they are of such size that they can be put on over any ordinary boots, yet do not prevent their wearer moving freely and rapidly. An offer of a very large number of these boots, I am told, has been made by a philanthropist, but I doubt if their use will become general

FRENCH EXPERIENCES.

Treatment of Wounds.

Dr. Chavasse, the Inspector-General of the French Medical Service, who was recently appointed the chief medical officer of the hospitals on the lines of communication, has issued a memorandum on the treatment of gunshot wounds. He advises that every wound and its surroundings should be painted once with 1 per cent. tincture of iodine, that antiseptic treatment, "including asepsis," should be systematically employed both in the first treatment of wounds and in operations, and that care should be taken to prevent the stock dressings being soiled by dust. Strict orders should be given that dressings should not be changed more often than is absolutely necessary, and that the tendency, specially among amateur nurses, to change them whenever they appear to be soiled by discharges, should be strongly repressed. Even though dressings appear to be soaked, yet if there be no evidence of excessive suppuration, if the wounded man be free from fever and pain, and if the dressings be not abundantly soiled with blood, which would indicate severe haemorrhage, Dr. Chavasse considers that it is sufficient as a general rule to moisten the surface of the dressing with a deodorant antiseptic, such as a weak solution of chlorinated soda, and, if necessary, to add another layer of cotton-wool. After indicating that conservative surgery should be practised as fully as possible, especially in the upper limb, Dr. Chavasse stated that the general indications for amputation during the first few days were disorganization of the limb and gangrene, since loss of substance of the soft parts, even though large, was often reparable. For cleansing large wounds in clearing hospitals within a few hours of the receipt of the wound, he advised the use of oxygenated water and hot sterile artificial serum. In the treatment of severe haemorrhage, where direct operation was impossible, he advised that an attempt should be made to arrest the haemorrhage by pads, and that in no case should a tight tourniquet or bandage be left on for more than one or two hours. He stated that in penetrating wounds of the abdomen the early employment of ice and opium had given results as good as, if not better than, suprapubic incision, although this operation might be necessary if definite peritonitis occurred. Suture of the intestine, even when done under the best conditions, had not given encouraging results. If the bladder or ureter were wounded cystostomy was indicated. For wounds of the kidney, if any operation were undertaken, it should not be more than incision and drainage.

M. Hartmann, in a communication to a recent meeting of the Académie de Médecine, stated that his experience led him to consider that tincture of iodine was useful only in the rare cases of non-infected bullet wounds. Nearly all wounds received were infected after an interval of twenty-four hours, and the object should be to ensure free openings and to irrigate with hydrogen peroxide or strong solution of carbolic acid. Afterwards, if the wound remained much infected, he used large local baths, or, where this was not possible, antiseptic sprays. He also recommended compresses soaked in solution of chlorinated soda as a simple and cheap dressing, which gave good results, especially in foul wounds with sanious discharge.

HOME HOSPITALS AND THE WAR.

1st Western General Hospital (T.F.).

The 1st Western General Territorial Hospital is established in the City of Liverpool Fazakerley Hospital, consisting of twelve blocks for wards, in addition to buildings set apart for administrative purposes. The hospital occupies an elevated and spacious site just outside the city boundary, and readily accessible by train and tram. Built for the treatment of infectious diseases by the Corporation of Liverpool, 160 beds were opened in 1901 for variola, and the remaining blocks, containing 350 beds, were completed in 1906 for other infectious fevers. At the beginning of the war the hospital passed under the control of the military authority, and the medical staff, consisting of four physicians, four surgeons, and specialists, was duly mobilized according to their military rank. Lieutenant-Colonel Burns Gemmel is the Commanding Officer. All the medical officers are well-known Liverpool medical men holding hospital appointments and engaged in practice in the city. Lieutenant Allen Naldrett, the Superintendent of the Royal Southern Hospital, is the Quartermaster. Many of the nursing sisters are drawn from the large Liverpool hospitals, and others have received their training in Liverpool. Thus harmony and efficiency were guaranteed at the very outset, and the hospital machinery is working thoroughly well and satisfactorily.

The wards are not only well lighted but bright and cheerful, and as the hospital was arranged for infectious diseases, isolation rooms and all the essentials for disinfection of clothing are provided.

The operating theatre is admirably equipped. The surgical instruments are a gift from Lieutenant-Colonel W. Alexander. The *x*-ray department is under the control of Captain Thurstan Holland, who recently related the results of his work at the Medical Institution before a large gathering of the members. There are also laboratories attached to the various blocks for pathological investigation. During the last three months some 3,000 soldiers drawn from the regiments serving in the Expeditionary Forces, some naval ratings, and about 60 Belgian soldiers have been patients. The almost universal impression produced by the soldiers in spite of their very real hardships—for many have been in the trenches in the vicinity of Ypres—is one of good, well-nourished bodies. Mentally, cheerfulness even among the seriously wounded, is a dominant characteristic. No animosity towards the enemy is shown in their accounts of their experiences. Naturally the surgical cases predominate, and some 450 beds are set apart for them; the remaining 150 are reserved for medical and special cases. The preponderance of shrapnel wounds over those caused by rifle bullets is striking. In more than one instance *x*-ray examination has revealed all over the body fragments of shell and shrapnel bullets. Generally speaking, if the foreign bodies cause no inconvenience, and the wounds are clean and healing, no attempt at removal has been made. Frequently the *x* rays have revealed a shrapnel bullet embedded in the head of a long bone which, owing to the wound having healed and to the absence of symptoms, would never otherwise have been suspected. The path of the missile and its final resting place in the body in relation to the point of entrance is in many cases bizarre. A bullet entered behind the centre of the clavicle, and became ensconced behind the carotid sheath on the same side. In another case a bullet was extracted from the acetabulum without damaging the femur, and in a third case a shrapnel bullet was discovered firmly embedded in the tissues between the spine and posterior superior spinous process of the ilium, some distance from the point of entry. In cases where *x* rays fail to reveal the cause of suppuration often enough a piece of clothing is found at the bottom of the wound. Conservative surgery is the keynote of treatment in a healed wound and no attempt is made to remove the foreign body when this gives rise to no symptom. Hydrogen peroxide and carbolic acid are among the antiseptics used in the treatment of suppurating tracts. In one case in which the right scapula was shattered by a shell fragment, tearing away the skin over the deltoid region and disorganizing the joint, leaving a large irregular wound, after removal of the bony fragments and excision of the head of the humerus, the wound soon assumed a healthy appearance and the surgeon has every hope of saving the limb.

During the past three weeks several cases of frostbite have been admitted. The toes are chiefly implicated, and probably in many cases the ungual phalanges will be lost. In one of the worst cases both feet are involved, and the line of demarcation is beginning to show itself at the ankle-joint. All the cases are of the black, dry type of gangrene, unaccompanied by pain of any severity.

There have been four cases of tetanus; two died and two recovered. Antitetanic serum and carbolic acid separately or conjointly have been the medicaments used.

The medical beds have been occupied chiefly by cases of rheumatism and nerve exhaustion. Exploding shells which have not caused wounds may have so shattered the nervous system as to render the man unfit for service; for the time being he is a physical wreck. Only one case of enteric fever has been admitted, and the patient belonged

to one of the Territorial units encamped in the vicinity of Liverpool. Over thirty cases of beri-beri were brought in a transport direct to Liverpool, and admitted to the hospital; all recovered. Of some eighteen cases of venereal disease one only was invalided from the Expeditionary Force. This is highly satisfactory.

The ambulance arrangements for the transit from the railway stations to the base hospital are admirable in every particular, and there is no delay in bringing the lying-down cases to the wards. The ambulance orderlies have proved themselves to be thoroughly efficient, and reflect credit on their instructors.

THE BRITISH RED CROSS SOCIETY.

Survey of the Work in France.

An interesting survey of British Red Cross work in the north of France is contained in a report by Sir Frederick Treves of his visit to the area, which was presented to the executive of the Society on December 23rd.

This report stated that the value and efficiency of British Red Cross work in France could be well gauged by a visit to the stores shed at Boulogne, by a study of the postings of the fleet of motor ambulances, and by the distribution of the surgeons, nurses, and orderlies in the employment of the Joint Committee.

The store at Boulogne contained the infinite variety of articles that come under the heading of Red Cross supplies, and the huge dépôt is described as a model of efficiency. The fleet of motor ambulances Sir Frederick considers to be the most valuable form of voluntary service ever rendered to the Army Medical Department. The ambulances are working everywhere, bringing down patients and returning with stores for the wounded. In the saving of life, the lessening of suffering, and in securing prompt surgical treatment of the wounded, the ambulances have done a work the value of which can hardly be exaggerated. Their efficiency in removing the wounded from the hospital trains to the wards or ships is a revelation to those who have only seen horse or hand carriage in operation.

The personnel of the Society is dispersed in many directions. Many surgeons are attached to the military and auxiliary hospitals, others are with motor convoys, or with trains or at rest stations. A few are with French troops.

Valuable work is done at Boulogne by a British Red Cross voluntary aid detachment located in seven railway wagons standing in a siding. There is a dispensing store, a surgery equipped with all necessaries for an emergency dressing station, and a kitchen from which at any hour of the day or night tea or cocoa and other refreshments are supplied to the wounded passing through. Three fully trained hospital nurses are included in the staff, and they render innumerable little services to the wounded. As many as 2,300 men have been fed in one day at this station.

The Voluntary Hospitals.

The report stated that there are seventeen hospitals in or about Boulogne, of which ten are military hospitals and seven voluntary hospitals under military control. The beds numbered thousands, but all have been needed, for between October 16th and December 11th the number of wounded arriving at Boulogne was very great. The Duchess of Westminster's hospital at Le Touquet occupies the Casino and contains 270 beds. The medical officer in charge is Major Gordon Watson, who gained experience in the South African war. An admirable *x*-ray room has been fashioned out of a garden storehouse while the dark room is a large bathing machine brought up from the beach. The operating theatre occupies the fencing saloon. The change from the ordinary life of the place which the war has brought about is illustrated by the presence in one of the wards of baccarat tables piled against the wall, and in the linen store of fantastic pictures of tango dancing. The dispensary is in the American bar. The hospital is well found and has gained a high reputation for good work.

The Allied Forces Hospital at the Hotel Christol, Boulogne, in charge of Major Ernest Miles, contains 189 beds, which have been largely occupied by wounded British officers. The hospital affords evidence of careful administration and is well equipped.

The Anglo-American Hospital at Wimereux occupies the Hotel des Bains. The medical officer in charge is Major Armstrong, I.M.S., and the London Hospital is well represented amongst the personnel. There is accommodation for 100 patients.

The British Hospital occupies the Hotel Belle Vue at Wimereux and has 102 beds. Here there have been difficulties owing to the fact that the building is not very well adapted for a hospital. The Australian Hospital, established at the Golf Hotel, is much exposed to gales from the sea, and some of the windows have actually been blown in. The chief surgeon is Colonel Eames, and the nine surgeons on the staff are all Australians. The Women's Hospital Corps Hospital is established in a large villa in Wimereux and is in the charge of Miss Garrett Anderson, M.D. It is worked entirely by women doctors and has 65 beds.

The Baltic Hospital, Calais, is situated in a large girls' school on the outskirts of the town, and is devoted solely to Belgian soldiers. It contains 105 beds, but there is an annexe for enteric cases containing 20 beds, of which 17 were occupied on the day of the visit. The hospital is rationed by the Belgian army. Major H. Stedman is the surgeon in charge. There have been troubles with the drains, but these and many other difficulties Major Stedman has surmounted. The hospital is a good one, doing splendid work. Enteric fever is apparently not increasing. It was reported that there were only 200 to 250 cases of typhoid among Belgian soldiers in the whole of Calais. New cases were coming in at the rate of about ten a day.

Dr. Hector Munro is doing work at Furnes, where he has the assistance of one other surgeon. The unit works with the Belgian troops, and its nine ambulances are provided by the British Red Cross Society. In times of pressure as many as 200 to 250 wounded men have been brought in during one day. The so-called Quaker Hospital near Ypres ministers to sick and wounded refugees from that town, and is frequently exposed to shell fire. The nursing is undertaken by refugee nuns from Ypres. But for the help of this advanced hospital, which is doing heroic work, the people from Ypres would be without medical and surgical aid.

The British hospital at Furnes deals solely with Belgian wounded; it occupies a Jesuit college, and has 80 beds. A light equipment is necessary, as Furnes is frequently shelled, and a rapid evacuation is always before the mind of the medical officer, Mr. Sonttar of the London Hospital. Very valuable surgical work has been done at this hospital.

NOTES.

Care of Soldiers' Feet.

Major Henry Dutch (London, W.) informs us that the following leaflet has been adopted by many commanding officers of new battalions and given to each man on enlisting:

The Care of Soldiers' Feet.

To prevent sore feet the soldier should attend to the following points:

Boots should fit with comfort, neither causing pressure or being too loose, causing friction. The leather, if hard, can be softened with dubbin or oil. Nails or seams inside the boots must be removed, and the boots should be properly laced.

Socks should fit easily, not too large or too small. *Dirty socks, badly-darned socks, socks with holes* or *too thin* are a frequent cause of sore feet.

Feet.—The feet should be washed and thoroughly dried daily and dusted with boracic powder. It is a good plan to soak the feet in a bucket of cold water, to which may be added a little permanganate of potash, alum powder, salt, or saltpetre. When blisters occur the serum should be let out with a clean needle, sterilized by passing through the flame of a match, the superficial skin not being removed. If sores occur they are best treated by the application of boracic lint or powder, a small piece of lint being strapped over the sore and renewed daily.

Corns and hard skin can be easily relieved with the new miniature corn planes or by applying a few drops of salicylic-collodion for three nights, when the corns can be picked off after bathing the feet in hot water. Any soreness between the toes can be relieved by packing in a little cotton-wool.

Major Dutch suggests that recruits wearing spectacles should be recommended to provide themselves with two pairs with curl sides.

MEDICAL OFFICERS WANTED.

Hunts Cycling Reserve Battalion.

Captain C. B. Moss-Blundell, Sanitary Service, R.A.M.C.(T.), and County M.O.H. for Huntingdonshire (56, High Street, Huntingdon), writes that the Hunts Cyclists Reserve Battalion is without a medical officer. He states that the probabilities of the officer seeing active service are great, and that he will be pleased to give any likely applicant further information.

2nd (Reserve) Welsh Field Ambulance.

We are requested to state that there are some vacancies for medical commissions in the 2nd (Reserve) Welsh Field Ambulance. Applications should be addressed to Lieutenant-Colonel Owen L. Rhys, 32, North Parade, Aberystwith.

West Lancs Clearing Hospital (T.F.).

There are vacancies for five medical officers in the West Lancashire Clearing Hospital (T.F.), which is a unit for the Expeditionary Force. The head quarters of the unit and the present training station are at Kendal, Westmorland. Particulars may be obtained on application to the Officer Commanding, West Lancashire Clearing Hospital, Kendal.

England and Wales.

[FROM OUR SPECIAL CORRESPONDENTS.]

LONDON.

MEDICAL EDUCATION OF WOMEN IN LONDON.

THE buildings of the London School of Medicine for Women in Hunter Street, Brunswick Square—not far from the Royal Free Hospital, which is the clinical hospital of the school—were completed in 1900. They were well designed and thoroughly suitable for their purpose, but, owing to the increase in the number of students, they are now proving inadequate to the growing needs of the school; it is therefore proposed to make an important addition to the existing buildings on an adjoining site. The new buildings, which will occupy an area of 75 ft. by 62 ft., will be in the shape of an L, its base fronting on Wakefield Street. The architect, Mr. H. V. Ashley, is carrying out the design in consonance with the architectural features composed by the late Mr. John Brydon for the existing building.

The new building will consist of four stories. In the half-basement accommodation will be provided for a pathological research department and an extension of the physics department, containing a lecture theatre to seat sixty students, six small dark-rooms, and lecturer's, demonstrator's, and preparation rooms.

The ground floor consists of a colonnade connecting the present block of buildings in Hunter Street with the new block, an extension of the chemical department, including a laboratory for 24 advanced students, lecturer's and demonstrator's and preparation rooms, balance and store rooms, as well as a Students' Union room, and some extra cloak-room accommodation.

The first floor will be devoted to an extension of the department of physiology, and will contain a large laboratory for advanced students, a good research room, demonstrators', preparation and dark rooms, a demonstration theatre with space for 50 to 60 students, and research and private rooms for the head of the department.

The second floor will be devoted to the extension of the department of anatomy. An additional dissecting-room will be provided, 64 ft. by 28 ft., with mortuary, store-room and preparation rooms adjoining. There will also be a good demonstration theatre, to seat 40 to 50 students, and a demonstrators' room. An animal house will be arranged on the roof.

It is estimated that the increased accommodation will enable the school to provide for an entry of about 75 students per annum. At the present time 212 students are in attendance.

The council of the school makes an appeal for £25,000 to defray the cost of the new buildings. The school was founded forty years ago, and has done very admirable work not only directly for its own students, but indirectly by setting a high standard before women who desire to become medical practitioners. Its direct influence is wide, for it claims that of the thousand women now on the *Medical Register* six hundred were at one time its students.

Scotland.

[FROM OUR SPECIAL CORRESPONDENTS.]

WOMEN AND THE MEDICAL PROFESSION.

IT would seem as if there were already visible signs pointing to an influx of women students into the medical profession. The great increase in the size of the first year classes in the Edinburgh School of Medicine for Women, to which reference was made in these pages in June (see JOURNAL for June 13th, p. 1324), has been fully maintained this winter. This influx, which had begun before the outbreak of war, will certainly not be checked by the military situation, which is already by its exigencies abroad making great demands upon the medical profession at home. It was probably, however, largely due to the new openings for women doctors which were made by the medical requirements of much of the new legislation regarding national insurance, certification and supervision of midwives, and school hygiene; in all these directions, as well as in those of general practice and asylum work, opportunities for women graduates have been multiplied of late years. Nor has the expansion reached a limit, for any new developments of the maternity and pregnancy benefit under the Insurance Act, or of antenatal clinics and baby consultations, will make still more marked the demand for women qualified to deal with these matters. At any rate, the facts that the first year classes in Edinburgh this winter number 34 or 35 students in place of the 12 or 15 of past sessions, mark a distinct advance in the popularity of medical practice as an opening for educated and aspiring women.

Correspondence.

THE NUMBER OF MEDICAL STUDENTS.

SIR,—The Registrars, Deans, and other officers of the Schools of Medicine, and of approved Scientific Institutions throughout the United Kingdom, have been good enough to furnish me with returns, showing the number of medical students in attendance this session, as compared with the number in attendance last year. As the statistics have an important bearing on many questions touching the future supply of qualified practitioners for the service of the country, I would ask you to publish the following figures.

Decrease in Enrolments October, 1914, as compared with preceding year.

First-year students	56 fewer.
Second-year students	237 ,,
Third-year students	237 ,,
Fourth-year students	211 ,,
Fifth (and higher) year students ...	300 ,,

The aggregate number of medical students now pursuing their curriculum with a view to qualification is thus about 1,000 smaller than in 1913.

Unless many senior students return to their studies within the next few months, the result will be that the number of young qualified practitioners added yearly to the ranks of the profession will during the next few years be from 200 to 300 less than before. This is equivalent to a diminution of about 25 per cent. of the average number annually added to the *Medical Register* on qualification. The number annually removed from the *Register* by death or otherwise has for some years past been about 800.

In view of the additional losses among senior practitioners due, directly or indirectly, to the war, the prospective diminution of our reserve supply calls for serious consideration. I am, etc.,

DONALD MACALISTER,
President.

General Council of Medical Education and Registration of the United Kingdom, 299, Oxford Street, London, W., Dec. 19th.

ANTISEPTICS IN WAR.

SIR,—Mr. Cheatle, in his short note in your issue of December 12th, speaks with great confidence of the value of applying an antiseptic paste to wounds in war. He does not seem to have considered the particular conditions in the present theatre of operations, either in respect

of climate, soil, or type of injury. He also appears to ignore the frequency with which wounds are infected with anaërogenic gas-forming organisms.

I cannot believe that the application which he recommends would give satisfactory results in a type of wounds that are most frequently the seat of serious infection. Such wounds are those caused by shrapnel balls, shell fragments and spent bullets, more especially those where a bone has been splintered; they are relatively large and ragged, and if the missile does not lodge, the wound of exit is of the explosive type. Fragments of clothing are carried along the track, clothing which is almost inevitably soiled with earth containing virulent organisms, for the earth is derived from fields where intensive culture is the rule, or from the sites of closely populated areas where village sanitation is still primitive.

To remove the probability of infection from this kind of injury, nothing but the full opening up of the wound and the mechanical removal of infective débris will suffice. Merely to squeeze on and into the wound a paste would, in many cases, render matters worse by plugging up the only exit for discharge; this applies with particular force to those cases in which there is a moderate-sized wound of entry only.

If the discharge from the wound is limited in any way, an unnecessary loss of life or limb may well be involved, should, as is frequently the case, gas-forming organisms be present.

It is, I think, dangerously misleading to quote experience in South Africa in advocating methods for wound treatment in the present war. In South Africa the vast majority of wounds were caused by the old pattern Mauser rifle bullet; whereas, in the present campaign, a large proportion of the wounds till recently has been the result of artillery fire. Rifle bullet wounds in South Africa would probably have healed quite as well if they had been powdered with a little dust from the veldt. Certainly this type of wound, when occurring in sparsely inhabited and little cultivated country, heals with great readiness under the most adverse conditions. From my experience in the Balkan war, I can say that wounds due to rifle bullets, even when left undressed and untreated for many days, healed soundly under a natural scab, and this occurred in half-starved and mud-stained troops.

In conclusion, may I question the justice of Mr. Cheatle's application of the word "disgraceful" to the condition of wounds of men arriving at home hospitals? It seems to me an instance of an unfortunate tendency, which is apparent among some of our brethren at home, to cast aspersions on the surgical treatment of our soldiers in France. But I venture to submit that, in the absence of personal observation of the local conditions, judgement should be reserved till those, who are by implication attacked, return home and are able to stand on their defence.—I am, etc.,

C. MAX PAGE,
Boulogne, Dec. 16th. Captain R.A.M.C. (Special Reserve).

SIR,—In reading Mr. Lenthal Cheatle's article in the BRITISH MEDICAL JOURNAL of December 12th (p. 1006), it occurred to me that the author scarcely does justice to the conditions of the work out here (France).

Iodine treatment of wounds was successful in the Russo-Japanese war, and owing to a clean, frost-bound and virgin soil little sepsis was experienced. In this war iodine has in my experience failed, and in this I agree with Mr. Cheatle. Strong antiseptics are clearly indicated.

Consider for a moment a common shell wound of the thigh. The projectile strikes the ground and casts up a shower of earth and manure and in the midst of this a large jagged splinter of metal strikes the man and carries a portion of his mud-soaked trousers into his thigh; he falls down into the muddy water at the bottom of the trench. Pathologically anaërobic organisms are carried into the depths of his muscles and act on a man whose resistance from cold and weariness is slight, assisted by a careful closure of the entrance and exit wounds by dressings. Under such conditions they multiply rapidly and under suitable anaërobic conditions spread within a few hours up and down the intramuscular planes of his thigh. Of what avail is the superficial application of any lotion, paste or powder? But little.

Let Mr. Cheatle see and smell the wounds as they come from a field ambulance only a few hours after infliction, or examine them on the *Trains Sanitaires* still within sound of the guns, and he will realize they enter the large hospitals here in a condition of advanced sepsis and inoculated with organisms peculiarly difficult to touch with antiseptics. Yet the evacuation of the wounded in this war is both rapid and efficient. Nevertheless we are engaged during a great part of the time in an unedifying struggle against pus. Necessary operations have to be postponed *sine die* until wounds have become clean.

It is difficult to know how this sepsis can be prevented, but the conditions will be undoubtedly improved when the ground is frozen.

I submit that Mr. Cheatle's statement that "many wounds have arrived in this country in a *disgraceful* condition" bears a reflection on the surgical work of the R.A.M.C. abroad which is unjustified by facts.—I am, etc.,

Boulogne. E. MUSGRAVE WOODMAN, R.A.M.C.

We referred the above letters to Mr. Cheatle, who sends us the following reply:

SIR,—Allow me to thank you for showing me the above correspondence.

My position is this. I say a wound is in a disgraceful condition when it is stinking and suppurating. To take a case of my own as an example: forty-eight hours after removing a foul-smelling, suppurating, and perforated appendix, the wound was offensive and suppurating, but in addition a larger area was affected because the healthy tissues through which I had cut were then involved. That wound was in a disgraceful condition, as I should have agreed with anybody who so said. As a matter of fact, matters were successfully dealt with by the application of the cyanide paste to all the lining surface of the whole wound.

I hope, therefore, Captains Musgrave Woodman and Page will not now consider that the adoption of the word "disgraceful" implied an attack or a reflection upon any of my professional brethren. I would substitute any word they suggest provided it did not mean satisfaction with the state of affairs to which I applied my term. There are many kinds of wounds in war, but as my critics say, in this war a great proportion are large and deep, and caused by the missiles of artillery. There are two ways of dealing with these wounds: (1) To prevent infection; (2) to deal with infection when it is present.

1. Captains Woodman and Page are agreed that wounds inflicted in South Africa were not exposed to the severe forms of infection as those which are being inflicted in France at the present time. Everybody is convinced upon that point. I can also see that the number involved and difficulty in getting into immediate contact with them render it practically impossible to prevent infection except in rare cases. One of my points is that it would be wise to have preventive means accessible for dealing efficiently with even rare cases. The want is not met by merely putting on an antiseptic dressing. Very likely there may be better ways of dealing with them than by the intelligent use of the cyanide and carbolic paste or by means of the lotion I mentioned. I am glad that Captain Woodman is convinced that iodine has failed. All cases of shell wounds which I saw in South Africa were septic except a few to which the cyanide and carbolic paste had been applied in a thorough manner almost immediately after the injuries. Although the severity of infection to which they were exposed was not so great as that which threatens the wounds received in France, the result justifies the hope that when a well-equipped man happens to be on the spot at the right moment he may save limb and life itself even now in France.

2. In dealing with the large and deep wounds that are already infected and which may contain foreign bodies, no one could imagine that the superficial application of lotion, powder, or paste would purify the deep internal parts. But even in these cases I would apply, as soon as possible, an efficient antiseptic in order to prevent fresh infection, while waiting for the essential adequate surgical interference.

My other point is after adequate surgical interference these wounds are relieved of their spore-bearing anaërobic and gas-forming micro-organisms with great rapidity by the use of efficient antiseptic treatment.

I have made bacteriological and clinical experiments of my own, and experiments have been made for me by an independent bacteriologist. These experiments show that the cyanide and carbolic paste effectually deals with the spore-bearing anaërobic micro-organisms. I will publish these results later. I find that these particular spore-bearing and anaërobic micro-organisms are very much more easily eradicated than the streptococcic and staphylococcic with which they are commonly associated in the infective process. No doubt the explanation of this is that the anaërobic organisms grow much more easily in damaged and necrosed tissue than in the healthier parts, while they do not possess the greater power of invasion which belongs to the pyococci.

There is not the same object gained in applying antiseptics to a wound from which the anaërobes have been expelled and only pyococci remain, but they form a protection against further infection.

Finally, I feel sure that the iodine method is not safe enough to ensure freedom from infection in those cases of amputation which are performed above deep, large, and septic wounds. From my point of view the preliminary preparation in the fight against possible infection requires more skill than the amputation itself: it is not so dramatic, but a successful result, although confidently expected, is a great triumph.—I am, etc.,

G. LENTHAL CHEATLE.

Haslar Royal Naval Hospital,
Dec. 20th.

SIR,—In most of the methods suggested or adopted for disinfecting wounds on the field, the main drawback in my estimation lies in the cumbrous or complicated nature of the container used.

I beg to suggest that the solution used by Mr. G. Lenthal Cheatle as described by him in the BRITISH MEDICAL JOURNAL of December 12th, p. 1066, be placed in a small glass capsule, such as is used for holding amyl nitrite. This could be enclosed in a gauze bag, and covered with impervious paper, and packed within the "first field dressing," either the old pattern or the "asepto" being used. The gauze bag should be of several plies in thickness, resembling an ordinary surgical swab, and tied with thread. When required for use, all that would be necessary would be to tear open the paper cover, break the capsule, and so allow the gauze pad to become saturated with the antiseptic solution. The wound could be swabbed all over with this solution, and the remainder of the dressing applied in the manner directed.

It is scarcely likely that the capsule would be broken accidentally, but even if it should, the impervious paper would prevent the loss of the antiseptic solution. Moreover, the weight and bulk of the packet would be very slightly increased, and any objection on this score would be practically negligible.

I intend having some of these capsules made up for general and V.A.D. use.—I am, etc.,

CAMPBELL HIGHET, M.B., C.M.,
Medical Officer Voluntary Aid Detachment,
Worcester 5.

Worcester, Dec. 15th.

ALCOHOL AND THE WAR.

SIR,—You were good enough to publish in your issue of November 21st an account of the Conference which took place on November 12th, under the presidency of His Grace the Archbishop of Canterbury, to consider the subject of alcohol and the war.

Since then I have been appointed Honorary Secretary of the Central Emergency Committee, which was formed by the Conference in order to secure the carrying out of the resolutions which were passed by that influential gathering.

It should be remembered that the Conference was called together in order to support Lord Kitchener's appeal to the nation, issued through the Press Bureau, asking that the public should "help the soldiers" in this matter, and especially in urging that steps should be taken to educate public opinion. It is clear that Lord Kitchener had in his mind something beyond the ordinary risks which are associated with alcoholism, and when we refer to his message to the troops at the outset of the war, we find that he warned them against the temptations connected with "wine and women," and said "you must entirely resist both."

Major Darwin, as an old soldier, and as one who has interested himself in the many difficult problems which bear upon the health and well-being of the nation, referred in his speech at the Conference to the appalling connexion between alcohol and venereal disease and the special conditions which had been created by the war, including the crowding together of large masses of men in centres unaccustomed to receive them.

This is but one aspect of a great question, but I mention it because I consider that a grave responsibility rests upon the medical profession in this matter. That the profession is rising and will rise to the occasion I do not doubt for a moment, and the speeches of Sir Thomas Barlow and Sir T. Clifford Allbutt at the Conference, as already reported by you, were of the greatest value. I venture, however, to appeal earnestly to medical men and medical women throughout our land to join in giving that support to Lord Kitchener's appeal which is needed at this moment. Every Lord Mayor and Mayor, and Chairman of District Councils has received an appeal from the Central Emergency Committee to take part in this movement, in the hope that Local Emergency Committees will be formed in each locality to ensure that the nation may respond to the call which comes to them to assist in promoting the utmost efficiency of all classes at this critical time.—I am, etc.,

CHARLES F. HARFORD.
Honorary Secretary, Central Emergency Committee.

55, Paternoster House,
London, E.C., Dec. 21st.

THE CAUSE OF HERNIA IN INFANTS.

SIR,—I agree of course fully with Dr. Cameron as to the collateral conditions which lead to the production of hernia, and, as I stated in the Banks Lecture, in most cases the hernial condition disappears. As regards the proportion which recur later, I stated there were no clinical statistics on the subject. Naturally, therefore, I "did not furnish any."

I think Dr. Cameron will agree that such recurrence is the chief cause of the national disabilities due to hernia if he reconsiders the development of my argument in the lecture, particularly (*a*) the topographical incidence of hernia in the adult, and (*b*) the position so clearly defined by Dr. Hamilton Russell.

Reflection on these unanswered facts will, I believe, convince Dr. Cameron that though by removal of dyspepsia, malnutrition, and bronchitis, the infantile hernia undoubtedly disappears, such treatment does not obliterate the sac or infundibulum, and that though "a firm muscular wall may develop," the appearance of a painless hernia in later years finds its simplest explanation in recurrence.—I am, etc.,

VICTOR HORSLEY.

London, W., Dec. 21st.

YELLOW FEVER.

SIR,—As the writer of the note on Macfie and Johnston's paper, published in the BRITISH MEDICAL JOURNAL, July 18th, 1914, p. 106, to which Dr. Johnston replies in your issue for December 19th, p. 1089, may I draw the attention of people interested in the matter to a paper by Dr. Wenyon and myself which appeared in the *Journal of Tropical Medicine and Hygiene* of December 15th, 1914, on this subject? As this paper is illustrated with a coloured plate comparisons of the so-called yellow fever parasite with the identical bodies found in the blood of normal guinea-pigs in England can easily be made. Again, as the points against this supposititious parasite are carefully gone into there it is not necessary for me to recapitulate them now.

Perhaps I might inform Dr. Johnston here, however, that I carefully read his paper and bestowed much attention upon it. This may relieve his mind as to my familiarity with its text. If Drs. Macfie and Johnston had looked at normal guinea-pigs' blood with sufficient care before doing their experimental inoculations they would not have fallen into the error they have made.—I am, etc.,

GEORGE C. LOW, M.D.

London, W., Dec. 18th.

THE "MEDICAL DIRECTORY."

SIR,—In reference to your remarks about the omission of the Abroad Section of the *Medical Directory*, we desire to point out that the compilation of this list is one which

has presented numerous problems to those who have had to undertake it. It has always contained only a selection of names, and it is not easy to know where to draw the line. We think the list has only been useful to a small proportion of the users of the Directory, but they are worthy of consideration, and the whole matter has again our serious attention.—We are, etc.,

London, W., Dec. 19th. J. AND A. CHURCHILL.

Obituary.

ALBERT VAN GEHUCHTEN.

ALBERT VAN GEHUCHTEN, Professor of the Anatomy, Pathology, and Treatment of Diseases of the Nervous System in the University of Louvain, died in Cambridge on December 9th.

The arrival of Professor van Gehuchten, of Louvain, in Cambridge was cordially welcomed. Both on personal and scientific grounds it was felt to be not only a great privilege to receive him but also a rich promise of help and inspiration for our schools. On the painful events which led to his visit I will say nothing except this, that both his town and country houses were burned, and with them manuscripts containing records of the last ten years of his work. With a courage worthy of his great nation he restrained his grief, and in a buoyant and hopeful spirit began work anew. Yet we saw only too well how bitter were the moments when at times his grief could not be restrained.

ALBERT VAN GEHUCHTEN.

The studentship maintained by the generosity of Dr. R. C. Brown, of Preston, at our Research Hospital happened to fall vacant, and by the assistance of Sir William Osler a like stipend was provided from the Rockefeller Fund; and, although the wards of the Research Hospital were occupied by wounded officers, the laboratory—an independent building—was placed at Professor van Gehuchten's service. In a few days it was manifest to Mr. Strangeways, and others of our circle, what a brilliant colleague we had secured. His methods were remarkably skilful and accurate, and with these opportunities his spirit and energy were renewed, and his bodily health seemed restored. One evening he complained of pain in the left iliac region, and twenty-four hours later we made a diagnosis of volvulus. Dr. Cairns, of Huddersfield, who was in surgical charge of the hospital, decided that operation was urgent, but, under all the circumstances, desired further assistance. Most kindly Mr. Waring came down at our request, a laparotomy was performed, the volvulus was released, and all went well. In a few days convalescence seemed established, the patient felt confident of recovery, was attending to his correspondence and receiving a few friends, when suddenly he complained of a terrible oppression in the region of the heart, and in a few minutes he passed away from a world of sorrow.

At his funeral the Roman Catholic Church was filled by a large congregation of university and townspeople, and of his professional and other colleagues and compatriots now in Cambridge, the Vice-Chancellor being one of the pall-bearers. It was universally felt that in van Gehuchten biological science had lost one of its most skilful investigators and most brilliant exponents. But of these accomplishments I am less competent to speak. Dr. F. E. Batten has very kindly written for me the following appreciation:

C. A.

On the occasion of the celebration of Professor van Gehuchten's jubilee of twenty-five years' teaching at the University of Louvain on December 1st, 1912, M. le Docteur Meens, in his presidential address, said: "The work of M. le Professeur van Gehuchten is so stupendous that when I was asked to preside on the occasion of his jubilee I was afraid that I should not in any sense be able to do justice to it."

From the time of his passing his second examination in Natural Science, van Gehuchten had attracted the attention of the late Professor Jean Baptiste Carnoy, who invited him to work in his laboratory, which formed at that time the rendezvous of the most brilliant students in science and medicine. Here van Gehutchen worked indefatigably, laying the foundations of a knowledge characterized by accurate observation and an instinctive rejection of all mere hypothesis and speculation which could not be controlled by observation and experience. Whilst still working in Carnoy's laboratory van Gehuchten passed his examination of D.Sc. with great distinction, after which he pursued his studies in Berlin and Frankfort. In 1887, at the age of 26, he returned definitely to Louvain, where he had been appointed by the University to fill the position of instructor in anatomy.

His first publication was in 1886, on the structure of muscle cells—a work in which the influence of Carnoy's opinions on the protoplasm formation and unity of cell structure is clearly shown. The work was followed by many others of a biological nature.

In 1890 Professor van Gehuchten published a study on the olfactory mucosa of mammals—a work which formed his first researches in the domain of neurology. That the study of the central nervous system involved in the preparation of this work made a profound impression on him is proved by the fact that from henceforward he applied all his energies to this particular branch of medicine, and so became one of the greatest masters in the science of neurology; for twenty-four years he has given us in rapid succession an uninterrupted series of researches and publications each challenging the other in interest and importance.

These publications may roughly be classified into four systematic groups.

The first, appearing between 1890 and 1896, embraces a series of important publications bearing for the most part on the structure of nerve centres—the olfactory bulb, the structure of the optic lobes, the nerve cells of the sympathetic nervous system, cerebro-spinal ganglia, etc. In this group our present-day conception of the neuron was placed on an unassailable foundation—namely, that the neuron comprises a cellular body, protoplasmic prolongations for cellulipetal transmission, and an axis cylinder prolongation for cellulifugal transmission, both kinds of prolongation having a free termination, the nerve conduction from one neuron to the other being affected by the contiguity of the end ramifications of the axis cylinder of one neuron to the protoplasmic prolongations of the neighbouring neuron. The conception that the neuron appeared as an independent and fundamental unit was the solid basis upon which van Gehuchten built all his later researches on the true origin of nerves, and on the course of fibre bundles in the cerebro-spinal axis. In 1897 began van Gehuchten's long and fruitful series of study on methylene-blue staining methods, a report on which he presented to the International Congress of Medicine at Moscow in that year. He found that this method was of greater value in the examination of the more intimate nerve structures and their modifications than that of Golgi, hitherto used, which had the disadvantage of being too coarse. Further research in this direction led to investigations on the phenomenon of chromatolysis, and all these investigations are important as forming the basis on which rested his study of the true origin of motor nerves. They gave rise to a number of works on nervous pathology, and were even applied to the complex study of organic lesions in mental affections, especially in dementia præcox, and led to van Gehuchten's interesting discoveries on the pathological anatomy of dementia. He proved that the pathological process of rabies had a special predilection for the sympathetic spinal and cerebral ganglia, producing in the nerve cells of these ganglia primary modifications

of a chromatolytic nature as well as secondary modifications due to the active proliferation of the endothelial capsule of the nerve cell, which leads to its destruction, and the formation of characteristic rabid nodules.

The second group of publications, commencing in 1898, deal with the origin or termination of the peripheral nerves and the tract of certain bundles of neurons in the cerebro-spinal axis, and, in these days of confused literature on the subject, form classic models by their compass, clearness and precision, as well as by the value and novelty of their conclusions. All these experimental researches, carried out by section, rupture, or more frequently by the extirpation of the nerve in rabbits, were corroborated by the study of comparative anatomy and embryology of the nervous system and by *post-mortem* investigations. Finally, by the discovery of a new method based upon the phenomenon of direct Wallerian degeneration, van Gehuchten gave an exactitude to the results of his studies of the intracerebral or medullary course of the motor nerves and certain central nerve tracts never hitherto attained. This indirect Wallerian degeneration was described by van Gehuchten in an exhaustive report presented to the International Congress of Medicine at Madrid in 1903. He showed that if, instead of dissecting a nerve it was torn out, degeneration followed not only of the peripheral but of the central portion of the nerve, such central degeneration being not retrogressive but descending, like that of the peripheral portion, this being due not to the direct separation of the nerve itself, but to the atrophy of the cells from which it originated and fatally injured by this violent traumatism. Having identified by his new method each one of the peripheral nerves, Professor van Gehuchten extended his ingenious researches into the complex field of the acoustic and olfactory nerve tracts, the central connexions of Deiter's nucleus, the superior cerebellar peduncle, the cerebro-bulbar fasciculus, etc., with most brilliant results. We would especially mention in this connexion his study on the inhibitive fibres of the heart, a problem which has puzzled many celebrated physicians, but resolved by van Gehuchten, who directly traced the connexion of these fibres to the pneumogastric nerve itself, and not to the spinal nerve.

The third group of publications, which deals with problems of nervous pathology, include studies on the central motor neuron or the pyramidal tract, acute anterior poliomyelitis in the adult, the pathogenesis of decubitus, Babinski's phenomenon, syringomyelia, aphasia, etc. Of his work bearing on the pyramidal tract the most important branch is that concerning the mechanism and seat of reflex movements, in which he showed that tendon reflex was independent of muscular tonicity, that section or compression of the human medulla is accompanied not by increase of all reflex movements, but by disappearance of both tendon and cutaneous reflexes.

Into the fourth group of publications may be relegated those works now sufficiently well known which were the outcome of his teaching at the university. Among them is an excellent anatomy of the nervous system, appearing first in 1895, and now in its fourth edition, which formed his principal work. There followed a whole library of handbooks for students bearing testimony to van Gehuchten's untiring zeal and anxiety to elucidate the mysteries of a science the intimate details of which he knew so well. In 1908 appeared an abridged edition of the *Anatomie* under the title *Les centres nerveux cérébro-spinaux*, specially prepared for the student of nervous pathology. From 1906–09 he published his *Cours d'anatomie humaine systématique*, with blank pages intercalated in the text on which the student might copy demonstrations made by the professor during his lecture—an excellent mnemotechnical exercise. Lastly may be mentioned his *Manuel de pathologie nerveuse*. All these works were published for the most part in various special journals—*Le Journal de Neurologie*, *La Cellule*, etc., and in 1900 van Gehuchten brought out *Le Névraxe*, a journal dealing with normal and pathological anatomy, of great value in the scientific world.

Professor van Gehuchten was a teacher of great capacity, esteemed by his students as much for the high conception he had of his professorial duties as for the pains he took to communicate his instruction in an interesting and sympathetic manner, illustrating his points step by step by drawings on the blackboard, demonstrations on the human body, and even by cinematograph films. In his work van Gehuchten was not only a clinician of great eminence, determining with mathematical exactitude the seat of lesions of the central nervous system, but a bold innovator in the domain of the therapeutics and especially the surgery of the nervous system. He obtained unlooked-for results in the surgical treatment of cerebral and medullary tumours; in obstinate neuralgia of the trigeminal nerve he proposed excision of the nerve branches to bring about atrophy of the cells from which they orignate, and hence destruction of the nerve itself and elimination of all pain; he modified Foerster's operation, and successfully proposed the less complicated method of resection of the post-radical filaments instead of the posterior roots.

These clinical and therapeutic triumphs proved to those who were still in doubt that absolutely pure and disinterested scientific research must finally lead to the elucidation of the most obscure pathological problems, and thus form the indispensable foundation of medical science.

F. E. B.

BERNARD PITTS, M.C., F.R.C.S.,

CONSULTING SURGEON TO ST. THOMAS'S HOSPITAL AND TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND STREET.

THE death of Bernard Pitts will be felt by a large circle of friends and colleagues, amongst whom he was held in high repute as a sagacious, bold, and skilful surgeon. He was one of those all too rare men who hate anything in the way of pretence or sharp practice, and did not hesitate to speak his mind freely and without fear when occasion seemed to demand plain speaking. He was not, possibly, so well known to the general public as his position in his profession seemed to warrant, but he disliked show and was content to do his work unostentatiously, without any effort to secure the rewards which publicity so often brings. He would not compromise, and, as he was ready to face difficult questions squarely and without fear, he may have got more of a reputation as a fighter than he really deserved. If he fought at all, he always fought for the right. He played the game, and he played it straight. At the time of his death Mr. Pitts was consulting surgeon to St. Thomas's Hospital and to the Hospital for Sick Children, Great Ormond Street. In 1876 he acted as surgeon during the Turko-Servian war, and two years later was appointed resident assistant surgeon at St. Thomas's. From this time onward until 1908, when failing health compelled him to resign, he worked continuously at St. Thomas's and at the Children's Hospital, teaching, lecturing, and doing his hospital work, in which he was indefatigable. He took a keen interest in the well-being of nurses after they had completed hospital training, and almost from the commencement was an active member of the council of the Nurses' Co-operation, which now numbers more than 500 members.

Mr. Pitts's life was devoted to his work, and he was ready at all times freely to place his skill at the service of those who were in need of his help.

Some few may remember Mr. Pitts's early work at St. Thomas's Hospital and his success as a pioneer in abdominal surgery. He was one of the first to use a median incision in cases of acute intestinal obstruction when the site of obstruction was unknown, instead of doing what was then the common practice—the operation of left lumbar colotomy. He was also one of the first to perform suprapubic cystotomy for the treatment of villous growth in the bladder, and he was a successful pioneer in the immediate treatment of intussusception by operation. Mr. Pitts lectured at the Royal College of Surgeons of England on the "Surgical affections of the air passages in childhood," a subject in which he had a large experience at the hospital in Great Ormond Street.

In his early professional life all open-air games and exercises had a great attraction for him, and though almost totally incapacitated during the last few years through illness and suffering, no word of complaint ever passed his lips. Those who knew him will retain an affectionate remembrance of his strong character and his unselfish devotion to the interests of others. In health and in sickness he was always the same. Religion was to him a reality, and he died in the faith of the Church

undaunted and undismayed by the sad fortune of his later years. By his death many will feel that they have lost a true friend.

DR. CLINTON WAGNER, of New York, one of the pioneers of laryngology in the United States, died in Switzerland on November 25th. He was born at Baltimore in 1837, and graduated in medicine at the university of that city in 1858. He entered the medical service of the army and served through the civil war with much distinction. Afterwards he visited Paris, London, Berlin, and Vienna, and on his return to America founded the Metropolitan Throat Hospital and Dispensary of New York, which soon became a centre for doctors wishing to study the speciality. Dr. Wagner was the first professor of laryngology in the New York Post-Graduate Medical School and Hospital. In 1873 he founded the New York Laryngological Society, now the Section of Laryngology of the New York Academy of Medicine. Dr. Wagner contributed largely to the literature of his special department of practice, and was a very inventive and enterprising surgeon. After a successful career he retired from practice several years ago, and thenceforward passed his life mostly abroad.

LIEUTENANT-COLONEL EDWARD LEWIS MAUNSELL, R.A.M.C. (retired), died at Southsea on December 7th. He was born on December 3rd, 1853, the youngest son of the late Major Francis Maunsell of the 4th King's Own and 54th Regiments. After taking the diplomas of L.R.C.S. and L.R.C.P. at Edinburgh in 1878, he entered the army as surgeon on July 31st, 1880, becoming surgeon-major on July 31st, 1882, and lieutenant-colonel on July 31st, 1900, and retired on November 3rd, 1906. For some years he held the post of Health Officer of Gibraltar.

DR. LEON LEREBOULLET, President of the French Medical Association, died recently at the age of 71. He was born at Strassburg where his father was incumbent of the Chair of Zoology and Comparative Anatomy in the Faculty of Science. Leon Lereboullet was appointed professeur agrégé at the army medical school of Val-de-Grâce in 1872. In 1877 he became professor of clinical medicine at Lille, and in 1890 he was elected a member of the Academy of Medicine. He collaborated with Dechambre on the *Gazette Hebdomadaire de Chirurgie* and was editor of the *Dictionnaire Encyclopédique des Sciences Médicales*. He was also the author of several works on medicine, and of a series of articles on the health service which produced a considerable sensation and attracted the attention of Jules Ferry and other leading statesmen. His son Pierre is professeur agrégé and physician to the Paris hospitals.

Universities and Colleges.

UNIVERSITY OF OXFORD.

THE following candidates have been approved at the undermentioned examinations:

FIRST B.M., B.CH. (*Organic Chemistry*).—E. A. Crook, W. Gover, R. B. Hervey-Wyatt, C. F. Krige, R. T. F. D. Roberts. (*Human Anatomy and Human Physiology*).—J. H. Beattie, E. ff. Creed, R. B. Hervey-Wyatt, G. H. Rossdale, J. J. Savage, N. F. Smith, S. C. Varley, J. P. S. Walker.

SECOND B.M., B.CH. (*Materia Medica and Pharmacology*).—E. W. Bowell, W. H. Butcher, G. I. Evans, G. T. Gimlette, J. M. Guilfoyle, G. A. Maling, A. L. Watts. (*Pathology*).—E. W. Bowell, W. Brown, J. B. Cavenagh, R. W. J. A. Cushing, A. G. East, V. T. Ellwood, L. Gameson, F. C. Gladstone, J. M. Guilfoyle, B. E. Wall. (*Forensic Medicine and Public Health*).—E. W. Bowell, L. R. Broster, W. Brown, R. W. J. A. Cushing, R. C. Fairbairn, B. E. Wall, H. A. B. Whitelocke. (*Medicine, Surgery, and Midwifery*).—L. R. Broster, W. Brown, F. W. Browne, C. H. Carleton, V. T. Ellwood, F. C. Gladstone, C. H. J. Harper, G. A. Maling, H. G. Morris, G. S. Robinson, B. E. Wall.

UNIVERSITY OF CAMBRIDGE.

THE following degrees have been conferred:

M.B.—Hamilton Hartridge, C. R. A. Thacker.

The following candidates have been approved:

THIRD M.B. (*Part I. Surgery and Midwifery*).—W. K. Bigger, P. R. Boswell, T. J. H. Hoskin, L. M. Ingle, J. H. Jordan, G. O. Maw, H. G. Oliver, D. V. Pickering, R. T. Raine, W. H. C. Romanis, C. M. Ryley, G. D. Sherwood.

VICTORIA UNIVERSITY OF MANCHESTER.

THE following candidates have been approved at the examinations indicated:

FINAL (M.B., CH.B.).—W. S. Booth, †Clara A. Loomas, J. G. McKinlay, K. Maximus, †H. A. Sandiford, H. Wilson, S. A. Winstanley, H. A. Sandiford.

* Awarded first-class honours and distinctions in obstetrics, surgery, and medicine.

† Awarded distinction in surgery.

Medicine only.—S. G. J. Dowling. *Forensic Medicine and Toxicology.*—R. Chevasout, J. S. Chorlton, S. G. J. Dowling, J. Fielding, G. B. Horrocks, †J. D. Kenyon, H. H. Stones.

‡ Passed with distinction.

THIRD M.B. CH. (*General Pathology and Morbid Anatomy*).—J. H. Albinson, H. Chadwick, W. Christopher, R. Colley, E. W. Fish, Eva L. Glasier, Alice M. A. Holt, R. L. Newell, F. C. Ormerod, Nesta H. Perry, Dorothy Potts, C. R. Sandiford, W. Stansfield, G. B. Wild. (*Pharmacology and Therapeutics*).—J. D. Byrd, E. W. Fish, E. R. Gilmore, J. B. Leigh, B. L. Lloyd, B. Walley, G. B. Wild. (*Hygiene*).—J. H. Albinson, E. W. Fish, E. R. Gilmore, J. B. Leigh, B. L. Lloyd, B. Walley, G. B. Wild.

SECOND M.B. AND CH.B.—§F. H. Anderson, G. E. Archer, Mercy D. Barber, W. T. G. Boul, Hilda K. Brade, C. F. J. Carruthers, Kathleen L. Cass, Ruth E. Conway, J. C. T. Fiddes, J. Holker, N. Kletz, E. N. P. Martland, A. B. Platt, Elizabeth C. Powell, J. Shlosberg, D. M. Sutherland, H. Taylor, H. Tomlinson. (*Physiology*).—A. M. Cotes, R. S. Paterson.

§ Awarded distinction in anatomy.

UNIVERSITY OF DURHAM.

THE following degrees have been conferred:

M.B.—A. C. Freeth, Grace W. Pailthorpe, E. C. G. Parker, H. Playfair-Robertson, Sarah L. Rook.

B.S.—J. B. Alderson, Grace W. Pailthorpe, Sarah L. Rook.

UNIVERSITY OF EDINBURGH.

GRADUATION CEREMONY.

DEGREES were conferred by Sir William Turner, Vice-Chancellor of the University, in the M'Ewan Hall, on December 18th. All the degrees with four exceptions were in the Medical Faculty. The following is a list of those on whom degrees and other awards were conferred:

M.D.—†R. M. Allan, *J. R. Boyd, †G. R. Bruce, W. M. Cairns, N. L. Lochrane, W. S. Malcolm, A. M. Masters, G. Pollock, †T. C. Ritchie, †G. H. Skinner, J. S. du Toit, R. W. L. Wallace, †G. Williams.

M.B., M.S.—G. D. Hamilton.

M.B., CH.B.—J. H. Baird, B. Earseghian, E. G. von B. Bergh, D. G. Boddie, W. K. Chalmers, U. J. Cherry, W. A. Coats, R. P. Cormack, Georgina E. Davidson, A. M. Duarte, A. J. Ferguson, Agnes R. H. Greig, H. Jackson, C. W. Lewis, H. S. Lewis, G. A. G. Macdonald, J. Macqueen, E. S. Mellor, J. J. Molyneaux, A. C. Murray, W. H. Pallett, P. V. Ramanamurty, ‡J. Ritchie, R. C. Rogers, †G. M. Scott, †C. G. Skinner, L. J. Spence, T. I. W. Sveinbjörnsson, P. G. Tuohy, H. M. Vickers, E. Wardman-Wilbourne, E. L. White, A. Wotherspoon.

D.T.M. AND HY.—Chik Hing Wan.

* Highly commended for thesis. † Commended for thesis.

‡ Second-class honours.

Sir William Turner, in addressing the graduates, said that the relation of the medical profession to the nation was different from what it was when he took his degree. Then the profession looked for its work and its rewards to private practice; now there was a highly organized public health service which was of the utmost value to the nation. The observation of so many uniforms in the audience, he continued, showed that a stage had been reached in which military life required a large number of medical practitioners. There was especial need that young graduates who had not yet settled upon any definite practice should consider how far they could meet the requirements of the nation in this respect. It was obvious that such a combination of things as now prevailed in the universities and in the schools of medicine all over the country should be properly acknowledged, and accordingly the University of Edinburgh was now preparing and about to issue a roll of those members of the university who had already joined the forces. He was happy to say that their roll now contained 1,500 names, including members of the staff, members of the teaching staff, graduates, and students, and embracing men in all the faculties. The graduates and students belonging to the Faculty of Medicine numbered 660. But the profession of medicine had also an important civilian side, because the civilian side of the nation was far larger than the combatant. The need of a proper provision of medical men in the army and navy had to some extent affected, or was likely to affect, the wants of the civilian population, more especially when the new armies went into the active line. In the towns there were doctors willing to take up the practice of a fellow practitioner who joined the services; but in some country districts—and this, he believed, applied more particularly to Scotland, where they had wide stretches of land, with relatively few people living on the land—the risk was run of there being no proper medical advice for the people living in those localities. This was an aspect that the young men of the profession should keep in mind. They had all the activity and enthusiasm of youth, and naturally wanted to put themselves in line with the other active members of the community and join the forces. But there were others again who might feel that their mission in life was rather that they should take a part in the civilian work in the profession, and he ventured to say that they were equally doing their duty although they did not go to the front.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH.

Fellowship.

The following gentlemen have been admitted Fellows: G. J. Adams, H. G. Barrie, F. J. Browne, H. E. Clutterbuck, P. Das, J. Flynn, A. J. Friedlander, H. E. Griffiths, J. Kirk, L. H. McBride, P. P. J. Stewart, W. G. Thompson, T. J. Williams.

Sir John Struthers Lectureship.

Dr. Johnson Symington, Professor of Anatomy in the Queen's University, Belfast, delivered the second of the Struthers Lectures in the Hall of the College on December 16th, the subject being observations on the relations of the inner surface of the cranial wall to the outer surface of the brain. The lecture was illustrated by specimens, casts, and photographs.

The Services.

ROYAL NAVAL DIVISION.

A memorial from the Lords Commissioners of the Admiralty fixing the rates of pay and allowances for officers and men of the Royal Naval Division has been approved by the King. It states *inter alia* that in the medical branch army officers are to receive army rates of pay. All officers, including army officers, are subject to a deduction of 2s. a day in pay when messed at the public expense. Field allowances of army officers are to be governed by army regulations, but the minimum rate is to be 5s. a day subject to the understanding that they do not draw any messing allowance under paragraph 535 of the Army Allowance Regulations.

Medical News.

We have received from the General Medical Council a list of corrigenda for the new *British Pharmacopoeia*. These are chiefly numerical, the strength of alcohol used in making one or two tinctures being altered, and one or two errors in decimal points being put right. Three corrections affect the notes which we have published. Liquorice root is now required to yield a certain minimum of extract, which, as we noted, was about 10 per cent. according to the original text, but is now altered to about 20 per cent. We mentioned the increase in alcoholic strength of orange wine to 15 to 17 per cent., but this is now altered to 12 to 14 per cent. We pointed out that there was no note in the text on the alteration in strength of hypodermic injection of cocaine, and this omission is now rectified.

In a paper read recently before the Royal Meteorological Society by Mr. W. F. Stacey, of University College, Reading, the following conclusions were drawn from the study of mean monthly and annual maps of relative humidity based on the 9 a.m. observations made at over ninety stations during the ten years 1901 to 1910: In winter the air over the interior of the country is more moist than that over the coastal regions; the minimum relative humidity occurs earlier in the year in the western parts of the country than in the eastern; in summer the air over the interior of the country is drier than that over the coastal regions; and the smallest range of humidity is found in the west and the greatest in the interior towards the east. The distribution of temperature appeared to be the chief determining factor in the distribution of relative humidity; sea influence, the direction and character of prevailing winds, and the configuration of the country had important effects on temperature, and therefore on relative humidity.

According to the *Bulletin administratif du ministère de l'instruction publique*, the total number of students in the medical faculties of France on January 15th, 1914, was 8,533, of whom 7,664 were men and 869 women. Of the men, 899, and of the women 469, were foreigners. The number shows a slight increase as compared with the figures for 1913. The students were distributed among the several universities as follows: Paris 4,397, Lyons 1,181, Bordeaux 887, Montpellier 702, Toulouse 462, Nancy 325, Lille 377, Algiers 202. Among the medical schools Marseilles headed the list with 320 students, Nantes coming second with 305, and Rennes third with 131. In the other schools the numbers varied from 106 at Rouen to 30 at Poitiers. Of the foreign students, the large majority were Russians; there were 575 in Paris, and 136 at Montpellier. Next came the Ottomans, of whom there were 67 in Paris and 15 at Montpellier. Other nationalities represented were Bulgaria, Roumania, Serbia, Greece, and the South American republics. There were 12 British students in Paris.

LETTERS, NOTES, ETC.

"Remember the Doctor."

A medical correspondent sends us the following extract from the *Financial News* of December 18th: "In paying Christmas accounts this year the public should avoid its habit of leaving the doctor's bill till last. The doctor needs his money as much as anybody else, and, inasmuch as doctors as a class are doing duty of untold value to the nation at the present time, they deserve the extra consideration of their patients. It is too often assumed that because the doctor keeps his motor car he can afford to wait indefinitely for his money. That is not a fact. The doctor should be among the first to get his cheque."

Splint for Compound Fracture of the Lower Extremities.

Dr. Martin J. Chevers (Withington, Manchester) writes: In the British Medical Journal of November 21st, p. 892, the report of the discussion on "Surgical experiences of the present war" states that Sir Frederic Eve said "he strongly recommended the use of Hodgen's splint in gunshot fractures of the femur, as it permitted dressing of the wounds without disturbance of the limb." I would like to draw your readers' notice to the cradle splint which I got Messrs. James Woolley, Sons, and Co., of Manchester, to make for me, and which I have had in constant use for many years, and which, in my humble opinion, fulfils to as great an extent and with many more advantages and greater stability Sir Frederic Eve's claims for Hodgen's splint. Full particulars, with sketch of the splint, can be seen in the British Medical Journal, September 29th, 1906, p. 779.

The Value of the Occiput in Ascertaining the Presentation.

Dr. J. Phillips (St. Clears, South Wales) writes: I wish to call attention to a matter of some diagnostic importance to accoucheurs, namely, the value of the occiput in making out the position of the head in vertex presentations. In Galabin's textbook on midwifery no special mention of this point is made, and I have also reason to believe that it is not particularly taught in some at least of the London hospitals. After many years in practice I have failed to discover any other portion of the undelivered fetal head which offers so sure and comparatively easy a way of locating the head position. The features to be sought for are: (1) The smooth triangular plate of the occiput lying between its superior curved lines and its superior curved borders; (2) this is depressed below the parietal bones in the process of moulding which takes place in parturition; (3) to follow the lambdoid sutures to the post fontanelle, with its three radiating lines. In lingering cases in primiparae, for instance, one of the commonest difficulties in the way of applying forceps is uncertainty as to the position of the occiput and the possibility of converting what is a first or second position into a third or fourth. It seems to me that in the great majority of cases, at any rate, it is only just these difficult attempts to deliver an occiput posterior that can evoke the suggestion (I have recently read it) of making it a routine practice to introduce *ante-partum* perineal sutures in anticipation of damage to the perineum. With the head below the brim the above signs are so distinctive that I consider it unjustifiable to deliver the head with forceps until the position is definitely ascertained.

Erratum.

In the Journal for December 19th, p. 1072, col. 2, line 22 from foot, for "inoculated troops" read "uninoculated troops."

INDEX TO THE EPITOME FOR VOLUME II. 1914.

READERS in search of a particular subject will find it useful to bear in mind that the references are in several cases distributed under two or more separate but nearly synonymous headings—such, for instance, as Brain and Cerebral; Heart and Cardiac; Liver and Hepatic; Renal and Kidney; Cancer and Epithelioma, Malignant Disease, New Growth, Sarcoma, etc.; Child and Infant; Bronchocele, Goitre, and Thyroid; Diabetes, Glycosuria and Sugar; Eye, Ophthalmia, and Vision, etc.

The Figures in this Index refer to the Number of the Paragraph, NOT the Page.

Printed and Published by the British Medical Association at their Office, No. 429, Strand, in the Parish of St. Martin-in-the-Fields, in the County of Middlesex.

AN EPITOME OF CURRENT MEDICAL LITERATURE.

MEDICINE.

1. Fungous Affections of the Hands and Feet.

IN a paper read at the last meeting of the British Medical Association in Australia two Sydney physicians emphasized the great importance of examining every case to which the diagnosis of dyshidrosis or cheiropompholyx seemed applicable, for the fungus of tinea albuginea, which they had succeeded in demonstrating in 80 per cent. of the cases submitted to them. Frau Dr. MARIE KAUFFMANN-WOLF now comes forward (*Dermat. Zeitschr.*, May, 1914) with the statement, founded on her experiences in Berlin, Paris, and Vienna, that about one-third of the intractable vesicular eczemas labelled cheiropompholyx are really hyphogenic in origin, and therefore not really difficult to cure, when once their true nature is recognized. The time is not far distant when every practitioner with a microscope will avail himself of the very simple technique, namely, saturation of scales and vesicle roofs in potash, and examination under a one-sixth objective, which is generally in use in the dermatological clinic, though even here it is occasionally neglected. After a short survey of the historical side of her subject—in which the names of Tilbury Fox and Whitfield in our country, and Sabouraud in France, are worthy of remembrance—the authoress describes the commonest sites of the infection and mentions three types of lesions which in her experience are the most common. These comprise a vesicular, a squamous, and an infected or pustular type. The vesicular type is most commonly met with in the interdigital clefts where the diagnosis from a true uncomplicated dyshidrosis can only be made with the aid of a microscope. A further preference is shown for the plantar aspect of the foot, especially at its junction with the internal border, a point well brought out in photographs 1 and 3 of the illustrations. The clinical appearances vary, of course, with the anatomical characteristics of the site infected, and a lesion on the back of the hand is usually of the circinate and conglomerate variety typical in the minds of most dermatologists of a deep trichophyton infection. The squamous type often suggests the exfoliating period of a dyshidrosis, but not infrequently there is a serpiginous advancing edge and a clearing centre which ought at least to arouse the suspicions of the examiner. It is invariably secondary to the vesicular variety, and tiny vesicles can always be demonstrated if carefully looked for, the contents of which, it can easily be realized, if absorbed, will lead to dryness and cracking of the distended walls and the appearance of a squamous variety. This has not infrequently to be diagnosed from psoriasis and tertiary syphilis of the palms and soles. Dr. Marie Kauffmann-Wolf's histological study of the actual skin levels affected explains very simply the varying occurrence of a delicate scaly margin, or a thick infiltrated edge, according to the depth of the original vesicles. It is hardly necessary to enlarge on the varying clinical pictures that the onset of a secondary infection with the staphylococcus may bring about. The name "pyodermia" must suffice in this connexion, and will, together with the other types above described, open up a new field of scientific clinical investigation that cannot but redound to the credit of the physician and the relief of the usually chronically affected patient.

2. The Oculo-Cardiac Reflex

LOEPER AND MOUGEOT (*Progrès médical*, January 31st, 1914), in discussing some cases of bradycardia in a communication to the Société de Biologie, contended that that symptom was due either to a heightened toxicity of the pneumogastric nerve or to an organic lesion of the conducting muscular *faisceaux*. Compression of the globes of the eyes only increases the bradycardia when this is of nervous origin. Bradycardia of nervous origin could be detected in three ways: (1) By the atropine test of Dehio, (2) by the amyl nitrite test of Josué and Godlewski, and (3) by the oculo-cardiac reflex. The centripetal path of this reflex is the trigeminal nerve; the centrifugal path is through the pneumogastric nerve, and the reflex centre seems to be where the vagus, in its intrabulbar passage, crosses the nucleus of the fifth nerve. The authors have noted this action of the vagus in at least three gastric cases, the oculo-cardiac reflex being first increased, and afterwards diminished or even abolished for a moment under the influence of as little as $\frac{1}{2}$ mg. of atropine. In investigating the oculo-cardiac reflex it is important to remember that the slowing of the pulse caused by pressure on the eyes does not constitute the whole reflex. The diminution of the amplitude of the beats and a fall of blood pressure also occur. In certain cases (two pulse tracings shown) the two latter phenomena may occur without the first. The authors regard the triad of symptoms which constitute the oculo cardiac reflex—slowing of the pulse, weakening of the pulse, and a fall of blood pressure—corresponding to three parallel phenomena of vagal origin, as representing respectively a negative chronotropic action, a negative inotropic action, and an excitation of the depressor nerve.

3. Unusual Type of Acid Intoxication in Infants.

ABT (*Amer. Journ. of Med. Sciences*, January, 1914) calls attention to a series of cases of a severe type of acid intoxication, usually fatal, and occurring mostly in previously healthy infants at about the weaning period. They differ from cases of cyclic vomiting in that the vomiting is not so persistent and sometimes scarcely occurs, and instead of presenting the persistent and uncontrollable emesis characterizing cyclic vomiting, the main features consist in rapid, superficial breathing, enlargement of the liver, low temperature, and rapid pulse, with the occurrence of tympany, obstinate constipation, and little or no vomiting towards the end. In most instances the parents are healthy, and in one family two children had died from the affection, and the third, though similarly attacked, recovered after a severe illness, while an instance is recorded of five children in the same family dying from the disorder, thus pointing to a familial type. Usually occurring in large, robust, previously healthy children, there may have been a stationary weight curve for several weeks prior to onset, and, if breast-fed, the infants show signs of hunger and dissatisfaction with the food because the milk is scanty or poor. The disease commences with diarrhoea, usually vomiting, and a moderate febrile reaction which tends to become lower later, and on the second or third day there is some abdominal distension, dyspnoea with rapid laboured respiration, and increased pulse-rate. The liver becomes markedly enlarged, and the urine contains albumin, hyaline and granular casts, acetone and diacetic acid, but no sugar. About the third day stupor, gradually deepening to coma, supervenes, death taking place in four or five days. At autopsy the predominating feature is fatty degeneration of the liver and other organs. In the case which recovered (two others having previously died) the baby was weaned and given rectal injections of 8 per cent. glucose in normal salt solution, 2 per cent. levulose and large doses of sodium bicarbonate by the mouth, half a drachm of whisky or sour wine every two hours, half-drachm doses of casein in oatmeal gruel every two hours, soy-bean soup three times a day, and subcutaneous infusion of sodium bicarbonate. It was assumed that there was an intolerance for fat, and consequently carbohydrates in the form of cooked starch and levulose were given in abundance. Clinically, experimentally, and therapeutically, the disease appears to depend upon some derangement of metabolism resulting in the production of toxic products from misdirected chemical processes.

SURGERY.

4. Acute Post-operative Dilatation of the Stomach.

S. E. WICHMANN (*Finska Läkaresällskapets Handlingar*, January, 1914) records the case of a farmer, aged 24, who suddenly developed appendicitis after having been quite well. Two days later laparotomy was performed under general anaesthesia with chloroform, which was administered for about forty-five minutes. The small intestine was extraordinarily empty, although no aperient had been given by the mouth. The appendix was perforated and was in the left side of the pelvis, where it was the centre of a circumscribed purulent peritonitis. The caecum lay behind the small intestine and was suspended by an abnormally long and movable mesocaecum. Four days after the operation, when every sign of

peritonitis had disappeared and the temperature and pulse were again almost normal, symptoms of acute dilatation of the stomach suddenly developed. The upper portion of the abdomen was much distended and pressure evoked nausea, but no pain. The lower abdomen was painless and flaccid. The percussion note over the stomach was tympanitic, but no splash could be elicited. In the course of about five hours one and a half litres of brownish-yellow fluid was vomited in small quantities at a time by the patient, who became pale and collapsed. Acute dilatation of the stomach was diagnosed, and another litre and a half of fluid was withdrawn by a stomach tube. The patient was turned over on to his right side with the pelvis raised. About seven hours later another litre of fluid was withdrawn from the stomach, after which the symptoms disappeared. During this attack the temperature rose to 39° C. and the pulse to 93. During and a few hours before this attack there was retention of flatus and faeces. After the patient had lain on his side for twenty-four hours he again lay on his back. In this position he felt perfectly well for about thirty-six hours, at the end of which another attack, more severe than the former, occurred. The pulse rose to 120 and the temperature to 38.5° C. The symptoms, treatment, and course of this attack were the same as before. The patient was kept on his right side for about five days, the amount of nourishment given by the mouth being cautiously increased. The temperature fell to normal in two days, but the pulse remained rapid for a week. Three weeks after the operation faulty closure of the laparotomy wound necessitated a second operation under general anaesthesia with ether. Six days after this operation, which lasted fifteen minutes, a third attack of acute dilatation of the stomach occurred during the night, the pulse rising to 100 and the temperature to 37.1° C. Postural treatment was at once resorted to, and in a few hours the attack had passed off. The patient was discharged four days later, and he suffered from no further gastric disturbances. Discussing this case, the author points out that the extreme emptiness and collapse of the small intestine observed in his case have frequently been noted in other cases, and he inclines to the view that this condition may favour prolapse of the intestine into the pelvis. This prolapse may excite gastric secretion and atony of the stomach. A long mesentery may favour this prolapse, while general anaesthesia may weaken the muscles of the stomach and thus pave the way to its dilatation. Postural treatment invariably affords relief, whereas in severe cases washing out the stomach is never sufficient alone to effect a cure.

