INDEX TO VOLUME II FOR 1914.

READERS in search of a particular subject will find it useful to bear in mind that the references are in several cases distributed under two or more separate but nearly synonymous headings—such, for instance, as Brain and Cerebral; Heart and Cardiac; Liver and Hepatic; Renal and Kidney; Cancer and Epithelioma, Malignant Disease, New Growth, Sarcoma, etc.; Child and Infant; Bronchocele, Goitre, and Thyroid; Diabetes, Glycosuria and Sugar; Light, Roentgen, Radium, *X* Rays; Status Lymphaticus and Thymus; Eye, Ophthalmia and Vision; Bicycle and Cycle; Motor and Automobile; Association, Institution, and Society; Paris, France; Berlin, Prussia, Germany; Vienna, Austria, etc. Subjects dealt with under the various main headings in the JOURNAL have been set out in alphabetical order under their respective headings—for example, "Correspondence," "Leading Articles," "Literary Notes," "Memoranda," "Reviews," etc.; while under "Original Articles," will be found a list of those who have contributed papers on scientific and clinical subjects, with the titles of their contributions.

An Address

ON

THE BRITISH MEDICAL ASSOCIATION IN AUSTRALASIA.

DELIVERED BEFORE THE WEST SOMERSET BRANCH OF THE BRITISH MEDICAL ASSOCIATION.

BY

J. A. MACDONALD, M.D., LL.D.,

PRESIDENT OF THE COUNCIL OF THE BRITISH MEDICAL ASSOCIATION.

As you have done me the honour to ask me to address you on the visit I made recently to Australasia at the request of the Council of the British Medical Association, I will do my best to give a cursory account of a tour which I can assure you has done me good, mentally as well as physically. It has done me good mentally because it has broadened my view of things. I am only sorry that more members at home do not go out and see their brethren in the Colonies. Those who made the journey would find that their medical brethren at the far side of the world are men it is well worth while to keep within the Association. They are an honour to any profession. They are quite as good in their professional practice as at home, and possibly some are better in some respects. They have more initiative, and more independence of thought and work. That, to some extent, arises from the fact that the individual practitioner is commonly more isolated. He has not at hand another man every time he feels some doubt and wants a second opinion. They have to act on their own initiative.

I started from London on December 19th last, and I may sum up the sea trip in a few words. With the exception of one day, curiously enough in the Mediterranean in the Gulf of Lyons, I had not a rough day at sea from the time I left till I got back, so that the whole of the time at sea was a pleasure. There were some interesting people on board the boat, including Sir Newton Moore, the Agent-General for West Australia, with whom I had many informing conversations, from which I learnt a great deal about Australia. On the way out the boat called at Gibraltar, Naples, Port Said, and Colombo. The bay of Naples is the most beautiful scene I have ever looked on, and I have now seen many famous bays, including Auckland and Sydney. Colombo, where we spent only a short time, is a beautiful place. At Fremantle, the first port touched in Australia, I had a lovely sail up the river to Perth; the temperature was 104° F. in the shade, but it was not disagreeable, for the climate is very dry. Perth is a very beautiful place, with fine roads and one of the nicest parks I saw, consisting in part of the natural bush. Here I met Mr. Scaddon, the Premier of Australia, a very interesting man and a typical instance of how a man may rise to an important position in Australia, for a few years ago he was driving an engine on the Coolgardie goldfields. In the course of conversation Mr. Scaddon mentioned that a new railway was being developed from Fremantle to Adelaide, which will open up some wheat country and a good deal of grazing land for cattle and sheep. I did not meet any of the medical men there because no arrangements could be made owing to the shortness of my stay. On the voyage round to Adelaide, some time before we were due to arrive, I was told, before I had left my cabin in the morning, that certain gentlemen wanted to see me. When I got on deck I found that three of the medical men and three reporters had taken the trouble to charter a boat and come out some considerable distance—twenty-five to thirty miles—to meet me. This struck me as very energetic, and I took it as a very great compliment. Adelaide is the most beautifully laid out city I have ever seen. It is arranged on the American plan of square blocks, and the streets are very wide, with trees on each side. The only drawback is that the city is very subject to sand-storms or dust-storms. When I got there the temperature was 103° in the shade, and this, combined with a dust-storm, detracted from the pleasure of my short visit. I had only an afternoon in Adelaide, but I met Dr. Poulton, President of the South Australian Branch, and some other members of the Association, and visited the hospitals and found them most up to date and thoroughly well equipped; they were, in fact, quite equal to the best we have at home, and the same may be said of practically every hospital I visited in Australia and New Zealand. I lunched with the members of the Branch Council in Adelaide, and had a pleasant chat on medical things in general.

The next place touched at was Melbourne, which I reached on a Wednesday. I had intended to go on to Sydney on the Friday, and to New Zealand on the following day; but at Melbourne I learnt that there was to be a meeting at Sydney on the Monday of the Federal Committee of the British Medical Association in Australia. This Federal Committee represents all the provinces of Australia, and I decided to attend its meeting in Sydney, as its members were anxious I should. I was very much delighted to have the opportunity of staying in Melbourne a few days longer, for it is beautifully situated and a very fine city. It has some 700,000 inhabitants, and the neighbourhood is very interesting and pleasant. I met several friends I knew at home, and cannot say anything too good of the hospitality shown to me and of all that was done for me. We had a very fine meeting of the medical profession, which I was asked to address. The profession in Australia is very interested in the British Insurance Act, for there is a proposal to introduce similar legislation in Australia. If I may judge from what was said, my address was of use; very many questions regarding the position of medical men in reference to the Insurance Act in England were asked and answered by me. At the end of the meeting a vote of thanks to me was proposed: I had been looking at a man in the room I thought I knew, and after the vote had been proposed and seconded, this gentleman rose to support it on the ground that he had known me longer than anyone else there, and he proceeded to tell a story. He said that I had been a master at the school he attended, and that I had then already earned a reputation for promptness of action and quickness of decision. He had been misbehaving himself in the class; he was standing on a desk, and would not come down when told to do so. The next thing that happened was, he said, that I caught him by the scruff of the neck and slung him out of the room. I had forgotten the incident, but it was quite true. As an example of the energy with which men do things in Australia I may relate how a member resident at Geelong, forty miles from Melbourne, when he learnt at the dinner

at which I was entertained that I was staying a few days longer than I had intended, went down to Geelong that night and gave notice to the men in the district; next day he returned to Melbourne and took me down to a luncheon at Geelong at which every medical man in the district was present. He drove me back again in the afternoon and then went back to Geelong that night. For a part of the way there was no road at all, and we were driving across open fields. I had a very pleasant time at Melbourne, where I was most hospitably entertained, and I should like in particular to acknowledge Sir Harry Allen's kindness in conducting me over the university.

The train journey from Melbourne to Sydney was an interesting progress, for the doctors had been informed beforehand of my visit, and at every station some turned up to have a chat. At Albury, on the border between New South Wales and Victoria, where a change had to be made into another train—for a very inconvenient arrangement exists in Australia, the railways being of different gauges in the various provinces—there was a meeting of medical men, and we had a chat about the Insurance Act—as usual. Many different points of view were advanced by various men, and I learnt much from their remarks. I should say that before I left Melbourne I had an interesting interview with the Minister of the Interior, an Irishman and a very able man. I was asked to meet him and the chief statistician of the Government on the question of the British Insurance Act, in view of the proposal to introduce an Insurance Act into Australia. The interview lasted three hours, the British Insurance Act, its weaknesses and advantages, were discussed, and I got an idea of the form of the bill to be proposed in Australia. I expressed a very strong opinion that one thing that had caused great difficulty with regard to the Act in England was the fact that the medical profession had not been consulted before it was drafted; I have heard since that the Federal Committee of Australia has received a promise from the Government that if a bill be introduced for Australia the British Medical Association would be consulted before it is drafted. After leaving Albury, while in another station, there was an explosion, and the whole carriage seemed to be in a blaze. It turned out that a gas pipe below the carriage had exploded. The train was shifted along the platform and the incident seemed over, but some fifty miles further on we found the carriage actually on fire. In running the air had fanned a charred piece of woodwork into a blaze. The train was stopped and the fire put out, but we had a rather disturbed night, for a gentleman in the sleeping car would insist on getting up every quarter of an hour to see if the car was safe. We got to Sydney at 6 in the morning. We found that a deputation had arranged to meet the train at 10 a.m., having forgotten that the Monday morning train arrived four or five hours earlier than on other days of the week.

I saw very little of Sydney at this visit, for I spent my two days there at the meeting of the Federal Committee, and I was very glad to do so, because I think my visit was fortunately timed. The Committee was discussing the possibility of the institution of State insurance. The position is interesting. The club work of medical men in Australia is far more extensive than in this country, but they are in a better position to command reasonable terms owing to the fact that they are more united, as about 94 per cent. of the medical men in active work in Australia are members of the British Medical Association. There were, of course, disagreements in regard to details, as in this country, but the medical profession in Australia has the wisdom to realize that small disagreements do not matter much. They all move together to win their main principles and form no new bodies as is being done at home. I dined with the Federal Committee and with the Branch of the Association before starting for New Zealand.

We had a splendid journey to Auckland. The boat was carrying about eighty medical men and women to the Congress, and we had many discussions, some of them all the more interesting because they were individual. I rather got at loggerheads with the women members of the profession on board. We had been discussing the question of women doctors, and, in reply to a question as to the position of women in the profession in this country, I hazarded the suggestion that women were not physically well fitted for the medical profession. Next day I was surrounded by five or six medical women, who tackled me on this point. Among them was a lady—a young woman who looked like a girl. She lived in a corner of New South Wales on the border of Queensland, and the nearest doctor to her was 150 miles away. She managed the whole of the medical work of the district herself, riding a bicycle, or a horse, or a camel to reach her patients, some of whom were sixty or seventy miles away. When she operated she had to give the anaesthetic herself, and, while operating, to get some common-sense individual to keep dripping the anaesthetic on the towel. On the boat from Sydney to Hong Kong on my way home I came across a family from the district who knew her; they said that she was absolutely adored by everybody. So I found that my opinion on the matter of female practitioners could not be sustained. Many women are employed in the Government service in Australia, especially in the inspection of school children.

I arrived at Auckland on Sunday evening, and during my stay there was the guest of Dr. and Mrs. H. Carrick Robertson, who were kindness itself, and made me feel quite at home. The Congress was opened on Monday by Lord Liverpool, the Governor of New Zealand, and was conducted on the same lines as our meetings here. After Dr. Purchas, the President, had delivered his address to the Congress in the evening, I had the honour of proposing a vote of thanks to the Governor, Lord Liverpool.

During the week I was present at various meetings of the sections, which were very well attended. While not presuming to judge of the value of the papers, I was much struck by the keenness of the discussions which followed. Many men took part in them, and the criticisms struck me as being very trenchant, showing great originality of thought and independence of judgement. This I concluded was due to the fact that the men were bound to be more dependent on their own judgement than we are at home.

The Congress at Auckland was one of the medical profession of Australasia; but at the last meeting a resolution was passed that the next Congress would be one of the British Medical Association in Australasia, though, of course, not confined to its members. It will be held at Brisbane in the autumn of 1916.

There were the usual social functions at Auckland; one very interesting one was the dedication of a new park, a part of the native bush some distance out of town, and a very lovely spot. The members were entertained by the Mayor of Auckland, Mr. Parr, who, I see, has received the honour of knighthood from the King.

The dinner was a great success; there was a very large attendance and some brilliant speaking. Among the speeches was a very important and statesmanlike utterance by Mr. Holman, the Premier of New South Wales. I responded to the toast of "The British Medical Association."

I was called on to address a general meeting of the profession on Monday afternoon on the subject of the Insurance Act. The audience showed an extraordinary interest in the subject, and after my address I had quite a lively half-hour or so answering many pertinent questions, which tested fully my knowledge of the Act. I think my address was probably of some use, as the profession in New Zealand is not so well organized as in Australia. However, they are going the right way about correcting this, as they are now employing paid organizers, and I have no doubt will soon be equal to Australia in their organization.

After the congress week we went to Rotorua in a special train provided by the Government. The party was in charge of Dr. Valentine, Principal M.O.H., New Zealand. We reached our destination in the evening, and the Resident Medical Superintendent asked me to visit the Baths at Rotorua about a mile and a half from where I was staying at Whakarewarewa. We found that arrangements had been made not only for inspecting the baths, but also for a display of the Maori dances—the Haka, danced by the men, and the Poi, the love dance, by the women.

The Thermal District is one any one who goes to New Zealand should certainly visit. Titiriki (Hell's Gate) is the name of a part of it. It is a terrible place; there is a little path, our guide got his stick down a crevice—

we were then in the middle of boiling mud—and were told that a portion had fallen in a day or two before. The Maoris in this district do not think of making a fire for cooking purposes. They dig a hole in the ground and cook their food in the natural boiling water which runs quite close under the surface of the ground. While looking out of the breakfast-room window at the Geyser Hotel I was rewarded by seeing the remarkable phenomenon of a geyser spring up within 150 yards of the window to the height of approximately 150 ft. After spending four days in the Thermal District I started with Dr. Sydney Jamieson, of Sydney, for Wellington, in the south of the Northern Island. At Tamaranui we embarked for the trip down the river Wanganui through a gorge with cliffs rising from 500 to 700 feet in height. They rose sheer like the wall of a house, and were clothed all the way up with ferns, tree ferns, and pines. The trip itself was rather exciting, because part of the time the steamer, which was specially constructed with a flat bottom made of steel, was travelling over rocks at the bottom of the river. It was a stream of rapids with intervening shelves. The journey took two days. We stayed the night at Pipiriki, a small place in the bush, where there is a beautiful hotel, quite up to date, and lit by electricity. We started next morning at 4.30 down the next part of the river, which is not so interesting, and arrived at Wanganui, where I took a day's rest with a friend. I got to Wellington on Saturday and sailed that night for the South Island to visit Christchurch. We had a very good meeting of the Christchurch Division, though it was summoned at short notice, and Dr. Jamieson and I addressed those present on contract practice and the Insurance Act.

In every place I went to see the hospitals, which are admirably arranged, fully up to date, and quite in keeping with anything we have here. Every hospital is subsidized by the Government to the extent of 24s. to the pound. I had a very pleasant time at Wellington on my return; I dined with the medical men at the Wellington Club, and there was a good meeting afterwards, which was addressed by Dr. Jamieson and myself. I stayed three days in Wellington, which were spent in visiting the hospitals and some of the interesting places around, and then went to Sydney, where I took matters easy, visiting the interesting places in the neighbourhood, in particular the beautiful harbour. I also went to Manly beach, where I enjoyed the surf bathing. I started for Hong Kong in the North German Lloyd liner *Prinz Sigismund*. I had extraordinarily good luck here; I had met the German Consul-General of the Pacific in New Zealand. When I met him again in Sydney and told him I was going by the North German Lloyd steamer he wrote and telegraphed to the captain of the ships and to the officials of the places I was going to call at, so that wherever I went somebody came to meet me, and things were made very pleasant for me. I should like here to acknowledge the courtesy that was shown to me by the various German officials, and particularly the Governor at Rabaul.

I was unfortunate at Brisbane. The steamer was due at 11 a.m., and the medical men had arranged to meet me at lunch; but we did not arrive until 5.30 p.m. Dr. Butler told me that about eighty men had come into the town to meet me, some from distances up to 100 miles; a certain number, however, had waited, and I had dinner with them, and spent a very pleasant few hours.

My journey from Brisbane to Hong Kong took me by German New Guinea and various islands in the Pacific which are now under German sway—for example, New Britain, the Caroline and Pillar Islands; I also visited the Philippine Islands, and spent a Sunday in Manila.

Hong Kong is a beautiful place, and at the season I visited it has a fine climate. I had intended staying only two days there, but owing to the late arrival of the steamer I missed the connexion and stayed a week. I was very glad this happened, as it is a most interesting place, and the people very gay and hospitable. I stayed with Dr. Sanders at the Matilda Hospital, and he and Mrs. Sanders saw that I had a very good time. I was made a member of the Hong Kong Club, which is a distinctly cheery place. I dined with the Governor, Sir P. May, and with the principal medical officer of the Navy Department, I attended the final of a senior tennis tournament and the final of a football cup competition among the soldiers stationed at Hong Kong. I played golf over two courses, and altogether enjoyed myself. But my whole time was not given up to frivolity. I attended a meeting of the members of the Hong Kong Branch, and they entertained me to dinner. We had a most interesting meeting, as, though the Insurance Act does not affect them, there were many other points to be discussed.

A new university has been established for the training of Chinese medical men, and the curriculum, I understand, will be recognized by the General Medical Council for registration. I was shown over the university, and had lunch with the Principal. I visited some of the hospitals; the most interesting was the Tungwa, which is for Chinese patients, and there I saw some plague patients. This hospital is divided into two parts; in one the treatment is on the old Chinese lines, in the other on modern lines by Chinese doctors trained in Europe or America. The patients are given the choice of which they will have. The plague was fairly prevalent while I was in Hong Kong, and the doctor at the Tungwa told me that the mortality was about 98 per cent.

I paid a visit to Canton, which I understand is a typically Chinese city. It is filthy, and the population teeming, yet in spite of the filth they seem healthy and happy. The most interesting thing about Canton is the life on the river, where I believe about a million people live in the sampans and junks; they are a people apart, living their whole lives on the river. After leaving Hong Kong I called at Shanghai, but my visit there was of the shortest.

I landed in Japan at Moji, sailed through the famous Inland Sea, visited Kyoto, Nyanoshita, Tokyo, Nikko, and Yokohama. I was not very much impressed with Japan, but there are some charming places and Fujiyama is very beautiful. Nikko I was lucky enough to see when the cherry blossom was in full bloom. We had a very uninteresting run across the Pacific from Yokohama to Vancouver; it is a very lonely sea; we only saw one ship during the ten days. We had the curious experience of a week with an extra day in it to make up for the time gained in travelling east. The days were arranged, Sunday, Monday, Tuesday, meridian day, Wednesday, Thursday, Friday, and Saturday. The run through Canada was very interesting to me, but has been so often described that I need say nothing about it. I visited the hospital in Toronto, which is the newest and most thoroughly equipped I visited. I returned from New York in the *Adriatic* and landed in England on May 21st, and found England the most beautiful place I had seen.