5. Experimental Cholelithiasis.

It has now been frequently proved that the occurrence of gall stones may be provoked experimentally by simultaneously preventing the flow of bile and injuring the biliary mucous membrane. Gall stones have also often been observed to be more or less intimately adherent to the wall of the gall bladder. Laméris (*Zentralbl. f. Chir.*, February 24th, 1914) has published the results of a research which he undertook in order to discover whether gall stones may arise actually within the gall-bladder wall. A study of the human gall bladder affected with cholelithiasis lends support to the view that this may occur. It has been shown that "Luschka's crypts" are present in large numbers in cases of chronic cholecystitis associated with gall stones, whereas it is still doubtful whether they are present at all in the normal gall bladder. Laméris experimented with a view to discovering whether similar appearances are to be noted in animals. Rabbits were employed for the investigation. The cystic duct was constricted, and the wall of the gall bladder injured by compression; in a few subjects a fine silk suture was drawn through the wall. A few days later 1 c.cm. of a twenty-four-hour old culture of *B. typhosus* was injected into the heart. Five of the animals died of the operation; 19 were killed at intervals of one to thirteen weeks afterwards. In 9 cases stones were found in the gall bladder; in 6 of the cases in which stones were absent it was found that too tight a ligature had been placed round the cystic duct, so that the gall bladder had been completely shut off. A single stone was found in one of the two animals which had not been given an injection of bacilli. In one subject, killed fifty-four days after operation, a large number of small gall stones were found intimately adherent to the wall of the gall bladder. Luschka's crypts were found in various stages of development on microscopic examination; none were found in thirteen normal rabbits. These crypts contained epithelial débris and bile pigment; the epithelial masses presented here and there a concentric arrangement, and may confidently be asserted to represent the first stage in the development of gall stones. It may therefore be affirmed that Luschka's crypts appear under the combined influence of biliary stagnation and an inflammatory condition of the mucous membrane of the gall bladder, and that gall stones tend to form especially in these crypts, and are afterwards extruded into the cavity of the gall bladder. It is not contended that the presence of these crypts is essential for the formation of gall stones, but only that under certain conditions the mucous membrane of the gall bladder has a great influence on the formation of stones. Again, it is hardly likely that these crypts, once formed, will disappear. As a corollary, therefore, cholecystectomy should be preferred to cholecystostomy for the treatment of gall stones associated with cholecystitis.

6. The Use of Fat in Surgery.

Binnie (*Surgery, Gynaecology, and Obstetrics*, March, 1914) discusses the uses to which fat may be put in surgery. He observes that in spite of its reputation as a tissue of poor resisting power, fat is well suited for transplantation. Haemostasis is frequently difficult to attain in wounds of vascular organs, such as the liver. Such wounds may be successfully treated by the use of omental grafts. The fragment of omentum must be large enough to fill completely the wound in the organ. The omental plug becomes adherent to the raw surface, prevents haemorrhage, and ultimately is converted into fibrous tissue. Omental grafts are also useful in preventing oozing of blood from a uterine incision after myomectomy, and also in preventing leakage of intestinal contents from intestinal wounds. For the latter purpose, however, omentum containing only a small proportion of fat should be employed, since the value of the graft depends entirely upon the fibrous tissue present. Another use to which fat may be put is to prevent fibrous tissue changes in the pia and adhesions between the meninges and skull in cases of traumatic epilepsy. The author also suggests that where a cavity is left in the brain, after removal of a tumour, a plug of fat may be useful in forming a suitable tampon. For aesthetic purposes fat may be employed to fill up the depressed areas under scars adherent to underlying bone, particularly on the face. For such purposes the tissue for transplantation should be obtained from the patient himself since heteroplasty commonly fails. Fat may also be employed to replace a breast removed for non-malignant disease. In one case quoted by Czerny, where it was necessary to remove one breast and a lipoma from the back of the same patient, an excellent cosmetic result was obtained by grafting the lipoma into the bed left by the mammectomy. Chaput and Makas have independently published methods by which bone cavities may be obliterated by the implantation of masses of fat. This method has been employed with success in cases of chronic osteomyelitis and easily accessible tuberculous foci. Another very important use to which fat may be put is to prevent union after the division of a bony ankylosis. Reunion is prevented by this means and a new joint may be obtained. Binnie also refers to the employment of fat in preventing the line of union from becoming adherent to neighbouring structures after the operations of tenorrhaphy or neurorrhaphy. To wrap a free or pedunculated flap of adipose tissue around the part is an excellent prophylactic measure in these cases. Finally, Tuffier has successfully grafted large masses of fat between the parietal pleura and ribs in bronchiectasis. Binnie suggests that the same method may be used to close suppurating and tuberculous pulmonary cavities.

7. Disinfection of the Hands.

Sorel (*Journ. des praticiens*, November 8th, 1913) points out that no procedure can render the hands sterile for long. When tincture of iodine is used he recommends that there should be no preliminary washing. Iodine appears to act rather as a varnish to the skin than as an antiseptic. The author remarks that bacteriologists know that a layer of fat limits microbial invasion and that the fat secreted by the sebaceous glands of the skin is an excellent barrier in their way. To obtain the best results the hands must be preserved in their normal physiological state, that is with regard to the integrity of the skin and the fat normally secreted by the skin; to do this it is best to avoid the use of hot soap and water and friction with a hard brush, and further to avoid dissolving the natural fat of the skin by immersion in benzine, ether, or any such fat solvents. It is also suggested that before operation the hands should be smeared over with vascline, the excess being wiped off with a sterile compress. The hands of the surgeon ought not to be exposed to cuts or bruises. The author advocates also the use of rubber

gloves in certain cases. There is no means of disinfecting the hands absolutely, but the foregoing suggestions are worthy of notice.

OBSTETRICS.

8. Eclampsia: Twin Labour with Entangled Funis.

DIETRICH (*Zentralbl. f. Gynäk.*, April 18th, 1914) attended a primipara, aged 23, who had just passed through two fits during labour. He at once gave an anaesthetic, which set up a third convulsion. The head had entered the pelvis, and the forceps was at once applied. Extraction proved unexpectedly difficult, though the child was very small, weighing but 5½ lb. and measuring a little over 16 in. Just as it was delivered the cord, which seemed unaccountably short, had to be tied while the child's abdomen lay close against the vulva. Then it was discovered that a second child lay in the uterus. The presentation being transverse, it was turned and extracted. The second child was as small and as light as the first, and both were females; the first lived, the heart of the second pulsated when it was born but soon ceased. The mother did well and had no more convulsions. The placenta of these undersized twins was very big, and there was only one amnion, common to both. The cords were not actually knotted at any point, but being quite distinct from their origin on the placenta and very long, they had become entangled in a most intricate manner and appeared to be very short. Each was caught in a loop of the other cord two or three inches above its insertion into the fetal umbilicus.

9. The Urine in Pregnancy.

THE following are the conclusions of an article giving the results of an experimental research as to the appearance of non-colloidal ninhydrin-reacting substances in the urine under normal and pathological conditions and during pregnancy, by F. H. FALLS and WILLIAM H. WELKER, Chicago (*Journ. Amer. Med. Assoc.*, June 6th, 1914): (1) The presence of non-colloidal ninhydrin-reacting substances in urine is of no value as a means of diagnosing pregnancy. (2) The reaction may be absent or inhibited in the urine of pregnant women, as well as in normal and pathological urine. (3) In the various urines treated the only difference in the ninhydrin reaction between the diffusates through parchment and the filtrates from the aluminium treatment were those of intensity of colours, the aluminium filtrates showing a less intense colour with ninhydrin. (4) In the urines reacting positively with ninhydrin the removal of colloidal substances favours the production of the blue colour given by this reagent with amino-acids. Such urines before diffusion or treatment with aluminium hydroxide give a colour which is not so strong and has more of a reddish cast. This is not the result of the dilution alone. (5) The occurrence of either albumin or indican appears to have no influence on the ninhydrin reaction applied to the colloidal-free urine.

GYNAECOLOGY.

10. Plastic Treatment for Complete Section of Ureter.

SEJOURNET (*Revue de gynéc. et de chir. abdom.*, March, 1914) writes on ureterorrhaphy for complete section or division of the ureter, and gives illustrations of all methods from that of Schopf in 1886 to the arterial suture type now shown, in Sejournet's opinion, to be the best. Complete section of the ureter is nearly always caused by surgical wounds inflicted during gynaecological operations. In a limited number of cases the upper end of the cut ureter can be sutured into an incision made through all the coats of the bladder. End to end, non-perforating interrupted suture of the divided ends of the wounded ureter, and entero-lateral anastomosis have proved unsatisfactory. Suture over an absorbable conductor is difficult; suture by invagination of the upper into the lower end of the ureter has been practised, with several modifications. Pozzi turns the free edge of the lower end down into its canal, and then invaginates the upper end and sutures it to the lower end thickened by the inversion of its edge. This method can be done quickly, and allows of the apposition of homologous tissues, instead of fibrous tissue to mucosa. Pauchet and Delbet claim the superiority of end-to-end suture, but performed after the method now practised for suture of arteries. Perfect coaptation of the divided edges, by a whip stitch suture of the finest linen or silk applied by very fine needles, is thus ensured.

11. Corpus Luteum Extract.

DANNREUTHER'S assertion that only corpora lutea vera contain the substances that are efficacious in gynaecological conditions led C. P. MCCORD (*Journ. Amer. Med. Assoc.*, April 18th, 1914) to undertake an investigation of the frequency of pregnancy in the slaughterhouse animals from which the corpus luteum extract used in organo-therapy is obtained. There is no anatomical difference between the corpus luteum of pregnancy and that of non-pregnant animals; whatever differences exist probably involve the chemical constituents rather than the anatomical structure. He found that the greater number of cows slaughtered in the packing houses from which the corpus luteum supply is obtained were mostly range cattle where the females and males run together. The greater number are at some stage of pregnancy. In forty cows examined, thirty-five yielded ovaries containing corpora lutea of such size as permitted dissecting out. Of these thirty-five, twenty-nine, or 83 per cent., were pregnant. Allowing this to be the usual figure, on account of the larger yield of corpus luteum from a pound unit of ovaries from pregnant animals, the proportion by weight may run much higher, even to 90 or 95 per cent. of corpus luteum verum. The figures may vary with an examination of a larger number of cattle, and, furthermore, a seasonal variation may alter the percentage of pregnancies; but if the above data at all approximate the general conditions, all corpus luteum preparations are derived in a large percentage from pregnant cattle.

THERAPEUTICS.

12. Intratracheo-Bronchial Injections in Asthma.

HENRI BOURGEOIS records his experience of this mode of treatment of asthma (*Bull. de l'Acad. de Méd.*, April 21st, 1914), and points out that Ephraim's method of intrabronchial pulverization of a solution of novocain-adrenalin, which gave remarkable results, has been but little used by others, probably owing to its complicated technique. Yet certain other authors have published records of benefit from either injections or intratracheo-bronchial pulverization. Bourgeois has used for his intratracheal injections a 5 c.cm. syringe and a long cannula, which is passed down the trachea to the bronchial bifurcation; the larynx is first thoroughly anaesthetized, and although anaesthesia of the tracheal mucous membrane is not indispensable, it is advantageous and is easily obtained by a spray of 10 drops of a 1 in 20 cocaine solution. Clinical experiments were tried with various medicaments; sometimes gomenolized oil was used (gomenol is a syrup used in pertussis, and is said to be prepared from the leaves of *Melaleuca leucadendron*), sometimes an aqueous solution of cocaine-adrenalin and novocain-adrenalin, sometimes an oily solution of adrenalin and novocain. The quantity of fluid injected was 5 c.cm. for adults and 2 c.cm. for children. The young asthmatics were thus treated both during the attacks and in the intervals between paroxysms; the adults were chronic asthmatics. The best results were obtained in cases of essential asthma treated during the attacks rather than in chronic or tuberculous cases. Bourgeois gives in illustration the case of a young woman, free from pulmonary lesions, who was in a state of asphyxia; fifteen minutes after an injection improvement followed. Another patient was utterly exhausted by his attacks; he fell asleep half an hour after injection, and slept on for fifteen hours. A tuberculous woman, who had been suffocated for fifteen days without a minute's sleep, began to breathe better fifteen minutes after injection. But these good results were less constantly seen when patients suffering from either essential or symptomatic asthma were injected during the interparoxysmal periods. All the fluids just mentioned were successful in certain cases, but the oily injections, whether of gomenol or novocain and adrenalin, were not always well borne; thus, two patients had after such injections an attack of dyspnoea severer than any of their asthmatic attacks. Bourgeois find, however, that aqueous novocain solution is at all times absolutely harmless, and is efficacious in incredibly small doses; latterly he has used injections of a 1 in 100 solution of novocain with 25 drops of 1 in 5,000 adrenalin solution. When these injections are given during the interparoxysmal period no

appreciable secondary phenomena are seen; when given at the moment of an attack there is seen at the end of ten minutes a subjective diminution of dyspnoea, then gradually the breathing becomes more frequent and easier, so that the patient can quit the sitting posture, lie down, and even fall asleep. An important consecutive phenomenon is an extremely abundant expectoration which favours bronchial permeability. Bourgeois holds that the good effect of these injections is probably due to the anaesthetic and vaso-constrictive action of the solutions. Although it is true, as Ephraim stated, that the injected fluid penetrates the lower lobe of the lung to only a feeble extent, yet Bourgeois reminds us of the extremely rapid absorption of an aqueous adrenalin solution, and its great diffusibility, and it is to this fact that it owes its efficacy. He says that the only contraindication is advanced age of the patient or arterial hypertension. He concludes that intra-bronchial injection of novocain-adrenalin is very successful in asthmatic attacks, and may be tried in the interparoxysmal period, although it is less constantly useful at such times.

13. The By-effects of Salvarsan.

M. V. Zeissl (*Berl. klin. Woch.*, March 9th, 1914) reviews the history of the treatment of syphilis by mercury—a treatment almost contemporaneous with the epidemic appearance of the disease in Europe in the fifteenth century—and refers to very numerous authorities to show that all the evil effects and accidents recently attributed to salvarsan have from time to time been attributed to mercury. Some of these, both as regards salvarsan and mercury, he admits may be really the effect of the drug acting under exceptional circumstances or in patients with some idiosyncrasy. The great majority of them, however, he holds to be merely manifestations of syphilis which have appeared not because of, but in spite of, the administration of the particular remedy. There seems to be hardly a single symptom of syphilis, except, perhaps, the initial chancre, which has not, at one time or another, by one author or another, been regarded as an effect of the mercurial preparations employed in treatment. Perhaps this idea reached the summit of absurdity in the thesis of Dr. Josef Herman in the sixtieth year of the last century, in which he proclaimed constitutional syphilis in general as really mercurial poisoning. The author takes an optimistic view of salvarsan and its future. Since July, 1910, he and his assistant, Bindermann, have treated over 1,000 cases of syphilis by salvarsan injected intramuscularly, and during the last year by neo-salvarsan injected intravenously. In not a single instance did any serious ill effect to the patient result; on the contrary, the effects were uniformly good. In no case was blindness, deafness, or paralysis observed to result from the injections; while some cases of insanity and five cases of partial deafness, due to syphilis, were cured. These exclusively good results were attained by minute attention to asepsis and the careful exclusion from the treatment of all persons who, owing to cardiac or other conditions, were unfavourable subjects. Undesirable results of a minor order, or, in exceptional cases, necrosis or injury to some particular nerve, may be caused by salvarsan, as these and other accidents, have long been known occasionally to result from the use or misuse of mercury. That the optic nerve in particular may suffer harm has quite recently been shown afresh by Frahauf in a communication to the Dermatological Society describing cases of amaurosis following the injection of insoluble salicylates of mercury. Yet no one has ever proposed to exclude such preparations of mercury from the armamentarium of the syphilologist. V. Zeissl concludes that Ehrlich's preparation is the most efficacious agent so far discovered for the treatment of syphilis, and that Ehrlich has by his discovery conferred a priceless boon on patients and physicians alike.

14. Organotherapy in Pulmonary Tuberculosis.

Zisoni (*Bollet. della Soc. Med.-Chir. di Modena*, January, 1914) gives brief details of five cases of phthisis (tubercle bacilli present in all) treated with calf's liver. Since the human liver is seldom attacked by tubercle and takes a considerable part in resisting tuberculous infection, the author thought it worth while to try it in the treatment of phthisis. The daily dose was from 150 to 250 grams (=5 to 8 oz.), given raw by the mouth. Taking the weight as a rough test of improvement, other things being equal, all the patients put on weight. As this is only a preliminary communication, further details are promised in a future paper. But the line of treatment is somewhat new, and may perhaps prove useful.

PATHOLOGY.

15. Double Monsters.

Baudouin (*Sem. méd.*, No. 47, 1913) describes a new pair of craniopagous twins which was recently on public exhibition. The monstrosity is named Emi-Lisa Stoll, and the two subjects are, as always, of the same sex, in this case feminine. The union is very marked, and comprises at least the two parietal bones in their entirety, but the faces of the two infants are not in the same antero-posterior plane, the two planes forming an angle of 90 degrees—that is to say, that when one infant is looking north the other is looking nearly east. In August, 1913, the children were 20 months old. They are very healthy, and at birth one measured 48 cm., the other 47 cm. Their bodies present no anomalies, except that the lower extremities are a little atrophied owing to the fact that it is impossible for the children to walk. The mother is strong and healthy, and has had three normal children (boys). The father is of middle height, though rather thick-set; there are several dwarfs in his family, and he has a sister whose face and body are covered with lanugo. The pregnancy was normal. The little girls are much alike; the hair is of the same colour and character, and the physical characteristics are similar in other respects. The capital point is the angle of the two heads. There may have been a kind of torsion of one body on the other before the osseous transformation of the parietals; but the author thinks it probable that in reality there was no such torsion, but rather a direct welding, even from the beginning of the development of the two beings. Most of the cephalopages are feminine, especially those which have lived, and the living ones have generally been born of multiparous mothers. It seems certain that in this case there are separate brains. Virtually the children act independently; one sleeps, while the other wakes, one laughs while the other cries. When awake they play together by throwing toys at one another over their heads. In character they are alike. They have lived longer than any other recorded case. No attempt at operation has yet been made in these cases, but the author thinks that in the present state of cranial surgery an operation might be successful, provided it were performed between the first and second year. Le Filliatse (ibid., No. 2, 1914) showed a pair of xiphopagous twins at the Academy of Medicine. This is the first living xiphopage born in France for 500 years. The mother is nine years older than the father; her other children, both by this and her former husband, are normal. At the confinement the one child presented by the vertex, the other was transverse; by version of the latter the two were delivered simultaneously, one by the head, the other by the feet. There was one large placenta and one cord for the two infants. The two little girls (Madeleine-Suzanne) are joined by a bridge uniting them at the lower part of the thorax and the upper part of the abdomen. On the median and inferior aspect of this bridge is the umbilical cicatrix. The bridge is 5 cm. long and 14 cm. in circumference; it is covered with skin and presents a hard portion of cartilaginous consistence, below which are two cords the size of goose quills stretching from one child to the other and not adherent to the umbilicus; between these parts is easily compressible tissue, in which intestinal movements can be felt whenever the children cry. The type is thus the same as the Siamese twins. Though their abdominal cavities communicate, the children have each an individual and complete organism. The measurements of the height, thorax, cranium and extremities are different, Suzanne being in all respects the larger. Madeleine's heart beat is 120, Suzanne's 130. The temperature of the two is hardly ever the same. The cry is different, and the nurse can tell which is weeping without seeing them. Madeleine's face is round, Suzanne's oval, but the colour of the eyes is the same. The blood count differs, Madeleine showing a notable increase of small mononuclear lymphocytes, so that there is evidently only a small exchange of blood at the point of union. Radioscopy shows that the hearts are independent and of normal aspect; the movements of the diaphragms are not synchronous. There are two stomachs, normally placed, the air space in each being large. The two small intestines are independent. In the upper part of the bridge of junction is a strongly cartilaginous band joining the two xiphoids; below this is small intestine. During deep inspiration and straining loops of the small intestine of Madeleine enter the abdominal cavity of Suzanne, returning to their proper place during expiration. No large intestine enters the bridge. The livers are independent and of normal aspect.

AN EPITOME OF CURRENT MEDICAL LITERATURE.

MEDICINE.

16. Arterial Hypertension and Cholesterinaemia.

C. CANTIERI (*Riv. crit. di Clin. Med.*, Florence, 1913, xiv, 657) expounds the theory advanced by Lemoine and others of the French school of medicine, according to which atheroma and arterio-sclerosis are the result of hypercholesterinaemia, or the presence of an excess of cholesterin in the blood. The cholesterin is an antitoxin that serves to neutralize a number of toxic substances in the blood. If present in excess, it cannot remain in solution, and so is precipitated in the arterial walls; in addition, it is held that cholesterin and its lipoid compounds all give rise to arterial hypertension by causing contraction of the involuntary muscle in the arterial walls. Lemoine and others have found an excess of cholesterin in the circulating blood of arterio-sclerotic patients; and they also find an excess of cholesterin in the walls of atheromatous arteries. Others have observed that alimentation with food containing an excess of cholesterin induces a process like arterio-sclerosis in rabbits, and leads to accumulations of cholesterin and other lipoids in various tissues; the experiment is less successful with dogs, as if there were a difference here between herbivores and carnivores. Cantieri quotes a number of the figures found for the percentage of cholesterin in normal blood; different authors give different figures, largely in accordance with the methods of extraction and measurement employed, but from 0.14 to 0.18 per cent. seems to be the average. He himself used Grigaut's method of estimating the cholesterin, and found values between 0.14 to 0.20 in six normal persons, averaging 0.175 per cent. In a series of nineteen arterio-sclerotic patients with or without high blood pressure, he found percentages of cholesterin varying between 0.10 and 0.205, averaging 0.15. No connexion could be observed between the height of the blood pressure and the quantity of cholesterin present; a patient with a blood pressure of 215 mm. Hg had 0.12 per cent. of cholesterin; another with a blood pressure of 150 had 0.20 per cent. of cholesterin in his blood. In addition Cantieri examined four patients with acute or chronic nephritis; the percentage of cholesterin varied from 0.19 to 0.24, the blood-pressure from 120 to 220 mm. Hg, again without there being any connexion between the two sets of figures. It is, indeed, generally agreed that hypercholesterinaemia and nephritis go hand in hand; Cantieri supports the various authors who have argued that there is no connexion between the high blood pressure these patients often show and the excess of cholesterin that is habitually present in their blood. He also failed to raise the arterial blood pressure by administering cholesterin as a drug. Many references to the literature of the subject are given.

17. Aerophagy and its Consequences.

CADE (*Prov. méd.*, April 25th, 1914) dwells on the importance of the part played by aërophagy in the pathology of digestion. The condition has come to embrace many of the forms of what has hitherto been known as flatulent dyspepsia. It may be voluntary and conscious, or involuntary, and it is with the latter class of case that the author deals. Air enters the digestive tube normally with the food taken—this is physiological, but becomes pathological when an excessive degree of salivation is provoked. Sialophagy, as shown by Hayem, plays an important part in the production of aërophagy. In certain cases, however, what may be called "dry" aërophagy occurs as the result of an effort of inspiration in which the glottis remains closed, the air meantime finding its way into the oesophagus. There are various types of the condition: (*a*) Pharyngo-oesophageal, (*b*) oesophageal, (*c*) gastric aërophagy. As a rule the air passes rapidly down the oesophagus, but when it does not do so, causes irritation and hypersecretion of mucus. When it reaches the stomach it is expelled by eructation. If it remains for any length of time it may cause spasm of the cardiac orifice. It may also pass into the intestine, and in that case is expelled per rectum. When in the intestine, the air, as a rule, is particularly localized at the splenic flexure, which is the highest point of the intestinal arc. According to the author, it is impossible to draw a hard-and-fast line between dyspeptic aërophagy and that dependent on neuropathic conditions. The gastric form of the condition is frequently accompanied by painful crises, and this is more especially the case when gastric ulcer is also present, there being also the further danger of rupture of the organ. The vomiting that occurs in aërophagy of this type has no preliminary nausea, and the frequent repetition of the attack may result in marked enfeeblement and emaciation. The gastric form of aërophagy, further, may provoke symptoms suggestive of angina; at other times of acute pulmonary oedema; and, again, of a systole and uraemia. The author remarks that recently Tissier and others have attributed post-operative acute dilatation of the stomach to an aërogastric crisis. Gaseous distension of the bowel, whether accompanied by aërepathy or not, is a common accompaniment of hysteria. The air accumulates at certain points in the intestine, and, according to their position, simulates in symptomatology a number of other conditions. In these circumstances radioscopy has rendered great service in determining the diagnosis. In the aërophagy of neuropathic origin, rest and sedatives, such as bromide and valerian, are indicated, and, if necessary, isolation and psycho-therapy. In that form of the trouble associated with dyspepsia these lines should also be followed, with, in addition, gastric sedatives, such as belladonna or bismuth, in large doses. In the case of acute gastric dilatation, the ventral decubitus will assist the exit of the air, and, if necessary, Faucher's tube may be used.

18. Renal Diabetes.

S. STROUSE AND A. H. BEIFELD (*Journ. Amer. Med. Assoc.*, April 25th, 1914) discuss the so-called renal diabetes, possibly traumatic in origin. The general conception that the kidney is practically passive in diabetes has been disputed, and they notice the various statements of authors in regard to this matter. Richter, von Noorden, and Weiland have pointed out that the development of albuminuria may be accompanied with decreased excretion of sugar, and, they say, it must be assumed that a relation may exist between glycosuria and the kidney, independent of the true metabolic disturbance. The term "renal diabetes" seems to be employed for a condition of glycosuria which has been associated with kidney disease and clinically differentiated from true diabetes by its independence of carbohydrate intake and its clinical course. In studying the recorded cases, one is struck by the many temporary derangements included under this head, and many of the cases cannot be taken as showing the existence of a separate disease. It has been shown, nevertheless, by Salomon that there exists a group of glycosurias even in youth that do not progress to diabetes mellitus. Lépine and Garrod have proposed that the term "renal diabetes" be dropped and the phrase of "glycosuria without hyperglycaemia" adopted in its stead. Many temporary derangements are classed as renal diabetes at present, and unless we restrict them to the condition defined in Lépine's and Garrod's definition we are not justified in recognizing a separate disease. Strouse and Beifeld go over the records of the more thoroughly reported cases, and give a full report of one of their own. The patient was a healthy young man in whose urine glucose was accidentally discovered during a life-insurance examination. About a year before he had had an injury to his head, but the connexion of this with the condition is not clear. There were no symptoms of diabetes mellitus. The blood-sugar was normal and the excretion of dextrose was practically independent of the carbohydrate intake. Under conditions that would intensify the symptoms of true diabetes in a person of his age (23), he continues in perfect health. The clinical course has not been at all like that of diabetes mellitus, but fully satisfies the diagnosis of renal diabetes or glycosuria without hyperglycaemia.

19. Enteralgic Attacks in Exophthalmic Goitre.

G. DESBOUIS reports a case of exophthalmic goitre in which attacks of abdominal pain were a prominent feature (*Bull. et mém. Soc. Méd. des Hôp. de Paris*, May 7th, 1914). Attacks of gastric pain are known to occur sometimes in this disease as well as bulimia; and recently Wolpe has studied the disturbances of gastric secretion which are seen occasionally. The danger of attacks of diarrhoea in the disease is well

known, and they have been known to simulate even tuberculosis or cancer of the intestine. Diarrhoea has also been provoked experimentally by the use of thyroid extracts. Kolb is quoted as having seen in one of his patients the disappearance of obstinate diarrhoea and the classic signs of exophthalmic goitre after partial resection of the thyroid body. The patient of Desbouis was a woman of 56, who, at the onset of the menopause, suffered from abdominal pains, which became more and more violent; they were sometimes worst in the evenings, sometimes when in bed. These pains were accompanied by suffocating sensations, with a sense of throat constriction, flushes of heat, and tremors; her friends found her very difficult to live with on account of her extreme irritability. The pains were not definitely localizable, but they were colicky, and pressure showed tenderness over the ascending and transverse colon; there was anorexia and constipation. The pains were not aggravated by meals, but she avoided eating as far as possible, as it provoked dyspnoea. She recalled the fact that when she was 12 years old she had similar attacks, together with a small goitre which lasted for four or five years. At the age of about 18 she had acute rheumatism, which did not affect her heart or her thyroid body. At 55 her menses left her for three months, and at the missed periods she had similar attacks to those of her girlhood, lasting for eight to ten days. During the last six months her goitre has increased in size markedly, and she now presents the typical picture of an exophthalmic goitre. Desbouis concludes that his case seems to show that, just as we may have attacks of gastric pain in exophthalmic goitre, so also we may have similar enteralgic attacks, which may be unaccompanied by any disturbance of intestinal secretion in the shape of diarrhoea.

SURGERY.

20. Results of the Operative Treatment of Empyema.

HIRANO (*Deut. Zeitsch. für Chir.*, Band cxxiv) gives the statistics relating to 118 cases of empyema treated in the Hazu Hospital at Ise, 1900-1911. The total includes 93 children, from infancy to 15 years of age. The results in adults were bad, the mortality-rate being 50 per cent., and the duration of treatment at least six months. In 4 of the 8 cured cases, repeated operations for the resection of ribs were performed. Of the children 72 per cent. recovered, and of these one-quarter recovered within three weeks; the death-rate was 14 per cent. Operation in the first instance consisted of simple resection of a rib. Drainage was effected by rubber tubing; packing the wound proved unsatisfactory. Bier's suction apparatus was frequently employed when healing was long delayed. WERNER (ibid.) presents a similar list of the 178 cases of empyema received in the Armits. Kinderhospital at Riga from 1900 to 1910. The highest mortality occurred in those cases with a mixed infection of staphylococci and streptococci. The prognosis of the older children is much more favourable than in the case of infants. Five children whose parents refused operation died; three children died on the operating table from heart failure. The death-rate for all cases was 21.9 per cent.; the average length of time under treatment fifty-seven days. Resection of a rib was the operation of election. Drainage was effected by means of a long tube connected with a vessel of water, so as to produce a siphon action. In the later years of the period in some cases two ribs were resected and the wound packed; the death-rate in these cases and the average length of treatment both tell in favour of the less severe operation. In 10 cases in which a single rib had been resected a chronic sinus persisted, necessitating further operation. Seven long-standing and neglected cases had to be treated by the resection of several ribs.

21. Resection of Cardiac End of Oesophagus.

FROM the clinic of Professor Witzel at Düsseldorf SCHWERS (*Zentralbl. für Chir.*, May 9th, 1914) writes of an improved technique devised by Witzel for the radical treatment of carcinoma of the lower end of the oesophagus. The great difficulty of suturing the stomach to the oesophagus after cardiac resection has demonstrated the impracticability of the abdominal route, as tried up to the present time, and no good results have hitherto followed the intrathoracic operation. Witzel's technique has been worked out on the dead body: the first stage consists in freeing the oesophagus through a thoracic incision; next the abdomen is opened, the oesophagus drawn down, and the diaphragm partially freed and pushed up; the diaphragm is stitched to the oesophagus as high as possible and the thorax closed. Resection may then be completed as an intra-abdominal operation. A somewhat extensive rib resection is necessary in the first stage. In fuller detail a curved incision is made, convex below, commencing at the left border of the sternum, at the junction of its middle and lower thirds, and running over the costal margin to about the mid-axillary line. Ribs 5 to 9 inclusive are resected extrapleurally, from the anterior axillary line behind and including the greater part of the costal cartilages in front. The pleura is incised by curved incision at the level of the fifth rib. The lung is drawn upwards and backwards: a longitudinal incision is made through the mediastinal pleura over the oesophagus, which is freed by blunt dissection, avoiding the vagi. The abdomen is next opened and the diaphragm incised at its opening in front. An incision is also made in the diaphragm for 2 in. in a forward direction from the oesophageal opening. The diaphragm is then pushed up as high as possible, and the gullet slowly but steadily drawn down. The enlarged oesophageal opening in the diaphragm is closed by suture from behind forwards, the oesophagus being stitched in. The pleura is then closed. The lower fourth of the gullet (from 4 in. to 5 in. on the dead body) is now an intra-abdominal organ, and resection of its lower end and of the adjoining portion of the stomach can be easily performed: the subsequent suturing of the oesophageal stump to the stomach also presents no special difficulties. An important point is that tension on the suture line is avoided: the oesophagus does not pull away from the stomach, but tends to be drawn down, owing to its attachment to the diaphragm. The details of the oesophageal suture are not entered into, but any method of course requires as adjuvant a temporary gastrostomy.

22. Cancer of Splenic Flexure.

P. E. TRUESDALE reports (*Journ. Amer. Med. Assoc.*, April 25th, 1914) two cases of cancer of the splenic flexure of the large intestine. He remarks on the rarity of cancer in this location, its slow development and late metastases. The lymphatic glands of the region are so related that the conditions for the spread of carcinoma are not favourable, and the statistics of Madeling and Mayo would indicate that the results of operation are rather more favourable than in cases of cancer in other localities. In each of Truesdale's two cases a resection of the splenic flexure was made and in both cases relief was obtained, though in one case there is evidence of recurrence of cancer in the cervix uteri a year later. Other similar cases are mentioned, and he concludes that the cure of cancer in this region of the bowel by excision can be reasonably assured. Nevertheless the outcome mainly depends, as in the other cases of cancer, on an early diagnosis. The article is illustrated.

23. The Prostatic Incident in Diabetes.

STERN (*Archives of Diagnosis*, January, 1914) calls attention to the frequent association of the prostatic and diabetic states, an association generally overlooked, such prostatic symptoms as difficulty in starting micturition, frequent nocturnal desire, etc., being attributed to the diabetic syndrome. Although the prostatic state consequent upon the hypertrophy of the gland does not usually manifest itself in otherwise normal individuals before the sixtieth year, in diabetics it may ensue from ten to thirty years earlier. While such early prostatism in the diabetic may be the result of a gonorrhoeal prostatitis in which the sugar-laden urine helped to perpetuate the inflammatory and hypertrophic processes, many diabetics with chronic prostatitis and hypertrophy give no history of a gonorrhoeal invasion, and consequently in such instances there must be either another infection underlying the inflammatory process, or the pathologic changes must have been directly evoked by the glucose, or by nutritive or secretory disturbances in the gland. Although the great majority of prostatic cases are of microbic origin, a certain proportion may be the result of systemic influences, as in the early prostatitis of diabetics. Prostatic disease of infectious origin and senile hypertrophic changes in the gland may antedate the diabetic state, and in this association there is no relationship between them as far as the origin of one from the other, or their production by a common factor, is concerned. Prostatic disease may, however, be the result of the diabetic urine, and represents more than a mere accidental occurrence, the frequent occurrence of cystitis in the diabetic being probably due to an enlarged gland originating the bladder complication. The prostatic state may also arise on a purely systemic basis, being the consequence of the same changes which give occasion to the

diabetic deterioration, or its direct result. It does not materially differ from the true status prostaticus of the aged, the main differences being that when it occurs on the foundation of a constitutional disease or anomaly it may develop at a comparatively early age, and be associated with hypertrophic changes involving the greater part of the gland. This constitutional prostatism is primarily an affection of inadequate or perverted blood supply, due either to a local or general angiosclerosis or to toxic elements in the blood, the changes in the prostate being a connective tissue or epithelial hyperplasia with atrophic changes as the condition becomes advanced. In a case recorded treatment directed towards the amelioration of the diabetes also relieved the subjective prostatic phenomenon.

OBSTETRICS.

24. Treatment of Suspended Animation in the Newborn.

G. SAKAKI (*Deut. med. Woch.*, April 2nd, 1914) criticizes the present methods of artificial respiration for asphyxia neonatorum. Were the respiratory tracts unobstructed, the dilatory methods advocated by Schultze and others, with pauses of three to four seconds after the completion of each phase, would be suitable enough. But slow movements which may sufficiently aërate the lungs in the absence of obstruction, are insufficient when the trachea and bronchi are choked with mucus. This prevents the active transmission of gases through the respiratory system, except at the height of the inspiratory and expiratory phases, when the differences of pressure within and without the chest are greatest. In the intervals between these phases, these differences of pressure are not great enough to allow an appreciable passage of gases on account of the obstructing mucus. This must, therefore, be removed, and the only way to do this satisfactorily is to shake the child rapidly up and down. The author bases this procedure on the familiar observation that when a considerable quantity of water is introduced into a system of capillary tubes, bubbles are formed which obstruct the passage of air. These are most easily got rid of by shaking the tubes up and down. The newborn child suffering from suspended animation is treated in the following matter: All foreign matter is thoroughly wiped out of the mouth and throat. The operator inserts the index fingers behind the shoulder into the axilla on both sides. His thumbs meet in front of the neck, and thus, by supporting the chin, prevent excessive flexion of the head. The remaining three fingers of each hand are spread obliquely over the back of the chest. Thus held, the child is shaken up and down by movements at the wrist, at the rate of 120 to 150 in the minute. They are, in fact, made as rapidly as possible, but not too vigorously. When they have lasted a couple of seconds or so, air may easily be heard passing through the bronchi. The child is now suspended upside down, and is lightly shaken up and down. This enables the mucus to stream from the mouth and nose, and the child breathes naturally. If, however, this does not happen, the manœuvre is repeated again and again till the child breathes naturally. This method usually takes a few minutes before the child is revived. The author admits that it may possibly give rise to an aspiration pneumonia; but this is a hypothetical evil of little importance compared with the danger of immediate death from asphyxia. The method is simple and, when necessary, can be practised before the cord is divided.

GYNAECOLOGY.

25. The Urinary System and Diseases of the Female Pelvic Organs.

J. G. CLARK AND F. E. KEENE (*Surg., Gynaec., and Obstet.*, January, 1914) discuss the relationship between the urinary system and diseases of the female pelvic organs. They observe that symptoms referable to impaired bladder function play an important part in the clinical history of many pathological conditions in the female. It is essential to recognize that in all cases the bladder is not the only portion of the urinary tract to be affected, but that in a small number of patients the lesion is more extensive, involving the ureter and kidney. It is therefore a matter of considerable importance for the surgeon not to limit his horizon to investigations of the pelvic organs only, whenever symptoms are combined with those referable to the urinary tract. Ureteral lesions fall into two broad groups—namely, those of mechanical origin, shown by dilatation of the canal and renal pelvis, and those due to infection. Ureteral compression by neoplasms—particularly cervical carcinoma and intraligamentary or impacted myomata—is commonly recognized, but that such an occurrence may occur with other still more frequent lesions is, in the authors' opinion, not sufficiently appreciated. Under quite normal conditions, the trigone often presents an entirely different appearance during the menstrual and intermenstrual periods. This is the result of the pelvic engorgement occurring immediately before and during the catamenia. The mucosa at such times is acutely congested, swollen, and oedematous. Clinically, this is often shown by the frequency of minor vesical symptoms or the exacerbation of cystitis during the menstrual flow. If the ureteral orifice is abnormally small, this periodic congestion is sufficient to produce urinary stasis and dilatation of the ureter and renal pelvis. Proof of this possibility is seen in cases of intermittent hydronephrosis, in which the symptoms are often associated with menstruation. Clark and Keene suggest that this same factor may explain the frequency of right-sided pyelitis by being superimposed upon a lax ureter, the result of nephroptosis. It is generally agreed that in women a freely movable right kidney is a frequent occurrence. Ureteral dilatation, therefore, according to the authors' theory, is purely of mechanical origin and may be secondarily exaggerated by inflammatory changes in the walls of the ureter which weaken its resistance to the internal pressure. The same remarks apply to the renal pelvis.

THERAPEUTICS.

26. The Treatment of Sciatica.

F. X. DERCUM (*Therapeutic Gazette*, April, 1914) lays stress on the importance of a correct diagnosis of any case of supposed "sciatica." True peripheral sciatica—whether it be merely neuralgic or neuritic—is usually unilateral. Diabetic sciatica is usually bilateral. We have to exclude the sciaticas due to compression by intrapelvic tumours or other lesions of the sacral plexus or cauda equina; and it is well to remember that sometimes what appear to be merely local sciatic pains are really of tabetic nature. Therefore a complete neurological examination together with a recto-vaginal examination and examination of the urine ought to be made in all cases of "sciatica." In the common local form there is usually tenderness over the sciatic notch or behind the head of the fibula or in the middle of the posterior aspect of the thigh. But it does sometimes happen that tenderness on pressure is present in cases that autopsy shows are due to intrapelvic tumour. The pain of sciatica is also increased by motion or by a constrained position of the limb or by passive extension. The cases of non-symptomatic sciatica occur in two distinct groups: (1) The slighter, in which the ankle-jerk on the affected side is either normal or only very slightly diminished, and (2) the severer, in which it is lost early; these latter cases are true neuritic cases and are slower in yielding to treatment than cases of the former neuralgic group. Dercum points out that the aim of treatment is (1) to relieve pain, and (2) to bring about a cure. The first is promoted by rest in bed; the limb must be put into the most comfortable position; if the case be a severe one, a long external splint extending from axilla to below heel or an anterior splint may be applied, the thigh and leg being very slightly flexed, or sandbags may be used instead of splints. In most cases, however, Dercum finds that rest in bed without splinting is all that is needed. He strongly praises full doses of salicylates with bromide, for example, 10 to 20 grains of the former with 20 to 30 of the latter, every four hours well diluted. It is essential "to make a massive impression within the first twenty-four or forty-eight hours with the salicylate." In average cases the pain markedly lessens, and even disappears promptly under these circumstances. Very soon we may diminish the dose of each drug by half, and rapidly discontinue them. Very severe pain at the onset may be treated by morphine gr. $\frac{1}{4}$ with scopolamine gr. $\frac{1}{100}$ hypodermically at bedtime, but this is seldom needed. Dercum warns against too prolonged rest or fixation of the limb in one position for too long a time, as contracture may thus result. He advises a routine practice of slight passive movement of the limb at hip and ankle, and as soon as practicable gentle massage and electrical treatment. Formerly he used remedies such as turpentine, arsenic, quinine, iodides,

antipyrin, and phenacetin, but with scant success. Various local measures are praised by writers, namely, injections or infiltrations of the region round the nerve with salt solution, perosmic acid, carbolic acid, antipyrin, and methylene blue. Lange injects from 70 to 80 c.cm. of 1 per cent. eucaine solution in an 8 per cent. solution of sodium chloride. Tropacocaine may also be used. Others have used stovaine 0.1 to 0.2 per cent., 10 to 20 drops of adrenalin hydrochloride solution 1 in 1,000, together with aq. destillat. to make 100 c.cm. Injections of the Schleich solution are said by Falten to give durable results. Intraspinal injections and epidural injections of Schleich solution or of sodium chloride, have done good: also alcohol perineural injections and intraneural ones of β-eucaine, and freezing of the tissues over the nerve by methyl chloride. Dercum ends his paper with a list of the many conditions which can give rise to a symptomatic "sciatica"—namely, lesions of the sacral plexus or of the cauda equina roots, lesions of the bones or other structures related with plexus or cauda roots, intrapelvic tumours, and diseases of pelvic viscera. In plexus affections the sciatic is only one of several nerves involved, so that we may here have pain in the small sciatic distribution as well, gluteal region, perineum, upper and inner aspect of thigh, etc. Bone diseases usually give very severe pain in the sciatic and other areas; skiagraphy is here of value in diagnosis. Pelvic visceral disease, such as carcinoma recti, is usually easy of detection. Less common causes of sciatic pain are displaced fibroid uterus, or large faecal accumulations, or gonorrhoeal infection of the vesiculae seminales, or trauma of the sacral plexus in instrumental delivery, or even prolonged pressure of the fetal head. Finally, Dercum warns us not to forget hysteria, for cases of hysterical "sciatica" have even been operated upon. Curiously he makes no mention of local hot air or hot applications of various sorts to the painful limb.

27. Intramuscular Injections of Arseno-benzol followed by Death.

Balzer and Baudouin (*Bull. de la Soc. Franç. de Derm. et Syph.*, No. 9, December, 1913) report the case of a young male patient, aged 18, who had recently been under treatment at a London Hospital, where, so he stated, four intravenous injections of neo-salvarsan had been administered without effect, either good or bad, for his offensive rhinorrhoea had persisted, and the typically gummatous lesion on his penis had not been influenced. The injections in London had been given in June and July, and the patient had no idea of the dosage on each occasion. On admission at the Bayin clinic in Paris a course of benzoate of mercury injections was given during August, and, these proving fruitless, Gibert's iodo-mercurial syrup was tried without any marked effect in September. It was not till October that neo-salvarsan 0.3 gram was four times (October 25th, November 1st, November 8th, and November 15th) intramuscularly injected. The ichorous nasal discharge continued, but the gumma of the penis began to cicatrize. On November 22nd 0.3 gram of ludyl—a salvarsan preparation which is supposed to have a more vigorous effect than neo-salvarsan—was given intramuscularly in oily suspension, and on November 26th the patient, after preliminary restlessness, vomiting, and delirium, became comatose, and died shortly after a temporary return of consciousness in deep coma on the following day. The autopsy revealed some congestion of the cortex of the brain without haemorrhage or meningitis. A chemical examination of the liver for arsenic resulted in a very high percentage being found there. The organ weighed 1,140 grams, and it was computed that it contained 2.622 cg.

28. Keratin in Cirrhosis of the Liver.

Zypkin (*Berl. klin. Woch.*, February 23rd, 1914) has tried keratin with what he regards as undoubted good results in the treatment of cirrhosis of the liver. The treatment is based primarily on the results of laboratory investigations by Professor A. J. Danilewsky, which indicated the ability of keratin to fix and render the glutin of the body, which is an essential element in the connective tissue, the overgrowth of which characterizes the disease. A further encouragement was derived from the good results reported in the treatment by keratin of certain diseases of the central nervous system, in which overgrowth and subsequent contraction of interstitial connective tissue formed a part. In this latter instance, it is true, there is an alternative explanation of the action of the drug possible. Keratin is almost identical in chemical composition with neurokeratin, an essential element of nerve cells and fibres, and it may be supposed that its beneficial influence in interstitial diseases of the nervous centres may be due to some direct action on the nerve cells and fibres, whereby their trophic condition was benefited. The cases treated by Zypkin were those in which there was marked obstruction to the portal circulation, resulting in ascites, oedema of the legs, and other usual consequences. Caffein or diuretin and other drugs had previously been tried without avail, and repeated paracentesis within short periods had been necessary. In the four cases detailed the exhibition of keratin was followed by a progressive improvement in the patients' condition. Eventually both ascites and oedema completely vanished, paracentesis was not again required, and the general condition of the patient was so much improved that they were able to resume work. The author concludes that keratin is a remedy of the utmost importance in the treatment of liver cirrhosis, the more so as there is no other drug from which we can hope for any good result in this disease. Its favourable action is confirmatory of the antisclerotic rôle which has been assigned to it. It possesses the further advantage of being without danger and unaccompanied by any serious undesirable by-effects.

PATHOLOGY.

29. The Myotonic Reaction

The term "myotonic reaction" describes a peculiar response of the muscles to electrical stimulation. The muscles are thrown into prolonged tetanic contraction by interrupted and continuous currents, and the state of contraction persists for a short time after the cessation of the stimulus, the muscle fibres afterwards slowly relaxing. This excitability of the muscles contrasts with that of the nerve trunk, which remains practically unmodified. The electrical syndrome of myotonic contraction has been the subject of an exhaustive study by Baboneix (*Arch. d'électr. méd.*, February 10th and 25th and March 10th, 1914), who states that the myotonic muscle responds to a faradic current by a slow contraction, followed by an equally slow relaxation (farado-tonic contraction). The contraction obtained by the direct application of the galvanic current is toxic, and continues for a certain time after the opening of the current (continuing galvano-tonic contraction). The graphic tracing obtained for this contraction shows it to be analysable into two contractions—the first rapid, and the second slow. The first is said to correspond to the excitation of the myofibrils, and the second to that of the sarcoplasm. The continuing galvano-tonic contraction (total myotonic reaction) is observed more particularly in two affections: (*a*) Thomsen's disease, in which the contraction is early, generalized, and constant; (*b*) various myopathies, in which it is early but not permanent, localized always to a small number of muscles, and sometimes replaced by a non-continuing galvano-tonic contraction. This latter contraction (the partial myotonic reaction of some authors) is seen in right deviation, and at the beginning of certain myopathies. The author proposes the following formula for the galvano-tonic contraction: (*a*) Thomsen's disease, continuing galvano-tonic contraction; (*b*) myopathies, galvano-tonic contraction, continuing or otherwise, according to the case; (*c*) right deviation, non-continuing galvano-tonic contraction. Most frequently the reaction is caused by a functional excitation of the sarcoplasm, or interfibrillar material of muscle tissue. In Thomsen's disease the myotonic reaction may certainly be attributed to the preponderance of this non-differentiated element of the muscle fibre. The preponderance appears to be due to a defect of development, the sarcoplasm retaining indefinitely its embryonic character and failing to be transformed into myofibrils. In myopathies the circumstances which bring about the development of the myotonic reaction are more mysterious. It may be that the muscular lesions result, either in annihilating the properties of the myofibrils, or exalting those of the sarcoplasm. The close relations which unite the myotonic reaction with right deviation are capable of an analogous interpretation. When a motor nerve is injured, and the periphery undergoes Wallerian degeneration, the corresponding muscles become the site of a transformation suggesting the atrophy of the differentiated muscle element (myofibrils), and the hypertrophy of the non-differentiated element (sarcoplasm). It is to these modifications, according to some authors, that right deviation is to be attributed, and although this ingenious hypothesis has been controverted, the author regards it as worthy of note that the myotonic reaction and right deviation are produced in analogous conditions, and that very frequently they appear to have a common origin.

AN EPITOME OF CURRENT MEDICAL LITERATURE.

MEDICINE.

30. The Moriz Weisz Reaction.

WEISZ found in 1910 that the addition of three drops of 1 in 1,000 potassium permanganate solution to fresh human urine diluted with two volumes of water produced a yellow coloration if the patient was phthisical. This reaction depends upon the oxidation of urochromogen into urochrome, according to Weisz. In 1911 he stated that if it were positive the patient's chance of recovery was small. He connected this new reaction with the well-known diazo-reaction of Ehrlich; he assumed that there were two forms of urochromogen (*a* and *b*), and that, while both gave the Weisz reaction with permanganate, only the *b* form, more highly oxidized than the urochromogen (*a*), gave a positive diazo-reaction. Mladenoff in 1912 investigated the Weisz reaction in eighty tuberculous patients; as regards cases of pulmonary tuberculosis, he obtained a positive result in 25 per cent. of those in the first stage of the disease, 65 per cent. in the second stage, and 84 per cent. in the third. Pierret and Leroy (1913) found the Weisz reaction always negative in health and in the first stage of phthisis, positive in 10 per cent. of patients in the second stage, and in 28 per cent. of those in the third stage; it was negative, too, in most cases of surgical tuberculosis, enteric fever, rheumatic fever, erysipelas, cancer, and severe diabetes. N. MARTELLI and D. PIZZETTI (*Il Policlinico*, Rome, 1914, sez. med., xxi, 182) have further investigated the Weisz reaction. They dilute the urine with 3 volumes (not 2) of tap-water; to one-third of a test-tubeful of diluted urine they add 5 (not 3) drops of fresh 1 in 1,000 solution of potassium permanganate dissolved in distilled water. If the reaction is negative, they repeat the test using the urine less diluted, until finally equal parts of urine and tap-water are employed. Drugs such as quinine, iodides, mercury, guaiacol, tannin, benzonaphthol, do not interfere with the reaction; nor do albuminuria or glycosuria. In each case control tubes of the diluted urine are employed as standards of colour. If the reaction is positive, a yellow colour lasting some twenty-four hours is produced. The authors argue that a positive result is not due to the presence of allantoin in the urine, as Pierret and Bardou state, and that it is never obtained with the urine of normal persons. They found a strong positive result constantly in the third stage of phthisis, a reaction of moderate intensity in one third of patients in the second stage, and no reaction at all in those in the first stage. In acute miliary tuberculosis the urine gave a very strongly positive Weisz reaction. A positive reaction was obtained in the acute stages of malaria, enteric fever, measles, and scarlatina; in some cases of simple febrile enteritis, and in grave cases of septic infection whether local or generalized. A positive result was obtained in two out of eight cases of severe nephritis, and occasionally in acute pneumonia and in pleurisy; it was always negative in acute or chronic articular rheumatism. The authors conclude that a positive Weisz reaction indicates that an abnormal catabolism of the proteins of the body is in progress. The disappearance of the reaction is a good sign in diseases such as phthisis, measles, scarlet or enteric fever, and septic conditions generally.

31. Acute Polymyositis.

J. SCHMAUTZER (*Med. Klin.*, February 15th, 1914) points out that acute polymyositis was not recognized as such till 1887, between which date and 1912 40 cases have been published. He records the case of an innkeeper, aged 46, who had suffered from articular rheumatism five years earlier. In June, 1912, he developed dysphagia. The Roentgen rays showed spastic contraction of the oesophagus 22 cm. from the front teeth. It was at first thought this might be an early sign of cancer. After three months' treatment with bougies the patient was much better, but in the end of November he became sleepless, lost his appetite, felt very tired, and suffered from pain in the shoulders, arms, and loins. The temperature was 100.4°, and the pulse 96. The right brachial plexus was tender and the movements of the right arm were limited by pain; otherwise there were no motor or sensory disturbances. The cardiac dullness was normal, but there was a soft systolic murmur over the apex of the heart. Bronchitis was present, and the urine contained albumin but no sugar. A few days later both pectoral muscles became painful and the patient sweated profusely. On December 10th a large swelling appeared on the extensor aspect of the right arm. The overlying skin was unaffected, and the swelling, which was painful and of a hard, doughy consistency, was situated in the muscle. A few days later the neck became swollen and painful, and yet a few days later a swelling appeared in the left arm similar to that in the neck and right arm. As the swellings in the neck and right arm disappeared others appeared in the forearms and on the backs of the hands, and the supraspinatus and infraspinatus muscles became painful. Later, both lower eyelids became much swollen, and both the temporal and masseteric muscles became swollen and painful. As the swellings passed off the bronchitis diminished, and this was, therefore, probably due to involvement of the bronchial muscles. The appearance of each new swelling was accompanied by fever, which was sometimes as high as 102.2°. The temperature was also somewhat raised in the intervals between the appearance of new swellings. Towards the end of January, 1913, when the lower eyelids were normal, the upper eyelids and the lips became swollen. A few days later the dysphagia reappeared and the patient could not swallow food, which regurgitated through the nose. The movements of the tongue were limited and speech became nasal. Later painful swellings appeared in the right thumb and in the adductors of both thighs. Towards the end of March the temperature rose over 102.2° and the pulse to 130. Death occurred early in April, 1913. The necropsy showed no tumour to account for the dysphagia. The microscopic examination of the left heart and of the tibialis anticus muscle showed myositis, and in the former numerous Gram-positive bacilli, resembling the Welch-Fraenkel bacilli, were found.

32. A Skin Reaction Indicative of Immunity against Typhoid Fever.

GAY AND FORCE (*Archives of Internal Med.*, March 15th, 1914), realizing that, although there is convincing proof of the protection conferred by vaccination against typhoid, there is but little evidence as to the actual duration and security of such immunization, have devised a method of indicating by a skin test whether actual protection still exists. While the agglutination reaction is of recognized value in diagnosis, it is no measure of the grade, or even of the existence, of protection from typhoid infection. The method consists in producing an abrasion of uniform size and depth just through the epidermis of the arm without drawing blood by means of a complete twist of a straight-edged chisel tempered to resist sterilization by burning alcohol, the skin having been cleansed with 95 per cent. alcohol. The most efficient typhoid bacillus preparation ("typhoidin") was found to be obtained by inoculating with *B. typhosus* 250 c.cm. of 5 per cent. glycerine bouillon, which, after incubating for five days, was reduced by evaporation to one-tenth its original volume, a control solution of sterile 5 per cent. glycerine bouillon being evaporated at the same time to equivalent volume. Two uniform abrasions are produced on the arm and the control solution gently rubbed into the inner spot with a sterile toothpick, the "typhoidin" solution being similarly applied to the outer spot. The reactions are observed six and twenty-four hours later, and more rarely at subsequent periods. In a very few instances the six-hour period shows in positive cases an accelerated reaction, which diminishes or disappears within twenty-four hours, though frequently a positive test persists for a week. In the majority of cases the control shows a heated abrasion not surrounded by an areola, though in the minority a slight zone of traumatic redness may occur, but on these latter, when there is a positive reaction in the "typhoidin" spot, it is easy to measure the differences between its areola and the control redness. A difference of 2.5 mm. between the two areolas has been chosen as indicating a positive reaction, the positive spot measuring from 4 to 12 mm. in diameter and being usually somewhat indurated and clearly demarcated. In negative cases there is the same reaction, or absence of reaction, on both the control and the "typhoidin" spots. Of 21 cases with a definite history of typhoid ranging from forty-one years to four and a half months previously, only one was negative (95 per cent.). The reaction was negative in 85 per cent. of

individuals without history of typhoid, the 9 per cent. of these giving a positive reaction probably having had a mild undiagnosed attack at some previous time. Of 15 individuals vaccinated by the army method from four and three-quarter years to eight months previously, 9 gave a positive skin reaction, and 25, vaccinated by the Gay-Claypole sensitized vaccine for from one to eight months previously, all gave a positive reaction. The test may be regarded as of value in indicating protection against typhoid whether acquired by recovery from the disease or by artificial immunization, and may eventually be used as an indication for revaccination.

SURGERY.

33. Surgical Treatment of Pulmonary Tuberculosis.

Lapeyre (*Arch. gén. de Chir.*, April 25th, 1914) opportunely reviews the surgical procedures which have been used for the treatment of phthisis. The operations fall into two classes. Those of the first class aim at producing collapse of the lung. The simplest operation of this type consists in the production of an artificial pneumothorax; proposed by Forlanini in 1882, and first performed in 1892, the method has now been extensively employed and reported upon. It is indicated in unilateral cases without extensive pleural adhesions; since the collapse of one lung throws increased work upon the other one, the operation is definitely contraindicated when there are obvious lesions upon both sides. With these restrictions, the method is applicable to 3 per cent. of cases of pulmonary tuberculosis. An analysis of the results shows that few of the cases are cured, though the majority are temporarily benefited. For cases with extensive pleural adhesions thoracoplasty has been advocated. Friedrich has elaborated the technique, which in his hands consists in resection of the ribs on one side from the second to the tenth, from their posterior angles to the costal cartilages. He confines the operation to cases of chronic phthisis, predominantly unilateral, and progressing in spite of medical treatment; in persons aged 15 to 40, and not markedly enfeebled; and where there are wide pleural adhesions. Cases of acute phthisis and those with visceral tuberculosis must be excluded. The operation is therefore of restricted applicability; it is severe and mutilating, and the after-history of 31 cases indicates that though palliative it does not cure. Wilms's modification consists of anterior and posterior section of the ribs, without removal. It is less dangerous to life and appears to be as efficacious as Friedrich's procedure, but there is no reason to suppose it will produce better results. A third operation, pneumolysis, aims at freeing the affected apex of the lung from the parietal pleura by digital separation, and filling the space with indifferent tissues, paraffin, etc., so as to compress the lung. The cases treated by this method are too few to afford sufficient data for criticism. Operations of the second class are those which do not attempt to produce lung collapse; they may be divided into pulmonary and extra-pulmonary operations. Of pulmonary operations, direct intrapulmonary injections and pneumotomy (opening and drainage of cavities) have both been abandoned after trial. Pneumectomy consists in excision of the diseased tissue, and but few cases have been treated in this way. It is perhaps worthy of more extended trial than it has so far received. Extra-pulmonary operations include ligature of the pulmonary arteries and veins, and section of the dorsal sympathetic roots; each method has been tried in one or two cases only. Freund's operation, called chondrotomy, consists in producing a pseudarthrosis in the first costal cartilage. The *rationale* is based upon *post-mortem* observations, which, according to Freund, show that apical phthisis is usually correlated with contraction of the first costal arch; this statement has, however, been controverted by Morriston Davies. The operation has been done in nine cases, all too recent to be of value for estimating its efficacy. Collapsotherapy, then, at present holds the field; but its limitations are strict, and the results not too good. Pneumectomy, perhaps, might be employed with present improved methods of diagnosis and technique. Though the surgical treatment of phthisis is still unsatisfactory, there is reason to hope that it will undergo further evolution. In any case it is necessary that the physician and the surgeon should unite their efforts if any advance is to be made in this discretion.

34. Local Anaesthesia.

J. J. King (*Journ. Amer. Med. Assoc.*, May 30th, 1914) describes a method of local anaesthesia which he has found most satisfactory for resection of the nasal septum. Half an hour before he begins, the patient takes by the mouth $\frac{1}{150}$ grain of scopolamine hydrobromide to allay nervousness and as the therapeutic antagonist to cocaine. Then with a cotton-wool applicator a 20 per cent. solution of cocaine hydrochloride is applied over every part of the mucous membrane of the septum, and this is immediately repeated. After the second cocaine application, King makes a similar one of a 1 in 1,000 epinephrin solution and following this an injection under the septum perichondrium and periosteum on each side of from 8 to 10 c.cm. of a sterile salt solution to which 5 minims of a 1 in 1,000 epinephrin solution has been added immediately before the injection. This completes the anaesthesia and infiltrates every portion of the septum membrane, blocks off the nerves, prevents shock, and renders the operation practically bloodless. It also aids in elevating the perichondrium from the cartilage and makes the dissection easy. He uses only 5 minims of epinephrin solution because this does not exceed the physiological dose of the hypodermic injection and he has found it sufficient to render the field bloodless without producing toxic symptoms.

35. Erroneous Interpretations of the Wassermann Reaction.

Ravaut (*Ann. de derm. et syph.*, vol. v, No. 5, May, 1914) says: (1) That in an avowed syphilitic the positive Wassermann reaction is a certain additional symptom of the disease, but on the other hand, a patient with obvious cutaneous or visceral luetic manifestations may exhibit a negative serum reaction; a negative reaction does not exclude syphilis. The practitioner should not allow the Wassermann reaction to play too large a part in the therapeutic plan of campaign. He ought, of course, to aim at obtaining and retaining a negative Wassermann reaction, but in old syphilitics this is particularly difficult and sometimes impossible. A negative reaction by itself is not a guarantee of cure or an indication for the suspension of treatment. (2) That in a case of suspected syphilis the reaction should be considered as an additional symptom, which in conjunction with others constitutes an important aid to establishing the diagnosis. (3) That in a patient whose Wassermann reaction is consistently positive, but who presents no antecedent history or sign of the disease, a thorough investigation is urgently indicated. It has been often established that a positive reaction may exist apart from the presence of the infection. Its value is, therefore, not an absolute one, and by itself is not sufficient evidence of the disease.

36. Splenectomy in Pernicious Anaemia.

R. Dahl (*Svenska Läkaresällskapets Forhandlingar*, vol. ii, 1914) records the case of a man, aged 50, who first developed pernicious anaemia in the summer of 1911. Arsenic proved effective when given during four exacerbations, but it had no influence on the fifth exacerbation. As these were growing in frequency, splenectomy was performed on December 20th, 1913, when the haemoglobin was 40 per cent., the red cells numbered 1,300,000, and the leucocytes 2,000. Of these, 40 per cent. were lymphocytes. The operation was followed by the appearance of normoblasts and Jolly's bodies. There was also marked leucocytosis. These features gradually diminished, the patient meanwhile improving steadily. A month after the operation the haemoglobin was 65 per cent., the red cells numbered 2,600,000, and the leucocytes 5,000. Of these, 20 per cent. were lymphocytes. During this month the patient had, however, been given arsenic. Discussing the value of splenectomy in pernicious anaemia, the author points out that 13 cases, in which this operation was performed, were published in German papers during 1913. One patient died of bronchopneumonia three days after the operation. All the other patients survived the operation, and derived more or less benefit from it. As, however, the operation was performed only a few months before publication—the first patient being operated on in March, 1913—permanent results cannot yet be claimed. Brühn-Fahreaus (ibid.) records the case of a woman aged 39, who, eighteen months earlier, had developed gastric symptoms, including abdominal pain independent of food, vomiting, and irregular action of the bowels. Pernicious anaemia and gastric achylia were diagnosed, and arsenic was prescribed with considerable success for a time. The gastric symptoms soon returned, attacks of diarrhoea alternating with constipation, and the abdominal pain being accompanied by anorexia, nausea, and vomiting. The latter ultimately prevented the absorption of the arsenic, the influence of which had begun to wane. Splenectomy was performed on January 3rd, 1914. This was followed by immediate improvement, the gastric symptoms disappearing altogether. The blood now

contained many nucleated red cells and other red cells containing basophile granules, or Jolly's bodies. The haemoglobin showed a slight rise from 43 to 46 per cent. The author suggests that though splenectomy probably does not remove the primary cause of pernicious anaemia, it yet eliminates an important factor in this disease.

37. Inflammation of the Gall Bladder.

THE importance and time of surgery in inflammation of the gall bladder is emphasized by J. TYSON (*Journ. Amer. Med. Assoc.*, April 25th, 1914), who reports three cases of cancer following this condition. The fulminating form often terminates in abscess, and if unrecognized may terminate in perforation. Next to the typhoid bacillus the colon bacillus is a frequent cause. A result appreciated only recently is adhesions, now recognized as frequent cause of pain in the right upper abdominal quadrant, formerly unrecognized. Other predisposing causes are sedentary habits, lack of exercise, tight lacing, child-bearing and abdominal tumours, which contribute to explain the fact that the condition is four times more frequent in women. The most important consequence on account of its frequency, is gall stones, and the relation of these to cancer is recognized; hence the necessity of prompt operation. Other results of neglected cholelithiasis hardly less serious are abscess of liver and biliary fistulas into various organs, including the veins, the intestine, the stomach, the bronchi, and the external integument. Atrophy of the gall bladder is not uncommon. Tyson believes that in doubtful cases exploratory operation is sometimes justified, the more so since other conditions may be discovered which would also require operative relief. He does not deny that cancer may precede gall bladder inflammation, but there is as much reason to believe that they were consequences in the case reported.

OBSTETRICS.

38. Exophthalmic Goitre and Pregnancy.

GELLHORN (*Trans. Amer. Gyn. Soc.*, vol. xxxviii, 1914) relates in full three cases in his experience, and concludes, after the consideration of the opinions of others, that the complication of pregnancy and exophthalmic goitre, while comparatively slight in some cases, may constitute a grave danger to the life of the mother. If the manifestations of Graves's disease are aggravated, notwithstanding medicinal and other conservative treatment, immediate interruption of pregnancy is indicated, and vaginal Caesarean section is the quickest, and therefore the best, method of interruption. Since it reduces the dangers from any operation on patients with exophthalmic goitre, spinal anaesthesia is preferable to any other form of anaesthesia. Gellhorn insists that girls with well-developed hyperthyroidism should be advised against marrying, and if Graves's disease has appeared after marriage, conception should be prevented. If vaginal Caesarean section be performed, tubal sterilization should be added.

GYNAECOLOGY.

39. Bilateral Tubal Carcinoma.

HÖRRMANN (*Monatsschr. f. Geb. u. Gyn.*, April, 1914) operated on a sterile married woman aged 42, a multipara. She had been growing very weak for several months, yet there were no pelvic pains, no evidence of intestinal disease and no irregularity of the catamenia. The patient was extremely emaciated, the uterine body could not be clearly defined, being surrounded on all sides by firm tumour masses. On the right side resistance could be felt above the pelvic brim; abdominal section was performed. A retort-shaped mass, filled with papillomatous masses of adeno-carcinoma sprang from the left cornu of the uterus. On the right cornu, in place of the appendages was a little red mass no bigger than a cherry-stone. Further on the right, and totally disconnected from the uterus, the right tube was discovered. It had become adherent to a coil of small intestine and its cancerous contents had burst into the bowel, which the operator resected. There were infected glands in the mesentery. The uterus, which bore a small myoma, was extirpated, but the patient died on the fifth day. Wiener, in discussing the case at a Munich society meeting, observed how extremely malignant primary cancer of the tube was now known to be. The growth advanced before the symptoms attracted much attention and there appeared to be no authentic instance of permanent cure after operation.

40. Gangrene of the Cervix.

HERGOTT (*Ann. de gynèc. et d'obstét.*, January, 1914) records a case of gangrene of the cervix caused by three injections of a concentrated solution of corrosive sublimate in an attempt to produce abortion at the seventh week of pregnancy. Following each injection the patient noted a blood-stained serous discharge. Two hours after the third attempt severe uterine contractions commenced, associated with profuse haemorrhage. The latter was controlled by douching with warm water. When admitted to hospital, Hergott noted that the cervix was in a sloughing condition. The vaginal fornices were also intensely swollen and commencing to slough, an extremely fetid discharge being present. In the course of a few days the cervical tissues disintegrated completely, and the whole, together with the adjacent portions of the vaginal mucosa, was detached. The cervix showed some cicatrization, and the patient appeared to be progressing satisfactorily when pulmonary embolism occurred, followed by general pyaemic infection and a fatal termination. At autopsy the cervix was found to have completely disappeared and the base of the broad ligament was the seat of a large abscess cavity. In the walls of the latter large thrombosed veins containing pus were present.

THERAPEUTICS.

41. Intraneural Injections of Alcohol in Neuralgia.

AFTER reviewing at some length the development of this treatment, J. FLESCH (*Wien. med. Woch.*, February 21st and 28th, 1914) gives an account of his own experiences since 1903. Of his patients 52 were women and 34 men. The nerves involved were the first division of the trigeminal in 6 cases, the second division in 20, the third division in 30, and two or more divisions in 15 cases. Other nerves involved were the auriculo-temporalis, zygomatico-facialis, alveolares superiores, occipitalis major, lingualis, intercostalis, naso-ethmoidalis—altogether 15 cases. In 10 cases only one injection was given. In 25 cases two injections, in 24 cases three injections, in 20 cases four injections, in 5 cases six injections, and in 2 cases ten injections were given to each patient. Of the injections 136 were peripheral, 38 were intermediary, 86 were deep, and 2 were made into the ganglion. Schlösser's method was adopted in 36 cases, Levy-Baudouin's in 62 cases, Braun's in 20 cases, and Ostwald's, Härtel's, or the author's method in 8 cases. The subsequent fate of the patients was followed in 62 cases. Of the 8 who showed no relapse 6 had been given peripheral injections and 2 had been given intermediary injections for isolated neuralgia of the lingual nerve. The author expresses surprise at this result of the peripheral injections. Three patients showed relapse after 23 to 26 months, 16 patients after 16 to 18 months, 18 patients after 8 to 12 months, 10 patients after 6 to 8 months, 4 patients after 2 to 4 months, and 2 patients after 4 to 6 weeks. Serious complications occurred twice. One patient had previously been operated on for inflammation of the jaw. Four grams of a 90 per cent. solution of alcohol were injected according to Braun's method into the foramen alveolare from the mouth. The operation was unusually painful, presumably on account of the previous inflammation. Next day the neck and retromandibular region were oedematous and the patient was febrile. Tracheotomy became necessary, and much gangrenous tissue was evacuated through a retromandibular incision. The wound healed in a few weeks, and the neuralgia did not recur. Another patient was a woman, aged 60, who received an injection of 2 grams of a 90 per cent. solution of alcohol injected into the foramen ovale through the incisura coronoidea. The injection was immediately followed by much giddiness, horizontal nystagmus to the left, and a tendency to fall over to the right. The pulse became rapid, and there was transitory amaurosis. All these symptoms passed off in ten minutes, and were probably due to irritation of the dura by the alcohol. Other accidents, including violent headache, oedema, effusion of blood, and facial paresis following peripheral injections into the second and third divisions of the trigeminal, were transitory only. In the one case in which alcohol was injected into the Gasserian ganglion according to Härtel's method, the result was bad. All sensation over the whole of the right side of the face was lost for several weeks, the patient could eat and speak only with difficulty, and the risk of ulceration of the cornea necessitated the constant use of bandages over the eye. Before injections of alcohol are given in any case, the teeth and nasal cavities

should be systematically examined, laxatives should be tried, then a course of aconito in gradually increasing doses, combined with hot air-baths, Roentgen, or radium treatment. Only when these conservative methods have failed and the neuralgia has been exactly located should alcohol be injected. When peripheral injections have failed, intermediary injections should be given. When these also have failed after a full week's trial, deep injections may be given after exact measurements of the skull have been taken in each case. When these injections also have failed after several weeks' observation, alcohol should be injected into the Gasserian ganglion according to Härtel's method. Resection of the ganglion should be resorted to only after all other measures have failed.