The question may be asked whether this journey has been of any use; judging from expressions used to me I have no doubt that the visit has done good. The members in Australasia are an honour to any association, and it is the duty of the Council of the Association to bind them closer to us. They are a well organized body, and I think at the present time there is not a symptom of anything like breaking away, but with a well organized body, so self-contained as the British Medical Association in Australasia, there is always that danger, and it is the duty of the Association at home to do what it can to hold them to us. They ought to be accorded the fullest measure of autonomy consistent with the Memorandum of the Association, as the conditions of life and practice are so different from ours. An occasional visit of some member of the Council would, as one prominent member of the Association in Australia said to me, do a great deal to hold the Association together. If I may express the opinion, I think that my visit was perfectly justified. Personally I have to thank the Council for giving me the opportunity of enjoying five months' good time; the colonial men want me to go out again. I may say this much: I would not adviso any man to undertake the journey under the same conditions as I did unless he is physically strong.

In conclusion, I regret that I had not arranged to take a longer time, as I was compelled to refrain from visiting several places, such as Dunedin and other Divisions in New Zealand and Tasmania, and several places in Australia, such as Ballarat. However, I hope the members of the Association in these places will understand that it was not the desire to visit them which was wanting, but the time in which to do it.

THREE CASES OF FRACTURE IN THE NEIGHBOURHOOD OF JOINTS TREATED BY PLATING.*

[WITH SPECIAL PLATE.]

BY G. H. COLT, M.B., F.R.C.S.,

ASSISTANT SURGEON TO THE ROYAL INFIRMARY, ABERDEEN, AND ASSISTANT TO THE PROFESSOR OF SURGERY, UNIVERSITY OF ABERDEEN.

THE three cases which form the subject of this paper will be related in some detail, because they serve to illustrate certain controversial points both as regards the treatment of fractures in the neighbourhood of joints and the employment of internal splintage in cases of compound fracture.

CASE I.

The first case is that of a domestic servant (J. D., aged 18), who was admitted to the Royal Infirmary on July 29th, 1913, and dismissed on September 3rd following. I am indebted to Professor Marnoch, under whose care she was, for permission to publish the case. On July 29th the patient fell off her bicycle on to her right elbow and sustained a severe compound fracture near the elbow-joint. The broken end of the shaft of the humerus pierced the skin on the posterior surface of the arm. The wound was ragged, about three-quarters of an inch long, and there was a smaller wound of the "burst" type. There was a considerable amount of swelling near the joint. The bone was replaced and the wound dressed with cyanide gauze. An internal angular splint was applied until the swelling should have subsided. The *x*-ray plates taken the day after the accident (Figs. 1 and 2) showed that there was a T-shaped fracture of the humerus with the upright part extending into the elbow-joint. The lower fragments had been displaced upwards and forwards. The amount of shortening was an inch and three-quarters. The patient's temperature remained normal, the swelling subsided, and the wounds healed.

DESCRIPTION OF SPECIAL PLATE.

Fig. 1.—Case I: One day after accident.

Fig. 2.—Case I: One day after accident.

Fig. 3.—Case I: Three days after operation.

Fig. 4.—Case I: Three days after operation.

Fig. 5.—Case I: Fourteen weeks after operation.

Fig. 6.—Case II: Eighteen months after operation.

On August 9th, eleven days after the accident, an attempt was made to reduce the fracture under a general anaesthetic, but no diminution of the shortening could be produced. The site of the fracture was therefore exposed through the middle line of the triceps, the scars of the wounds being enclosed in the skin incision, which was 4½ in. long. It was necessary on two occasions to feel with a finger in the wound for the lower fragments. These could not be seen, as they had been forced well into the brachialis anticus muscle, which intervened between the three parts of the broken bone. By means of a Lane's bone-holding forceps applied during partial flexion of the forearm, combined with its forcible extension downwards, the lower fragments were with great difficulty brought out of the wound. They were seen to have been largely denuded of periosteum on their posterior surfaces. The triangular plate seen in Fig. 4 was secured to them. It will be remembered that the lower end of the humerus has a peculiar shape, the bone being much curved, and that whereas the condylar portions are relatively thick, the bone which separates the olecranon fossa from the coronoid fossa is very thin. The plate used is the only plate readily procurable which meets the needs of this particular case. To have fixed the plate to the lower end of the humerus first, and later to the fragments, would have been difficult, if not impossible. In the first place, because the lower fragments could not be maintained in the correct position and close up to the plate with a sufficient degree of firmness to allow of the screws being properly inserted, and secondly, because it would have been difficult to ascertain the correct position of the upper part of the plate on the shaft of the bone so as to make sure that the screw holes in the lower parts would be situated over the thicker portions of the fragments. While the lower fragments were being fixed, the shaft of the humerus projected backwards beyond the upper part of the plate. After their fixation the lower end of the shaft was brought in front and placed in the angle formed by the plate and the fragments, and then backward extension was made until the plate was in apposition with the back portion of the lower end of the shaft, thus bringing all three pieces of bone into correct alignment. The strain on the screws in the lower fragments during this manœuvre was considerable, but there seemed to be no other way of obtaining correct alignment. The upper screw was placed in position, and then the middle screw, which it will be seen passed through both the shaft and the lower and outer fragment. The periosteum was intact over the posterior portion of the shaft, and the plate was placed over it. The triceps aponeurosis was sutured with catgut and the skin closed with silkworm gut. An external angular splint was applied and the arm bound to the chest. The operation took two hours to perform.

Gentle passive movement of the elbow-joint was commenced on the third day and continued every other day without producing pain. The wound healed by first intention. The *x*-ray photographs taken on August 12th and 13th (Figs. 3 and 4) show the position of the fragments in antero-posterior and lateral views. It will be seen in Fig. 3 that there is a small piece of bone left free in front of the humerus, possibly it is in the brachialis anticus muscle. Gentle massage and passive movements with occasional active movements were continued until the patient left the infirmary, three and a half weeks after operation. At this time the biceps and triceps were acting well, the movements of flexion and extension at the elbow-joints were well performed, but were stiff, especially in complete extension. Pronation and supination were perfect. The circumference of the arm at the site of the transverse portion of the fracture was one inch greater than on the sound side at the same level.

Seven and a half weeks after the operation movements of flexion and extension were gently carried out under chloroform. The movements were accompanied by considerable cracking of adhesions, especially near the lower end of the scar, where the aponeurosis of the triceps was adherent to the skin. A certain amount of swelling appeared after this, especially towards the back of the joint, and the skin became discoloured. There was much pain in the arm for three days. There was no evidence of sepsis. On November 7th, thirteen weeks after the operation, and for no other reason than that the arm was still swollen, the plate was removed. It was found to be covered at the back with a layer of granulation tissue, the upper screw was slightly loose, but had to be rotated before it could be withdrawn. The three other screws were quite firm. The fragments had apparently united in good position. The scar tissue between the skin and the triceps muscle was freed and the wound closed. This wound healed by first intention. An *x*-ray photograph taken on November 18th (fourteen weeks and two days after the plating), seen in Fig. 5, showed that there was a curious and interesting buttress of bone extending from just below the transverse portion of the fracture to a point some 3 in. higher up the shaft. The small fragment of bone before mentioned is hidden by the lower part of this new formation. The site of the transverse portion of the fracture has apparently yielded very slightly, so that the lower fragments are a trifle more flexed than immediately after the operation. Skiagrams were taken on subsequent dates up to seven and a half months after operation, with a view to observing any changes that might occur. There was a certain amount of diffuseness of outline, especially of the lower fragments; the buttress of bone became denser and the central cavity smaller. It seems to me that the probable explanation of the buttress of bone is that at the time of the accident a layer of osteogenetic cells on the surface of the bone was carried forwards with the periosteum into or towards the brachialis anticus muscle. The severity of the blow probably drove the lower fragments upwards and forwards—that is to say, the displacement was caused by the blow and not by subsequent muscular action, and the osteogenetic layer and periosteum were forcibly stripped off the shaft. The osteogenetic

cells then produced new bone. The diffuseness of outline is possibly due to the absence of periosteum on the posterior aspect of the lower part of the bone, there being no membrane left which definitely limited the production of bone in this situation. This case illustrates very well the importance of *x*-ray examination long after operation. Looking only at the plates taken shortly after operation one would be inclined to say that the result is good.

On January 16th, 1914, nearly twenty-two weeks after the operation, the condition of the arm was as follows: It was the same length and diameter as its fellow. The biceps and triceps acted strongly and freely. The lower part of the triceps was adherent to the skin. Flexion and extension were performed freely and without pain. The movement of extreme flexion was 5 degrees of arc less on the injured side, and the movement of extension was 40 degrees less. The exact cause of limitation was not clear. The uninjured arm has 150 degrees of arc as its full complement of flexion and extension, and on the injured side 105 degrees were present, the chief loss being in full extension, as already mentioned. Pronation and supination were perfect. The joint did not grate or crack when moved, except in extreme extension. There was no "rheumatism." This is the condition now, seven and a half months after operation. Probably arrangements will be made for a course of Tallerman baths, and, later on, perhaps movements of the joint under chloroform will be carried out, but at the present time it is too early to say whether the ultimate result will be better or worse than at present.

CASE II.

The second case was sent to me by Dr. Gibb. A single woman, aged 48, on July 30th, 1912, was getting over a three-foot fence, when she tripped forwards and caught her right foot in some heather, sustaining a compound fracture of both bones of the leg at the same level—namely, 2 in. above the ankle-joint.

The fracture was put in splints by the local medical man, and the patient conveyed to a nursing home, a distance of about 18 miles, without further injury to the leg. There was a clean-cut wound, half an inch long, on the outer side of the leg, leading to the fracture of the fibula. The ankle-joint was swollen and boggy to palpation. The patient stated that there had been some earth removed from the wound, and two small pieces were visible.

An hour after admission, under a general anaesthetic, the leg was thoroughly cleansed and the skin disinfected. An incision 3 in. long was made down to the bone on the inner side over the site of the tibial fracture and the edges of the wound clipped to the edges of a slit cut in a piece of sterilized linen. The periosteum was stripped up with the rest of the tissues, and the two tibial fragments were united by a Lane's plate. Almost exact apposition of the fragments was obtained and the screws held firmly without any undue strain on the bone. The skin was closed with silkworm gut; otherwise the Lane technique was followed exactly, and the operation itself was one of great ease. It was noticed that when the wound was closed the lower part of the internal saphenous vein crossed the lower part of the plate obliquely. The vein was not ligatured, because it was thought advisable to interfere with the circulation as little as possible. The limb was placed on a moulded back splint with footpiece and two side splints were buckled on. The splints were swung from a cradle. The patient received a single dose of tetanus antitoxin.

The wounds healed by first intention, and the stitches were removed on the eighth day. On the ninth day there was considerable redness and swelling of the limb near the ankle, with oedema of the skin, but there was no rise of temperature and no throbbing or pain. A diagnosis of thrombosis of the internal saphenous vein was made, and on the succeeding day it was possible to palpate the vein as a firm cord in the leg nearly as far as the knee. There was no antitoxin rash and no pain or swelling in the small joints of the hands or feet. The wounds did not suppurate. The patient left the home and returned to her flat on the fourteenth day. Care was taken during the entire transit to keep the splints swung from the cradle so that there was no jarring of the limb. At the end of the third week the splint was removed and the patient moved the ankle-joint. A "Croft" plaster-of-Paris splint was then applied, and daily massage commenced, the region of the plate and thrombosed vein being carefully avoided. On the twenty-sixth day the patient got up on crutches. Six and a half weeks from the operation the Croft splint was discarded and a crêpe Velpeau bandage worn; the patient at this time began to bear a little weight on the limb.

Three and a half weeks later, having acquired plenty of confidence and being able to walk without assistance, she slipped and fell, receiving a severe blow from a fender on the middle of the shin of the fractured leg, but no serious harm resulted. Twelve weeks from the time of the accident the patient was walking without a limp, and was instructed to do the ordinary exercises for flat-foot. These she has continued to do ever since, although four months after the accident the arch of the foot on the injured side was equal to that on the sound side, and was as quickly restored on movement. At this time the scar was sound, the swelling of the foot very slight, the size and tone of the muscles of the leg equal to those on the sound side, and the patient could wear ordinary boots without inconvenience.

The condition eighteen months after the accident was as follows: There was slight swelling of the outer aspect of the foot towards evening. This swelling is absent in the morning. There was a slight pulpy swelling in the line of the peroneal tendons at the back of the fibula. This condition is much more marked on the sound limb, and could therefore hardly be ascribed to the accident. The scar of the operation was only visible on close inspection. It was supple and freely movable. The plate was not definitely palpable. The internal saphenous vein could be felt here and there below the knee. Dorsal flexion of the foot was about two degrees greater on the right or injured side than on the left, whereas ventral flexion was some three degrees less, and was not performed so strongly or so rapidly as on the left side. Eversion and inversion on the injured side were slightly less than on the sound side, but the difference was scarcely measurable. The patient was able to raise herself on her toes with the heels together twenty times consecutively without effort, and to perform the exercise of outward rolling of the foot. She walked ten miles at a stretch during September, 1913, and noticed that the foot did not swell after this exertion. There was no perceptible difference in size or tone between the muscles of the two legs. There was no pain and no "rheumatism" in wet and cold weather. Dr. Philip took another pair of *x*-ray photographs (Figs. 6 and 7). One of these shows that the upper part of the plate is possibly covered by callus, but in the absence of an oblique view this is uncertain. There is possibly some rarefying osteitis of the lower fragment, but we have no *x*-ray photograph of the sound limb taken at the same time, or with a tube having an equal degree of hardness, for exact comparison. A portion only of the line of fracture is visible, and the fracture of the fibula is not seen.

DESCRIPTION OF SPECIAL PLATE.

Fig. 7.—Case II: Eighteen months after operation.

Fig. 12.—Case III: Nine months after osteotomy and eighteen months after accident.

CASE III.

The third case is that of a male, aged 29, who was sent in to Professor Marnoch. Professor Marnoch was on the point of leaving for a holiday, and very kindly passed the case on to me. The accident occurred in this way: Two motor cyclists travelling towards each other at a relative speed of sixty-five miles an hour collided. The foot-rest of the oncoming machine caught the patient's left leg just above the ankle. The patient was knocked off and lay with the injured leg in a pool of water for one hour. His left thumb was partially torn off and there was also a severe lacerated wound over the left patella. The other cyclist sustained a severe fracture of the lower end of the left femur.

Dr. Cran, of Banchory, and Dr. Davidson, of Torphins, brought the injured men to Aberdeen, and eight hours from the time of the accident operation was performed. The left thumb was amputated through the proximal

phalanx and the flexor tendon sutured to the dorsal expansion. The wound over the patella contained some blades of grass, which were removed, the skin sutured and the wound drained. There was a severe compound comminuted fracture of the left tibia and a simple comminuted fracture of the left fibula at the same level, namely, about an inch and a half above the ankle-joint. Under a general anaesthetic the edges of the skin were excised over the tibial fracture and the tissues pared down to the bone. The incision was prolonged upwards. It was then seen that the periosteum was destroyed over the tibia, and some of it that was left was black with mud. It was therefore removed. There were several small fragments of bone also discoloured with mud, and about three teaspoonfuls of bone pulp mixed with mud. All these were removed and the wound swabbed out with hydrogen peroxide. It was then clear that the anterior tibial artery and vein had been severed. The posterior tibial was intact. The exact extent of the fracture was not discovered until later on. Removal of the bone pulp and mud left an irregular gap in the tibia 1½ in. long in front, 2 in. long in the medullary portion, and extending nearly the whole thickness of the tibia, so that the shaft could only be made to touch the lower fragments at the posterior surface of the bone. Part of the largest tibial fragment had been split off, so that the fracture extended into the ankle-joint, which was full of blood. These two pieces were pinned together with the nail seen in Fig. 1, and then, the foot being held well forwards and the toes pressed upwards, a Lane's femur plate nearly four inches long was used to bridge the gap between the shaft and the larger of the lower fragments. The two middle screw holes were left without screws because there was no bone underneath them. The plate held firm, and the chief lower fragment touched the shaft at its posterior border. The fracture of the fibula did not communicate directly with the wound, so it was left alone. The wound was sewn up and a small tube placed at the bottom of the gap in the tibia. The wounds were dressed, the limb placed on a moulded back splint with footpiece, and two side splints strapped on and the splints swung from a cradle. The patient received 20 c.cm. of tetanus antitoxin.

The temperature was highest on the third day, when it was 101.8° F. On the fifth and sixth days there was a severe urticarial rash, but no pain in the smaller joints of the hands and feet. The patient took food well. The tube was removed on the tenth day, and the stitches also. The scar stretched and gave way in the middle, but was covered with epithelium on the twenty-second day. On the eighteenth day an aluminium splint, carefully moulded to the curves of the limb, and padded with a thin quilted pad, was fitted in the place of the splint used at first, and two aluminium side splints were strapped in place. This system rendered it safe to move the patient to the electrical room, and the *x*-ray photographs (Figs. 8 and 9) were taken through these splints by Dr. Levack. They showed that there were some five pieces of bone left in the lower part of the tibia and five in the fracture of the fibula. Both these fractures extended into the ankle-joint, so that indirectly the fibular fracture communicated with the septic portion of the wound. The most important fact, however, appeared to be that the lower largest fragment of tibia was tilted at an angle to the shaft, the fragment being rotated on a transverse axis with its upper portion forwards. When the corresponding outline of a normal bone is compared with the *x*-ray plate, the amount of rotation is found to be 23 degrees of arc. The probable explanation of this tilting is that the fragment did not move when the foot was held up in its correct position. Its small size and the fact that the curves on the patient's right or normal tibia are more marked than in most cases led to the fixation being made in a faulty position.

On the twenty-first day the skin sloughed over the plate. On the twenty-third day Professor Marnoch, in consultation, expressed the opinion that it was inadvisable to do anything further at that time, as this would involve disturbing the plate and it might not be possible to obtain a firm hold again. He considered that it might take some time for the gap in the bone to close up.