42. Treatment of General Paralysis.

H. DAMAYE (*Prog. méd.*, June 6th, 1914) insists on the fact that in the treatment of general paralysis and other syphilitic psychoses the use of antisyphilitic remedies is not everything, and that they should not be prescribed straight away unless the general bodily nutrition be good. Not only have many clinicians found that such remedies either fail to do good or do positive harm in general paralysis, but alienists know only too well how often tuberculous lesions are found on necropsies of general paralytics. Damaye's plan in all these cases of syphilitic psychoses and general paralysis is to attend first of all to the patient's general health. He prescribes raw meat, raw eggs; remedies which stimulate leucocytosis, such as collargol and iodine, and trophic substances, such as cacodylates; these remedies often do great good in these cerebral conditions. In addition he gives cod-liver oil or guaiacolized cod-liver oil, and sometimes "iodized antiscorbutic syrup." He finds that this supporting treatment greatly improves both the mental and the physical state. In the next stage of the treatment, which is begun as soon as the physical condition is satisfactory, the raw meat, raw eggs, and super-alimentation is continued, with the addition of antisyphilitic remedies—namely, at first injections of hectine or atoxyl, and then mercurials. The patient, thanks to his previous over-alimentation, now bears mercurials well. Periods of arsenical and mercurial treatment can be alternated, and some iodide of potassium is given as well. Damaye gives details of three cases of general paralysis thus treated with good results. He claims that in this disease, as in other syphilitic psychoses, this preliminary treatment by over-alimentation and tonics does control the meningo-encephalitic lesions as far as they are controllable by any means whatsoever. (One or two minor points in this abstract are taken from Damaye's previous article on the treatment of syphilitic psychoses in *Archives internat. de neurol.*, March, 1914.)

43. Salvarsan Copper.

EHRLICH AND KARRER have succeeding in combining salvarsan with various metals, and, on the principle of applying as many poisons for infecting parasites as possible, suggest that such a combination might be of service in therapeutic endeavours. Among these combinations is one in which salvarsan is attached to copper. This is, for the time being, known as K_3. It is a yellowish-red, finely granular powder, forming a clear solution of a dark olive greenish-brown colour in twice normal sodium hydrate solution, or in 1 per cent. cane sugar solution. The dose suggested by Ehrlich was 0.1 gram of the powder. G. BAERMANN (*Munch. med. Woch.*, January 6th, 1914) has experimented with this substance in a series of tropical infections in Sumatra, and records the results obtained. He gave the dose three times, with a two days' interval between the doses. He regards 0.15 gram as the maximum dose, 0.2 having been followed by high fever, with marked vasomotor and nervous disturbances. It produces both local and general manifestations in framboesia (yaws), and on the whole acts more energetically than simple salvarsan. The spirochaetes disappeared from smear preparations almost completely within twenty-four hours and quite completely within forty-eight hours. Excised portions of the affected tissues showed advanced curative processes in from four to fourteen days. No parasites could be found in them. Even the most severe cases heal in a surprisingly short space of time. In 9 out of 13 cases a single injection of 0.1 gram of K_3 converted a positive Wassermann into a negative one, but in 3 of these cases the reaction became positive at a later date. In one case of quartan malaria with schizontes and free gametes the effect of the injection was the disappearance of the parasites from the blood. They had not reappeared up to the time of reporting. Four cases of tertian malaria yielded in the same manner to the treatment, the parasites disappearing from the blood. In one case in which an unusually large number of parasites were present in the blood, a very few schizontes appeared in the blood after an interval of one and a half months, but the author is doubtful whether this was not a case of reinfection. As a rule, the number of quartan and tertian parasites were found to be increased during the first two hours after the injections, but they disappeared within the following twenty-four hours. The temperature sank within a short time of the injection and remained normal. A similar turning out of the parasites was observed in 2 cases of pernicious malaria, in which, however, only small rings and no gametes were seen. In 5 cases in which young gametes and crescents were present, as well as schizontes, only the latter were affected. The preparation proved itself quite inactive in amoeboid dysentery. In leprosy (mixed form) it exerted a distinct action on the nodules, ulceration, and general health.

44. Artificial Pneumothorax in Pulmonary Tuberculosis.

WILLIAM C. VOORSANGER (*Journ. Amer. Med. Assoc.*, May 9th, 1914) reviews literature on the subject of artificial pneumothorax, and reports three cases of his own, all different in type, progressive, advanced, and hopeless, which were selected for lung compression, to relieve the cough and expectoration, and not with a hope of arresting it. In the former sense, he thinks, the procedure must be looked on as successful. He therefore adds to the indications which were given for lung compression the following: Hopelessly advanced cases in which, after careful examination, it is ascertained that cough and expectoration is being produced from a large cavity in one lung, even though the other is badly infiltrated. His cases number 14, and have been selected from those which, after a fair test, did not respond to other well-tried methods of treatment. All of his cases were, whenever possible, controlled by roentgenograms before operation. All compressions were made by the Forlanini method with 0.5 per cent. novocain anaesthesia. He believes that artificial pneumothorax can be successfully employed outside of the hospital or sanatorium if the technique employed is perfect.

PATHOLOGY.

45. Bactericidal Action of Bile.

R. TOIDA (*Zentralbl. f. Chir.*, May 2nd, 1914) obtained bile from thirty-five living men and eight live dogs by puncture of the gall bladder. He found that bile from healthy subjects was always sterile. Various pathogenic bacteria react differently when provided with bile as a culture medium. *B. coli communis* and *B. typhosus* flourish when placed in bile; it is a somewhat less favourable medium for the growth of *B. paratyphosus* B, the Shiga-Kruse dysentery bacillus, and the bacillus of Asiatic cholera. Bile is definitely inferior to broth as a medium for *Staphylococcus pyogenes aureus*, though growth occurs. *Streptococcus pyogenes* and the pneumococcus grow either very feebly or not at all. Dog's bile was generally found to be a worse medium than human bile. The morphology and staining reactions of the bacteria investigated were not affected by growth in the fluid. The virulence of *B. coli communis* is enhanced by culture in bile. Other workers (Neufeld, Hirokawa) have observed decomposition of sodium taurocholate by bacterial action; this is not confirmed by the author's observations. Toida's work was done in Japan, where the biliary secretion possibly differs slightly from that of the average European; he finds that his results, however, are in general agreement with those of other workers.

46. The Effect of Tobacco Smoke.

CARGINALE (*Rif. Med.*, May 30th, 1914) has subjected rabbits to prolonged exposure to tobacco smoke, using the ordinary Tuscan cigar and one denicotinized. The animals were fumigated for two hours at a time at intervals of six hours. Another group were subjected to rapid and repeated inhalations. The experiments were continued for three or four months and showed that long and repeated inhalations caused a moderate degree of anaemia of an orthoplastic type, which disappeared in a few days after inhalation was discontinued. Probably the anaemia was more due to the changes set up in the respiration, from diminished oxygenation rather than to any direct toxic action from tobacco. No vascular changes (inflammatory or degenerative) were observed. No difference was noticed in effects produced, whether ordinary or denicotinized cigars were used.

AN EPITOME OF CURRENT MEDICAL LITERATURE

MEDICINE.

37. Acute Pneumonia during the First Days of Life.

TH. E. HESS THAYSEN (*Jahrb. f. Kinderheilk.*, Berlin, 1914, 3 F., xxix, 140) points out the ease with which the erroneous diagnosis of atelectasis of the lungs may be made in infants up to 3 days old dying with acute pneumonia of the catarrhal variety. Three main forms of pneumonia in such infants are recognized: First, specific pneumonia, including the syphilitic and the very rare tuberculous varieties and other forms of placental origin; secondly, septic pneumonia caused by the aspiration of septic material into the lungs during birth, particularly amniotic fluid, and possibly also due in some cases to the inspiration of air loaded with septic bacteria; and, thirdly, catarrhal pneumonia, hitherto ill defined and ill characterized. Hess Thaysen points out that the macroscopic diagnosis of catarrhal pneumonia is quite impossible in a child dying fifteen hours after birth, and may be impossible in children that have lived twenty-four hours. It could be made with fair certainty in four out of six infants living twenty-four to forty-eight hours; the pneumonic lung tissue was dark red in colour, firm and brittle in consistency, and thus distinguishable from the atelectatic portions. The macroscopic diagnosis was easily made in two cases of children dying on the third day. In none of these instances was the purulent bronchitis diagnosable by the naked eye, though found in every instance microscopically; it becomes macroscopically visible only on the fourth or fifth day. Evidence of pleurisy in catarrhal pneumonia is seen only in infants surviving six or seven days, and but rarely even then. Coming next to the microscopical description of the so-called catarrhal pneumonia, Hess Thaysen remarks that in the earliest cases small areas of infiltration may be found in all the lobes of the lungs; as time passes the inflammation becomes much more marked in the lower lobes, and may disappear from the upper. A difficulty in diagnosis is introduced by the fact that the exudation into the alveoli is serous in these infants, and not fibrinous; it may easily be confused with the amniotic fluid aspirated into the lungs, which is clear and contains fatty or myelinoid droplets. The presence of foreign bodies in the lungs of these infants is constant; they consist of squamous, horny epithelium derived from the infant's mouth or the mother's vagina, particles of meconium, and fatty droplets derived from the degenerated epithelial cells that have been aspirated; in addition, fatty or myelinoid droplets derived from desquamated and degenerated alveolar epithelial cells are commonly found, especially if the examination is made many hours after death. It is curious to see how little these foreign bodies may irritate or affect the lungs in which they lie; they may be found in infants 10 days old, without having given rise to any inflammatory reaction or emigration of leucocytes. Unless infected with pathogenic bacteria, therefore, amniotic fluid aspirated in moderate quantity into the lungs may be apparently harmless. In the earliest cases of catarrhal pneumonia the inflamed alveoli show a serous exudation, a scanty leucocytic infiltration, a few red cells that may often have been aspirated into the lungs, some desquamation and fatty degeneration of the alveolar epithelium, and some oedema of the inflamed alveoli. Later on the alveolar and bronchial inflammation becomes more suppurative in character. In 5 cases Hess Thaysen made bacterial cultures from the lungs and other tissues; in all of them *B. coli* was grown, and Gram-positive streptococci were recovered from the lungs in each instance. Discussing the etiology of this catarrhal pneumonia, he argues that a placental intrauterine infection could not have taken place in any of his 14 infants aged 3 days or less; he also dismisses the probability (though not the possibility) that they were infected by breathing infected air. He concludes that the streptococci causing the pneumonia were aspirated with amniotic fluid into the lungs during or immediately after birth, the mothers and their vaginal secretions being in no way abnormal. In 5 out of the 14 infants artificial respiration by Schulze's method had been found necessary immediately after birth. He decides that the so-called catarrhal pneumonia of these very young infants is misnamed; it lacks all catarrhal characters under the microscope, and is in reality a mild septic or inhalation pneumonia, suppurative and not catarrhal. The so-called septic pneumonias of infants are caused by the aspiration into the lungs of pus or definitely septic secretions derived from the mother; in these infants pleurisy is the rule as well as pneumonia, and the infection is no doubt severe. He concludes by dividing the pneumonias of the earliest days of life into four classes according to their etiology, as follows: (1) Placental infections, as in syphilis, tuberculosis, pneumococcal pneumonia, a few cases of streptococcal or staphylococcal pneumonia; (2) aspiration pneumonias, due to the aspiration of either the septic or the normal contents of the maternal passages; (3) aërogenic pneumonias, probably rare; (4) metastatic pneumonias, secondary to a primary infection of the intestine, navel, etc., no doubt extremely rare.

38. Acute Spasm of the Oesophagus.

GUISEZ (*Journ. des praticiens*, March 4th, 1914) points out that the rather prevalent idea that spasm of the oesophagus is essentially a transitory affection, occurring generally in a neurotic patient, is an erroneous one. The course of a case of a moderate grade of severity is as follows: The patient may have slight, vague, and fleeting sensations of oesophageal contraction, and suddenly, when eating, finds it impossible to swallow a bolus of what may be insufficiently masticated food. He may try to drink, but the fluid is immediately rejected, frequently through the nose. At the same time he complains of a sensation of choking and swelling in the throat; his facies is distressed and his eyes become injected. This may last for some minutes, or even for some hours, and then, either spontaneously or under the influence of belladonna or morphine, matters return to normal. The tendency is for these crises to recur at variable intervals but with increasing frequency, until a sort of permanent spasmodic contracture of the oesophagus results. The passage of an oesophageal catheter is easy in these cases. This is the most usual type of oesophageal spasm to be met with. But apart from these cases, which are only serious in respect of the tendency to permanent contraction of the oesophagus, the author has noted graver cases in which complete closure of the tube had resulted with no definite intermission. The patient is unable to swallow anything, even saliva. Oesophagoscopy, which has been of much value in this condition, shows the existence of violent contraction of the upper end of the oesophagus, and to a lesser degree of the cardiac end. No other lesions have, as a rule, been found to be present to account for this. The treatment consists of progressive forcible dilatation with olivary bougies and lavage by means of the oesophageal sound. As the condition occurs generally in neuropathic subjects, paralysis of the muscles of the pharynx suggests itself as a possible explanation, as has also labio-glosso-pharyngeal paralysis. Careful local examination of each case, however, has always negatived these suggestions. Some weeks may elapse before the condition has quite passed off, and it only does so as the result of repeated dilatations by means of graduated bougies. Unless dealt with in this way, the life of the patient may be seriously menaced. It has sometimes happened that food becomes arrested in the intrathoracic portion of the oesophagus, remaining in a sort of closed cavity between the contracted upper and lower sphincters of the oesophagus. The etiology of many of these cases is obscure, but the diagnosis is easily made by means of oesophagoscopy, and the treatment is as has been already mentioned.

39. Idiosyncrasy to a Diet of Kidneys.

G. BUSCHAN (*Med. Klin.*, January 4th, 1914) describes his personal experiences of idiosyncrasy to kidneys. In the autumn of 1911 he ate steamed kidneys and rice at the mid-day meal. In the afternoon of the same day he was seized with violent itching, followed by urticaria of the whole body, colic, and profuse diarrhoea. An hour later, while he was drinking coffee, he suddenly felt faint, and both arms began to twitch. A little later he was again fully conscious, and though feeling very exhausted, he experienced no paralyses or disturbances of speech. A colleague could find no enlargement of the heart, the action of which was feeble. There were no adventitious cardiac sounds, and the pulse was not accelerated. The

cause of this attack was obscure. Other persons who had partaken of the same meal were not upset by it. Syphilis and alcoholism could be excluded, and there was no sign of arterio-sclerosis or disease of the heart. The author had been experimenting on himself for some time with thyroid tablets, and had raised the dosage to ten tablets (0.1 gram) in the day. It was not clear whether the tablets, the mid-day meal, or the hot weather combined with a strenuous life should be credited with the attack. On two earlier occasions the author had developed urticaria, colic, and diarrhoea after eating soup made from crabs. But he had also often eaten kidneys with impunity. That these were, however, the cause of the attack in 1911, became evident when, in September, 1913, a meal of stewed kidneys, this time without rice, provoked a similar attack. This was more severe, consciousness being lost repeatedly, and the action of the bowels being involuntary. The urticaria and the other symptoms passed off rapidly, leaving the patient much exhausted. That this attack was due to idiosynerasy to kidneys, and not to decomposition of the kidneys or ptomaine poisoning, is proved by the other members of the author's family partaking liberally of the same food without ill effects. The author, who traces the clonic contractions of the first attack to oedema of the brain, can find no record of a similar case.

SURGERY.

50. The Treatment of Fractures.

In view of the fact that several fatalities have been reported by experienced surgeons following the open method of treatment of fractures, and from observation of a large number of cases, Macgruder (*Amer. Journ. of Surg.*, January, 1914) is of opinion that closed fractures, when treated as such, always unite more quickly than when treated by the open method. He considers that operation is only indicated when wide displacement of the fragments is present, and when correct apposition is impossible. The method should only be adopted when hospital facilities are obtainable. The type of case which essentially calls for operative interference is an articular fracture, when ankylosis is probable. Here the best results are obtained after exact coaptation and suturing of the fragments. To obtain favourable results from the open method, operation should be early, and massage, followed by early passive motion gradually made active, should form an essential part of the treatment. Macgruder observes that in the case of open fractures, the operative treatment to be adopted is that which most nearly reduces them to the type of the closed fracture, apart from the question of drainage. He considers that gunshot fractures should be treated like fractures of the open type contaminated by street dust, and in addition to the usual treatment, anti-tetanic serum should be administered. The aim in all open operations must be to secure exact coaptation and reduction of the fragments. In the author's opinion, this is most readily secured with the aid of wiring, the most trustworthy metal suture being the tinned-steeled-annealed wire. For the soft tissues, 60-day chromicized catgut is advocated. Owing to the dangers of osteomyelitis, the medullary canal should, if possible, be avoided. The author observes that the use of plates and clamps is growing less and less every year. The weights of the smallest Lane plate and that of the smallest wire necessary to hold the same fragments in correct apposition are 34½ grains as compared with 1⅝ grains. Delayed or non-union appears to be a frequent complication in fractures of the femur, humerus, and tibia, especially in patients subjected to the open method of treatment. This occurs even more often when foreign bodies like steel plates have been employed, in spite of the fact that blood clot and tissue fragments have been removed. Delayed union following operation is more common in fractures of the femur than in those of the tibia, owing to the greater trauma necessary in the former. The author's experience, therefore, does not coincide with that of Lane as to the value of the steel plate in hastening consolidation, although in some cases excellent fixation is obtained; in others it appears actually to retard consolidation even when the soft structures heal by first intention and there is not the slightest evidence of infection. Bony union of the femur occurring ten weeks after steel plating would, in Macgruder's opinion, probably be as far advanced in six or seven weeks in the absence of any foreign body. The ideal treatment of fractures, therefore, is that which effects by the closed method, and without recurrence of displacement, anatomical reduction. The second best procedure is that of the open method by which reduction is secured and maintained without the use of any foreign body. Operation only has a legitimate field when coaptation cannot be secured and maintained without it.

51. Prostatectomy under Local Anaesthesia.

Legueu (*Bull. et mém. de la Soc. de Chirurgie*, May 19th, 1914) has performed prostatectomy sixteen times under local anaesthesia. He points out that in prostatectomy operations local anaesthesia has been extensively employed for the suprapubic area, but it has always been found necessary to administer a general anaesthetic for the actual enucleation of the prostate. This combination of local and general anaesthetics has the disadvantages of both methods without always furnishing the corresponding advantages. After several experiments he has evolved a technique in which he states that he has now complete confidence and facility. The method used is infiltration by a 0.5 solution of novocain, to which adrenalin is added in the usual way; 10 to 20 c.cm. of this solution is run into the bladder with the fluid used for distending the viscus. The abdominal wall at the site of incision is infiltrated with the solution, plane by plane, according to established principles, and an incision made down to the bladder. Experience has shown that the presence of novocain in the distending fluid is insufficient to anaesthetize the bladder wall; the latter is therefore injected along the site of incision with about 10 c.cm. of the solution, which is run right and left into the thickness of the bladder wall. The bladder having been opened, two fingers of the left hand are gently passed down to the prostate, which at this stage is still sensible. The prostate is anaesthetized by injecting fluid round it, into what will be the plane of cleavage; seven or eight points are chosen, arranged roughly in circular fashion on the base of the bladder, and into each of these 5 to 10 c.cm. of the solution are run through a syringe. Legueu employs specially made long, strong needles, having a variety of curves at their ends. For surrounding a large projecting middle lobe a needle with a wide curve is required; for the sides and anterior angles a needle bent at right angles is most suitable. The needle is guided by the operator's right hand, aided by the two fingers of the left hand in the bladder; these two fingers remain in the bladder throughout this stage of the anaesthetization. The piston of the syringe is pushed by an assistant, who experiences a sense of resistance should the point of the needle penetrate the adenoma; but when the needle is properly placed the solution runs easily. When the whole periphery of the prostate has been infiltrated, two injections are made into the prostatic urethra in order to anaesthetize the mucous membrane where it will be torn across. Shortly after the injections have been made the enucleation may be proceeded with without the patient experiencing any sensation. Legueu uses in all about 120 c.cm. of the solution, half of which quantity is devoted to the prostate. As a matter of fact, the infiltration of the abdominal wall in his clinic is now effected by an assistant in the anteroom; and the "second stage" of the operation takes a quarter of an hour, about twelve minutes of which is occupied in infiltrating the surroundings of the prostate. Among the earlier cases some pain was experienced during the enucleation, especially if the latter was at all difficult; but experience in the technique has overcome the initial uncertainty, and the operation is now quite painless.

52. The Wassermann Reaction.

Captain C. F. Craig, Medical Corps, U.S.A. (*Journ. Amer. Med. Assoc.*, April 18th, 1914), reports on the variations of the Wassermann reaction in untreated syphilitic cases. While an extensive experience has convinced him of the great value of the reaction as a test for syphilis, he finds that there are many phenomena connected with it as yet unexplained. With one of these he deals in his paper. The technique of the test is the same as that employed by him during the past four years in his routine work, being a modification of the original Wassermann and Noguchi technique. A human haemolytic system was employed instead of the sheep system of Wassermann and an alcoholic syphilitic antigen was used and the serums always inactivated before being tested. Each patient's blood was titrated every day for one week, the quantities of serum employed being 0.02 c.cm., 0.04 c.cm., 0.06 c.cm., 0.08 c.cm., and 0.1 c.cm. The quantity of blood serum used in his routine Wassermann tests is 0.08 c.cm., so that this quantity may be taken as the diagnostic amount given in the tables. A control of 0.1 c.cm. of the serum titrated was always employed. Tables are given of the results in the primary, secondary, and latent stages of syphilis. The two cases of primary untreated syphilis showed such variations of the Wassermann reaction as would have rendered the

diagnosis doubtful had the spirochaetes not been demonstrated in the lesions. In four secondary cases, likewise untreated, the study made it evident that the strength of the Wassermann test may vary from a double-plus or positive reaction to a negative one in the same patient within a few days and with the presence of marked symptoms of syphilis. Four latent cases which had shown no symptoms for a year previous, though they gave a double-plus reaction before the titrations were commenced, showed like variations. The daily titration of untreated syphilitics thus revealed great variations and show that a negative or doubtful reaction is of no value for a negative diagnosis. As regards the cause of these variations, Craig is inclined to the view that the complement-fixation reaction is often of a dual nature, there being a specific reaction between the substances extracted from the spirochaetes and antibodies in the syphilitic serum and a non-specific reaction between lipoids present in the extract and lipotropic substances in the serum. The fact must be recognized that in untreated cases of syphilis such variations may occur and that a single negative reaction is absolutely worthless in diagnosis. The patient should be subjected to repeated examinations when a negative reaction is obtained before being considered free from infection.

OBSTETRICS.

53. Quadruplets.

P. HOLST (*Tidsskrift for den Norske Lacgeforening*, April 1st, 1914) was summoned to a 4-para, aged 38, whose previous confinements had apparently been normal. He found a small live female infant, which the midwife said had been born before her arrival after a breech presentation. For several hours after this birth there had been no labour pains, and the patient felt relatively well. On examination a head presentation was discovered, a fetal murmur was audible over the umbilicus, and so many large and small prominences could be felt through the abdominal wall that triplets were diagnosed. Glanduitrin was injected, but it only induced cramp-like pain, which lasted half an hour and did not advance labour. Forceps were therefore applied, and a dead female infant was delivered. There were still no labour pains. A hand was therefore introduced, a leg seized, version performed, and a living male infant delivered, with arms above the head. As no pains had occurred half an hour after this birth an attempt was made to express the placenta. The first result of this was the presentation of a tense bag of membranes which protruded far beyond the external genitals. It was ruptured, and immediately afterwards, while pressure was maintained over the fundus, a dead male infant was shot on to the floor like a ball from a cannon. It was accompanied by some liquor and quickly followed by a placenta with a double amnion and the two male infants' funiculi, the insertion of which was marginal. Directly afterwards the second placenta with one amnion and two centrally inserted funiculi, belonging to the female infants, was expelled. There was no excessive haemorrhage, and the puerperium was normal. The four infants were of the same size; the two dead infants each weighed 1.5 kilos and measured 38 cm. in length. No. 1 died 10 days old; No. 3, though not showing much vitality at first, was still alive at the age of 6 months, and has an excellent chance of survival. Both parents were pure-bred Lapps.

GYNAECOLOGY.

54. Vaginal Drainage.

P. B. BLAND (*Journ. Amer. Med. Assoc.*, June 27th, 1914) thinks that there is a tendency at the present time to neglect drainage. As regards female pelvic operations, he believes that, while more surgeons than ever use the vaginal route, there are still some who do not adequately recognize its advantages. Abdominal drainage has many objectionable features in these cases. No one can claim it as a safer method, and it necessitates for the patient a prolonged convalescence and hospital treatment. This is of serious economic importance to many patients. It is attended with greater discomfort and danger of infection, and if this is escaped, the angle through which drainage has been placed and removed heals by second intention and predisposes to rupture. The dangers incurred in removing an abdominal drain, from the possible breaking up of adhesions carrying bowel or omentum or of pulling them into the incision are also mentioned by the author. In a recent discussion of the subject, it was stated as a disadvantage of vaginal drainage that it could not remain as long on account of its becoming offensive. This is an error, because the foulness of a drain does not depend on the length of time it is allowed to remain nor does it of itself cause harm. It is a sign that offensive material is being carried away that would otherwise remain and do mischief. It is his practice not to remove or allow a vaginal drain to be removed under six days, and he frequently allows it to remain eight or ten days without harm. It should not be removed too early, before the walling-off process by adhesions has formed, and if it is allowed to remain for some days repacking and redraining is avoided. In cases of extensive pyosalpingitis and pelvic peritonitis with dense adhesions and infection limited to below the sacral promontory, Bland believes that drainage should be instituted by the vaginal route, though he admits that in a few cases both routes should be used. He says: "In conditions such as mentioned above it has been my custom to begin the operation with a premeditative view of establishing drainage by making a preliminary free posterior vaginal incision. This procedure has the additional advantage of frequently allowing the escape of unsuspected free exudate, and thus, to a certain degree at least, safeguarding the patient from dissemination. After the posterior vaginal wall is freely incised and accumulated material allowed to escape, the cavity of Douglas is cleansed by gentle dry sponging, after which a tampon of plain gauze is placed in the pelvic cavity. This is allowed to remain until after the abdominal incision is made when it will prove in a measure a guide to the operator and in many cases point out to him the lines of cleavage in separating existing adhesions." Bland prefers iodoform gauze for a drain because it acts also as a compress. After removing the diseased organs, he thoroughly cleanses the cavity and introduces the tampon of iodoform gauze in a quantity sufficient to fill the pelvis and thoroughly cover raw stumps and surfaces, and leaves it in for from six to eight days, removing it under a short chloroform anaesthesia. No repacking should be done and no douches given for several days.

THERAPEUTICS.

55. Friedmann's Tuberculosis Vaccine.

WINDRATH (*Med. Klin.*, May 31st, 1914) has treated 23 cases of pulmonary tuberculosis with Friedmann's vaccine, and strictly in accordance with his directions. Frequent microscopic examinations were made of the preparation, the methods of staining employed being the Ziehl-Neelsen and the Gram-Much. On two occasions the vaccine was found to be contaminated with staphylococci. Patients were treated in every stage of the disease, and in every case tubercle bacilli were demonstrable in the sputum. The dose of every intragluteal injection was 0.3 gram of No. 1 solution. In 3 cases this dose was repeated in the same manner after an interval of eight weeks. No intravenous injection was given. The patients were examined again eight days after an injection, and the condition of the lungs before and after treatment was invariably controlled by Roentgen ray examinations. The sputum was also repeatedly examined, and the patients' subjective status was noted. The results were very discouraging. No change in shadows thrown on the screen could be detected, and areas of lung which previously showed imperfect expansion continued to do so after the treatment. In 7 cases the injections were followed by marked progress of the disease, and in 8 cases by slight progress. Only in 8 cases was improvement observed, and this was slight. The cough and expectoration increased in 13 cases, and decreased in 9; in 1 they remained as before. In 2 cases the temperature rose over 39°, in 6 cases over 38°, in 8 cases over 37.5°. In 7 cases the injections provoked no appreciable rise of temperature. In 1 case an abscess formed at the site of the second injection, and in 3 cases painful infiltrations were observed. In 1 case in the second stage of the disease there had been no fever till an injection was given. The temperature now rose to 39.5°, and the patient felt very ill. After eleven days, during which the fever continued unabated, a severe haemoptysis occurred, and the temperature rose to 40°. The patient died fifteen days after the injection. A necropsy was not made, but as the case closely resembles one recorded by Vulpius as a sequel to an injection of Friedmann's vaccine subsequently proved to have been contaminated with highly virulent organisms, it is possible that in the author's case also death was due to septicaemia.

Even in the 8 cases in which improvement followed the injections, the author points out that this may have been due simply to institutional treatment, which commonly effects equally good results. The author concludes that the vaccine is not only useless, but very dangerous.

56. Radium Treatment of Cancer of the Prostate.

Radium has a real action on cancer of the prostate, according to Pasteau and Degrais (*Arch. Roentgen Ray*, No. 165, 1914). The radium tube may be introduced surgically through the perineum or through the bladder. In the former case the prostate is opened up and a radium tube placed in the interior of each lobe, the tubes being left in position for any length of time required, and withdrawn by a thread to which they are attached. In the case of insertion through the bladder, on a suprapubic puncture an intravesicular radium application may be made after any cystostomy for retention, infection or haemorrhage. The radium tube, again, may be introduced through the rectum, where the whole of the posterior surface of the prostatic lobes is within reach. In this case surface applicators under the varnish will be used. The prostate itself may also easily be reached by the urethra, into the prostatic region of which a radium tube can be introduced; the radium will then be in the best possible position for attacking the neoplasm. Even better results may often be obtained by the simultaneous introduction of a radium tube into the urethra and a radium application into the rectum. In this manner all the advantages of the cross-fire method are obtained without surgical intervention. The best results are forthcoming when the part is irradiated every three, four, or six days, for from two to four hours each day with 20 to 50 mg. of radium enclosed in a silver tube 0.3 to 0.5 mm. in thickness, the treatment being suspended for three weeks or more after five or six sittings. It is claimed that radium treatment brings about such a reduction of an inoperable tumour that a prostatectomy can be undertaken without danger. It will suppress haematuria, and in certain cases may lead to a complete disappearance of the tumour and of the enlarged glands.

57. Appendicular Organotherapy.

E. Savini (*Compt. rend. Soc. de Biol.*, January 30th, 1914) refers to the current teaching that the vermiform appendix is a rudimentary, useless, and dangerous organ which ought to be removed in every case of laparotomy. Against such a view it always seemed strange that an atrophying or disappearing organ should present such a well-marked anatomical structure and so varied and abundant a pathology, points which do not occur in truly rudimentary organs. Reference is made further to the researches of R. Robinson (1907 and 1913) on the mechanism of the closure of the appendix, and its physiology; Robinson showed experimentally that the appendix is an independent and useful organ, endowed with some digestive power on albuminoids, and to a less extent on carbohydrates, but especially remarkable in that it secretes an acid liquid which plays the part of a hormone that stimulates the caecum and provokes contractions of its muscle. The appendix, then, has a quite definite and useful function. Savini has experimented on a large number of normal individuals in order to study the effect of this organotherapy of the appendix, taken by the mouth. His results are as follows: A small dose of the dry powder of the appendix (about one-quarter of a gram) gives rise, after an interval of from fifteen to thirty minutes, to abdominal gurglings which may continue for about thirty minutes; about an hour later a rather abundant stool, of average consistency, is expelled; Savini has never seen any colic or diarrhoea produced by this treatment; a repetition of the same dose at intervals gives the same effect each time. The minimum active dose is one of about 10 centigrams; but sometimes one must give a larger dose than the average one of a quarter of a gram. Savini has for some time tried this therapy in cases of chronic constipation, with or without caecal stasis, in muco-membranous colitis, chronic appendicitis, and after appendicectomy. But, although his results have been favourable, he reserves his full conclusions for a future paper, as he has not yet made a large enough number of clinical observations on the subject. But he says that his experiences agree with those of Robinson, and enable us to conclude that appendicular organotherapy has a remarkable excito-motor effect on the large intestine. It has, in short, the same kind of effect on that segment of the intestine as the duodenal secretion exerts on the pancreas, liver, and glands of the intestine. Further study of the physiology of the vermiform appendix is needed. As the pathogeny of constipation is manifold, one may, says Savini, entertain the possibility of the existence of a chronic constipation due to appendicular insufficiency.

58. Concentrated Salvarsan Injections.

Habermann (*Dermat. Zeitschr.*, April, 1914, vol. xxi, No. 4), in a carefully considered description of the results of 175 concentrated salvarsan injections in 84 patients, emphasizes and warns against the following series of symptoms of intolerance: (1) Erythema of the head and face, feeling of heat and dyspnoea—fourteen times in 14 patients; (2) three times in 3 patients these symptoms progressed to collapse, and loss of consciousness with a small—almost insensible—pulse, cyanosis, and inactive pupils; (3) marked oedema of the face on six occasions in 5 patients; (4) nausea and vomiting after thirty-eight injections in 27 patients; (5) abdominal and dorsal pain five times in 4 patients; (6) diarrhoea, the same; (7) thirty-two injections in 26 patients were followed by headache; and (8) thirteen times in 11 patients there followed temperatures of over 100.5° F. It is noteworthy that all these reactive phenomena were of an exceedingly fleeting duration, and in the most pronounced case lasted only one day. They have sufficed, however, to induce the writer to return to the old diluted infusion method of injection, during the administration of which they did not occur in so high a percentage of cases. It would appear that with neo-salvarsan the disadvantages of concentrated injections are not conspicuous, but on a basis of 40 cases the author does not at present consider himself entitled to pronounce an opinion.

PATHOLOGY.

59. Variability of Dysentery Bacilli.

Barber, in a paper on the variability of certain strains of dysentery bacilli as studied by the single-cell method (*Philippine Journal of Science*, Section B, Tropical Medicine, vol. viii, Sec. B, No. 6, December, 1913), reaches the following conclusions: (1) From a culture of *Bacillus dysenteriae*, Flexner type, derived from a single cell, three series of single-cell isolations were made at intervals of about five months; the first series gave 5 maltose-fermenting variants out of 21 isolations, the second 5 out of 60, the third 1 out of 123. The other single-cell cultures, as well as the parent culture, render maltose alkaline. (2) The non-fermenting type produces secondary colonies consisting of normal and involution cells, either of which may develop acid or alkaline producing cultures. An ordinary transfer from a secondary colony, including many cells of both sorts, gives an acid-forming culture. (3) Selection from the acid-producing type failed to produce any but similar types, and selection from the alkaline-producing type gave only alkaline, provided secondary colonies were not chosen. (4) Mixed cultures, consisting of an equal number of cells of each type, showed that the two types may exist side by side through from 10 to 15 daily transfers, but with a tendency for the acid to outstrip the alkaline. (5) Transfer in maltose broth gave no increase in the acid-producing power, except in old cultures. (6) Growth in various substances other than maltose failed to alter materially the characteristics of the two types. (7) In a specific serum the two types showed approximately the same agglutination. (8) A permanent new race, characterized by morphological peculiarities, was obtained by the selection of an aberrant cell from a culture of dysentery of the Shiga-Kruse type.

60. Effect of Section of Intercostal Nerves on Uterine Contractions.

In the course of some experiments to determine the influence of paramedian laparotomy upon the production of peritoneal adhesions, E. P. Quain (*Amer. Journ. of Surg.*, April, 1914) observed an interesting effect upon a female rabbit. An aseptic incision was made through the linea alba in the epigastrium and the anterior parietal peritoneum on each side of the incision moderately bruised; the wound was then closed, and the last three intercostal nerves on the left side were excised through an incision across the ribs behind the costal margin. Twelve days after the operation the animal was found dead; it had been pregnant, and had miscarried. The right uterus was found empty; the left uterus contained unexpelled rabbits and placentae, but the placentae were detached. Evidently the uterus on the side of intercostal nerve extirpation had been unable to empty itself, but the author is not prepared to say whether this was merely a coincidence or whether the nerve destruction on that side had any influence on the uterine contractions.

AN EPITOME OF CURRENT MEDICAL LITERATURE.

MEDICINE.

61. Prognostic Significance of a Blood Count in Phthisis.

M. WEISS (*Wien. med. Woch.*, January 24th, 1914) finds lymphocytes vary in number in phthisis, a high lymphocyte count indicating a good prognosis, and a low count indicating the reverse. This leucocyte has been shown by Bergel to produce a fat-splitting ferment which dissolves the capsule of the tubercle bacillus. In an early stage of infection, when the patient's reaction is satisfactory, the number of the lymphocytes is increased by 25 to 40 per cent. In many cases of tuberculosis of several years' standing, the patient's resistance to infection has become raised, and the lymphocyte count is high. In other cases, of recent infection and poor resisting powers, this count is low. One patient, whose pulmonary tuberculosis had lasted a year and who was not invalided thereby, showed a violent von Pirquet reaction and a lymphocyte count of 36 per cent. Another patient with "closed" tuberculosis and slight fever, showed a lymphocyte count of only 8 per cent. The disease ran a rapid and fatal course. Frequent examinations of the blood of one patient may show a lymphocyte count falling as the disease progresses. The lymphocyte count may become low before a diazo or urochromogen reaction appears in the urine; and as these reactions are unreliable guides to prognosis, the lymphocyte count is a valuable supplement in this connexion. A lymphocyte count is also a valuable guide to the action of drugs, and in three cases treated with compounds of iodine, the count rose from 16 to 26 in one, from 17 to 23 in another, and from 17 to 19 in the third case. The prognosis in all three cases was at first bad, and von Pirquet's reaction was negative, but after treatment with iodine the reaction became positive, and a year and a half later all the patients were doing well. The neutrophile leucocytes are of less importance in prognosis; when tuberculosis is advanced, many mononuclear neutrophile leucocytes appear. The eosinophile leucocytes usually disappear in advanced forms of tuberculosis, but their presence has no prognostic significance. The condition of the red cells is also no guide to prognosis, for though they fail both in quantity and quality in the advanced stages of tuberculosis, many other factors may be responsible. Besides, by the time the red cells have deteriorated, other conditions pointing to a bad prognosis are numerous and obvious. By quantitative analysis of the daily excretion of urobilin in cases of advanced phthisis, the author concludes that the deficiency of red cells is due, not to haemolysis, but to faulty production of red cells in the bone marrow.

62. The Wolff-Junghans's Test in Gastric Cancer.

SMITHIES (*Amer. Journ. of Med. Sci.*, May, 1914) studied the value of the quantitative estimation of dissolved albumin in gastric extracts (Wolff-Junghans's test) in the diagnosis of gastric cancer. Of 3,950 patients presenting themselves for test-meal examination in the Mayo clinic 747 were instances where gastric extracts showed achylia, or association with conditions likely to be confused with malignancy, and these were all tested for soluble albumin by the Wolff-Junghans's method. In 78.4 per cent. a check upon the diagnosis was afforded by operation. At 4 p.m. the day before the examination of the gastric extract 1 oz. of castor oil was administered, to be followed at 6 p.m. by a motor test meal of mixed food, and at 7 p.m. twenty raw, seedless raisins. At 7 a.m. the next morning a secretory test meal of 6 grams of second-day bread and 200 c.cm. of water were given, and removed an hour later, the specimen being thoroughly mixed, filtered through double hydrochloric-acid-washed papers, and tested for dissolved albumin within an hour of removal from the stomach. Six test tubes of about 20 c.cm. capacity are required for each test, being numbered serially from 1 to 6, and receiving respectively 1 c.cm., 0.5 c.cm., 0.25 c.cm., 0.1 c.cm., 0.05 c.cm., and 0.025 c.cm. of the filtered gastric extract, these amounts being readily measured with a 1 c.cm. pipette graduated in 1 to $\frac{1}{100}$ c.cm. By means of a 10 c.cm. pipette, graduated in 1 to $\frac{1}{10}$ c.cm. the volume in each test tube is next consecutively brought up to 10 c.cm. volume with distilled water, thus giving from the tubes 1 to 6 dilutions of gastric juice, varying respectively from 1 to 10 to 1 to 400 namely, 1 to 10, 1 to 20, 1 to 40, 1 to 100, 1 to 200, 1 to 400—these figures being termed "units" of precipitable albumin. After inversion of the tubes several times to insure complete mixture, 1 c.cm. of the reagent is carefully layered upon the contents in each tube in order to precipitate the albumin in solution. The reagent used contained phosphotungstic acid 3 c.cm., hydrochloric acid 10 c.cm., 96 per cent. alcohol 200 c.cm., distilled water to 2,000 c.cm. If there has been dissolved albumin in any of the tubes a pearly white ring of precipitated albumin appears at once at the junction of the reagent with the diluted gastric contents, and if this occurs in the tubes 1 to 3 (that is, units of albumin from 10 to 50), but is not present in the remaining tubes, the test is regarded as negative. If tubes 1, 2, 3, and 4 exhibit rings (units from 10 to 100), the test is considered doubtful, only the presence of rings in tubes 1, 2, 3, 4, 5, and above (units from 10 to 200 or 400) constituting a positive test. Of the 747 gastric extracts, 42.6 per cent. were positive, 15.7 per cent. doubtful, and 42.4 per cent. negative. The test was positive or suspicious in 80 per cent. of the cases of gastric cancer, being a more constant finding than the absence of free hydrochloric acid, the presence of lactic acid, the glycyltryptophan test, tests for occult blood, and the demonstration of gastric motor inefficiency, but it was not so consistent in its manifestation as the demonstration of organisms of the Boas-Oppler group, or the increase in the formol index. The test was inconstant in extragastric malignancy, gastric syphilis, and nephritis. In the diagnosis of malignant and non-malignant achylias the test is of considerable value when interpreted in connexion with other clinical and laboratory data, positive reactions being rarely obtained in the achylias of primary anaemia, simple achylia gastrica, and simple achlorhydrias unassociated with motor inefficiency. Simple gastric and duodenal ulcers, especially when accompanied by pyloric stenosis and gastric atony, may give confusing results, and the presence of blood in gastric extracts may produce atypical positive tests.

63. Non-parasitic Chyluria.

COURTY (*Prov. méd.*, May 16th, 1914), dealing with this condition, points out that the characteristics of a true chyluria are that the urine contains all the elements of the chyle, including fats and fibrinogen. In these circumstances the urine is white in colour, varying in intensity. Chyluria must not be confused with phosphaturia, pyuria, or lipuria. Speaking generally, chyluria is one of the manifestations of filariasis, but more recent observations seem to prove the existence of a chyluria not so caused. It is admitted that the filaria of Bancroft produces chyluria by mechanical obstruction of the lymphatic circulation. Equally obstruction may be caused by a calcified gland or by cancer of the pylorus and should result in chyluria, but this is clinically difficult of proof as cases of chyluria are rare. At the same time in patients who have never been out of Europe, and whose blood contains no suggestion of filaria, chyluria has nevertheless occurred. This non-parasitic form of chyluria may occur at any age, and has been observed as early as 15 years and as late as 67. Very often in those cases there are signs of old tuberculosis. The onset as a rule is insidious, but sometimes the patient is seized with violent pains in the renal region; in other cases a sudden attack of retention of urine is the first indication, following some difficulty of micturition. This retention is not prolonged, and the patient passes a milky urine containing filiform whitish clots. In this case the fibrinogen of the chyle has been transformed into fibrin in the interior of the urinary passage, and the clots so formed obstruct the urethral orifice. In one case referred to by the author the patient suffered from chills, pains in the back, increased pulse-rate and mental depression. An important difference between the commencement of chyluria due to filariasis and non-parasitic chyluria is that in the former there is generally a haemato-chyluria, while in the latter the urine is absolutely milky. The initial pains and retention may occur again and again in the course of the disease, and, as in the parasitic form of this disease, the condition is often intermittent over a considerable period. The horizontal position generally aggravates it, and then on waking in the morning it is most marked. The author quotes the conclusions of Hertz as showing that diet has very little effect upon the

condition, but that exercise increases it. The opacity of the chylous urine does not always clear up by ether. It always contains leucocytes, a variable quantity of albumin, and sometimes sugar. According to most observers the functions of the kidneys are very little affected. Cystoscopic examination has shown, according to some authorities, that the chylous urine comes from the right ureter. So far as the pathogeny of the condition goes, it has to be noted that chyluria is only a symptom in itself and signifies the existence of a lympho-urinary fistula the result of lymphatic hypertension from pressure or otherwise. The prognosis of a case of non-parasitic chyluria depends essentially upon the original cause of the condition and any treatment possible is bound up with this also.

SURGERY.

64. The Pleura in Artificial Pneumothorax.

RÉNON (*Journ. des praticiens*, April 25th, 1914) points out how necessary it is to ascertain the state of the pleura before, during, and after the production of artificial pneumothorax. If the patient has had massive pleurisy and effusion the chances are that adhesions of a more or less formidable character exist and that the introduction of air is impossible. One of the indications of this state of affairs is retraction of the intercostal spaces and absence or marked diminution of vocal resonance. A radioscopic examination is also of assistance in the diagnosis. If the adhesions are scattered and feeble, so far as a radioscopic examination can show, there is every justification in attempting the production of artificial pneumothorax. During the operation the state of the pleura also is important, and it must be accurately ascertained that the pleural sac has been entered. This can be done with the assistance of Küss's apparatus. If the needle has penetrated the pleural cavity the manometer will indicate a negative pleural pressure with oscillations from 10 to 15 cm. in amplitude. If, on the other hand, the needle has penetrated a cavity of limited dimensions owing to adhesions, the oscillations of the manometer will be only of feeble amplitude. If the instrument has penetrated the lung the oscillations will be very small and equal above and below the zero of the manometer. After the operation pleural effusions are not infrequent. They are of three different varieties: (*a*) Septic effusions; these are not as a rule so much due to an infection of the pleural cavity in the course of operation from without as to the escape of infected air from the lung owing to the rupture of a cavity if the insufflation has been made under too great pressure. The patient is suddenly seized with a violent pain in the side, the temperature rises rapidly, and from the point of puncture a purulent fluid can be seen exuding. The danger in these cases is considerable, and evacuation of the pus with free drainage is essential. (*b*) Purulent tuberculous effusion, practically in the form of a cold abscess. (*c*) Serous effusion; this is unfortunately a fairly common occurrence after artificial pneumothorax. It is tuberculous in character, as inoculation of guinea-pigs has shown. The progress of these cases varies, but is generally hopeful. The author's experience of artificial pneumothorax, in spite of such accidents, confirms his opinion of its real value. At the least the procedure gains time and retards the progress of the malady. The immediate results are often excellent, but rarely last for long, and cases of cure are very exceptional. In his opinion it is one of the least harmful methods of treatment, but is destined to disappear when the therapeutics of tuberculosis have made serious progress in other directions.

65. Treatment of Secondary Haemorrhage following Nephrotomy.

F. VOELCKER (*Zentralbl. f. Chir.*, June 13th, 1914) has found that dangerous bleeding is more likely to occur some days after nephrotomy than directly after the operation. A careful haemostasis of the kidney at the time of operation goes far to prevent the occurrence of bleeding later. The most important vessels are the large arteries lying deep in the kidney near the pelvis. Any spurting point should have an individual catgut ligature so far as practicable; if the wound is filled with blood and an accurate view cannot be obtained, a haemostatic forceps should be applied temporarily to the bleeding area, and the region surrounded by a haemostatic suture. Capillary haemorrhage is controlled by closure of the kidney and suture of the capsule. If in spite of these precautions serious haemorrhage occurs during the after-treatment of a nephrotomy case, the situation brooks no delay. The amount of blood which has already been lost via the ureter is often more considerable than one suspects, and no time should be spent in carrying out general measures such as injections of gelatine or hypertonic saline; treatment should be local, and the best is to retrieve the kidney and ligature the bleeding point. It is frequently impossible to find the bleeding point in an exsanguinated patient; and sometimes the haemorrhage is a general capillary oozing. In such cases secondary nephrectomy is often the only means of saving the patient's life. In one such case the author dwelt with the situation successfully by bringing the kidney out of the wound and leaving it there for some time with a compressing bandage round it. Nephrolithotomy of the right kidney was performed on a patient who eight years previously had had a stone removed from his left kidney. A week after operation there was severe bleeding from the wound in the loin and also into the bladder. Plugging the wound had no effect. Nephrectomy was considered out of the question, as both kidneys were infected. The kidney was freed and brought to the surface. In order to prevent haemorrhage into the bladder, a loose ligature was placed round the ureter, the kidney was bound up in a narrow sterile bandage, and haemorrhage ceased. Two days later the ligature was removed from the ureter. The kidney was unbound on the next day, and replaced with some difficulty a day later, after lying for four days outside the wound. No further bleeding occurred, and the patient did well.

66. Ankylosed Jaw.

J. B. MURRAY (*Journ. Amer. Med. Assoc.*, June 6th, 1914) discusses the subject of arthroplasty for intra-articular bony and fibrous ankylosis of the tempero-mandibular articulation, and reports nine cases. The most common type of ankylosis is the bony, which may be due to extensive suppuration of the middle ear, a local osteitis, metastasis from local infection elsewhere in the body, or it may be a part of a general metastatic arthritis or the result of a transmitted trauma from the chin. All parts of the jaw may be affected singly or together, and the anterior root of the zygoma is often involved. The middle-ear disease is the most common cause. The abscess may burrow forward into the joint or it may involve the subzygomatic temple zone and produce myositis with cicatricial contraction. The diagnosis as to the side involved is often very difficult. When the ankylosis is bony, there is complete fixation; but when the ankylosis is fibrous, there is some motion in the jaw, and in the para-articular ankyloses there is always some motion. In the intra-articular ankyloses there is sometimes a little lateral motion on the unaffected side, a minute fraction of an inch on forced effort at opening the mouth, a point which is worth remembering. By clinical observation and experience, Murphy has learnt that an accurate diagnosis of the side involved in unilateral cases occurring early in life can be made by noting the deviation and contrast formation of the two sides of the face. It seems full and round on the ankylosed side, but on the opposite one it is flattened and deformed. The chin is always retracted and turned to the ankylosed side. If ankylosis occurs late in life this is not so prominent, and if the case is recent there is not much deformity. In only one case of the nine reported did Murphy fail to diagnose the side affected, and in this he was misled by the history. He performs a typical and uniform arthroplasty, using the pedicled flap, consisting of fat and the aponeurosis of the temporal muscle as the interposing material. The technique is not difficult, but must be exact in its details in order to obtain good results. The steps are: (1) The L-shaped incision coming down perpendicularly to the upper border of the zygoma and extending forward on its upper margin ¾ inch; (2) division of the ankylosis and removal of the segment of the mandibular neck; (3) raising the flap of temporal fascia and fat; (4) interposing and fixing the flap in place; and (5) closure of the wound. The results obtained are gratifying. In only one case did Murphy fail to have good results. The cases are reported. There is some danger of injuring the facial nerve in operating otherwise than with the L-shaped incision. There is also another danger. One cannot divide the ankylosis in the line of the original articulation for fear of penetrating the base of the skull. Murphy, therefore, always removes the condyle of the inferior maxilla and does not clean out the glenoid fossa to make an opening. The internal maxillary artery must be borne in mind in removing bone, as it hugs the inner side of the neck very closely. If injured, it should be ligated at the bifurcation of the external carotid. After-treatment is very important. Mastication should be started at the end of two weeks.

OBSTETRICS.

67. Severe Intraperitoneal Haemorrhage from a Corpus Luteum.

At a discussion in the obstetrical, gynaecological section of the Swedish Medical Society on the subject of intraperitoneal haemorrhage from the ovaries, E. Bovin (*Hygiea*, vol. 76, No. 7, 1914) pointed out that, when the haemorrhage has been severe, the presence of extrauterine pregnancy has never been convincingly disproved. Slight haemorrhages, on the other hand, do occur about the uterine appendages in connexion with ovulation or menstruation. When laparotomies have been performed immediately before or during menstruation he has frequently found small quantities of dark liquid blood in the pouch of Douglas. In one case he had operated for appendicitis on a girl, aged 19, at a time when menstruation was just due. He found a newly ruptured follicle, distended with blood, in one ovary; and there were about two dessertspoonfuls of liquid blood in the pouch of Douglas. Next day normal menstruation set in and lasted four days. A. Troell (ibid.) recorded the following case: An unmarried woman, aged 24, had suffered off and on for the past year from abdominal pain, practically limited to the epigastrium. She had previously been quite well, and menstruation had been normal. Her last menstruation, early in October, was also normal, but on the 22nd of the same month she suddenly developed rigors and great pain and tenderness in the right lower abdomen. She felt exceedingly unwell, but did not vomit. On admission to hospital next day she was much collapsed, the pulse was 80, and the temperature was 37.7° C., but there was no marked anaemia. The area of maximum tenderness and resistance was just below McBurney's point. No vaginal examination was made. Appendicitis was diagnosed, and the abdomen was opened by McBurney's incision. When the peritoneum was opened a little fluid blood escaped. A ruptured tubal pregnancy was suspected, but, as the perfectly healthy appendix was easily found, it was removed. An examination of the uterine appendages made through the incision, which had been enlarged downwards and to the middle line, revealed a round, soft, elastic tumour, of the size of an orange, attached to the uterine appendages on the right side. It consisted, not of a pregnant tube, but of the right ovary, which was partially converted into a bag of blood. Liquid blood flowed from an opening, no larger than a goose's quill, in the wall of this tumour, which was removed. The uterus, the right tube, and the left uterine appendages were normal. The microscopic examination of the right ovary showed the blood-filled cavity to consist of a corpus luteum. No evidence of a fertilized ovum was found. As, however, a complete set of serial sections was not examined, the absence of an ovarian pregnancy is not proven.

GYNAECOLOGY.

68. Spontaneous Amputation of the Uterus.

L. Ruppert (*Wien. klin. Woch.*, March 12th, 1914) records a case of a widow, aged 72, whose uterus was invaded by a large, non-pedunculated myoma which caused the uterus to rotate on its long axis till its body was united to the cervix only by a few shreds of serosa. The patient had previously been well, she had aborted once, but had never given birth to a mature infant. During the past year she had been subject to brief attacks of cramp-like abdominal pain. The dimensions of the abdomen had slowly increased during nine months, and the patient had detected a hard swelling in the abdomen. After the abdominal pain had grown more severe and continuous for a week, during which the patient had frequently fainted, she was admitted to hospital with the diagnosis of intestinal obstruction. She had not passed faeces or flatus for three days, but there were no disorders of micturition and the temperature was normal. The pulse was rapid, the face drawn, the tongue dry, and the mucous membranes were pale. The whole of the distended abdomen was tender, and between the symphysis and a point a handbreadth below the umbilicus, a hard, movable, round swelling could be felt. This was evidently connected with a hard, round swelling to be felt by vaginal examination in the pouch of Douglas. The position of the cervix seemed normal. The lateral aspects of the abdomen were dull on percussion. As the pulse was rapid and collapsing, and the patient's condition did not warrant an immediate operation, stimulants were given and the operation was deferred till the next day, when she had partially revived. A laparotomy performed in the middle line below the umbilicus revealed a large quantity of dark fluid blood in the peritoneal cavity and a cyanosed tumour attached to the posterior wall of the uterus. About a litre of fluid and clotted blood was removed, and the uterus was now seen to be attached to its cervix merely by a few strands of serosa, which gave way as soon as the uterus was pulled on. The uterus was restored to its normal position by rotating it three times 180 degrees. Its ligaments were clamped and divided, and the tumour, which was larger than an infant's head, was removed, together with the uterus and its appendages. The stump of the cervix was covered with peritoneum and the abdomen closed. The wound healed by first intention and a rapid recovery was effected. Discussing the mechanism of this amputation the author suggests that the round ligaments cut into the uterus as it rotated and thus facilitated its division at the junction of the body with the cervix. The process was evidently acute, and the movements of rotation were unchecked by any adhesions.

69. The Heart and Uterine Fibroids.

McGlinn (*Trans. Amer. Gynec. Soc.*, vol. xxxviii, 1913) publishes tables based on the records of 5,700 autopsies. In 244 subjects fibroid tumours of the uterus were discovered. McGlinn analyses this series, and concludes that a definite entity of a "fibroid heart" cannot be admitted. If the fibro-myomatous new growth were the cause of all the cardiac lesions in the series, then every tumour, regardless of its size and situation, should be extirpated—a contention that the most radical surgeon would hardly admit. Uterine myomas occurring in middle and advanced life are practically always associated with selerotic heart lesions, part of a general process bearing no relation to the fibroid. Large tumours, by increasing the work of the heart and fibroids, causing pressure on the pelvic circulation, may produce hypertrophy and secondary dilatation of the heart. Anaemia from haemorrhages, infections, and certain degenerations of the tumour may affect the heart secondarily, causing changes, such as fatty degeneration, brown atrophy, and cloudy swelling, but these changes in the majority of instances are caused by conditions entirely foreign to the tumour.

THERAPEUTICS.

70. Stability of Synthetic Suprarenal Preparations.

The stability of suprarenal extract was frequently called in question, and the same doubts have been expressed regarding the synthetically prepared suprarenal compounds. During the last few years Schlesinger (*Zent. f. Chir.*, March 21st, 1914) has observed the effects of injection of suprarenal products. The observations were made in the course of clinical practice. In his earlier observations he often found that on opening a bottle the contents had a rosy-brown colour. At that time rubber stoppers were used for the bottles; since the almost universal use of glass stoppers for the phials of synthetic extract, the contents are almost always colourless when the bottle is first opened. In these observations only freshly-opened bottles were used, and if the contents were not clear and colourless they were rejected. The dilutions for injection were made up immediately before use. The same technique was employed in all cases. In a certain number of instances no effect on the vasomotor mechanism was produced by injection. The cases in which no physiological effect occurred fall into two classes. Thus occasionally, while performing a number of similar operations, using the same technique and the same solution, in one case vaso-constriction would be much less pronounced than in the others. The author is compelled to the conclusion that an individual idiosyncrasy is the explanation of such an occurrence; for some reason the vasomotor mechanism in some individuals reacts less evidently to suprarenal preparations than in the majority of people. Secondly, out of a large number of ampoules employed, about 1 in 30 was found to be deficient physiologically. The ampoule was not condemned until it was found to be useless after trying it on at least three or four subjects, using all the above precautions. At first the observer thought that the particular phial might have deteriorated through age. He therefore obtained a number of bottles which had been made up for periods varying from six months to five years. They were all found to be clear and colourless when opened, and to produce completely satisfactory vaso-constriction. A number of the solutions which had been found to be inactive were sent back to the makers, who reported that they appeared to be chemically unchanged; and when tested in the Pharmacological

Institute at Freiburg they were found to be physiologically active for animals. It may be deduced that some samples of synthetic suprarenal preparations undergo some change, which cannot be detected by our present chemical methods, by which they become inactive for the human subject while remaining active for some animals. The author is not prepared to explain this occurrence in the present state of our knowledge of the subject. That some samples undergo changes while still within the sealed phial is shown by the fact that if several bottles are opened at the same time and kept under precisely similar conditions, the contents of some will become tinted in a few hours, while that of others will remain clear for eight days or more. These observations were all made with suprarenin solutions already made up by the manufacturers; the author has little experience of preparations put up in tablet form.

71. A Simple Hot-air Cautery.

FONBELLE AND AMAT, two practitioners whose work lies mainly among the natives of Southern Algeria, where venereal sores have to be treated in large numbers and in most unfavourable circumstances, have devised a simple and highly effective hot-air cautery, with which they claim very considerable success in the cure of soft chancres (*Bull. de la Soc. Franç de Derm. et Syph.*, February, 1914, No. 2). A spirit lamp and an old Paquelin cautery, of which only the hollow handle and four or five inches of metal continuation designed for attachment to the rubber tube and air-pump remained, was the sole material available. The handle of the spirit lamp, of soft iron, was bent upwards, bayonet fashion, and the upper extremity pierced to admit the metal continuation of the cautery handle at such a height (2 cm.) that the latter would lie in the hottest part of the spirit flame when lighted. The metal continuation was shaped with pliers to as fine a point as possible, and projected, when complete, some two or three inches distally to the spirit flame. The advantage of this instrument lay in the fact that the right hand when grasping the cautery handle controlled it completely, and could guide it unassisted with lamp alight and heating the metal continuation to any part of the patient's body, while the left hand manipulated the rubber ball and produced an equable air current. The latter was found experimentally to have a temperature of about 150° C. at 0.5 cm. from the orifice, 100° C. at 1 cm., and somewhere between 70° and 80° C., and the optimum temperature for this sort of work, at 1.5 cm. For the average soft sore three applications—one every third day—were found sufficient, and marked improvement was generally noted a very short interval after the first. A mild iodoform paste sufficed for all purposes between the sittings.

72. Electrical Treatment in Gout.

NUYTTEN (*Arch. d'électr. méd.*, April 25th, 1914), reporting on the electrical treatment of gout, states that so far as general treatment is concerned, the electro-therapeutic modalities are limited practically to two—namely, the currents of high frequency, and generalized electrical gymnastics, given according to Bergonié's method. Many experimenters have found that high-frequency currents in their general application have a manifestly accelerating action on the azotic metabolism. Little is known of the mechanism of the currents' action; the most likely hypothesis is that the effects are to be attributed to a direct trophic influence on the cell. The condenser couch appears to give better results than the cage of autoconduction. As to the generalized electrical gymnastics or passive ergotherapy of Bergonié, the author regards this method as marking an important progress in the therapeutics of diseases of nutrition. His own experience has proved that a rapid amelioration of the general state is obtainable, the insomnia disappearing, and pain being lessened. Of other general methods, the static bath may render service when there is neurasthenia or insomnia; and in the chronically constipated, abdominal galvanization may be useful as a means of bringing about the disappearance of one of the causes of the autointoxication. For local treatment, galvanization at a high intensity is the principal electrical method available. In acute crises the galvanic current has a remarkable action, so that often an impending attack is staved off after the first or second sitting; but even when the trouble is permanent, the cartilages being befouled with uratic deposits, and when there is articular stiffness, galvanization still remains the treatment of choice. The analgesic action of the continuous current is felt if the applications are sufficiently long and intense (20 to 50 milliampères for from twenty to forty minutes, according to the surface of the electrodes and the sensibility of the patient). Lithium ionization as an adjunct to the simple application of the galvanic current offers certain advantages and no inconveniences, and other ions have been used with success. The currents of high frequency have been employed for local treatment in two principal forms; the effluve, and the diathermy. The former appears to have a vasomotor and particularly an analgesic action. In the case of diathermy the action seems to be doubtful, at least two observers noting an increase of pain, and, apparently, the results are mediocre.

73. Adrenalin Chloride in Exophthalmic Goitre.

I. L. VAN ZANDT records a case of exophthalmic goitre which he treated by adrenalin chloride solution (*Amer. Med.*, April, 1914). Bearing in mind the alleged antagonism between the thyroid and the adrenals, he thought that the excessive action of the thyroid in the disease might be controlled and possibly cured by adrenalin. The patient, a woman of about 30, had one child aged 10. There was no history of miscarriages. She had generally good health until four and a half years ago, when she developed exophthalmic goitre. She has had but little treatment, and has steadily refused surgical measures. The author was summoned hastily to see her, and found her almost dead from "heart failure"; her pulse was very feeble and intermittent—60 to the minute. After strychnine hypodermically, followed by strychnine and a preparation of *Cactus grandiflora*, she rallied by the next day; the depression seems to have followed a severe attack of vomiting. At this time she had extreme exophthalmos, tachycardia, and a large goitre visibly pulsating, extreme nervousness, and a sense of something terrible impending; she had a constant headache with occasional very severe paroxysms. About eight days later six drops of adrenalin chloride solution was given four times a day; this was dropped into a spoon and a few drops of water added, but not enough to cause swallowing, and this was kept in the mouth to be absorbed therefrom. The author says this method is next to a hypodermic injection in rapidity and certainty of action. Within half an hour the visible pulsation had ceased and the flushing of the face was lessened. A month later all her signs and symptoms had greatly diminished, her nervousness was all gone, and she said she had never felt better. Her continuous headache had left her after the first dose, and had not returned. Van Zandt admits that she is not yet cured, but he claims that if this action of adrenalin is at all uniform in exophthalmic goitre it will furnish an excellent preparatory treatment for surgical intervention.

PATHOLOGY.

74. Paralysis Agitans and Parathyroid Glands.

GREENWALD (*Amer. Journ. of Med. Sci.*, February, 1914), following up the suggested relationship between parathyroid insufficiency and paralysis agitans, which is founded upon the symptoms noted after the removal of the parathyroids in lower animals, attacked the subject from another direction, previous experiments upon dogs having shown a marked diminution in the excretion of phosphorus after parathyroidectomy. This diminution persists until tetany appears, and analyses of the blood and serum of parathyroidectomized dogs show a distinct increase in the phosphorus content, due to an increase in those phosphorus compounds which are insoluble in acetone, alcohol, or ether, but which are soluble in a mixture of dilute hydrochloric or acetic acid and picric acid. On the assumption that parathyroid insufficiency is a factor in the etiology of paralysis agitans, a similar increase in acid-soluble phosphorus would probably be found in the blood serum of patients suffering from the disease, and this point was investigated, as also in normal individuals for comparison. On the morning the blood was taken no food was given, in order to avoid any variations due to its character and stage of absorption, and sixteen hours after the last meal blood was drawn from one of the veins of the forearm into sterile test tubes and allowed to clot. The serum, after being freed from cells and haemoglobin, was treated with acetone in order to precipitate all the protein and inorganic phosphate, only the lipoid phosphorus remaining in solution. After filtration and extraction the acetone was distilled off and the phosphorus determined by Bang's modification of the Neumann method. As a result of these investigations it was found that the amount of acid-soluble phosphorus in the blood serum of patients suffering from paralysis agitans was not greater than that of other individuals, so that they do not support the view that parathyroid insufficiency plays a part in the etiology of the disease.

CONTENTS.

EIGHTY-SECOND ANNUAL MEETING
of the
British Medical Association,
ABERDEEN, JULY, 1914.

PROGRAMME OF BUSINESS.

President: WILLIAM AINSLIE HOLLIS, M.A., M.D., F.R.C.P., Consulting Physician, Sussex County Hospital, Brighton.

President-elect: Sir ALEXANDER OGSTON, K.C.V.O., M.D., LL.D., Consulting Surgeon, Aberdeen Royal Infirmary; Surgeon in Ordinary to H.M. the King in Scotland.

Chairman of Representative Meetings: THOMAS JENNER VERRALL, M.R.C.S., L.R.C.P., Consulting Surgeon, Sussex County Hospital, Brighton.

Chairman of Council: JAMES ALEXANDER MACDONALD, M.D., M.Ch.R.U.I., LL.D., Honorary Physician, Taunton and Somerset Hospital, Taunton.

Treasurer: EDWIN RAYNER, B.A., M.D.Lond., F.R.C.S. Eng., Consulting Surgeon, Stockport Infirmary, Stockport.

The Eighty-second Annual Meeting of the British Medical Association will be held in Aberdeen in July, 1914. The President's Address will be delivered on Tuesday, July 28th, and the Sections will meet on the three following days. The Annual Representative Meeting will begin on Friday, July 24th, at 10 a.m.

The Address in Medicine will be delivered by ARCHIBALD EDWARD GARROD, M.D., F.R.C.P., F.R.S., Physician, St. Bartholomew's Hospital, London.

The Address in Surgery will be delivered by Sir JOHN BLAND-SUTTON, Surgeon to the Middlesex Hospital, London, W.

The Popular Lecture will be delivered by Professor J. ARTHUR THOMSON, M.A., LL.D., Natural History Department, Marischal College, Aberdeen.

THE SECTIONS.

The scientific business of the meeting will be conducted in sixteen Sections, which will meet on Wednesday, July 29th, Thursday, July 30th, and Friday, July 31st.

The President, Vice-Presidents, and Honorary Secretaries of each Section constitute a Committee of Reference for that Section, and exercise the power of inviting, accepting, or declining any paper, and of arranging the order in which accepted papers shall be read. Communications with respect to papers should be addressed to one of the Honorary Secretaries.

A paper read in the Section must not exceed fifteen minutes, and no subsequent speech must exceed ten minutes.

Papers read are the property of the British Medical Association, and cannot be published elsewhere than in the BRITISH MEDICAL JOURNAL *without special permission.*

The following sixteen Sections have been authorized by the Council:

ANATOMY AND PHYSIOLOGY.

President: Professor ROBERT W. REID, M.D., F.R.C.S., Aberdeen. *Vice-Presidents:* DENIS P. FITZGERALD, M.B., B.Ch., Cork; J. STRICKLAND GOODALL, M.B., F.R.C.S., London, S.E.; Professor J. KAY JAMIESON, M.B., C.M., Leeds; Professor J. A. MACWILLIAM, M.D., C.M., Aberdeen. *Honorary Secretaries:* NORMAN J. CALDER, M.B., Ch.B., Anatomy Department, Marischal College, Aberdeen; EDWARD PROVAN CATHCART, M.D., D.Sc., Department of Physiology, University of Glasgow; R. J. GLADSTONE, M.D., F.R.C.S., University of London, King's College, Strand, W.C.; HUGH MACLEAN, M.D., Chemical Pathology Department, St. Thomas's Hospital, London, S.E.

The following papers have been accepted:

BOYD, Sidney. A Note on a Congenital Anomaly of the Duodenum Encountered during Operation.
CALDER, Norman J. Rare Anatomical Anomalies.
CATHCART, E. Provan. The Influence of Carbohydrate on Metabolism.
CULLIS, Winifred. The Distribution of Nerves in the Heart.
EDIE, E. S. Some Experimental Work on the Action of Enzymes.
GARDNER, A. D. The Sugar of Blood and Urine.
GLADSTONE, R. J. Description of some Australian and Tasmanian Skulls.
GOODALL, J. Strickland, and RICHARDS, Hedley N. D. Some Instrumental Variations in the Human Electro-Cardiogram.
LEVY, A. Goodman. Ventricular Fibrillation, the Cause of Death under Chloroform.
MCKENDRICK, Emeritus Professor J. G., F.R.S. Theories of Hearing with Analogies from the Gramaphone, with a Demonstration of Improvements on the Gramaphone and the Obliteration of Noise.
MCKENZIE, Ivy. The Reptilian Heart and its Significance in the Interpretation of the Co-ordinating Muscular Systems in the Mammalian.
MCKENZIE, Ivy, and ROBERTSON, Jane I. Some Further Researches on the Anatomy of the Bird's Heart.
MACLEOD, Professor J. J. R. (Cleveland, U.S.A.). Some Recent Researches on Sugar Metabolism.
MACWILLIAM, Professor J. A. (1) The Regulation of the Heart Beat. (2) Some Points in the Action of Chloroform.
MELVIN, G. S., and MURRAY, J. R. Some Observations on Blood Pressure.
ORR, J. B. A Contribution to the Metabolism of Creatine and Creatinine.
REID, Professor R. W., and TOCHER, J. F. Anthropometric Characteristics of Students of Medicine in the University of Aberdeen.
RIDDOCH, G. The Sympathetic System of a Full-time Fetus.
ROBERTSON, Jane I. (1) The Phylogenetic Development of the Bulbar and Ventricular Septa of the Heart. (2) Cardiac Malformations in which the Great Efferent Vessels arise from the Right Ventricle.
TRIBE, Mrs. The Existence of Vasomotor Nerves in the Lungs.

DERMATOLOGY AND SYPHILOLOGY.

President: ALFRED EDDOWES, M.D., M.R.C.P., London. *Vice-Presidents:* R. CRANSTON LOW, M.B., F.R.C.P.E., Edinburgh; J. M. HENDRIE MACLEOD, M.D., M.R.C.P., London, W.; J. A. NIXON, M.B., F.R.C.P., Clifton, Bristol; J. C. OGILVIE WILL, M.D., C.M., Aberdeen. *Honorary Secretaries:* J. FARQUHAR CHRISTIE, M.B., C.M., 7, Alford Place, Aberdeen; J. D. PRYDE MCLATCHIE, M.B., C.M., 34, Welbeck Street, London, W.

The following programme has been arranged:

July 29th.—Discussion on the Need for more Method in the Conflict with Lupus and Ringworm. To be opened by Dr. NORMAN WALKER.

July 30th.—Discussion on the Modern Treatment of Syphilis. To be opened by Mr. J. E. R. MCDONAGH.

July 31st.—Independent papers.

DAVIS, Haldin. Infantile Eczema.
MCDONAGH, J. E. R. The Rationale of the Wassermann Reaction.
TOMKINSON, J. Goodwin. Three Cases of Lahore Sore.
WALTER, J. C. M. On the Use of Antimony in Syphilis.
WILLIAMS, A. Winkelried. Keratodermia Blenorrhagica.

The following syllabus of his opening paper has been supplied by Dr. NORMAN WALKER:

Lupus: Statistics of cases attending the Royal Infirmary during the past twenty-two and a half years. Particulars of their attendances. Discussion of the various methods of treatment employed. Outcome. The difficulties of treatment. Lupus carcinoma. Suggestions. *Ringworm and Favus:* Statistics of cases; evidence of epidemics; effect of school inspection; opening of special schools and of more organized treatment.

The following is an abstract of Mr. J. E. R. MCDONAGH's opening paper:

The chancre should be excised when possible; failing that, it should be cauterized; and, failing cauterization, mercurial ointment should be rubbed in until every trace of the induration has vanished. In the primary stage, roughly, five intravenous injections of neo-salvarsan should be given, allowing about four or five days to intervene between each injection. Mercurial treatment should be continued for one year in the form of intramuscular injections given in three courses of eight weekly injections and allowing two months to intervene between each course; for the first three weeks of each iodides should be given internally. In the eruptive stage, roughly, seven injections of neo-salvarsan should be given, and mercurial treatment for two years. In the recurrent stage the patient should be treated as if in the eruptive stage, but a cure is far less likely to result. In the gummatous stage two injections of salvarsan should be given and one or two courses of intramuscular injections of mercury and iodides, since no more can be expected than to cure the symptoms. In the latent stage, provided the patient is perfectly healthy and nothing abnormal can be found upon thorough examination, in spite of the Wassermann reaction being positive, no treatment is indicated, because a positive Wassermann reaction is by no means necessarily indicative of active syphilis; it is often rather a measure of the host's protective capacity against the organism. Pure meningeal and pure arterial lesions of the central nervous system can be markedly benefited by intravenous injections of neo-salvarsan and mercury. Some cases of tabes are slightly improved, some are made worse or unaltered; most cases of general paralysis of the insane are made worse or unaltered. Intrathecal injections of salvarsanized serum exert a beneficial and rapid action upon pure meningeal lesions. They may improve cases of tabes or leave them unaltered. They may slightly improve cases of general paralysis of the insane, but on the whole they tend to make such cases worse. Every woman who has once given birth to a syphilitic child should be treated throughout the whole of each succeeding pregnancy, first with five intravenous injections of neo-salvarsan at weekly intervals, and for the rest of the nine months with mercury. Congenital syphilis is best treated with mercury. Every case of syphilis should be treated individually, as no two are alike. The treatment should be guided by clinical observations, and little or no reliance should be placed upon any existing bacteriological or serological test. A spontaneous cure in most stages is possible, and all that treatment does is to stimulate the factors which are responsible, therefore no treatment will kill directly all the phases of the *Leucocytozoon syphilidis.*

Contributions of drawings, photographs, microscope and other specimens relating to dermatology and syphilis are invited for the Pathological Museum, and should be sent as early as possible to Aberdeen.

DISEASES OF CHILDREN, INCLUDING ORTHOPAEDICS.

President: JOHN THOMSON, M.D., F.R.C.P.E., Edinburgh. *Vice-Presidents:* ANDREW FULLERTON, M.Ch., F.R.C.S.I., Belfast; H. M. W. GRAY, M.B., F.R.C.S.E., Aberdeen; E. MUIRHEAD LITTLE, F.R.C.S., London; J. HUGH THURSFIELD, M.D., F.R.C.P., London. *Honorary Secretaries:* A. S. BLUNDELL BANKART, M.C., F.R.C.S., 14, Harley Street, London, W.; D. WATSON GEDDIE, M.B., C.M., 13, Golden Square, Aberdeen; H. TYRRELL GRAY, M.C., F.R.C.S., 60, Harley Street, London, W.

The following programme has been arranged:

July 29th—(1) Discussion on Congenital Dislocation of the Hip. To be opened by Mr. T. H. OPENSHAW.

July 30th.—(2) Discussion on the Thymus Gland in its Clinical Aspects. To be opened by Dr. ARCHIBALD E. GARROD.

July 31st.—(3) Joint discussion on the Diagnosis of Chronic Pulmonary Tuberculosis in Infancy and Childhood (See Section of Medicine).

The following papers have been accepted:

FINDLAY, Leonard, and ROBERTSON, Madge (Glasgow). The Treatment of Congenital Syphilis.
FRASER, William (Edinburgh). The Influence of the Thymus and Certain other Ductless Glands on the Epiphyses.
MACLENNAN, Alexander (Glasgow). The Technique of Thymectomy.
MCNEIL, Charles (Edinburgh). The Association of Abnormal Types of Pneumonia and of Tuberculosis in Children with Thymo-lymphatic Hyperplasia.
MCWALTER, J. C. (Dublin). Lime Salts in Children's Diseases.
ROTH, Paul B. (1) The Treatment of Torticollis; and (2) The Practical Treatment of Lateral Curvature of the Spine.
WILKIE, D. P. D. (Edinburgh). Appendicitis and the Status Lymphaticus.

ELECTRO-THERAPEUTICS AND RADIOLOGY.

President: SAMUEL SLOAN, M.D., F.R.F.P.S., Glasgow. *Vice-Presidents:* W. J. S. BLYTHELL, M.D., Kersal, Manchester; DAVID LAWSON, M.D., Nordrach-on-Dee,

N.B.; J. R. LEVACK, M.B., C.M., Aberdeen. *Honorary Secretaries:* M. R. J. HAYES, F.R.C.S.I., 35, Upper Fitzwilliam Street, Dublin; W. L. LOCKE, M.B., Ch.B., 31, Queen Anne Street, London, W.; F. PHILIP, M.B., 183, Great Western Road, Aberdeen.

The following programme has been arranged:

July 29th.—(1) An Introductory Address by Professor LEDUC on Cerebral Galvanization. (2) Discussion on the Therapeutic Value of High-Frequency Currents; to be opened by the PRESIDENT.

July 30th.—Discussion on (1) The Comparative Value of X Rays and Radium in the Treatment of Maligunt Growths; to be opened by Dr. HERNAMAN-JOHNSON and Dr. JOHN MACINTYRE. (2) Electro-Therapy in Neurasthenia; to be opened by Dr. AGNES SAVILL, followed by Dr. W. F. Somerville. (3) Demonstration by Dr. C. F. BAILEY on Testing and Treating Muscles by the Condenser Method.

July 31st.—(1) Joint discussion on the Diagnosis of Chronic Pulmonary Tuberculosis (see Section of Medicine). (2) Discussion on X-Ray Diagnosis in Gastro-intestinal Conditions, with Special Reference to Appendicitis; to be opened by Dr. HERTZ.

GYNAECOLOGY AND OBSTETRICS.

President: F. W. NICOL HAULTAIN, M.D., F.R.C.P.E., Edinburgh. *Vice-Presidents:* Professor J. ALEXANDER KYNOCH, F.R.C.P., F.R.C.S., Dundee; Professor R. G. MCKERRON, M.D., C.M., Aberdeen; T. G. STEVENS, M.D., F.R.C.S., London; W. C. SWAYNE, M.D., Clifton, Bristol. *Honorary Secretaries:* H. S. DAVIDSON, M.B., F.R.C.S., 6, Atholl Place, Edinburgh; S. G. LUKER, M.D., F.R.C.S., 1, Harley Street, London, W.; ALEXANDER MITCHELL, M.B., 2A, Albyn Place, Aberdeen.

The following programme has been arranged:

July 29th.—Discussion on the Treatment of Fibromyomata. To be opened by Dr. ARCHIBALD DONALD (Manchester), followed by Professor Gauss (Freiberg).

July 30th.—Discussion on the Management of Pregnancy and Labour in Contracted Pelves. To be opened by Dr. HENRY JELLETT, followed by Professor Frank (Cologne).

Pathological Demonstrations and independent papers.

The following papers have been accepted:

MCWALTER, J. C. Drug Treatment of Dysmenorrhoea.
MURRAY, H. Leith. Acidosis and the Nitrogen Particles in Pregnancy.
SHANNON, David. The cases of Contracted Pelvis admitted to Professor Kerr's Clinic in the Glasgow Maternity Hospital between the years 1909 and 1913.

The following is a synopsis of Dr. JELLETT'S paper:

From a clinical standpoint contracted pelvis may be divided into two main classes—symmetrical contractions and asymmetrical contractions. The paper deals with the former contractions alone. They may be divided into four degrees, based on what experience shows is the necessary treatment of each. In the first degree one may assume that the child will be delivered spontaneously if of normal size. In the second degree it may be assumed that delivery of a living child per vaginam is only possible if the size of the child is diminished or the size of the pelvis increased. In the third degree spontaneous delivery through the pelvis of a viable child is impossible. In the fourth degree delivery through the pelvis is impossible, even if the child be reduced by a destructive operation to the maximum extent, and so Caesarean section is the only treatment, whether the child is alive or dead. The author confines his remarks to the treatment of the second degree, and contrasts in connexion with it delivery through the pelvis—the induction of premature labour or pubiotomy or symphysiotomy—and Caesarean section. The objections to induction are the risk of septic infection during the operation, its general uncertainty, and the fact that a small child, naturally delicate, results. There are, on the other hand, very few arguments in favour of it, except that for the general practitioner it is simpler to perform than either of the other operations, and that it does not necessitate a "cutting" operation. Caesarean section has in its favour simplicity, certainty, absence of all laceration of the genital tract, easy labour, quick recovery, and an improved fetal prognosis. On the other hand, once a Caesarean section is done, it will probably always have to be done in subsequent labours, because to get best results it must be done at the beginning of labour, and so no time can be given in which to see if the patient can deliver herself. Pubiotomy, on the other hand, is a smaller operation in a favourable case; in an unfavourable case it is a bigger operation. It tends to cause, and practically always does cause, a permanent enlargement in the pelvis, and this allows the patient in most cases to deliver herself spontaneously in subsequent pregnancies. On the other hand, it is prone to cause laceration and injury to the surrounding parts, labour is prolonged and painful, and the fetal prognosis is worse unless the condition of the fetus is carefully watched. The great advantage of pubiotomy is its effect on future pregnancies. In 19 cases operated on in the Rotunda Hospital by Dr. Tweedy or the author all the patients recovered, and in all the child was born alive. These 19 patients had had 29 labours prior to the performance of pubiotomy, 7 of the children being born alive and 22 dead. Subsequent to pubiotomy they had 15 labours, in which 12 children were born alive and 3 children were born dead, and 2 of these deaths were due to complications in no way associated with pelvic contraction. The author's general conclusion is that pubiotomy is preferable to Caesarean section in the second degree of contracted pelvis, unless there are special circumstances or complications present, and that perforation is only permissible when the child is dead.

LARYNGOLOGY, RHINOLOGY, AND OTOLOGY.

President: H. LAMBERT LACK, M.D., F.R.C.S., London. *Vice-Presidents:* J. M. BOOTH, M.D., C.M., Aberdeen; J. S. FRASER, M.B., F.R.C.S.E., Edinburgh; A. A. GRAY, M.D., F.F.P.S., Glasgow; T. H. LIVINGSTONE, M.D., F.R.C.S.E., Newcastle-on-Tyne. *Honorary Secretaries:* O. ST. J. GOGARTY, M.D., 15, Ely Place, Dublin; J. F. O'MALLEY, F.R.C.S., 16, Weymouth Street, London, W., H. PETERKIN, M.B., 17, Bon Accord Crescent, Aberdeen.

The following programme has been arranged provisionally:

July 29th.—Discussion on the Treatment of Inoperable Growths of the Nose and Throat. To be opened by Mr. W. D. HARMER (Diathermy), followed by Dr. WILLIAM HILL (Radium) and Dr. JOHN MACINTYRE (X Rays).

July 30th.—Discussion on Oto-sclerosis. To be opened by Dr. A. A. GRAY (Etiology and Pathology), followed by Mr. J. S. FRASER (Clinical Aspects), Mr. G. J. JENKINS (Various Methods of Treatment), and Mr. F. F. MUECKE (Auditory Re-education).

July 31st.—Mr. J. S. FRASER (Edinburgh): Demonstration—The Pathology of Labyrinthitis. Mr. WATSON-WILLIAMS (Bristol): Demonstration—Intranasal Operations for Frontal Sinus Disease. Dr. BROWN KELLY (Glasgow): Paper—The Difficulties and Dangers of Exploratory Puncture of the Antrum of Highmore.

The following is an abstract of Dr. GRAY'S opening paper on Oto-sclerosis:

Etiology: There are many contributory factors, but individual predisposition appears to be the most important factor. How this predisposition comes into existence is one of the chief problems of the future in the case of oto-sclerosis. *Pathological Anatomy:* The most obvious change is absorption of the dense bony tissue of the capsule of the labyrinth, associated as a rule with simultaneous deposition of new-formed porous bone. The diseased area is most commonly found immediately in front of the oval window. The sharp demarcation of the affected portion is one of the most characteristic features of the disease. In many cases the stapedio-vestibular synostosis is obliterated and the stapes becomes fixed to the walls of the oval window by bony union. In the early stages of the disease changes are not demonstrable in the sound-perceiving structures. In the later stages of the disease changes are usually found in the nerve structures.

Contributions for the division of the Museum set apart for preparations, specimens, drawings, and instruments relating to the work of the Section should be sent to Dr. Henry Peterkin, 17, Bon Accord Crescent, Aberdeen.

MEDICAL SOCIOLOGY.

President: JOHN GORDON, M.D., Aberdeen. *Vice-Presidents:* J. MUNRO MOIR, M.D., Inverness; DAVID NICOLSON, C.B., M.D., Camberley, Surrey; GEORGE WILLIAMSON, M.B., Aberdeen. *Honorary Secretaries:* DAVID RORIE,

M.D., 1, St. Devenick Terrace, Cults, Aberdeen; Dr. ANNE WATSON, 22, Waverley Place, Aberdeen.

The following programme has been arranged:

July 29th.—Discussion on the Responsibility of the State as regards Venereal Disease. To be opened by Dr. GEORGE ROBERTSON (Edinburgh), followed by Professor E. Pontoppidan (Copenhagen), and Drs. A. K. Chalmers, Louise McIlroy, and Lachlan Grant.

July 30th.—Discussion on (1) a State Medical Service *versus* a Panel System; to be opened by Sir JOHN COLLIE, followed by Drs. H. H. Miles, R. C. Buist, Lauriston Shaw, and Milson Rhodes. (2) Medical Certification (otherwise than in regard to Insanity); to be opened by C. SANDEMAN, Esq., K.C., followed by Drs. A. C. Farquharson and J. C. McVail.

July 31st.—Discussion on the Duty of the State towards the Early Environment of the Child. To be opened by Dr. LESLIE MACKENZIE (Edinburgh), followed by Drs. John Carswell and Thomas Dewar.

The following is a syllabus of Sir JOHN COLLIE'S opening paper:

The National Insurance Act is a form of State medical service. The principles of the construction of the Act. Quotation from the speech of the Chancellor of the Exchequer to the first meeting of the Advisory Committee. The scheme of medical benefit. The panel system chosen by the British Medical Association. Free choice of doctor: its obviously necessary limitations. Payment by attendance or by the capitation system. Own arrangements and contracting out. Advantages of panel or medical list system; limitation of State control to the minimum; preserving the best of the individualistic idea; preserving a healthy amount of competition. The curse of "institutionalism." Our national characteristics are against any mathematical "brigading" for any purpose. Irregular practice certain to follow any whole-time salaried system.

The following is a syllabus of Dr. MACKENZIE'S paper:

(1) *Ante-natal Care:* Enforcement of pre- and post-confinement rest periods. Relation of inefficient infancy to daily work of expectant mother. (2) *Birth:* Registration and training of midwives. Notification and registration of births and "dead" births. Refer to Dr. J. W. Ballantyne's paper on stillbirths. General enforcement of Notification of Births Act. Infant mortality in relation to defective environment of child or mother. (3) *Health Visiting:* Natural sequence of notification of births. Illustrations from Edinburgh system. Need for administrative nucleus of statutory health authority with organization of voluntary assistance. (4) *Infant Clinics and Milk Dépôts:* Reference to Dr. McLeary's book. French system of consultation centres and milk clinics. Restaurants for mothers; Coullet system. German organization. Crèches. (5) *Pre-School Age Clinics:* Duty of health authority. Danger of environmental influences in years between 1 and 5. Infections and their sequelae. Tuberculosis. Open-air homes. This brings infant forward to school age. (6) *General Measures:* Municipal pure milk supply. Housing; clearance of town and country slums; uncrowding of houses; improvement schemes; town planning. The statutory powers available for these objects.

MEDICINE.

President: F. J. SMITH, M.D., F.R.C.P., London. *Vice-Presidents:* J. R. CHARLES, M.D., F.R.C.P., Clifton, Bristol; G. MAITLAND EDMOND, M.D., C.M., Aberdeen; HERBERT FRENCH, M.D., F.R.C.P., London; Professor A. W. MACKINTOSH, M.D., Aberdeen; Professor T. K. MONRO, M.D., F.F.P.S., Glasgow; Professor A. M. STALKER, M.D., C.M., Dundee. *Honorary Secretaries:* D. BARTY KING, M.D., M.R.C.P., 6, Devonshire Street, Portland Place, London, W.; W. RATTRAY PIRIE, M.B., C.M., 20, Bon Accord Square, Aberdeen.

The following programme has been arranged:

July 29th.—Discussion on Headache: Its Causes and Treatment. To be opened by Dr. HARRY CAMPBELL.

July 30th.—Discussion on Artificial Pneumothorax in Pulmonary Tuberculosis. To be opened by Dr. RIST (Physician to the Laënnec Hospital, Paris).

July 31st.—Conjoint discussion on the Diagnosis of Chronic Pulmonary Tuberculosis in Infancy and Childhood. To be opened by Dr. D. B. LEES, Dr. CLIVE RIVIERE (Section of Diseases of Children), and Dr. IRONSIDE BRUCE (Section of Radiology).

Paper:

MCKENDRICK, J. S. (Glasgow). Splenectomy in relation to the Treatment of Anaemia.

Headache.—In opening the first discussion Dr. HARRY CAMPBELL will deal with the subject on the following lines: By headache is usually meant pain felt anywhere above the base of the skull. It is a symptom of many different morbid conditions acting singly or in combination, and the only classification of which headaches admit is one based upon causation. The various causes of headache may be grouped under three main heads: (1) Organic disease of the parts actually involved in the ache, such as meningitis and tumour; (2) irritation in other areas, as from eye-strain, diseases of the nasal passages, and accessory sinuses; (3) morbid states of the blood, as manifested by "plethora," anaemia, high blood pressure, abnormal urine, etc. These constitute much the most important causes of headache, and it is in the detection and removal of them that the skill of the physician is most severely put to the test.

Artificial Pneumothorax.—Dr. RIST, in opening the second discussion, will bring forward the following points: (1) *How should we select suitable cases for pneumothorax treatment?* And are such cases often met with? One-sided phthisis of an upper lobe, with cavity, which offers the best chances of success to the pneumothorax therapy, is a very common form of tuberculosis of the lung. It occurs seldom only to the physician who does not submit all his patients to an *x*-ray examination. But the pleuroscope discovers more cavities than the stethoscope. (2) *Is it advisable to attempt pneumothorax treatment in acute or subacute cases of cascous pneumonia?* In the author's opinion, although the chances of complete recovery are small, one very often succeeds in improving such cases in a remarkable way. (3) No doubt *pleural effusions* are the most important and the commonest complication of artificial pneumothorax. As a rule, they are of tuberculous nature. Some are very small, and can only be detected with the help of the pleuroscope. If they do not disappear rapidly, their volume generally increases, and they may be of very long duration. Although they are by no means an obstacle to the continuation of the treatment, they must be considered, in the author's opinion, as a rather unwelcome occurrence. The thickening and hardening of the visceral pleura, which is the unavoidable consequence of a long-lasting effusion, means the complete and permanent loss of the respiratory function for the compressed lung, which will never be able to expand again after the cure is completed. If such a lung was very extensively diseased when the treatment began, the function would have been lost anyhow. But if the greater part of the lung was in a sound condition, its permanent exclusion is a serious matter. This consideration weighs heavily against the pneumothorax treatment of so-called incipient cases. (4) Apart from its efficacy as a cure, artificial pneumothorax has put before us quite a number of highly interesting scientific problems, and at the same time provided us with the means of investigating some of them. The study of a series of cases of artificial pneumothorax with the pleuroscope throws unsuspected light on several physio-pathological problems; it has enabled us to discover many curious phenomena, such as Kienboeck's paradoxical movement of the diaphragm or the inspiratory displacement of the mediastinum or the increased amplitude of heart beats, which are of great physiological or physio-pathological importance.

Tuberculosis in Infancy and Childhood.—Dr. D. B. LEES has supplied the following abstracts of the remarks to be made by him in opening the third discussion: The susceptibility of young children to the infection of tuberculosis has long been known to the workers in children's hospitals. Of late the use of tuberculin as a test has given prominence to this subject, and *x*-ray examinations have contributed to our acquaintance with it. The object of this opening paper is to attempt to show that the diagnosis of chronic pulmonary tuberculosis in infants and young children can be effected by the ordinary methods of physical examination of the chest. Careful percussion of a patient in the proper position easily detects in cases of pulmonary tuberculosis a series of small dull areas at the apices and elsewhere, which recur regularly in case after case of this infection, and with a localization

which is limited to this disease. Over these areas there is usually a marked defect of air entry, but there may be no morbid sound heard on auscultation even when the dull areas are of large size. Six of these areas—two in the upper part of each upper lobe and one in the upper part of each lower lobe—correspond to the sites indicated by pathological observation (Fowler) as the earliest foci of pulmonary tuberculosis. In addition to these dull pulmonary areas a special area at the root of the lung (chiefly on the right side), due to enlarged bronchial glands, can sometimes be detected in tuberculous adults, especially in those who suffer from "asthma." X-ray examination confirms the existence of these dull pulmonary and glandular areas. They are important for prognosis as well as for diagnosis, and the six typical areas at the four apices ought to be carefully measured and their size recorded at regular intervals by a simple form of diagram. In children the clinical picture of chronic pulmonary tuberculosis is different from that in the adult, owing to the greater freedom of the lymphatic circulation in the young child and the consequent tendency of the tuberculous infection to spread along the peribronchial lymphatics to the bronchial glands at the root of the lung. In virulent infections or in cases with feeble resistance disastrous results may follow from pressure on the vagus or on the root of the lung, and the lung itself may be secondarily affected. The thickened bronchial tubes and swollen glands are easily seen by *x*-ray examination, but in order to avoid false inferences we must remember (1) that no sound conclusions can be based on a screen examination without a photograph; (2) that for a satisfactory photograph the apparatus must be of the very best and the exposure very short; (3) that even a first-rate photograph requires the utmost caution in its interpretation. A second cause of distortion of the clinical picture of chronic pulmonary tuberculosis in young children is their great liability to infection by many different microbes, each of which may produce bronchopneumonia and therefore dull areas in the lungs. Yet it is probable that the presence of the six dull apical areas characteristic of pulmonary tuberculosis is sufficient evidence either of a mixed infection or of the previous existence of tuberculosis in the child attacked.

Dr. CLIVE RIVIERE has supplied the following summary of his paper:

Chronic pulmonary tuberculosis only a curiosity in infancy. In childhood tuberculosis of thoracic glands nearly always clinically the first stage of disease, generally some secondary involvement of lung tissue; hence the name Hilus Tuberculosis. This adeno-pulmonary disease runs a different course to phthisis, with which it is apt to be confused; it requires a different prognosis, different treatment, and hence separate consideration under the head of diagnosis. Apical phthisis far less common in childhood. *Tuberculosis of Thoracic Glands: Hilus Tuberculosis:* Numerous special signs nearly all unreliable. Two signs of real value: one a characteristic physical sign over the lung, never accurately described in the past, and hence practically new; the other of necessity modern—examination with *x* rays. Differential diagnosis from phthisis. *Apical Phthisis in Children:* Diagnosis no more difficult than in adults save for the uncertainty of obtaining sputum. The most reliable physical signs obtained by gentle percussion, but the diagnosis dependent on a careful weighing of evidence derived from many signs and symptoms, none of which are alone pathognomonic.

NAVAL AND MILITARY MEDICINE AND SURGERY.

President: Surgeon-General WM. MAXWELL CRAIG, M.B.Ed., C.B., R.N., Haslar. *Vice-Presidents:* Surgeon-General P. H. BENSON, I.M.S., Upper Walmer; Brigade-Surgeon-Lieutenant-Colonel R. GRAY, I.M.S., Aberdeen; Major G. R. LIVINGSTON, M.D., R.A.M.C.(T.F.); Lieutenant-Colonel GEORGE SCOTT, R.A.M.C. (ret.), Aberdeen. *Honorary Secretaries:* Captain CECIL JOHNSON, R.A.M.C. (T.F.), Cricklewood, East Sheen, London, S.W; Lieutenant-Colonel FRANCIS KELLY, M.D., R.A.M.C.(T.F.), West Craibstone Street, Aberdeen.

The following programme has been arranged:

July 29th.—Discussion on (1) the Treatment of Wounded in Naval Warfare; to be opened by Fleet Surgeon D. WALKER HEWITT, R.N. (2) Gangrene in War; to be opened by Captain C. MAX PAGE, R.A.M.C.(S.R.).

July 30th.—Discussion on (1) the Treatment of Syphilis; to be opened by Lieutenant-Colonel T. W. GIBBARD, R.A.M.C., and Major L. W. HARRISON, R.A.M.C. (2) On Common Ailments in Camp: their Prevention and Treatment; to be opened by Captain C. JOHNSON, M.B., R.A.M.C.(T.F.).

July 31st.—A lecture, with limelight illustrations, on Experiences of the Northern Party of Captain Scott's Expedition, by Staff Surgeon G. MURRAY LEVICK, R.N.

The following synopses of the papers introductory of discussions in this Section have been supplied by their authors:

Fleet Surgeon WALKER HEWITT:

Treatment of Wounded in Naval Warfare.—Difficulties we have to contend with on board ship in our treatment of the wounded; comparison between ourselves in this respect and the Royal Army Medical Corps. Our medical arrangements and fighting efficiency. The first aid party and its duties; necessity for thorough training in carrying the wounded. First aid by the surgeons in the dressing stations *versus* treatment on the spot where the wounded fall by first aid party. The nature of the wounds and the question of haemorrhage and sepsis. Methods of conveying the wounded to the dressing stations illustrated. Preliminaries before going into action. The selection of the dressing stations in various classes of ships. The necessity for a specially trained first aid party on ships not carrying a medical officer. The question of a pure air supply to our dressing stations during action; suggestions as to the best means of averting the dangers of suffocating fumes to our wounded down below. The actual surgical treatment of the wounded on board the fighting ships and the question of "shock"; our duty to the minor as well as the serious cases. The question of speedy removal of the wounded after action and the necessity for the hospital ship.

Captain C. MAX PAGE:

Gangrene in War.—Consideration of types of gangrene which may be met with in war. General outline of treatment. Any distinction in type from the gangrene met with in average civil practice due to the youth and vigour of the subjects. In the Balkan war an apparently idiopathic symmetrical gangrene was frequently observed of a nature which had not been previously described. An account of the clinical phenomena of this condition as observed by the author and as reported by others. Its etiology probably similar to that of frostbite. Alternative suggestions. Treatment as practised and observed. Prophylactic considerations.

Lieutenant-Colonel T. W. GIBBARD:

Treatment of Syphilis: (1) Review of more important work relating to the treatment of syphilis during the year. (2) Comparison of results obtained at the Military Hospital, Rochester Row, with different methods of administering salvarsan. (3) Comparison of results obtained at Rochester Row with the best results obtained on the Continent. (4) Salvarsan-natorium.

Captain CECIL JOHNSON:

Common Ailments in Camp.—This paper is intended to open a discussion on the best means of preventing minor ailments in camp and at the same time to show how these ailments affect the members of the Territorial Force by causing the loss of one or more days' training. The remarks will be treated under two headings; (1) Modes of prevention before camp, (2) modes of prevention during camp. A plea will be put forward for a stricter medical examination of recruits and also that all recruits should be examined before camp by a regimental medical officer, and only in very special circumstances by a general practitioner not holding a commission in the R.A.M.C. It will be suggested that outside of the ordinary medical examination recruits should be refused on account of bad teeth and also on general and moral grounds. During camp the subject of clothes will be treated (especially socks and boots), food and drink, cleanliness of person and tents, removal of tents at least every seven days, means for drying clothes, etc. A "foot" inspection will be advocated and also an inquiry into the state of bowels on the second day with subsequent treatment, and the friendly co-operation of other officers shall be asked for in all the duties undertaken by the regimental medical officer.

NEUROLOGY AND PSYCHOLOGICAL MEDICINE.

President: F. W. Mott, M.D., F.R.C.P., F.R.S., London. *Vice-Presidents:* Donald J. Armour, F.R.C.S., London; James Neil, M.D., Oxford; William Reid, M.D., Aberdeen; H. Campbell Thomson, M.D., F.R.C.P., London. *Honorary Secretaries:* H. de Maine Alexander, M.D., Aberdeen District Asylum, Kingseat, Newmachar; M. D. Eder, M.R.C.S., L.R.C.P., 7, Welbeck Street, London, W.; A. W. Falconer, M.D., M.R.C.P., 18, Bon Accord Square, Aberdeen.

The following programme has been arranged:

July 29th.—Discussion on the Diagnosis and Treatment of Parenchymatous Syphilis. To be opened by Dr. F. W. Mott, followed by Dr. Plaut (Munich) and others.

July 30th.—Discussion on the Significance of the Unconscious in Psycho-pathology. To be opened by Dr. C. G. Jung (Zurich).

July 31st.—Independent papers:

Bruce, L. Campbell. Demonstration—The Pathology of Disseminated Sclerosis.
Hyslop, J. B. Anger in its Medico-Psychological Aspects.
Mackenzie, Dr. (Inverness). Some Considerations regarding Insanity in the Highlands.
Miller, Crichton. The Psychic Factor in Insomnia.
Turner, W. Aldren. Epilepsy and Brain Tumours.
Wilson, A. S. Kinnier. The Temporo-Sphenoidal Form of Epilepsy.

Dr. Mott's opening paper on the Diagnosis and Treatment of Parenchymatous Syphilis will be accompanied by a lantern demonstration and cover the following ground:

(1) The importance of the study of the pathology of general paralysis and tabes (in the light of recent researches) in respect to their diagnosis and treatment. (2) Syphilis a disease of the lymphatic system. The lymphatic systems of the brain and spinal cord in relation to the mode of entry of the spirochaetes or their toxins into the central nervous system. The cerebro-spinal fluid, a secretion of the choroid plexus, in relation to the pathology of parenchymatous syphilis. The importance of the condition of the fluid in relation to diagnosis and treatment. (3) The existence of spirochaetes in the central nervous system in relation to the pathology of parenchymatous syphilis. The infection of the central nervous system, the evidence of its occurrence, the time of its occurrence, latency. Personal observations on a series of 100 cases of general paralysis, in which spirochaetes were found in the brains in 65 per cent. (4) The correlation of cortical spirochaetosis with the morbid histological changes and phenomena of neuronic irritation and destruction, with their attendant clinical signs and symptoms. (5) Experiments on animals in relation to the therapeutic action of mercury and arseno-benzol compounds. (6) Theories regarding the causation of parenchymatous syphilis: (*a*) Modification of the spirochaete and evidence thereof; (*b*) the hypersensibility of the neurones; (*c*) a lowered resistance of the neurones. (7) Neurorecidive, or Herxheimer's reaction in relation to treatment by salvarsan. (8) Recent developments in the treatment of parenchymatous syphilis by intrathecal injection of salvarsanized serum and of hypertonic solution of neo-salvarsan. The results in general paralysis.

OPHTHALMOLOGY.

President: C. H. Usher, M.B., F.R.C.S.Edin., Aberdeen. *Vice-Presidents:* A. R. Galloway, M.B., C.M., Aberdeen; Karl A. Grossmann, M.D., F.R.C.S., Liverpool; N. Bishop Harman, M.B., F.R.C.S., London; A. H. H. Sinclair, M.D., F.R.C.S.Edin., Edinburgh. *Honorary Secretaries:* F. R. Hill, M.B., C.M., 62, Warwick Road, Carlisle; Miss Euphan M. Maxwell, M.B., 19, Lower Baggot Street, Dublin; W. Clark Souter, M.D., 2, Bon Accord Square, Aberdeen.

The following programme has been arranged:

1. Discussion on the Choice of a Cataract Operation. To be opened by Mr. E. E. Maddox.

2. Discussion on the Hygiene of Reading and Near Vision. To be opened by Mr. J. Herbert Parsons.

3. Discussion on the Teaching of Ophthalmology to Medical Students. To be opened by Dr. Maitland Ramsay.

In his opening paper Mr. Maddox will submit two questions for debate: (1) Is it better for each surgeon to keep to one mode of operating so as to acquire the greatest facility in its performance, or is it better to vary the character of operations to suit the needs of individual patients? (2) In the latter case, what are the indications which should guide us in selecting the appropriate operation for each patient? The chief desiderata in the selection of a cataract operation are (1) safety, (2) visual result, (3) beauty of eye, (4) brevity of procedure, (5) fewness of operative interferences. (1) *Safety* holds the premier place. The bearing upon it of a conjunctival flap, of a Desmarre's bridge (1851), and of suturing after simple extraction will be considered, also the dangers of lavage apparatus. A simple device will be shown. The habit of doing a preliminary iridectomy whenever simple extraction is not contemplated makes for safety. A mode of doing it with the minimum of traumatism will be advocated, and a keratome for the purpose shown. (2) *Visual result* comprises (*a*) vision with test types under optical correction, (*b*) vision without correction (*c*) post-operative astigmatism. Each of these factors deserves attention. (3) It is important to preserve *beauty of the eye* in certain cases by securing a circular pupil, especially if the iris be light-coloured and well exposed in a comparatively youthful patient. In later life the drooping of the lid renders this consideration unnecessary. (4) *Brevity of procedure;* the self-control of some patients is extremely short. For these a limbal incision after a preliminary iridectomy may be best, being the briefest, especially if the capsule be opened by the knife during the incision, or else Horner Smith's procedure be done. (5) *Fewness of operative interferences;* here intracapsular operations lead the way, since they entirely obviate the necessity of needling for after-cataract. Failing an intracapsular extraction, "simple" or "combined extraction" may be chosen, with or without simultaneous or early division of the posterior capsule. Four conclusions: (1) A simple extraction, subconjunctivally performed, with a small mobile pupil and the capsule split opposite thereto, exhibits the greatest boon surgery can confer upon an eye. In addition to its beauty it enables the patient to walk in the street without spectacles, if need be. Its consideration should not be omitted when a quiet amenable patient, not too old, presents a mature, uncomplicated cataract. Prolapse of the iris can be guarded against by suturing the flap or by a Desmarre's bridge. (2) Failing simple extraction, a preliminary iridectomy should be done whenever practicable. (3) Failing both (1) and (2), combined extraction should next be considered, with either a limbal incision or a conjunctival flap. (4) Lastly, intracapsular operations should only be done under the best conditions of assistantship and (if among the white races) in a certain class of patients only. These operations present advantages and disadvantages.

PATHOLOGY AND BACTERIOLOGY.

President: W. S. Lazarus-Barlow, M.D., F.R.C.P., London. *Vice-Presidents:* C. H. Benham, M.D., M.R.C.P., Hove; Charles Bolton, M.D., F.R.C.P., London; J. C. G. Ledingham, M.B., Ch.B., London; J. H. Teacher, M.B., F.F.P.S., Glasgow. *Honorary Secretaries:* G. Mellis Duncan, M.B., C.M., 12, Bayview Road, Aberdeen; J. F. Gaskell, M.D., M.R.C.P., 23, Ladbroke Grove, London, W.; J. W. Trevan, M.D., B.S., St. Bartholomew's Hospital, London, E.C.

The following programme has been arranged:

July 29th.—Discussions on (1) the Action of Radiations on Cells and Fluids; to be opened by the President. (2) The Biochemistry of Immunity Reactions; to be opened by Dr. Carl Browning, followed by Drs. J. H. Thicle, J. Cruickshank, and Mr. Mackenzie Wallis.

July 30th.—Joint discussion on the Pathology of Heart Function (see Section of Pharmacology).

July 31st.—Discussion on the Importance of Variability among Bacteria and its Bearings on Diagnosis. To be opened by Dr. W. J. Penfold.

Papers:

Hort, E. C. Recognition of Haemic Infections of the Urine and its Diagnostic Value.
Morgan, J. M., and Teacher, J. H. Aneurysm of the Aorta due to Bacterial Infection.

In his opening paper Dr. Lazarus-Barlow deals with his subject on the following lines:

The great potency of radium and its widespread distribution suggest that the beneficial results in medicine

which have been ascribed to its action in minute quantities may be real. Nevertheless, definite scientific grounds for such a view are almost completely wanting, and the object of the discussion is, on the one hand, to formulate some idea of the facts in our possession; but even more, on the other hand, to indicate the wide field for fruitful research that is unexplored. It is known that with relatively large doses of (radium) radiations the nucleus is the part of the cell in which the most obvious modifications are seen; that paraplastic cell substances (Altmann's granules) may be modified by exposure to alpha radiation; and that starch may be converted into dextrin by *x* radiation. These facts indicate that cell metabolism may be profoundly altered by radiations, but the limits of such alteration are unknown. At first it was assumed upon physical grounds that alpha, beta, and gamma radiations would act similarly upon cells if due account were taken of their different contents of energy and range; but there is some evidence that this is not the case, specific types of rays being associated with special types of pathological change. From the more definitely remedial side there is a small amount of evidence that radium radiations can act beneficially on cell life, and a greater reason for believing that certain quantities can stimulate cell multiplication. But whether under the conditions all the activities of the cell are improved so that an intrinsically better type of cell results, or whether one function of the cell is exalted at the expense of others, is unknown. Hence there is room for a very large amount of work upon the effect of radiations in all branches of biological science, and particularly in vegetable and animal physiology and physiological chemistry.

Dr. W. J. PENFOLD will show that from recent studies it emerges that not only fermentation power but also all culture and serum reactions are subject to variation. This variation and selection have been shown to occur within the body in the course of infection, while in the laboratory the precise factors in the environment effecting the selection have been individually examined. It will be shown that the facts so far established on the subject affect: (*a*) bacterial classification; (*b*) the recognition of bacteria, the standards adopted by the hygienist, epidemiologist, and the clinical bacteriologist; (*c*) the vaccinist, whether he be engaged in immunizing patients or in producing serums for passive immunization.

PHARMACOLOGY, THERAPEUTICS, AND DIETETICS.

President: Professor J. THEODORE CASH, M.D., LL.D., F.R.S., Aberdeen. *Vice-Presidents:* F. J. CHARTERIS, M.D., Glasgow; O. F. F. GRÜNBAUM, M.D., F.R.C.P., London; J. C. MCWALTER, M.D., Dublin. *Honorary Secretaries:* W. J. DILLING, M.B., Ch.B., Materia Medica Department, Marischal College, Aberdeen; J. M. FORTESCUE-BRICKDALE, M.D., 52, Pembroke Road, Clifton; J. DAVENPORT WINDLE, M.D., Cippenham Lodge, Southall.

The following programme has been arranged:

July 29th.—Discussion on Recent Advances in the Relationship between Chemical Constitution and Pharmacological Activity. To be opened by Dr. FORTESCUE-BRICKDALE.

July 30th.—Joint discussion on the Pathology of Heart Function, including the Experimental Pharmacology and Therapeutics of Pathological Conditions of the Heart. To be opened by Dr. THOMAS LEWIS, followed by Sir James Barr and Dr. J. Mackenzie.

July 31st.—Discussion on the Pharmacology and Therapeutics of the Animal Extracts, exclusive of Thyroid Extract. To be opened by Professor NOEL PATON (Physiology) and Dr. O. F. F. GRÜNBAUM (Therapeutics).

Papers:

GUNN, J. A. The Pharmacology of the Isolated Human Uterus and Fallopian Tubes.
MCWALTER, J. C. Notes on Cerii Oxalas.
MUTHU, J. Chowry. Clinical Observations on Diet in the Treatment of Pulmonary Tuberculosis.

The following is an abstract of Dr. FORTESCUE-BRICKDALE'S opening paper:

Although the pharmacological action of any substance introduced into the body must ultimately depend upon its chemical structure, and all implied in that term, yet at present it is only with regard to the simplest chemical bodies that any deductions as to pharmaco-dynamical properties can be made from a consideration of their structural formulae alone. The action of complex substances—for example, the alkaloids—can only be determined experimentally in each case, though a new body having close structural analogy to one of known action would probably act in a similar manner. The difficulties in correlating structure and action are great, and arise mainly from the biological side. We are ignorant of the way in which molecules as a whole act on protoplasm, and have little knowledge of the underlying causes of selective action. As an introduction to this discussion we may summarize our knowledge of the way in which chemical structure directly or indirectly influences pharmacological action in the following way. It must be understood that changes in structure considered in this way only include such alterations as lead to new bodies chemically comparable with the first. Alterations in chemical structure may affect the pharmacological action of a substance, (*a*) by altering its behaviour before absorption, that is, in the alimentary canal; (*b*) by altering its general or special reactivity as regards body cells and fluids after absorption. These two headings may be subdivided as follows: (*a*) The behaviour of a body in the alimentary canal may be changed by alterations (i) in its physical properties, for example, solubility, (ii) in its chemical properties, for example, its reaction to acids and alkalis; (*b*) after absorption or after intravenous or hypodermic injection the physiological action of a substance may be altered (i) by alterations involving changes in its physical properties, such as its solubility in body fluids or its degree of dissociation in solution, (ii) by changes in structure leading to more or less easy synthesis, reduction, or oxidation, (iii) by changes in the outlying parts of the molecule which affect its special reactivity with certain cells in the body—that is, by changes (*a*) in the composition, (*β*) in the position of the side chains or reactive atomic groups, (iv) by profound changes in its essential molecular arrangement which may affect its special or general reactions with cells or organs. Such changes fall into two groups, both relating to the special relations of the atoms, namely (*a*) changes in valency, (*β*) stereo-isomeric changes.

STATE MEDICINE AND MEDICAL JURISPRUDENCE.

President: Professor MATTHEW HAY, M.D., LL.D., F.R.C.P.I., Aberdeen. *Vice-Presidents:* E. LEE COLLIS, M.B., B.Ch., London; Professor F. W. EURICH, M.D., Bradford; W. HABGOOD, M.D., Sutton; W. LESLIE MACKENZIE, M.D., F.R.C.P., LL.D., Edinburgh. *Honorary Secretaries:* R. BALFOUR GRAHAM, F.R.C.S.E., Leven, Fife; W. ALEXANDER MACNAUGHTON, M.D., County Buildings, Stonehaven, Kincardineshire; FRANK E. ROCK, M.D., Town Hall, Edmonton, N.

The following discussions have been arranged:

1. On Death Certification. To be opened by Sir VICTOR HORSLEY.

2. On Malingering. To be opened by Sir JOHN COLLIE.

3. On the Period and Duration of Infectious Disease. To be opened by Dr. J. H. BUCHAN.

4. On the Administrative Treatment of Tuberculosis. To be opened by Dr. J. T. WILSON (the county standpoint) and Dr. A. S. M. MACGREGOR (the city standpoint).

The following papers have been accepted:

BUSHNELL, F. G. The Administrative Control of Tuberculosis and the Public Health Minister, Department, and Service.
CHALMERS, A. K. Certification of Births and Deaths.
CHILDE, C. P. The Advisability of suitable Steps being adopted by the State and by Municipal Authorities to secure the Earlier Treatment of Persons suffering from Cancer.
COLLIE, Sir John. Thirty-one Thousand Consecutive Medical Examinations conducted chiefly for the Public Service.
CROFTON, W. M. Preventive Inoculation of Tuberculosis, and the Possibility of this on a Large Scale.
ESSLEMONT, J. E. Garden Cities for Consumptives.
GUY, J. The Causes of the Fall in the Tuberculosis Death-rate.
JESSELL, G. The Organization and Management of a Tuberculosis Dispensary.
LEDINGHAM, J. O. G. The Experimental Aspect of the Carrier Problem, with special reference to Typhoid Fever.
MACRAE, Farquhar. Anaphylaxis in the Antitoxin Treatment of Diphtheria.
MCWALTER, J. W. The Necessity of Reforming the Coroner's Inquest.
MILNE, R. The Prevention of Infectious Disease.
MUTHU, Chowry D. J. Tuberculosis in India.
PREST, E. E. Sanatorium Benefit and the Position of Sanatoriums in their Relation to the Treatment of Chronic Cases of Pulmonary Tuberculosis.

Ross, E. H. Intracellular Parasites in Acute Measles and Scarlet Fever.
Thomson, H. H. The Care and Control of the Tuberculosis Patient as an Individual.
Wynne, F. E. Death Certification, with some Criticisms on the International List of Causes of Death.

SURGERY.

President: J. Scott Riddell, M.V.O., M.B., C.M., Aberdeen. *Vice-Presidents:* J. Grant Andrew, C.M., F.R.F.P.S., Glasgow; Arthur Connell, F.R.C.S.E., Sheffield; W. McAdam Eccles, M.S., F.R.C.S., London; T. Eagleson Gordon, F.R.C.S.I., Dublin; Professor John Marnoch, M.B., C.M., Aberdeen; Alexander Miles, F.R.C.S., Edinburgh. *Honorary Secretaries:* G. H. Colt, F.R.C.S., 12, Bon Accord Square, Aberdeen; Rupert Farrant, F.R.C.S., 59, Queen Anne Street, London, W.; J. M. Graham, F.R.C.S.E., 5, Castle Terrace, Edinburgh; S. Thompson Irwin, M.Ch., F.R.C.S.Edin. 29, University Square, Belfast.

The following programme has been arranged:

Wednesday, July 29th.—Discussion on the Etiology and Treatment of Carcinoma of the Tongue. To be opened by Mr. W. G. Spencer, followed by Professor H. Morestin of Paris, and a demonstration by Professor J. K. Jamieson and Mr. J. F. Dobson (see below).

Thursday, July 30th.—Discussion on the Surgical Treatment of Arthritic Deformities. To be opened by Mr. Robert Jones.

Friday, July 31st.—Discussion on Anoci-association, or the Evolution of the Shockless Operation. To be opened by Mr. H. M. W. Gray.

Papers.—The following papers have been accepted:

Boyd, Sidney A. The Newer Indications for Removal of the Spleen.
Don, A. Pott's Disease in Cervical Region, with Methods of Bony Splinting.
Edington, G. H. A Method of Opening the Abdomen for Appendicectomy.
Gordon, T. E. Duodenal Haemorrhage.
Gunn, J. A. The Action of Certain Drugs on the Isolated Human Vermiform Appendix (with a demonstration).
Hey Groves, E. W. A Simple Form of Bed-rest for Maintaining the Fowler Position (with a demonstration).
Jamieson, Professor J. K., and Dobson, J. F. The Lymphatics of the Tongue (with a demonstration of specimens prepared by Gerota's method).
Milligan, William. Some Practical Considerations in the Diagnosis and Treatment of Abscess of the Cerebellum, with a record of cases subjected to operation.
Page, C. Max. The Treatment of certain cases of Appendix Abscess.
Rowell, H. S. Mechanical Considerations of the Human Foot, with special reference to Flat-foot.
Russell, R. Hamilton. The Treatment of Urethral Structure by Excision.
Wheeler, W. I. de C. A further report on Three Cases of Abdominal Aneurysm treated by Operation.
Wilkie, D. P. D. Acute Appendicitis and Acute Appendicular Obstruction.

TROPICAL MEDICINE.

President: Professor W. J. R. Simpson, C.M.G., M.D., London. *Vice-Presidents:* Daniel E. Anderson, M.D. Lond. and Paris, B.Sc., F.R.S.E., London, W.; J. Mifford Atkinson, M.B., London; Henry Fraser, M.D., Kuala Lumpur, Federated Malay States. *Honorary Secretary:* G. A. Williamson, M.D., 15, Forest Road, Aberdeen.

The following programme has been arranged:

Wednesday, July 29th.—Discussion on Kala-azar and Allied Conditions. To be opened by Fleet Surgeon P. W. Bassett-Smith.

Thursday, July 30th.—Discussion on the Education and Position of the Sanitarian in the Tropics. To be opened by Colonel King, I.M.S., C.I.E.

Friday, July 31st.—Discussion on the Surgical Treatment of Colitis and Post-Dysenteric Conditions. To be opened by Mr. James Cantlie.

Papers:

Bahr, P. H. Recent Researches in Sprue.
Birt, Colonel C., A.M.S. Sand-Fly Fever.
Fraser, H., and Stanton, A. T. The Rice Theory and Recent Conclusions.
MacCallan, A. F. The Ankylostomiasis Campaign in Egypt.
Marett, Captain P. J., R.A.M.C. The Bionomics of Maltese Phlebotomi.

A Special Subsection of the Museum is being reserved for exhibits in Tropical Medicine, and the Pathological Museum Committee, Marischal College, will be glad to hear as soon as possible from intending exhibitors, and will later forward information as to packing, insurance of exhibits, etc., the expense of which will be borne by the Association.

Honorary Local Treasurer—
George Williamson, M.B.,
256, Union Street, Aberdeen.
Honorary Local Secretaries—
Thomas Fraser, M.B.,
16, Albyn Place, Aberdeen.
Fred. K. Smith, M.B.,
7, East Craibstone Street, Aberdeen.

PROVISIONAL PROGRAMME.

The following is the provisional time-table for the Aberdeen Meeting:

Friday, July 24th.

10 A.M.—Annual Representative Meeting.

Saturday, July 25th.

9.30 A.M.—Representative Meeting.

Monday, July 27th.

9.30 A.M.—Council Meeting.
10 A.M.—Representative Meeting.

Tuesday, July 28th.

9 A.M.—Exhibition of Surgical Instruments, Drugs, etc. The Exhibition will remain open until 6 p.m. on this and the three following days.
9.30 A.M.—Representative Meeting.
2 P.M.—Annual General Meeting.
*8.30 P.M.—Adjourned General Meeting, President's Address.

Wednesday, July 29th.

9 A.M.—Religious Services.
10 A.M. to 1 P.M.—Sectional Meetings.
12.30 P.M.—Address in Medicine.
2.30 P.M.—Secretaries' Conference, followed by Dinner.
3.30 P.M.—Garden Party by Town Council in Duthie Park.
*8.30 P.M.—Reception by University in Marischal College.

Thursday, July 30th.

9 A.M.—Council Meeting.
10 A.M. to 1 P.M.—Sectional Meetings.
12.30 P.M.—Address in Surgery.
* 7.30 P.M.—Annual Dinner.

Friday, July 31st.

9 A.M.—Council Meeting.
10 A.M. to 1 P.M.—Sectional Meetings.
12.30 P.M.—Graduation Ceremony in Marischal College.
6 P.M.—Annual Exhibition closes.
8 P.M.—Popular Lecture, Marischal College.
*8.30 P.M.—Reception by Branch (Music Hall).

Saturday, August 1st.

Excursions.

* Academic dress or uniform should be worn on these occasions. Members desiring to have robes provided for them at Aberdeen should communicate with Messrs. Ede, Son and Ravenscroft, 93 and 94, Chancery Lane, London, W.C.; Mr. William Northam, 9, Henrietta Street, Strand, London W.C.; or Messrs. L. Y. and J. Nathan, 4, Hardman Street, Liverpool.

PATHOLOGICAL MUSEUM.

The Committee of the Pathological Museum, organized in connexion with the Annual Meeting, proposes to arrange the material under the following heads:

1. Exhibits bearing on discussions and papers in the various sections.

2. Specimens and illustrations relating to any recent research work.

3. Instruments relating to clinical diagnosis and pathological investigation.

4. Individual specimens of special interest or a series illustrating some special subject.

It is also proposed to make an effort to gather together series of exhibits relating to the pathology of the circulatory

system and the ductless glands; the effect of radium on malignant growths; pyelo-radiography and *x*-ray photographs of brain, skull, and gall stones, and of ancient and historical surgical instruments.

While making these suggestions the Committee, of which Dr. G. M. Duncan is chairman, will welcome specimens illustrating other subjects. The Museum will occupy a central position in the same building as that in which the sectional work is to be carried on.

Communications may be addressed to the honorary secretaries, Dr. A. W. Falconer and Mr. William Anderson, F.R.C.S., Pathological Department, Marischal College, Aberdeen.

RECEPTION ROOM.

THE reception room will be open during the annual meeting in the Advocates' Hall, Broad Street, Aberdeen, and members are advised to call there as soon as possible after their arrival in Aberdeen. They will there find full information at their disposal and will be able to obtain a copy of the daily journal.

ACCOMMODATION IN ABERDEEN.

A LIST of hotels and lodgings available in Aberdeen during the Annual Meeting is published in the advertisement pages (10 and 11) of this issue. Members desiring further information on this subject are asked to communicate with Dr. F. Philip, Honorary Secretary of the Hotels and Lodgings Committee, 29, King Street, Aberdeen.

At a recent meeting of the General Committee, consisting of influential citizens, the intention to give a hearty welcome to members of the Association was made evident, and a very large amount of private hospitality is likely to be offered. The Local Executive Committee hopes that members will not be led by the answers they may get from some of the hotels to suppose that the accommodation available in Aberdeen is filled up; any member who has difficulty in finding accommodation should not hesitate to communicate either with Dr. F. Philip, as above, or with Dr. Thomas Fraser, one of the honorary local secretaries, at the same address.

RELIGIOUS SERVICES.

THE annual service for the Association will be held in the West Parish Church of St. Nicholas (Church of Scotland) at 9 a.m. on Wednesday, July 29th. At the same hour a Roman Catholic service will be held in St. Mary's Cathedral, and a service of the Episcopal Church in Scotland in the Cathedral Church of St. Andrew's.

ANNUAL EXHIBITION.

THE annual exhibition of surgical instruments, drugs, foods, etc., held during the annual meetings of the British Medical Association, will be arranged this year in the Marischal College, where also the Sections will meet, where the General and Representative Meetings of the Association will take place, and where the Addresses in Medicine and Surgery will be delivered. The exhibition on this occasion will, therefore, occupy a central and convenient position, and members will have an excellent opportunity of inspecting the exhibits.

THE JOURNEY TO ABERDEEN.

Special Vouchers.—Railway facilities similar to those offered in previous years will be available this year—that is to say, return tickets, valid from July 22nd to August 3rd, will be issued at a single fare and a third on the presentation of a voucher, which will be supplied, to members who intend to go to Aberdeen, by the Financial Secretary and Business Manager, British Medical Association, 429, Strand, London, W.C., on receipt of the notification form. A separate voucher is required for each passenger.

Tourist Tickets.—The attention of those who intend to travel to Inverness or other places north of Aberdeen is drawn to the tourist ticket arrangements. The advantage of a tourist ticket is that it is available for six months, and the holder has the privilege of breaking the journey at many places *en route*. The tourist ticket from London to Inverness costs £3 3s., third class. In many instances a member travelling from England may find it more advantageous to take a tourist ticket than to make use of the special voucher.

London to Aberdeen by Sea.—Members travelling from the south may like to be reminded that they can make the journey from London by sea. The boats of the Aberdeen Steam Navigation Company, which are lighted by electricity and in every way well appointed, sail from Aberdeen Wharf, Limehouse, E., every Wednesday and Saturday (see advertisement, page 14). The return fares, available for six months, are—first cabin 45s., second cabin 25s.; private cabins can be obtained for an extra fee. A boat will leave on Wednesday, July 22nd, at 11 a.m., and on Saturday, July 25th, at 1 p.m. Further particulars will be published or can be obtained on application to the company at Aberdeen Wharf, Limehouse, or the City Passenger Agency, 25, Cannon Street, E.C.

RAILWAY FACILITIES FOR MEMBERS STAYING IN THE NEIGHBOURHOOD OF ABERDEEN.

DURING the meeting reduced fares, with a minimum of 1s., will be granted to places within a radius of fifty miles from Aberdeen. Members who propose travelling to and from Aberdeen daily should use the first half of the ticket on the first journey and the return half on the last journey; the reduced fares for the intermediate journeys will be granted on production, at the time of booking, of the card of membership.

Weekly Season Tickets.

Members staying at Banchory or Cruden Bay can obtain season tickets enabling them to travel to and from Aberdeen daily during the week of the annual meeting at the following rates: Cruden Bay, 10s.; Banchory, 8s. 8d. The season tickets will be issued from intermediate stations at proportional rates.

On the Caledonian Railway to Stonehaven and intermediate stations, during the meeting, return tickets will be issued at Aberdeen to places where members wish to reside. These tickets will be available for the day of issue or following day, or from Saturday to Monday, at a single fare and a third for the double journey, minimum 1s. Season tickets are also available for more than one journey, at a charge of not less than the accumulated fares per day as above, the minimum being 1s. a day.

GOLF COURSES AT ABERDEEN AND IN ITS VICINITY.

Balgownie.—The course of the Royal Aberdeen Golf Club. A seaside links course of over 6,000 yards in length, and well known as one of "The Best Courses." The Ulster Cup competition will be played on these links. Water is laid on to the putting greens. There is a large and commodious club-house. The course is of the out-and-home variety, and "bogey" varies from 78 on a calm day to a more difficult 80 with a stiff north-easter. The amateur record is 76, the professional 73. Golfing members of the British Medical Association have been made honorary members of the club from July 24th to 31st.

The course can be reached by tramway car to the Bridge of Don or by taxi. There is also an adjacent relief course of nine holes, which is the course of the Aberdeen Ladies' Golf Club.

Murcar.—This course is on the same stretch of coast as Balgownie, which it adjoins. It can be reached by the club motor bus running on rails from the brickworks close to the entrance road leading to Balgownie. Car to Bridge of Don as before. The course is of good quality, but shorter than Balgownie. Sunday golf without caddies. (Visitors 1s. 6d. a day; 2s. 6d. on Saturdays and Sundays.)

Bieldside.—The inland course of the Deeside Golf Club can be reached by train to Bieldside station, which it immediately adjoins, by tramway car or motor. This is a very good inland course of eighteen holes; the lies through the green are excellent, and the putting greens in good condition. The club-house adjoins the first tee. (Visitors 1s. 6d. per day, 5s. a week.)

Balnagask.—This course is on the sea coast immediately south of Aberdeen harbour, and is easily reached by the Torry tramway or by motor. The soil and turf is not of the regular seaside type, being more of the inland variety. There are eighteen holes of no great length; a club-house adjoins the links. (Visitors 1s. a round, 1s. 6d. per day, 5s. per week.)

Public Links.—These can be reached by car, and are nearest to the town. There are eighteen holes, but the course is on the short side, and suffers from overcrowding.

Aboyne.—This inland 18-hole course is 32 miles from Aberdeen. It is reached by train to Aboyne or by motor. The turf is splendid and the surrounding scenery delightful. A club-house is attached. The council of the Aboyne Golf Club has agreed to offer honorary membership to members attending the annual meeting on production of their membership card.

Cruden Bay.—One of "The Best Courses." Thirty miles from Aberdeen by train or road. A delightful course, with fine sea views. There are many good sporting holes, and the putting greens are always in good condition. A first-class hotel, under the management of the railway company, immediately adjoins the links, and the Kilmarnock Arms Hotel in the village can be highly recommended. Sunday golf without caddies. The links belong to the railway company, and the charge is 1s. 6d. a day (2s. on Sunday), 1s. a day to visitors staying at the railway company's hotel.

Banchory.—Inland course, sixteen miles from Aberdeen, rail or motor. Free to members of the Association on production of membership card.

ARRANGEMENTS FOR LADIES.

A COMMITTEE of ladies has been formed to look after the comfort and interests of ladies accompanying members to Aberdeen. The Aberdeen Medico-Chirurgical Society has granted the use of its rooms at 29, King Street, as reception rooms for ladies from July 24th to 31st. There will be provided a rest-room, a writing-room, a tea room, and a dressing room. There will also be an office in the building where information regarding ladies' entertainments and motor drives will be given and tickets supplied. A member of the Ladies' Committee has given the use of her flat at 245, Union Street, where ladies living out of the town may dress for the evening entertainments. It is hoped that a corps of lady guides will be available for the assistance of visitors.

Provisional Programme of Entertainments for Ladies.

Games.—Several tennis clubs have given the use of their courts. All ladies who are members of recognized golf clubs will be made honorary members of the Aberdeen Ladies' Golf Club (Balgownie). A golf match will be arranged for Thursday afternoon, July 30th, between lady visitors and the Aberdeen Ladies' Golf Club, also a putting and approaching competition on Friday, July 31st, at Balgownie at 10 a.m. Those who wish to enter for these competitions are requested to send their names and handicaps (L.G.U. if possible) as soon as possible to Miss Westland, 22, Albyn Place.

Entertainments.—Tuesday morning, July 28th: A visit to the Art Gallery—limited to 35. Wednesday morning, July 29th: Concert, including bagpipe playing and Highland dancing, etc., in the Music Hall Buildings. Thursday morning, July 30th: A descriptive tour through Old Aberdeen, with visits to St. Machar's Cathedral and King's College—limited to 35.

Visits to Institutions.—Conducted parties can visit the following educational, charitable, and philanthropic institutions: The Day Nursery, the Church of Scotland Home for Working Boys, the Home for Working Girls, the Maternity Hospital, the Morningfield Hospital for Incurable Diseases, the Oakbank Industrial School for Boys, and the Home for Widowers' Children.

Short Motor Drives for Ladies.—On the mornings of Wednesday, Thursday, and Friday (July 29th, 30th, and 31st) private motor cars have been offered to take a party of ladies to the following places: Wednesday, Drum Castle; Thursday, Crathes Castle; Friday, Muchalls Castle. Permission has kindly been granted to visit these places of historical interest. Ladies desirous of availing themselves of these drives are requested to inform Miss Grainger Stewart, Glendee Cottage, West Cults, Aberdeenshire, before July 24th if possible.

EXCURSIONS.

IT is the hospitable custom of members residing in or near the town in which the annual meeting of the British Medical Association is held to arrange that opportunities should be afforded to visiting members to see the town and its immediate neighbourhood, and also to plan excursions to more distant places within easy reach.

Aberdeen and the North of Scotland will not be backward in following this example, and those who are making such arrangements have, indeed, probably suffered from an embarrassment of choice, inasmuch as within reach of Aberdeen there is much beautiful river, mountain, and loch scenery. We give below some particulars of the provisional arrangements so far made, but this information must be prefaced by the general observation that the meeting falls at a season when the beauty spots of Northern Scotland are beginning to be crowded, and that it is therefore essential that members should as far as possible make up their minds early in regard to the excursion or excursions they wish to take, and notify their intention to the Secretary, Mr. G. H. Colt, F.R.C.S., 12, Bon Accord Square, Aberdeen, at once.

The Committee will have to make arrangements for travelling facilities, catering, etc., with the railway companies and hotels, and all these arrangements must be made in advance. In the case of certain excursions the number must be limited and places will be assigned in order of application. A special office will be open in the reception rooms in Aberdeen and will be provided with time-tables, programmes, and guide-books, containing full information as to the many places of interest which may be visited from Aberdeen. The railway companies will make special concessions, but members of the Association should note that they must produce their tickets of membership when booking in Aberdeen for any excursion.

The following arrangements have been made:

FOR REPRESENTATIVES.

The Annual Representative Meeting begins on Friday, July 24th, and will no doubt be continued on Saturday, July 25th. Arrangements have been made by members in Aberdeen for running a special train to Cruden Bay on Sunday, July 26th, leaving Aberdeen in the morning and returning the same evening. Slain's Castle, Bullers o' Buchan, and Whinnifold, the scene of Bram Stoker's *Mystery of the Sea*, and a fine golf links are all within walking distance. Luncheon can be taken at the hotel at Cruden Bay, and Representatives who wish to make this excursion are particularly requested to send their names to Mr. Colt as early as possible.

SHORT EXCURSIONS FROM ABERDEEN.

Deeside and Donside may both be seen on any one day by a circular tour through Alford to Strathdon and Ballater, and so back to Aberdeen. The excursion will occupy the whole day, starting at 8.5 or 9.30 a.m., and arriving back in Aberdeen at or about 7 p.m. The journey from Alford to Ballater will be made by motor car, and it is therefore essential that adequate notice should be given. The fares for the round are: First class, 12s.; third class, 9s.

The following half-day excursions may be taken on either Wednesday, July 29th, or Saturday, August 1st:

To Speyside, returning from Garten.—The train will leave at 1 p.m., and luncheon will be served on it for a limited number. The party will reach Aberdeen on the return journey at 10.32 p.m. Fare 2s. 6d.

To Ballater at 1.15 p.m., including coach drive to Balmoral. Aberdeen will be reached at 10 p.m. Fare 2s. 6d. Coach drive 2s. 6d. extra.

To Aboyne, to visit Fungle, Aboyne Castle, and Glentanar. The party will leave at 1.15 p.m. and reach Aberdeen again at 10 p.m. Fare 2s. There will be opportunity for golf on these two excursions.

To Elgin, where the cathedral can be visited. The train leaves Aberdeen at 12.30 p.m., and the party will arrive there on the return journey at 9.35 p.m. Fare 3s.

To Banff, Cullen, and Buckie, leaving at 12.30 p.m., and reaching Aberdeen again at 9.35 p.m. Fare 2s. 6d.

To Alford and Oyne, to visit the prehistoric fort on Nether Tap of Bennachie and Maiden Stone. The train leaves Aberdeen at 1.37 p.m., and reaches it again at 8.52 p.m. Fare 1s. 6d.

Cruden Bay.—The train leaves Aberdeen at 1.30 p.m., and the return train is due at 8.33 p.m. Fare 2s. 6d., including use of golf course.

Stonehaven and Muchalls.—Visits may also be made on Wednesday or Saturday to Stonehaven to see Dunottar

Castle, Raedykes Camp, the Ogham Stone, the Druidical Circles, old Fetteresso Church, Cowie Churchyard, and to Muchalls for the coast scenery and rocks. Both at Stonehaven and Muchalls golf may be played, and at Stonehaven tennis and golf also.

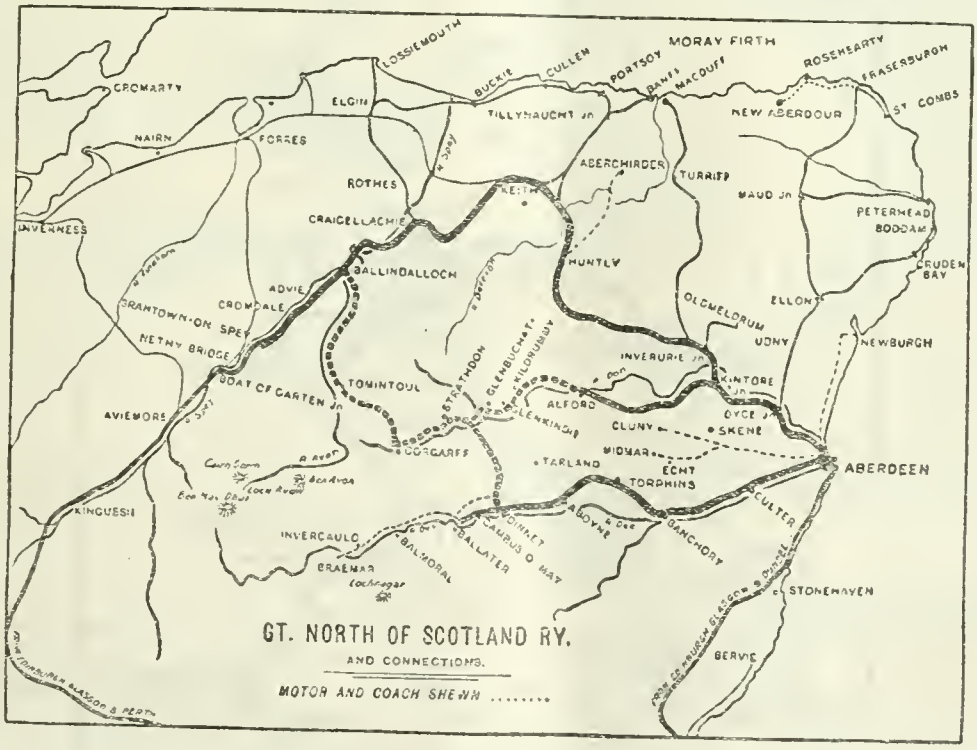
Glen of Drumtochty.—A party of 200 will be able to make an excursion to the Glen of Drumtochty on July 29th, and a similar party will be arranged on August 1st. This is a most charming round trip, passing many places of historical and archaeological interest, among them being Edzell, with its golf course and castle, Auchinblae, Drumtochty, Clatterin Brigs, and Fettercairn. This is a half-day excursion, leaving shortly after 1 p.m. and getting back to Aberdeen on Wednesday a little before 9 p.m. and on Saturday soon after 7 p.m. If desired it could be arranged for a half of each party to coach from Fordoun and the other half from Edzell. The fare for the round is from 5s. to 6s.

LONGER EXCURSIONS.

[*For these excursions names must be sent in early in order that suitable arrangements may be made.*]

Three Rivers Tour.

On Saturday, August 1st, a tour will be made by a party not exceeding forty to the valleys of the Dee, Spey, and Don. The same tour can also be taken on Wednesday, July 29th. The party will go from Aberdeen by train as far as Dinnet, and will motor to Strathdon, where luncheon will be taken. It will then go by coach from Cockbridge to Tomintoul, the highest village in Scotland, where tea will be taken. The return will be by Ballindalloch, Speyside, and Donside, to Aberdeen. The fare for the round will be—first class, 20s.; third class, 15s. This tour will occupy the whole day, from 8 a.m. to 10.30 p.m.



Grantown and Speyside.

This trip has also been arranged for a party of 200 on Wednesday, July 29th, and Saturday, August 1st. At Grantown, which is one of the chief health resorts of Strathspey, the valley of the Spey opens out into a large wide plain—the Cairngorm mountains to the left and the Monadh Liath range to the right. The party will start on each day at 2 p.m., and reach Aberdeen on the return journey at 11.15 p.m. Cold luncheon can be arranged on the train for a limited number. The fare will be 2s. 6d., third class.