At the end of the sixth week the patient was anaesthetized, and the ankle-joint moved as freely as possible. The plate was then removed. It was necessary to unscrew the screws, although they were slightly loose. The pin was also removed. It was found that the bones had just united. The granulations where the plate had been were scraped away, the wound partly closed and drained, and the moulded splint was reapplied. At the end of the ninth week a "Croft's" splint was applied, daily massage instituted, and the patient got up on crutches. *X*-ray plates, taken thirteen weeks from the time of the accident and seven weeks from the removal of the plate, showed that consolidation was proceeding. There was a small bridge of bone between the shaft of the fibula and one of its fragments (see also Fig. 10). At this time a small sinus existed where the tube had been. Towards the end of the fourth month the patient was able to walk with the aid of two sticks.

At the end of the fifth month the sinus had healed, the dent in the bone where the gap had been was smaller, and the shortening was only a quarter of an inch. The movements of the ankle-joint were limited, but devoid of creaking or grating. The leg muscles were much wasted and their tone was bad. The patient was advised to wear a leather wedge on the inner side of the sole of the boot, and to walk with the toes turned in. At the end of the seventh month the leg was very painful during the day and at night. The joint scarcely moved.

At the end of the eighth month the joint began to yield a creaking sensation when examined, but was not swollen. There was a tender spot on the bone, on the inner side just above the joint, so that the patient could not sleep when the leg was turned on that side. There was considerable swelling of the ankle at night. Fig. 10 shows the condition in lateral view. In consultation with Dr. Smart, who was attending the patient, it was agreed to continue massage and movement of the joint by a skilled masseuse.

Up till now massage had been done by the patient and by friends. The masseuse moved the joint thoroughly and this resulted in a great effusion of blood into it. The leg became so painful that the patient was unable to walk on it. It was clear that something more radical would have to be done. The choice lay between osteotomy at the site of the fracture with rectification of the lower fragments and arthroplasty. The latter operation would have consisted in this case in opening the ankle-joint from in front, removing the front portion of the lower end of the tibia with its articular cartilage, and in rounding off the surface of bone so as to make a new ankle-joint in the correct position. A portion of deep fascia from the thigh would then have been inserted so as to separate the joint surfaces. This proceeding, although of undoubted use in many cases, seemed to me to offer nothing radical as regards restoring the line of action of the muscles, and further it would have involved the risk of opening the ankle-joint and perhaps the production of more adhesions. In choosing osteotomy it seemed that the spicules of bone near the fibular fracture could be dealt with at the same time and the condition of this part of the leg ascertained with respect to any interference with the action of the peroneal muscles that might be present. It was recognized that the operation would be one of considerable difficulty. A moulded aluminium splint was carefully shaped to the sound leg with the foot held in a position of extreme dorsiflexion, and padded with a thin quilted pad.

One week less than ten months from the accident the patient was anaesthetized and the adhesions in the ankle-joint broken down. The sites of the fractures were exposed, and the bridge of bone and projecting spike attached to the fibula removed. They lay under the tendon of the peroneus longus. The tibia was divided at the site of fracture, the bone being found to be dense and devoid of medullary cavity. An attempt was made to rectify the position of the lower fragment, but this was found to be impossible until the fibula had also been divided, and when the correct position of the foot had been secured in this way the ends of the fibula did not come into proper alignment, the lower fragment being tilted forwards and inwards. The tibial and fibular fragments were plated to the shaft, this being difficult to do on account of their small size and the proximity of the ankle-joint. The wounds were closed and dressed, and the limb splinted and swung from a cradle. The operation took three hours and a quarter to perform, and it was followed by severe pain lasting for three days. The highest temperature recorded was 99.4° F.

The wounds healed by first intention. Massage and passive movements were carried out daily, commencing on the third day. The plates had been so firmly fixed that there was no great risk in doing this; but, in view of the risk of rarefying osteitis supervening or of sequestration of any of the original fragments present at the time of the accident, it was considered advisable to remove the plates. This was done at the end of the

seventh week under a general anaesthetic, the opportunity being taken to move the ankle-joint freely before removing them. There was no cracking of adhesions when this was done. The screws were found to be quite firm, and the fractures were found to have united. The limb was again placed on the moulded splint until the wounds were healed, and on the tenth day a Croft's splint was applied. Massage and active movements were carried out from the seventh day. A piece of the old scar tissue from the original wound at the time of the accident sloughed immediately over the tendon of the tibialis anticus, and this has resulted in a slightly adherent scar. The patient had a course of Tallerman baths to the limb for three weeks, but I regret to say I have no note of the dates. This treatment resulted in considerable softening of the scars, and seemed, if anything, to improve the condition.

He was allowed to stand on both legs ten weeks after the osteotomy, and soon began to walk. From this time onwards there has been a steady improvement, which is a striking contrast to his progress after the original setting of the fracture. The condition nine and a half months after the osteotomy, or eighteen months after the accident, is as follows: There is occasionally slight pain on the outer side of the foot, and he has a tired feeling in the ankle if he walks any distance. There is a slight limp, but the patient can walk without any limp if he tries to do so. He is able to walk six miles at a stretch, he can cycle and "dance every dance," but the ankle is painful if he walks on uneven ground or if he forcibly inverts the foot. The circumference round the malleoli at 5 p.m. is 11 in., as compared with 9½ in. on the sound side. The swelling is much less in the morning. The shortening is half an inch. All the scars are supple and non-adherent except in the one place mentioned—namely, over the tendon of the tibialis anticus. This is improving. The patient's right or sound foot is abnormal as regards movements, there being less dorsiflexion than is usual. Comparing the two sides: The right or sound side has dorsiflexion 4 degrees of arc and of plantar flexion 47 degrees of arc, or 51 degrees in all. The left has dorsal 5 degrees, or 1 degree more than on the sound side, and of plantar 5 degrees, or 42 degrees less than on the sound side. Eversion and inversion on the injured side are about two-thirds of the extent of those on the sound side, and they seem to compensate very largely for the loss of plantar flexion. There is no flat-foot. The maximum circumference of the leg on the sound side is 14 in., and on the injured side 13½ in., the tone of the muscles being about equal. The thigh muscles are equal on the two sides. The patient has therefore recovered with ½ in. of shortening, ½ in. of wasting, and considerable diminution in plantar flexion. This does not seem to inconvenience him, but in view of the risk of arthritis being set up, I am at present advising against moving the joint under chloroform. The *x*-ray plates (Figs. 11 and 12) show that there is bone deposited between the lower ends of the tibia and fibula. There is otherwise no callus formation. The gap in the tibia is smaller and the various fragments seem to have consolidated well.

There are some interesting points about these three cases. In the first place the question arose as to whether operative interference was advisable or not, and if it was, whether plating should be carried out at the same time or the fracture merely set. In the first case, that of T-shaped fracture into the elbow-joint, reduction could not be effected by ordinary means, and even through an open wound was difficult to perform, probably because of the violence of the original blow. There was no element of sepsis after the wound had healed. If the fracture had been left and later the fragments resected, the brachialis anticus would probably by then have been caught in the callus and perhaps only freed with difficulty. The fracture extended further up the arm than the majority of such fractures. Resection would have resulted in about 2 in. of shortening, and probably a flail-like joint. In the second case, where there was a transverse fracture of both bones 2 in. above the ankle-joint, there was sepsis of the fibular fracture, but possibly no sepsis of the tibial one. With care such a fracture could have been treated without plating, and a good position of the bones secured, but the performance of massage and movements would have required great care. By plating such a fracture one obtains a rigid result from the start, and there is much less anxiety as regards the likelihood of displacement occurring when the splints are changed or massage and movement employed. The plate was placed as far away from the septic focus as possible, and that is one reason why it was not placed on the outer surface of the tibia. Lane[1] says, "It is unwise to place a steel plate directly beneath the skin incision, and wherever possible it is well to bury the plate beneath muscle rather than immediately under the skin." It seems to me that the latter proceeding might make the operation one of difficulty in certain cases of fracture in the lower third of the leg. It might possibly lead to an adherent scar between the skin and the tibialis anticus. The fixation of the plate might have to be abandoned in some cases owing to the difficulty of inserting the screws while the muscles are retracted. The inner side is much more accessible, no muscle or tendon is interfered with and the tissues are about ⅜ in. thick over the bone. The chief risks seem to be that the plate may be jarred by a direct blow, or that the tissues over it may slough. In the present case neither of these things has happened; the patient wears boots and the scar is often subjected to pressure.

In the third case, according to general opinion, operation was indicated, but plating was strongly contraindicated. Walton,[2] however, is in favour of plating early as against waiting until sepsis has disappeared, on the ground that sepsis is unlikely to be increased by the operation; whereas by waiting the opportunity of obtaining exact apposition of the fragments may be lost owing to the changes which occur in the bones and surrounding tissues. A case in some respects similar to the present one is recorded by Negus.[3] Tetanus, however, supervened, and, though the patient's life was spared, he lost his leg. Hey Groves[4] mentions a case similar to mine in which, by means of a sliding splint, an extension of 10 lb. weight was maintained on the foot while the wound healed and the bones united, but vicious union resulted, and the patient was crippled for life. The foot was saved, but the ankle-joint became stiff. The amount of shortening, if any, is not mentioned.

Personally I doubt if the foot in Case III would have been saved without the use of a plate. The extreme severity of the injury and the flail-like condition at the site of fracture would have made it exceedingly difficult to control the foot and leg by means of external splints alone. Hackenbruch's fracture clamp apparatus was not in use at that time. It would have suited the case well enough provided there had been no swelling of the limb after its application. It would have required considerable care in use, and perhaps the plaster would have had to be frequently changed under general anaesthesia, which in some cases is contraindicated. My great regret, however, in this case is that I was deceived by the apparent correct position of the lower fragments at the time of the first operation. To have recognized that their actual position was incorrect would have saved the patient some months of great pain and disability. The error arose chiefly from the abnormal curve of the bone as seen on the sound side, and from the small size and fixity of the largest of the tibial fragments, combined with the fact that the foot came into good position.

In all three cases the patients were anxious and willing to assist their own cures in every possible way. This largely accounts for the result in Case III. The patient was a man of sound physique who carried out all instructions to the letter, and often at the cost of much pain.

The chief points about the technique of plating are so well known that they need not be mentioned. Before the Lane technique came in an ordinary bradawl and screwdriver were often used with complete success. The tedious nature of many of these operations is partly due to the use of long-handled instruments, which, though it may secure the greatest degree of asepsis in the greatest number of cases, often makes the operation more difficult. The actual mechanical difficulties are apt to be greater than those which arise in carpentry, because of the difficulty of holding the fragments firmly without any give while the screw holes are bored and the screws inserted. It is essential to have the holes the right size for the screws, neither too tight nor too loose, and it is advisable to test the drills and screws on a piece of bone beforehand. The screwdriver should fit the slot of the screw properly, and be less in width than the diameter of the head of the screw. To have to stop or alter the operation on

account of difficulties arising under these headings argues a lack of prearrangement and practice. There are two common causes of failure to get the screws to hold well, and I mention them because they are not as well known as the others. One is that the hole in the plate is not strictly concentric with the hole in the bone; in this case the screw enters with difficulty, and if much strain is thrown on it it may break off. The other common cause is that the screw is tightened too much; in this case it acts as a cutter, and removes the thread in the bone. This makes it loose just as if the hole had been too large from the start, and though the hold may be useful against movements in the plane of the plate, it is useless against movements in the direction of the axis of the screw. In these ways useful positions may be sacrificed, and in a difficult case no others may be obtainable. Again, if the screw is overtightened much strain is thrown on the bone, pressure atrophy occurs and the screw quickly works loose. This probably in part explains those cases in which, apart from sepsis, the screws, though tight at the conclusion of the operation, are found to be loose when the plate is removed. To estimate by the feel of the screwdriver that the correct position has been attained and the correct degree of tightening ensured is an art that comes most readily to those who are used to working in hard wood, bone, and ivory. Hey Groves[5] mentions that Lambotte pointed out that the hold obtained in the bone by the thread of a screw used for metal work has a distinct advantage over the hold obtained by the thread of a screw used for wood. The tap-screw suggested by O'Neill Sherman[6] is a simple way of employing the metal work screw. I show to-night a section through each kind of screw cut from a bone after inserting the screws, and you see the advantage of the metal work thread as regards the hold obtained. One small point may be mentioned as its use is not generally known. To steady the shaft of a bone lying fully exposed in the wound one can place it under a broad band made of flexible sheet metal. This sometimes enables drilling and screwing to be done with great ease in an otherwise difficult case. For the sake of speed and accuracy some kind of geared drill is used. Some of those on the market do not allow of the point being kept steady while the handle is turned. By massing the chief weight one-third of the distance along from the handle to the point and by having the handle relatively heavy and arranged vertically, the instrument can be made to conform to the laws of dynamics and the point of the drill is steadied. Most will agree that the small fly-screw so often present in these instruments may catch in the tissues in a difficult case and so prevent the drill from revolving.

As to the use of splints. It seems to be agreed that external splints are necessary, certainly in difficult cases or where the screws do not hold well. They impede massage and movement, and their removal and reapplication twice a day is apt to be tedious. It seems to me that a better result is obtained by using a moulded splint thinly padded than by using a straight splint thickly padded. In the case of the leg, diminution of pain and muscular spasm, and greater ease in nursing are obtained by swinging the splint, which is shaped so that the leg is slightly flexed at the knee. In the case of a compound fracture the dressing is done without letting down the limb, so that any movements due to pain are at once taken up by the swing, and the site of fracture is not jarred. The patient can also turn partly on his side to sleep without risk of the thigh rotating relatively to the leg in the sleeve of strapping or bandage. There seems to be less after-stiffness of the knee when the joint is kept bent than when it is kept on a straight splint. In an aseptic case, after the stitches have been removed, the "Croft" or "Bavarian" splint has so many advantages that its use is becoming general. The ease with which it is made and the simplicity of its removal and reapplication make its use ideal in these cases when massage is employed or *x*-ray photographs have to be taken.

In conclusion, I must thank you for having given me such a patient hearing during the reading of a somewhat technical paper.

NOTE ON HAEMOSTASIS BY APPLICATION OF LIVING TISSUE.

BY

SIR VICTOR HORSLEY, F.R.S., F.R.C.S.

MANY years ago, acting on a hint obtained from Magendie's *Physiologie*, I showed that it is very easy to arrest bleeding from bone by the use of an aseptic plastic wax which can adhere to the cancellous spaces and to their walls. This method is now, I believe, in general use.

On the other hand, it is difficult to stop bleeding and haemorrhagic oozing from soft tissues except by the employment of a ligature, or pressure with a gauze tampon, or by irrigation with hot liquid (110° F. to 115° F.). For a long time I employed amadou for this purpose in experimental investigations where asepsis was not required, and with good results, as it adhered well to the bleeding point. To obtain, however, the same result in aseptic operations is not so simple. The factors which had to be obtained were:

1. Asepticity.
2. Adhesiveness.
3. Thrombokinesis.

In view of my personal experience of the work of the late Dr. Wooldridge, it occurred to me that probably the best material would be living vascular tissue—that from the (injured) surface of a cut fragment of muscle, in all probability, thrombokinetic processes would most readily start; not merely on account of the plasma and plasmatic corpuscles of the tissue, but also the thrombokinetic by-products in the effused blood and the development of so-called blood platelets.

Such a fragment of the animal's own muscle offered all these advantages, and also asepticity. I was rather surprised to find that the necessary factor of adherence was also satisfied in a very remarkable degree.

If the bleeding point—for example, from the cut surface of the brain, liver, or any soft tissue—be gently pressed with gauze, and this instantly replaced by a piece of living muscle, and pressure again applied from fifteen to twenty seconds, it will be found that the muscle fragment closely adheres to the tissue it is applied to.

Such adhesion is necessarily limited by the pressure at which the blood is escaping from the bleeding point. By direct experiment on divided arteries (including the aorta) in the cat and dog, I found that a muscle haemostasis would resist as much as 60 to 80 mm. Hg blood pressure.

Further histological investigation of the exceedingly thin viscous layer occupying the plane of contact of the two masses of tissue shows that it contains blood platelets, fibrin fibrils, etc., in a considerable degree, and within a short space of time (five to ten minutes) of commencing the preparation.

To estimate the degree of active thrombokinesis I also tested the utility of the muscle after it had been boiled for five minutes at 100° C. Such boiled tissue had a very poor haemostatic effect. It seemed as if this was partly owing to the great loss of adhesiveness which is caused by the heat coagulation completely altering the physical surface of the muscle tissue.

Of other tissues I have only exhaustively tried fascia fully, and with the result that it has not proved satisfactory. It has not the factor of adhesiveness sufficiently well marked, though it can be employed where it is not convenient to take a piece of muscle. When experimental research had shown the remarkably rapid haemostatic effect of living tissue I used it freely in operations—above all, where it was necessary and convenient to leave a resting plug or tampon in a wound. Where an operation has been performed in two stages, I have occasionally had the opportunity of examining the isolated muscle tissue, and found it firmly attached and "organized." In no instance has any ill effect followed its employment.

AT a meeting of the Society for the Study of Inebriety, to be held in the rooms of the Medical Society of London, Chandos Street, Cavendish Square, on Tuesday, July 14th, at 4 p.m., a discussion on "Proposed Legislation for Inebriates" will be opened by Dr. J. W. Astley Cooper, Resident Physician of the Ghyllwood Sanaterium and Retreat for Inebriate Patients.

PRELIMINARY CLINICAL REPORT ON A NEW AND ECONOMICAL METHOD OF RADIUM THERAPY BY MEANS OF EMANATION NEEDLES.

BY WALTER C. STEVENSON, M.D., B.CH., D.P.H.,
SURGEON AND X-RAY OFFICER, DR. STEEVENS'S HOSPITAL; SURGEON, ORTHOPAEDIC HOSPITAL, DUBLIN.

SINCE the publication of papers by Professor Joly[1] and myself[2] I have been enabled, by the kindness of the Council of the Royal Dublin Society, to carry out an investigation on this method of treatment. The results I have so far obtained with the limited supply of emanation at present at my disposal are, I think, sufficiently encouraging to justify a short account of the technique I have employed since April 9th. The method, and the results that can be obtained in favourable cases, are conveniently illustrated by the two following examples:

CASE I.—*Inoperable Parotid Tumour.*

Mrs. B. (Fig. 1). The tumour began nine months ago, and grew steadily. It was quite fixed to the lower jaw; the patient

Fig. 1.—Case I. Inoperable parotid sarcoma, before treatment.