Ballater, Balmoral, and Braemar.

Arrangements have been made for a party of 500 to visit Royal Deeside on Saturday, August 1st. The party will travel to Ballater by a train leaving Aberdeen at 7.45 a.m., and by coach from Ballater to Balmoral. Lunch will be taken in a marquee in Balmoral grounds. From Balmoral after luncheon the party will proceed by coach to Ballater, and return to Aberdeen by a train arriving there at 6.15. Members wishing to travel to Edinburgh, Glasgow, etc., from Aberdeen by the trains at 5.30 and 5.35 p.m. can return from Balmoral by the railway company's motor via Crathie to Ballater, and proceed thence by the train due to arrive in Aberdeen at 5.15. It will be possible for a few members to obtain private motors at Ballater by previous arrangement, and to drive to Braemar and Linn of Dee, lunching at Braemar and joining the party at Ballater on the return journey. The return fare to Ballater is 2s. 6d., and from Ballater to Balmoral 2s. 6d., luncheon and tea extra.

Aviemore (Further Speyside).

This is an alternative to the last excursion, and will afford to those who may have been unable to avail themselves of the Three Rivers tour an opportunity of seeing the lovely country of Further Speyside. The party will leave Aberdeen on Saturday morning, August 1st, and will reach Aberdeen in the evening. Members who may wish to return south via Perth on Saturday evening should make their own arrangements with the stationmaster at Aviemore, where luncheon will be taken. The return fares are: First class, 20s. 8d.; third, 11s. 1d.

ARCHAEOLOGY.

It is proposed to arrange excursions for members specially interested in Scottish history, archaeology, geology, and mountain and marine scenery. Among the places to be visited will be druidical circles on Kingcausie and at Aquhorties, the prehistoric fort on the Mither Tap of Bennachie, and the Maiden Way at its foot, the underground houses at Kildrummy, the vitrified forts at Tap of Noth and at Finavon, near Forfar, the sculptured stones at Aberlemno, and many other places of particular interest to archaeologists.

STRATHPEFFER SPA.

The medical men of Strathpeffer Spa and Dingwall, along with the hotel proprietors, have arranged to invite forty members of the Association who may be interested in health resorts and spas, for two days, from Saturday, August 1st, to Monday, August 3rd. As the accommodation in the hotels at this time of year is taxed to the utmost, it is absolutely necessary that those intending to take advantage of this hospitable invitation should send in their names at once to Dr. Duncan, Strathpeffer Spa. Although the number of invited guests is limited to forty, those who may be in the neighbourhood of Inverness or Strathpeffer will be entertained to luncheon on either of the days mentioned. The baths will be open for the use of the guests, and the courtesy of the golf course will also be extended to them.

Special fares will be granted by both the Great North of Scotland and Highland Railway Companies, but the better plan would be for those travelling from England to take tourist tickets direct to Strathpeffer via Aberdeen (third class return fare 67s. 3d.). These tickets can be made

available to return via Dunkeld and Perth, but it is essential that passengers should ask for tickets so routed at the time of booking.

INVERNESS, ELGIN, NAIRN, AND THE HIGHLANDS.

The members of the Northern Counties of Scotland Branch of the Association have organized a series of excursions for those members who propose to visit Inverness and neighbourhood. It is anticipated that many who attend the annual meeting will complete their holiday by visiting the North of Scotland. In order to facilitate arrangements, the medical men in Inverness, Elgin, Nairn, and Strathpeffer Spa are anxious to get the names of those members who propose visiting these places as soon as possible so as to have some indication as to probable numbers. The tourist season is very heavy during July and August, and as hotel accommodation is somewhat limited, private hospitality will be extended to a certain number.

Members travelling from England who take a return ticket to Aberdeen at the specially reduced rate (fare and a third), and afterwards decide to remain in Scotland beyond the period for which such ticket would be valid can do so upon payment of the difference between the special reduced fare and the ordinary tourist fare. Those who can with confidence make their arrangements in advance may find it advantageous to take tourist tickets to Inverness (first class, £7 6s. 11d.; third class, £3 3s., from London by rail throughout). These tickets, which are available for six months, permit a break of journey northward at Aberdeen, and are available to return via the Highland Railway by Inverness, Aviemore, and Dunkeld, going on to Edinburgh or Glasgow. The journey may be broken at any of these places on the way south. Tourist tickets may also be obtained from any of the larger towns in England and Wales. Full particulars can be gathered from the *Guide to the Highlands*, which may be obtained from the Traffic Manager of the Highland Railway Co., Inverness.

It will be found that the tours can be extended in various ways, and can be made to include a return by the West of Scotland. We are indebted to Messrs. Stockwell and Co., Passenger Ticket Agents, 8, Beak Street, Regent Street, S.W., for the following sample tours from London:

[The following tourist tickets are available for six months, but the steamer portion of the tour must in all cases be completed on or before September 30th.]

Railway map; the system of the Highland Railway is shown by the darker line.

BY LONDON AND NORTH-WESTERN RAILWAY.

Fort William and Inverness Circular Tour No. 2.—Fares: First class, 170s. 8d.; third class, 78s. 9d. Out from Euston Station, via Carlisle, Carstairs, and Aberdeen to Inverness by rail, returning from Inverness by McBrayne's steamers through the Caledonian and Crinan Canals to Oban, thence by rail direct to London.

Fort William and Inverness Circular Tour No. 4.—Fares: First class, 160s. 2d.; third class, 81s. Out from Euston Station, via Carlisle, Carstairs, and Aberdeen to Inverness by rail, returning from Inverness by McBrayne's steamers through the Caledonian and Crinan Canals to Glasgow, thence by rail to London.

BY GREAT NORTHERN RAILWAY.

Inverness Circular Tour No. 1.—Fares: First class, 160s. 2d.; third class, 81s. Outward journey, from King's Cross Station, via Edinburgh, Forth and Tay Bridges, and Aberdeen, to Inverness by rail, returning by the McBrayne's steamers through the Caledonian and Crinan Canals to Oban, thence by rail, via Edinburgh, to London.

Inverness Circular Tour No. 2.—Fares: First class, 176s. 8d.; third class, 78s. 9d. Outward journey, from King's Cross Station, via Edinburgh, Forth and Tay Bridges, and Aberdeen, to Inverness, returning from Inverness by McBrayne's steamers to Glasgow, thence by rail, via Edinburgh, to London.

The excursions in Inverness district include a trip up the Caledonian Canal, motor runs to Culloden Moor, Cawdor Castle, Speyside, and to Glenurquhart, Strathglass, Loch Marce, Loch Duich. All these are delightful excursions typical of Highland scenery. Nairn, with its fine golf course, will be an attraction to many, while Elgin, with Lossiemouth as a golfing centre, will charm others. To men who are not golfers, drives to Grantown on Spey and Craigellachie have been arranged.

The names of intending visitors should be sent in to one of the undermentioned not later than July 10th: Dr. J. Munro Moir (Inverness), Dr. Stephen (Elgin), Dr. E. Wilson (Nairn), who will be pleased to give any information as to hotel accommodation, private hospitality, etc.

In order that the arrangements should run smoothly it is absolutely necessary that those in charge of them should know how many members are likely to take advantage of the special excursions planned, and it is suggested that although July 10th is stated to be the last day for giving in names, members should, as soon as their arrangements for holidays are complete, notify one or other of the gentlemen whose names are given above.

Nairn.

The arrangements for those visiting Nairn are as follows: The party will arrive during the forenoon of

Saturday, August 1st; there will be a reception by the Provost, followed by luncheon. In the afternoon there will be a motor run by Culloden Moor, visiting the battle-field, and on the homeward run Kilravock and Cawdor Castles. On Sunday there will be a motor run to the upper reaches of the Findhorn (Glenferness and Dulsie). On Monday the baths and the golf course will be open to the visitors.

The medical men of Nairn are prepared to offer private hospitality over the week-end to twenty members. Members intending to make this excursion are requested to communicate at once, and in any case not later than July 10th, with Dr. Eric Wilson, Wyvis View, Nairn.

Elgin, Lossiemouth, and Grantown.

The arrangements for those visiting Elgin and Lossiemouth are as follows: The party will arrive during the forenoon of Saturday, August 1st. After luncheon (probably at Elgin) golfers will proceed to Lossiemouth, where there is a fine course; for others motor drives will be arranged to Gordon Castle, Fochabers, or the Roman Well, Burghead; the town of Elgin, with its cathedral, museum, and hospital, may also be visited.

On Sunday afternoon a motor drive for the whole party will be arranged to Grantown, proceeding there by the Speyside route and returning by way of the banks of the Findhorn and Forres. By this route some very picturesque Highland scenery will be traversed. On Monday the Lossiemouth Golf Course will be open to visitors.

It is particularly requested that the names of those who wish to visit Elgin and Lossiemouth be received by Dr. J. Stephen, Murrayfield, Elgin, by July 18th at latest, or as much earlier as possible.

Inverness.

Several excursions have been arranged for those members who go on to Inverness from Aberdeen:

1. *Kyle of Lochalsh and Loch Duich.*—This is a very fine bit of scenery, the railway journey from Inverness along the Beauly Firth, thence from Dingwall past Garve and Achnasheen, passing Loch Carron, along the shore of which the railway winds until within a mile or so of Kyle of Lochalsh. A trip will be made on one of MacBrayne's steamers up Loch Duich amidst beautiful Highland scenery.

2. *Loch Maree* will be visited by another party. Passengers will leave the train at Achnasheen and join a motor car which goes by Loch Rosque, and after a drive of about six miles reaches the beautiful Loch Maree. No pen can describe the beauties of this part of Ross-shire, with the towering Ben Slioch and Ben Eay on either side. These are whole-day excursions.

For those who do not care for a long journey, motor runs will be arranged:

3. *Glen Urquhart.*—By Loch Ness side to Drumnadrochit, up Glen Urquhart, crossing the hill to Cannich, returning to Inverness by Strathglass and Beauly, a beautiful run through very fine mountain scenery.

4. *Stratherrick and Strathnairn.*—Another party will go up to Loch Ness on the opposite side from No. 1 party to the Pass of Inverfarigaig, up Stratherrick crossing to Strathnairn.

5. To *Culloden Moor* and Cawdor Castle.

6. To *Fort Augustus* by the Caledonian Canal by MacBrayne's steamers—possibly calling at the Falls of Foyers on the way.

On the return of 4, 5, and 6 parties, the Provost and Magistrates of Inverness will publicly receive the members of the Association, and entertain them to luncheon. The afternoon will be given up to garden parties, etc.

A LIST of periodical publications, official reports, and Blue Books in the Library of the British Medical Association available for issue to members on loan has been printed, and copies can be obtained free on application to the Librarian, at the house of the Association, 429, Strand, W.C. The regulations governing the loan of these publications are stated in the introduction to the list. The Library is open for consultation from 10 a.m. till 5 p.m. (on Saturdays till 2 p.m.).

Association Intelligence.

PROCEEDINGS OF COUNCIL.

A MEETING of the Council was held at 429, Strand, London, W.C., on Wednesday, June 24th. The proceedings lasted from 10 o'clock in the morning until 7.30 in the evening.

Present:

Dr. J. A. MACDONALD, Chairman of Council, in the chair.
Mr. T. JENNER VERRALL, Bath, Chairman of Representative Meetings.

Dr. JOHN ADAMS, Glasgow
Dr. J. MITFORD ATKINSON, London (Hong Kong and China, etc., Branches)
Dr. R. M. BEATON, London
Dr. M. G. BIGGS, London
Dr. CHARLES BUTTAR, London
Dr. H. J. CAMPBELL, Bradford
Mr. W. F. CHOLMELEY, Wolverhampton
Dr. J. SINGLETON DARLING, Lurgan
Dr. E. J. DOMVILLE, Chelwood
Dr. DAVID EWART, Chichester (New Zealand Branch)
Dr. FRANK FOWLER, Bournemouth
Dr. ADAM FULTON, Basford, Nottingham
Mr. T. W. H. GARSTANG, Altrincham
Surgeon-General J. P. GREANY, I.M.S., Ealing (Indian Medical Service)
Dr. T. D. GREENLEES, Weymouth (South African Branches)
Dr. MAJOR GREENWOOD, London
Dr. J. R. HAMILTON, Hawick, N.B.
Dr. G. E. HASLIP, London
Mr. W. T. HAYWARD, Oxford (Victorian, South and West Australian Branches)
Mr. P. NAPIER JONES, Crowthorne
Mr. F. CHARLES LARKIN, Liverpool
Mr. ALBERT LUCAS, Birmingham
Dr. C. H. MILBURN, Hull
Mr. E. C. MONTGOMERY-SMITH, London
Dr. GEORGE PARKER, Bristol
Sir JAMES PORTER, K.C.B., LL.D., London (Royal Navy Medical Service)
Dr. F. J. Smith, London
Mr. D. F. TODD, Sunderland
Mr. E. B. TURNER, London
Mr. DENIS WALSHE, Graigue
Mr. E. H. WILLOCK, Croydon
Dr. O. R. M. WOOD, Woolpit

RETURN OF THE CHAIRMAN.

The Chairman was warmly congratulated on his safe return from his Australasian tour.

APOLOGIES.

The President, the Treasurer, Sir James Barr, Mr. W. F. Brook, Dr. John Gordon, Dr. Livingstone Loudon, Dr. J. Munro Moir, Dr. J. E. Moorhouse, and Professor A. H. White sent letters of apology for non-attendance.

DEATHS.

The CHAIRMAN reported the deaths of Dr. B. H. Mumby of Portsmouth, a member of the Council, and Dr. J. H. Keay of Lewisham, a former member of the Council, and was requested to convey to the respective families votes of condolence on their bereavement.

THE TREASURER.

The Council expressed its sincere sympathy with the Treasurer in his illness and an earnest hope for his speedy recovery.

RESIGNATIONS.

The CHAIRMAN reported the resignations of Colonel H. J. Waller Barrow, the Representative of the Army Medical Service on account of ill health, and Mr. C. Courtenay Lord.

VOTE OF THANKS TO DEPUTY CHAIRMAN OF COUNCIL.

The Council placed on record its appreciation of the able way Sir James Barr acted as deputy during the absence of the Chairman in Australasia.

REPRESENTATIVE FROM AUSTRALIAN BRANCHES.

Mr. W. T. Hayward, of Adelaide, was welcomed upon his attending the Council for the first time as the representative of the South Australian Branch.

DR. J. A. MACDONALD'S VISIT TO AUSTRALASIA.

Communications were read from the New Zealand Branch, New South Wales Branch, and the Federal Committee of the Association in Australia expressing satisfaction at Dr. Macdonald's recent visit to Australasia.

Dr. Macdonald gave an account of his tour, similar to but somewhat briefer than that contained in his address to the West Somerset Branch, published in this week's Journal (page 1).

Dr. Greenlees, Chairman of the Dominions Committee, moved a vote of thanks to Dr. Macdonald for his address. He felt confident that the visit had done good, and only regretted that Dr. Macdonald had not been able to visit South Africa also; he assured him of a hearty welcome if and when he found it possible to do so.

Dr. Hayward, in supporting, said that Dr. Macdonald had given a racy account of his journey to Australia, for the accuracy of which he could vouch. The visit had done a great deal to make stronger the bonds between the Australian Branches of the Association and the mother society. Personally he was indebted to Dr. Macdonald, because, when he might have been enjoying himself, he chose to sit at the meeting of the Federal Committee, with the temperature at about 100°, for two whole days, giving advice with delicacy and tact on all matters which came within his purview. Dr. Macdonald had made himself a prime favourite by his tact, his bonhomie, his energy and sound common sense. He made all the medical men with whom he came in contact in Australasia feel that they were a part of a great profession.

The motion was unanimously adopted.

The Council ordered that a vote of thanks be sent to the Presidents and Secretaries of the various Branches and Divisions visited by Dr. Macdonald, to the Federal Committee of Australia, to the Chief Medical Officer of the Government of New Zealand, to Dr. Billinghurst and Professor Macfarlane of Hong Kong for the courtesy and hospitality extended to the Chairman of Council.

Sir Thomas Roddick.

It was decided to forward the congratulations of the Council to Sir Thomas Roddick, of Montreal, President of the Association in 1897, upon the honour of knighthood recently conferred upon him by His Majesty the King.

University of Wales.

Dr. E. J. Maclean was nominated a Representative of the Association upon the Medical Board of the University of Wales for a further term.

Postal Vote.

The Chairman of Council read a letter from the Sheffield Division concerning the question of a postal vote on the matter of the proposed Special Fund, when it was decided to inform the Sheffield Division that the Council is of opinion that each Division should conduct the postal vote as a Divisional matter in the way it thinks best.

Annual Meeting at Newcastle, 1917.

The Chairman reported receipt of a letter from the Honorary Secretary of the North of England Branch inviting the Council of the Association to hold the Annual Meeting in 1917 in Newcastle-on-Tyne. The Council decided to thank the North of England Branch, and to file the invitation for consideration in due course.

FINANCE COMMITTEE.

In the absence of the Treasurer, the Chairman of Council presented the report of the Finance Committee.

Accounts.

The accounts for the quarter ending June 6th, 1914, amounting to £10,934 0s. 2d., were received and approved, and the Acting Treasurer was empowered to pay those unpaid.

Appointment of Assistant Medical Secretary.

Mr. C. Courtenay Lord, Gillingham, was appointed Assistant Medical Secretary as from October 1st, 1914.

Appointment of Solicitor to the Association.

Mr. W. E. Hempson was reappointed Solicitor to the Association.

Heard *v.* Pickthorne.

A sum of £10 was voted to Mr. P. C. Raiment, Honorary Secretary to the National Medical Guild, as compensation for the loss he sustained in giving financial assistance to the plaintiff in the case of Heard *v.* Pickthorne.

Candidates for Election to the Association.

The candidates whose names appeared on the notice convening the meeting were elected members of the British Medical Association.

Election of Vice-Presidents.

It was decided to recommend to the Representative Body that Dr. W. Ainslie Hollis, President of the Association for 1913–14, be elected a Vice-President of the Association. Also that Mr. W. T. Hayward, Chairman of the Australian Federal Committee, be elected a Vice-President.

SCOTTISH COMMITTEE.

As from January 1st, 1915, there will be established a Scottish Office with a whole-time Scottish Medical Secretary in addition to the present Clerk. The Scottish Medical Secretary will be appointed by the Council on the recommendation of the Scottish Committee, and the salary will be £600 per annum.

House of Lords Midwives (Scotland) Bill (No. 81).

The Council approved in the present instance of the Scottish Committee being named in the House of Lords Midwives (Scotland) Bill (No. 181) as the body to appoint medical representatives on the proposed Central Midwives Board for Scotland.

ORGANIZATION COMMITTEE.

Students' Union.

The Council decided to report to the Representative Body that in its opinion the formation of a Students' Union on the lines suggested in Minute 197 of the Annual Representative Meeting, 1909, is, for the present at least, impracticable.

Grants to Branches for 1914.

It was decided that grants for 1914 be made to the following Branches: Aberdeen, Gloucestershire, Oxford and Reading, Shropshire and Mid-Wales, Surrey, and Ulster.

Election of Members of Council, 1914–15, and 1915–16 by Grouped Representatives under By-Law 43 (C).

(*a*) 1914–15.

Pursuant to the authority conferred on the Council by Minute 260 of the Annual Representative Meeting, 1913, the Council decided to group the United Kingdom constituencies for election of twelve members of Council for 1914–15 in the same manner as for 1913–14, the constituencies of the new Kent, Surrey, and Sussex Branches taking the place of those of the late South-Eastern Branch.

(*b*) 1915–16.

It was resolved to recommend to the Representative Body that the grouping of constituencies for election of twelve members of Council, 1915–16, be similar to that for 1914–15, discretion being, however, left to the Council to make any modifications in the grouping rendered necessary or desirable owing to numerical changes or formation of new Divisions or constituencies or modification of those bodies as at present existing.

Grouping of Branches not in United Kingdom for 1915–16.

The Council will recommend to the Representative Body that the grouping of the Branches outside the United Kingdom for the election of seven members of Council for 1915–16 be the same as for 1913–14—that is, that the Ceylon Branch be grouped with the Indian Branches, and that the Hong Kong and China, and Malaya Branches, together form a constituency for the election of one member of Council.

Grouping of Divisions for Representation in Representative Body, 1914–15.

In view of the fact the Rochdale Division, which had temporarily dropped to below the necessary 50 members to entitle it to separate representation, would, before the Representative Meeting at Aberdeen, be above 50 members, it was accorded separate representation in the 1914–15 Representative Body.

SCIENCE COMMITTEE.

MIDDLEMORE PRIZE.

In view of the adjudicators' report on the essays submitted it was decided that the Middlemore Prize be not awarded for the current year, and that the prize be open for competition in 1915.

CENTRAL ETHICAL COMMITTEE.

REGULATIONS RELATIVE TO THE INSERTION IN THE "BRITISH MEDICAL JOURNAL" OF NOTICES REGARDING APPOINTMENTS.

The Representative Body will be recommended to rescind all its previous decisions relating to the Warning Notice, and to empower the Council to approve Regulations, which in the opinion of the Council are appropriate, relative to the insertion in the BRITISH MEDICAL JOURNAL of notices regarding appointments, and that the control of these notices be in future left entirely in the hands of the Council.

POSITION OF MEDICAL PRACTITIONERS IN CONNEXION WITH PUBLICATIONS TO THE PUBLIC ON MEDICAL SUBJECTS.

The Representative Body will be recommended to adopt the principle that every medical practitioner who contributes to or in any way assists in the preparation of any publication on medical subjects intended for the use of the public must hold himself responsible for any undue or improper advertising that may take place in connexion with such publication, and also for the scope and distribution of the work.

CASE UNDER ARTICLES 10 AND 11.

Having received a special report from the Central Ethical Committee with regard to representations of a Division with reference to a member of the Association, the Council resolved that the member in question should be expelled from membership of the Association.

MEDICO-POLITICAL COMMITTEE.

FEES FOR MEDICAL EXAMINATIONS FOR LIFE INSURANCE.

The Representative Body will be invited to decide the question of principle as to (*a*) whether fees for life insurance examinations should be based on the amount of evidence required in confirmation of the examiner's professional opinion of the life, or (*b*) whether there should be a fixed minimum fee for that opinion irrespective of the number of questions to be answered.

PAYMENT OF SHIP SURGEONS FOR ATTENDANCE UPON FIRST AND SECOND CLASS PASSENGERS.

The Representative Body is recommended to adopt the following principles:

1. That fees for medical and surgical attendance should be payable by first and second class passengers in all cases of illness and injury except those due to the natural conditions of the voyage.
2. That in those cases where the ship surgeon is at liberty to charge a fee the minimum fee shall be 5s. and 2s. 6d. per attendance in the case of first and second class passengers respectively.
3. That accounts for any such fees should not be subject to any preliminary scrutiny by the commander, but it is clearly understood that any passenger questioning the legitimacy of any charge may make representations accordingly to the commander.

FEES FOR MEDICAL CERTIFICATES UNDER THE MENTAL DEFICIENCY ACTS.

The Representative Body will be advised to approve that the fee for medical certificates under the Mental Deficiency Acts signed by the "usual medical attendant" should not be less than £1 1s.

TELEPHONE SERVICE RATES.

A reply of the Postmaster-General as to the telephone service rates will be reported to the Representative Body for its information.

PUBLIC HEALTH COMMITTEE.

ADVERTISEMENTS FOR TUBERCULOSIS OFFICERS.

It is recommended to the Representative Body that the Model Scheme for the Treatment of Tuberculosis, when adopted by the Representative Body, be circulated to Municipal Councils, Insurance Committees, and other bodies which it may concern with a view to obtaining their co-operation.

DEPUTATION TO MEMBERS OF THE GOVERNMENT ON SECURITY OF TENURE AND SUPERANNUATION FOR MEDICAL OFFICERS OF HEALTH.

The best thanks of the Council were given to Sir Philip Magnus, M.P., and Dr. Addison, M.P., for their services in securing the reception of the recent deputation on the security of tenure of medical officers of health by the Chancellor of the Exchequer, the President of the Local Government Board, and the President of the Board of Education, and also to those members of Parliament who showed their sympathy by attending.

HOSPITALS COMMITTEE.

WORKMEN'S MEDICAL AID ASSOCIATIONS AND MEMBERS OF STAFFS OF VOLUNTARY HOSPITALS.

It was decided that the support of the Association be given to any action tending to prevent the spread of medical aid institutes which may be taken by any Branch or Division with the consent of the Council of the Association.

NAVAL AND MILITARY COMMITTEE.

RESIGNATION OF A MEMBER FROM THE COMMITTEE.

Owing to illness Colonel H. J. Waller Barrow has had to resign his seat on the Committee. In his stead it is recommended that Colonel R. I. D. Hackett, A.M.S. (ret.), be appointed.

THE SHORTAGE OF MEDICAL OFFICERS IN THE ROYAL NAVY.

A report on the shortage of medical officers in the Royal Navy was approved, and a copy ordered to be forwarded to the Admiralty with an intimation that it was proposed to publish the report in the BRITISH MEDICAL JOURNAL. The report has also been printed in pamphlet form for circulation to the deans of medical schools for distribution (i) to intending candidates for entry into the Royal Navy Medical Service and (ii) in the libraries and reading-rooms of the various medical schools.

INSURANCE ACT COMMITTEE.

RETURNED MEDICAL CARDS.

The Representative Body is recommended: (i) That it is no part of the duty of a panel practitioner to correct and keep up to date the list of addresses of insured persons.

(ii) That a medical practitioner should be entitled to charge private fees to those insured persons demanding treatment of him but who fail to produce their medical cards, in view of the instruction of the various Insurance Commissioners to Insurance Committees than when the medical card system is in full operation a practitioner would be entitled, on giving treatment, to require insured persons on his list to present their medical cards, should such a course appear necessary.

RELATION OF BRITISH MEDICAL ASSOCIATION TO PROPOSED FEDERATION OF LOCAL MEDICAL AND PANEL COMMITTEES.

It is recommended to the Representative Body that in the event of the proposed Federation of Local Medical and Panel Committees being formed, it be granted adequate representation on the Insurance Act Committee of the British Medical Association, and that the decision as to the exact amount of such representation be deferred until the policy of the Federation has been confirmed by the Local Medical and Panel Committees concerned. Further, that the necessary amendments be made in the Regulations of the Association to allow of two direct representatives being nominated by the proposed Federation of Local Medical and Panel Committees for election by the Representative Body on the Council of the British Medical Association, such representatives to be members of the Association.

Provided that other arrangements for co-operation are satisfactory, the work of the proposed Federation and Association will be carried out by the same staff on the premises of the Association; and that, subject to payment by the Federation on an agreed tariff, the Association will

place the following facilities at the disposal of the proposed Federation :

(i.) Office accommodation.
(ii.) Clerical assistance.
(iii.) Printing, etc.
(iv.) Space in the SUPPLEMENT to BRITISH MEDICAL JOURNAL for reporting the proceedings of the Federation and its Branches.

Co-operation will be encouraged between the Scottish, Irish, and Welsh Executive Committees of the proposed Federation and any separate Committees set up by the Association in those countries.

If the above proposals are accepted by both the Association and the proposed Federation, the Federation shall not take action independent of the Association in any negotiations with lay bodies.

The whole of the foregoing decisions are provisional only, dependent upon whether the Representative Body is satisfied with the constitution, powers, objects, etc., of the proposed Federation.

APPOINTMENT OF AND REFERENCE TO INSURANCE ACT COMMITTEE.

It was decided that the Representative Body be recommended to appoint an Insurance Act Committee for the forthcoming session, 1914–15, and that the present Committee be empowered to report direct to the Representative Body as to the constitution and reference of the Insurance Act Committee for 1914–15, after consideration of the constitution, powers, objects, etc., of the proposed Federation of Local Medical and Panel Committees, and having regard to any proposed co-operation between the Association and the Federation.

NON-PANEL COMMITTEE.

CONSULTANTS EMPLOYED FOR PURPOSES OF INSURANCE ACTS.

The Representative Body is recommended to define that the policy of the Association should be opposed (with some possible special exceptions) to whole-time consultative appointments in connexion with the Insurance Acts, and that it should be in support of the performance of such duties being open, under conditions of free choice and adequate remuneration, to all registered medical practitioners qualified to perform them.

SUPPLEMENTARY REPORT OF COUNCIL.

The Supplementary Report of the Council was approved, and was published in the SUPPLEMENT of June 27th, p. 474.

Meetings of Branches and Divisions.

[*The proceedings of the Divisions and Branches of the Association relating to Scientific and Clinical Medicine, when reported by the Honorary Secretaries, are published in the body of the* JOURNAL.]

BIRMINGHAM BRANCH.

THE annual meeting of the Birmingham Branch was held at the Medical Institute on June 18th, when Mr. HASLAM (the retiring Chairman), Dr. PURSLOW (the Chairman-elect), and twenty-two other members were present.

Election of Officers.—The following officers were duly elected:

President-elect: Dr. J. Orton (Coventry).
Honorary Treasurer: Mr. J. Furneaux Jordan.
Honorary Secretaries: Dr. Smallwood Savage and Mr. Seymour Barling.

Annual Reports.—The following reports were approved: Report of the Council, with the balance sheet; report of the representative (Mr. A. Lucas) on the Central Council; report of the Ethical Committee; and report of the Pathological and Clinical Section.

Presidential Address.—Dr. PURSLOW (President) delivered his inaugural address on "The Diagnosis and Treatment of Miscarriage."

GLASGOW AND WEST OF SCOTLAND BRANCH: GLASGOW NORTH-WESTERN DIVISION.

Annual Meeting.—Presentation to Dr. Caskie.

THE annual meeting was held on June 25th, when Dr. A. T. CAMPBELL presided, and eleven other members were present.

Midwives Bill.—In accordance with the suggestions of the Scottish Committee of the Association, it was agreed to support the Midwives Bill introduced into the House of Lords by Lord Balfour of Burleigh, and that the members of Parliament representing the area of the Division should be informed of this decision and asked to give it their active support in Parliament.

Election of Officers.—The following office-bearers were elected for the ensuing year :

Chairman: Dr. John Lindsay.
Vice-Chairman: Dr. James Todd.
Honorary Secretary and Treasurer: Dr. Edward J. Primrose.
Representative to Representative Meetings: Dr. A. T. Campbell.
Representatives to Branch Council: Drs. Morton, Primrose, and Inglis.
Executive Committee: Drs. Baird, Snodgrass, Graham, A. G. Hay, D. J. Mackintosh, M.V.O., Caskie, J. G. Gray, and W. A. Stuart.

Induction of Chairman.—The CHAIRMAN then introduced his successor, Dr. Lindsay, and mutual expressions of appreciation and thanks were made and received.

Annual Report of Central Council.—The annual report of the Council was then discussed. In regard to the question of a special fund, the recommendations A, B, C, D, and E (p. 320 of the SUPPLEMENT of May 2nd, 1914) were, after discussion, adopted, on the motion of Dr. CASKIE, with the proviso that the liability of the guarantors to the Defence Fund ceased. It was also agreed that the Fund should be in the form of a trust, and, as moved by Mr. WHITEHOUSE, that the whole matter should be subject to the suggestions in Sub-appendix III of Appendix X, and referred back to the Divisions for thorough discussion by the profession.

Insurance Acts.—Answers to the questions in the schedule of the Future Developments of the Insurance Acts Committee were filled in. The Representative to the Representative Meeting was instructed according to these findings, and was directed in voting upon other matters to use his own discretion.

Presentation to Dr. Caskie.—A very interesting ceremony took place before the official business part of the meeting. Dr. JOHN LINDSAY, speaking on behalf of the profession, referred to the work Dr. Caskie had done as Honorary Secretary to the Division for the past four years, especially during the time when the Insurance Act was under discussion in Parliament. Dr. Caskie had ungrudgingly accepted the extra burden, and had performed his task well and faithfully. The profession was under a deep sense of its indebtedness to him, and he called upon the Chairman to make the presentation which marked the recognition of this. Dr. CAMPBELL read the illuminated address inscribed on vellum, and presented it with a cheque to Dr. CASKIE, who, in a few chosen words, thanked the subscribers for their kindness and appreciation of his services.

LANCASHIRE AND CHESHIRE BRANCH: BURNLEY DIVISION.

THE annual meeting of the Division was held in the Bull Hotel on June 26th, when Dr. SCOTT was in the chair.

Election of Officers.—The following officers were elected for the ensuing year:

Chairman: Dr. A. E. Bird.
Vice-Chairman: Dr. T. M. Scott.
Honorary Secretary and Treasurer: Dr. W. J. Purves.
Representative for Representative Meetings: Dr. H. J. Robinson (re-elected).
Representative on Branch Council: Dr. Jas. M. Ferguson (re-elected).
Executive Committee: Drs. Chas. A. Anderson, S. T. Biggs, A. Callam, F. E. Crossley, W. Crabtree (Nelson), T. G. Crump, J. Gardner, A. C. Glashan, J. J. Harty (Colne), A. Heys, H. Holden, J. Hoyle, J. A. Mackenzie, F. W. Marsden, G. S. Pullen, R. C. Rodgers.

Annual Report of Division.—The report of the committee was adopted. It stated that there was a slight drop in the membership—from between 100 and 90 to between 80 and 90. This was to be expected after the passing of the Insurance Act. There had been five meetings of the Division, with good average attendances, 17 committee meetings, with excellent attendances (average about 14), as well as several subcommittee meetings and deputations. Several Association matters had been dealt with, and much discussion took place with regard to such matters as raising the subscription to the Association to £2 2s. per annum, and the raising of a fund for the development

of the organization and protection of the medical profession. Much work had also been done regarding the Insurance Act, over-certification, etc. The dispute with the Poor Law Guardians has occasioned a great amount of work. The Division was still trying to bring about a settlement with the guardians; several letters had been sent to them and to the Local Government Board, and the committee had held three deputations with the guardians, two under the chairmanship of the Local Government Board inspector. The guardians made offers to each of the nine Poor Law medical officers, but the latter most loyally replied that the matter rested with the Division of the British Medical Association, and each instructed the committee to refuse the offer for them. This was splendid loyalty to the Division and to themselves, and would go a long way towards obtaining a satisfactory settlement, and, as last year, the committee trust and rely on the written pledge of the members of the profession to uphold the late district medical officers and public vaccinators, and support them and the profession as a whole against under-payment and sweating of their services.

Votes of Thanks.—Hearty votes of thanks were accorded to the committee, to Dr. Scott for his able and untiring work as president; to the Representatives, Drs. Robinson and Ferguson, for their valuable and able work; and to Dr. Bird, late honorary secretary and treasurer, for his efficient work rendered to the Division.

LEINSTER BRANCH:

EAST LEINSTER DIVISION.

THE annual general meeting of the East Leinster Division was held in the Royal College of Physicians, Dublin, on June 23rd.

Election of Officers.—The following were appointed officers for the ensuing year:

Chairman: Dr. R. L. Heard.
Vice-Chairman: Dr. W. F. Law.
Honorary Secretary and Treasurer: Dr. Peacocke (Blackrock).
Representative: Colonel Johnston.
Deputy Representative: Dr. Peacocke.
Representatives on Branch Council: Drs. Dampier-Bennett, Good, Johnston, Law, and Peacocke.
Executive Committee: The officers and Drs. Dampier-Bennett, Dawson, Furlong, Good, Hatch, Groves, Lynn, Usher, and Professor White (*ex officio*).

METROPOLITAN COUNTIES BRANCH:

EAST HERTFORDSHIRE DIVISION.

THE annual meeting of the East Hertfordshire Division was held at the North Herts and South Beds Hospital, Hitchin, on June 18th. Dr. J. H. GILBERTSON was in the chair, and eleven members were present.

Election of Officers.—The following officers were elected:

Chairman: Dr. Clark (Cheshunt).
Vice-Chairman: Dr. Sturge (Hoddesdon).
Secretary and Treasurer: Dr. Ledward (Letchworth).
Assistant Secretary: Dr. de Vine (Stevenage).
Representative on Branch Council: Dr. Charles Hitchin).
Executive Committee: Drs. Addison, Boyd, Brittain, Dockray, Fell, Wells, and Windsor.
Representative for Representative Meeting: Dr. J. H. Gilbertson (Hitchin).
Deputy Representative: Dr. H. D. Ledward (Letchworth).

Honorary Secretary's Annual Report.—The report of the Division for the year 1913–1914 stated that the membership now stood at 52, a decrease of 7 during the year. Five meetings had been held during the year, at two of which scientific papers were read, the average attendance being fifteen. The financial statement showed a balance in hand of £4 17s. 1d. On the motion of Dr. BOYD, seconded by Dr. BINNING, the report was adopted.

Insurance Acts: Reports from Future Developments Committee.—The report in reference to future development of Insurance Acts was considered and answers given to most of the questions asked. One or two questions were left unanswered owing to time not being available for adequate discussion.

Medical Representative on Insurance Committee.—It was resolved to nominate Dr. A. J. Boyd as the Representative of the East Hertfordshire area on the County Insurance Committee, and to discourage any other nomination.

Vote of Thanks.—The meeting terminated with a very hearty vote of thanks to the retiring chairman, Dr. J. H. Gilbertson, proposed by Dr. MACFADYEN and seconded by Dr. WELLS.

Garden Party.—Members of the Division and ladies were afterwards entertained by Dr. and Mrs. Gilbertson.

GREENWICH AND DEPTFORD DIVISION.

THE annual general meeting of this Division was held on June 24th.

The late Dr. Keay.—The Chairman, Dr. R. D. MUIR, before entering on the business of the meeting, proposed a vote of sympathy with Mrs. Keay, on the recent death of Dr. J. H. Keay, and suggested that an expression of the appreciation of the Division of the self-sacrificing labours of Dr. Keay on behalf of the profession should be entered on the minutes. Dr. R. CORFE seconded the motion, which was carried unanimously.

Annual Representative Meeting.—The Rev. Dr. S. D. Bhabha was elected Representative for the Representative Meeting, and was instructed to vote against the motions of the Plymouth, Altrincham, and St. Pancras and Islington Divisions (as regards National Insurance Act), and in favour of the motion of the St. Pancras and Islington Division as regards treatment of tuberculosis.

ST. PANCRAS AND ISLINGTON DIVISION.

A MEETING of the St. Pancras and Islington Division was held in the Midland Grand Hotel, King's Cross, on June 19th.

Annual Report of Division.—The Honorary Secretary and Treasurer, Dr. J. WILSON, presented the annual report drawing special attention to the large number of resignations of membership during the past year, the number now being 152 as compared with 210 at the end of December, 1913.

Election of Officers.—The following officers were elected for the ensuing year:

Chairman: Dr. A. R. Roche.
Honorary Secretary and Treasurer: Dr. Norman Glaister.
Representatives to Branch Council: Dr. A. Alexander and Dr. O. A. Wickham.
Executive Committee: Drs. A. Brown, Crabb, Glinn, Goodchild, Maughan, Rattray, S. Rowntree, Turner, Wilson, Wylie.

Representation on Islington School Treatment Centre.—The meeting considered the question of procedure of election of Managing Committee for Islington School Treatment Centre, and on the motion of the Chairman (Dr. RATTRAY), seconded by Dr. J. WILSON, it was resolved *nemine contradicente:*

> That the five local practitioners who constitute the committee shall be elected by the members of the profession residing and practising in the borough of Islington, London County Council electoral area, by nominating and voting at a meeting called for the purpose, and that the said committee shall elect its own chairman, honorary secretary, and honorary treasurer.

Insurance Act.—With reference to schedule of questions *re* future developments of the Insurance Acts (SUPPLEMENT of June 13th, p. 436) it was unanimously agreed that the time before the meeting was too short to adequately consider a series of questions of such complexity and scope.

Vote of Thanks.—A vote of thanks to the retiring Chairman, Dr. Rattray, and the Honorary Secretary and Treasurer, Dr. J. Wilson, was proposed by Dr. GLAISTER and seconded by Dr. BEATON. Both Dr. BEATON and Dr. RATTRAY made very kindly reference to the work which had been undertaken and carried out by the Honorary Secretary, Dr. Wilson, during his and their term of office, at a time when the secretarial work of the Division was of the most arduous and onerous nature. Dr. RATTRAY in his reply thanked the Division, and the Executive Committee in particular, for their kindness, sympathy, and support during his term of office. The Honorary Secretary and Treasurer, Dr. WILSON, having made a suitable reply, the business of the meeting was brought to a close.

SOUTH-WEST ESSEX DIVISION.

A MEETING of the South-West Essex Division was held on June 25th in the Wesleyan Schoolroom, Leyton, when Dr. POTTINGER ELDRED presided.

Insurance Act.—The schedule of questions on future developments of Insurance Acts were considered, and the following were the decisions reached:

1. Provision of Institutional Treatment.—(*a*) No. (*b*) Yes, in favour of Government supplying fund. (*c*) No. (*d*) Yes.
2. Excessive Claims for Sickness.—(*a*) Yes. (*b*) There are other causes, chief of which is easy access to doctor without paying a special fee. (*c*) Yes. (*d*) No check possible.
3. Proposed New Services.—(*a*) Yes, most decidedly. (*b*) Division would like a new authority created. (2) Details as to Services.—(*a*) Division makes no fresh suggestions. (*b*) Yes, certainly.

Nursing.—(*a*) Yes. (*b*) Yes.

Referee-Consultants.—The Division agrees with the suggestions.

Treatment Centres.—The Division agreed with suggestions.

One member suggested that at hospitals formed by the Government arrangements should be made for the treatment of middle-class patients at a small fee for attendance and operations. It was, however, thought that, although the middle classes are always neglected, still no Government would consent to anything which recognized a difference between classes, and therefore, after some discussion, the matter was dropped.

MIDLAND BRANCH:
Holland Division.

A meeting of the Holland Division was held at the White Hart Hotel, Boston, on June 26th, when Dr. Pilcher presided, and six other members were present.

Joint Meeting of Divisions.—On the motion of Dr. Mason, seconded by Dr. Rendall, it was resolved that the joint meeting of the Holland and Kesteven Divisions for the purpose of instructing the Representative be held at the Carre Arms Hotel, Sleaford, on July 19th.

Insurance Act.—The memorandum regarding future developments of the Insurance Acts was considered and the questions appended thereto answered.

Financial Statement.—The financial statement showed a balance in hand of about £8.

MUNSTER BRANCH.

The annual general meeting of the Munster Branch was held on June 20th, when Dr. W. Donovan (Queenstown) was in the chair. Reports were read regarding developments in the medical service of the Insurance Acts and on the distribution of funds of Divisions and Branches. A list of constituencies for election of Representative Body was considered.

Election of Officers.—The following were elected;

President: Dr. M'Call (Crosshaven).
Vice-President: Dr. W. Donovan (Queenstown).
Retiring President: Dr. J. Reid (Bandon).
Member of Central Council: Professor H. Corby.
Representative to Representative Meeting: Dr. McFettridge.
Representative to Irish Committee: Dr. J. Giusani.
Branch Council: Drs. H. R. Townsend, Lucy Smith, O. McCarthy, P. T. O'Sullivan, D. J. O'Connor, E. Murphy, J. T. O'Connor, C. Yelverton Pearson, W. Ashley Cummins, A. S. Nance (Bantry), R. Foott (Monkstown), J. Devane (Limerick).
Honorary Secretary: Dr. Philip G. Lee (10, St. Patrick's Hill, Cork).
Ethical Committee of the Branch: Dr. W. Donovan, Dr. D. J. O'Connor, Dr. Philip G. Lee.

NORTH LANCASHIRE AND SOUTH WESTMORLAND BRANCH.

The annual meeting of the Branch was held at Lancaster on June 24th. Dr. Barling succeeded Dr. Daniel as president.

Election of Officers.—The officers of the Branch for the year are:

President: Dr. A. S. Barling.
President-elect: Dr. G. A. Johnston.
Vice-President: Dr. G. Parsons.
Treasurer: Dr. W. D. Barrow.
Secretary: Dr. J. Livingston.

The members present were entertained at tea by the President.

OXFORD AND READING BRANCH:
Reading Division.

The annual meeting of the Reading Division was held in the Royal Berkshire Hospital on June 25th, when Dr. Abram was in the chair, and nineteen other members were present.

Election of Officers.—The following officers were elected for the ensuing year:

Chairman: Dr. Napier Jones.
Vice-Chairman: Dr. Guilding.
Representative: Dr. Holden.
Deputy Representative: Dr. Napier Jones.
Executive Committee: Two new town members of the Executive Committee—Drs. Abram and Clowes—were then elected in place of Drs. Guilding and Holden. The remaining town and county members of the Executive Committee were re-elected *en bloc*.
Ethical Committee: The Executive Committee.
Honorary Secretary: Dr. Lambert (re-elected).

Vote of Thanks to Dr. Napier Jones.—The meeting had previously accepted the resignation of Dr. Napier Jones from the office of Representative with great regret, and on the motion of Dr. Abram, seconded by Dr. Bokenham, a hearty vote of thanks was accorded to him. Dr. Abram pointed out that he had been an ideal Representative, hard working and outspoken, and that many of the recent resolutions passed at the Representative Meetings had originated in his brain. He had, in fact, overworked himself on behalf of the Division. Dr. Napier Jones acknowledged the vote of thanks, referring to the genuine pleasure which he had derived from the Representative Meetings and from the knowledge that he had been so well supported by the Division. The Division had always sent him to the meetings with clear mandates, with which he found himself in entire sympathy. In seconding the election of Dr. Holden as Representative, he pointed out that the Division would be electing a member whose ability and presence would entitle his opinions to respect and consideration. The profession was passing through a critical time, and the Division needed an able Representative. The election of Dr. Holden would supply the need.

Future Developments of the Insurance Acts.—The meeting then discussed the questions sent out by the British Medical Association with a view to enabling the Future Developments of the Insurance Acts Committee to lay before the Representative Meeting a report on the views of the members of the Association, as to the lines on which future changes in organization of medical service under the Insurance Act should proceed. Answers to the questions were agreed to. During the discussion, the following suggestions and opinions were expressed:

Hospital Accommodation.—Dr. Bokenham felt that the accommodation for in-patients at the Royal Berkshire Hospital was very inadequate for the population in the area of the Division. Dr. Abram suggested that the lack of accommodation affected surgical rather than medical cases. Dr. Susmann endorsed Dr. Bokenham's view. He found that surgical cases were sometimes kept waiting weeks for admission, and that owing to the pressure on beds certain surgical cases were discharged at too early a date after operation.

Loans from the Government to Hospitals for Building.—Dr. Abram pointed out the danger of increased control over hospitals by the Government which such loans would involve. Dr. Hope thought the question was one to be settled not by the Divisions but by the Government and hospital authorities. Dr. Roalfe-Cox suggested that the proposal referred not solely to existing hospitals, but to the building of new cottage and other hospitals.

Dr. Rowland proposed and Dr. Hope seconded:

> That the reply to this question shall be to the effect that the matter is one for the Government and boards of management of hospitals to settle.

This motion was withdrawn in favour of the following, proposed by Dr. Napier Jones and seconded by Dr. Coleman:

> That the matter needs most careful consideration before any change in existing arrangements is made.

This resolution was passed, after an amendment that the reply be simply "Yes" had been put to the vote and lost.

Payment of Honorary Medical Staffs of Hospitals for Treating Insured Persons.—Opinions on this question were divided. After some discussion it was, on the motion of Dr. NAPIER JONES, seconded by Dr. HELDEN, resolved:

That the reply to the question be in the affirmative.

The addition of the words "but that no payment be made to members of honorary medical staffs" was not sanctioned by the meeting. The addition was proposed by Dr. ABRAM and seconded by Dr. LAMBERT, their suggestion being that any moneys received for treatment of insured persons should be taken by the hospitals.

Causes of Excessive Sickness and Medical Benefit Claims by Insured Persons.—Several members spoke on this question. Some thought that a good deal of illness had been untreated before the Insurance Act came into operation, notably cases of anaemia in factory girls. Others thought that the appointment of referees would considerably reduce the number of claims. One member pointed out that the fact that no sick benefit was granted during the first three days induced insured persons to remain on the funds for at least ten days. Another member stated that certain people were over-insured, paying to clubs as well as to the State, and that they found it advantageous to be ill.

Frequency with which Insured Persons consult Doctors.—The general opinion of the meeting seemed to be that doctors were not consulted unnecessarily; that no check should be suggested to consultations with doctors; that it was the best policy to encourage insured persons to seek advice early. Replies were returned in accordance with these views.

Provision of a Nursing Service.—It was decided that the provision of a nursing service was desirable, but that the State registration of nurses was most important.

Clinical Laboratories.—Dr. ABRAM thought that clinical laboratories should be connected with hospitals, when well equipped pathological departments were available in the hospitals of any area. Dr. DONALDSON expressed the opinion that, even in the vicinity of universities, hospitals should undertake the clinical work. In this way university professors would be allowed time for research work. Moreover, hospital pathologists had to depend for their incomes not only on the salary received from the hospital, but also on fees received for pathological work in private practice.

Appointment of Referees and Consultants.—Dr. SUSMANN believed that there was a distinct need for referees and consultants, but that in certain districts they should not be whole-time officers, the amount of work being insufficient. Other members held the view that whole-time officers were more likely to form unbiassed opinions than part-time officers. Dr. DICKSON (Hungerford) regretted that the Division had passed the resolution fixing a guinea as the minimum fee for a referee's opinion on an insured person. Before that decision he and his colleague at Hungerford had examined cases for one another at a fee of 5s. when the approved societies asked for a second opinion. The approved societies declined to pay the guinea fee, and no consultations now occurred.

Offer of an Approved Society to appoint a Referee.—Dr. THOMPSON (Newbury) reported that the Domestic Servants' Association had offered to appoint him their referee, fixing the fee for each examination at 10s. 6d. He had declined the offer, and the approved society in question had then written pointing out that the fee fixed by the British Medical Association was 10s. 6d., and asking him to read the letter at a meeting of the Reading Division. The letter stated that other approved societies had found medical men willing to act as referees for a fee of 10s. 6d. Dr. NAPIER JONES drew attention to two facts:—(1) That the British Medical Association fixed the *minimum* fee at 10s. 6d., and Divisions were entitled to agree upon a higher fee. (2) That the appointment of referees by approved societies at a fee of 10s. 6d., mentioned in the letter, had not been made by the British Medical Association.

Votes of Thanks to retiring Chairman.—In proposing a vote of thanks to Dr. Abram for his services as Chairman of the Division during the past year, Dr. SUSMANN referred to the valuable work he had done and to the judgement and discretion which he had shown in fulfilling his duties. The motion having been seconded by Dr. NAPIER JONES, was passed unanimously. Speaking in acknowledgement, Dr. ABRAM expressed the pleasure which he had always derived from working with his medical colleagues for their common welfare.

Minor Operations at the Hospital.—Dr. BOKENHAM said that a considerable number of minor operations, such as circumcision and removal of adenoids, were performed at the Royal Berkshire Hospital by the resident medical officers. These operations could be performed by general practitioners in the patients' homes, and in many cases the patients were well able to afford to pay a small fee for them. In other cases the parish authorities would be willing to pay the parish medical officer's fees for the operations.

SOUTH-WESTERN BRANCH.

THE seventy-fifth annual meeting of the South-Western Branch was held on June 23rd at the Royal Hotel, Plymouth. The retiring President, Mr. G. YOUNG EALES (Torquay), took the chair at the opening of the meeting, when there were forty other members present.

Annual Report.—The annual report showed that the membership on April 30th was 479, as compared with 504 in the previous year. This was considered satisfactory in view of the great increase in membership during the Insurance Act campaign and the recent increase in subscription to two guineas. The report enumerated the matters which had chiefly occupied the attention of the Branch during the year. With regard to the relation of Divisions and Branches to Local Medical Committees, it was pointed out that this question had been complicated by the formation of Panel Committees. The enlargement of the powers of Branch Councils—a subject dealt with in the annual report of the Central Council, the recommendations of which would come before the Annual Representative Meeting—was also dealt with. On the question of midwifery fees, it was stated that this matter had now become of comparatively small importance, since the amendment of the Insurance Act placed the midwifery benefit at the disposal of the parturient woman, and this had considerably reduced the difficulty of providing for the remuneration of medical men when called in. The question of the necessity of arranging terms for the future treatment of uninsured persons upon the expiration of contracts had also received attention. It was stated that the Branch Council had determined that it was advisable to bring about an amalgamation of Divisions for special purposes corresponding to the area of the administrative county of Devon. The matter would come before the Annual Representative Meeting at Aberdeen, and probably it would be found best to establish joint committees rather than to seek amalgamation. The appointment of Dr. Frank Roper as Assistant Branch Secretary had greatly helped the secretarial work of the Branch. The financial statement for the year showed a balance in hand of £16 12s. 8d.

Election of Officers.—The report was adopted on the motion of the PRESIDENT, seconded by Dr. NOY SCOTT. The next annual meeting of the Branch will be held at Exeter and Mr. John M. Ackland was appointed President-elect. The Honorary Secretary (Dr. Russell Coombe) and the Assistant Honorary Secretary (Dr. Roper) were re-elected.

Induction of President.—Mr. EALES then gave way to Mr. Woollcombe, the President-elect, remarking that Mr. Woollcombe was known as one of the leading surgeons of the South-West, and one eminently fitted to conduct the meeting of the Branch.

Vote of Thanks.—Mr. ACKLAND proposed a vote of thanks to the retiring President, and that Mr. Eales's name be added to the list of Vice-Presidents. Mr. EALES, in reply, said he had been keenly interested in the affairs of the Branch all his professional life. He had held the office of Secretary five years, and had been their representative on the Central Council of the Association. He had had a quiet year of office as President, and he believed Mr. Woollcombe would have a quiet year, but he anticipated that after the next twelve months their trouble with the Government would begin again.

Early Recognition of Cancer.—The President, Mr. W. L. WOOLLCOMBE, then delivered an address on the responsibility of the medical profession to the municipal authorities, and through them to the public in regard to the earlier recognition of the more common forms of cancer. All

medical men did what they could by advice to individual patients, but that was too often the shutting the door after the horse had been stolen. What was wanted was organized, combined, and sustained effort. Every medical man had found himself many times face to face with the tragic and humiliating experience of being consulted by a patient for what was thought to be a trifling complaint, only to find a condition of helpless malignancy. Why was it that a disease which above all others was so marked that it was almost impossible to mistake the significance of its early manifestations in most of its common forms, should yet be the very one to which the public paid no attention? There were two reasons. First, it was a widespread and firmly-held popular dictum that cancer was incurable; secondly, the picture which the average person formed of a cancer case was that of a wretched, emaciated, cachectic creature, racked with pains, and probably suffering from an offensive discharge; consequently no significance was attached to any symptoms short of these. Medicine had for years been in possession of positive knowledge that cancer was local in origin. For an appreciable time it was amenable to cure by removal, if it occurred in a position where removal could be carried out with sufficient freedom, and in the great majority of cases it did occur in such situations. Statistics showed that in women 80 per cent. of all cancers occurred in the breast and organs of generation. In men a similar percentage occurred in the lips, tongue and alimentary tract, and, with a comparatively unimportant exception, these were all within reach of free removal, though not all so easy of early recognition. All were agreed that for early cases there was nothing at present to take the place of thorough removal by the knife. In setting about the task of painting a new picture of the early and curable cancer case, the medical profession must at first confine itself to certain common types which had well-marked symptoms and work out a series of dogmatic, clearly-defined axioms, easy to understand, and free from uncertainty. For instance, any lump, however small, occurring in the breast of a woman over 40 was serious, and should be shown to a doctor at once. It was more than likely cancer; any uterine bleeding after the menopause demanded instant skilled advice. It almost always meant cancer. Any pimple or sore on the lip or tongue of a man over 40 was probably cancer, but curable if shown at once, and rectal bleeding in a patient over 40, even if quite slight, was serious, and should be reported to a doctor. These examples could be multiplied with ease. In the endeavour to put the public in possession of the knowledge it itself possessed, the medical profession must work through the municipal councils, whose health committees had the power to initiate the necessary measures. All teaching on the subject must be simple, dogmatic, and concise. A start had been made in a few places. At Portsmouth Mr. Childe had been very active in preaching these doctrines, with distinctly noticeable effect, but the only national effort so far was that of the Central Midwives Board, which had issued a leaflet to all midwives concerning uterine cancer. Members of the medical profession should get some members of the Municipal Council to introduce the subject, and have it referred to a committee, with instructions to report, perhaps, with the help of the Division of the British Medical Association. Other measures suggested were: (1) The calling of meetings to which district nurses, midwives, district visitors, and other ladies interested in charitable work and visiting among the poor—perhaps even the clergy themselves—should be invited. (2) The publication in the press, at intervals, say, of a month, of a notice emphasizing a few simple and definite points to assist people in the early recognition of cancer. (3) The provision of facilities for the examination of suspected material from cancer cases amongst the poor. (4) The bringing of pressure to bear on the Local Government Board to make cancer a notifiable disease. This would probably do some good, but the scheme would work quite well without it. After the thanks of the meeting had been conveyed to the President, he proposed the following resolution, which was seconded by Mr. RUSSELL COOMBE, and carried unanimously:

> That this meeting of the South-Western Branch of the British Medical Association wishes earnestly to call the attention of public health authorities to the high death-rate from cancer, and to the appalling state of ignorance that exists in the minds of the public with regard to its early symptoms; and to urge them, as guardians of the public health, to instruct their health committees to consider and report what steps should be taken to remedy this state of things; also to offer the services of the council of the South-Western Branch of the British Medical Association in drawing up a report should such services be required.

Medical Benevolent Association.—Before the commencement of the meeting, the HONORARY SECRETARY called attention to the Devon and Exeter Medical Benevolent Association, and urged all medical men practising in Devonshire to join it. The association had £3,000 invested, and a subscription list of £80 a year. It had money for the purpose, but was unable to do anything for medical men or their widows unless they were members.

Excursion.—In the afternoon excursions were made to Bantham, where the company were entertained by Dr. FOX; to the Batten golf links, and to Devonport Dockyard.

Presentation to Dr. Donbavand.—After the annual dinner in the evening the members gathered in the Palm Court of the Royal Hotel, where the President made a presentation on their behalf to Dr. Edgar J. Donbavand in recognition of his work as honorary secretary of the Branch. The presentation took the form of a piece of plate, a cheque, and a roll of the subscribers, numbering more than ninety. Mr. R. JACQUES paid eloquent tribute to the services of Dr. Donbavand, which had been particularly arduous and valuable during the last two or three years. Dr. DONBAVAND returned thanks.

STAFFORDSHIRE BRANCH:

MID-STAFFORDSHIRE DIVISION.

THE twelfth annual general meeting of the Mid-Staffordshire Division was held on June 23rd at the Trent Valley Hotel, Lichfield. The chairman, Dr. F. M. ROWLAND, and eighteen other members were present.

Election of Officers.—The following officers were elected for the ensuing year:

Chairman: Dr. F. M. Rowland.
Vice-Chairman: Dr. A. E. Hodder.
Honorary Secretary: Dr. T. D. Stuart Shaw.
Executive Committee: Drs. Rowland, Hodder, Lowe, Stack, G. Reid, Clendinnen, C. J. Armson, J. N. Cookson, Dixon, Freer, Gettings, and Stuart Shaw.
Representative at Annual Representative Meeting: Dr. W. M. Clendinnen.
Representatives on Branch Council: Drs. W. G. Lowe, G. Reid, and Stack.

Special Fund.—Matters referred to Divisions were considered at length. With regard to the question of the Special Fund a postal vote had been taken, but the result was so indecisive that the Representative was instructed to use his own discretion as to voting, the Division, however, expressing the definite opinion that a trade union would be preferable to a trust, but only in the event of the Special Fund being supported by a large majority of the profession.

Supersession.—Dr. ROWLAND then proposed, and it was unanimously resolved, that the following become a rule of the Division:

> That in the opinion of this Division it is always desirable that a doctor before accepting a patient during an illness should satisfy himself that the superseded practitioner has been notified.

WEST SOMERSET BRANCH.

THE seventy-second annual meeting of the West Somerset Branch was held at Bridgwater on June 26th. In the unavoidable absence of Mr. Penrose Williams, the chair was taken by Dr. BALFOUR STEWART, Past-President, and twenty-two other members were present.

Annual Report.—The annual report and balance sheet for 1913 were adopted.

Election of Officers.—The following officers were elected:

President-elect: Dr. A. E. Joscelyne (Taunton).
To Fill the Vacancies on the Council: Drs. Alcock and Murphy.
Honorary Secretary and Treasurer: Mr. Chas. Farrant (re-elected).
Ethical Committee of the Branch: The Council of the Branch.

Vote of Thanks.—A hearty vote of thanks was accorded to Mr. Farrant for the energetic way in which he had carried out the duties of Honorary Secretary and Treasurer to the Branch during the past year.

Future Developments of the Insurance Acts.—The question as to the future developments of the Insurance Acts was referred to the Council to answer.

Dr. W. C. G. COLLINS (Cannington), the new President, then took the chair.

Address by Dr. J. A. Macdonald.—Dr. J. A. MACDONALD then delivered the address which is published in this issue of the JOURNAL (p. 1). Dr. Macdonald was heartily thanked at the conclusion of his address.

Luncheon.—An adjournment was made for luncheon, at which twenty-two sat down.

Visit to Cannington.—After luncheon Dr. Collins invited the members to Cannington, where a very enjoyable afternoon was spent. Some played tennis, and others watched a boxing and gymnastic display by the boys of the Cannington Industrial School. It was late before the party broke up, everybody feeling that it had been a very successful meeting.

YORKSHIRE BRANCH:

BARNSLEY DIVISION.

A MEETING of the Barnsley Division was held on June 27th.

Vote of Condolence.—The Honorary Secretary was requested to write to Mrs. Thompson, the widow of Dr. Andrew Thompson of Dodsworth, expressing the sympathy of the Division with her in her sad bereavement.

Election of Officers.—The following officers were elected:

Chairman: Dr. Castle.
Vice-Chairman: Dr. Townsley.
Honorary Secretary: Dr. H. F. Horne.
Representative: Dr. Castle.
Representatives on Branch Council: Drs. Burman and F. J. Sadler.
Executive Committee: Drs. Goodman, Wallis, White, Allott, Harvey, and Johnson.

Future Developments of the Insurance Acts.—The memorandum received from the Medical Secretary, Form D31 A, was carefully considered and answered.

HUDDERSFIELD DIVISION.

THE annual meeting of the Huddersfield Division was held at the Huddersfield Royal Infirmary on June 19th.

Annual Report of Division.—The annual report stated that three meetings had been held during the year, with an average attendance of 11, and that the membership was now 51, a decrease of 10, due to 8 resignations and 2 deaths.

Election of Officers.—The following officers were elected for 1914–15:

Chairman: Dr. G. W. Crosland.
Vice-Chairmen: Dr. J. Irving, Dr. Braithwaite.
Honorary Secretary and Treasurer: Dr. A. L. McCully.
Representative for Representative Meetings: Dr. D. L. Cairns.
Representative on Branch Council: Dr. D. Wilson, jun.
Executive Committee: Dr. Ian Campbell, Dr. W. H. Smailes, Dr. Draper, Dr. Latimer Walker, Dr. F. Knaggs, Dr. P. Rattray, Dr. R. H. Rigby, Dr. Edward Walker, Dr. William Bell, Dr. H. Tansley.

WAKEFIELD, PONTEFRACT, AND CASTLEFORD DIVISION.

THE annual meeting of this Division was held at the Clayton Hospital, Wakefield, on June 24th, when the chair was occupied by Dr. HILLMAN, and nine other members were present.

Election of Officers.—The following officers were elected:

Chairman: Dr. G. B. Hillman (Castleford).
Vice-Chairman: Dr. E. W. Selby (Doncaster).
Honorary Secretary: Dr. W. Eardley (Goole).
Representative to Representative Meetings: Dr. Hillman.
Deputy Representative: Dr. Eardley.
Treasurer: Dr. W. Steven.
Representative to Branch Council: Dr. Steven.
Executive Committee: The above officers, and the following: Drs. J. J. W. Campbell (Castlerod), W. F. Chrispin (Castleford), J. H. Battersby (Doncaster), A. Thomson (Wakefield), R. May (Wakefield), L. A. Johnson (Normanton), H. Scholefield (Normanton), J. Orford (Pontefract), E. B. Osmond (Pontefract), W. Stanger (Wakefield).

Annual Representative Meeting.—The annual report of the Central Council having been considered, it was agreed to instruct the Representative to vote in favour of the establishment of the proposed Special Fund and its protection by means of a trade union.

Eye Specialists.—The HONORARY SECRETARY reported that a meeting of the Executive Committee of the Division had been held on February 26th to consider further the question of an advertisement of the West Riding County Council, which had been refused insertion in the BRITISH MEDICAL JOURNAL. Dr. STEVEN reported that at the Branch meeting at Sheffield on March 18th it was resolved:

> That in the opinion of this meeting £350, as offered by the Education Committee of the West Riding County Council, for a whole-time eye specialist is totally inadequate to secure the services of an experienced surgeon, and that the lowest fee offered should be £500.

Model Organization Rules.—It was decided to consider the model organization rules at a meeting of the Executive Committee, and then put the question of their adoption on the agenda for next meeting of the Division.

Finance.—The Treasurer, Dr. STEVEN, reported that there was a balance at the bank of £22 10s. 6d. (exclusive of interest for the past year) on account of the fund for payment of the Representatives at the Representative Meetings. Upon the proposal of Dr. STANGER, seconded by Dr. JOHNSON, the Treasurer was authorized to pay the Representatives who attended the Representative Meetings in July and December, 1913, at the rate of £1 1s. a day.

Future Developments of Insurance Acts.—Circulars D 31 and D 31 A regarding future developments of the Insurance Acts was referred to the Executive Committee for consideration, with a view to answers being returned to the questions contained therein.

Association Notices.

Special Representative Meeting, Aberdeen.

On the requisition of the Council, notice is hereby given under Article 31 and By-laws 36 and 73, that a Special Representative Meeting of the Association will be held on Monday, July 27th, 1914, at 12 noon, at the Marischal College, Aberdeen, for the purpose of considering the following Report and Recommendation of Council (paragraphs 211 and 212 of Supplementary Report of Council, 1913–14), and, if considered advisable, amending By-law 67 accordingly:

SCOTTISH COMMITTEE.

211. The work of the Scottish Committee is growing, and it is found increasingly difficult for the Chairman to be able to attend all the Committee meetings in Scotland and Council and Committees in London as well. The Committee consequently desires to be able to elect a Deputy Chairman as well as Chairman. By-law 67 provides that each Standing Committee shall appoint from its own number a member of Council as Chairman, in order that the Council may be able to keep in touch with each Committee. The Scottish Committee wishes to be an exception to this By-law and to be able to have a Chairman not necessarily a member of Council, but that effective co-ordination shall be maintained by insisting that one of its three officers—Chairman, Deputy Chairman, or Honorary Secretary—shall be on the Council. As the Scottish members desire the change as early as possible, the Council has arranged that a special session of the Representative Body shall be held at Aberdeen on Monday, July 27th, 1914, at 12 noon, for the purpose (only one month's notice of such an alteration of By-laws being required in the case of a Special Representative Meeting).

212. The Council recommends:

> RECOMMENDATION GG.—That the Special Representative Meeting, Aberdeen, amend existing By-law 67 of the Association, which reads as follows:
>
> 67. Each Standing Committee shall appoint from its own number a Member of Council as Chairman,
>
> to read as follows:
>
> 67. Each Standing Committee except the Scottish Committee shall appoint from its own number a Member of Council as Chairman. The Scottish Committee shall appoint from its own number a Deputy Chairman, as well as a Chairman, and either the Chairman or the Deputy Chairman or the Honorary Secretary of that Committee shall be appointed from amongst members of Council.

T. JENNER VERRALL,
Chairman of Representative Meetings.

June 24th, 1914.

ELECTION OF MEMBERS OF COUNCIL BY GROUPED REPRESENTATIVES.

NOTICE is hereby given that Nominations for Candidates for election of Members of Council by grouped Representatives for the year 1914–15 will be received by the Medical Secretary up to the end of the first hour of the proceedings of the Annual Representative Meeting on Friday, July 24th, 1914. Each Nomination must be on the prescribed form, copies of which will be forwarded by the Medical Secretary on application.

Separate forms have been prepared: (I) For Nomination by a Division (through its Representative), and (II) for Nomination by a Representative of a Constituency included in the Group, and those applying are requested to state for which purpose the form is desired.

The voting papers will be issued at the Representative Meeting to each Representative or Deputy Representative of a Constituency in the United Kingdom in attendance at the Meeting.

By order of the Council,
ALFRED COX,
Medical Secretary.

June 24th, 1914.

CHANGE OF BOUNDARIES.

LEIGH AND WIGAN DIVISIONS.

THE following change has been made in accordance with the Articles and By-laws of the Association, and takes effect as from the date of publication of this notice:

That the urban district of Golborne be transferred from the area of the Wigan to that of the Leigh Division.

Representation in Representative Body.—Unaffected.

BRANCH AND DIVISION MEETINGS TO BE HELD.

BIRMINGHAM BRANCH: COVENTRY DIVISION.—Drs. L. E. Price and D. Davidson, Honorary Secretaries, give notice that a constituency meeting of the Nuneaton and Tamworth and Coventry Divisions will be held at the Coventry Hospital on Friday, July 17th, at 4.15 p.m., to instruct the Representative.

DORSET AND WEST HANTS BRANCH.—Dr. Frank Fowler, Honorary Secretary (29, Poole Road, Bournemouth), gives notice that the summer meeting of the Dorset and West Hants Branch will be held at the Town Hall, Bridport, on Wednesday, July 8th, at 3.30 p.m. Mr. C. Edwards, Vice-President, will read a paper, "Dr. Roberts, a Bridport Worthy." Dr. H. C. Manning will open a discussion on "The Theory and Practice of Tuberculin Treatment." The Bridport practitioners very kindly invite members to luncheon at the Greyhound Hotel (1.30 to 2.30), and Mr. and Mrs. Edwards, Granville House, have kindly offered to give tea. By kind permission of the Mayor, the Municipal Archives will be on view at the Town Hall from 2.30 to 3.30. The West Dorset Golf Club kindly offer members the free use of the club at West Bay. Plans of the proposed new Bridport Hospital will be on view.

EAST YORK AND NORTH LINCOLN BRANCH.—Dr. H. L. Evans, Honorary Secretary, gives notice that the annual meeting of this Branch will be held in Hull on Friday, July 10th. Accounts, election of officers, etc.

LANCASHIRE AND CHESHIRE BRANCH: ST. HELENS DIVISION.—Dr. F. J. Knowles, Honorary Secretary (Victoria Square, St. Helens), gives notice that the annual meeting of this Division will take place at St. Helens on Wednesday, July 8th. Business: (*a*) Election of officers. (*b*) Financial. (*c*) To consider matters contained in the SUPPLEMENT of June 13th. (*d*) General.

METROPOLITAN COUNTIES BRANCH: CITY DIVISION.—Dr. A. G. Southcombe, Honorary Secretary (83, Sidney Road, Homerton, N.E.), gives notice that a special general meeting of the Division will be held in Balfour Hall, Kingsland Road, on Tuesday, July 7th, at 9.30 p.m., to consider the adoption of the model rules of organization for the Division.—Following the special meeting an ordinary general meeting will be held for the usual business, and especially to consider the Supplementary Agenda for the Representative Meeting (SUPPLEMENT, June 27th).

NORTH WALES BRANCH.—Dr. H. Jones Roberts, Honorary Secretary (Llywenarth, Penygroes, S.O.), gives notice that the annual meeting of the Branch will be held on Tuesday, July 14th, at Benllech, Red Wharf Bay, Anglesey.

SOUTHERN BRANCH.—Dr. James Green, Honorary Secretary (Brandon House, Mile End, Landport, Portsmouth), gives notice that the forty-first annual meeting of the Southern Branch will be held at the South-Western Hotel, Southampton, on Thursday, July 9th, at 1 o'clock. Agenda: Correspondence. Election of officers for 1914–15 (scrutineers' report). Annual Report of Council. Balance sheet. Council's recommendation *re* travelling expenses of secretaries of Divisions. Adoption of new rules of organization. Alterations of rules of golf competition. General business. At the conclusion of the business the President for the coming year (Mr. G. H. Cowen) will take the chair and deliver an address. Mr. Cowen invites the members to luncheon at the hotel, at 1.45, and to afternoon tea, to which ladies are invited, at 4 o'clock. The golf competition will be played off at the Stoneham Golf Club directly after luncheon. Excursions will also be arranged. Members intending to accept the President's hospitality will oblige by sending word to that effect to Dr. W. A. Simpson, 3, Waterloo Road, Southampton, as early as possible, but not later than July 6th.

SHIP SURGEONS SUBCOMMITTEE.

THE following practitioners have consented to act as "Correspondents" of the Ship Surgeons Subcommittee, and are prepared to discuss with any ship surgeon in their area any matter of interest either to that surgeon or to ship surgeons in general, and to forward representations to the Subcommittee in regard to any question in connexion with which central action seems desirable:

Correspondent.	*Port.*
Dr. J. Godding, 56, Leadenhall Street, London, E.C.	London.
Dr. A. G. Hinks, 40, St. Vincent Row, Southend-on Sea	London.
Dr. H. T. Bates, Church Road, Wavertree, Liverpool	Liverpool.
Dr. C. Carlyle, 13, Menlove Avenue, Mossley Hill, Liverpool	Liverpool.
Dr. C. J. Cooke, 1, Sussex Terrace, Plymouth	Plymouth.
Dr. J. C. H. Beaumont, Chinsura, Khartoum Hill Road, Southampton	Southampton.
Dr. O. V. Currie, Union Castle Buildings, 58, Adderley Street, Capetown	Capetown.

Ship surgeons visiting these ports and desiring to discuss matters of interest to the service are invited to place themselves in communication with the correspondent for the port.

The Medical Secretary, 429, Strand, London, W.C., will be glad to hear from practitioners in passenger ports not mentioned above who are willing to act as correspondents to the Subcommittee.

Ship surgeons are also asked to forward for the guidance of the Subcommittee, either to one of the above correspondents or to the Medical Secretary, British Medical Association, 429, Strand, London, W.C., their views upon the following questions:

(1) Whether ship surgeons should receive full sea pay while in port *plus* a subsistence allowance at the same rate granted to the chief officer, with a possible liability to have to report every day at the office of the company, or whether they would prefer to receive full sea pay only in port without such liability; subsistence pay, however, to be paid upon those days in port when any duty connected with the ship is performed.

(2) Their views generally on the question of annual leave being granted with full pay to permanent ship surgeons.

THE LIBRARY OF THE BRITISH MEDICAL ASSOCIATION.

BOOKS NEEDED TO COMPLETE SERIES.

THE Librarian will be glad to receive any of the following volumes, which are needed to complete series in the Library:

American Association of Genito-Urinary Surgeons. Transactions. 1906.
American Climatological Transactions. Vols. 1, 4 5, 6.
American Dermatological Association Transactions. Vols. 5, 7, 8, 11, and 29.
American Journal of the Medical Sciences. New series, vols. 4, 5, 1842–3; vols. 14, 15, 1847–8; vols. 18–30, 1850; vol. 33, 1857; vol. 46, 1864–5; vol. 59; or any parts of these vols.
South African Medical Journal. February and April, 1895. Titles, Vols. 3 and 4.
United States Department of Agriculture, Bureau of Animal Industry. Reports 1–7, 10–14.
United States Hygienic Laboratory Bulletins. Nos. 3, 8, 9, 10, 11, 12, 13, 15, 17, 18, 19, 24, 29, 43.
Virchow's Archiv. Vols. 1–150.
Watt. Bibliographia Britannica, 4 vols., 1824.
Yearbook of Pharmacy. 1912.

LOCAL MEDICAL AND PANEL COMMITTEES.

EDINBURGH.

PANEL COMMITTEE.

A MEETING of the Burgh of Edinburgh Panel Committee was held on June 24th. Dr. DEWAR occupied the chair, and thirteen members were present.

Budget Proposals.—The Committee had under consideration the Budget proposals so far as they affect the national insurance scheme. After discussion of the general question, Dr. ORR moved, and Dr. MORRISON MCINTOSH seconded, the following motion, which was agreed to unanimously:

To ask the Commissioners in how far the proposals under the Budget are designed to affect non-insured as well as insured persons.

Discussion then took place as to whether the administration of the new scheme should be placed in the hands of the local authority, the Local Insurance Committee, or an entirely new committee. On the motion of Dr. MARTIN, seconded by Dr. ROBERTSON, it was unanimously resolved:

That in the opinion of the Panel Committee, it is inadvisable that the administration of the New Developments in Medical Treatment, outlined in this year's Budget proposals in connexion with the Insurance Act, be wholly in the hands of the Local Insurance Committee or Local Authority.

On the question of the administration being placed in the hands of a new committee, Dr. MORRISON MCINTOSH moved, and Dr. ORR seconded, the following motion, which was carried unanimously:

That a Joint Committee, composed of representatives elected by the following bodies, should be instituted: (*a*) The Insurance Commissioners; (*b*) the Insurance Committee; (*c*) the County or Borough Council; (*d*) the Local Hospitals (Board of Management and Medical Staff); (*e*) the Local Medical or Panel Committee); (*f*) the University and Colleges (where practicable); (*g*) Local Public Nursing Association.

Circular to Practitioners.—The following circular, dealing with certification and excessive drugging, was passed by the Committee for distribution to practitioners on the Edinburgh panel:

CERTIFICATION.

It is within the knowledge of the Panel Committee that some doctors are still lax in their method of dealing with sick benefit certificates. This is probably due to an insufficient knowledge as to the procedure. For the information and guidance of insurance practitioners it may be well to make some definite statements as to the granting of these certificates.

I.—There must be no ante-dating or post-dating.

Ante-dating refers to the initial or declaring-on certificate.

Post-dating refers to the final or declaring-off certificate.

The Initial Certificate.—Dr. A. sees Mr. X. on January 10th. He must fill up and sign the certificate with the date January 10th, and not January 7th, 8th, or 9th. The essential point is that each certificate must be dated for the day on which the patient is seen, as it is a document stating an actual fact, and must be a true statement of what has taken place for the guidance of societies.

If, as it occasionally happens, a patient is confined to bed for two or three days, and is under the belief that he will be better after a little rest and simple home treatment, and therefore does not care to trouble the doctor, the latter may on his first visit when sent for, while granting the initial certificate with the date on which the patient is seen, add the words or such like "that from the signs and symptoms shown, and from the statement made by the patient that he has been confined to bed for two or three days, he believes the statement to be true." This procedure does not entail a hardship upon a well-meaning patient, and leaves it open to the society to pay or not, as it thinks fit. At all events, it removes the stigma of a possible complaint being made against the doctor for acting harshly, it does not penalise an honest and careful insured person, and does not unduly cast a burden on the society's funds, as the patient is legally entitled to have these first days counted as waiting days in the case of a first illness.

The Medical Service Subcommittee has recommended that the doctor should, if the patient is suffering from an ailment which would incapacitate him or her from working even for a few days, or which might develop into a more serious condition, give Form Med. 34 on his first visit. In this connexion it is to be remembered that the initial certificate does not carry with it any obligation on the part of the society to pay sick benefit, but is only an indication that the insured person is suffering from an ailment which may in due course entitle him or her to sick benefit.

Sick benefit is only paid on the production of the second or continuation certificate at the end of a week or thereby according to the rules of the society.

Post-dating.—In granting the final or declaring-off certificate, the doctor cannot be allowed to sign and date this certificate until or after the day when the patient's incapacity for work has ceased.

II.—The greatest care must be taken in signing the second or continuation certificates. These have to be signed at certain intervals, and before signing these certificates the doctor must satisfy himself by a personal examination that the patient continues to be unfit for work. These certificates must not be granted on any consideration to messengers, without the patient having been seen by the doctor.

When in doubt as to fitness or unfitness to work, it would be well for the doctor to seek the opinion of a colleague in justice to himself and the society. Medical referees will shortly be appointed, when it will be open to every insurance practitioner to avail himself of their services in these doubtful cases.

III.—Finally, if any practitioner after investigation by the Medical Service Subcommittee is found to be persistently granting continuation certificates when not actually required, a recommendation may be made by the Insurance Committee to the Commissioners requiring them to exercise their powers under Regulation 45, 12, and Regulations Part VI:

Where the Insurance Committee are of opinion that the continuance on the panel of a practitioner will be prejudicial to the efficiency of the service of insured persons, they may make representation to that effect to the Commissioners.

EXCESSIVE DRUGGING.

It is well known to the Committee that some practitioners are still in the habit of prescribing excessive quantities of drugs, expensive drugs, when their exact equivalents might be used, and are being used by many practitioners in private practice, and articles which are being used for their food value and not exactly for their medicinal value. This matter was pointed out to practitioners in a former circular, but in order to bring it home a few cases may be cited.

1. One panel doctor ordered five phylacogen tubes within a fortnight at a cost of £3, four india-rubber bandages at 2s. 6d. each for one one patient at one time, and in the previous month seven of these bandages for three patients.

2. One panel doctor gave five prescription orders, the five bottles as prescribed containing more than two quarts of pure alcohol. The cost of these five forms was respectively 34s. 6d., 17s. 4d., 15s. 9d., 14s. 3d., 14s. 3d., a total of £4 16s.

3. Orders for seventeen tubes of phylacogen were found in one chemist's parcel prescribed by one doctor. Cost £10. Phylacogens are now disallowed.

4. One patient received within three weeks, twelve flannel bandages 15s., and ointment 11s.

5. One chemist, by orders from one doctor, supplied to eighty patients 76 lb. of cod-liver oil emulsion, and 74 lb. of malt and cod-liver oil emulsion to forty patients in one month.

It may also be pointed out that during the year 1913 the average price per prescription form rose from 3¾d. in January to 11¾d. in December, and this year the average cost still remains as high as in December. The cost per head for 1913 was 1s. 2d., as compared with 8d. and 9d. in many areas in Scotland, and the Commissioners, after investigation, have found that the insured persons in the 8d. and 9d. areas receive just as good treatment as those in this area. One districts in this area is as high as 2s. 2d. per head. These facts clearly show that at present there is excessive prescribing as to quantities or expensive drugs.

The Committee would earnestly appeal to practitioners to be extremely careful in their prescribing. Otherwise the penalty of surcharging or deducting from practitioner's remuneration the cost when it is proved to be excessive and unnecessary will be put in force by the Insurance Committee.

JOHN CRAIG,
June 24th, 1914. Honorary Secretary.

The Treasurer, Dr. MORRISON MCINTOSH, reported, in response to the voluntary call, that out of 94 panel practitioners, 75 had, up to date, paid £1 1s. each, while 6 had refused to subscribe anything, and one or two had resigned from the panel. With these exceptions, he stated that he expected to be able to collect most of the balance still outstanding. On the motion of the CHAIRMAN, a hearty vote of thanks was accorded to Dr. Morrison McIntosh for the very successful way in which he had carried out the collection of the levy.

On the motion of Dr. CRAIG, the Treasurer was empowered to pay to the chairman his out-of pocket expenses, incurred in connexion with his visit to London in March last in connexion with the Conference of Local Medical and Panel Committees.

PERTHSHIRE.

A MEETING of the Local Medical and Panel Committees of Perth and Perthshire was held at Perth on June 26th, when Dr. STIRLING was in the chair and nine other members were present.

Report of Subcommittee.

Over-prescribing by Panel Practitioners.—Dr. TROTTER stated that he had been in communication with the Pharmaceutical Committee and the doctors concerned. It was proposed in the meantime not to surcharge for over-prescribing, as this had probably occurred through inadvertence on the part of doctors, but that doctors and chemists should all be circularized by the Insurance Committees, warning them on the subject. This circular was submitted for approval.

Over-charges in Chemists' Accounts.—Dr. HUME stated that a large number of accounts had been gone over, and it was found that mixtures formed a very small proportion of the prescribing, so that the charges for water only amounted to a very small total, in comparison with the large sums received by chemists for dispensing ready-made pills and other preparations which were specially favoured by certain doctors in preference to combinations of *British Pharmacopoeia* drugs. A number of expensive prescriptions were read to the meeting.

On the motion of Dr. TROTTER, seconded by Dr. HAIG, the report was adopted, and Dr. Trotter was authorized to write to the Clerk of the Insurance Committee that steps

were being taken to remedy over-prescribing, but that in the meantime no surcharging of doctors would take place.

Budget Proposals.

The meeting considered at length the various Budget proposals with regard to certain important extensions of medical service under the Insurance Acts. It was decided by a majority that grants for clinical purposes and nursing should be administered by Insurance Committees, with an adequate representation from hospital managers and staffs, instead of by public health authorities.

LIVERPOOL.

Local Medical Committee.

The forty-first meeting of the Committee was held at the Medical Institution on June 19th, when the chair was taken by Mr. Larkin, and ten other members were present.

Representatives on Insurance Committee.—In view of the forthcoming election by the medical profession of Liverpool of two representatives on the Liverpool Insurance Committee, the meeting unanimously supported the nominations of Mr. F. Charles Larkin and Dr. W. B. Bennett.

Meeting of the Profession.—It was decided that a meeting of the Liverpool medical profession should be held at the Medical Institution on Tuesday, June 30th, at 3.30 p.m., to consider the following agenda:

1. Report of proceedings of the Local Medical Committee since the last general meeting.
2. Financial statement by the Treasurer.
3. Scheme for the constitution of future Local Medical Committees.
4. Question as to how the Committee is to be financed in future.

Panel Committee.

Meetings of the Liverpool Panel Committee were held at the Medical Institution on June 2nd and June 19th, when the chair was taken by Mr. F. C. Larkin.

Meeting of Panel Practitioners.—The Secretary read a report of the special meeting held under the chairmanship of Mr. Larkin on May 21st, to which all the Liverpool panel practitioners had been invited to confer with the Panel Committee; the proceedings of the Panel Committee were reported to the meeting, and a motion by Dr. Shaw, seconded by Dr. Moyles, that the fund to cover the expenses of the Panel Committee should be raised compulsorily under the provisions of the National Insurance Act, 1913, was carried by a large majority, after an amendment suggesting a voluntary fund had been defeated by 25 votes to 15. It had further been resolved that a Local Panel Association should be formed, and at the meeting of the Panel Committee on June 2nd, it was decided to appoint a Subcommittee to draw up a scheme.

Expenses of Committee.—It was resolved to request the Liverpool Insurance Committee to allot a sum sufficient for the administrative expenses of the Panel Committee; a subcommittee appointed to consider the matter estimated the annual expenditure of the Committee at £130.

Model Schemes.—A letter was read from the Insurance Commissioners with reference to proposed modifications of certain of the clauses and rules of Model Schemes A and B, which were considered by the Committee to be decided improvements.

Treasurer.—Dr. S. H. Shaw was appointed treasurer of the Committee.

Distribution of Panel Funds.—The Committee approved the proposals of the Special Subcommittee contained in a communication from the administrative officer with regard to the method of distribution of the balance of the available panel funds.

WARWICKSHIRE.

Panel Committee.

A meeting of the Panel Committee for Warwickshire was held on June 23rd at Leamington, when Dr. J. Orton (Coventry) presided, and twelve other members were present.

Medical Referees.—The Secretary reported that he had had correspondence with a doctor with regard to referee work, and that the doctor had agreed to send a printed notice to those doctors whose patients he was requested by a society to visit.

Election of Committee.—The Secretary reported that he had received a letter from the Commissioners assenting to the scheme drawn up by the Committee for the election of the new Panel Committee, and thanking the Committee for its expedition in completing the scheme; also announcing that Mr. Whitehead, Clerk to the Insurance Committee, had agreed to act as returning officer without fee for his personal services.

Expenses of Committee.—The Finance Committee submitted its report, and, on the motion of the Chairman, seconded by Dr. C. K. Lunn, it was resolved:

> That the Secretary be paid £37 for his out-of-pocket expenses and services during the period January, 1913, to March, 1914.

Payment of Members.—A discussion took place on the question of payment to members of the Committee. On the motion of Dr. A. Joseph, seconded by Dr. C. K. Lunn, in was agreed that members attending meetings of the Panel and Insurance Committees should be paid 5s. for every meeting they attended, the motion to be retrospective from the formation of the Panel Committee.

Honorarium to Secretary.—On the motion of Dr. Powell, seconded by the Chairman, it was agreed that the Secretary should be paid an honorarium of £50 a year from the formation of the Panel Committee.

Reports of Medical Service Subcommittee.—The Secretary reported the receipt of a letter from the British Medical Association on the necessity of treating the names of doctors mentioned in cases dealt with by Medical Service Subcommittees as strictly confidential. The Committee agreed with the suggestion.

Representatives on Insurance Committee.—The Committee nominated Drs. Latimer, Greene (Stratford-on-Avon), and Relton (Rugby), on behalf of the panel doctors of the area, to represent them on the Insurance Committee.

Certificates.—The Secretary reported the results of the conference held in London by the Commissioners on June 16th, at which the Chairman and Secretary attended, with regard to the proposed alterations in dealing with certificates of inability to work.

WEST RIDING OF YORKSHIRE.

Local Medical and Panel Committees.

Meetings of the Local Medical and Panel Committees were held at Wakefield on April 24th, May 22nd, and June 12th.

New Member.—Dr. H. Steinbach (Knaresborough) attended as representative for Harrogate and Ripon, vice Dr. Pringle, resigned.

Publication of Lists of Panel Doctors.—It was decided to call the attention of the Commissioners to the fact that, in spite of their recommendation to replace the name of "doctor" by a number or cypher, the Insurance Committee had issued to its members a list of the doctors and the number of each one's patients.

Disputed Removals.—This matter was referred back to the Subcommittee, with instructions to interview the clerk, and, if necessary, request an interview with the Medical Benefit Subcommittee, and thus endeavour to get some sort of working arrangement.

Model Schemes for Election of Panel Committee.—A report from the Subcommittee having been considered, it was decided to inform the Commissioners that it was proposed to adopt with certain modifications Model Scheme B, which provided for election by meetings of panel practitioners summoned for the purpose by a returning officer, but objected to the unnecessary expense of a returning officer. The Commissioners in reply had suggested that on the ground of expense the number of constituencies should be reduced to six, in place of the present thirty-six. In this way it would be necessary to hold only six meetings. They had further stated that the expense of the election would form part of the administrative expenses of the Committee, and refused the request of the Committee to extend the term of office from one to three years. It was resolved:

> That the Secretary be instructed to write again to the Commissioners pointing out that six meetings for election of representatives are insufficient to meet the needs of the vast area of the West Riding, and that the electors would not be able to turn up in sufficient numbers to make the election representative.

The Secretary was directed at the same time to press again for permission to carry out the election on the previous lines, the election of the present Committee having proved simple, inexpensive, and satisfactory to all concerned.

Range of Medical Services.—A letter having been read from the Clerk of the Insurance Committee regarding a panel doctor's request for payment for circumcision, it was agreed that the operation came within the ordinary routine of general practice, and therefore was not outside the scope of medical benefit under the Act. It was also decided that attendance on an insured person for gangrene during the month following her confinement was part of the attendance on the confinement.

Co-ordination of Local Medical and Panel Committees.—It was resolved to subscribe £25 to the proposed organization to co-ordinate the work of Local Medical and Panel Committees, and to safeguard and promote the interests of those represented by them. A letter from the Leicester Local Medical and Panel Committe urging that the new organization should be registered as a trade union was ordered to lie on the table.

Excessive Ordering of Drugs.—A letter with regard to excessive ordering of drugs was approved for circulation to doctors on the panel.

Model Scheme for Election of Local Medical Committee.—In view of the general desire throughout the area that the personnel of Local Medical and Panel Committees should be the same, it was decided to adopt Model Scheme A, which provides that the Local Medical Committee shall consist of the members for the time being of the Panel Committee for the area.

Medical Referees.—The following resolution was adopted:

> That the Secretary be instructed to circularize the practitioners of the West Riding area that the temporary scheme of medical referees, which was adopted by the Local Medical Committee in September, 1913, will remain in force till a system of Government referees is carried out, and that each practitioner is requested to observe the said scheme loyally in the future as in the past.

Financial Statement.—The financial statement, which was approved, showed a balance in hand of £6 2s. 11d.

CROYDON.

PANEL COMMITTEE.

THE following were duly elected on June 25th to serve on the Panel Committee: Drs. E. M. Cowell, T. A. Dukes, G. G. Genge, F. Nicholls, G. Wale, P. Harris, J. H. Thomson, J. L. Menzies, F. Murphy, A. P. Allan, F. Beard, S. H. C. Air, S. S. Simmons, F. D. Atkins, A. Rose, J. C. S. Peatson, H. L. Sells, C. G. C. Scudamore, E. H. Willock.

The above members of the Panel Committee, together with the following ten medical men, who were duly elected on June 25th last to serve on the Local Medical Committee, constitute that Committee: Drs. C. Wray, J. S. Richards, E. L. Adams, J. Wayte, R. C. Brown, G. Lewin, J. Davidson, C. O. Fowler, R. L. Pinkerton, P. W. James.

The Committees take office after July 15th next.

NEWPORT (MON.).

PANEL COMMITTEE.

IN accordance with the scheme circulated by the Welsh Insurance Commissioners, a new Panel Committee (of eighteen) was elected on June 26th. The following practitioners were returned as duly elected after a ballot:

W. J. Greer, F.R.C.S. (Chairman)	J. Lloyd Davies, M.R.C.S.
S. Hamilton, M.D. (Honorary Secretary)	C. B. Gratte, M.R.C.S.
E. Rhys Harries, M.D.	J. Hurley, L.R.C.S.
V. Crinks, M.R.C.S.	J. Lane, M.B.
W. Basset, M.R.C.S.	W. M. James, M.R.C.S.
J. Buckner, L.R.C.S.	J. McGinn, F.R.C.S.I.
T. G. Lewis, M.B.	O. Morgan, L.R.C.S.
J. Cook, M.R.C.S.	Rees Morgan, L.R.C.S.
	J. F. Neville, L.R.C.S.
	C. S. Vines, M.R.C.S.

DENBIGHSHIRE.

PANEL AND PHARMACEUTICAL COMMITTEES.

A JOINT meeting of the Panel and Pharmaceutical Committees was held at the Queen's Head Hotel, Chester, on June 22nd. Dr. E. Moss was unanimously elected to the chair.

Excessive Prescribing.—On opening the discussion on excessive prescribing, it was stated that the Panel Committee had come to the decision to write to each practitioner on the panel asking him to make every effort, consistent with the adequate treatment of the patient, to keep the average price per prescription as low as possible. Mr. ADAMSON, speaking for the Pharmaceutical Committee, stated that in asking for that joint meeting, the object had been, not to prevent the medical men from prescribing good medicine, but to come to some mutual arrangement whereby the cost of medicine for insured patients might be reduced. Dr. ROWLAND said that the question of excessive prescribing had two aspects—namely, the quantities of the drugs ordered and the number of prescriptions written, both of which had their influence on the drug fund. It was resolved:

> That a suggestion should be made to the practitioners in the county that they should, as a general rule, prescribe 8-oz. mixtures with ½-oz. doses.

Repeat Prescriptions.—Dr. ROWLAND said that it was quite usual for a patient to require the same medicine continuously for some weeks, and it simplified matters greatly for the doctor if he was allowed to order "repeats." He quite recognized the difficulty in tracing the prescriptions, but he felt it was a matter for the individual chemist to deal with. The CHAIRMAN observed that the Commissioners had definitely refused to sanction repeat prescriptions. Speaking for the Pharmaceutical Committee, Mr. L. B. ROWLAND said that he felt it would be unwise for chemists to adopt a rigid attitude in this matter, and Mr. T. J. ROBERTS that, in their circular letter, the Commissioners stated that they regarded "repeats" as a matter for working arrangement between practitioners and chemists. Mr. E. D. JONES, Clerk to the Insurance Committee, said it must insist upon having copies of the original prescription made on forms ordering "repeats." On the motion of Mr. L. B. ROWLAND, seconded by Dr. MORRIS-JONES, it was resolved:

> That "repeat" prescriptions may be written, subject to the following conditions:
> (*a*) That no other item be prescribed on a form ordering any "repeat."
> (*b*) That the date of the original prescription be given on the form.
> (*c*) No repeat to be ordered when the original prescription was ordered more than twenty-one days previously.
> (*d*) That the practitioner shall supply a copy if requested by the chemist.

Emergency Dispensing.—Dr. ROWLAND said that in his view, since dispensing had been taken out of the hands of doctors for those insured persons who lived within a mile of a chemist's shop, it was the duty of the chemist to dispense for these patients at all times. There was some discussion, in the course of which Dr. MORRIS-JONES said that in Colwyn Bay if a prescription was marked "urgent" there was no difficulty in getting it dispensed. The following motion, proposed by Dr. MEDWYN HUGHES, and seconded by Dr. J. D. LLOYD, was carried:

> That this joint meeting of Panel and Pharmaceutical Committees recommends the Insurance Committee to allow extra dispensing fees for prescriptions dispensed by chemists outside their ordinary hours of business; such prescriptions to be marked "urgent."

Marking Prescriptions.—Dr. ROWLAND reported that practitioners had received a circular letter as to marking prescriptions for the appropriate funds, but there was some difficulty as to the correct fund for certain drugs for tuberculosis patients. Dr. MIDDLETON held that drugs for the treatment of concomitant diseases in tuberculous patients should be marked "ordinary," and charged accordingly. Dr. LLEWELYN WILLIAMS (Medical Officer to the Welsh Commission) held that all drugs prescribed for these patients should be marked "Sanatorium," and charged to the Memorial Fund. On the motion of Dr. Moss (Chairman), seconded by Dr. MORRIS-JONES, it was resolved:

> That in future prescription forms be marked "Panel," "Sanatorium," "Temporary Resident," and that this be a recommendation to the Insurance Committee.

Mr. E. D. JONES said that it would be a convenience to the Insurance Committee if temporary residents' prescriptions were marked with the area from which the patient came.

Stock Mixtures and Proprietary Preparations.—It was proposed and seconded:

That no stock mixtures should be prescribed except from the tariff and the B.P.C., unless the practitioner had private formulae, for which he might arrange with the local chemists.

Whereupon the following amendment was proposed:

That stock mixtures may be prescribed, but that no particular wholesaler's name may be written on the form.

There was considerable discussion, during which Mr. L. B. Rowland remarked that many concentrated mixtures were practically infringements of the Food and Drugs Acts in that certain preparations nominally contained in them could not conform to the *British Pharmacopoeia* standards. It was referred to a subcommittee to consider the questions of stock mixtures and the tariff, and to report, as early as possible, to a joint meeting of Panel and Pharmaceutical Committees. The following gentlemen were appointed to serve on the subcommittee:—Panel Committee: Dr. Moss (Wrexham), Dr. J. D. Lloyd (Chirk), Dr. David Lloyd (Denbigh). Pharmaceutical Committee: Mr. J. W. Adamson (Colwyn Bay), Mr. L. B. Rowland (Wrexham), Mr. T. J. Roberts (Ruthin), and Mr. E. D. Jones, Clerk to the Insurance Committee.

GLAMORGAN.

Panel Committee.

A meeting of the County of Glamorgan Panel Committee was held in Cardiff on June 22nd. Dr. W. E. Thomas was in the chair, and twelve other members were present.

Medical Referees.—A discussion took place on the subject of medical referees and the minimum fee of 10s. 6d., and a resolution was passed directing the Secretary to send a synopsis of important matters to every panel practitioner.

Travelling Expenses.—A letter was read from the Insurance Commissioners stating that the travelling expenses of members attending meetings of the Panel Committee could not be met out of any sums paid to that Committee under the provisions of Section 33 (2) of the National Insurance Act.

Election of Returning Officer.—The election of the new Panel Committee to hold office after July 15th was considered, and Dr. J. Shaw Lyttle was appointed the returning officer.

INSURANCE COMMITTEES.

LONDON.

A meeting of the London Insurance Committee was held on June 25th.

Distribution of the Unallotted Funds.

As briefly noted in the last issue (Supplement, p. 495), the Committee gave further consideration to the question of the distribution of the unallotted funds. The Medical Benefit Subcommittee advised the Committee either to proceed at once to distribution, or to express the opinion that the Commissioners should distribute.

Mr. F. Coysh, Chairman of the General Purposes Subcommittee, moved that the Committee adopt the first alternative. He said the payment to the doctors was based on a system of credits, and the Committee could have varied the basis of credits if it had passed a resolution to that effect during the medical year. As it had not, it followed that it admitted the basis of the doctors' acceptances as that on which payments were to be made for services rendered.

Mr. Kingsley Wood moved the following amendment:

That having regard to the decision of the Committee, "that it is undesirable that any medical man on the London panel should undertake to treat a larger number of insured persons than 2,000," the Committee is not prepared to distribute the surplus moneys in the panel fund on a *pro rata* basis unless or until a legal decision has been obtained or a further parliamentary authority has been given.

He did not accept the explanation given as to why the Committee was debarred from preparing a scheme for distribution; he did not believe any regulation under the Act was dependent upon considerations of time. No one could say that the system of distribution provided under Article 40 (3) was just. He had received many letters from doctors with small lists, who pointed out that they had taken on panel work chiefly on the assumption and on specific promises that their lists would be augmented from those who had not chosen a doctor. The resolution would treat those doctors very badly, and by putting money in the pockets of those with large lists, would encourage a bad medical service.

Mr. O. E. Warburg seconded the amendment.

Dr. B. A. Richmond said that as long ago as October 13th, 1913, a report was submitted to the General Purposes Subcommittee which set out the exact position which would arise. That report was not dealt with because the Committee was waiting for a legal opinion. The amendment would not solve the pressing problem now before the Committee of getting more doctors in industrial areas; it would penalize those who had devoted their lives to work in those areas. It was assumed that the doctor with a big list was necessarily doing bad work and was an inefficient member of the service, but it was remarkable that many more complaints in proportion came before the Committee in respect of doctors with small lists.

Mr. R. J. Mills, an approved society representative, urged that the agreements with the doctors only provided for a payment per head on acceptances, and made no promise of a bonus. He and other members had a mandate from their organizations not to agree to a method of distributing the money which they did not regard as right or advisable.

Dr. H. H. Mills said that the covering letter issued with the agreement promised that doctors on the panel would be paid in respect of all insured persons. If an agreement as to distribution had been made before the end of the medical year it would have been accepted by everybody, and medical practitioners regretted that an agreement was not reached.

Dr. Lauriston Shaw remarked that it was agreed that the doctors on the panel collectively were entitled to the money; they had a right to expect reasonable expedition. Any reasonable method of distribution would probably be accepted by the doctors.

Mr. P. Rockliff stated that the Commissioners had approved in some areas, since the end of the 1913 medical year, alternative methods of distribution.

On being put to the meeting the amendment was carried by 27 votes to 25, and then adopted as a substantive resolution.

Legal Rights of Panel Practitioners.

The Medical Benefit Subcommittee reported that in the case of a practitioner who became an inmate of an asylum, the insured persons on his list were notified that he had ceased to practise in the area and were provided with forms for the selection of other practitioners. The practitioner, after his discharge, served a writ on the Committeee claiming £94 for professional services between January 14th and March 31st. The Committee's solicitors advised that, inasmuch as treatment had been provided by a locumtenent during the doctor's absence, the Committee should settle the claim by consent. The practitioner had accepted £90 and £5 costs in full settlement of his claim.

In regard to the action brought by Dr. Salter for the restoration of his name to the medical list (British Medical Journal, June 27th, p. 1437), a question was asked as to why the Committee had never been asked to confirm the action of the Subcommittee in removing the name, and a full report was promised for a subsequent meeting.

Complaints against Practitioners.

The Committee endorsed the action of the Medical Service Subcommittee in a number of cases of complaints against practitioners.

In six cases, in which the circumstances do not call for special mention, the Subcommittee found that complaints of neglect were unsubstantiated.

An approved society made a complaint as to certification in a case in which an insured person continued to work while drawing sickness benefit, and was sentenced to imprisonment therefor. The Subcommittee, on the evidence, upheld the doctor's certificate as bona fide; the man had just been operated upon for an abscess, he had bronchitis, a troublesome cough, cardiac irregularity, and was emaciated, but, unknown to the doctor, he went to work. A case in which failure to provide treatment was due to a doubt whether a person was on a doctor's list, the corrected list not having been received from the Insurance Committee, was adjudged to be met by the payment by the doctor of 2s. 6d. expended in obtaining treatment

elsewhere. An approved society complained that a practitioner had suppressed information because in giving a certificate of incapacity for varicose veins and rheumatism he did not also state that the patient was pregnant. The Subcommittee found that the certificate was a proper one, as it stated the actual cause of incapacity.

A complaint of failnre to attend was found to be substantiated, and the Subcommittee stated that about 4,000 persons were divided between the practitioner and a partner. The Subcommittee had come to the conclusion that the practitioner was unable to give adequate treatment to all the insured persons for whom he was responsible, and had decided to remove from his list without further inquiry the name of any insured person who made application. A second complaint was made against the practitioner that he sent a prescription on receipt of a verbal message given to his secretary and without seeing the patient. The Subcommittee thought the doctor's methods of conducting his practice were not satisfactory. It was understood that he had only recently obtained his qualifications and joined the panel. He was cautioned that an improvement in his methods must be shown.

It was alleged that a practitioner declined to provide treatment because the request to visit had not been received before 10 a.m., and that he made callous remarks on the matter. Another practitioner diagnosed the case as serious, and had the patient's relatives sent for from the country. Before the Subcommittee the practitioner admitted that he lost his temper, and said that he would have provided treatment if it had been a private case. The Subcommittee found that the practitioner refused to provide treatment, although he was actually in the house, and had been informed that the patient was seriously ill. It had concluded that the doctor did not properly appreciate his responsibilities towards insured persons. This practitioner had previously been censured. The Subcommittee had therefore decided to make representations to the Insurance Commissioners with a view to the removal of the practitioner's name from the panel.

MANCHESTER.

Sanatorium Accommodation.

AT a meeting of the Manchester Insurance Committee on June 23rd attention was drawn to statements as to the sanatorium accommodation which had been the subject of a question in the House of Commons, and seemed to reflect on the Manchester Insurance Committee. The Chairman said he thought there had been some confusion in the press between the Manchester Committee and other Committees, and it ought to be made clear that the statement did not refer to Manchester. Councillor Jackson, the chairman of the Sanatorium Benefit Subcommittee, said he took it that the statements did not refer to treatment, but only to accommodation; though Manchester was not directly referred to, it was somewhat short of hospital accommodation for advanced cases of tuberculosis, and up to the present had been able to deal properly only with the early cases. According to the recommendations of the Departmental Committee on Tuberculosis, Manchester ought to have about 300 beds, but as a matter of fact it had something like 330—namely, 150 at Baguley, 62 at Delamere, 50 at Abergele, and 70 at Clayton, while they had also about 20 cases in the Manchester Infirmary. The accommodation at Baguley was being increased, and when completed he thought the pressure might be met, though he still had some doubts.

It appears that the statement referred to really referred to the Salford Insurance Committee; it was to the effect that of 88 people who applied for sanatorium benefit, it could be given to three only. The fact is that on May 13th the Salford Sanatorium Benefit Subcommittee considered 88 cases. Of these, 42 were old cases, all recommended for a further period of treatment, ten of them in residential institutions; and all have received the treatment recommended except one, who went to Australia, and another who on examination at the dispensary was found not to be suffering from tuberculosis. Of the new applications, 45 were recommended for sanatorium benefit, and all have received it, eight being in residential institutions. It is unfortunate that the Drinkwater Park Hospital of the Salford Corporation, where many of the patients receive sanatorium treatment, still retains its old name of "hospital," as it is now in every sense of the word a sanatorium for early cases of tuberculosis.

SALFORD.

Alleged Over-prescribing.

AT the monthly meeting of the Salford Insurance Committee on June 25th the Clerk read a letter from the Commissioners with reference to the request of the Committee that the Commissioners should hold an inquiry in Salford as to the alleged over-prescribing. The Committee had not felt competent to decide between the report of the Pharmaceutical Committee, which named sixteen of the panel practitioners as having exceeded the average in the amount of their prescriptions per insured person treated in the last year, and the report of the Panel Committee, which recommended that none of these practitioners should be surcharged for over-prescribing. The Commissioners replied that they had no power to hold an inquiry, but would be prepared to arrange a conference at their offices if the Committee so desired, where representatives of the Committee, the doctors, and the chemists might discuss the points at issue.

Several members of the Committee thought there was some danger under the present system of going to the opposite extreme—that is, of under-prescribing—as each doctor was individually responsible for the cost of his own prescriptions. In that case the insured persons would suffer, and the medical members of the Committee were asked to state their opinion as to whether the 2s. available for drugs and appliances was adequate.

Dr. BRADLEY said the amount required in such places as Salford must be larger than in rural or seaside places. The reason for the big bill in Salford was not the cost of the individual prescriptions, which was only about 7d. on the average, but that so many insured people required treatment. In April there were over 17,000 sick people out of an insured population of 85,000. His own private view was that the 2s. was not sufficient in Salford.

Dr. TAYLOR said he did not think it was possible to say whether 2s. was sufficient or not. The cost for last year was 2s. 7¾d. per insured person, and if all the doctors who were alleged to have over-prescribed were cut out, the 2s. was even then not sufficient for the remainder; it would have needed about 2s. 2d. to pay the chemists in full. But the first year was exceptional in many ways, and should not be taken as a criterion. Looking at the first five months of the present year, since the system came into operation by which the doctors were credited with the whole 9s. but debited each with the cost of his own prescriptions, it seemed that the 2s. was more than sufficient, and there was undoubtedly some danger of under-prescribing. Thus he did not think the Committee was in a position at present to make any representations to the Commissioners with regard to the 2s. being too small an amount.

After further discussion, the feeling was expressed that, after all, the dispute between the Panel and Pharmaceutical Committees might be referred back to them to see if they could not arrive at some understanding or compromise which could be accepted by the Insurance Committee, and this was accordingly resolved.

EDINBURGH.

Allocation of Funds.

AT a meeting of insurance service practitioners on the Edinburgh panel, held on June 4th, when Dr. DEWAR was in the chair and thirty-seven practitioners were present, it was unanimously agreed, after full discussion of the method of distribution of the balance remaining in the panel fund, that the money should be divided equally among the practitioners on the Edinburgh panel.

At a meeting of the Insurance Committee for the burgh of Edinburgh, held on June 25th, a report was submitted by the Medical Benefit Subcommittee to the Insurance Committee recommending the Committee to adhere to its former proposal that the funds available should be divided on the basis of the scheme approved for a personal allocation, and that the sum so paid should be accepted in full settlement and final discharge of all claims against the Insurance Committee for the year ended January 11th, 1914.

Dr. BOWIE said that while there was some justification for the proposal that the medical men who had the smallest panel should get most of the unallocated persons, but the proposal of the Subcommittee was quite different. Under it a doctor who had six insured persons on his list would receive the sum of £24, whereas those who had 1,500 to 2,000 on their lists would get £12 each, which was ridiculous.

Mr. EUNSON contended that the money should be equally divided as desired by the doctors, who were the only parties interested.

Eventually the Committee's recommendation was rejected by 22 votes to 15, and the motion for equal distribution was adopted by 25 to 7.

INSURANCE NOTES.

Elections.

Insurance Committees.

The Insurance Commissioners have issued regulations providing that the members of Insurance Committees who come into office on July 15th, 1914, shall hold office until July 15th, 1917.

Panel Committees.

Under the regulations issued by the Joint Committee of Insurance Commissioners for the election of Panel Committees it was provided in Part II, 5 (2) that the Commissioners should appoint a returning officer, and that the election, whether contested or not, should be carried out by this officer. It appears that the Commissioners while retaining the right to appoint the returning officer proposed that his expenses should be defrayed by the Panel Committee. Strong objection has been taken to this proposal; it was felt that the Commissioners if they desired to appoint an outside official to do any work in connexion with the Panel Committee, should bear the expense. The Commissioners, we understand, have seen the justice of this contention, and have in certain districts arranged that the clerk to the Insurance Committee shall act as returning officer without expense to the Panel Committee.

The Manchester Warehousemen and Clerks' Association.

The difficulty of the directors of the Manchester Warehousemen and Clerks' Association in dealing with the medical benefit of its members who are doubly insured for medical treatment, that is, in the National Insurance and in the association, has not yet been solved. The scheme of the directors was rejected by a meeting of the members, and at an unofficial meeting of members held last week a committee was appointed to bring pressure to bear on the directors. Several suggestions were made, but eventually the following resolution was passed:

> That the directors approach the doctors and ascertain at what price they will attend our voluntary members per head per annum, or as an alternative per visit at home or surgery. Until the above figures are available, voluntary members desiring medical attention to pay 6d. per month in addition to the present contributions, and doctors' bills to be met by the 2s. 6d. per visit at home or surgery.

This resolution is to be brought before the directors, with the request that they will meet the committee at an early date to consider the whole matter. When the Insurance Act came into operation all the medical officers of the association, who numbered something like a hundred, resigned their positions, and it now remains with the profession to decide what attitude it will take in case the directors approach the doctors in the way suggested.

A Brighton Drug Stores and the Chemists' List.

An Inquiry Committee under Part VII of the Medical Benefit Regulations, 1912, sat at the offices of the Commissioners, Buckingham Gate, on July 1st, to hear representations by the Brighton Insurance Committee that the restoration to the list of chemists of the firm of Sharp's Drug Stores, Limited, trading at 49, Edward Street, Brighton, would be prejudicial to the efficiency of the medical service. During 1913 the name of the firm was erased from the register of pharmacists because the Registrar of the Pharmaceutical Society was satisfied that dispensing had ceased to be done by a registered pharmacist or under his direct supervision. The Insurance Committee alleged admissions by the managing director of the company that prescriptions were dispensed by a man who kept a tobacconist's shop some distance away and came to the drug stores in the evenings, and that on occasion they were dispensed by an unqualified person acting on telephoned instructions by the tobacconist-ex-druggist. Recently the firm regained admission to the register of pharmacists—having again appointed a superintending qualified dispenser—and it applied for restoration to the insurance list of chemists. The Insurance Committee asked the Commissioners to say, having regard to the incidents above outlined, that the firm was not a suitable one for inclusion in the list. The decision of the Commissioners will be announced later.

"Rep. Mist."

We have received from a pharmacist in London a memorandum in which he makes the following objections to the use of "Rep. mist.":

It seems that the medical profession as a whole do not appreciate the very real objection which pharmacists have to "repeat mixtures."

The pharmacist receiving "rep. mist." has first to ascertain that he holds the original prescription or his own copy thereof. It has not infrequently happened that a second prescription has gone elsewhere, and the "rep. mist." has apparently referred to a mixture the patient has been taking for some time, therefore the doctor's intention is frustrated by no fault of the pharmacist. Very few medical men write either initials or addresses; we have heard of a case where three "Mrs. Browns" got each other's medicine, they being patients of the same doctor who wrote "rep. mist." for them all.

The time of the pharmacist is taken up by searching for originals among prescriptions which are not those of only one doctor but many, and he has further to make the necessary copies for the Insurance Committee, a work for which he receives no remuneration, and which he was given to understand was to be done by the doctor.

The point that "rep. mist." gives rise to conscious and unconscious recommendation of a particular pharmacist might also be made, and that to take advantage of the fact that his refusal to dispense them leads to personal loss is, to say the least, ungenerous.

From the point of view of the patient, the objection, over and above that which is both his and the pharmacist's, is the hindrance to changing from one dispenser to another (the "free choice" promised by the Act), the probable running backward and forward for copies or further particulars of the prescriptions, and the very real danger of obtaining the medicine belonging to someone of the same name, or of getting a prescription dispensed that has been superseded by one of more recent date.

INSURANCE ACT IN PARLIAMENT.

Committee on Excessive Sickness.

Mr. Charles Bathurst asked when the Departmental Committee upon excessive sickness, in connection with the National Insurance Act, ceased taking evidence; how many meetings it had since held, and when its report was likely to be issued.—In reply, Mr. W. Benn said that the Committee had finished taking evidence and hoped to report at an early date.

Transfers.

Mr. W. Benn has informed Mr. Worthington Evans that each case of disputed transfer is decided after consideration of the statements of the society and the insured person.

Medical Benefit.

Outstanding Payments.

Mr. Stewart asked whether the Insurance Committee for Cheshire had paid all the balances due to the panel doctors for the year ending January 15th, 1914; and, if not, what was the amount of outstanding payments due and when they would be liquidated.—Mr. Wedgwood Benn said that the settlement of accounts for the 1913 medical year had been delayed in the case of the area referred to, pending consideration by the doctors concerned of certain outstanding questions as to the method of distribution to be adopted.

Sanatorium Benefit.

Mr. Hamilton asked a question with reference to statements made at a recent meeting of the South Manchester guardians that there was no provision at the Withington Hospital for dealing effectively with the 112 men and 41 women suffering from consumption, and to a lady guardian's further statement at the same meeting that, as a member of a Local Insurance Committee, she was aware that 88 people applied for sanatorium treatment and that it could only be given to 3; and inquired what provision has been made in this district to supply sanatorium treatment.—The Parliamentary Secretary to the Local Government Board said that the Manchester Corporation had provided 323 sanatorium and hospital beds for the treatment of consumption on March 31st, 1914, and was proceeding rapidly with the provision of further beds. Special inquiry would be made into the matter.

Naval and Military Appointments.

ROYAL NAVAL MEDICAL SERVICE.

THE following notifications are announced by the Admiralty: Fleet Surgeon ROBERT L. DICKINSON, to the *Temeraire*, July 14th. Fleet Surgeon WALTER H. S. SEQUEIRA, to the *Tyne*, July 14th. Fleet Surgeon FREDERICK FEDART, M.B., to the *Impregnable*, vice Shand, July 1st. Fleet Surgeon JOHN H. STENHOUSE, M.B., to the *Hibernia*, July 1st. Fleet Surgeon JAMES MOWAT, M.B., has been placed on the retired list at his own request, April 1st. Staff Surgeon EDWARD B. KENNY, M.B. (retired), has been reinstated on active list. Staff Surgeon REGINALD ST. G. S. BOND, M.B., F.R.C.S., to the *Commonwealth*, on recommissioning, June 23rd. Staff Surgeon JAMES A. THOMPSON, M.B., to the *Glory*, temporary, undated. Staff Surgeon RICHARD S. OSBORNE, to the *St. George*, vice Mowat, June 20th. Staff Surgeon LLEWELLYN LINDOP, to the *Birmingham*, vice Osborne, June 20th. Staff Surgeon EDWARD B. KENNY, to the *Pembroke*, additional, for disposal, July 7th. Surgeon HENRY E. Y. WHITE, M.B., to the *Commonwealth*, on recommissioning, June 23rd. Surgeon JOHN C. F. D. VAUGHAN has been promoted to the rank of Staff Surgeon, with seniority of May 19th.

ROYAL NAVAL VOLUNTEER RESERVE.

HENRY C. W. NUTTALL appointed Surgeon, and to be attached to the Mersey Division, June 6th.

ARMY MEDICAL SERVICE.

SURGEON-GENERAL WILLIAM BABTIE, V.C., C.B., C.M.G., M.B., is appointed an Honorary Surgeon to the King, vice Surgeon-General Sir W. L. Gubbins, K.C.B., M.V.O., M.B., June 1st.

Colonel T. P. WOODWARD, from half-pay, late R.A.M.C., has been appointed Deputy Director of Medical Services, Aldershot.

ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel F. W. C. JONES has been ordered to Tidworth to succeed Colonel T. J. O'Donnell, D.S.O.

Major S. H. FAIRRIE has been noted for service in India with the Southern Army.

Major J. C. B. STATHAM has left the London District for duty at Sierra Leone.

Captain R. F. O'T. DICKINSON has been posted to Dublin District for duty.

Captain ALBERT E. F. HASTINGS is removed from the service, May 1st.

Lieutenant N. BEDDINGFIELD has been noted for service in the Mediterranean Command.

Lieutenant F. C. COWTAN has been noted for a tour of service, Northern Army, India.

SPECIAL RESERVE OF OFFICERS.

ROYAL ARMY MEDICAL CORPS.

LIEUTENANT HENRY H. MULBOLLAND is confirmed in his rank.

Lieutenant JOHN McG. SCOTT, M.B., resigns his commission, June 1st.

Lieutenant THOMAS WARRINGTON is confirmed in his rank.

Cadet DOUGLAS H. MURRAY, from the St. Andrew's University Contingent, Officers' Training Corps, to be Lieutenant on probation, May 25th.

Cadet FRANCIS R. H. MOLLAN, from the Royal College of Surgeons in Ireland Contingent, Officers' Training Corps, to be Lieutenant on probation, May 20th.

Cadet WILLIAM B. JEPSON, from the London University Contingent, Officers' Training Corps, has been appointed a Lieutenant on probation, May 16th.

IDRIS D. EVANS, late Cadet-Quartermaster, Durham University Contingent, Officers' Training Corps, has been appointed a Lieutenant, May 21st.

INDIAN MEDICAL SERVICE.

LIEUTENANT-COLONEL V. G. DRAKE-BROCKMAN is granted privilege leave for two months and fifteen days combined with furlough for five months and nine days, with effect from May 1st.

Major J. R. J. TYRRELL is posted as Agency Surgeon, Bundelkhand, with effect from May 1st.

Captain C. I. BRIERLY is posted as Civil Surgeon, Peshawar, with effect from May 1st.

Surgeon-General A. M. CROFTS, C.I.E., K.H.S., is permitted to retire from the service, with effect from May 25th.

Lieutenant-Colonel H. E. DRAKE-BROCKMAN, I.M.S., has been granted six months' combined leave, with effect from April 18th.

The services of Captain R. G. G. CROLY, I.M.S., have been placed at the disposal of the Madras Government for civil employment.

Captain A. H. NAPIER, I.M.S., has been appointed to the Bacteriological Department and posted to the Central Research Institute, Kasauli.

Colonel A. O. EVANS, Inspector-General of Civil Hospitals, Burma, is granted with effect from May 25th, 1914, combined leave for eight months—namely, privilege leave from May 25th, 1914, to August 24th, 1914, and leave on private affairs from August 25th, 1914, to January 24th, 1915.

Lieutenant-Colonel G. J. H. BELL, M.B., Inspector-General of Prisons, Burma, is appointed to officiate as Inspector-General of Civil Hospitals, Burma, during the absence on leave of Colonel A. O. Evans, or until further orders.

A good service pension of £100 per annum has been conferred on the Hoooourable Surgeon-General R. W. S. LYONS, M.D.

INDIAN SUBORDINATE MEDICAL DEPARTMENT.

Senior Assistant Surgeon with the honorary rank of Lieutenant to be Senior Assistant Surgeon with the honorary rank of Captain: LEWIS M. CABRAL, January 1st.

To be Senior Assistant Surgeons with the honorary rank of Lieutenant: First Class Assistant Surgeons HERBERT W. V. COX, HERBERT JAMES GALLOWAY, WILLIAM C. M. CHARTERS, GEORGE C. F. HOLMES, CHRISTOPHER C. A. WALE.

The King has approved of the retirement of Senior Assistant Surgeons and Honorary Captains DANIEL R. DAVIES (December 23th, 1913), CHARLES N. GREGG (December 31st, 1913), WILLIAM FORRESTER (March 3rd, 1914).

TERRITORIAL FORCE.

ROYAL ARMY MEDICAL CORPS.

Second East Anglian Field Ambulance.—ERNEST B. HINDE, M.B., F.R.C.S.Edin., to be Lieutenant, April 20th.

Third Highland Field Ambulance.—Lieutenant WILLIAM L. ROBERTSON, M.B., F.R.C.S.Edin., to be Captain, April 19th.

Third South Midland Field Ambulance.—Captain CYRIL C. LAVINGTON resigns his commission, June 17th.

First Wessex Field Ambulance.—Lieutenant LANGFORD G. DAVIES, M.B., resigns his commission, June 17th.

Second East Lancashire Field Ambulance.—CLEMENT A. WEBSTER to be Lieutenant, May 16th.

Third West Lancashire Field Ambulance.—ROBERT D. B. FREW, M.D., to be Lieutenant, May 14th.

First London (City of London) General Hospital.—Major Sir ANTHONY A. BOWLBY, C.M.G., F.R.C.S., and Major Sir W. P. HERRINGHAM, M.D., have been appointed Lieutenant-Colonels, June 20th.

For Attachment to Units other than Medical Units.—BASIL HUGHES, M.B., F.R.C.S., to be Lieutenant, March 1st. HUGH H. ROBINSON to be Lieutenant, April 25th.

Attached to Units other than Medical Units.—Captain ALLAN F. RUTHERFORD, M.B., to be Major, February 1st. ARCHIBALD C. HADDOW, M.B., to be Lieutenant, May 15th.

TERRITORIAL FORCE RESERVE.

ROYAL ARMY MEDICAL CORPS.

COLONEL WILLIAM COATES, C.B., resigns his commission, and is granted permission to retain his rank, and to wear the prescribed uniform, June 13th.

Lieutenant-Colonel CHARLES G. GRANT, from the list of officers attached to units other than medical units, to be Lieutenant-Colonel, May 22nd.

Vital Statistics.

HEALTH OF ENGLISH TOWNS.

IN ninety-seven of the largest English towns 9,168 births and 4,497 deaths were registered during the week ended Saturday, June 20th. The annual rate of mortality in these towns, which had been 13.3, 13.2, and 13.5 per 1,000 in the three preceding weeks, fell to 12.9 per 1,000 in the week under notice. In London the death-rate did not exceed 12.2, against 11.8, 12.7, and 12.8 per 1,000 in the three preceding weeks. Among the ninety-six other large towns the death-rate ranged from 2.2 in Ealing, 4.6 in Northampton, 4.9 in Acton, 6.6 in Edmonton and in Eastbourne, 7.2 in Gloucester, and 7.4 in Ilford to 18.5 in Wolverhampton, 18.9 in Liverpool, 19.1 in Bradford, 20.1 in Blackpool, 20.3 in Barnsley, and 21.5 in South Shields. Measles caused a death-rate of 1.3 in Manchester, 1.4 in Smethwick, 1.6 in St. Helens and in Sheffield, 1.8 in Darlington, and 2.1 in Bootle and in Warrington; and whooping-cough of 1.0 in Oldham, 1.4 in Plymouth, in Cardiff and in Warrington, and 3.3 in South Shields. The mortality from the remaining infective diseases showed no marked excess in any of the large towns, and no fatal case of small-pox was registered during the week. The causes of 29, or 0.6 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest; of this number 6 were recorded in Liverpool, 3 in Birmingham, 3 in Gateshead, and 2 each in Portsmouth, Cambridge, Sheffield, and Sunderland. The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, which had been 2,910, 2,970, and 2,993 at the end of the three preceding weeks, had further risen to 3,038 on Saturday, June 20th; 405 new cases were admitted during the week, against 377, 339, and 391 in the three preceding weeks.

In ninety-seven of the largest English towns 9,192 births and 4,193 deaths were registered during the week ended Saturday, June 27th. The annual rate of mortality in these towns, which had been 13.2, 13.5, and 12.9 per 1,000 in the three preceding weeks, fell to 12.1 per 1,000 in the week under notice. In London the death-rate was also equal to 12.1, against 12.7, 12.8, and 12.2 in the three preceding weeks. Among the ninety-six other large towns the death-rate ranged from 4.9 in Swindon, 5.5 in Bournemouth, 5.6 in Southend-on-Sea, and 6.1 in Hastings to 17.3 in Liverpool and in Middlesbrough, 18.3 in Oldham, 18.4 in Smethwick, 19.8 in Wakefield, and 21.1 in Stockton-on-Tees. Measles caused a death-rate of 2.0 in Smethwick, 2.1 in Warrington, 2.5 in York, and 2.8 in Oldham; and whooping-cough of 2.1 in Warrington, and 2.4 in Barrow-in-Furness. The mortality from the remaining infective diseases showed no marked excess in any of the large towns, and no fatal case of small-pox was registered during the week. The causes of 29, or 0.7 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest; of this number 6 were recorded in Liverpool, 4 in Stockton-on-Tees, 4 in Birmingham, and 3 in St. Helens. The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, which had been 2,970, 2,993, and 3,038 in the three preceding weeks, further rose to 3,088 on Saturday, June 27th; 440 new cases were admitted during the week, against 339, 391, and 405 in the three preceding weeks.

HEALTH OF SCOTTISH TOWNS.

IN the sixteen largest Scottish towns 1,276 births and 641 deaths were registered during the week ended Saturday, June 20th. The annual rate of mortality in these towns, which had been 15.6, 16.0, and 14.4 per 1,000 in the three preceding weeks, rose to 14.6 in the week under notice, and was 1.7 per 1,000 above the rate in the ninety-seven large English towns. Among the several towns the death-rate ranged from 8.8 in Kilmarnock, 10.1 in Motherwell, and 10.5 in Clydebank to 18.3 in Leith, 18.7 in Greenock, and 18.9 in Hamilton. The mortality from the principal infective diseases averaged 1.5 per 1,000, and was highest in Clydebank and Hamilton. The 306 deaths from all causes in Glasgow included 16 from whooping-cough, 9 from infantile diarrhœa, 8 from measles, 3 from scarlet fever, and 1 from diphtheria. Three deaths from measles were recorded in Dundee, 3 in Hamilton, and 2 in Clydebank; from diphtheria, 2 deaths in Aberdeen and 2 in Motherwell; from whooping-cough, 2 deaths in Greenock; and from diarrhœa and enteritis, 4 deaths in Dundee, 2 in Aberdeen, and 2 in Hamilton.

In the sixteen largest Scottish towns 1,301 births and 605 deaths were registered during the week ended Saturday, June 27th. The annual rate of mortality in these towns, which had been 16.0, 14.4,

and 14.6 per 1,000 in the three preceding weeks, fell to 13.8 in the week under notice, and was 1.7 per 1,000 above the rate in the ninety-seven large English towns. Among the several towns the death-rate ranged from 10.5 in Clydebank, 11.0 in Falkirk, and 11.3 in Motherwell to 18.0 in Aberdeen, 19.0 in Kirkcaldy, and 23.0 in Perth. The mortality from the principal infective diseases averaged 1.2 per 1,000, and was highest in Leith and Aberdeen. The 265 deaths from all causes in Glasgow included 15 from whooping-cough, 5 from measles, 3 from scarlet fever, 3 from diphtheria, 2 from enteric fever, and 2 from infantile diarrhoeal diseases. Four deaths from diarrhoeal diseases were registered in Aberdeen and 2 in Leith, and 3 deaths from diphtheria in Aberdeen.

HEALTH OF IRISH TOWNS.

DURING the week ending Saturday, June 20th, 641 births and 410 deaths were registered in the twenty-seven principal urban districts of Ireland, as against 636 births and 415 deaths in the preceding period. These deaths represent a mortality of 17.7 per 1,000 of the aggregate population in the districts in question, as against 17.9 per 1,000 in the previous period. The mortality in these Irish areas was therefore 4.8 per 1,000 higher than the corresponding rate in the ninety-seven English towns during the week ending on the same date. The birth-rate, on the other hand, was equal to 27.7 per 1,000 of population. As for mortality of individual localities, that in the Dublin registration area was 17.6 (as against an average of 19.5 for the previous four weeks), in Dublin city 18.1 (as against 20.5), in Belfast 17.1 (as against 16.4), in Cork 19.0 (as against 18.4), in Londonderry 11.4 (as against 10.8), in Limerick 23.0 (as against 20.3), and in Waterford 30.4 (as against 19.9). The zymotic death-rate was 2.2, as against 1.8 in the previous week.

During the week ending Saturday, June 27th, 665 births and 364 deaths were registered in the twenty-seven principal urban districts of Ireland, as against 641 births and 410 deaths in the preceding period. These deaths represent a mortality of 15.7 per 1,000 of the aggregate population in the districts in question, as against 17.7 per 1,000 in the previous period. The mortality in these Irish areas was therefore 3.6 per 1,000 higher than the corresponding rate in the ninety-seven English towns during the week ending on the same date. The birth-rate, on the other hand, was equal to 28.8 per 1,000 of population. As for mortality of individual localities, that in the Dublin registration area was 15.5 (as against an average of 17.9 for the previous four weeks), in Dublin city 17.6 (as against 19.5), in Belfast 17.5 (as against 17.0), in Cork 12.9 (as against 17.0), in Londonderry 10.1 (as against 11.4), in Limerick 12.2 (as against 18.9), and in Waterford 13.3 (as against 19.0). The zymotic death-rate was 1.6, as against 2.2 in the previous week.

Hospitals and Asylums.

ROYAL EDINBURGH ASYLUM, MORNINGSIDE.

The Work of a Century.

RATHER over one hundred years ago the then managers of this asylum presented to the general meeting of contributors the first annual report for the year 1813. Although the asylum was incorporated by Royal Warrant in 1807, it was not till June 19th, 1813, that the first patient was admitted. During that year 6 patients in all were admitted, 1 was discharged as recovered, 1 removed by her relatives, and 4 remained in the asylum at the end of the year. Since its opening 21,942 patients have been under treatment in this institution, and, as the managers well say in their report, it is impossible to overestimate the debt of gratitude which the community owes to the benevolent persons who conceived the idea of the asylum and who undertook the tedious and trying work of raising the funds necessary to give effect to their views.

The proposal for the establishment of the asylum was originally made by the President of the Royal College of Physicians of Edinburgh, and its object was to provide for the care of insane persons who were still in a recoverable state by members of the Royal Colleges of Physicians or Surgeons. The Lord Provost of the City and others holding high official positions agreed to form themselves into a body of trustees to carry the scheme into operation.

The institution was thus launched under the most favourable auspices, both medical and lay, but even the most sanguine of its originators could hardly have foreseen the immense amount of beneficent work to be accomplished and the world-wide influence to be wielded by this great institution under the direction of successive distinguished physician-superintendents.

Report for 1912.

Turning to the statistics for the year 1912, the Physician-Superintendent, Dr. G. M. Robertson, shows that on January 1st, 1912, there were 753 patients on the general register, and on the last day of the year 784. The total cases under treatment during the year numbered 975, and the average number daily resident was 756. During the year 222 were admitted, of whom 186 were first and 36 not-first admissions. In 72 the attacks were first attacks within three, and in 37 more within twelve, months of admission; in 36 not-first attacks within twelve months; in 66 the attacks, whether first attacks or not, were of more than twelve months' duration, and 11 were congenital cases.

The total admissions were classified according to the forms of mental disorder into: Simple mania, 23; delusional mania, 6; simple melancholia, 30; delusional melancholia, 24; and agitated melancholia, 3; delirious insanity (including in this acute delirium, subacute delirious insanity, and mild confusional states), 39; systematized delusional insanity, 16; dementia praecox, 14; general paralysis, 24; dementia, 33; congenital defect, 3; moral insanity, 6; and morphomania, 1.

As to probable causation, alcohol was assigned in 28, syphilis in 27, and other toxins in 8 more; epilepsy, gross brain disease, and apoplexy, etc., in 12; other bodily disorders in 8; child-bearing in 5; physical exhaustion in 18; critical periods in 59; bodily trauma in 1, and mental stress in 23. Hereditary influences were ascertained in 68, and congenital defect existed in 6, whilst no cause could be assigned in 98. Previous attacks had occurred in 64. The proportion of cases of alcoholic insanity (11.2 per cent.) was less than usual.

Syphilis.

Dr. Robertson gives particular attention in his report to general paralysis. Of the 24 general paralytics admitted only 1 was a woman. As there were 107 male admissions, 21.5 per cent., or over 1 in 5, suffered from this disease. The average admission-rate of general paralytics at this institution has been over 19.5 per cent. Such statistics, Dr. Robertson says, reveal a state of affairs urgently calling for public attention. "Large numbers of soldiers," he says, "used in the past to fall victims to it, but medical treatment in the army has become so thorough and scientific that, after twelve or fifteen years, this profession will probably cease to supply its proportion of cases. Can something of the same kind not be done for men in the civil population? They would no doubt require to be educated to a sense of their dangers, and the value of early treatment, by short addresses or printed warnings in their workshops. This insurance or some other public authority would require to make provision for treatment, which would not be difficult or expensive owing to the short time now required, and the medical profession should be given the power of exercising more pressure than at present for insisting upon treatment till a cure be obtained. If these measures were successful, in fifteen years not only general paralysis, but a host of serious maladies, would decrease enormously in number. The one policy of merely ignoring the existence of these ills is now inexcusable and something must be done."

Recoveries and Deaths.

During the year 58 were discharged as recovered, giving a recovery-rate on the admissions of 35.0 per cent.; also 50 as relieved and 21 as not improved. During the year 62 died, giving a death-rate on the average number resident of 7.4 per cent.

The deaths were due in 26 to diseases of the nervous system, including 16 from general paralysis; in 10 to diseases of the respiratory system, including in this 6 from pulmonary phthisis; in 14 to diseases of the heart and blood vessels, but excluding 5 from cerebral haemorrhage entered among the deaths for nervous diseases; 2 from kidney disease, and 10 from general diseases, including 8 from senile decay.

The low death-rate from consumption (under 10 per cent.), and the fact that 3 of the cases suffered on admission from the disease of which they died, show a satisfactory state of affairs as regards this disease.

Research and Post-Graduate Teaching.

It need hardly be said that the best traditions of this asylum as a centre of scientific research and teaching are fully maintained under Dr. Robertson's direction, but it should be mentioned that since the University of Edinburgh created its Diploma in Psychiatry, a post-graduate clinical lecture has been delivered weekly of a higher and more technical nature than the ordinary classes for students. The lectures are attended by the full staff of the asylum, to the benefit, Dr. Robertson says, of teachers and taught alike.

GENERAL HOSPITAL, BIRMINGHAM.

THE number of patients treated in 1913 was 64,815, and of these 5,908 were in-patients and 58,815 out-patients. There has been a great pressure on the beds, as there has been a list of from 180 to 200 cases awaiting admission during the greater part of the year. Many cases that needed treatment have been in consequence sent away, while at the same time there has been overcrowding in some of the wards. A ward which has been kept up to the present for emergencies was opened; but this addition of ten beds only gave very slight relief. A large number of insured patients have been treated in the hospital, but the Insurance Commissioners have made no arrangement for the treatment of these patients when seriously ill, and the hospital has only received £13 7s. 11d. from approved societies, and no single subscription from the Insurance Committees. The ordinary income was £31,990 and the total income from all sources £38,350, while the ordinary expenditure was £29,319, and the total expenditure £30,482. A number of important improvements in the building have been approved, and will add considerably to the efficiency of the work of the hospital, and also to the comfort of the resident, nursing, and domestic staffs. The most important of these alterations consists in a considerable enlargement of the pathological department, which will enable more clinical investigation work to be undertaken, and obviate the delay and inconvenience existing under the present conditions. The personnel of the massage department has been increased, and, in view of the necessity of this form of treatment, a large addition to the accommodation of this department is proposed. The work of the *x*-ray department has increased greatly, and a movable *x*-ray apparatus has been purchased to enable patients to be radiographed without removal from the wards. Some additions are also contemplated to the operating theatres. It has been resolved to place in the hospital a tablet in memory of the late Mr. John Roderick. Mr. Albert Toft has been entrusted with this work.

Vacancies and Appointments.

WARNING NOTICE.—Attention is called to a Notice (see Index to Advertisements—Warning Notice) appearing in our advertisement columns, giving particulars of vacancies as to which inquiries should be made before application.

VACANCIES.

ABERGAVENNY: MONMOUTHSHIRE ASYLUM.—Locumtenent Assistant Medical Officer (male). Terms, £6 6s. per week.

BARROW-IN-FURNESS: NORTH LONSDALE HOSPITAL.—Male House-Surgeon. Salary, £150 per annum.

BEDFORD COUNTY HOSPITAL.—Assistant House-Surgeon. Salary, £100 per annum.

BIRKENHEAD BOROUGH HOSPITAL.—Senior House-Surgeon (male). Salary, £120 per annum.

BIRMINGHAM AND MIDLAND EAR AND THROAT HOSPITAL.—House-Surgeon. Salary at the rate of £100 per annum.

BIRMINGHAM: CITY MENTAL HOSPITAL.—Assistant Medical Officer (male). Salary, £200 per annum.

BIRMINGHAM GENERAL DISPENSARY.—Resident Medical Officer. Salary, £240 per annum.

BIRMINGHAM: QUEEN'S HOSPITAL.—(1) House-Physician; (2) Two House-Surgeons. Salary at the rate of £50 per annum.

BOARD OF CONTROL (MENTAL DEFICIENCY ACT).—Medical Superintendent of a State Institution for Defectives to be opened near Liverpool. Salary, £800 per annum.

BOLINGBROKE HOSPITAL, Wandsworth Common, S.W.—House-Surgeon (male). Salary at the rate of £75 per annum.

BOLTON INFIRMARY AND DISPENSARY.—Third House-Surgeon. Salary, £110 per annum.

BRADFORD ROYAL INFIRMARY.—House-Surgeon (male). Salary, £100 per annum.

BRENTFORD UNION.—Second Assistant Medical Superintendent of the Infirmary, etc. Salary, £175 per annum, rising to £200.

BRIGHTON: ROYAL ALEXANDRA HOSPITAL FOR SICK CHILDREN.—House-Surgeon. Salary, £100 per annum.

BRISTOL ROYAL INFIRMARY.—Honorary Ophthalmic Surgeon.

BRITISH MEDICAL ASSOCIATION.—Scottish Medical Secretary. Salary, £600 per annum.

BUXTON: DEVONSHIRE HOSPITAL.—Assistant House-Physician. Salary, £100 per annum.

CAMBERWELL TUBERCULOSIS DISPENSARY, Brunswick Square, S.E.—Assistant Medical Officer. Salary, £250 per annum.

CARDIFF: KING EDWARD VII HOSPITAL.—Two House-Surgeons. Salary, £60 per annum.

CHELSEA HOSPITAL FOR WOMEN, Fulham Road, S.W.—Surgeon.

CHELSEA PARISH INFIRMARY.—Second Assistant Medical Officer. Salary, £140 per annum.

CHEPSTOW UNION.—Medical Officer for the Tintern District. Salary, £40 per annum.

CHORLEY: RAWCLIFFE HOSPITAL.—House-Surgeon (male). Salary, £100 per annum.

COLONIAL OFFICE.—Two Assistant Medical Officers for Ankylostomiasis Campaign in Trinidad and Grenada. Salary, £400 per annum without quarters or £350 with free quarters.

DEVON EDUCATION COMMITTEE, Exeter.—Assistant School Medical Officer and Oculist. Salary, £300 per annum.

DEVONPORT: ROYAL ALBERT HOSPITAL.—House-Surgeon. Salary at the rate of £150 per annum.

DURHAM COUNTY HOSPITAL.—House-Surgeon. Salary, £150 per annum.

EAST LONDON HOSPITAL FOR CHILDREN, Shadwell.—(1) House-Physician: (2) Medical Officer to Casualty Department (males). Salary at the rate of £75 and £100 per annum respectively.

ESSEX EDUCATION COMMITTEE.—Medical Inspector. Salary, £300 per annum, rising to £400.

EVELINA HOSPITAL FOR SICK CHILDREN, Southwark, S.E.—House-Surgeon. Salary at the rate of £75 per annum.