Fig. 2.—Case I. Showing position of needles.

was unable to open her mouth, and fed herself by forcing food, usually crumbled biscuits, upwards under the overhang of the upper front teeth.

Mr. Keegan, to whom I am indebted for the following history, operated on the tumour in November, 1913, and found an indefinite growth, the size of a large cherry, infiltrating the masseter muscle, and without any sign of a capsule. The patient at the time would not allow any operation which might lead to disfigurement. Microscopic examination by Professor McWeeney proved the growth to be a mixed parotid sarcoma. The subsequent clinical history confirmed the diagnosis of malignancy, and later the case was sent to me by Mr. Blayney as inoperable, to try the effect of radium treatment.

At 11.15 p.m. on April 17th, I inserted from behind forwards into the tumour five needles, parallel to one another and about

Fig. 3.—Case I. Showing amount patient could open her mouth after one month's treatment. Before treatment she could not separate her teeth.

Fig. 4.—Case I. Fifty-two days after first treatment.

8 mm. apart. They contained altogether 5.08 millicuries of emanation in glass capillary tubes. I left them in till 12.45 p.m. on April 19th. The strength would then have been reduced to 3.8 millicuries, giving an average of 4.8 millicuries for thirty-seven and a half hours. On April 21st the patient could open her mouth a little better, and on April 27th considerably better. The tumour was also less fixed. On April 29th I inserted six needles containing 17.2 millicuries altogether, from behind forwards (average 15.5 millicuries), for thirty-five and a half hours. Immediately after removal they were re-inserted for twenty-four hours at right angles to their former position (Fig. 2). The average was 13.3 millicuries for twenty-four hours. On May 18th, a month and a day after treatment was begun, the patient could open her mouth to the extent shown in Fig. 3. On that date I inserted five needles containing altogether 4.4 millicuries of emanation in glands in the submaxillary region, and left them in for two and a half days (average 3.5 millicuries). For a fortnight after this dose I thought no effect had been produced by the very small quantity I had used, but I was mistaken, as soon afterwards a distinct diminution of the size of the glands occurred, and the patient was able to open her mouth still wider than illustrated in Fig. 3. During and for some days after each treatment the radiated tissues swelled, and the patient was unable to open her mouth so well. The photograph (Fig. 4) was taken on June 8th. The patient states she can now see her left ear in a mirror, and can put her finger in the external meatus, both of which she had been unable to do for some months. The tumour is no longer fixed. There is no mark on the skin to show where the needles were inserted. The patient has gained 6 lb. during the treatment. After the next treatment I intend sending her home for three weeks, and my present purpose is to give her another treatment in about two months.

CASE II.—*Scar Fixing Wrist.*

Miss K. T. (Fig. 5). The right wrist was burned and lacerated by a calendering machine five years ago, and she had done no work since; history of pieces of tendon having been cut away when first treated. For the past two or three years the fibrous scar was a constant source of pain, which kept her awake at night. The wrist and fingers were fixed in a flexed position, and she kept her whole hand quite rigid. She could move the thumb and first finger a little, the other three fingers not at all.

On May 7th six needles were inserted as illustrated (Fig. 5), and left in for forty-six hours. Average 5.5 millicuries. When the needles were removed the patient stated that the pain had disappeared. Five days later the scar was soft and the wrist could be straightened by strong extension. She could move her thumb and first finger better, and, to my surprise, could flex her other fingers to a considerable extent. She attended Steevens's Hospital as an extern patient for the next week or ten days for massage and manipulation, and her power of movement continued to improve and the pain did not return. She,

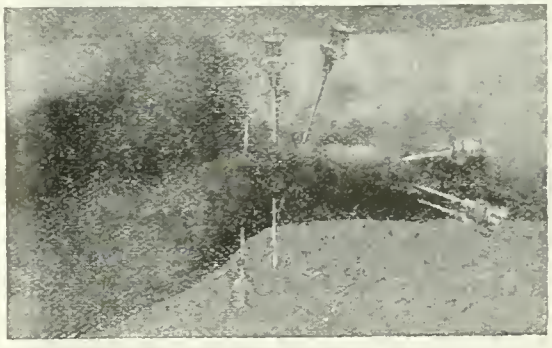

Fig. 5.—Case II. Showing position of needles in fibrous scar.

however, discontinued attending the hospital, and wrote to me saying her arm was much better and that she could not attend as she had again started work.

The results I have obtained in other cases still under treatment are also encouraging. A cancer of the floor of the mouth, with extensive glandular involvement, has improved; the glands are smaller and less fixed, and the floor of the mouth less prominent. A recurrent cancer of the breast has been considerably relieved of pain and tenderness, and the patient sleeps much better; the supraclavicular glands, into which I inserted the needles, have diminished in size, and the oedema of the arm has considerably decreased. I have just begun treatment of malignant glands of the neck, which I was unable to remove by operation. There is already some diminution of haemorrhage in a case of cancer of the cervix uteri, which Dr. Tweedy found by an exploratory laparotomy to be too extensive for removal, and handed over to me. In this case the needles were inserted into three different localities of the cervix for twenty-four, twenty-four, and forty-eight hours respectively, and then the capillary tubes were removed from the needles and packed into a

small cannula, which was inserted into the os for three days, each day being pushed a little further up.

When the capillary tubes became too weak in emanation to be buried separately in a malignant growth, I have collected them into a cannula and used them for tuberculous sinuses, etc.

All the patients—eleven in number—on whom I have used the emanation were treated as in- or out-patients in Dr. Steevens's Hospital.

In no case did I use a general or local anaesthetic for inserting the needles; in the breast case I have inserted six needles a dozen times in various localities.

The needles I have used are ordinary steel serum needles as supplied by any medical instrument maker. I get them at Messrs. Smith and Sheppard, Dublin, for 6d. each with tops, and 3d. each without. Their external diameter is 1.4 mm., their thickness 0.3 mm., and the diameter of their bore 0.8 mm. The glass capillaries have as maximum dimension an external diameter of about 0.76 mm., an internal diameter of 0.46 mm., and a thickness of 0.15 mm.; 1 cm. of these capillaries would theoretically be capable of holding the emanation equilibrium of about 3 grams of radium at atmospheric pressure.

The emanation needles, as I have employed them, have decided advantages.

1. They are an economical method of using the therapeutic properties of radium.

2. Clinically, they are easily and safely employed, without an anaesthetic or the use of an operating theatre.

3. They admit of very accurate dosage.

4. They permit a tumour to be subdivided into areas which can be efficiently treated by small quantities of emanation.

The economy of rays has already been dealt with to some extent in the papers referred to. It depends upon the amount of cross-fire that results both from the primary and secondary rays, and also on the fact that the soft gamma and beta rays, which are in the majority, and which are usually screened off in deep radio-therapy, are here depended upon for their therapeutic effects. It is permissible to utilize these soft rays whether they be gamma or beta rays (or x rays and beta rays when x-rays are used), because (*a*) they are all ionizing agents and must in any case result as secondary rays in every method of radiation by means of radio-active elements (or a Crookes's tube); (*b*) they are unhesitatingly employed in surface conditions when radium is used practically unscreened.

The collection of needles get, so to speak, at the surface of the deep parts, and radiate them as uniformly as it is possible to do at the surface, provided that the sources of radiation are within range of the soft rays—that is, the needles are not more than 3 cm. apart, which is about the average distance of human tissues traversed by these soft rays. (1) As in surface conditions due consideration is given to the relation between the length of exposure on the one hand and the amount of screening and of the source of radiation on the other.

I do not think I could have obtained as marked effects by any other method of radium therapy known to me, taking into consideration the duration of treatment and the amount of emanation available. From April 9th to June 8th I received altogether 139.7 millicuries of emanation in capillaries, or an average of 15.5 millicuries per week. It must be remembered that half the emanation had disappeared in 3.86 days, and owing to the hour at which it was necessary to collect and measure it, usually 5 per cent. was lost before I could insert it.

There is no difficulty and little danger in introducing fine needles into a growth that is suitable for this method of treatment. It is necessary to have some respect for large blood vessels, though I have found from experience that it is possible, with small quantities of emanation, to go fairly near the carotid, jugular, and subclavian vessels. Unless by a gross miscalculation or misjudgement, it is almost impossible to cause any extensive sloughing.

I have noticed on several occasions a bead of pus when I extracted a needle, especially if it had been left in more than thirty-six hours and contained a fair amount of emanation. The pus is sterile; I could get no growth from it in three days, although I plated it out on several occasions. The minute hole has always sealed up at once and has given no further trouble. Lately I have made a practice of testing the firmness of the needles in the tissues. Soon after insertion the needles are grasped more tightly by the tissues; they then gradually become loosened again. If a needle has too little emanation, or is taken out too soon, it requires a little force to remove it, and a drop of blood usually appears at the hole left. When the needles were in a dependent position, they became so loose on one occasion that they dropped out. When they become loose I remove them, and reinsert them if desirable. The loosening of the needles and the formation of the pus may be due to some extent to the presence of a foreign body, but not altogether, so that I think that the firmness test has a distinct use in judging the effect produced, at least with the doses I have been employing.

It is obvious that this needle method admits of fairly fine adjustment of dose, as the dose depends on five factors: (1) The amount of emanation in each capillary; (2) the length of the capillary; (3) the number of capillaries used; (4) the distance between the needles, and (5) the time they are left in.

The duration of treatment depends upon the amount and concentration of the emanation in the capillaries and the thickness of, and distance between, the needles; but if these factors are constant, the duration is relatively independent of the number of needles, as a greater number of needles simply means a larger area of tissue under simultaneous treatment. Briefly, as the emanation decays, the plan is to leave the needles in longer and put them closer together.

Since it has been only possible to obtain an average of 15 millicuries of radium emanation per week, I have thought it best to employ six needles at a time. I insert them parallel to one another at one operation, but if possible, at right angles to the first position at the next insertion in the same area, as in Case I. In the breast case I mapped out the area so as to leave as long an interval as possible between the treatments of adjacent areas, and thus to lessen the chance of over-exposure at any part. I endeavour to treat one part efficiently by insertions in various directions, before going on to the next. This was not a method of choice, but of necessity. In this particular case, however, it seems to promise as good a result as can be reasonably expected.

The essential point of this technique is to radiate deep structures on the same lines as superficial structures. It aims at uniformity of radiation with a minimum loss of energy by screening. It is nearly as suitable for radium salts as for emanations, since Professor Joly has shown that the salts, melted by an electrically-heated platinum loop, will flow into the smallest practicable tube by capillary attraction.

By the method one can, for instance, primarily attack the base of a rodent ulcer, not the surface; or both the base and the surface can be attacked simultaneously, which will give the maximum effect.

It is obvious that the therapeutic value of a given quantity of radium or its emanation is theoretically increased by this method as compared with other methods of burying. My clinical observations tend, I think, to confirm the theoretical considerations. I have frequently heard the statement that with less than 50 mg. of radium there is very little hope of doing much good in malignant disease. Only once did I use more than 22 millicuries of emanation—never as much as 30; yet the photographs and history of Case I, in which only 17.2 millicuries was the maximum amount used at one time, show very definite effects.

In conclusion, I have to thank the Council of the Royal Dublin Society for providing me with radium emanation from the 34 mg. of radium (element) they possess at present. I am particularly indebted to Mr. R. J. Moss, the registrar of the society, for his kindness and the trouble he has taken to carry out the laboratory work, and for his skill in making the fine capillary glass tubes to fit the needles I use, for collecting the emanation in them, and for dividing the tubes into lengths suitable for the case to be treated.

[1] On the Local Application of Radium in Therapeutics. By J. Joly, Sc.D., F.R.S. Read at the scientific meeting of the Royal Dublin Society, March 24th. *Proceedings*, May 8th, 1914. [2] *Medical Press and Circular*, March 11th, 1914.

THE X-RAY TREATMENT OF TUBERCULOUS GLANDS.

By HAROLD MOWAT, M.D.Edin.,

MEDICAL OFFICER IN CHARGE OF X-RAY AND ELECTRICAL DEPARTMENT, METROPOLITAN HOSPITAL; RADIOGRAPHER TO THE ROYAL HOSPITAL FOR DISEASES OF THE CHEST, CITY ROAD.

The great advantage of the *x*-ray treatment of tuberculous glands is that it saves the patient the unpleasantness of undergoing in many instances a severe operation. The results are equally satisfactory whether the glands are large or small, numerous or scanty, superficial or deep, because by means of filters the penetrating power of the rays can be controlled, and by using hard tubes those glands deeply situated can be reached. Even when the glands have broken down and are fungating great improvement results, as will be noted in one of the cases, which unfortunately ceased to attend the hospital when showing marked improvement.

It is advisable to use a hard *x*-ray tube, and it is also necessary to filter the rays through aluminium or felt; I generally filter through 1.5 mm. of aluminium. The current should range from 2 to 3 milliampèremetres, and the rays be applied directly to the affected parts, a suitable lead-glass screen being used of the requisite size. The exposure given should be at any rate one full Sabouraud dose, but in some cases it is advisable to exceed this by about a quarter. Cases may be treated twice a week; most of those reported were only seen once a week or even less frequently, owing to the difficulty of persuading the patients to come to hospital; had the attendances been more regular even more rapid cures would have resulted.

The following is a record of cases recently treated:

1. S. P., aged 10. Large mass of tuberculous glands situated on right side of neck. Treatment was given once a week for seven weeks. At the end of that time all trace of glands had disappeared. A marked improvement was noticed after the fourth treatment. The patient has been seen within the last week and no recurrence has taken place.

2. F. H., aged 1 year 10 months. Mass of fungating tuberculous glands in neck. From December 8th to 22nd four treatments were given, and a very marked improvement noticed. After this the child was not brought back, and on inquiry it was ascertained that the parents could not afford the railway fare to come to hospital.

3. S. M., aged 11. Tuberculous glands in submaxillary triangle; one large mass on the right side 2½ in. by 2 in., smaller mass on left side ½ in. by ½ in. Thirteen treatments have been given during period of two and a half months. Glands have greatly diminished, are softer, and freely movable.

4. M. H., aged 31. Tuberculous glands on left side, very extensive and numerous. Ten years ago the patient had an operation on this side. Since then glands have returned worse than before. Twelve treatments have been given over period of two months. There has been a great improvement, and now only one gland is left.

5. D. O., aged 19. Tuberculous glands; large mass on right side of neck, also large submental glands. Eleven treatments have been given over period of two and a half months, and although the glands are still felt they have diminished in size, are softer, and movable.

6. W. J., aged 7. Tuberculous mass in left side of neck. Five treatments have been given over period of one month, and considerable improvement is noted.

7. H. W., aged 23. Tuberculous suppurating glands in neck. Six treatments have been given over period of one month; the glands have disappeared, and the surface has healed.

8. G. M., aged 11. Suppurating glands in axilla. Two treatments only required for complete dissolution.

SAN FRANCISCO will next year celebrate the opening of the Panama Canal and its own rebuilding after the earthquake by a big International Exposition, during which 226 congresses are to be held. It would seem that the biggest must be the International Congress of Engineers, for at it Colonel G. W. Goethals, the engineer of the Panama Canal, is to preside, it is said, over "25,000 delegates from forty different world nations." The meeting of the International Association of Nurses is to be attended by 6,000 delegates, but apparently they will come from fifteen nations only. The Panama-Pacific Dental Congress "will bring more than 3,000 delegates with a clinic of more than 30 chairs"; eye, ear, and throat specialists are to hold congresses also, and the American Academy of Medicine is to meet in the city during the Exposition, as are also many other societies for the discussion of mental hygiene, tuberculosis, cancer, and many other matters of more or less directly medical interest. Hospital equipments are to be exhibited, and a model emergency hospital is already at work.

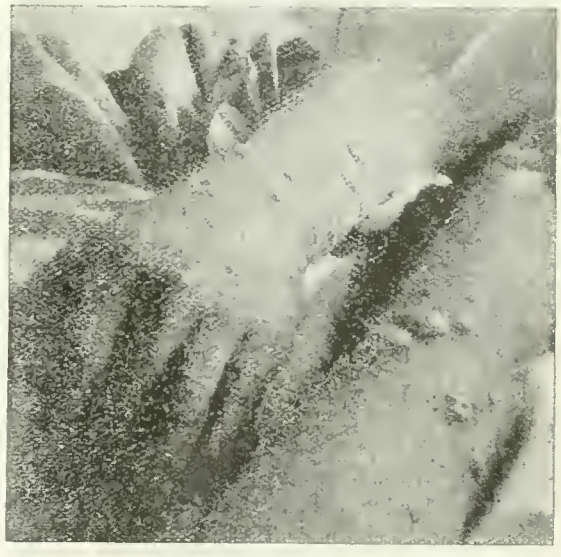
A SUSPECTED CASE OF FOOT AND MOUTH DISEASE IN MAN.

By VERNON WHITBY, M.B., M.R.C.S.,

LIEUTENANT, R.A.M.C.

Foot and mouth disease is so rare in man that the following case should be of interest.

The patient was a soldier aged 19, who gave no history of any previous illness. At Kilworth Camp, on March 17th, whilst carrying some boiling water, he fell and scalded his left wrist; later an open septic wound developed. On March 26th—that is, nine days after receipt of the injury—he became aware of burning sensation in the mouth and on his hands, quickly followed by the formation of blisters. He was admitted to hospital on the same day. On the following day his face was flushed and rather congested, the temperature was 101°, the pulse 100, the lips were swollen, and there was a marked vesicular eruption, rapidly becoming pustular, all over buccal mucous membrane. There was difficulty and pain on protrusion of the tongue, which was coated, and on which a few vesicles were seen. The breath was very fetid, salivation free, and the speech thick; the nasal and conjunctival mucous membranes were clear. There was a well-marked vesicular eruption on both forearms, wrists, and hands, extending between the fingers and to the sides of the nails; the palms were most affected; the feet were also implicated, but not to such a marked degree. The eruption was primarily vesicular; the vesicles varied in size from that of a mustard seed to a sixpenny piece, were situated on a hyperaemic base about one-eighth of an inch in width, showing no tendency to coalesce; they were larger on the forearms than elsewhere. They caused a burning sensation, and



were tender on pressure; no itching. The bowels were constipated; otherwise there were no other gastro-intestinal symptoms. The heart, lungs, and abdomen normal. All superficial reflexes were very brisk. During the next three days the rash became more pronounced; a few isolated vesicles appeared on the face, neck, abdomen, and thighs. The mouth was very sore, the vesicles having coalesced, ruptured, and given rise to shallow ulcers, with yellow sloughy bases, the mucous membrane of the lips had the appearance of one continuous yellow slough, the margins of the lips were crusty and dry; there was no excessive secretion of saliva. There was great difficulty in taking fluid nourishment, but no pain on swallowing. The vesicles on the extremities showed no tendency to pustulate, and there was no involvement of lymphatic glands. Serum from vesicles revealed no organisms; a few polymorphs were found. There was no leucocytosis; eosinophilia was present to the extent of 10 per cent. The urine was high coloured, acid, specific gravity 1027, cloud of albumin, no deposit, *nil* microscopically.

The temperature, which had remained at 101°, fell on the sixth day, to continue normal.

Convalescence was uneventful. The serum in the vesicles became absorbed, and the skin scaled, leaving faintly pigmented areas. The albuminuria disappeared.

The reasons for suspecting this case to be one of foot and mouth disease are:

1. The disease followed the course of an acute specific fever, its toxaemic origin is shown by the distribution of the rash, the presence of albumin in the urine, and the temperature.

2. It did not resemble the other hydroa.
3. There was an open wound on the wrist.
4. Foot and mouth disease was prevalent in the district.

It is interesting to note that a stray collie dog used to frequent the patient's hut for feeding purposes. I made inquiries about this dog, and heard that it had been drowned, because it was suffering from mange of the left ear, and was so thin and weak that it could hardly walk.

Specimens of serum from vesicles and saliva were sent to the laboratory at Millbank, where a rabbit and guinea-pig were inoculated with negative results.

A CLINICAL TEST FOR THE ESTIMATION OF THE PERCENTAGE OF GLUCOSE.

BY

G. C. PARNELL, M.R.C.S.,

CONSULTING SURGEON TO THE HOME AND INFIRMARY FOR SICK CHILDREN, LOWER SYDENHAM, S.E.

A QUICK method of estimating correctly or even approximately the percentage of sugar in urine in which it is found to be present by Fehling's test, whether in the consulting-room or at the bedside, is much to be desired. The precipitation of the suboxide of copper with Fehling's test is so apparent, whether a small or large quantity of glucose is present in the urine under examination, that it affords no guide to the estimation of the amount.

I hope to demonstrate that with Moore's test the colours resulting from boiling equal parts of diabetic urine with liquor potassae do vary in direct proportion to the amount of glucose that exists in samples under examination. Not having at my command a sufficient number of urines containing different proportions to verify this, it occurred to me to manufacture them by the addition of anhydrous glucose to samples of healthy urine; and while experimenting with these I found that, whether an equal proportion of glucose was added to healthy urine or to distilled water, and each boiled with equal parts of liquor potassae, the resultant colours were practically the same.

By making separate solutions of ½, 1, 2, 3, and 4 per cent., equivalent to 2, 5, 10, 14, and 19 grains per ounce, and boiling these with equal parts of liquor potassae, five test tubes were prepared, showing a constant and decided difference in the shades of colour. This result having been established, the next step was to ascertain if the colours, corresponding to different amounts in the prepared solutions, coincided with those urines in which the amount of glucose had been previously estimated by Pavy's test.

Through the kindness of Mr. C. H. Wells, of Dr. Adams, and the assistants at the Clinical Research Association in supplying me with many samples. I was able to confirm, after repeated experiments, that this was so. A further step was to obtain coloured glasses to correspond with these results, and Messrs. Powell and Sons, of Whitefriars, London, E.C., carefully produced these, the exact shades of the different solutions containing known amounts of glucose. Upon each glass, the size of a microscopic slide, is marked the percentage, the number of grains per ounce, and the number of parts per 1,000.

To obtain accurate results the amount of diabetic urine or manufactured solutions must be boiled with equal parts of liquor potassae; there must be no guesswork, and all that is required is an ordinary 2-drachm measure, or, better still, a pipette. Each sample must be thoroughly boiled, and this cannot be done without a holder for the test tube of some description. The test tubes should not be larger or smaller than ⅝ to ⅝ of an inch in diameter, and the liquor potassae should be fresh. It is not possible to mistake the difference of the shades in the alternate glasses between ½ per cent. to 4 per cent., as they are well marked. Between the colour produced by solutions containing 4 per cent. and 5 per cent. of glucose, although it is slightly deeper in the latter than in the former, an error might arise, so that if the colour produced in any sample of urine under examination should be darker than the 4 per cent. glass, some of the original urine should be diluted with equal parts of water and equal portions of this dilution and liquor potassae boiled. The resultant colour, when found to correspond with any of the test glasses, will give the percentage, the grains per ounce, or the parts per 1,000, multiplied by 2. Again, should the colour at this examination be found to be still deeper than that of the 4 per cent. glass, the following course should be pursued: Dilute the original urine with two parts of water, boil an amount with the same quantity of liquor potassae, compare the result with the test glasses, and when found to be similar multiply the amounts engraved upon the glass by 3. In like manner, with three dilutions, multiply by 4, and so on. As the correctness of these observations can be verified only by comparison with estimations made with Pavy's apparatus, it is necessary to point out that two or more observers very seldom arrive at the same conclusions in regard to any given sample of urine under examination, owing to the difficulty of noting identically the moment when the decoloration takes place. Even when the apparatus is all ready in a laboratory, and all the reagents fresh, errors may arise from bubbles of air remaining in the burette; from the dropping of its contents being too slow, whereby the boiling is too prolonged, causing the suboxide to fall, in consequence of the dissipation of the ammonia before the examination is complete; or from conducting the experiment in a bad light. How many further errors are likely to arise when analyses are made upon the few cases that occur in the course of an average year's work of a general practitioner! It is therefore unfair to criticize hastily the results of the colour tests by comparison with those obtained by Pavy's method, unless the latter is conducted by an analyst or by some one constantly using it.

I have no wish here to discuss the fallacies that may arise when Moore's test is used alone, as it might lead to the conclusion that the colour test is not reliable. I intend it to be purely a clinical one, not to take the place of Pavy's test, and only to be used after Fehling's test has demonstrated the reduction of the copper. With this evidence, especially if the patient's history points to some glycosuric condition, it is more than probable that glucose is the substance under consideration, and the colour test will then supply some important additional information. I trust it will be found to be of service to those in active practices by saving time—to the analyst by affording him information as to the amount of dilution he is likely to require before commencing an examination with Pavy's apparatus, and to the consultant by enabling him to obtain an approximate percentage of the amount of glucose present in the urine at the first examination of his patient.

I endeavoured to obtain differences in the shades of colours that would have represented smaller amounts than percentages, but so far I have not found them of practical use. By superimposing the ½ per cent. glass on the 1 per cent. glass a colour equal to 1½ per cent. of glucose is produced, and the ½ upon 2 per cent. equals 2½ per cent., but the ½ upon 3 gives no distinguishing colour. The 1 per cent. glass upon 2 does not produce the colour given by 3 per cent.

All the colours produced by boiling high or low percentages of saccharine urines with liquor potassae unfortunately become lighter in shade after remaining in the test tubes for a few days, and therefore cannot be permanently utilized.

It has been pointed out to me since this article was written that the idea of roughly estimating the percentage of glucose by the colours produced with Moore's test was suggested as long as thirty-four years ago. In Russell Reynolds's *System of Medicine* (vol. v, 1879, p. 369) Dr. (now Sir William) Gowers says:

> When a lemon-yellow tint is produced with this test, the urine contains about five grains of glucose to the ounce, ten grains give a light sherry tint, fifteen grains a dark sherry tint, and twenty grains or over a port wine colour.

On the same page it is mentioned that Dr. Meymott Tidy proposed to employ the test for quantitative analysis by means of a colour scale, but it is added that the method was not sufficiently accurate to be of use, except as affording a rough approximate indication of the amount of sugar present. Whether the method I have suggested, with the aid of the five coloured glasses, which correspond accurately to known amounts of glucose in prepared samples for comparison, will bring the colour test into a practicable form or not I must leave readers to decide. Should it do so, there can be no question of its simplicity when

compared with other methods of examination for the estimation of glucose in saccharine urines.

Appended for reference are given the parts per 1,000, and the percentages (grains by weight in 100 minims) corresponding to the number of grains per ounce (480 minims).

The former is calculated by dividing the number of grains per oz. by 0.4375. The latter by multiplying the number of grains per ounce by $\frac{1}{3}\frac{0}{8}$, a result of simple proportion.

The coloured test glasses in a pocket-case can be obtained from Messrs. Down Brothers, St. Thomas's Street, Borough, S.E.

Grains per oz.	Parts per 1,000.	Grains per 100 minims.	Grains per oz.	Parts per 1,000.	Grains per 100 minims.
1	2.28	0.208	11	25.14	2.29
2	4.57	0.416 (say $\frac{1}{2}$ p.c.)	12	27.40	2.50

A CASE OF CYCLOPIA.

BY

DANIEL DOUGAL, M.D.,

HONORARY ASSISTANT SURGEON FOR WOMEN, NORTHERN HOSPITAL; PATHOLOGIST, ST. MARY'S HOSPITALS, MANCHESTER.

AND

T. MILNES BRIDE, M.D.,

HONORARY ASSISTANT SURGEON, MANCHESTER ROYAL EYE HOSPITAL.

THE essential features of this malformation are the absence of a well-formed nose in its natural position, the presence of one orbit in the middle line of the face containing a single eye or one showing varying grades of duplicity, and defective development of the upper part of the face and anterior portion of the brain, these abnormalities being the result of incomplete development of the fronto-nasal process with approximation and fusion in the middle line of the two superior maxillary processes.

As regards the frequency of its occurrence, Hannover has collected 109 cases in the human subject, so that it may be regarded as a comparatively frequent type of monstrosity, although sufficiently rare to warrant the publication of any examples which may occur.

The mother of the case here reported was admitted to St. Mary's Hospitals in October, 1912, being then in the seventh month of her pregnancy, and suffering from ante-partum haemorrhage due to placenta praevia. She had previously given birth to eleven children, none of whom presented any abnormal features.

DESCRIPTION OF CYCLOPS.

The child, a male, was stillborn, and weighed 5½ lb. The head was proportionately large owing to the presence of well-marked hydrocephalus; in the centre of the face was a diamond-shaped opening, bounded above and below by the fused upper and lower lids respectively, and enclosing what appeared to be a single eyeball provided with two corneae. Immediately above this opening, and jutting forwards from the middle line, was a cylindrical projection, the proboscis, and running outwards from the base of the latter were two elevations, representing the eyebrows. Beneath the orbit was a deep sulcus running transversely across the face, whilst below this was the upper lip, devoid of any trace of philtrum, but otherwise well developed. The face showed no other abnormality, the ears and lower jaw being well formed.

The Eye.

This organ, contained in a single large orbit, was found to be composed of two globes fused together in the middle line and having a median groove above and below. All the extrinsic muscles were found to be present with the exception of the internal recti. On the anterior surface of either half of the globe was a complete cornea through which could be seen the iris enclosing a circular pupil, the portion of sclera separating the two corneae was covered with conjunctiva, whilst overlying the middle portion of this was a tough fibrous band half an inch in width and running from the proboscis above to the junction of the fused lids below. A horizontal section of the organ showed that the globes were complete units, and perfect in all component parts except at their juncture, where the sclerotic and choroid were found to be absent, that the retinae were thrown into folds not apparently due to mechanical detachment, and that the optic nerves were fused except at the point of expansion into the retinae, where there was some evidence of separation. As regards the lids, all four lacrymal papillae were present.

The Nasal Apparatus.

The proboscis was situated immediately above the orbit in the position of the glabella, and measured 1¼ in. in length by ¾ in. in breadth; in shape it was irregularly cylindrical, somewhat constricted at its proximal end and provided with a depression at its free extremity; in the floor of this depression was a small opening leading into a large central cavity lined with mucous membrane and containing a quantity of mucus. The proboscis was somewhat rigid from the presence of a cartilaginous plate beneath the floor of the cavity, and had a covering of skin resembling that of the face. This structure represents the soft parts of the nose, which are in an abnormal position from the approximation of the superior maxillary bones. The following bones normally connected with the structure of the nose were absent: the ethmoid, presphenoid, vomer, inferior turbinate, nasals, lacrymals, and premaxillae.

A mesial section through the skeleton of the face showed the palate bones fused together; in front of this the superior maxillae were separated by a thin membrane, deficient above and below, supposed to represent the nasal mucosa, while further forward they were firmly united to form the alveolar margin. The vault of the palate was narrow and not fissured, the soft palate and uvula were well developed, the latter being notched at its extremity, whilst behind was a rounded cul-de-sac, into which opened the Eustachian tubes. The upper jaw contained six tooth germs.

The Cranium and Brain.

The ossification of the cranium was not deficient, but the sutures were increased in width, owing to the hydrocephalic condition, the anterior fontanelle being much larger than normal. The anterior cranial fossa was very small, the middle fossa deep and narrow, and the posterior fossa well formed.

The brain was not sufficiently well preserved for a careful examination to be made, but there appeared to be a single hemisphere, which was flattened out by the large hydrocephalic sac situated above it; the convolutions and fissures were incompletely marked, and the falx cerebri absent.

No other malformations were found, the child being well developed with the exception of the abnormalities above described.

With regard to the type of cyclopia represented by this specimen, the presence of the proboscis places it in that designated by Saint-Hilaire "rhinocephalus," as distinct from the cyclocephalic type, in which this organ is absent.

A CASE OF LEFT DUODENAL HERNIA IN A CHILD.

By FREDERICK C. PYBUS, M.S., F.R.C.S.,
SURGEON TO THE HOSPITAL FOR SICK CHILDREN, NEWCASTLE-ON-TYNE, ETC.

Cases of duodenal hernia are sufficiently rare to warrant the publication of individual examples. Some idea of their frequency can be gained from Barnard's[1] figures. Out of the 669 cases of intestinal obstruction occurring during thirteen years at the London Hospital, 13 were due to internal herniae, and of these 2 were the result of hernia into the duodenal fossae.

The fossa into which this hernia occurred corresponds to the paraduodenal, as described originally by Landzert. Of the peritoneal fossae in this region, Moynihan[2] insists that the paraduodenal is the only one capable of forming a hernial sac. There is still considerable confusion in the nomenclature of these fossae, and this type of hernia is frequently alluded to as the duodeno-jejunal.

The paraduodenal fossa lies to the left side of the spine, and to the left side of the ascending part of the third portion of the duodenum, which forms the inner border of its orifice. The remainder of the orifice is bounded above, below, and on the outer side by a fold of peritoneum containing the inferior mesenteric vein. The left colic artery lies in the peritoneum of the anterior wall. The sac extends towards the left, and lies behind the descending mesocolon.

The anatomy of the sac in the case described below corresponds exactly with this description. So far as I have been able to gather from a perusal of the cases it is the first in which a portion of the large intestine formed part of the contents of the sac.

The patient had been ill five days when I saw him, and being the child of poor parents attempts had been made to get him admitted to a general hospital, children's hospital, and fever hospital without success, either on account of these institutions being full or their having no accommodation for dealing with such a case. It is, perhaps, fortunate that the condition was not one of urgent strangulation, or the result might have been very different.

Dr. Maclean of Ashington has kindly written me a history of the case, which is as follows:

Note by Dr. Maclean.

E. T., male, aged 5 years, developed scarlet fever on December 15th, 1913. He did well until the evening of December 25th, when he complained of abdominal pain, which was then considered due to the eating of a banana. On Friday morning, December 26th, I saw him. His temperature and pulse were normal; the pain resembled colic. On abdominal examination there seemed a resistence and fullness on the left side. The bowels had not been moved for two days, and castor oil was prescribed. I had a suspicion that there might be an intussusception, and asked my locumtenent, Dr. McKenzie, to see him in the evening, and he reported him better, though the bowels had not moved. Next morning (December 27th) Dr. McKenzie again saw him, and found a definite mass in the left flank. We both examined the boy in the afternoon, and diagnosed an intussusception.

On account of the boy having scarlet fever we could not get him admitted to hospital, and tried soap and water enemas and large injections of water, without benefit.

On December 28th the temperature was normal, pulse rather rapid, sickness was stopped, no blood had been passed per rectum, and nothing abnormal could be felt per rectum, but the mass in the abdomen could be easily palpated. On December 29th Mr. Pybus operated at the boy's home, and on opening the abdomen found a large internal hernia. Peeling commenced a few days after the operation. The boy has made a splendid recovery, and is now running about the streets.

Operation by Mr. Pybus.

When I saw the patient on December 29th, 1913, there was no fever, the pulse was 104, the tongue was furred but moist, and there was a decided acetone smell in the breath. The child was peevish and restless, but when asked where the pain was the hand was passed over the epigastrium. The abdomen was slightly distended, and a mass was found on the left side. Rectal examination was negative.

Under the anaesthetic distended coils of small intestine could be seen in the right side of the abdomen. There was a rounded visible swelling on the left side of the abdomen about the size of an ostrich egg, situated to the left and chiefly below the level of the umbilicus. The lump was tense, slightly movable, and resonant on percussion. The left loin was free of any swelling.

I opened the abdomen in the middle line below the umbilicus. Some clear fluid escaped from the peritoneum. The first noticeable point was the small amount of small intestine present; this was limited to the right side of the abdomen and pelvis. The intestine itself was congested and slightly distended. On drawing the intestine aside the mass was seen covered by peritoneum, in which could be seen the left colic artery. The swelling appeared to contain intestine. No collapsed intestine could be found, so a coil of small intestine was traced upwards and the appendix was seen projecting from the mouth of a retroperitoneal sac. By means of traction on this part combined with pressure on the sac the contents were reduced with ease; they were congested but not damaged. The reduced intestine consisted of the caecum, part of the ascending colon and a considerable amount of small intestine, probably most of the ileum. The caecum, ascending colon, and termination of the ileum had a long mesentery.