GLOUCESTERSHIRE EDUCATION COMMITTEE.—School Medical Inspector. Salary, £250 per annum, rising to £300.

HALIFAX: ROYAL HALIFAX INFIRMARY.—Second and Third House-Surgeons. Salary, £120 and £100 per annum respectively.

HERTFORD COUNTY HOSPITAL.—Resident Medical Officer. Salary, £100 per annum.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton.—(1) Assistant Physician. (2) Assistant Resident Medical Officer; salary, £100 per annum. (3) House-Physician; honorarium, 30 guineas for six months.

HOVE: LADY CHICHESTER HOSPITAL.—Resident Medical Woman. Honorarium, £30.

HULL: ROYAL INFIRMARY.—(1) Honorary Assistant Ophthalmic Surgeon; (2) Casualty House-Surgeon; (3) Assistant House-Surgeon. Salary for (2) and (3) £80 and £100 per annum respectively.

INVERNESS DISTRICT ASYLUM.—Assistant Medical Officer. Salary, £200 per annum.

KENT COUNTY ASYLUM, Maidstone.—Fourth Assistant Medical Officer (male). Salary, £250 per annum.

KIDDERMINSTER INFIRMARY AND CHILDREN'S HOSPITAL.—House-Surgeon. Salary, £100 per annum.

KING EDWARD VII SANATORIUM, Midhurst.—Second Assistant Medical Officer. Salary, £150 per annum, rising to £200.

KING'S LYNN: WEST NORFOLK AND KING'S LYNN HOSPITAL.—House-Surgeon. Salary, £150 per annum.

LAMBETH PARISH INFIRMARY.—Fourth and Sixth Assistant Medical Officers. Salary for former, £160 per annum, rising to £200; and for latter, £150 per annum.

LEEDS PUBLIC DISPENSARY.—Junior Resident Medical Officer. Salary, £130 per annum.

LEEDS TUBERCULOSIS ASSOCIATION.—Resident Medical Officer for the Sanatorium at Gateforth. Salary, £100 per annum.

LIVERPOOL INFECTIOUS DISEASES HOSPITAL.—Assistant Resident Medical Officer. Salary, £150 per annum.

LIVERPOOL SCHOOL OF TROPICAL MEDICINE.—Research Assistant in the Runcorn Research Laboratory. Salary, £150 per annum.

DOOLEY, G. G., L.R.C.P. and S.Irel., District Medical Officer of the Howden Union.

HENDRY, J. A., M.B., Ch.B.Aberd., District Medical Officer of the Bakewell Union.

HERLEY, Randal, L.R.C.P. and S.Edin., L.F.P.S.Glasg., Ophthalmic Surgeon to the Dewsbury and District Infirmary.

HOLMES, Gordon M., M.D.Dubl., F.R.C.P., Physician to the Royal London Ophthalmic Hospital, Moorfields.

JONES, Howard, M.B., B.S.Lond., M.R.C.S., L.R.C.P., Honorary Anaesthetist to St. Mark's Hospital for Diseases of the Rectum.

LUKE, G. F., L.R.C.P. and S.Edin., L.F.P.S.Glasg., Medical Officer of the Tempo Dispensary District of the Enniskillen Union, vice Dr. Hackett, resigned.

MACKAY, C. G., M.B., Ch.B.Glasg., District Medical Officer of the Newport (Mon.) Union.

MONOD, Gustave, M.D.Paris, M.R.C.P.Lond., Physician to the Vichy Thermal Hospital.

MORTON, Hugh, M.D., Ch.B.Glasg., Professor of Physiology, Anderson College of Medicine, Glasgow.

MYERS, Bernard, M.D.Edin., M.R.C.P.Lond., Out-patient Physician to the Royal Waterloo Hospital for Children and Women, London, S.E.

OLIVER, M. W. B., M.B.Camb., F.R.C.S.Eng., Assistant Surgeon to the Central London Ophthalmic Hospital.

PEEK, J. Harold, M.D., Ch.B.Edin., D.P.H.Cantab., Assistant County Medical Officer of Health for Flintshire.

RANSFORD, W. R., L.D.S.Eng., Dental Surgeon to the Civil General Hospital, Rangoon.

RENNY, Eustace G., M.R.C.S.Eng., L.R.C.P.Lond., Honorary Assistant Surgeon and Anaesthetist to the Essex County Hospital, Colchester.

RICHMOND, Arthur, M.B., Ch.B., Tuberculosis Officer for Berkshire, vice Dr. Norris, resigned.

RICHMOND, D. Stevenson, M.B., B.S.Glasg., Medical Officer of Health to Cwmamman Urban District Council, and also as Medical Officer to Post Office, Garnant and Glanamman.

ROBERTS, C. Rupert, M.D., F.R.C.S., F.R.C.P., Examiner in Midwifery and Diseases of Women to the Conjoint Board, London.

SHERRETT, Frank B., M.B., B.Sc.Lond. and Vict., D.P.H., M.R.C.S., Assistant Medical Officer of Health and Chief Assistant School Medical Officer for the County Borough of West Ham.

STEADMAN, F. St.J. S., M.R.C.S., L.R.C.P., L.D.S., D.P.H., Assistant Dental Surgeon to the Royal Dental Hospital.

STEVENS, T. G., M.D., F.R.C.S., Obstetric Surgeon to St. Mary's Hospital, Paddington, W., vice Dr. William J. Gow, F.R.C.P., resigned.

WYCHE, E. M., L.R.C.P., M.R.C.S., D.P.H.Lond., Senior Medical Inspector to the Nottingham Education Committee.

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths is 5s., which sum should be forwarded in Post Office Orders or Stamps with the notice not later than first post Wednesday morning in order to ensure insertion in the current issue.

BIRTHS.

GREATOREX.—On the 21st June, at Manor Drive, Halifax, the wife of R. W. Greatorex, M.B., of a son.

RIGGALL.—On June 26th, at the Queen Alexandra Sanatorium, Davos Platz, Switzerland, the wife of Surgeon R. M. Riggall, R.N., a son.

MARRIAGE.

ODGERS—HIGGINS.—On Tuesday, June 30th, at All Saints, Ennismore Gardens, by the Rev. W. E. Addis, M.A., Norman Blake Odgers, M.Ch., F.R.C.S., third son of the Rev. Dr. Odgers, of Oxford, to Mabel, youngest daughter of G. Randell Higgins, The Croft, Burcote-on-Thames, Oxon.

DEATHS.

MUGLISTON.—On the 24th June, Dr. H. Boyes Mugliston, elder son of G. T. W. Mugliston, M.D., at his residence, "Coo-ee," Brent Knoll, Somerset.

MUGLISTON.—On the 30th inst., G. T. W. Mugliston, M.D., at his residence, "Birsey," Hatch End, Pinner, aged 89 years.

DIARY FOR THE WEEK.

POST-GRADUATE COURSES AND LECTURES.

Post-Graduate Courses and Lectures are to be given next week at the following schools, colleges, and hospitals:

CENTRAL LONDON THROAT AND EAR HOSPITAL, Gray's Inn Road, W.C.

DUBLIN: ROTUNDA HOSPITAL.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton, S.W.

HOSPITAL FOR SICK CHILDREN, Great Ormond Street, W.C.

LONDON HOSPITAL MEDICAL COLLEGE, Turner Street, E.

LONDON SCHOOL OF CLINICAL MEDICINE, Dreadnought Hospital, Greenwich, S.E.

LONDON SCHOOL OF TROPICAL MEDICINE, Royal Albert Dock.

MANCHESTER HOSPITALS: Post-Graduate Clinics.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC, Chenies Street, London, W.C.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen Square, London, W.C.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

ROYAL HOSPITAL FOR DISEASES OF THE CHEST, City Road, E.C.

WEST END HOSPITAL FOR DISEASES OF THE NERVOUS SYSTEM, Welbeck Street, W.

WEST LONDON POST-GRADUATE COLLEGE, Hammersmith, W.

[*Further particulars can be obtained on application to the Deans of the several institutions, or in some instances from our advertisement columns.*]

DIARY OF THE ASSOCIATION.

Date.	Meetings to be Held.
	JULY.
7 Tues.	City Division, Balfour Hall, Kingsland Road, 9.30 p.m.
8 Wed.	Dorset and West Hants Branch, Bridport, 3.30 p.m.; Luncheon, 1.30 to 2.30 p.m.
	St. Helens Division, Annual Meeting, St. Helens.
	London: Insurance Act Committee.
9 Thur.	Southern Branch, Annual Meeting, Southampton, 1 p.m.; Luncheon, 1.45 p.m.
10 Fri.	London: Therapeutic Subcommittee, 2.30 p.m.
	London: Medico-Political, Medical Inspection and Treatment of School Children Sub-Committee, 7 p.m.
	East York and North Lincoln Branch, Annual Meeting, Hull.
11 Sat.	London: Science Committee, 10.30 a.m.

Date.	Meetings to be Held.
	JULY (*continued*).
14 Tues.	London: Standing Ethical Subcommittee, 2.30 p.m.
	London: Metropolitan Counties Branch Council, 4 p.m.
	North Wales Branch, Annual Meeting, Red Wharf Bay, Anglesey.
17 Fri.	Coventry Division, Coventry Hospital, 1.15 p.m.

ANNUAL MEETING, ABERDEEN, 1914.

Annual Representative Meeting, Friday, July 24th, and following days.
Special Representative Meeting, July 27th.
Presidential Address, Tuesday, July 28th.
Sections—July 29th, July 30th, and July 31st.
Annual Exhibition, July 28th–31st.
Excursions, August 1st.

Printed and published by the British Medical Association at their Office, No. 429, Strand, in the Parish of St. Martin-in-the-Fields, in the County of Middlesex.

SUPPLEMENT
TO THE
BRITISH MEDICAL JOURNAL.

British Medical Association.

MEDICAL DEPARTMENT, R.N.

REPORT ON THE SHORTAGE OF MEDICAL OFFICERS IN THE ROYAL NAVY.

THE following report has been approved by the Council of the British Medical Association and forwarded to the Admiralty.

Following the leading article in the issue of the BRITISH MEDICAL JOURNAL of February 28th, 1914, on the present Shortage of Officers in the Naval Medical Service, the Medical Secretary has received many letters which are illuminating as to causes, and temperate in form. They nearly all endorse, and none of them traverse the statements contained in the above-mentioned article of 28th February (Appendix i.), which should now be taken together with the present remarks and suggestions based upon the correspondence referred to.

The Memorandum on pages 974 and 975 of the BRITISH MEDICAL JOURNAL of 2nd May last (Appendix ii.) also fairly condenses the statements made in several letters.

The correspondence has revealed unsatisfactory conditions of service. Men of about 26 years' of age—the average age of entry of Medical Officers—are not readily attracted to the Naval Life of to-day which for the most part consists of a monotonous existence round outlandish parts of Home Coasts. The former pleasant alternations of Home and Foreign Stations with ever varying social and sporting facilities have gone for the vast majority. Most men over 35 are married, and theirs is a hard struggle living in a mess afloat and maintaining homes on shore, which they rarely see—a position which has become acutely accentuated by the increased cost of living as well as by irksome regulations afloat.

Disabilities of the Naval Medical Service as compared with the Army Medical Service.

In mid-Victorian times the comparative hardships of the Sea Service were recognised by the Authorities, and partially compensated for by higher rates of pay for Naval compared with Army Medical Officers. This position is now reversed. The disabilities of the Naval Medical Service have been multiplied and increased, and its old attractions have practically disappeared, while the Army Medical Service has advanced, and rightly too, in every direction professionally and materially. Most important of all, perhaps, its Officers have been given complete control of their own affairs, and mutual respect has grown up between them and the other branches of the Army. To-day the R.A.M.C. is maintained without difficulty up to strength by a plentiful supply of the best class of candidates, there being at each half-yearly Entrance Examination 3 or 4 competitors for every vacancy. On the other hand, the Navy is about 70 Officers short of its small establishment of ten years' ago, although since then the Fleet has increased, it is believed, to the extent of upwards of 21,000, and the growing process continues. The exact numbers are not known, but it is obvious that at least from 80 to 100 ships must, at the present minute, be short of complement of Medical Officers—a situation which would swiftly be in ghastly evidence if war broke out. The Reserves of Medical Officers are also understood to be of the most meagre description. Although in the correspondence received the present First Lord is, rightly or wrongly, credited repeatedly with being Gallio-like in his attitude towards the Medical Service of the Navy, we do not believe that he can view a serious situation of this kind with satisfaction.

Relative Strength of Medical Officers in Army and Navy.

The following figures for 1914-15, which are approximate, are very instructive:—

		Present Total Personnel.	Present Establishment of Medical Officers.
Army		240,400	982
Navy:			
(a) The Fleet	147,900		
(b) Dockyards and Civil Employees	56,600	204,500	525

It follows from the above that the complaints received as to overwork in Shore Medical Establishments, and the lack of leave and study leave for all, must be well-founded. Further, the relative number of medical officers to total strength of Force should be considerably higher in the Navy than in the Army, because they cannot possibly be evenly distributed in the Navy—many medical officers having to be isolated in small ships with complements of 100 and 150 men—and hence the officers available for general work are much reduced.

To equalise as far as possible the Naval with the Military Medical Service, and to secure what the Navy has every right to claim, namely, a fair share of highly qualified candidates for entry, the following have been generally stated to be among the most urgent needs, and the remedies suggested :—

Improved Remuneration.

1. At least equal pay, retired pay and emoluments for the Director-General, Surgeons-General and Deputy Surgeons-General, and for the three lower ranks of the Service, increase of pay to the extent of at least 3s. per day to each officer. The last increase in 1910 only added about £8 per annum per officer to the three junior ranks, and, taken together with the non-publication of the report of the Durnford Committee, this was regarded as merely specious juggling with figures and did no good.

Increased Opportunities for Professional Study.

2. Post-graduate courses every six years up to the rank of Deputy Surgeon-General. Hospital courses of six months duration for officers selected to qualify in special subjects.

Specialists.

3. Creation of a comparatively fair number of appointments for specialists, carrying extra pay, in such subjects as Operative Surgery, Electro-therapeutics, Bacteriology, Venereal Disease, Anaesthetics, Ophthalmology, Throat, Nose and Ear Diseases, Physical Training, State Medicine, additional Professorships at the R.N. Medical School, Greenwich, at present glaringly under-staffed, etc., etc.

The number of R.A.M.C. officers employed as specialists is 174, and each receives 2s. 6d. a day extra pay as such. Only in a very few instances are these officers exempted from general duty, their specialist work being additional. Besides these, there are at present 31 R.A.M.C. officers seconded for special service elsewhere, such as the Egyptian Army, Sudan Civil Service, and under the Colonial Office. Any such outside Government appointments for Naval medical officers are so few and far between as to be negligible, and as for appointments which might be classed as "Specialist" in the Naval Medical Service, there are not a dozen all told. It is now a matter of common knowledge what a great and far-reaching economy these and other wise arrangements have proved to be to the army. In the words of Lord Haldane: "They have repaid the outlay over and over again."

Half Pay.

4. Medical officers should be placed on half pay only at their own request, or on account of misconduct. Officers in the three junior ranks should, on returning from sea, or when waiting for appointment, automatically become attached temporarily to the Medical School at Greenwich, or to one or other of the three great home hospitals for duty and instruction. Aimlessly idling away time, rusting on half pay, is bad for the individual and eventually worse for the Service.

Fixed Head-Quarters.

5. Known in the Navy as "Port of Division." If the medical officers, especially those who are married, were allowed, as far as practicable, to select and be attached to a port in the same way as the seamen, it would go some way towards lessening the present frequency of uncertain and expensive movements of homes.

Suggested Roster.

6. Roster established to which all Officers should have access, and see how they stand for Home and Foreign, Sea and Shore Service. It has been represented that this should be rigidly adhered to, but there may be difficulties in the way of working it rigidly and automatically. Appointments vary widely in their requirements, and also Officers in their qualifications for them; *e.g.*, obviously the operating Staff of a great Hospital could not be detailed in accordance with the mechanical requirements of a roster.

The short notice of change of appointment usually given by the Admiralty is much complained of, as sudden transfers seriously disturb private and domestic arrangements, and not infrequently lead to much expense.

Graduated Charge Pay.

7. Charge Pay at 3s. 6d. per day at present allowed to sea-going ships having complements of over 650 should be extended on a graduated scale commencing say at 1s. 6d. per day for small ships, 2s. 6d. per day for intermediate-sized ships till the present 3s. 6d. scale, which should remain, is reached.

Leave.

8. The R.A.M.C. is allowed 61 days a year at home and abroad. When out of England this leave may be accumulated for 2 or, on certain stations, 3 years. The establishment being up to full strength, this leave is invariably obtainable.

In the Naval Service 42 days' leave a year is allowed at Home, but abroad only 14 days a year is allowed to accumulate, and now, owing to Shortage of Medical Officers, even these small allowances are not always obtainable. It is stated that Medical Officers going on short leave have sometimes even to find a substitute for their duty—a system which ought not to exist.

Higher Appointments, Promotion, and Relative Rank.

9. In the Army Medical Service there are Full Pay Appointments for 12 Surgeons-General and 32 Colonels. They are promoted by selection from an established List of 130 Lieutenant-Colonels. In the Naval Service there are Full Pay Appointments for 3 Surgeons-General and 8 Deputy Surgeons-General. They are promoted by selection from a Fleet Surgeons' List already numbering between 150 and 200 Officers and still increasing. It is thus obvious that the chances of promotion to the higher medical ranks of the Naval are very small indeed when compared with the Military Service. If the Naval Service establishments were increased to 10 *Full Pay* appointments of Surgeons-General and 20 Deputy Surgeons-General, and Half Pay appointments in these ranks swept away, the two Services would then be approximately on a level in these respects for the present *authorised* numbers of Medical Officers as established for the Navy of 1904. If the Admiralty were so disposed, it would have no difficulty whatever in finding suitable employment for all these Officers. It has already in recent years accomplished this very freely in the case of Flag Officers, and also, moderately, for Engineer Officers. The higher ranks of the latter were raised in a short space of time from 12 to 30.

For an establishment of 10 Surgeons-General and 20 Deputy Surgeons-General there ought to be an established List with assigned appointments for about 80 Fleet-Surgeons if calculated on the same ratio as the R.A.M.C. Lieut.-Colonels. Promotion to Fleet Surgeon is practically by seniority and hence has resulted in a great excess of numbers. There are numerous complaints of the length of time, at present about 12 years, men have to serve in this rank. A few years ago this system prevailed and the same difficulties arose in the R.A.M.C. with an unwieldy and unnecessarily large list of Lieut.-Colonels. This was got over by reducing the establishment of these Officers to 130 with a like number of appointments suitable to their rank. Henceforth promotion was by selection into vacancies as they occurred. Majors passed over were allowed to serve on in their rank till qualified for retirement as per scale. A similar adjustment could be carried out in the Navy by the creation of a higher list of Fleet Surgeons, the Officers on the Junior List passed over being permitted to complete 20 or at most 24 years' service and obtain the present scales of retirement granted at those periods.

Fleet Surgeons should not be regarded as interchangeable with Juniors and liable to be detailed by Executive Officers for Junior Duties.

Relative Rank.

10. The appointment of Director-General should *ipso facto* carry equal relative rank with the Director-General A.M.S.—the present strangely complicated Regulations governing it being cancelled. Also the Director-General on taking over and on giving up his appointment as such should, in the same manner as the Military Medical Director-General, be accorded the honour of being received by the Sovereign, *i.e.*, in this respect be placed on all fours with Flag Officers in important command, Naval Attaches, &c. In this way the dignity and importance of high office is emphasised and made manifest to the Services. Complaint is made that the advance in relative rank of the Naval Medical Officer lags years behind that of other Branches, and that Fleet Surgeons who rank with Commanders, *i.e.*, with, *but after*, Lieut.-Colonels remain junior to all Lieut.-Colonels R.A.M.C., with whom they ought to be on the same level. Medical Officers are now, as stated above, on an average about 26 years of age on entry. If they were given the rank of Staff Surgeon at 6 years, and that of Fleet Surgeon at 12 years, they would still be considerably older than Executive Officers, of similar standing, and about the same age as Engineer and Accountant Officers. To place the proposed grade of Senior Fleet Surgeons on all fours with Lieutenant-Colonels R.A.M.C. they should rank *with* Lieutenant-Colonels, *i.e.*, *with* Captains R.N. under 3 years' seniority. The arrangements outlined would abolish the very real and universal grievance of Fleet Surgeons of 50 years of age and upwards having to live in the uncongenial surround-

ings of a Ward Room, obnoxious alike to the individual and detrimental in many ways to the Service generally. An arrangement on these lines would sweep away much discontent, and efficiency would gain without any unnecessary disturbance of the Naval Service generally.

Withdrawal on Gratuity.

11. In case of failing for a second time to pass the qualifying examination for promotion to the rank of Staff Surgeon, Surgeons are required to withdraw after 8 years on a reduced gratuity. It is considered that withdrawal with reduced gratuity should take place immediately after the second failure. It is objectionable for a declared failure to have to serve on for a year or two afterwards, and under circumstances when the services rendered are likely to be more or less inefficient and perfunctory.

Pensions.

12. A. *Widow's Pensions* are said to be on a lower scale in the Naval than in the Military Service—this means that the provident Naval Medical Officer must expend more money in life assurance than his military *confrère*.

B. *Good Service Pensions.*—The Medical compares badly with other branches of the Naval Service in this respect. For Surgeons-General there are 3 pensions of £100 a year each. For Executive Officers there are 10 of £300 a year each awarded to Flag Officers, and 12 of £150 a year each to Captains. Engineer Officers receive 2 of £200 a year each and 2 of £150 a year each; Officers of Royal Marines, 6 of £200 a year each; Colonels and Lt.-Colonels, 2 of £150 a year each. It follows from this that Medical Services are presumably regarded as of smaller value than those of the other classes of Officers named.

Executive Interference in Medical Affairs.

13. This is a delicate matter, but it is necessary that it should be as clearly realised by intending medical Candidates as it is by Officers in the Service. From the time the Medical Officers of the Army were given complete command over the personnel and all affairs of their Department, that Service has rapidly advanced until it has reached the remarkable efficiency of to-day. This autonomy is the most precious possession of the A.M.S., and forms the greatest outstanding difference between it and the Naval Medical Service. So long as this difference continues it is bound to profoundly influence many of the best class of young medical men imbued with a healthy ambition and proper self-respect, when making choice of a career between the Naval and Military Services. In the Navy afloat much of the medical administration is carried out by the Executive, with or without reference to the Medical Officer—for example, such medical arrangements in a squadron as detail of Medical Officers for Survey Boards, Medical Guard, etc., etc. Some Commanding Officers regard the placing of a man on the Sick List, or sending him to Hospital, or bringing him forward for invaliding, as resting with them, the Medical Officers merely recommending. All official letters are by Admiralty Order written by the Captain *over his signature*—consequently he is the official mouthpiece on, for example, general matters of Hygiene, and may or may not consult the Medical Officer exactly as he thinks fit. By comparatively recent orders the old and well understood term of Commanding Officer has been extended from the Captain to include the 2nd in Command and also the Officer of the Watch. This gives the power, on occasion, to very Junior Executive Officers, who may if so disposed, subject Medical Officers who may be old enough to be their fathers to petty annoyances "just to show their authority." From these because they are within the law there can be no appeal.

Courts-Martial.

14. It is felt that when Officers or other Members of the personnel of the Medical Branch are on trial, or when medical affairs are involved, one or more Medical Officers should be Members of the Court, *i.e.*, the Naval Medical Service should be represented on these Courts in the same way as the Army Medical Service now is on Military Courts-Martial.

Boats.

15. In many ships boats are treated as if they were the personal property of the 2nd in Command. He generally assigns one to his own personal use, and it is often difficult for a Medical Officer to get a boat at all, at other than routine hours, except as a personal favour on the part of the Executive Officer.

Cabins.

16. This is an old grievance. A Medical Officer may have to occupy a smaller cabin after 20 years and at the end of his service afloat than when he first joined. The system of labelling cabins has been mostly a failure or worse, as far as Medical Officers are concerned, and yet the remedy appears to be simple. When a ship is about to be built, cabins according complement should be arranged for, those for Commanders to and Officers of the same relative rank being of the size now generally arranged for Commanders only. This done all cabins should be numbered and selected by those concerned strictly in order of seniority.

Mess President.

17. No matter what his age and standing may be a Departmental Officer can never preside on an official occasion if an Executive Officer is present. This is at bottom merely a question of social precedence, and may seem a small matter, yet the fact remains that it can be, and sometimes is, made tiresome and unnecessarily irritating by a bumptious young Executive Officer to older Officers, medical and others.

Many petty annoyances and personal grievances mentioned in the correspondence have not been dealt with. This memorandum will it is hoped indicate the chief reasons why at present the Medical Service of the Navy is not popular in the Medical Schools of this country, and why it is that appeals on its behalf by the Medical Director-General or any one else are not likely to meet with much response. The Board of Admiralty as a whole is doubtless honestly anxious to re-establish an efficient Medical Service, and it will succeed in doing so when it applies the proper remedies to the present unhappy state of affairs.

[Two articles published in the BRITISH MEDICAL JOURNAL are given in appendices to the report. The first article was that published in the JOURNAL of February 28th, 1914, page 497, on "The Increased Shortage of Medical Officers for the Navy." The second was the memorandum published in the JOURNAL of May 2nd, 1914, page 974, entitled "The Medical Service. R.N.—Remedies for Existing Defects."]

British Medical Association.

EIGHTY-SECOND ANNUAL MEETING, ABERDEEN, JULY, 1914.

THE Eighty-second Annual Meeting of the British Medical Association will be held in Aberdeen in July, 1914. The President's Address will be delivered on Tuesday, July 28th, and the Sections will meet on the three following days. The Annual Representative Meeting will begin on Friday, July 24th, at 10 a.m.

Honorary Local Treasurer—
GEORGE WILLIAMSON, M.B.,
256, Union Street, Aberdeen.

Honorary Local Secretaries—
THOMAS FRASER, M.B.,
16, Albyn Place, Aberdeen.
FRED. K. SMITH, M.B.,
7, East Craibstone Street, Aberdeen.

THE SECTIONS.

The scientific business of the meeting will be conducted in sixteen Sections, which will meet on Wednesday, July 29th, Thursday, July 30th, and Friday, July 31st.

The President, Vice-Presidents, and Honorary Secretaries of each Section constitute a Committee of Reference for that Section, and exercise the power of inviting, accepting, or declining any paper, and of arranging the order in which accepted papers shall be read. Communications with respect to papers should be addressed to one of the Honorary Secretaries.

A paper read in the Section must not exceed fifteen minutes, and no subsequent speech must exceed ten minutes.

Papers read are the property of the British Medical Association, and cannot be published elsewhere than in the BRITISH MEDICAL JOURNAL *without special permission.*

PROVISIONAL PROGRAMME.

The following is the provisional time-table for the Aberdeen Meeting:

FRIDAY, JULY 24TH.

10 A.M.—Annual Representative Meeting.

SATURDAY, JULY 25TH.

9.30 A.M.—Representative Meeting.

MONDAY, JULY 27TH.

9.30 A.M.—Council Meeting.
10 A.M.—Representative Meeting.

TUESDAY, JULY 28TH.

9 A.M.—Exhibition of Surgical Instruments, Drugs, etc. The Exhibition will remain open until 6 p.m. on this and the three following days.
9.30 A.M.—Representative Meeting.
2 P.M.—Annual General Meeting.
*8.30 P.M.—Adjourned General Meeting, President's Address.

WEDNESDAY, JULY 29TH.

9 A.M.—Religious Services.
10 A.M. to 1 P.M.—Sectional Meetings.
12.30 P.M.—Address in Medicine.
2.30 P.M.—Secretaries' Conference, followed by Dinner.
3.30 P.M.—Garden Party by Town Council in Duthie Park.
*8.30 P.M.—Reception by University in Marischal College.

THURSDAY, JULY 30TH.

8 A.M.—National Temperance League Breakfast.
9 A.M.—Council Meeting.
10 A.M. to 1 P.M.—Sectional Meetings.
12.30 P.M.—Address in Surgery.
1.15 P.M.—Irish Medical Schools' and Graduates' Association, Luncheon.
7.30 P.M.—Annual Dinner.

FRIDAY, JULY 31ST.

9 A.M.—Council Meeting.
10 A.M. to 1 P.M.—Sectional Meetings.
*12.30 P.M.—Graduation Ceremony in Marischal College.
6 P.M.—Annual Exhibition closes.
8 P.M.—Popular Lecture, Marischal College.
*8.30 P.M.—Reception by Branch (Music Hall).

SATURDAY, AUGUST 1ST.

Excursions.

* Academic dress or uniform should be worn on these occasions. Members desiring to have robes provided for them at Aberdeen should communicate with Messrs. Ede, Son and Ravenscroft, 93 and 94, Chancery Lane, London, W.C.; Mr. William Northam, 9, Henrietta Street, Strand, London, W.C.; or Messrs. L. Y. and J. Nathan, 4, Hardman Street, Liverpool.

SECTION OF MEDICAL SOCIOLOGY.

State Medical Service versus Panel System.

(A CORRECTION.)

IN the particulars with regard to this Section, published in the SUPPLEMENT of July 4th, page 4, there was an unfortunate blunder, which we regret to learn has caused Sir John Collie some inconvenience. A syllabus was there published, which it was stated was an outline of Sir John Collie's opening paper. As a matter of fact, this syllabus should have been attributed to Dr. Mills, who is to follow Sir John Collie. The syllabus of Sir JOHN COLLIE'S paper is as follows:

"A State Medical Service does not mean the nationalization of medicine. Effect of the inclusion in the National Health Act of the uninsured persons in the industrial community. The value of the co-ordination of preventive and clinical medicine. The effect of a State Medical Service on general medical practice: its advantages and disadvantages. Free choice of doctor."

SECTION OF SURGERY.

The following are abstracts of the papers initiatory of discussions in this Section:

Carcinoma of the Tongue.

Mr. W. G. SPENCER: After describing a subepithelial small round-cell infiltration to be found in the neighbourhood of lesions that are or are about to become cancerous, the author will state that cancer of the tongue is practically always preceded by a recognizable lesion which endures generally longer than three months before it becomes cancerous. After dealing with the treatment of these he will describe the operative indications that may be afforded by histological examination of the tissues in the neighbourhood of a chronic lesion. In any case which is deemed inoperable he will suggest that the continuous use of non-irritating antiseptics to disinfect the ulcerated surfaces, and the relief of pain by drugs, continue to be the only measures advisable. Alternative measures which have been tried of late years either fail to relieve, or do so by producing a surface disinfection which is better effected by antiseptics.

In the course of the demonstration which is to follow this paper Professor KAY JAMIESON and Mr. J. F. DOBSON, after dealing with the anatomy of the cervical lymphatic glands, will show that for the removal of glands no operation except Crile's block dissection is adequate, and will demonstrate when bilateral and unilateral gland operations can be practised. They will also show the method of invasion of glands, and that it is not necessary or practicable to remove the large lymphatic trunks. Then after considering the bearing on the subject of Lenthal Cheatle's work, they will show that though in some early cases an intrabuccal operation may suffice if care be taken to cut the tongue off close to the hyoid bone, the only satisfactory treatment in advanced cases is free extra-buccal excision of the tongue combined with Crile's block dissection. Finally they will deal with the considerations which should influence the question of dividing the whole procedure into one or more stages.

Surgical Treatment of Arthritic Deformities.

Mr. ROBERT JONES, after dealing with the etiological and pathological classification of arthritis, will show that every case of arthritis is a potential but preventable deformity. He will then deal with the treatment of "sound" and "unsound" ankylosis respectively, and in speaking of osseous ankylosis will show that osteotomies are especially applicable to the femur. He will encourage osteoplastic operations on the spine for adults, and in speaking of arthroplasty will show that the choice of a flap is of less importance than good technique, and a sense of proportion. In regard to results, stability will be shown to be more important than mere movement, and in cases of tuberculosis preference over this operation will be given to procedures below the joint, such as the author's pseudo-arthrosis of the hip. It will be shown that operation is justifiable in severe osteo-arthritis of the hip-joint, and that the removal of excrescences and arthrodesis, and the author's pseudo-arthrosis for the later stages, may be performed. These procedures are designed for the relief of friction which is the cause of the pain.

Anoci-association.

Mr. H. M. W. GRAY: The subject is dealt with from a purely practical standpoint. No theories as to conditions of nervous system, circulation, blood, etc., are touched upon. The measures which may be taken in order to prevent shock are fully discussed; those which may be used to combat shock already present are very shortly referred to. His own practice, carried out in a class of work which represents the practice of the average surgeon throughout the kingdom, described. The treatment of the patient before, during, and after operation, discussed, especially matters concerning the mental attitude of the patient, the administration of narcotics and general anaesthetics, the technique necessary during operations, and finally the best method of using local anaesthetics. Certain considerations with regard to procuring surgical cleanliness, diet, etc., are not dealt with. A special method of using ether and local anaesthesia, described especially with reference to the performance of abdominal operations. The author's endeavour will be to indicate procedures that will prevent shock and yet are applicable by surgeons handicapped by want of plentiful funds and assistance.

SECTIONS OF PHARMACOLOGY, THERAPEUTICS, AND DIETETICS, AND PATHOLOGY AND BACTERIOLOGY.

The undernoted propositions will be put forward by Dr. THOMAS LEWIS in opening the discussion which is to be held by this Section in conjunction with the Section of Pathology and Bacteriology. Its subject is the pathology of heart function, including the experimental pharmacology and therapeutics of pathological conditions of the heart.

(1) That there is no direct knowledge of disordered "rhythmicity" or disordered "conductivity," etc., in the human heart, using these terms in their special senses;

and that Wenckebach's classification of irregularities, based as it is upon Engelmann's hypothesis, rests upon an insufficiently secure foundation. (2) That auriculo-ventricular heart-block is conditioned by interference, be it through direct nervous or chemical channels, with the auriculo-ventricular conducting system, and especially with the auriculo-ventricular node and bundle. (3) That premature contractions, paroxysmal tachycardia, auricular flutter, and fibrillation have the same essential pathology, whose simplest expression is the premature contraction. (4) That certain of the preparatory processes which precede the normal contraction on the one hand, and the extra-systolic contraction on the other, are essentially different. (5) That it has not been shown that abnormal nerve impulses playing upon a normal heart may be responsible for extrasystolic contractions; but that it has been shown that nervous impulses playing upon a supersensitive or irritable organ may provoke these contractions.

SECTION OF ELECTRO-THERAPEUTICS AND RADIOLOGY.

The following additional papers have been accepted:

BAILEY, C. F. (1) Electro-therapy in Neurasthenia. (2) Testing and Treating Muscles by the Condenser Method.
CUMBERBATCH, E. P. Diathermy for the Destruction of New Growth.
LILIENFELD, Dr. Some New Apparatus.
NUTTALL, H. High-frequency Currents in Insomnia.
ORAM, W. C. Some Remarks on Gall Stones.
SLOAN, S. The Possibility of Detecting any Change taking place—Chemical, Physical, or Biological—in the Mid-Polar Region of a Continuous Galvanic Current.

The demonstration mentioned in our last issue as to be given on July 30th by Dr. C. F. Bailey will be given by Dr. E. P. Cumberbatch.

High-frequency Currents.

The following is a syllabus of the paper with which the President, Dr. SAMUEL SLOAN, will introduce the discussion on this subject:

The improper use of high-frequency currents and consequent reaction of feeling in respect of them. The importance of a knowledge of general medicine as well as of electro-physics by those engaged in testing the value of the treatment. The study of the physiological effects in disease in man of more importance than that of the physiological effects in animals in health. Results of the author's investigations in this field. Are the good effects mainly psychic or mainly physical, or are they due to the accompanying treatment? Importance of eliminating these doubts by employing these currents at first only in cases which no other treatment has benefited and without any change in habits or environment or diet. Selection of suitable cases and modes of administration.

SECTION OF TROPICAL MEDICINE.

The following are synopses of the papers initiative of the discussions in this Section:

Kala-azar.

Fleet Surgeon P. W. BASSETT-SMITH: An historical review, more particularly of recent research, relating to the etiology of kala-azar, showing the wide distribution of the Leishmania parasite. Division of the infections into two main groups: (1) General, and (2) local. A short description of the morphological and cultural characters of the parasites and the pathological changes produced by them. A short summary of the etiological facts known as affecting the Indian and Mediterranean forms of kala-azar and the relationship of the clinical types found in the different geographical areas, showing their probable identity with some details of an interesting case under the author's charge of an adult infected at Malta. The variations in the local form of the disease known as Oriental sore, with particular reference to the tropical American type.

The Sanitarian in the Tropics.

Colonel W. G. KING, I.M.S., C.I.E.: In Great Britain it is possible for the sanitarian readily to obtain opinions by specialists in any of the subjects with which he has to deal. He may also send materials to laboratories with which he is not personally connected, or, at a few hours' notice, he may get a specialist on any subject to accompany him to the field. Sanitary works that he advises are rarely of urgency, and there are available plenty of specialists or contractors for estimating and for execution of such works, whether they be major, minor, or petty. In the tropics, however, except in a few large municipal towns, such conditions cannot be expected. Consequently, as the brain capacity of a human being is limited and the money and time expended in education for a specific calling should be in proportion to what is actually requisite, instead of securing the sanitarian for the tropics by the roundabout process of teaching him medicine fully, his five-year course of education should be so arranged that subjects connected with cure of disease should be largely repressed, in favour of theoretical and practical special training in the sciences that directly concern him. His official position should be such as to give him the right, untrammelled by fear of loss of office or hope of favour, to place his advice directly at the disposal of the ultimate sanctioning authority of finance; and Tropical Public Health Services should be organized on such lines as to make this possible.

Surgical Treatment of Colitis.

Mr. JAMES CANTLIE: The sigmoid flexure—anatomy and functions as an organ—a colo-sigmoid and a sigmo-rectal pylorus. Intussusception to a slight extent of sigmoid flexure into rectum the normal condition; increase of intussusception in diseased state; condition in acute and chronic dysentery, in post-dysenteric states, and other lesions; meaning of "tenesmus" and explanation of the condition. The value of the sigmoidoscope, introduction of instrument, appearance of bowel when inspected, seat of lesion the lower two inches of sigmoid flexure in chronic cases; ulcers, scars, granulations, and congestion; mucous colitis, so-called; comparison of chronic urethral discharge and rectal discharge. Treatment: Diet of but slight importance; unless pathogenic amoebae present, drugs of but little use. Treatment of ulcers by pure carbolic acid; sea-water as enemata; passage of sigmoidoscope by mechanical effects curative; recurrences due either to mechanical obstruction or to germ infection. Surgical treatment: Opening sigmoid, washing out the colon by way of appendix; removal of diseased area; removal of colon; tendency to malignancy.

RECEPTION ROOM.

THE reception room will be open during the Annual Meeting in the Advocates' Hall, Broad Street, Aberdeen, and members are advised to call there as soon as possible after their arrival in Aberdeen. They will there find full information at their disposal and will be able to obtain a copy of the *Daily Journal*.

ACCOMMODATION IN ABERDEEN.

A LIST of hotels and lodgings available in Aberdeen during the Annual Meeting is published in the advertisement pages (6 and 7) of this issue. Members desiring further information on this subject are asked to communicate with Dr. F. Philip, Honorary Secretary of the Hotels and Lodgings Committee, 29, King Street, Aberdeen.

At a recent meeting of the General Committee, consisting of influential citizens, the intention to give a hearty welcome to members of the Association was made evident, and a very large amount of private hospitality is likely to be offered. The Local Executive Committee hopes that members will not be led by the answers they may get from some of the hotels to suppose that the accommodation available in Aberdeen is filled up; any member who has difficulty in finding accommodation should not hesitate to communicate either with Dr. F. Philip, as above, or with Dr. Thomas Fraser, one of the honorary local secretaries, at the same address.

ARRANGEMENTS FOR LADIES.

A COMMITTEE of ladies has been formed to look after the comfort and interests of ladies accompanying members to Aberdeen. The Aberdeen Medico-Chirurgical Society has granted the use of its rooms at 29, King Street, as reception rooms for ladies from July 24th to 31st. There will be provided a rest-room, a writing-room, a tea-room, and a dressing-room. There will also be an office in the building where information regarding ladies' entertainments and motor drives will be given and tickets supplied. A member of the Ladies' Committee has given the use of her flat at 245, Union Street, where ladies living out of the town may dress for the evening entertainments. It is hoped that a corps of lady guides will be available for the assistance of visitors. For further particulars see SUPPLEMENT, July 4th, p. 11.

THE JOURNEY TO ABERDEEN.

Special Vouchers.—Railway facilities similar to those offered in previous years will be available this year—that is to say, return tickets, valid from July 22nd to August 3rd, will be issued at a single fare and a third on the presentation of a voucher, which will be supplied, to members who intend to go to Aberdeen, by the Financial Secretary and Business Manager, British Medical Association, 429, Strand, London, W.C., on receipt of the notification form. A separate voucher is required for each passenger.

Tourist Tickets.—The attention of those who intend to travel to Inverness or other places north of Aberdeen is drawn to the tourist ticket arrangements. The advantage of a tourist ticket is that it is available for six months, and the holder has the privilege of breaking the journey at many places *en route*. The tourist ticket from London to Inverness costs £3 3s., third class. In many instances a member travelling from England may find it more advantageous to take a tourist ticket than to make use of the special voucher.

London to Aberdeen by Sea.—Members travelling from the south may like to be reminded that they can make the journey from London by sea. The boats of the Aberdeen Steam Navigation Company, which are lighted by electricity and in every way well appointed, sail from Aberdeen Wharf, Limehouse, E., every Wednesday and Saturday (see advertisement, page 4). The return fares, available for six months, are—first cabin 45s., second cabin 25s.; private cabins can be obtained for an extra fee. A boat will leave on Wednesday, July 22nd, at 11 a.m., and on Saturday, July 25th, at 1 p.m. Further particulars can be obtained on application to the company at Aberdeen Wharf, Limehouse, or the City Passenger Agency, 25, Cannon Street, E.C.

RAILWAY FACILITIES FOR MEMBERS STAYING IN THE NEIGHBOURHOOD OF ABERDEEN.

DURING the meeting reduced fares, with a minimum of 1s., will be granted to places within a radius of fifty miles from Aberdeen. Members who propose travelling to and from Aberdeen daily should use the first half of the ticket on the first journey and the return half on the last journey; the reduced fares for the intermediate journeys will be granted on production, at the time of booking, of the card of membership.

Weekly Season Tickets.

Members staying at Banchory or Cruden Bay can obtain season tickets enabling them to travel to and from Aberdeen daily during the week of the Annual Meeting at the following rates: Cruden Bay, 10s.; Banchory, 8s. 8d. The season tickets will be issued from intermediate stations at proportional rates.

On the Caledonian Railway to Stonehaven and intermediate stations, during the meeting, return tickets will be issued at Aberdeen to places where members wish to reside. These tickets will be available for the day of issue or following day, or from Saturday to Monday, at a single fare and a third for the double journey, minimum 1s. Season tickets are also available for more than one journey, at a charge of not less than the accumulated fares per day as above, the minimum being 1s. a day.

ANNUAL EXHIBITION.

THE annual exhibition of surgical instruments, drugs, foods, etc., held during the annual meetings of the British Medical Association, will be arranged this year in the Marischal College, where also the Sections will meet, where the General and Representative Meetings of the Association will take place, and where the Addresses in Medicine and Surgery will be delivered. The exhibition on this occasion will, therefore, occupy a central and convenient position, and members will have an excellent opportunity of inspecting the exhibits.

GARDEN PARTIES.

IN addition to the garden party to be given by the Provost and Town Council of Aberdeen in Duthie Park on the afternoon of Wednesday, July 29th, garden parties will be given at the Deeside Hydropathic, which has a nine-hole approaching and putting course, and tennis, croquet and bowls; at Inchmarlo House, on the north bank of the Dee about two miles beyond Banchory, which has first-class provision for tennis; at Parkhill House on the Don, surrounded by fine woods and within easy reach of three small lochs; at Banchory House, on a beautiful sweep of the river Dee about a mile beyond the historic bridge of Dee; and at Nordrach-on-Dee, which has extensive and beautiful grounds.

GOLFING ARRANGEMENTS.

ABERDEEN and its immediate neighbourhood is rich in golf courses. Particulars with regard to them were published in the SUPPLEMENT last week, page 9; they include Balgownie, Murcar, Bieldside, Balnagask, Aboyne, Cruden Bay, Banchory, and the public links at Aberdeen.

The Ulster Cup.

The competition for this cup will take place on the Balgownie Links on Thursday, July 30th. The Ulster Cup was presented by the Ulster Branch at the Annual Meeting of the British Medical Association at Belfast, in 1909. It is played for under the following conditions laid down by the Ulster Branch: "Bogey play under handicap, not exceeding 18; cup to become the property of the member of the Association winning it twice in succession, or three times in all; one round of 18 holes to be played on one day at the Annual Meeting with no previous play." The cup is a copy of the famous Ardagh Cup now in the National Museum in Dublin; its history is known from the eleventh century. The competition for the cup has always been good, and the winners have been as follows:

1909	...	...	Dr. Shackleton (Holywood).
1910	...	...	Dr. G. E. Haslip (London).
1911	...	...	Dr. McCardie (Birmingham).
1912	...	...	Mr. Albert Lucas (Birmingham).
1913	...	...	Dr. H. L. Hatch (Pinner).

Intending competitors should send their names and addresses, along with their club handicap, to Dr. Alexander, Kingseat Mental Hospital, New Machar, Secretary of the Golf Subcommittee.

EXCURSIONS.

ARRANGEMENTS are being made to afford to members attending the Annual Meeting opportunities of visiting many places of beauty and interest in the north-east of Scotland and the Highlands. Particulars were published in the SUPPLEMENT to the JOURNAL of last week. It is desirable that members should make up their minds as to the excursion or excursions they wish to take as early as possible, and that they should communicate their preference to Mr. G. H. Colt, F.R.C.S., 12, Bon Accord Square, Aberdeen.

Members of the Representative Body should note that arrangements have been made by members in Aberdeen for a special train to Cruden Bay on Sunday, July 26th, leaving Aberdeen in the morning and returning the same evening. Representatives who wish to take part in this excursion should send their names to Mr. Colt at once if they have not already done so.

As was noted last week, it will be possible during the meeting to make afternoon excursions to many places of interest within easy reach of Aberdeen, and longer tours have been arranged for Saturday, including one to Inverness, Elgin, Nairn, and the Highlands. There will also be some tours of intermediate length on Wednesday, starting early in the afternoon and returning to Aberdeen in the evening. For further particulars and maps see SUPPLEMENT, July 4th, pp. 10, 11, 12 and 13.

THE LIBRARY OF THE BRITISH MEDICAL ASSOCIATION.

A LIST of periodical publications, official reports, and Blue Books in the Library of the British Medical Association available for issue to members on loan has been printed, and copies can be obtained free on application to the Librarian, at the house of the Association, 429, Strand, W.C. The regulations governing the loan of these publications are stated in the introduction to the list. The Library is open for consultation from 10 a.m. till 5 p.m. (on Saturdays till 2 p.m.).

Meetings of Branches and Divisions.

[The proceedings of the Divisions and Branches of the Association relating to Scientific and Clinical Medicine, when reported by the Honorary Secretaries, are published in the body of the JOURNAL.*]*

BIRMINGHAM BRANCH:

CENTRAL DIVISION.

THE annual meeting of the Central Division was held at the Medical Institute, Birmingham, on July 1st, when the Chairman of the Division, Dr. PURSLOW, presided, and about thirty-six members were present.

Election of Officers.—The following officers were elected:

Chairman: Dr. Lilley.
Vice-Chairman: Dr. Lydall.
Honorary Secretary: Mr. Percival Mills.
Representatives on the Branch Council: Dr. Dain, Dr. W. R. Jordan, Mr. B. J. Ward, Dr. Trumper, Dr. Lydall, and Dr. Thomas Wilson.
Executive Committee: Dr. Purslow, Dr. Wilkes, Dr. Burges, Dr. J. J. Bekenn, Dr. Boeddicker, Dr. Pooler, and Dr. Henton White.

Annual Report of Division.—The annual report of the Executive Committee was received and adopted.

Vote of Thanks.—Votes of thanks were passed to the retiring officers, and the meeting expressed especially the thanks of the Division for the services of Dr. Hadley, one of the retiring secretaries, whose untiring energy had been of inestimable value during a trying period in the history of the Association.

Annual Representative Meeting.—The meeting then instructed the Divisional Representatives on the matters referred to Divisions, and empowered the Executive Committee to deal with any motions of which notice might be received subsequently.

BORDER COUNTIES BRANCH.

THE forty-seventh annual meeting of the Border Counties Branch was held at the County Hotel, Carlisle, on July 3rd, when Dr. EASTERBROOK occupied the chair.

Annual Report.—The report of the Branch Council and financial statement were submitted and approved.

Election of Officers.—The following office-bearers for the ensuing year were elected:

President: Dr. Fisher (Whitehaven).
President-elect: Dr. Livingston (Dumfries).
Past President: Dr. Easterbrook (Dumfries).
Secretary and Treasurer: Mr. Norman Maclaren (23, Portland Square, Carlisle).
Additional Secretary, with seat on the Scottish Committees: Dr. Livingston (Dumfries).
Branch Council: Representatives from Cumberland Division (Drs. Fisher, Edington, and Hill); Representatives from Dumfries and Galloway Division (Drs. Huskie, Maxwell Ross, and Scott); Members elected by Branch (Drs. Barnes, Crerar (Maryport), Muriel, Irving, Bell, and Gilroy); *Ex officio* members: Secretary of Cumberland Division (Dr. Anderson, Garlands, Carlisle) and Secretary of Dumfries and Galloway Division (Dr. Robson).
Representative on Central Council: Dr. Livingstone Louden (Hamilton).

Model Rules.—The revised rules, which had been circulated to all members of the Branch, were adopted.

Presidential Address.—Dr. EASTERBROOK then introduced the new President, Dr. FISHER, who delivered an address on National Health Insurance. On the proposal of Dr. EASTERBROOK, seconded by Dr. HILL, a most cordial vote of thanks was given to the President for his address.

CAMBRIDGE AND HUNTINGDON BRANCH.

THE seventieth annual general meeting was held at St. Ives, Hunts, on July 2nd.

Election of Officers.—At the business meeting the following officers were elected:

President: Dr. Grove.
Vice-Presidents: Dr. Newton, Dr. Meacock.
Representative: Dr. Young.
Honorary Secretary and Treasurer: Dr. Haynes.
Members of Branch Council: Drs. Deighton, Garrood, Gunson, Roderick, Stevenson, Waters, and Wright.

Luncheon.—Dr. and Mrs. Grove entertained the members and their wives to luncheon in the Corn Exchange, the company including the Mayor of St. Ives, Sir George Askwith.

Presidential Address.—The PRESIDENT afterwards gave an address on infant feeding.

EAST ANGLIAN BRANCH:

WEST SUFFOLK DIVISION.

A MEETING of the West Suffolk Division was held at the Angel Hotel, Bury St. Edmunds, on June 30th, when Dr. CAIE was in the chair, and eight other members were present.

Representation on Representative Body.—On the motion of Dr. BARWELL, seconded by Dr. HINNELL, the Secretary was instructed to write to the Medical Secretary, Dr. Cox, as follows:

> The Division wishes to be represented and would point out that small Divisions are small mainly because their members are widely scattered, and if they have no independent representation they have no representation at all. In the opinion of the Division it is important that such areas should be represented because the conditions of practice in them is very different to those in more densely populated areas.

Fees for Clubs.—After consideration of the replies to the circular, the recommendation of the Executive Committee was carried, with an amendment proposed by Dr. WOOD, seconded by Dr. BARWELL, making it read as follows:

> The Division recommends the rates and rules of the Suffolk County Medical Club as the basis for private club work, these having been officially approved by the British Medical Association, and asks all medical men practising in West Suffolk to transfer their private clubs to the Suffolk County Medical Club.

On the motion of Dr. BARWELL, seconded by Dr. G. C. GRAY, it was carried *nemine contradicente*:

> That the fee for uninsured club members should not be less than 8s. 6d. per annum.

The Secretary was instructed to issue a circular embodying the two preceding resolutions to every practitioner in the area.

Annual Report of Council.

The annual report of the Council was considered. With regard to the Special Fund, the Representative was instructed to vote in favour of recommendations of Central Council A, B, C, D, E, but to vote against the proposal that the administration of such a fund should be placed in the hands of a trade union (BRITISH MEDICAL JOURNAL SUPPLEMENT, May 9th, p. 339, paragraphs 77 and 83). With regard to amendments *re* Special Fund (SUPPLEMENT, June 27th, p. 437), the Representative was instructed as follows: To oppose paragraphs 47, 48, 49; to support paragraphs 50, 51, and 52.

On the question of school clinics, the Representative was instructed to support any resolution embodying the principles outlined in paragraph 5 of the Memorandum, p. 281, BRITISH MEDICAL JOURNAL SUPPLEMENT, May 2nd. It was further agreed that if the Representative Body passed resolutions in conformity with these principles, a subcommittee of three members should consider the matter as it affects the area of the Division, and that Dr. Bygott, the county school medical officer, should be invited to be present. Drs. Batt, Hinnell, and Wood were elected to serve on the subcommittee, which was requested to report to the next meeting of the Division.

The SECRETARY then gave a summary of the remaining important recommendations of Council, namely, as to (1) referendum, (2) Council to act on delegation, (3) reduced subscription to newly registered members, (4) notice of Special Representative Meeting, (5) State registration of nurses, (6) payment for assistance to midwives, (7) certificates under Insurance Act, (8) tuberculosis scheme. The Representative was instructed to vote in favour of all these, except that in regard to the State registration of nurses.

With regard to the Supplementary Report of Council, the Secretary was instructed to vote in favour of all the Council's recommendations, and in the case of life insurance examinations to support the principle of a fixed minimum fee.

Regarding the Notices of Motion for the Annual Representative Meeting (BRITISH MEDICAL JOURNAL SUPPLEMENT, June 27th, p. 484) the Representative was instructed to support amendments 1 and 2, but to oppose rider 4. The

Representative was instructed to support the rider requesting the Council to obtain further evidence on the matter of the State registration of nurses, and also to support the rider "That the Central Defence Fund be now closed."

The Division approved of the action of the Executive Committee in replying to questions from the Special Committee as to the future development of the Insurance Act.

EDINBURGH BRANCH.

The annual meeting of the Edinburgh Branch was held in the hall of the Royal College of Surgeons on June 26th, when Mr. Cathcart, President, was in the chair.

Election of Officers.—The office-bearers for the year 1914–15 were elected as follows:

President: Dr. John Playfair.
President-elect: Professor F. M. Caird.
Vice-Presidents: Dr. Carlyle Johnstone and Dr. James Ritchie.
Honorary Treasurer: Dr. James Ritchie.
Honorary Secretaries: Dr. John Stevens and Dr. John Eason.

The election of Dr. J. R. Hamilton as member of Council for the Edinburgh and Fife Branches for 1914–15 was intimated.

The Representatives to the Annual Representative Meeting, so far as elected, and the Representatives of the Division to the Branch Council, were also intimated.

Vote of Thanks.—A vote of thanks was passed to the retiring President, Mr. Cathcart, and after Mr. Cathcart replied Dr. Carlyle Johnstone occupied the chair.

Annual Report and Financial Statement.—The Treasurer submitted his annual report, and Dr. Stevens submitted the report of the Branch Council for the year, which were approved.

Scottish Committee.—Dr. J. R. Hamilton reported on the work of the Scottish Committee, especially referring to the subject of contract practice and the action taken in support of Lord Balfour's Midwives Bill. He reported that the Central Council had decided to appoint a whole-time Scottish Medical Secretary, whose office would be located in Edinburgh. The election would be made on the recommendation from the Scottish Committee. Dr. Stevens explained the proposed modification in the constitution of the Scottish Committee.

Queen Mary Nursing Home.—Dr. W. R. Martin was elected to the vacancy on the board of management of the Queen Mary Nursing Home.

Local Guarantee Fund.—It was intimated that an application had been received for a contribution from the Local Guarantee Fund, and the Branch Council had granted it. Dr. James Ritchie reported on the response which had been made to the levy. Two-thirds of the levy had now been returned to those guarantors who had responded. It was decided that the Guarantee Fund should now be abrogated.

Revision of Rules.—The Branch Council was instructed to revise the rules of the Edinburgh Branch and report to a future meeting. The following new rule was unanimously approved of:

That one Honorary Secretary of each Division be *ex officio* a member of the Branch Council.

Votes of Thanks.—Votes of thanks were accorded to Dr. Carlyle Johnstone (Vice-President), Dr. James Ritchie (Honorary Treasurer), and to Dr. J. R. Hamilton, for his work on the Council of the Association and the Scottish Committee.

South-Eastern Counties Division.

The annual meeting of the South-Eastern Counties Division of the Edinburgh Branch was held at Newtown St. Boswells on June 29th, when Dr. Blair, Chairman, presided, and eight other members were present.

Index and Suspense Slips.—There was some discussion on the subject of remuneration of practitioners under the Insurance Act, but, on the Secretary pointing out that further inquiry was in process of being made, discussion was postponed until definite information were available.

Election of Officers.—The following officers were elected:

Chairman: Dr. P. C. McRobert (Runic Cross, Innerleithen), on the termination of Dr. Blair's term of office.
Vice-Chairman: Dr. J. Young (Earlston).
Representative on Branch Council: Dr. J. Carlyle Johnstone.
Representative to Representative Meetings: Dr. William Blair.
Deputy Representative to Representative Meetings: Dr. T. Luke.
Executive Committee: Dr. A. J. Campbell, Dr. N. P. Fairfax, Dr. A. Rolger, Dr. J. J. McMillan, Dr. B. Henderson, Dr. G. Gunn Bannerman.
Honorary Secretary and Treasurer: Dr. M. J. Oliver.

Vote of Thanks.—On the motion of Dr. Oliver, a vote of thanks was accorded Dr. Blair for his able services in the chair during the past year. Dr. Blair expressed his thanks.

Report of Council.—Dr. J. R. Hamilton expressed his opposition to the formation of a trade union within the profession, and, with regard to the establishment of an Organizing Medical Secretary with an office in Scotland, said that he considered the office should be located in Edinburgh, as the metropolis of the country. Dr. Blair asked Dr. Hamilton whether the Council had any particular views as to contract practice amongst uninsured persons. Dr. Hamilton replied that it had been found that there were only about 2,000 practitioners entirely without contract practice. The meeting considered the Report of Council as published in the Journal, together with the memorandum on the subject of future developments of the Insurance Acts. The meeting considered the various questions raised, and instructed the Secretary as to the replies to be made. On the motion of Dr. J. Carlyle Johnstone, it was agreed that the office of the Organizing Medical Secretary to be appointed shortly should be in Edinburgh.

Annual Report of Executive Committee.—The Secretary submitted the report of the Executive Committee for the past year. It showed that the number of members in the Division was fifty-eight, two members having resigned during the year. Four meetings of the Division had been held, the subjects of debate having been entirely medico-political in character. The Executive Committee had not been convened on any occasion, as it had been possible to deal with all matters of urgency at meetings of the Division.

Communications.—The Secretary read a letter from the Medical Secretary of the Association, dated June 20th, referring to the views of the Insurance Acts Committee on various matters relating to the work of Local Medical Committees, and particularly to the disclosure of the names of practitioners against whom complaints had been made, which had been the subject of investigation by Medical Service Subcommittees.

GLOUCESTERSHIRE BRANCH.

Special Meeting.

A special general meeting of the Oxfordshire Branch was held at the hospital, Stroud, on May 7th, when the President was in the chair and twenty-nine members were present.

Surgical Treatment of Diagnosis.—Mr. James Sherren, F.R.C.S., of the London Hospital, gave an address on the diagnosis and surgical treatment of indigestion. A discussion followed, in which the President, Mr. Coode, Dr. Collins, Dr. Mitchell, Mr. Holmes, and Dr. Hebblethwaite took part.

Vote of Thanks.—On the motion of Mr. Howell, seconded by Mr. Braine-Hartnell, a vote of thanks was accorded to Mr. Sherren.

Annual Meeting.

The annual meeting of the Branch was held at the Royal Infirmary, Gloucester, on May 21st, when the President was in the chair, and forty members were present.

Election of Officers.—The result of the elections for 1914–15 was as follows:

President: Dr. J. F. Johns (Cheltenham).
Council: Drs. E. Dykes Bower, C. Braine-Hartnell, E. C. Carter, J. R. Collins, A. B. Davies, E. A. Dent, J. Goss, W. W. Grosvenor, J. Howell, J. S. Mellish, G. A. Peake, N. H. Pike. *Ex officio*, Dr. D. Knight.
Scrutineers: Drs. Wayland Ancrum and T. S. Ellis.
Auditors: Drs. E. A. Dent and G. A. Peake.
Ethical Committee: Drs. T. S. Ellis, D. H. Fowler, J. S. Mellish, H. E. Waddy, and J. G. Soutar.
Secretary: Dr. D. E. Finlay.

Annual Report of the Division.—The annual report was taken as read and passed. It showed a decrease of 10 in membership. There had been thirteen Branch meetings during the year, at eight of which scientific or clinical matters had been discussed, while at five medico-political, ethical, or kindred matters were debated. The average

attendance at the scientific meetings had been twenty-four. Six Council meetings had been held, with an average attendance of eight. The financial statement showed a small balance in hand.

Annual Representative Meeting.—The business for the Annual Representative Meeting was postponed for a special meeting.

Decompression of the Brain.—An address was given by Mr. BATHE RAWLING, F.R.C.S. (St. Bartholomew's Hospital), on decompression of the brain in relation to injury and disease, illustrated by lantern slides. Mr. J. E. H. ROBERTS, F.R.C.S. (St. Bartholomew's Hospital), read a short paper on some experimental work.

Votes of Thanks.—On the motion of Mr. CUTHBERT, seconded by Dr. PRUEN, votes of thanks were accorded to Mr. Bathe Rawling and Mr. J. E. H. Roberts.

Dinner.—Forty-one sat down to dinner at the Bell Hotel after the meeting.

KENT BRANCH:

BROMLEY DIVISION.

THE annual meeting of the Bromley Division was held at the Bell Hotel, Bromley, on July 3rd.

Election of Officers.—The following officers were elected for 1914–15:

Chairman: Dr. W. F. Umney (Sydenham).
Vice-Chairman: Dr. T. W. Bailey (Orpington).
Honorary Secretaries: Dr. Tennyson Smith and Dr. Chisholm Will.
Treasurer: Dr. Tennyson Smith.
Representative to Representative Meetings: Dr. Tennyson Smith.
Deputy Representative: Dr. G. R. Stillwell.
Representative on Branch Council: Dr. C. E. M. Lewis.
Executive and Ethical Committee: Drs. Michael and Pringle (Penge), Hawke and Stillwell (Beckenham), Codd, Lewis, and Yolland (Bromley), Douse (Bromley Rural), T. D. Miller (Sidcup).

Organization Rules.—The Organization Rules were considered in detail, and adopted as the rules of the Division.

Annual Representative Meeting.—The annual report of the Council having been considered, it was resolved to instruct the Representative to support the formation of a Special Fund, and to vote for the amendment by Brighton in favour of a trust. In the event of this amendment being defeated, and in order to obtain the necessary majority for the proper establishment of the Special Fund, the Representative was instructed to support the report of the Council. It was unanimously resolved that if any trade union were formed, such union must be under the supervision of the Association, and that the procedure should not be by incorporation with any existing trade union.

Representative's Expenses.—It was unanimously resolved that a levy be made on the members of the Division to meet the Representative's expenses at the forthcoming Annual Representative Meeting.

Votes of Thanks.—Votes of thanks were accorded to Dr. Yolland (Bromley) for his services as Chairman of the Division during 1913–14, and to Dr. Umney for presiding at the meeting.

LANCASHIRE AND CHESHIRE BRANCH.

THE annual meeting of the Lancashire and Cheshire Branch took place at Knutsford on June 17th, when there was a fairly good attendance of members. The usual routine business was transacted.

Election of Officers.—The following officers were elected for 1914–15:

President: Dr. T. W. H. Garstang (Altrincham).
Vice-Presidents: Dr. Robert Harris (Southport), Dr. F. P. Bassett (St. Helens).
Secretary: Mr. F. Charles Larkin, F.R.C.S. (Liverpool).

Luncheon.—At noon the members partook of luncheon provided by the members of the Mid-Cheshire Division.

Induction of President.—At the conclusion of a meeting of the Branch Council the annual meeting commenced, when Dr. R. C. Brown of Preston surrendered his office of President, which he has thrice filled with great success, to Dr. GARSTANG, who read his presidential address, entitled "Personal reminiscences of the Association." The address was much appreciated, and will, it is hoped, be published separately.

Clinical Papers.—Dr. A. ADAMS gave a demonstration of the artificial pneumothorax, and Mr. JOHN MORLEY read a paper on conditions simulating chronic appendicitis. These papers will be reported in a subsequent issue. Dr. CRAVEN MOORE gave a short address on uraemia, especially in relation to the symptom of haemorrhage.

Excursions.—The afternoon after 3 o'clock was spent in several delightful excursions arranged by the local committee. A very pleasant afternoon was spent by those who inspected the antiquities of Knutsford, under the expert guidance of the Rev. G. A. Payne, the author of *Mrs. Gaskell and Knutsford.* A visit was paid to the picturesque Unitarian Chapel, built in the troublous times of 1689 in as retiring a situation as possible and still unspoilt by restoration. It contains a good deal of roughly hewn oak, and an outside staircase leads to the gallery. Here in its early days Matthew Henry preached. In the little graveyard are the tombs of Mrs. Gaskell and her friends the Misses Holland. The latter are supposed to be the originals of "Miss Jenkyns" and "Miss Matty" in *Cranford.* In the Free Library some interesting first editions of Mrs. Gaskell's books were inspected, and a quaint old portrait of a medical member of the Holland family. After viewing some of the old timber houses in the narrow streets of Knutsford, and a memorial tower to Mrs. Gaskell of an uncertain style of architecture, the enclosed open space known as the Heath was reached. From this spot can be seen the house of her aunt, in which Mrs. Gaskell spent her youth. Not far away is a red-brick gabled structure in which lived Edward Higgins, the hero of the "Squire's Tale," who, while living in Knutsford as a highly respected country gentleman, was also highwayman and murderer. Forty of the members motored to Northwich, where, through the kindness of Mr. Geo. Malcolm (managing director) they descended the old rock-salt mine. They went down the shafts (336 ft.) in buckets into the salt seam 90 ft. thick and walked a full mile through the workings and saw the salt being blasted. Some members visited the beautiful gardens of Arley Hall and Tatton, while others were the guests of Dr. Macdougal and the Committee of the Saddlebridge Epileptic Colony, while still others accepted the invitation of Dr. Fennell, the captain of the Knutsford Golf Club, and played the ancient and royal game.

Annual Dinner.—The annual dinner was, for the convenience of members, held in Manchester at the Queen's Hotel, and a delightful evening was spent under Dr. Garstang's chairmanship.

Annual Report of Branch Council.—The report stated that the membership of the Branch was now 1,871. During the year 32 members had joined, but over 200 had resigned; the report stated that it was anticipated that after the rush to join the Association during the insurance campaign was over a good many would resign. The increase in the subscription no doubt had also had some effect, but attention was drawn to the fact that the subscription only amounted to the sum of 1½d. a day, whereas it was known that the working man would often contribute as much as 10 per cent. of his wages to his union. Two intermediate scientific and clinical meetings had been held, one in Liverpool and one in Manchester. The Branch Council had met four times, with an average attendance of twenty-four, and numerous committee meetings had been held. The Divisions reported 139 meetings in 1913 as against 231 in the previous year; the Council expressed the hope that this did not indicate that the Local Medical and Panel Committees were absorbing the interest of the profession to the detriment of the Division meetings. Though the local affairs of these committees were important enough in their way, they should not be allowed to take such a position in the minds of members as to shut out greater and vital matters. If this were to come about the profession would be most effectively split into a number of small bodies without power for united action, since the British Medical Association alone offered an organization capable of helping the profession in its difficulties.

BOLTON DIVISION.

THE twelfth annual meeting of the Bolton Division was held at the Infirmary on June 23rd, when Sir THOMAS FLITCROFT was in the chair, and fourteen members were present.

The Annual Report.—The annual report and balance sheet for the last year were adopted.

Election of Officers.—The following officers were elected:

President: Sir Thomas Fliteroft.
Vice-President: Dr. Mothersole.
Representative on Branch Council: Thomas O'Neill.
Honorary Secretary and Treasurer: Thomas O'Neill.
Executive Committee: Drs. C. Macfie, Laslett, J. M. Thornley, Rolland, Dowling, Kilpatrick.
Auditors: Drs. T. Boulton and D. Gray.

Annual Representative Meeting.—The annual report of the Central Council having been considered, it was agreed that the Representative should use his own discretion in voting at the Representative Meeting. Special consideration was given to the terms of the Minute 68 of the Special Representative Meeting, December, 1913, which alluded to the half-guinea fee to be paid to local medical referees for the examination of insured persons. This recommendation had been adopted at a meeting of the Division held in November last. On the motion of Dr. Mallett, Dr. Thornley seconding, the meeting agreed that the terms of the Minute 68 be adhered to.

Future Developments of the Insurance Acts.—The report on this subject was considered and the schedule of questions answered.

Rochdale Division.

A meeting of the Rochdale Division was held in the Wellington Hotel, Rochdale, on July 2nd, when Dr. Geddes, the Vice-Chairman, was in the chair and ten members were present.

Annual Representative Meeting.—Dr. Walker, the Representative, went over the financial statement of the Association contained in the Supplement of May 2nd. The recommendations of the Council in its annual report and supplementary report were then considered, and the Representative was instructed on certain matters, and others were left to his discretion.

Administration of Medical Benefit.—It was resolved:

> That this meeting is of opinion that the administration of medical benefits under the Insurance Acts should be undertaken by the medical profession.

METROPOLITAN COUNTIES BRANCH.

The sixty-second annual meeting of the Branch was held on June 26th at the offices of the Association, 429, Strand; Dr. R. Langdon-Down, President, was in the chair, and about forty members were present.

Election of Officers.—The following is a list of the officers elected for the year 1914–15:

President: Dr. F. J. Smith.
President-elect: Dr. Major Greenwood.
Past-President: Dr. R. Langdon-Down.
Vice-Presidents: Dr. Theodore Dyke Acland, Dr. John Arthur Percival Barnes, Dr. Evan Jones, Dr. Percy Rose.
Honorary Treasurer: Mr. Atwood Thorne.
Honorary Secretaries: Dr. Reginald E. Crosse, Mr. N. Bishop Harman, F.R.C.S.
Representatives on the Central Council: Drs. H. B. Brackenbury, Charles Buttar, James Galloway, and F. J. Smith.

Annual Reports.—The annual report of Council for the year 1913–14 and the balance sheet for the year 1913 were considered. Arising out of the second paragraph of the report concerning the election of a Local Medical Committee for London, the Chairman said that the Committee had now received the recognition of the Insurance Commissioners. The report was thereupon adopted. The annual report of the representatives on the Council was submitted, and in accordance with the rules of the Branch received.