The orifice of the sac was situated to the left side of the duodeno-jejunal flexure, and this intestine formed its inner margin. It was bounded elsewhere by a fold of peritoneum, which was thick at its free edge. Although the contents of this edge could not be definitely seen, the inferior mesenteric vein could be traced up to it. The orifice was oval in shape, the longer diameter being 2 in. and in the vertical direction; the transverse diameter was about 1½ in. Three fingers could be inserted into the aperture, which looked towards the right side. The sac was limited to the left side of the spine, and extended outwards towards the descending colon, upwards to the kidney, and downwards, in a longer direction, to the left iliac fossa, the left colic vessels being seen in its anterior wall.

In order to prevent recurrence I thought of attempting to drag out the sac and remove it, but as this might have proved a long undertaking I obliterated the orifice by suturing the free edge to the side of the duodenum by interrupted catgut sutures. Some saline was introduced into the peritoneum, and the abdomen closed.

The scarlet fever seemed to have no ill effect on the course of the recovery. The anatomical details were investigated as far as possible, and I noted the absence of at least the superior and inferior duodenal fossae at the side of the duodenum. The large size of the orifice accounted for the absence of any strangulation, although there was complete obstruction, brought about possibly by the terminal entrance of the caecum and ascending colon. There was no sharp colic accompanied by crying and curling up, such as is frequently seen in children suffering from intestinal obstruction. A diagnosis of duodenal hernia was not made before operation, although on exploration the condition was immediately recognized. The absence of blood or mucus contraindicated intussusception, and our diagnosis was intestinal obstruction, due to adhesions over a tuberculous focus covered by resonant intestine.

REDUCTION OF OLD ELBOW DISLOCATION BY OPERATION.

By FRED. D. BIRD, M.S., Hon. F.R.C.S.,
LECTURER ON SURGERY, MELBOURNE UNIVERSITY.

It is seldom that a dislocated elbow is left unreduced long enough to negative reduction by manual means. When, however, operation is necessary, the following measures which I practised recently on a dislocation three months old seem to me adequate to produce a good result.

A rounded flap is turned down, as in the operation for suturing or plating an ordinary fractured olecranon, which fracture is then achieved by the very large cutting forceps used by veterinary surgeons to split down a horse's molar tooth, previous to extracting it in two parts. Care is taken that the bite of the forceps does not invade the integrity of the shaft of the ulna; the section, which with this very powerful forceps is a clean one, is made a very little above the junction of the olecranon with the shaft. Some freeing of the lateral tissues allows of the turning up of the olecranon process. The joint is not seen now, as it would be in a recent fracture, because there is a large amount of adventitious tissue in the enlarged joint area. This material is very dense—dense enough to throw a not unimportant shadow on the skiagram, as I have several times observed, and requires cutting with a knife for its removal, after which the back part of the trochlear surface of the humerus can be seen. The large lever devised by Lane for use in plating the thigh bone is now inserted with its point beneath the trochlea. This, with manipulation of the forearm, exercises leverage sufficient to replace

the end of the humerus in its normal position as regards the forearm bones, flexion and extension being impressed on the joint to see that everything is free. Before reduction is accomplished a slight use of the knife or scissors on the lateral tissues may be requisite. When it is accomplished, the olecranon fragment is turned down into position and secured there by a wire or plate; if by the former a drill-hole has been made in it before section of the bone. Several sutures are used in the lateral expansions of the triceps tendon, the skin edges iodined and coapted.

In four days a single passive motion of flexion and extension is made and again at the end of the week; a splint is necessary only if there be much pain after the operation.

The result in the case mentioned, that of a healthy middle-aged woman admitted under my care at the Melbourne Hospital, though not perfect was excellent. The disability beforehand was very great and no traction had any effect upon the position of the bones. It was only at operation that one could realize what a solid mass preventing replacement the new tissue provided. The maxim learnt was that traction could only do harm and had no chance of consummating reduction.

NAPHTHALENE FOR THE DESTRUCTION OF MOSQUITOS IN COVERED CISTERNS AND WELLS.

By A. W. BACOT, F.E.S.,
ENTOMOLOGIST TO THE LISTER INSTITUTE.

WHILE the following experiments are admittedly of a slight and tentative character, the results appear of sufficient general interest and importance to warrant their publication, in the hope that workers abroad, where experiments on a practical scale are possible, may be induced to try naphthalene as a deterrent to the breeding of mosquitos. For any exposed water surface oil as at present used would certainly be more effective, but in such windless situations as wells and covered cisterns naphthalene has an obvious advantage owing to its slow evaporation and the fact that the vapour is fatal to the adults, which are apt to seek cover in such situations.

Flake naphthalene sprinkled on the water surface as used in these experiments imparts a slight flavour to the water; but if no contact takes place, and it is suspended above the water surface, this defect is obviated. Lack of opportunity to continue the experiments has prevented my thoroughly testing its effectiveness as a larvicide when used under these conditions, but I am of opinion that further experiments would yield a satisfactory method for its application.

The experiments with the adult insects, while they certainly point to the prevention of any breeding in closed cisterns, also afford hope that such species as *Stegomyia fasciata* might be prevented from taking up their quarters in the quiet nooks and corners within doors that they are stated to seek out for tenancy.

Experiments with Adult Culex pipiens.

Method.—Half-pint waxed-card cream jars of 330 c.cm. capacity were prepared by placing discs of wet blotting paper at the bottom; on this the flake naphthalene was scattered; the mosquitos were introduced and the jars, covered with mosquito netting, placed on the laboratory bench. The temperature during the trials was about 63° to 66° F.

No. 1.—Ten adult *Culex pipiens* put into each of two jars prepared as above; in one 1 gram of naphthalene was scattered (1 in 330).

Control:

1½ hrs.	All living.
9 hrs.	All living.
20 hrs.	All living.
68 hrs.	2 dead.

Test Jar:

1½ hrs.	3 dead or stupefied.
5 hrs.	9 " "
20 hrs.	All dead or stupefied.

No. 2.—In the second test difficulty was experienced in getting equal numbers into each jar, and tests were made with 0.5 gram, 0.2 gram, 0.1 gram.

	Control.	Using 0.5 gram = 1 in 660.	Using 0.2 gram = 1 in 1,650.	Using 0.1 gram = 1 in 3,300.
2 hrs. ...	All living	3 down; 4 living	All living	All living
3 hrs. ...	All living	4 down; 3 living	All living	1 dead
17 hrs. ...	All living	All dead	All dead or dying	All dead or dying
42 hrs. ...	All living	—	—	—
66 hrs. ...	1 dead; 6 living	—	—	—

No. 3.

	Control.	Using 0.05 gram = 1 in 6,600.	Using 0.02 gram = 1 in 16,500.	Using 0.01 gram = 1 in 33,000.
18 hrs. ...	All living	All dead	All down; 3 capable of feeble movement	1 dead; 3 down, but capable of feeble movement
43 hrs. ...	All living	—	—	—
63 hrs. ...	All living	—	—	—

Experiments with Larvae.

Method.—Into each of two square-bottomed troughs, having a surface area of 72½ in. (462 cm.), 4 litres of strained rain water was poured.

1. 100 active larvae (86 in penultimate and 14 in final larval instar) were then added.

On the surface of one 1 gram of flake naphthalene was added (1 in 462 surface area). Both troughs were covered with mosquito netting stretching over a wooden frame that raised the walls of the receptacles to 6 in. above the water surface. Both troughs were then placed on the laboratory bench close to the window. Temperature from 65° to 67° F. Within twenty-four hours all the larvae were dead in the trough which had the naphthalene scattered in it. *Result, all killed.* None were dead in the control trough, and the larvae developed satisfactorily.

2. The experiment was repeated with 90 small and 10 large larvae in each jar, only 0.5 gram of naphthalene being used=1 in 924 surface area. Temperature 60° F. After twenty-four hours only a few of the large larvae remained active. After twenty-seven hours all were dead in the test trough. *Result, all killed.* The larvae in the control were all living and most of them developed to the pupa stage.

3. The experiment was again repeated with 16 large and 84 small larvae in each trough, only 0.2 gram of naphthalene being used—1 in 310 surface area. Temperature 60° to 65° F. After twenty hours a large number had ceased to move in the test trough, but a few survived after seventy-two hours, when the naphthalene had all evaporated. *Result,* all the small and some of the large larvae killed—10 or 12 per cent. survived.

Pure naphthalene can be obtained from wholesale chemists for 3d. per lb. for quantities of 14 lb. or over. In bulk it may be obtained direct from the gas companies.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

THE ETIOLOGY OF TYPHUS FEVER.

(Preliminary Note.)

WE wish briefly to record the results of our examination of the blood and urine in 25 cases of typhus fever during a recent outbreak in Belfast, as well as of the cerebro-spinal fluid.

The urines, many of which were catheter specimens collected by a special method to exclude air contamination, were examined when fresh, and also after incubation for twelve hours. In all of them we found before the crisis a minute organism which we believe has not yet been described. It was also found in the lysed deposit of the fresh blood taken by venupuncture before the crisis, in the cerebro-spinal fluid, and again in the fresh urine of five bonnet monkeys in whom after the lapse of a well-marked incubation period we had induced a continued fever by inoculation of human typhus blood collected before the crisis. It disappeared from the urine of the injected monkeys after their fever had subsided.

The organism in question appears to be pleomorphic, being cocco-bacillary in form, and we shall in future refer to it as a cocco-bacillus. In fresh specimens it varies between 0.25 μ and 0.6 μ in its greatest diameter, and in its smaller forms passes through carefully tested Berkefeld filters. It is both Gram-*positive* and Gram-*negative* in the

same preparations. The smallest forms are almost impossible to recognize with the ordinary 1/12 oil immersion lens, but are well seen with a 1.5 mm. apochromatic.

We also find in the fresh blood and urine of both man and monkeys when infected, as well as in their incubated blood and urine, an exactly similar, though much larger, pleomorphic organism, which is also cocco-bacillary. This grows well on the ordinary laboratory media, and appears, in its different phases, to be identical with the large coccal and bacillary organisms individually and independently described by Dubieff and Bruhl, by Wilson of Belfast (who recognized their secondary importance), by Fuerth, by Müller, by Marcus Rabinowitsch, by Predtjetschensky, and by Plotz. On injection of these organisms into monkeys we could produce no fever or other pathogenic effects.

We wish to express our cordial thanks to Sir Thomas Stafford, Bart., who as Medical Commissioner of the Local Government Board in Dublin kindly invited our investigations, and put us into touch with Dr. O'Brien, Local Government Inspector in Belfast. To the latter and to Dr. G. Robb, Medical Superintendent of the Fever Hospital at Purdysburn, as well as to Dr. W. J. Wilson, Queen's University, and to Professor Symmers, Professor of Pathology, we wish to express our gratitude for their generous help and advice. Full details of the morphology, cultural characteristics, serological, inoculation, and sugar reactions of the cocco-bacillus, which is the subject of this note, will be published shortly.

ANTE-PARTUM HAEMORRHAGE.

MRS. F., aged 29, 4-para, a thin, anaemic woman, seven months pregnant, had been working rather hard cleaning and lifting during April 11th. She suddenly felt "something snap," and found she had a severe loss. She sent for the midwife, who immediately sent for me. I arrived about 10 p.m., to find the woman in bed fairly comfortable. She had had rather severe haemorrhage, and liquor amnii also had escaped. Everything appeared normal; the vertex was felt, the os was the size of a shilling, and there was no sign of placenta. I enjoined rest and watching. On visiting her next morning, I found she had just had another flooding. She was now obviously in labour, but pains were very weak and there was a loss with each; the os was the size of a florin.

As waiting appeared risky, I decided to deliver at once. My neighbour, Dr. Galletly of Northwold, gave an anaesthetic. I had no difficulty in dilating the os with my fingers, and turning was quite easy. There was smart haemorrhage after the child was born, and I therefore proceeded to remove the placenta. This was nearly torn through at the upper part, leaving a piece attached to the fundus. This was peeled off with some difficulty and the whole removed. The uterus contracted well, and the woman made an excellent recovery, considering the severe flooding she had had, only requiring quinine for the headache usual in such cases.

It was a matter for congratulation that the membranes ruptured when haemorrhage took place, otherwise the case might have had a very different aspect and termination.

Feltwell, Brandon, Norfolk.

CONGENITAL SYPHILIS TREATED BY NEO-SALVARSAN.

THE patient was a child, aged 13 years, one of a family of four children. The father had had syphilis. The mother had had no miscarriages; all the other children were healthy. The patient at the age of 7 years lost her sight owing to interstitial keratitis. She was treated at a hospital, and recovered after six months. She is now able to see very well. Both legs became ulcerated at this time, and the condition grew much worse until eight months ago, when both tibiae were exposed and eroded. The patient was treated from that date with mercury and potassium iodide and by fomentations locally. The condition improved. On May 1st she was given an injection of neo-salvarsan and two more were given within a fortnight. On June 23rd both legs had almost completely healed, and the child's health was much improved.

British Medical Association.

CLINICAL AND SCIENTIFIC PROCEEDINGS.

NORTH LANCASHIRE AND SOUTH WESTMORLAND BRANCH.

AT the annual meeting of the Branch, held at Lancaster, on June 24th, Mr. A. S. BARLING, the new President, opened a discussion on operations for the cure of hernia. He said that from the very birth of surgery these operations had been performed, but for present purposes it was only necessary to go back to the time of Zutzer, who in 1838 introduced a plug of the scrotum into the canal. In 1861 John Wood, of King's College, brought to notice a new method. He reduced the hernia, and then by means of a wire applied in a particular way, hauled up the sac into the canal and fixed it there. This was the first operation to give anything like a good result, and was the means of many cures. It held its place for many years as the standard treatment. So far surgeons had acted on the principle that a plug should be formed in the canal. Wood (of Shrewsbury) made one of the first steps in the right direction. He invaginated the unopened sac within the abdomen and fixed it there. This was just prior to the great revolution in surgery. Down to this time operators were crippled by their fear of wounding the peritoneum. These fears were shortly to be banished, and in 1871 Lister excised the sac, refreshed the edges of the wound, and closed it with catgut stitches. This was often erroneously referred to as Banks's operation. The work of Czerny, Risel, Annandale, Ball, and McBurney was reviewed, and then the more modern operations of Macewen, Barker, Bassini, Halstead, Kocher, and O'Hara were taken in detail and their merits contrasted. The recent advocacy of the use of silver filigree was criticized, and it was pointed out that it had been used by Phelps so long ago as 1895. The speaker concluded by saying that several of the later operations were quite satisfactory, but expressed his own preference for those in which the sac is severed above its neck and the stump fixed well away from the internal ring. That which he usually adopted was Bassini's with the addition of O'Hara's stitch.

Exhibits.—Dr. COUPLAND gave a very interesting demonstration from slides, specimens, and dissections. He began by demonstrating the atrio-ventricular band of His in the heart of a calf, and explained its importance in heart-block, mentioning that recent work had shown the presence of nerve fibrils, so that its real function was still in dispute. His next subject was an exhibit of specimens, photographs, etc., of the *Simulium* fly, which it had been suggested was connected with the occurrence of pellagra. Specimens of *Simulium venustrum*, kindly sent by Professor Howard (U.S.A.), were among those shown. A mounted slide of the biting field fly, *Stomoxys calcitrans*, drew attention to the more recent opinion that it is really the carrier of the pellagra infection. Chromatolysin in cells of the spinal cord was illustrated from a fatal case of pellagra, and the Golgi method of displacing nerve structure was shown in the brain of a kitten. A racy discourse followed on the subject of fleas, attention being drawn to the plague flea, and the position of hairs on the leg, which character differentiates the human flea from all others. Some remarks on two slides illustrating *Spirochaeta pallida* were followed by specimens of the beetle *Xestobium tessalatum*, responsible for serious damage to the timber in the Westminster Hall. Members regretted that such an interesting amount of material had to be disposed of in something like fifteen minutes. Dr. ALEXANDER, the PRESIDENT, the TREASURER, and the HONORARY SECRETARY showed cases, specimens, and radiograms.

Reviews.

THE ORIGIN AND PREVENTION OF TUBERCULOSIS.

A COMBINED attack by all the civilized communities of the world should result in victory, but in dealing with such a secretive enemy as tuberculosis even such powerful forces may find themselves baffled or even vainly exhausted. The means which by common consent are being used to check the spread of the disease cannot be said to have achieved results as yet which are in any way commensurate with the amount of labour, time, and money that have been expended. Death-rates have been lowered and incipient cases have been arrested, but the disease goes on, especially amongst the young. Although much is known about the initial stages in childhood, there is evidently much more to know, and careful and repeated study is still as necessary as ever in order that this further knowledge may be gained. A careful investigation carried on by Dr. BACMEISTER[1] of Freiburg into the various means by which pulmonary consumption may be set up in the human subject renders it only too evident that a vast amount of trustworthy evidence is still wanting before these conditions can be satisfactorily explained. That the human type of bacillus is by far the most frequent exciting agent must be generally recognized, but the routes by which it may gain access to the apex of the lung are many. Dr. Bacmeister has paid special attention to the question of conveyance of bacilli by the blood and lymph streams, and, in spite of the more obvious route by way of the bronchi, has satisfied himself as to the possibility of infection of the apex by tubercle entering the body by any route. With regard to the relative frequency of one or another channel of entry, he can find no trustworthy evidence. A certain degree of immunity produced by infection in childhood with either form of bacillus is undoubtedly to be recognized, but does not appear to be proof against a direct infection of a fresh strain from without in later years.

The question of limitation to one or both lungs for long periods is not as yet satisfactorily answered. If the disease in them is set up by direct inhalation, it follows that a vast number of persons must inhale such infected air without harm, many of them having proved themselves to be suitable hosts for the bacillus in their earlier years. Something more than local infection has to be assumed, and the discovery of the true nature of that something may do much to bring about a more successful campaign than has as yet been undertaken.

Dr. Bacmeister's monograph will be found to be full of thoughtful suggestion, and a very full bibliography has been drawn upon in the course of his work. Chief among the agencies for checking the spread of tuberculosis stands the education of the public, without whose intelligent co-operation the efforts of individuals must be in vain. The travelling lecturer in his caravan can tell the story in the villages, but the greater danger lies in the towns, and it is to the educated town-dweller that we must look to spread the necessary knowledge by example and precept. Under the title of *The Great White Plague*,[2] Dr. E. O. OTIS, of Boston, published, some five years ago, a full account of tuberculosis for the special enlightenment of laymen. He has recently issued it under another title, with such alterations and additions as have become necessary as the result of increased experience. Writing essentially for the guidance of the public, he has adopted a somewhat more positive tone than would be appropriate in addressing medical readers. His book presents a very full and complete account of the present state of the case against tuberculosis, and many dogmatic assertions may be allowed to remain as such until displaced by knowledge founded upon a firmer basis. The disease has carried off too many a shining light from the worlds of poetry, music, and medicine, and the loss of these cannot be expressed in material terms, but the yearly cost to the communities in every busy centre of commerce can be estimated in actual figures, which reach an appalling amount when the wasted expenses of education and preparation for a life's work come to be considered. The susceptibility of children and young adults is universally recognized, but preventive measures do not seem to be pursued with equal vigour in all countries. The many and varied agencies now at work in this direction in the United States cannot fail to make an impression upon the spread of the disease in years to come, and it is greatly to be desired that similar activity should be shown in this country to meet so well known a requirement. Even the most elementary forms of treatment by sunlight and fresh air are not yet understood in the homes of the poorer town-dwellers. The dread of draughts and the imaginary evils of night air render many of our crowded tenements more suitable for the growth of pathogenic organisms than of human beings. Dr. Otis's work takes cognizance of every detail of the subject, and contains a vast amount of practical information upon all the rules for treating, and the means for combating, the presence of tuberculosis. The need for segregation or control of the advanced case is daily becoming more and more realized. No real progress can be made in the general arrest of the progress of consumption so long as the seeds of the disease are permitted to be scattered broadcast.

OPHTHALMOLOGY.

DR. CURT ADAM has prepared a third edition of a pocket-book of ophthalmology[3] for German students and general practitioners. He assumes that those for whom it is written find the use of the ophthalmoscope very difficult, and in consequence he does not explain its management, and the volume contains little about diseases of the fundus. Two methods of examination are described and recommended—focal illumination and examination with the loup, and illumination of the media with a concave mirror. We cannot help feeling that Dr. Adam has under-estimated the powers of the student and general practitioner; there is nothing inherently difficult in the use of the ophthalmoscope, especially by the indirect method, and with a little practice any man of ordinary ability can acquire sufficient proficiency to diagnose gross changes in the fundus—such conditions, for example, as optic neuritis, optic atrophy, albuminuric retinitis, disseminated choroiditis, and massive haemorrhages. It seems, therefore, a pity that Dr. Adam has not included simple ophthalmoscopy among his subjects. Again, refraction is treated apart from retinoscopy; but modern refraction work is based upon accurate retinoscopy, and a man who cannot master retinoscopy both with and without a dilated pupil will be well advised to leave refraction alone. These are the only criticisms we have to make upon an otherwise excellent book. The subject is treated in a well-balanced manner. Modern methods are described, and the chaff is ruthlessly separated from the wheat. The first portion of the book deals with examination by focal illumination and with a concave mirror, and then with general methods of treatment. The uses and contraindications of the drugs used in ophthalmology are clearly explained. A consideration of the Wassermann reaction is followed by directions for injecting salvarsan. Curiously enough, neo-salvarsan is not mentioned. Radium receives full consideration, and a chapter is devoted to anaesthesia. The dangers of general anaesthesia are, we think, exaggerated, and while we agree that chloroform should be entirely banished from ophthalmology, ether skilfully administered is a useful and safe anaesthetic. The special division of the book deals with the various diseases of the eye, and most careful directions are given for differentiating iritis from glaucoma and from conjunctivitis. Perhaps too much weight is attached to the fact that the pupil is generally dilated in glaucoma, and enough stress is not laid upon the presence of keratitis punctata in cases of iridocyclitis. The final chapters are devoted to accidents to the eye and to the important question of compensation. Considerable space is given to the visual acuity demanded for the

[3] *Taschenbuch der Augenheilkunde für Aerzte und Studierende.* Von Dr. Curt Adam. Third edition. Berlin and Wien: Urban and Schwarzenberg. 1914. (Cr. 8vo, pp. 303; 71 figures; 5 plates. Bound, Mk. 8.)

various branches of military service in both the German and Austrian armies. Finally the author gives a list of useful prescriptions.

DR. GUIRAL'S short essay[4] on the diagnosis of trachoma, spring catarrh, and of follicular conjunctivitis is devoted to one of the most difficult subjects in ophthalmology—the differential diagnosis of trachoma from other forms of chronic conjunctivitis which resemble it closely. He gives a short account—too short to be really valuable—of the clinical appearances of each disease, followed by a description of the microscopic anatomy of the lesions characteristic of each. The histology is depicted in thirty-five plates of photomicrographs, and another plate is devoted to drawings of the naked eye lesions. The drawings are exceedingly poor; the photographs are good, but a photomicrograph is generally unsatisfactory if the magnification is great. Good drawings, though more expensive, are much more effective. We note with surprise that the presence of large numbers of eosinophile cells in the blood, in the secretion from the lids, and in the tissues of an eye suffering from spring catarrh receives no mention, although it has a great diagnostic value; in fact, in a doubtful case, it is the most important factor in diagnosis. No mention is made of the association of trachoma and spring catarrh, which is common in Egypt and the near East. It is in such cases that diagnosis is really difficult. Few ophthalmologists now recognize follicular conjunctivitis as a distinct clinical entity, but regard it rather as a condition produced by a variety of causes, such as infection with the Morax-Axenfeld bacillus, struma, atropine, and other sources of irritation. A chronic strumous conjunctivitis associated with pannus may simulate trachoma so closely that the diagnosis can only be made with certainty by watching the result of treatment. The author lays no stress upon this difficulty. The book is really a reprint of an address to a conference of the Havannah Society for Clinical Study, and no doubt served as a useful opening to a discussion; but apart from this it has little value, and contains nothing that cannot be found in a good textbook.

The second edition of *Ophthalmic Surgery*[5] by CHARLES H. BEARD, of Chicago, is very little larger than its predecessor published in 1910, although, as the author states, it contains 33 per cent. more text and an addition of eighty illustrations. Chapters on the newer operations for glaucoma and the surgical treatment of detachment of the retina have been added to this edition. When dealing with the lacrymal sac the operations of Harrison Butler and Toti are given in detail. Each department of ophthalmic surgery is considered in all its aspects from a surgical point of view. Some of the operations are distinctly novel. Take, for instance, the vacuum fixation of the lens and flap suture in the operation for removal of the lens in its capsule. This operation was introduced by Hulen of Houston, Texas. The essential features are the insertion of a suture into the conjunctival flap previous to the removal of the lens, and the introduction into the anterior chamber of a pipe which is connected with a vacuum bottle. The lens is, by means of a vacuum, held rigidly in the orifice of the pipe, as in the sucker of an octopus. The lens is then rotated so as to tear the suspensory ligament, and then it is supposed to come away, capsule and all, but it might be imagined that such a procedure would be fraught with the greatest danger to the eye. Considerable attention is devoted to the removal of foreign bodies from the eye and also to their localization. The illustrations, which are in many instances reproductions of photographs, complete the book, which is thorough, and will be of great use as a work of reference in looking up details of operations.

The third edition of *Modern Ophthalmology*,[6] by DR. JAMES M. BALL, of St. Louis, is a very large and heavy book of over 900 pages, and is now published in a single volume instead of two volumes, as was the case at least with the first edition, which appeared ten years ago. The first chapter is on the embryology, anatomy, and physiology of the eye; then the theory of the ophthalmoscope is discussed, and the various methods used in the examination of the eye are explained. After this diseases are discussed. The author still has an obvious affection for the use of probes and styles in the treatment of diseases of the lacrymal apparatus, but he also gives a description of the operation for the removal of the sac. Many coloured plates and black-and-white drawings illustrate diseases of the conjunctiva, and one plate is devoted to the ordinary conjunctival micro-organisms. There is a very good drawing of the microscopic appearance of the cornea in a state of interstitial keratitis, but the two showing the notched and peg-shaped teeth are diagrammatic to a degree, and look like an illustration of the jaws of a rat-trap. The description of the operation of needling a lamellar cataract is out of date. The needle is pushed through the cornea instead of at the extreme periphery; the incision in the capsule is made quite small instead of as large as possible, for it is said to be "far safer to repeat the operation several times at intervals of a month or more than to make too extensive an opening at one time." Most cataracts in young people will have entirely disappeared in about a month or six weeks if an extensive opening be made without even letting the lens out, while the amblyopia from disuse which is bound to occur in a young child as the result of keeping the eye blind for months is a thing which has to be seriously reckoned with. In speaking of the results of cataract extraction we should imagine that most modern surgeons would strongly object to class their results as the author does, who considers that vision of $\frac{2}{200}$ ($\frac{6}{6}$) or better to be good results, $\frac{1}{200}$ to $\frac{1}{200}$ ($\frac{1}{6}$ to $\frac{5}{6}$) as moderate results, while eyes retaining only perception of light, are classed with those which have none, as failures. Tobacco amblyopia and other toxic amblyopias receive but scant treatment. The author is greatly opposed to the continous use of myotics in glaucoma and considers that all patients should be given the benefit of operation. Iridectomy is the operation which is advised, and he is evidently not much in favour of scleral trephining, for when discussing the treatment of haemorrhagic glaucoma he states that "such questionable procedures as paracentesis of the cornea, scleral trephining, and stretching of the external nasal nerve are out of place." There cannot be many surgeons at the present time who would class these three methods together and consider them all equally inefficacious. He does, however, state that "Elliot's operation seems to possess distinct advantages over other methods of trephining." The references to colour blindness are out of date. Most of the illustrations are excellent, but some are distinctly below the average, and the same might be said of the text, which varies considerably. For such a large book it is curious that it should be so scrappy in parts while other sections are unduly long. Owing to want of time on the part of the author several well-known ophthalmologists have written special chapters and have assisted in the writing and revising of other parts.

DISEASES OF CHILDREN.

DR. JOHN LOVAT MORSE'S *Case-Histories in Paediatrics*[7] may be read with very great interest and pleasure. He describes it as "a collection of histories of actual patients selected to illustrate the diagnosis, prognosis, and treatment of the diseases of infancy and childhood, with an introductory section on the normal development and physical examination of infants and children." Each case is considered fully, and occupies about two or three pages upon an average. In the first place a short history is given, and then an accurate account of the findings, both negative and positive, of the physical examination. To this succeeds a discussion of the differential diagnosis, and a few remarks upon prognosis. Lastly, the treatment is fully described. This order has the great advantage that the reader first encounters a description of the case as

Moores Ball, M.D., LL.D., Dean and Professor of Ophthalmology, the American Medical College of St. Louis. Third edition, revised and enlarged. Philadelphia: F. A. Davies Co. London: Stanley Philips. 1913. (Sup. roy. 8vo, pp. 936; 24 plates; 445 figures in the text. 31s. 6d. net.)

[7] *Case-Histories in Pediatrics.* By J. L. Morse, A.M., M.D. Second edition. Boston: W. M. Leonard. 1913. (Roy. 8vo, pp. 639; illustrated. 5.50 dollars.)

it presents itself for diagnosis, and enjoys the mental exercise of himself deciding upon the probabilities before he arrives at the author's own conclusion. Two hundred actual cases are so described, and among them are found examples of nearly all maladies of childhood, common and rare, which are likely to be found in a lifetime of practice. No doubt the cases will sometimes appear to have an unnatural crispness and simplicity. It is impossible in such a work to catch all the indefinable elements of doubt and uncertainty which exist in actual practice. No doubt, too, in actual practice we must not hope to achieve in 200 cases such a series of 200 successful diagnoses as is presented in the text. For example, we shall not often find the explanation of persistent constipation and malnutrition in the accidental substitution of gravity cream for 10 per cent. top milk (p. 193). Nevertheless, the book is one of value to the student of children's disease, and a great variety of valuable information is presented in a novel and entertaining form.

In his book, *Leitfaden der Säuglingskrankheiten*,[8] Dr. WALTER BIRK of the University of Kiel has put together in short compass an account of the present teaching on infantile disorders in Germany. As is natural and right in a book upon the maladies of the first year of life, the disorders of digestion and nutrition occupy the first place. In describing these the author follows closely the teaching of Czerny, in whose clinic he was formerly chiefly assistant. The part played by overfeeding in infancy, and especially the ill effects of excess of fat in predisposed infants, as might be expected, are strongly emphasized, and a good description of the "exudative diathesis" of Czerny is given. The infective disorders of early infancy are also dealt with clearly and fully. The purpose of the book is entirely practical. In consequence the discussion of the symptomatology and the therapeutics of the various disorders is accorded most space, while theoretical considerations are only dealt with in so far as they are necessary to a proper understanding of the conditions. The author has done his work well, and has compressed into a comparatively short book all that is practically most useful in the great advances which have been made since the century began in the knowledge of the nature of the common complaints of the newly-born and of infants throughout the first year of life. To read this book is to realize how recent and yet how great is our knowledge of the pathology of the artificially fed infant.

Dr. J. MCCAW says in the preface to his *Diseases of Children*[9] that of textbooks dealing with diseases of children it cannot be said that there is a scarcity, but that he believes that there is room for yet another of moderate dimensions and modest price. These advantages the book certainly possesses, and it can be recommended as reflecting well the present teaching upon the disorders of childhood. But it suffers from extreme condensation. The author has not been content to limit the field covered by the book; he has endeavoured to make it a complete textbook in miniature. For example, he considers it necessary to devote space to a description of the so-called diseases of Buhl and Winkel. Knowledge of the pathology of the infective disorders of the newly-born is now advanced to such a point that the attempt to describe those conditions as separate pathological entities might well be abandoned. The observations of Winkel in Dresden in 1879 are now only of historical interest. The same disproportion is apparent in the illustrations, for of nine photographs illustrating types of disease three are devoted to a case of congenital hypertrophy of the colon. As a result, many disorders of great frequency have perforce to be dismissed with a very few words of explanation.

CHEMISTRY.

MELLOR'S *Introduction to Modern Inorganic Chemistry*[10] is a less comprehensive book than the same author's *Modern Inorganic Chemistry*, noticed in these columns about a year ago. Much of the matter is the same in both, the later volume being intended to suit students who want to start with a rather simpler book, and the more advanced portions of the earlier one therefore omitted. The matter is clearly presented, and the ground usually included in an elementary textbook is well covered. Theory and history are given in good proportion, the student being guided to both by the path of observable facts; curves showing the relations between given variables are employed almost from the first, but the demand made on mathematical knowledge is quite elementary. At the end of each chapter a number of questions are given, taken from various university and other examination papers, which will be of assistance to both students and teachers.

A Third Year Course of Organic Chemistry,[11] by Dr. T. P. HILDITCH, is intended to form a sequel to Dunstan's *First Year Organic Chemistry* and Thole's *Second Year Organic Chemistry*. Of these, the former deals with the aliphatic or open chain compounds, and the latter with the carbocyclic or benzene group; Dr. Hilditch's book completes the series by a discussion of the heterocyclic compounds—that is, ring compounds in which other elements besides carbon form constituent parts of the ring—as well as of the more complex aliphatic and carbocyclic compounds. Naturally, in a work having this scope, the matter is presented in a somewhat condensed style, which assumes a good deal of previous knowledge, and structural formulae abound on almost every page. The principal aliphatic compounds dealt with are the polypeptides and carbohydrates, to which over a hundred pages are devoted, and of carbocyclic substances the terpenes come in for discussion at some length. The whole of the matter is more fully dealt with than in textbooks which aim at covering a wider ground, and advanced students will find the book well suited to their needs.

In the applications of chemical analysis to particular manufactures it is usual to find that many special routine tests have been evolved which can often be carried out quite well by persons having very little theoretical knowledge. Dr. WIECHMANN'S work on *Sugar Analysis*[12] will prove of great use in laboratories where such testing has to be regularly carried out; the author does not assume chemical knowledge on the part of the reader, but begins with directions for such elementary operations as the use of a balance and the taking of specific gravities. From this he passes on to directions for the various tests required during the processes of manufacturing and refining sugar, as well as for the testing of the various materials used, such as bone black, tricalcic phosphate, coal, and lubricating oils. Finally, a considerable number of tables is given, referring to the conversion of polarimeter readings into strengths of sugar solution and other technical matters.

NOTES ON BOOKS.

THE author of a very good book on cooking, entitled *Cookery for Every Household*,[13] sets out with the proposition that "there is perhaps no science which has done more for the health and happiness of mankind than that of good cooking." If we waive the objection to calling that a science which is more properly denoted an art, we may, perhaps, admit the general truth of the proposition. The plan of the book is convenient: the first chapter deals with the kitchen, marketing, and the care of food. The author, Miss FLORENCE B. JACK, speaks in a rather half-hearted way about cooking by gas; she is enthusiastic about cooking by electricity, but the calculations of cost are based on a rate of a penny a unit. Stocks and soups, fish, meats, sauces, and so on are dealt with in separate chapters, each consisting of a general introduction followed

Wiechmann, Ph.D. Third edition, rewritten. London: Chapman and Hall; New York: J. Wiley and Sons, Inc. 1914. (Demy 8vo, pp. 319; 7 figures. 12s. 6d. net.)

[13] *Cookery for Every Household.* By Florence B. Jack. London: T. C. and E. C. Jack. 1914. (Cr. 4to. pp. 721; illustrated. 3s. 6d. net.)

by recipes of which there are altogether over 3,000. There is a separate section on invalid cookery, with a suitable introduction, and another on drinks and beverages—a subject very often omitted in cookery books. For making coffee Miss Jack recommends the ordinary earthenware percolating coffee-pot. Undoubtedly very good coffee can be made with it, and it has the great advantage of being easily cleaned. There is a short section on paper-bag cookery, a French glossary, and a set of seasonable dinners, breakfasts, and luncheons for spring, summer, autumn, and winter; and a good index. Altogether the book is very complete, and its portly appearance is, perhaps, not a serious objection. Its merits can only really be tested in the kitchen, but as it is written by an ex-Principal of the School of the Domestic Arts in Edinburgh, it may be taken to represent a large experience.