Induction of President.—Dr. Langdon-Down, in introducing his successor, Dr. F. J. Smith, took the opportunity of tendering his very sincere thanks for the generous help and support he had received during his office. The Council, which had been most industrious and attentive, had been very fortunate in having as chairmen of its active committees men who threw their heart and business-like aptitude into the work of the Branch. It was a matter of congratulation that throughout the year the services of the Ethical Committee had not been required. Last but not least he tendered his thanks to Mr. Bishop Harman, the Secretary of the Branch. His work had been a little more onerous on account of the illness of his colleague Dr. Crosse. Dr. Langdon-Down said that he looked back on his term of office with pleasure; his regret in relinquishing the chair was tempered by the knowledge that his successor, Dr. F. J. Smith, was a strenuous leader in medical politics, and that in the early days of his (Dr. Langdon-Down's) membership of the Council Dr. Smith was a very hard working honorary secretary of the Branch. Dr. Smith, as they all knew, was a member of the staff of the London Hospital, of which school he had himself the good fortune to be a student. He would like to add a curious coincidence; at the present moment both the President himself, the incoming President, and the President-elect all hailed from the London Hospital. In the name of the Branch he invited Dr. Smith to take up the duties of his honourable position as President of the Metropolitan Counties Branch, which he now relinquished. Dr. Smith, having briefly returned thanks, read the address, which is published at page 63 of this issue of the Journal. On the motion of Dr. John Clarke, seconded by Dr. Crichton, a vote of thanks was accorded to the president for his address.

Vote of Thanks to Retiring President.—On the motion of Mr. E. B. Turner, seconded by Dr. Major Greenwood, a cordial vote of thanks was accorded to Dr. Langdon-Down for his services in the chair during the past year, and duly acknowledged by him.

Finchley and Hendon Division.

A meeting of the Finchley and Hendon Division was held on June 26th.

Election of Officers.—The following were appointed office-bearers:

Chairman: Dr. T. W. Hicks.
Vice-Chairman: Dr. F. W. Andrew.
Honorary Secretary: Dr. William Stanley Rooke.
Assistant Honorary Secretary: Mr. E. B. Jones, F.R.C.S.
Representative for Representative Meeting: Dr. A. G. Duncan.
Representatives on Branch Council: Drs. William Stanley Rooke and T. W. Hicks.
Executive Committee: Drs. R. W. Baron, J. B. Baker, A. J. Beadel, E. B. Jones, W. R. Orr, Miss Helen N. Payne, C. F. Winkfield.

OXFORD AND READING BRANCH:

Oxford Division.

The annual meeting of the Oxford Division was held at the Randolph Hotel, Oxford, on June 26th, when about twenty members were present. The annual report stated that during the year three meetings had been held, with an average attendance of forty to fifty. Since January, 1914, there had been eighteen resignations. The balance sheet was read and accepted.

The late Dr. Neil.—The Honorary Secretary was requested to write to Mrs. Neil, widow of Dr. Neil, Superintendent of Warneford Asylum, expressing the sympathy of the Division with her in her sad bereavement.

Election of Officers.—The following officers were elected for the ensuing year:

Chairman: Dr. Good.
Chairman-elect: Dr. Boissier.
Vice-Chairmen: Dr. O'Kelly and Sir William Osler.
Honorary Secretary and Treasurer: Dr. Gillett.
Divisional Representative: Dr. Yelf.
Executive Committee: The above officers and the following: Drs. Duigan, Hitchings, Penrose, Long, R. H. Sankey, Summerhayes.

Physical Basis of Insanity.—A very interesting paper was read by the Chairman, Dr. Good, on the physical basis of insanity, in which he pointed out that while heredity might be a predisposing cause there was generally some physical cause also operating.

Medical Referees.—On the motion of Dr. Duigan, seconded by Dr. Higgs, it was resolved *nemine contradicente:*

> That a minimum fee of one guinea for referee work be binding on medical men in the city and county. A notice of this to be sent to all members and non-members in the city and county.

Panel and Medical Committee.—The following nominations were made for co-option on the Panel Committee: Dr. Collier, Mr. Whitelocke, Dr. Duigan, Mr. Drew, Dr. Gillett.

Tea.—After the meeting Dr. and Mrs. Good entertained several members and their wives to tea at Littlemore, where they also had a very interesting time in being shown over the asylum.

SOUTH MIDLAND BRANCH:

BEDFORD DIVISION.

THE annual meeting of the Division was held on June 23rd at the residence of Dr. F. S. LLOYD (Luton), the retiring Chairman, who kindly invited the members to luncheon.

Election of Officers.—The following officers were elected:

Chairman: Dr. Kilham Roberts.
Vice-Chairman: Dr. Harvey Goldsmith.
Secretary and Treasurer: Dr. Birks.
Representative at Representative Meetings: Dr. J. W. Bone.
Representatives on Branch Council: Drs. Dixon, Rose, H. M. McC. Coombs, and *ex officio* members.
Executive Committee: Drs. L. G. Nash, J. M. O'Meara, W. A. Sharpin, Dixon, and Archibald, and *ex officio* members.

Annual Report of Division.—The SECRETARY presented the annual report for the year ending December 31st, 1913.

Pyuria.—Mr. FRANK S. KIDD, F.R.C.S., read a very interesting paper entitled "The diagnosis of a case of pyuria."

Annual Representative Meeting.—The meeting considered the report of Council, and gave instructions to the Representative with regard to it and as to the questions raised by the Future Developments Committee. (SUPPLEMENT, June 13th, p. 433.)

Special Fund.—The Secretary was instructed to take a postal vote of all practitioners resident in the area of the Division with regard to the proposed Special Fund.

NORTHAMPTONSHIRE DIVISION.

THE annual meeting of the Northamptonshire Division was held in the Board Room of the Northampton General Hospital, on July 2nd, when Dr. COOKE was in the chair, and eight other members were present.

Annual Report of Division.—The SECRETARY submitted the annual report, which showed that the membership of the Division on December 31st, 1912, was 120, and on December 31st, 1913, 126. No grants were received from head quarters, but there was still a balance in hand of £4 18s. 2d. There had been four Divisional meetings during the year, which were all concerned in carrying on the routine work of the Association.

Election of Officers.—The following officers were elected:

Chairman: Dr. W. H. Bull.
Vice-Chairman: Mr. N. B. Odgers.
Honorary Secretary and Treasurer: Dr. Hichens.
Representative for Representative Meetings: Dr. L. W. Dryland.
Deputy Representative: Dr. J. P. Roughton.
Representatives on Branch Council: Drs. Arthur, Greenfield, and Robson.
Executive Committee: Drs. Cropley, Linnell, Tolputt, Relton, and C. Powell.
Representatives on South Northants Nursing Association: Drs. Darley and Hope.

Expenses of Representative.—On the motion of Dr. BAXTER, seconded by Dr. LINNELL, it was agreed that the Representative of the Division should be paid a guinea a day for expenses when at the Annual and Special Representative Meetings, if the money could be legally granted.

County Nursing Committee.—A discussion took place on the proposed County Nursing Committee, and it was decided to state that the Association wished to be officially represented on the County Nursing Committee, and that the model nursing rules should be adopted.

Annual Representative Meeting.—The agenda for the Annual Representative Meeting were generally discussed, and the matters concerned were left to the discretion of the Representative.

SOUTH WALES AND MONMOUTHSHIRE BRANCH:

NORTH GLAMORGAN AND BRECKNOCK DIVISION.

THE annual meeting of the North Glamorgan and Brecknock Division was held at Pontypridd on June 18th.

Election of Officers.—The following officers and committees were elected:

Chairman: Dr. H. Davies-Jones.
Vice-Chairman: Dr. J. Morgan Rees.
Secretaries: Drs. C. J. Weichert and Dr. A. T. Jones.
Representative at Representative Meeting: Dr. W. E. Thomas.
Deputy Representative: Dr. D. N. Morgan.
Representatives on Branch Council: Drs. H. Davies-Jones, B. M. Lewis, C. Biddle, D. N. Morgan, J. Morgan Rees.
Executive and Ethical Committee: The members were re-elected.

SOUTH-WESTERN BRANCH:

EXETER DIVISION.

A MEETING of the Exeter Division was held at the Royal Devon and Exeter Hospital on July 3rd, when Mr. A. C. ROPER was in the chair, and ten members were present.

A reply was read from the Medical Secretary to the following questions:

(1) Further instructions with regard to the Treatment of Tuberculous Persons not Insured under the National Insurance Act.—Members were referred to the Model Scheme, Appendix VII, in the SUPPLEMENT, May 2nd, 1914, pars. 10 and 17. This scheme received very careful consideration at the hands of a thoroughly representative subcommittee, and they came to the conclusion that the scale of minimum fees laid down would cover both insured and uninsured, and provision is therefore made for mileage. (2) The policy of the Association as regards the question of the salary, superannuation, and security of tenure of Whole-time Assistant School Medical Officers.—Members were referred to Appendix V, par. 6, of the Public Health Section of the Annual Report of Council, page 289 in the SUPPLEMENT, May 2nd, 1914.

Annual Representative Meeting.—The annual report of Council (SUPPLEMENT, May 2nd, 1914) was considered and instructions given to the Representative.

Appendix V. The meeting took exception to pars. 17 and 18, because they considered them impracticable. The idea of local clinics or treatment centres was generally approved of by the meeting; but, until these were formed, it was not understood how the staffs of hospitals could forego the usual treatment.

The meeting considered that par. 5 (p. 281) of the memorandum on treatment at voluntary hospitals of school children found defective on medical inspection should be strongly pressed.

The meeting considered it very desirable that every effort should be made to prevent medical certificates given in bona fide being used as a weapon of offence against medical men. Strong disapproval was expressed of medical aid institutions, or anything which would promote them.

It was decided to support any means of preventing insured persons making their own arrangements with unqualified persons.

The meeting considered that the question of the attendance, on the receipt of a relieving officer's order, of a Poor Law medical officer upon persons in charge of police was a matter of great importance and should be strongly supported.

The questions sent by the Medical Secretary on the instruction of the Future Developments of Insurance Acts Committee (SUPPLEMENT, June 13th, 1914) were answered.

Special Fund.—It was decided to take a postal vote on the proposed "Special Fund" (pars. 156–7, SUPPLEMENT, May 2nd, 1914).

WEST CORNWALL DIVISION.

THE annual meeting of the Division was held at the Royal Cornwall Infirmary, Truro, on June 30th:

The following officers were elected for the ensuing year:

Chairman: Dr. A. Shaw (St. Austell).
Vice-Chairman: Dr. C. Branwell (Penzance).
Honorary Secretary and Treasurer: Dr. L. L. Phillips (Redruth).
Representative on Representative Body: Dr. M. Taylor (Helston).
Deputy Representative: Dr. F. Chown (Hayle).
Representatives on the Branch Council: The Chairman, the Vice-Chairman, the Honorary Secretary, and Dr. Chown.
Executive and Ethical Committee: Drs. M. Taylor (Helston), A. Permewan (Redruth), A. Shaw (St. Austell), L. Phillips (Redruth), A. Goldie (Par), R. Nesbitt (St. Just), W. Wilson (Penzance), F. Chown (Hayle), F. Hichens (Redruth), H. Sutton (Truro), W. Whitworth (St. Agnes), H. Sharp (Truro), J. Haughton (Falmouth), W. Gilchrist (St. Austell).

Budget Proposals.—The questions on the 1914–15 Budget proposals with regard to future developments of Insurance Acts were fully discussed and answered.

Medical Referees.—A report was submitted on the result of the appeal not to accept less than 10s. 6d., etc., for acting as referee under the Insurance Act. The SECRETARY reported that over 100 notices had been sent out, and 81 replies had been received. One replied in the negative because he thought the fee should be 21s.; one replied in the negative because he was a whole time medical officer of health; four replied deliberately in the negative; one replied in the affirmative, but has since written to withdraw his reply because he finds other men accepting less. The failure of those who had not replied, and the action of those who had deliberately replied in the negative, were

the subject of criticisms. Eventually the matter was referred to the next meeting to consider what steps should be taken.

School Medical Officers.—A letter was read from the Secretary of the School Medical Service Group of the Society of Medical Officers of Health, and the Representative was instructed to support their resolution at the Representative Meeting.

Annual Representative Meeting.—The agenda for the Representative Meeting was considered and the Representative instructed thereon. The Division was specially in favour of supporting the riders by Plymouth and Altrincham *re* the formation of a special fund and the National Medical Guild, and the following resolutions were carried unanimously:

That this meeting of the West Cornwall Division strongly supports the rider of the Altrincham Division and instructs its Representative to vote in favour of this rider.

That the following be added to the agenda of the Representative Meeting: That it be an instruction to the Council that they take the necessary steps to effect such alterations in the by-laws of the Association as will secure that members of the National Medical Guild be admitted to membership of the British Medical Association at an annual subscription of one guinea.

SURREY BRANCH:

KINGSTON DIVISION.

A MEETING of the Kingston Division was held at Surbiton Cottage Hospital on June 30th, when Dr. A. E. EVANS was in the chair, and eleven others were present.

Insurance Acts.—The schedule of questions (SUPPLEMENT, June 13th, p. 436) were discussed and the decisions recorded were unanimous.

I.—Provisions for Institutional Treatment.—(*a*) No. But at present London makes up our deficiencies. (*b*) No. (*c*) No. (*d*) Yes.

II.—Excessive Claims for Sickness Benefit.—(*a*) Yes. No excessive increase noted in this area. (*b*) The present system does tend to encourage patients to consult doctor unnecessarily. No check should be put on the patient's right but he should be encouraged to consult the doctor early.

III.—Proposed New Services. (1) Control.—(*a*) Yes. (*b*) The Division agrees with the proposal to set up new joint committee as in paragraph (18). (*c*) Not at present. (2) Laboratories. (*a*) Not at present. (*b*) Yes.

Nursing—(*a*) No. (*b*) In area of this Division nursing appears satisfactorily carried on by charitable agencies. Opinion of meeting is that this should continue.

Referee Consultants.—Yes.

Treatment Centres.—The Division does not approve of the establishment of treatment centres.

YORKSHIRE BRANCH:

HALIFAX DIVISION.

THE annual meeting of the Halifax Division was held at the Mikado Café on June 30th, when Dr. DRURY was in the chair, and twenty-four other members were present.

Annual Report of Division.—The annual report and balance sheet of the Division for the year 1913 was read, and, on the motion of Dr. PRIESTLEY LEECH, seconded by Dr. MARSHALL, was adopted.

Election of Officers.—The following were elected officers of the Division for next year:

Chairman: Dr. P. V. Fry.
Vice-Chairman: Dr. E. W. S. Hughes.
Representative for Representative Meeting: Dr. A. Drury.
Representatives on Branch Council: Dr. Priestley Leech.
Honorary Secretary: Dr. W. B. Wishart.
Executive Committee: Drs. T. W. Arnison, J. F. Hodgson, G. G. Lawson, J. Marshall, Armitage Morton, J. Sproull, Gardner Oakley, Branson.

Organization.—Dr. FRY then took the chair, and after returning thanks for the honour conferred on him, urged in a brief speech the importance of organization. Dr. DRURY, the retiring Chairman, then addressed the meeting on the urgent necessity for organization and unity in the profession. He pointed out that the existing organization—the British Medical Association—had done immense work for the profession, the benefits and advantages of which were available for all. The recent struggle had not resulted in such total failure as some still appeared to think. The victory on adequate remuneration, free choice of doctor, and freedom from friendly society control had been won by the unceasing efforts of the Association. It was only by means of organization and unity that the profession could resist the attempts being made, or likely to be made, to deprive medical men of the advantages gained in the long and fierce struggle. Dr. Drury urged men who were members to stick to the Association. He appealed to those who had recently left the Association (not many locally) to come back, and to those who had never joined he made an impressive appeal to become members. Many of the attacks made upon the Council were, he said, altogether unwarranted, and were made in ignorance of the functions of the Council. The policy of the Association was dictated peripherally and not centrally. This meant that each member had a voice and a vote in controlling the policy. For this reason men should make themselves familiar with all matters brought up for discussion and decision, and should attend the Division meetings, where their views would receive consideration. It too frequently happened that men neglected this and reserved their criticisms until after matters had been decided. Attempts to split the Association should be resolutely resisted. No organization could better serve the needs of the profession. Associations formed for special purposes might exist side by side. Those already existing found the British Medical Association with its wide sphere and influence essential for pressing forward their work. After all the greatest danger to the profession arose not from without so much as from dissensions and lack of unity within. At the recent conference with the Insurance Commissioners it had been pointed out that the profession had deliberately chosen the "panel" system, and that it was "up against" the profession to justify that choice by making the panel system as efficient and successful as possible. There was the possibility of a whole-time State Medical Service if the panel system did not prove satisfactory, but he did not think it was likely to be instituted under any other circumstances. An interesting discussion followed, and a number of questions were asked. Dr. LEECH urged members to stick to the panel system and the Association, as he believed they would be much worse off under a whole-time State Medical Service. Votes of thanks were passed to Dr. Drury for his address and for the able way in which he had occupied the chair during the past year.

Unqualified Dentists.—A member asked if a medical man might give anaesthetics for a qualified dentist, the latter being present at the operation, but the actual extraction being done by an unqualified assistant. After some discussion the Secretary was instructed to place the matter before the Ethical Committee.

Association Notices.

Special Representative Meeting, Aberdeen.

On the requisition of the Council, notice is hereby given under Article 31 and By-laws 36 and 73, that a Special Representative Meeting of the Association will be held on Monday, July 27th, 1914, at 12 noon, at the Marischal College, Aberdeen, for the purpose of considering the following Report and Recommendation of Council (paragraphs 211 and 212 of Supplementary Report of Council, 1913–14), and, if considered advisable, amending By-law 67 accordingly:

SCOTTISH COMMITTEE.

211. The work of the Scottish Committee is growing, and it is found increasingly difficult for the Chairman to be able to attend all the Committee meetings in Scotland and Council and Committees in London as well. The Committee consequently desires to be able to elect a Deputy Chairman as well as Chairman. By-law 67 provides that each Standing Committee shall appoint from its own number a member of Council as Chairman, in order that the Council may be able to keep in touch with each Committee. The Scottish Committee wishes to be an exception to this By-law and to be able to have a Chairman not necessarily a member of Council, but that effective co-ordination shall be maintained by insisting that one of its three officers—Chairman, Deputy Chairman, or Honorary Secretary—shall be on the Council. As the Scottish members desire the change as early as possible, the Council has arranged that a special session of the Representative Body shall be held at Aberdeen on Monday, July 27th, 1914, at 12 noon, for the purpose (only one month's notice of such an alteration of By-laws being required in the case of a Special Representative Meeting).

212. The Council recommends:

RECOMMENDATION GG.—That the Special Representative Meeting, Aberdeen, amend existing By-law 67 of the Association, which reads as follows:

67. Each Standing Committee shall appoint from its own number a Member of Council as Chairman,

to read as follows:

67. Each Standing Committee except the Scottish Committee shall appoint from its own number a Member of Council as Chairman. The Scottish Committee shall appoint from its own number a Deputy Chairman, as well as a Chairman, and either the Chairman or the Deputy Chairman or the Honorary Secretary of that Committee shall be appointed from amongst members of Council.

T. JENNER VERRALL,
Chairman of Representative Meetings.

June 24th, 1914.

ELECTION OF MEMBERS OF COUNCIL BY GROUPED REPRESENTATIVES.

NOTICE is hereby given that Nominations for Candidates for election of Members of Council by grouped Representatives for the year 1914–15 will be received by the Medical Secretary up to the end of the first hour of the proceedings of the Annual Representative Meeting on Friday, July 24th, 1914. Each Nomination must be on the prescribed form, copies of which will be forwarded by the Medical Secretary on application.

Separate forms have been prepared: (I) For Nomination by a Division (through its Representative), and (II) for Nomination by a Representative of a Constituency included in the Group, and those applying are requested to state for which purpose the form is desired.

The voting papers will be issued at the Representative Meeting to each Representative or Deputy Representative of a Constituency in the United Kingdom in attendance at the Meeting.

By order of the Council,
ALFRED COX,
Medical Secretary.

June 24th, 1914.

CHANGES OF BOUNDARIES.

NORTHANTS AND WARWICK AND LEAMINGTON DIVISIONS. THE following change has been made in accordance with the Articles and By-laws of the Association, and takes effect as from the date of publication of this notice:

That Rugby and district be transferred from the area of the Northants Division of the South Midland Branch to that of the Warwick and Leamington Division of the Birmingham Branch, the areas of these Divisions and Branches being modified accordingly.

Representation in Representative Body.—Unaffected.

SUGGESTED CHANGES OF BOUNDARIES.

PROPOSAL FOR REORGANIZATION OF AREA OF NORTH OF ENGLAND BRANCH.

Notice is hereby given under Article 13 and By-law 73 to all concerned of a proposal made by the North of England Branch Council that for the existing scheme of Divisions of that Branch there be substituted Divisions as follows:

(1) *In Northumberland.*

1. *North Northumberland:*—Berwick-upon-Tweed M.B., Berwick-upon-Tweed R.D., Norham and Islandshires R.D., Glendale R.D., Belford R.D., Rothbury U. and R.D.s, Alnwick U. and R.D.s, Amble U.D., Morpeth M.B., Morpeth R.D., Ashington U.D., Bedlingtonshire U.D., Newbiggin-by-the-Sea U.D.

2. *Hexham:*—Bellingham R.D., Haltwhistle R.D., Hexham U. and R.D.s.

3. *East Northumberland:*—Castle Ward R.D., Newburn U.D., Gosforth U.D., Blyth U.D., Tynemouth R.D., Cramlington U.D., Weetslade U.D., Seghill U.D., Earsdon U.D., Whitley and Monkseaton U.D., Wallsend M.B., Willington Quay U.D.

4. *Newcastle-upon-Tyne:*—Newcastle-upon-Tyne C.B.

5. *Tynemouth:*—Tynemouth C.B.

(2) *In Durham.*

6. *South Tyne:*—Gateshead C.B., Felling U.D., Hebburn U.D., Jarrow C.B., South Shields C.B., South Shields R.D. (except Harton and Whitburn C.P.'s).

7. *North Durham:*—Ryton U.D., Blaydon U.D., Whickham U.D., Tanfield U.D., Annfield Plain U.D., Stanley U.D., Crag Head C.P. and Greencroft in Lanchester R.D., Chester-le-Street U.D., Chester-le-Street R.D. (except Usworth, Washington, Plawsworth, and Witton Gilbert C.P.s).

8. *Sunderland:*—Harton and Whitburn C.P.s in South Shields R.D., Sunderland C.B., Sunderland R.D., Usworth and Washington C.P.s in Chester-le-Street R.D., Houghton-le-Spring R. and U.D.s, Hetton U.D., Easington R.D. and Seaham Harbour.

9. *Mid Durham:*—Benfieldside U.D., Consett U.D., Leadgate U.D., Lanchester R.D. (except Crag Head C.P. and Greencroft), Plawsworth and Witton Gilbert C.P.s in Chester-le-Street R.D., Durham M.B., Durham R.D., Tow Law U.D., Crook U.D., Brandon and Byshottles U.D., Willington U.D., Spennymoor U.D., Bishop Auckland U.D., Shildon and East Thickley U.D., Auckland R.D., Sedgefield R.D.

10. *Stockton:*—Hartlepool R.D., West Hartlepool C.B., Hartlepool M.B., Stockton M.B., Stockton R.D.

11. *Darlington:*—Weardale R.D. and Stanhope U.D., Barnard Castle U. and R.D.s, Darlington M.B., Darlington R.D.

(3) *In the Yorkshire Portion of the Branch.*

12. *Cleveland:*—To consist of the existing Cleveland Division, with in addition the Yorkshire portion of the existing Darlington Division.

Written notice of the above proposal has been given to the Divisions concerned, and the matter will be determined in due course by or on behalf of the Council of the Association. Any member affected by the proposed change and objecting thereto is requested to notify the fact, with his or her reason therefor, to the Medical Secretary, 429, Strand, London, W.C., by August 11th.

BRANCH AND DIVISION MEETINGS TO BE HELD.

BIRMINGHAM BRANCH: COVENTRY DIVISION.—Drs. L. E. Price and D. Davidson, Honorary Secretaries, give notice that a constituency meeting of the Nuneaton and Tamworth and Coventry Divisions will be held at the Coventry Hospital on Friday, July 17th, at 4.15 p.m., to instruct the Representative.

MIDLAND BRANCH: HOLLAND DIVISION.—Dr. R. Tuxford, Honorary Secretary, 12, Wide Bargate, Boston, gives notice that a meeting of the Holland and Kesteven Divisions will be held at the "Carre Arms" Hotel, Sleaford, on Sunday, July 19th, at 3 p.m. Business: To instruct the joint Representative to annual meeting.

NORTH WALES BRANCH.—Dr. H. Jones Roberts, Honorary Secretary (Llywenarth, Penygroes, S.O.), gives notice that the sixty-fifth annual meeting of the Branch will be held at the Glanrafon Hotel, Benllech, Anglesey, on Tuesday, July 14th, at 2.45 p.m. Luncheon at 2 p.m. Tickets, 3s. Agenda: To introduce the President-elect. To receive the report of the Branch Council. To elect President for 1915–16. To elect Honorary Secretary. To report election of members on the Branch Council. To elect a Representative on the Welsh Committee. To select places for the meetings in 1915. To present a motor car to Dr. Emyr Owen Price, in recognition of his services to the Branch and profession in North Wales. Subsequently the President will deliver his address, and the following papers will be read: Dr. A. Norman Leeming: Some Fractures treated by Lane's Plates and Screws, with Photographs before and after. Dr. H. Drinkwater: The Longevity of Eminent Medical Men. Dr. J. Murray Bligh: Infant Feeding. Dr. John Elliott: (*a*) Specimens from a Case of Lymphatic Leukaemia; (*b*) Case of Chronic Pneumonia treated with Pneumococcus Vaccine. Benllech is the terminus of Holland Arms—Red Wharf Bay and Benllech Railway, and is about fifteen minutes' walk from the Glanrafon Hotel. Lord Boston having kindly permitted the members attending the meeting to view the Roman remains at Llugwy, all who wish to avail themselves of the opportunity will please notify Dr. J. R. Prytherch, Llangefni, before Monday, July 13th. Conveyances will leave Benllech at 4.30 p.m.

SOUTH WALES AND MONMOUTHSHIRE BRANCH: SOUTH-WEST WALES DIVISION.—Dr. D. R. Price, Honorary Secretary, Ammanford, Carmarthen, gives notice that the annual meeting of the Division will be held at the Ivy Bush Hotel, Carmarthen, on Tuesday, July 14th, at 3 p.m.

MEMBERS ELECTED TO THE BRITISH MEDICAL ASSOCIATION

(January 9th, 1914, to June 26th, 1914).

BY THE COUNCIL.

Beaman, Winifrid Kelsey, Captain R.A.M.C., M.R.C.S., L.R.C.P.Lond.
Burnett, Maurice, Lieut. R.A.M.C., M.R.C.S., L.R.C.P.Lond.
Calvert, Edward, Lieut. I.M.S., B.A., M.B.
Gibson, Arthur William, Major R.A.M.C., L.R.C.P. and S.Edin.
Heffernan, Francis Joseph Christopher, Major R.A.M.C., F.R.C.S.I.
Hughes, Algernon Fitz-Roy, M.B., B.Ch.Edin., Soufriere, St. Lucia, B.W. Indies
Nolan, Robert Howard, M.B., Ch.B.Edin., Northern Section, Surrey Camp, Eastern Railway, Kaduna, Northern Nigeria
Reboul, Adrien Ernest Emile, M.D., L.R.C.P. and S.Edin., Villa des Bluets, Chatêl-Guyon-les-Bains, Puy de Dôme, France.
Ritchie, Michael Balfour Hutchinson, Capt. R.A.M.C., M.B., B.Ch.Univ. Aberd.
Walsh, Patrick Joseph, Lieutenant I.M.S., M.B., B.Ch., B.A.O., R.U.I.
Williamson, Maurice Joseph, Capt. R.A.M.C., M.B., Ch.B.Aber.

BY BRANCH COUNCILS.

Aberdeen Branch.

Cran, James, M.B., University Club, Union Terrace, Aberdeen

Assam Branch.

Ferryman, R. C. P., Esq., Lahoal P.O., Assam
Boyd, William, M.B., Clevedon T.E., Kulaura P.O., A. B. Railway, South Sylhet
Cameron, A. D., Esq., North Lakhimpur, Assam

NATIONAL INSURANCE ACT.

The Second Annual Report of the Commissioners.

The second annual report[1] on the administration of National Insurance relates to the year ending June 30th, 1914. A volume of nearly 600 pages, its space is occupied by five separate reports—by the four National Commissions and the Joint Commission—a short introductory chapter, and some eighty appendices. There is no index, but as in the preceding volume, reference to any particular point is facilitated by the provision of an excellent table of contents. The report is for the most part merely a historical record of what each Commission has done during the twelve months to which the volume relates, and these actions, so far as they have been of specific medical interest, have been noted in our columns as they occurred.

Nevertheless it contains scattered passages not of this order. In the general introductory chapter, for instance, stress is laid on the fact that the most interesting part of the Commissioners' work up to the present has been the bringing of the resources arising under the scheme of National Insurance into co-operation and co-ordination with previously existing organizations dealing with the immense variety of questions and problems with which the National Insurance is concerned. Almost every type of social question is involved, directly or indirectly, in the administration, but those with which it is most closely connected are the public health and economic conditions. There is also a statement to the effect that the working of medical benefit has revealed the great loss which the country has suffered in the past through inability of large sections of the community to obtain adequate treatment. There has existed no organization for the mass of illnesses which require to be treated in the patient's home, and the institution of the panel service, apart from providing home treatment when suitable for practically the whole of the working population, seems to have laid "a foundation on which extended provision can suitably be based."

The experience gained under the Act is thought to confirm the theory that the provision of curative facilities is of little avail unless accompanied by financial provision to relieve the economic conditions of distress which otherwise would arise owing to the absence of the head of the family from work. Substantially, it has been proved that any attempt to divorce the two factors creates a vicious circle. Furthermore the Act, by providing free treatment and weekly cash payments during sickness, has, it is suggested, brought medical men into areas whose inhabitants were previously not in a position to seek medical advice, and has thus created a new demand for doctoring. It is also held to be clear that before the introduction of the Act expectant mothers worked up to the last possible moment in order to have money in hand to meet the expense of a confinement. In view of their receipt of maternity benefit and also of their being able, when working women, to receive ordinary sickness benefit if ill, expectant mothers are now in a position to seek and also to obey medical advice during pregnancy.

Elsewhere, in a discussion on the excessive claims made by women, it is suggested that part of the excess is due to the effects of pregnancy, and it is indicated that there will have to be some revision of the finance of the Act in respect of women; probably the contributions made by women are insufficient and there will have to be some alteration of the statutory apportionment of these contributions between the societies and the sinking fund. An equalization fund is also mentioned to which Parliament may be asked to contribute, to meet the needs of societies among whose members sickness is liable to be especially heavy; those composed, for instance, mainly of chemical workers. Another passage the tone of which, if nothing else, seems to justify its quotation in full is the following:

> As regards the certifying doctors on whom in great measure the societies are bound to rely, it is impossible to doubt that there has been, in many quarters, too little recognition of the high degree of confidence which Parliament reposed in the medical profession when it decided to withdraw the administration of medical benefit from the approved societies and thereby largely to place in the hands of the profession the well-being of the societies, whose expenditure on sickness benefit is no less dependent on sound certification than on efficient administrative supervision. There is no doubt that great improvement in certification is both necessary and practicable.

This passage occurs in a chapter signed by the chief actuary of the Joint Commission. He does not seem fully to appreciate the reasons which led Parliament to remove the administration of medical benefit from the friendly societies, and is no more entitled to say whether improved certification is practicable than would an average medical man be justified in laying down the law as to the applicability of the differential calculus to national insurance statistics. *Ne sutor ultra crepidam.*

Also worth quoting, but for different reasons, are eighteen paragraphs which appear in the report of the English Commissioners, under the title of "Medical Benefit—General Review." They are as follows:

> Medical Benefit.—General Review.
>
> 455. Many of the difficulties which beset the administration of medical benefit arise directly out of those features of freedom and elasticity which are most characteristic of the system established by the Legislature, and which constitute its peculiar value as reflecting, as regards the insured population on the one hand, the bent of the national temperament, and as regards the medical profession on the other (in accordance with their express desire), the conditions of private practice. In essentials, therefore, the present medical benefit scheme may be described as the embodiment in an administrative system of a nexus of private and voluntary relations between individuals; and the special problems presented are fundamentally concerned with the reconciliation of those apparently diverse propositions. The provision for many millions of insured persons, wherever they happen to be in Great Britain, of medical treatment by means of access to, and free selection from the ranks of a service in which all qualified medical practitioners and pharmacists are free to be enrolled requires a machine not only far-reaching and comprehensive, but elastic and adaptable, not only complex, by reason of the many intricate personal relations involved, but also swift in action and responsive to the sudden emergencies of disease.
>
> 456. From this point of view an examination of the system resolves itself into two parts, the one concerned with its effect upon the insured population, the other with its consequences as regards the medical profession and the service afforded by them.
>
> 457. As regards the insured population, a necessary consequence of the embodiment of these relations into a system is the establishment of a procedure. The requisite procedure must be adaptable to, and keep touch with, the multiplicity of conditions throughout which the insured person's access to benefit is to be preserved; it must necessarily be of the simplest; and it must, moreover, be operated, not by any external sanctions, but by the minimum degree of action by the insured person himself in his own immediate self-interest. These canons have been carefully observed, and so far as possible secured, in the actual construction of the administrative machinery; but the problem which necessarily arises with any system, however simple, is not only to convey to the insured population a sufficient knowledge of the steps necessary to be taken by them and of the facilities and advantages offered, but also to induce them to take those steps and to choose a doctor forthwith without waiting until they are ill. Difficulties naturally result, therefore, from ignorance of the nature of the provision afforded, and from ignorance and inertia with regard to the steps necessary to access.
>
> 458. These difficulties can doubtless be completely removed as, with increasing experience, the insured population becomes more completely educated as to the nature and details of the system. It was not to be expected that over ten million persons could in the course of a few months become conversant with even the outlines of the scheme, or that it would be possible to put them, individually, in possession of effective knowledge as to the appropriate steps to be taken in all circumstances. Nevertheless, so far as information is available, the progress which has been made is very striking. At the end of 1913, the first year of medical benefit, the number of insured persons returned as having chosen, and been placed on the lists of, panel doctors alone in England represented 96 per cent. of the total insured population (excluding that of Manchester and Salford, where this criterion does not apply). In all probability these lists contain some duplication in respect of insured persons who have, upon removal, chosen a doctor in the new area without being immediately removed from the list of the doctor in the area they have

[1] Report for 1913–14 on the Administration of National Health Insurance. London: His Majesty's Stationery Office. (Cd. 7496.) Price 2s. 5d.

left. On the other hand, the figures do not include the insured persons who have selected an approved institution or been allowed to make their own arrangements; and it may be taken that the figure of 96 per cent. substantially represents the fraction of the insured population who have taken steps to secure the advantages of the benefit. Again, in London, where the administration has been attended by exceptional difficulties, and a less successful result might have therefore been expected, the figure returned on the above basis, in respect of panel doctors' lists only, amounts to over 90 per cent. of the insured population.

459. It is not, therefore, the case that, as has been stated, any large proportion of the insured population is without access to benefit on the ground of objections to the nature of the service offered or owing to any inadequacy or failure of the administrative machinery. These statements are, it is believed, based upon the fact that the registers of most committees include a substantial number of insured persons who have not chosen a doctor in the area. But experience has shown that this section of the register includes the bulk of the inflation referred to above in paragraph 448; and the fallacy of the assumptions based upon these data is proved by the result of an investigation recently conducted in a district of the metropolitan area with the object of inducing insured persons in their own interests to exercise their right of selection.

460. This investigation, which dealt with about two thousand cases from the section of the register above referred to, taken at random and without any selection, disclosed the circumstances shown in the following table:

Sample Examination of Cases of Insured Persons shown on Register as NOT *having Chosen a Doctor.*

Grounds for Apparent Inaction.	Percentage.
1. Already on doctor's list, but not returned as such owing to misapprehension or clerical error...	31.2
2. Removed—	
(*a*) From the area	4.6
(*b*) From the United Kingdom	1.4
(*c*) Leaving no trace	27.6
3. Neglect	19.6
4. Ignorance of procedure	4.3
5. Ceased to be insurable	3.6
6. Dead	0.5
7. Joined army or navy	0.5
8. Preferred private doctor	3.8
9. Have paid privately for treatment	0.6
10. Miscellaneous grounds (for example, contemplate leaving United Kingdom, insurability in doubt, etc.)	2.3
	100

461. Thus the great majority, amounting to nearly 70 per cent. of the insured persons concerned, proved either to have removed from the area (being in all probability on the list of a doctor in another area), to have left the country, or otherwise ceased to be entitled to the benefit, or to be already on the list of a doctor in the area though not returned as such owing to some misapprehension or clerical error. Ignorance of procedure was responsible for the failure to choose a doctor in 4 per cent. only of the cases, while sheer neglect accounted for nearly 20 per cent.

462. Of the persons in Class 8 who stated that they had preferred a private doctor, some stated that they were giving up a private doctor and intended to choose a panel doctor. Some were accustomed to obtain treatment through an unrecognized medical club or institute, or possessed opportunities of obtaining treatment gratis, while of the others it may be inferred that they include some persons who, if and when they have occasion to require a doctor, may, notwithstanding, have recourse to the panel. Similarly the persons in Class 9 who had paid privately for treatment probably include some persons who had so paid in ignorance of their rights, and who will in future avail themselves of them. But even without the discount which must obviously be made from both classes on these considerations, the percentage of persons who, on account of ignorance, preference, or prejudice, deliberately refuse to avail themselves of their medical benefit is negligible, inasmuch as, without any allowances, and assuming the average found in the cases dealt with to be maintained in the rest of the persons represented by the section of the register referred to, the two classes in question only account for 0.27 per cent. and 1.7 per cent. respectively of the insured population of the area.

463. So far, therefore, as the insured population is concerned, there appears to be no reason for dissatisfaction with the present position or the progress which has already been made as regards the working of the system. Knowledge is rapidly spreading; and the introduction of the medical card system should, it is believed, effect a great advance by providing insured persons with an almost universally available means of access in nearly all circumstances which are likely to arise.

464. Turning now to the aspect of the system as it concerns the medical profession and the medical service, it is, similarly, in connexion with those features which preserve the conditions of private practice that difficulties have been encountered and are liable to arise. All qualified practitioners are entitled to be enrolled in the service, and insured persons are entitled to a free choice from among the practitioners so enrolled. As in ordinary course of private practice, the principles of open competition are mainly relied upon to secure for the competent man as large and remunerative a practice as he can successfully undertake, and to preclude his acquisition of a larger number of patients than he can properly attend. The principles of economic supply and demand are in the main relied upon to recruit the ranks of the service in any particular district or area (although it is, of course, the first duty of the Insurance Committee to secure a panel which is amply adequate for the service of the area), and to secure a local distribution of the available practitioners which will enable their services to be utilized with the least amount of waste and overlapping. Further, the relations between doctor and patient are still to a considerable degree the private relations of private practice, and remain so unless and until either party invokes the authority administering the benefit to do justice in the matter of a complaint or dispute.

465. Dealing first with the last mentioned point, there appears to be little doubt that the personal relations between panel practitioners and their panel patients are, generally speaking, entirely satisfactory. Complaints are comparatively rare in most districts; while reports from all parts bear witness to an increasing spirit of mutual understanding. As regards the standard and quality of the treatment given, this naturally varies, as it must inevitably do under a system which, reproducing the free elements of private practice, admits all qualified practitioners without selection. But, at the lowest estimate of the position, an enormous number of men and women are now receiving treatment for their ailments who previously were accustomed to go without; while, on the other hand, insured persons have been enjoying, at the hands of the more conscientious and competent doctors, a service of the standard of that accorded to remunerative patients of the well-to-do classes. Signs are not wanting, moreover, that definite tendencies are in operation, originating with the medical profession themselves and fostered by the responsible authorities, to raise the standard of the whole of the industrial practice of the country and to enhance the value of the insurance service.

466. As regards the nature and quality of the supply of medicines and appliances under the present system, there have been no grounds for dissatisfaction. Questions have been raised in a very few isolated instances as to the quality of the drugs furnished; but no cases have been reported which, upon investigation, have justified any allegations that the drugs supplied in connexion with the insurance service were of an inferior standard.

467. In the matter of certification, however, where under the present system the nexus of relations reaches its highest degree of complication as between doctor, patient, Insurance Committee, and approved society, it cannot be said that at present equally satisfactory results have been attained. In this province the medical benefit system replaced, not the conditions of private practice, but the pre-existing relations of contract practice between the club or lodge and their medical officer. These relations involved a close touch between the society and the doctor acting as custodian of the society's funds; and as the circumstances attending the early stages of medical benefit were such as to impair in some respects the nature of the understanding between societies and the medical profession, their mutual confidence has had to be restored. Administrative action is, however, being taken to overcome the difficulties which have arisen. Moreover, the spirit of co-operation, as already stated, is growing; and already, in some areas, the medical profession and the approved societies have of their own motion established a rapprochement with the happiest practical results.

468. The number of doctors on the panels in England (excluding duplicates within each area, but including doctors on more than one panel) amounts to over 16,000, while over 10,000 shops are available for the supply of medicines or appliances, or both, to insured persons. The

number of doctors has steadily increased, as will be seen from the following comparative figures:

Strength of panels on	January 15th, 1913	...	13,996
,, ,,	April 14th, 1913	...	15,659
,, ,,	October 13th, 1913	...	15,870
,, ,,	May 31st, 1914	...	16,059

The total increase in strength since the commencement of medical benefit is thus over 2,000.

469. As regards the sufficiency of the number of panel doctors available for the country as a whole, there can be no possible doubt. On the figures given above, and after an allowance is made for the elimination of duplicates, the average number of insured persons per panel doctor is only about 760, a number for which responsibility can, except under abnormal conditions, be accepted by a single doctor with the greatest ease. In proceeding to consider the actual distribution of insured persons among doctors, it must be remembered that this is likely to be governed by two factors, namely, the relative extent of the personal powers and opportunities of doctors of acquiring a practice, and their local distribution and relative availability.

470. As regards the first consideration, it is natural to expect that the forces of competition would result in the existence of lists above and below the average in size; and properly so, since it is right that competence and thoroughness in attendance should be recognized and rewarded by a large practice and corresponding remuneration. The early circumstances of medical benefit were, however, such as to disturb for the time being the operation of the competitive forces. In some districts doctors delayed coming on the panel at the outset, with the result that many selections were made before the panels were complete, and no opportunity subsequently arose for a change of doctor until the end of the year. Nevertheless, the actual position as it existed prior to the first opportunity for change was far from unsatisfactory. Taking the figures of 100 Insurance Committees of a representative character, it appeared that at the end of 1913 over 50 per cent. of the panel practitioners had 500 or less insured persons on their lists, 70 per cent. had 750 or less, 80 per cent. had 1,000 or less, 90 per cent. had 1,500 or less, while over 96 per cent. had no more than 2,000. While the number of insured persons for whom a panel practitioner can properly accept responsibility will, of course, vary with his personal competence and the extent of his private practice, lists of the size above mentioned could not, save in exceptional circumstances, be deemed excessive; and as regards the isolated instances in which doctors' lists greatly exceed these figures, it is generally the case that the practice is shared with a partner or assistant. There are doubtless cases, however, in which a redistribution of panel patients could be effected with advantage to the patients themselves and the standard of the service afforded. Reforms in this respect are taking place, and will continue to do so, as the insured population become aware, and avail themselves, of their opportunities of changing their doctors; and the whole question is attracting the careful attention of Insurance Committees and the medical profession locally.

471. In general it may be said that the commencement of medical benefit found a local distribution of practitioners reasonably adequate to the local distribution of the population and to the varying incidence of sickness. This was, of course, due to the fact that the principles of supply and demand had under the previous conditions of private practice resulted in a local distribution most suitable on economic grounds. In some districts, however, particularly in London, notwithstanding the existence of much sickness and disease, the poverty of the population offered no inducements to doctors to practise; and one of the first results of the commencement of medical benefit was to indicate these districts in which the paucity of resident practitioners proved only too clearly the grave conditions which had previously existed and the timeliness and value of the advantages which the medical benefit provisions of the Insurance Act afforded. It was surmised that the new economic position would attract practitioners to such districts; and this expectation, though it is as yet early to expect any complete adjustment, has not been falsified. In one of the London boroughs in which these serious conditions previously existed four new practitioners have started in panel practice, in another borough eight, and in another nine new practitioners have started in panel practice, while in a district comprising several small boroughs, where a marked shortage previously existed, at least five new practitioners have joined the panel, the total amounting to a net addition of twenty-six to the ranks to the medical profession in these districts in London alone.

472. A general review of medical benefit would not be complete without a reference to the manner in which Insurance Committees have discharged their functions. The constitution of Insurance Committees, containing, as they do, a majority of insured persons' representatives whose interests, as individuals, are identical with those of the insured population, and who, on behalf of their constituent approved societies, have the strongest motives for encouraging the suppression of sickness and disease, has fully justified the objects with which it was devised. Further, the presence on these Committees of representatives of doctors, chemists, nurses, and midwives has rendered them peculiarly suitable for undertaking the task of administration with expert knowledge and with full acquaintance and sympathy with local conditions, while the Council representation has enabled the Committee to profit by the experience of persons versed in public life, and has afforded a most valuable link between the Committee and the local authority. Insurance Committees have successfully discharged many onerous duties of administration and negotiation, and their enthusiasm and interest in the problems with which they have to deal is uncommon in the history of similar local bodies. In particular, it is worthy of record that although the provisions of Section 63 of the 1911 Act regarding excessive sickness are as yet not wholly available, at least one instance has come to notice in which, through the activity of the Insurance Committee and the general operation of the Insurance Act, attention has been drawn to the existence of grave insanitary conditions, and steps taken to put the public health law into operation.

Appendices.

The eighty-one appendices cover over a hundred pages, and chiefly consist of tables. From one of them it would appear that there are in Scotland 1,499,135 insured persons of all classes, and that in charge of them there are 1,790 doctors, of whom 571 are on two panels, and 20 on as many as four. We are unable to find precisely corresponding figures in regard to other countries. There is also a table entitled "Case Value Results," which is of some interest, as it is assumed to afford some indication of the varying degrees of sickness incidence as between area and area. The case value is obtained by dividing the panel fund of the Insurance Committee of the area by the number of cases treated by the doctors within it; the number 100 is taken as the average, and the extremes are 183.35 (Cambridgeshire) and 73.01 (in the county borough of Bristol). Another appendix which is of interest as throwing a sidelight on the working of the Act is a list of the various official documents issued in connexion with it. Apart from circulars to approved societies they number over 200.

LOCAL MEDICAL AND PANEL COMMITTEES.

LONDON.

Panel Committee.

Centres for the Co-operation of Practitioners.

Discussion was continued, at a meeting of the London Panel Committee on July 7th, on the statement in the Budget that grants would be provided for certain public health and insurance purposes, including the establishment of centres for the co-operation of practitioners on the panel. The Panel Service Subcommittee invited the Committee to express opinions contained in resolutions published in the Supplement, June 13th, p. 448.

Dr. J. A. Butler criticized the proposals on the ground that they would be the forerunners of a State medical service and would be unjust to doctors who had provided adequate waiting room and surgery accommodation. Neither did he think centres would be as convenient as surgeries to the patients.

Dr. T. F. Keenan considered that the general practitioner in many districts was badly served by the hospitals; the large hospitals should be converted into smaller local establishments, which could be distributed throughout London.

Other speakers doubted if the time was ripe to consider such far-reaching changes in methods of medical practice.

Dr. A. Welply reminded the meeting that centres of co-operation actually formed part of the Budget, and it was necessary that panel practitioners should influence the Government in the details of its proposals.

Dr. LAURISTON E. SHAW remarked that the Cabinet would be deciding almost immediately how the money would be spent, and if panel practitioners did not make a suggestion it would be left to those who were so fond of a State medical service to impress their views on the Government. He thought the resolutions propounded the best way of dealing with the question. The other suggestion was that the great hospitals should be given money to start outpost hospitals to which they would send clinical practitioners from whom panel practitioners would be able to get a second opinion. Panel practitioners would be very unwise if they allowed the holders of that view to get the first shot. Differences in the size of practitioners' lists and variations in local conditions should not be allowed to create disagreements which might prevent the money coming to panel practitioners as a whole.

Dr. G. B. BATTEN proposed, and Dr. R. J. FARMAN seconded, an amendment which would have had the effect of omitting all details, and would only express the Committee's approval of the principle of centres of co-operation.

Dr. J. J. ATTERIDGE thought the meeting must go into details. He feared that if the centres were restricted to industrial patients it might lead to the State sending salaried doctors to see industrial patients at centres instead of leaving the work to the panel practitioners.

After further discussion it was agreed that it might be unwise to include a chemist in the staff of the centres, and the clause to this effect was struck out, as was the clause limiting the centres to industrial patients. With these variations the resolutions were adopted as follows:

(i) That the proposed centres for the co-operation of practitioners on the panel should be established and should be sufficiently numerous.
(ii) That a centre should provide consulting-rooms for a number of practitioners and accommodation for a trained nurse, an *x*-ray operator, and a clerk.
(iii) That arrangements should be made for the occasional attendance of consultants.
(iv) That the centres should be under the joint control of the Insurance and Panel Committees.

Distribution of the Unallotted Funds.—The Committee passed resolutions describing the last reason given by the London Insurance Committee for not distributing the unallotted funds among practitioners on the panel as a frivolous one and appointing a deputation to interview the Insurance Commissioners and approach the Government on the question.

Proprietary Drugs and Preparations.—The Committee had before it instances of alleged excessive prescribing, and for the guidance of the Drugs and Appliances Subcommittee (which checks prescriptions) passed resolutions that proprietary medicines and secret remedies held out to the public for self-treatment, preparations in the nature of wholly-manufactured foods, and branded preparations where the formula was fully known, should not be prescribed at the cost of the drug fund.

BUCKINGHAMSHIRE.

A MEETING of the Bucks Local Medical and Panel Committee was held at the Royal Bucks Hospital on June 30th, when Dr. BAKER was in the chair, and ten other members were present.

Refractions.—The request that in cases when the panel doctor tested refraction cases he should previously inform the patient that there would be an extra fee, was ordered to be mentioned in a memorandum to practitioners.

Certificates.—The Committee considered a complaint by the agent of a society against a practitioner, alleging that he gave a certificate without seeing the patient, and that he had neglected the patient. The doctor attended, and stated that he was under the impression the patient would come to see him, and no request had been made to him for a visit; that he was in weekly communication with the mother, and she never asked him to visit, although he had told her to let him know if the patient was worse, and that it was for the convenience of the patient that he had signed the certificate. He, however, expressed his regret that he had done so, and said it would not occur again. The matter then closed.

Chemists' Subcommittee.—The report of the Chemists' Subcommittee was received. The resolution passed on February 27th last was rescinded, and a resolution adopted to the effect that the Panel Committee agreed to the chemists receiving £35 for their expenses out of the medical benefit fund.

New Member.—At a meeting at Slough to elect a member in the place of Dr. Charsley there was a very poor attendance, but Dr. Fraser consented to act.

Expenses of Committee.—It was resolved that a levy of ¼d. per person on the list be made for the next quarter.

Honorarium to Honorary Secretary.—It was resolved that an honorarium of fifty guineas be presented to the Secretary out of the funds of the Committee.

Payments to Panel Practitioners.—A letter was read from the Secretary of the Insurance Committee, enclosing one from the Commissioners, stating that only 90 per cent. was to be paid on account in future instead of 95 per cent. It was resolved:

That this Committee agrees to only 90 per cent. being paid, but they do so under protest, as they consider that a deduction of 5 per cent. will be ample in this county.

Memorandum to Practitioners.—The Secretary was instructed to issue a memorandum, after approval by the Chairman, to all on the panel, giving instructions in several matters that had come before them.

GLOUCESTERSHIRE.

PANEL COMMITTEE.

A MEETING of the County Panel Committee was held at the Royal Infirmary, Gloucester, on June 19th, when Dr. CAMPBELL was in the chair, and fourteen others were present.

Solvency of Insurance Committee.—A letter was read from the Commissioners, dated June 3rd, in answer to Dr. Campbell's letter as to the solvency of Gloucestershire Insurance Committee.

Allocation of Insured Persons.—The meeting agreed to certain modifications in arrangements for the allocation of unassigned persons as accepted by the Chairman. On the motion of Dr. BELL, seconded by Dr. COX, it was resolved:

That unless the money owing to the doctors was paid within one month the arrangements for allocation of unassigned persons be withdrawn.

Secretarial Duties.—Dr. CAMPBELL communicated new points regarding the Secretary's duties to the Panel Committee and the collection of the voluntary fund.

Medical Certification.—Dr. CAMPBELL gave an account of the meeting in London on June 16th, between the Commissioners and Chairmen and Secretaries of Panel Committees *re* Medical Certification for Sickness Benefit.

Prescribing for Tuberculous Patients.—The attention of the Committee was drawn to the prescribing of doctors on wrong forms for tuberculosis patients. It was suggested that a copy of the letter supplied by the Insurance Committee should be sent to all panel doctors.

Agreement for 1915.—On the motion of Dr. PERROTT, seconded by Dr. BELL, it was resolved:

That the agreement for 1915 should be issued at least three months before the end of the year, for comment.

INSURANCE NOTES.

LONDON INSURANCE COMMITTEE.

THE London County Council is entitled to appoint 19 out of the 80 members of the London Insurance Committee, and 3 of its nominees must be medical practitioners. The Council has selected the following as its medical representatives for the year 1914–15: Sir John Collie, M.D., Sir Shirley Murphy, and Dr. R. M. Beaton.

FEES TO MEDICAL REFEREES.

The question of the fee to be paid to a medical referee called in to give an opinion in the case of any insured person continues to give rise to difficulties in various areas, and it is a matter for great regret that a uniform fee has not been established throughout the country. The Special Representative Meeting in December last was of opinion that the fee should not be less than 10s. 6d., but for various reasons in certain areas smaller fees, of 7s. 6d. or even 5s., have been accepted. It seems, however, clear that where such fees are accepted the practitioners in the area should only accept these lower fees when acting as referees in the area in which they have been recognized; should practitioners in such area

be called on to report on a case in some adjoining area they should take care to conform to the practice in the other area; should they fail to do so by accepting a lower fee they are not only acting in opposition to the interests of their neighbours but, in fact, contrary to the wishes of the profession in that area.

Protest Meeting of London Panel Practitioners.

A meeting convened by a number of London panel practitioners was held at the Caxton Hall, London, on July 2nd, to protest against the action of the London Insurance Committee in respect of the distribution of the funds accumulated in respect of insured persons who have not chosen a doctor. Dr. W. Coode Adams presided. No invitation to attend the meeting was received by the British Medical Journal, but we are informed that about 500 practitioners were present. According to a report published in the *Morning Post*, this meeting was held in connexion with a Panel Practitioners' Political Union recently formed in London.

The Chairman read a letter from Dr. C. Addison, M.P., containing the following observations:

I do not wonder at the panel men's protest at the action of the London Insurance Committee. They are thoroughly justified in doing so. I think it would be wise that you should be received not only by the Chancellor of the Exchequer, but by Mr. Masterman as well.

The Chairman expressed the apprehension that the question of the distribution of the unallotted funds would give rise to difficulties every year unless it was taken out of the hands of the Insurance Committee—a body which acted from mixed motives—and put under the control of the Government or the Commissioners.

Dr. J. A. Angus described the matter of the unallotted funds as a disgraceful chapter in the early history of Insurance Act administration in London. He urged practitioners to use their influence at the next London County Council election against those members of the Insurance Committee who were also members of the County Council, and who had been parties to the disgraceful treatment of panel practitioners.

Dr. H. J. Cardale remarked that although the Commissioners admitted the doctors' claims they were making very little effort to see that the money was paid. The Government should be approached, because panel practitioners made their first bargain with the Government, and could prefer their demands, not as a favour, but as a right.

Dr. B. A. Richmond declared that the unallotted money could only be the property of the doctors in the insurance service.

Dr. Lauriston E. Shaw urged that the action taken should be unanimous. Panel practitioners should beware of strife between doctors with large and small lists in the distribution of the money.

The meeting passed, with one dissentient, a resolution expressing the opinion that the action of the London Insurance Committee was a direct violation of all the pledges given by the Government, the Commissioners and the Insurance Committee; and that such conduct had discredited all these bodies. The meeting called upon the Government to redeem immediately its pledges, and demanded that the Chancellor of the Exchequer should receive a deputation.

The following deputation was appointed: Drs. W. Coode Adams, J. A. Angus, H. J. Cardale, R. J. Farman, B. A. Richmond and A. Welply.

We have received the following letter with reference to this meeting:

Sir,—If the Botha-like way in which the Caxton Hall meeting of last week was conducted is a sample of the methods of the new organization which promoted it, it augurs ill for its future. For a chairman not named in the notices calling the meeting, and not elected by it, to announce that he is not going to allow amendments to the resolution he and his friends have drafted is as alien to the true spirit of trade unionism, which was invoked, as anything one can imagine.

That my amendment, previously communicated to him, which embodied everything of moment in the resolution, but suggested arbitration as the most practical solution of the difficulties of money allocation, was, after a show of fair play, despotically ruled "out of order," was the plainest proof that the men who are contending for a *pro rata* distribution have no confidence in the justice of their own claims.

Far the greater number of the men on the London panel are men with small lists. Why they should allow themselves to be led blindfold by the big-list men, who, while pretending to speak for the whole body, openly announce their intention, if they can procure such a division of the "surplus," of pocketing the greater part of it themselves, passes my comprehension! Such a division means actual ruin to many a small-list man. Dr. Angus was allowed to speak in favour of a *pro rata* division, I was instantly forbidden even to allude to its unfairness! So "Fair play and no favour" is not to be the motto of the new organization.

We small-list men have our contract rights if we will but be wise enough to stick to them. For 1913 the right of proceeding against the London Insurance Committee for breach of contract expires on the 11th inst. by the provisions of the Public Authorities Protection Act of 1893. I have, therefore, after patiently waiting to the last moment for the London Insurance Committee to do justice, commenced legal proceedings, which I shall certainly not drop unless some proposal as equitable as the one my amendment suggested is accepted by the Government and carried into speedy execution.

The Commissioners, it appears, are now stultifying their own consents to other schemes by laying it down, on "legal advice," that nothing but a *pro rata* distribution is allowable under the regulations. The proposition that one clause in a set of regulations can be intended, and made, to govern a state of things wholly created by the violation of previous clauses of the same regulations is the "tallest" substitute for a legal argument that I have yet met with. Besides this, the subsections relied on refer to a doctor's "list," which has, to comply with the regulations, to be made after assignment and to include assigned persons. No legal doctor's "list" therefore exists in London, which again prevents the application of these clauses to the existing facts. If any attempt is made to apply these clauses to the distribution of the surplus, it can be easily stopped by an appeal to the courts for an injunction, which I should at once make. Nothing but fresh legislation, or submitting the whole question to arbitration, can solve the problem.—I am, etc.,

11, St. Mary's Terrace, Paddington Green, W., July 6th. H. Bazett.

ENFIELD.

Meeting of Practitioners.

A meeting of the medical practitioners in the Enfield district was held on July 6th, under the chairmanship of Dr. Howard Distin.

Great indignation was expressed at the state of chaos evidently existing in the department of the Middlesex Insurance Committee dealing with the card registers. The following resolutions were passed unanimously and ordered to be sent to the Insurance Commissioners:

(*a*) That this meeting of medical practitioners on the Enfield panel protests against the unnecessarily elaborate scheme of election to the Panel Committee, and especially against the expense placed upon the funds of the Panel Committee caused by holding these elections annually.

(*b*) This meeting further records its opinion that the action of the Commissioners in practically ignoring all representations made to them by the Panel Committee, and even joint representations from the County Insurance Committee and the Panel Committee, is calculated to deter practitioners from serving on these Committees and wasting their time on futile deliberations.

IRELAND.

The Annual Report of the Commissioners.

The official report on the second year's working of the Insurance Act, issued last week, though it passes briefly and lightly over the certification muddle in Ireland, yet, when carefully examined, is found to contain some very disquieting news. The number of societies actually wound up in Ireland is only five, but that this number is not considerably greater is due to the rigid application of the rule, "solvency first and benefits afterwards." It is held to be indisputable that a large number of the other Irish societies only keep out of bankruptcy by not paying benefits that they ought to pay. The report states that the majority of county councils and county borough councils in Ireland have in preparation at present schemes for the treatment of tuberculosis, but it is to be regretted that the schemes generally are not in a more forward stage of preparation. With regard to the operation of

sickness and maternity benefits, the report states that the difficulty of obtaining medical certificates was met to a certain extent by the setting up of panels of certifying doctors in some of the Insurance Committee areas and by the appointment of medical advisers in the remaining areas. In the latter areas, however, the medical advisers furnish certificates only in cases referred to them by the societies, and do not furnish primary certificates. Societies in many cases continue, pending the setting up of a more efficient system, to accept, in cases where a medical certificate is not readily obtainable, a report from a sick visitor, extracts from reports of medical relief visitors, and written statements of clergymen, magistrates, or other responsible persons, and avail themselves of the services of the medical advisers only in doubtful cases.

INSURANCE ACT IN PARLIAMENT.

Insured Persons (Ireland).

In reply to Mr. Gretton, Mr. Benn said that the latest available figures showed that there were 729,598 insured persons in Ireland, of whom 717,798 were members of approved societies.

Lectures.

Mr. W. Benn informed Mr. Astor that lectures had been provided under Section 60 (1) (*b*) of the National Insurance Act by one committee in England (Leicestershire) and four in Scotland.

Departmental Committee on Excessive Sickness.

In reply to Mr. C. Bathurst, Mr. Benn stated that the Departmental Committee on Excessive Sickness had held sixty meetings, and that no meeting had been held since the evidence was concluded.

Sanatorium Benefit (Dependants).

Mr. W. Benn has informed Mr. Astor that the following Insurance Committees have applied, under Section 17 of the National Insurance Act, 1911, for contributions from the local authorities and the Exchequer towards the expenditure on sanatorium benefit where the benefit has been extended to dependants:

Scotland.—Counties: Ayr, Fife, Haddington, Lanark, Renfrew. Burghs: Arbroath, Clydebank, Coatbridge, Dunfermline, Inverness, Kilmarnock, Kirkcaldy, Rutherglen, Wishaw.

Ireland.—Meath.

In *Wales* the procedure has been modified by the provisions of Section 42 of the National Insurance Act, 1913. All Welsh Insurance Committees had extended the benefit to dependants, and grants from the Exchequer, equivalent in amount to corresponding contributions from the rates, had been made in respect of all areas except Pembrokeshire. In England the method of procedure under the Hobhouse grant had been adopted in the place of procedure under Section 17 of the National Insurance Act, 1911.

Medical Necessities.

Lord Ninian Crichton-Stuart asked whether it was proposed to make any additions to the list of medical necessities in the Second Schedule to Part 1 of the National Insurance Act, in view of specific diseases or accidents obtaining in certain industries.—Mr. W. Benn said that the question of any addition to the schedule of prescribed medical and surgical appliances, to which presumably the question referred, would be considered in connexion with the revision of the Regulations.

CORRESPONDENCE.

Statistics of a Country Practice.

Dr. Geoffrey Price (Kineton, Warwick) writes: In my small country practice I obtained the following statistics, which may be useful at the present time:

	No. on List.	Total A. and V.	A. and V. per head.	Cash Received.	Payment per A. or V.
				£ s. d.	s. d.
State-insured patients (year ending Dec. 31st, 1913)	223	1,053	4.72	69 3 4	1 4
Provident medical club patients (year ending June 30th, 1914)	158	1,457	9.2	30 2 2	nearly 5d

If and when the Insurance Committee squares up its accounts, the payment per attendances and visits will reach to about 1s. 9d. I provide drugs to two-fifths of the insured.

The provident medical club is under strict rules; it is limited to families earning £1 a week or less, and the membership consists mainly of old people, women, and children.

The subscriptions (collected by local secretaries) are as follows:

	Per Annum.
Males over 16	... 9s.
Females over 16	... 7s.
One child under 14	... 4s.
Two children under 14	... 8s.
Three children or more under 14 ...	... 9s.
Children 14 to 16 (each)	... 5s.
Old age pensioners	... 5s.

I provide all drugs.

A large proportion of members are those who are always ill or who possess big families.

If the Insurance Act were extended to dependants of insured persons, no doubt a larger proportion of robust persons would be included in comparison with the membership of the provident medical club. An income limit of £160 would admit three-fourths of the uninsured population of this part of the country (for here every employed person is *ipso facto* insured). At any rate, I should be mainly dependent for my living on insured or dependants of insured.

Many of my visits are two or three miles away. Fivepence a visit and medicine does not pay by any means; 1s. 9d. a visit and medicine will just pay here, but in large towns, where the cost of living—for example, rent and rates especially and wages for servants—is almost double, 1s. 9d. a visit by no means pays. But in order to reach this low standard it seems clear to me that nothing less than *18s. a head* must be asked for dependants (including medicine), because on an average each requires to be visited twice as often as does an insured person.

If the income limit were reduced to £52, then 9s. a head for dependants might be accepted for the sake of sweet charity.

Vital Statistics.

THE REGISTRAR-GENERAL'S ANNUAL REPORT.

The Seventy-fifth Annual Report of the Registrar-General, dealing fully with the vital statistics of England and Wales for the year 1912, has just been issued. The present report is the second of the new series, and continues to tabulate the statistics in the improved form initiated in the report for the preceding year. The adoption of administrative areas instead of registration areas as the units of tabulation, of a classification of causes of death on the lines of the International List of Causes of Death, and of a system of distribution of births and deaths of non-residents in the several areas, which were the essential innovations in the report for 1911, appear to have met with general approval, and have been repeated in the report for 1912. Such improvements as it has been found possible to make in these reports do not involve any addition to the data hitherto collected, nor any change in the method of collection. Alterations in these respects, desirable as they are for both statistical and administrative reasons, would necessitate a revision of the system of registration, which could only be effected by legislation. Some new tables have been introduced into the present report, and the secondary classification of causes of death, which was begun in the 1911 report for the first nineteen causes in the International List, is carried on for the causes numbered 20 to 38 in the List. This section comprises both tuberculosis and syphilis, and in regard to the forms and complications of these important diseases much information has now been tabulated for the first time. Other special features of this volume which may be noticed are (*a*) the tabulation of the births registered in 1911 according to the parents' occupation and (*b*) the table showing for each administrative area the population adjusted for institutions and the calculated annual deaths from which the standardization factor is derived. The statistics of

occupational fertility, as tabulated in the report, confirm the conclusions of students who have investigated the subject by the aid of less complete data to the effect that fertility varies greatly with social status, being with few exceptions lowest for professional and other middle class occupations and highest, as a rule, for those representing unskilled labour. It is not possible here to pursue the subject in detail, and reference must now be made to the principal statistical facts of the year.

Marriages.

The marriages registered during 1912 numbered 283,834, and were equal to a rate of 15.5 persons married per 1,000 of the population at all ages, which was slightly above the average rate for the preceding ten years. During the seventy-five years (1838–1912) covering the period of civil registration of marriages the rate has ranged from a maximum of 17.9 in 1853 to a minimum of 14.2 in 1886, the mean annual rate for the whole period being 15.8 per 1,000. Marriage-rates are, however, more accurately calculated on the basis of the marriageable section of the population, and in comparing rates over a number of years account has also to be taken of variations in the age constitution of this section of the population. Calculated in this way, there appears to have been a fall of about 23 per cent. in the marriage-rate since the period 1870–72. The mean age at marriage continues to advance both for men and for women, and in 1912 was 29.12 and 26.84 years respectively. There has been a concurrent decrease in the proportion of marriages of minors, which fell from 77.8 per 1,000 and 217.0 per 1,000 for husbands and wives respectively in 1876–80 to 39.2 and 139.4 per 1,000 in 1912.

Births.

There were 872,737 births registered during 1912, of which 835,209 were legitimate and 37,528 were illegitimate. The birth-rate in proportion to the total population of both sexes and of all ages was 23.8 per 1,000; it was 0.6 per 1,000 less than that recorded in 1911, and was no less than 3.4 per 1,000 below the average of the rates for the ten years 1901–10. The birth-rate was at its maximum in this country during the period 1876–80; since that date it has fallen almost uninterruptedly, and in 1912 was only 67.4 per cent. of what it was in 1876–80. This comparison is made on the crude rate, calculated on the total population; and when the rates are based on the female population between the ages of 15 and 45 years the fall is even more marked, the fertility as shown by the births in 1912 being only 62.4 per cent. of that in 1876–80; for legitimate births the ratio was 64.7 per cent., and for illegitimate only 54.9 per cent. As was pointed out in the previous report, the crude birth-rate is higher in Wales than in England, and that a broad division of the latter into North (counties north of the Humber), Midlands, and South (counties south of the Thames), gives the highest rate in the north and the lowest rate in the south. Again, by aggregating the county boroughs, the other urban districts, and the rural districts respectively, it is shown that the crude rate is highest in the boroughs and lowest in the rural districts. When, however, allowance is made for the differences in the constitution of the several populations, the rural districts show a greater fertility than either of the two classes of urban areas, and the county boroughs are shown to have a distinct advantage over the smaller urban districts. Carrying the process further and ascertaining the "effective fertility" by calculating the survivors at the end of the first, second, and fifth years of life, it is found that, while the rural districts maintain their superiority, the county boroughs fall below the smaller urban districts; London, which is dealt with separately, comes highest as regards its actual fertility, and ranks next to the rural districts in its effective fertility.

Deaths.

The deaths registered in England and Wales during 1912 numbered 486,939, of which 250,232 were among males and 236,707 among females. These deaths corresponded to a rate of 13.3 per 1,000 of the population, or 0.2 per 1,000 below the rate for 1910, which was the lowest recorded up to that time. During the period 1901–1912 the standardized death-rate, calculated on the age-constitution of the population in 1901, has fallen from 16.9 per 1,000 in that year to 12.9 per 1,000 in 1912, and in eight of these twelve years the rate has been successively the lowest on record. A similar fall in the mortality is also observed as a rule in other countries for which statistics are given in the report. Comparing the mortality of the two sexes it is found that male mortality at all ages is 21 per cent. greater than that of females (after making allowance for the less favourable age-constitution of the female section of the population), and that there is some excess in each quinquennial period of age except 10 to 15 years. The predominant causes of the excess of mortality among males were infantile diseases, violence, pneumonia, and phthisis. The rate of infantile mortality during 1912 was the lowest on record, the deaths of children under 1 year of age being equal to 95 per 1,000 of the registered births, which was 10 per 1,000 below the previous lowest on record (1910), and 22 per 1,000 below the average for 1906–10.

Causes of Death.

The principal causes or groups of causes contributing to the total deaths are shown in the report to be diseases of the nervous system, which caused 111 per 1,000 of the total deaths, organic heart disease 98, bronchitis 82, phthisis 78, pneumonia 77, cancer 77, old age 67, premature birth and diseases of early infancy 65, and violence 41 per 1,000. The death-rate in 1912 was lower than in 1911 from tuberculosis, from enteric fever, from diphtheria and croup, and from diarrhoeal diseases. The mortality from measles was above the average for the preceding ten years, but from scarlet fever the mortality was lower than in any previous year except 1911. The death-rate from cancer was again higher than in any preceding year.

The inquiries sent to medical practitioners asking for further information respecting deaths which had been indefinitely certified were fewer than in 1911. The total number of such inquiries was 9,912, to which 8,305 replies were received, against 12,563 inquiries and 10,718 replies in 1911. Of the 8,305 replies relating to deaths in 1912, 6,064 contained information amplifying that previously given in the certificates; 940 of such replies related to cancer, 430 to syncope, heart failure, 352 to tuberculosis, 264 to violence, 249 to peritonitis, 247 to cerebral tumour, and 235 to other tumours.