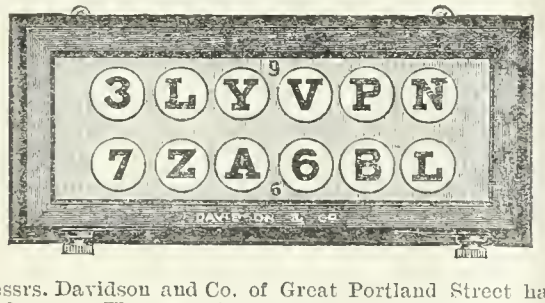
It has often been said that no man is a hero to his valet; there are nevertheless a few rare characters who have the power of winning the respect and affection of all with whom they come in contact, and whose greatness is recognized and acknowledged even by those with whom they are on the most familiar and intimate terms. *Sister Henrietta*,[14] the story of whose heroic life-work in the hospitals of South Africa has been published by her sister, Miss STOCKDALE, and the Dowager Lady LOCH, seems to have possessed to the full this happy faculty of arousing the interest and sympathy of others; and the charm of her striking personality can be felt even through the medium of cold print. The memoir of her life is composed for the most part of her own letters, written to friends and relations in England during her thirty-seven years' work in Kimberley and Bloemfontein; but it also contains a short biography by her only sister, who gives a most interesting account of the early years of this noble *maîtresse femme*. From her we learn that almost from childhood Sister Henrietta's heart was set upon the path she afterwards trod with such unflagging zeal; but that she was no mere visionary is proved by the success of her ceaseless efforts to raise the standard of nursing in the hospitals under her care. Her nature, indeed was as much akin to that of Martha as of Mary, for she combined a deep and fervent piety with the practical qualities required of one who was destined to become one of the pioneers of nursing in South Africa. Her letters reveal her as a woman of high ideals and lofty aspirations, of whose saintly and courageous life it might truly be said that it

> has flowed
> From its mysterious urn, a sacred stream
> In whose calm depths the beautiful and pure
> Alone are mirrored.

MEDICAL AND SURGICAL APPLIANCES.

Test Type.

DR. C. B. MOSS-BLUNDELL (Huntingdon) writes that in testing the eyes in large schools he has frequently found that the scholars have been able materially to assist their power of vision by committing the test type to memory. To obviate this he designed a system of movable type which proved so successful in practice that



Messrs. Davidson and Co. of Great Portland Street have made one. The type is mounted on a ribbon, which travels behind a white plate with circular windows. The tape runs on rollers, and by a half turn of the roller the order and lettering of the type are completely changed, so that several variations of lettering are obtained at will. The apparatus measures 10 in. by 4 in. by 1 in., and may be conveniently carried in the bag of the medical inspector. Dr. Moss-Blundell suggests that one might with advantage be permanently fitted in all large schools.

Apparatus for X-ray Therapeutics.

From the Sanitas Electrical Company, Limited (61, New Cavendish Street, London, W.), we have received particulars of some new introductions of *x*-ray apparatus, the purpose of which is to secure a "hard" or penetrating radiation. The apparatus includes a new *x*-ray generating machine, constructed on the principle of an alternating current generator, but having a special cut-out contrivance which enables any desired portion of the current phase to be used for the working of the tube, so that a more or less hard beam of *x* rays is under control. Another interesting contrivance is an apparatus fitted with a high-tension change-over switch for bringing into play in rapid periodic sequence four *x*-ray tubes from a single outfit. The efficiency of the tube so far as concerns the emission of hard rays is improved by this intermittent working, and the device has the further advantages of lengthening the life of the individual tube, and of utilizing fully the output of the current generator. The swinging motor arrangement of Dr. Hans Meyer, of Kiel, represents another refinement of *x*-ray therapeutics; it provides that the tube, after being centred on a suitable area for treatment, shall be swung continuously from one side to the other, thus ensuring a cross-fire action upon the part. The Sanax mercury interrupter of this firm maintains the reputation to which it is entitled by virtue of its ingenious design and mode of action, whereby the uncleanliness and wastefulness attached to many mercury interrupters are eliminated.

ROYAL COMMISSION ON VENEREAL DISEASES.

THE following is the official report issued to the press by the Secretary of the Commission:

Importation of Syphilis.

At the forty-third meeting of the Royal Commission on Venereal Diseases, evidence was given by Dr. J. J. Pringle, physician in charge of the skin department of Middlesex Hospital and president of the Dermatological Section of the Royal Society of Medicine.

Dr. Pringle stated that of 36,151 cases of skin disease dealt with in the out-patient department of the Middlesex Hospital during the last twenty-five years, 1,853, or rather over 5 per cent., presented indubitable evidence of syphilis. This figure did not represent the number of patients who had attended the hospital for syphilitic manifestations, but only those who had been referred to the special department as suffering from some affection of the skin. Of the 1,853 cases of syphilis 925 were males and 928 females. Dr. Pringle thought that this apparent equality of incidence in the two sexes was due to the fact that men do not willingly attend hospitals during working hours, except for diseases which in their opinion threaten life or cause grave discomfort or pain. On the other hand, anything causing disfigurement impelled women to seek medical advice. Of the 1,853 cases of syphilis already mentioned, nearly 24 per cent. were foreigners.

Dr. Pringle stated that he could not see his way to supporting or advocating any measure of compulsory notification of venereal diseases. The medical profession was, he thought, practically unanimously opposed to it, and even if made confidential its effects upon the public would be merely to drive them to seek treatment from unqualified persons.

His experience both in hospital and private practice convinced him that much of the syphilis existent in England was of foreign importation. He believed that a considerable number of prostitutes left their own countries because they were unable to ply their trade there, and came over to England and spread the disease in this country. It was important that this matter should be further investigated, and that steps should be taken to deal with it.

THE firm of C. Reichert, of Vienna, has issued in English an abridged catalogue of microscopes and accessory apparatus of its manufacture. It can be obtained from the firm's London agents, H. F. Angus and Co., 83, Wimpole Street, W.

[14] *Sister Henrietta, C.S.M. and A.A., Bloemfontein-Kimberley, 1874–1911.* Edited by Dowager Lady Loch and Miss Stockdale. With two portraits. London: Longmans, Green and Co. 1914. (Post 8vo, pp. 157. 2s. 6d. net.)

ONE HUNDRED YEARS AGO.

THE TEACHING OF MIDWIFERY IN LONDON IN 1814: HAIGHTON AND BLUNDELL.

PERHAPS the most important event in the teaching of midwifery in London in the year 1814 was the association of young James Blundell with his uncle, Dr. Haighton, although doubtless no one at the time thought much of this addition to the staff of obstetric lecturers, unless it was Blundell himself. John Haighton[1] was now 59 years of age, and had been lecturing on both physiology and midwifery for a long time. He was a Lancashire lad,[2] had been a pupil of Else at St. Thomas's Hospital, had then become a surgeon to the Guards, had resigned on being appointed demonstrator of anatomy at St. Thomas's under Henry Cline (who had first lectured for and then succeeded Else in 1781), and but for the appearance of a more brilliant star (Sir Astley Cooper) would doubtless have continued to shine among the anatomical and surgical luminaries of the time; indeed, so skilful a surgeon was he and so promising an anatomist that John Hunter had nearly taken him as his assistant in lecturing. As it was, Haighton in 1789 turned to physiology and midwifery, succeeding Dr. Skeete as lecturer in the former and being associated with Dr. Lowder in the latter subject, and teaching both in the courses for the united hospitals—St. Thomas's and Guy's. It was in physiology rather than in midwifery that Haighton found his sphere, and most of his published works were concerned with the former, although he did find time to write on "True and spurious Caesarean operation." After a paper on "Fractured olecranon," published in *Medical Commentaries* in 1785, he wrote in 1789 on the "Powers concerned in the act of vomiting," and on "Two experiments on the mechanism of vomiting" (*Memoirs of the Medical Society of London*); in 1792 his "Experiments made on the laryngeal and recurrent branches of the eighth pair of nerves" were made known, and some three years later his most important "Experimental inquiry concerning the reproduction of nerves" appeared in the *Philosophical Transactions*. In this inquiry he tested the repair of nerves by the recovery of their physiological function after division, an epoch-making advance in physiological methods. His "Experimental inquiry concerning animal impregnation," in which he used rabbits for the investigation, was ingenious, but failed because of the imperfect microscopic knowledge then available. Another subject on which he wrote was *Deafness*, and for this work he was adjudged the silver medal of the Medical Society of London in 1790. In 1814 he was beginning to suffer from asthma, a very troublesome complaint for a lecturer, and so he called to his assistance James Blundell, his nephew, who had studied under him at the United Borough Hospitals, and who in the past year (1813) had graduated M.D. at Edinburgh. In 1818 Blundell relieved him of the lectures entirely, and also began to lecture on physiology. Dr. Haighton lived, however, till 1823, and took an interest doubtless in his nephew's growing success both as a lecturer and as an obstetrician.

James Blundell's success, indeed, was phenomenal; for years he had the largest class on midwifery in London, and although he ceased to lecture in 1836, and had long retired from the practice of his profession before his death, at the age of 87, in January, 1878, yet he died with great riches, his personalty being sworn under £350,000. Munk[3] writes about him in 1878: "He was little known to the present generation of physicians . . . he died very wealthy, more so, indeed, than any physician of whom we have record." This was the man who in 1814 stepped into his asthmatic uncle's classroom to aid him in his lectures in midwifery.

From the *Medical and Physical Journal*[4] for 1814 can be obtained the programme of the conjoint course of lectures in the two London hospitals that year:

St. Thomas's and Guy's Hospitals.—The winter course of lectures at these contiguous hospitals will commence in the first week of October, viz.:

At St. Thomas's: Anatomy and the Operations of Surgery, by Mr. Astley Cooper and Mr. Henry Cline. Principles and Practice of Surgery, by Mr. Astley Cooper.

At Guy's Hospital: Practice of Medicine, by Dr. Babington and Dr. Curry. Chemistry, by Dr. Babington, Dr. Marcet, and Mr. Allen. Experimental Philosophy, by Mr. Allen. Theory of Medicine and Materia Medica, by Dr. Curry and Dr. Cholmeley. Midwifery and Diseases of Women and Children, by Dr. Haighton. Physiology or Laws of the Animal Economy, by Dr. Haighton. Structure and Diseases of the Teeth, by Mr. Fox.

These several lectures are so arranged that no two of them interfere in the hours of attendance, and the whole is calculated to form a complete course of medical and chirurgical instruction.

Dr. Blundell's name does not appear in the list, his uncle's asthma, we can imagine, not beginning to be disabling in its intensity till the fogs of October had set well in; but he came forward (more or less bashfully) to play his part during the session.

Among the many books belonging to the late Sir James Y. Simpson which have recently been presented to the Royal College of Physicians of Edinburgh by his nephew, Sir Alexander Simpson, there is a thin volume of eighty-eight pages (interleaved with leaves carrying manuscript notes), entitled "*A Syllabus of the Lectures on Midwifery Delivered at Guy's Hospital by Dr. Haighton.* London: Reprinted in the year 1814 by E. Cox and Son, St. Thomas's Street, Borough." This, therefore, gives the very lecture headings used by Haighton and Blundell in their conjoint course of instruction on midwifery in the autumn of 1814 and winter of 1814–15, and one can follow the students of Guy's and St. Thomas's almost day by day as they were led deeper and deeper into the knowledge of obstetric science by their teachers. With regard to the MS. notes on the intercalated pages in this copy of Haighton's *Syllabus* there is no certain information forthcoming, but Sir Alexander Simpson is inclined to think they were made by Professor James Hamilton, who was Sir James Simpson's predecessor in the Chair of Midwifery in the University of Edinburgh from 1800 to 1840. From their nature they were certainly not made by a student, for they contain references to the writer's management of difficult midwifery cases. For instance, here is one supplementing what is said about phlegmasia alba dolens, called simply "swelling of the lower limbs."

Dr. Haighton, in the *Syllabus*, remarks that this disease may attack one or both legs; I have never seen it attack both at the same time, the other being affected as the one got well. In one case it seemed as if this disease was hereditary: in the case of Ly [Lady] Clark of Penicuick House. It strikes me that the word "hereditary" should be used here only in that sense which denotes that irritable parents in general will have irritable offspring, and in this manner may be explained the reason why it descends from parent to child. The lymphatic glands in one person may be more irritable than in another, and similar causes will not produce similar effects in people of different temperaments. It is well known that the bite of a leech is accompanied with violent inflammation in all the members of a family, and that certain substances taken into the stomach will produce eruptive complaints, and that this idiosyncrasy will be produced in the offspring, as is the case with myself in eating fish.

The condensed statements of the *Syllabus*, being of the nature of literary pemmican, do not give any indication of the flavour, force, pungency, and wit of the information supplied *viva voce* by the lecturers, and especially by the younger one of the two. Fortunately Blundell's book is available, so that it is possible to compare the dry bones of the notes with the stirring addresses (they were little less) clothed in telling phrases of the fully reported lectures. In the *Syllabus* (p. 55), under the heading of "Craniotomy," is the sentence: "Observations on the propriety of opening the head, with cautionary remarks"; but in the book (p. 326)[5] the following passage appears:

Of all the obstetric operations, there is none, perhaps, more easily performed than that of perforation; and many a life, I fear, has fallen a sacrifice to this facility of execution. Of all the operations of our art, however, there is none more dreadful—not to say "more *awful*"; for—call it "embryotomy," "craniotomy," "cephalotomy," or by whatever elegant term you please—in this operation a dagger is struck into the head of an innocent child, often still living; and the brains, much reduced to a soft pulp, are suffered to escape at the opening! Much evil, and some good, arises, in society, from not calling things by their right names! This practice, however, I am aware, grows out of the nature of man, and cannot be amended. Helenize then, and Latinize, as much as you please. "Suaviter

sonat"; but never suffer a polished and classical appellation to bring before your minds an idea of this operation, divested of that salutary horror with which, I conceive, it ought at all times to be contemplated. Dreadful, however, as the operation is, the safety of the mother sometimes peremptorily requires its performance.

If the printed page gives anything like a true transcript of Blundell's lectures, it is not difficult to understand why so many students flocked to his classroom, for vivacity is combined with sympathy and pathos with humour in a way which must have been very attractive and interesting. It is hardly to be thought that the young lecturer stepped at once into his full stride in this, the first, year of his assisting his uncle; but there would be passages in the lectures when the spirit, almost prophetic, bubbling up within him, would refuse to be restrained by conventional terms and polite phrases, and would pour forth in a torrent of mingled invective, appeal, and sad humour that was nearly Carlylean (although the Sage of Chelsea had not yet begun to thunder). There would be some, perhaps, among Haighton's students who would not be overcome with grief when an unusually bad attack of asthma in the uncle sent the nephew into the classroom, and when one of the periods of declamation was well entered upon many pencils would cease to traverse the paper as Blundell's hearers listened spellbound or burst into applause. Take this passage, dealing with the choice of suitable perforator, and notice the combination of practical useful advice on matters of construction with sarcasm and a personal allusion:

> Some of these instruments are made very light and elegant—qualities of which I do not myself approve. A light perforator is apt to bend in the shank or to break. Besides, a roughness of appearance well becomes the austere duties which it is designed to discharge. [Note how well chosen the words are and how fine is the point of the irony.] In choosing a perforator take care that the joint is very firm; otherwise, when the instrument is in action, disruption and dislocation may occur. It is better, too, that the blades should not touch each other laterally at the joint, in order that no part of the vagina may be enclosed and injured there. Except the point, all other parts of the instrument should be smooth and rounded. "Thou shalt not kill" might perhaps, with great propriety, be engraved on one blade of the instrument. To the obstetric eulogist, Sir Anthony Carlisle, I commit the choice of a motto, from the same decalogue, for the other blade.

One can well imagine the delight with which the class would welcome the allusion to Sir Anthony Carlisle, "handsome and good-humoured but very vain and crotchety,"[6] surgeon to Westminster Hospital, who had written the pamphlet on *The Impropriety of Men being employed in the Business of Midwifery*. The delicate satire of the phrase "obstetric eulogist" would be immediately perceived by Blundell's hearers, and the duller students would ask the brighter ones, or those with a more extensive acquaintance with the Ten Commandments, "What motto from the decalogue does he mean?" and would receive as answer, "Why, thou shalt not bear false witness against thy neighbour, to be sure." And, ever afterwards, in their professional life, these students could hardly pick up a perforator with feticidal intent, without seeming to see in burning letters on the one blade, "Thou shalt not kill," and on the other, printed in green—the green of envy—"Thou shalt not bear false witness against thy neighbour," be he surgeon or obstetrician or physician. There was more taught in Blundell's classroom than midwifery in these days.

Some of Blundell's illustrative case records, too, were full of dramatic intensity. Whilst lecturing on eclampsia and the risks of the child being expelled unnoticed during the convulsions and being suffocated in the bedclothes, he told this story:

> A lady, in the end of her pregnancy, was seized with convulsions. Her attendant was sent for, and decided that there were no indications of labour, and that a stay was unnecessary. Quitting the house, then, the midwife returned on the morrow, early in the morning, when the patient was found dead. The child, too—the birth of which no one seems to have suspected—lay lifeless beneath the clothes. In managing human affairs, the *men* have done so many foolish things, that they have no claim whatever to treat with severity the errors of the *women*. Allow me, however, to remark that, in this instance, the error—a great one—was committed by a *female* practitioner. "Felix quem faciunt aliena pericula cautum!" (happy is he who learns caution from the dangers of others). Remember the story. It is worth a parable, or an apologue; for it conveys a useful truth.

One could hardly be dull when one's teacher was in the habit of exploding such bombs during the lecture!

Little space is left to speak of Blundell as a physiologist, and yet, notwithstanding the charm, the impressiveness, the high note of distinction of his obstetric lectures, it was as a seer in matters physiologico-obstetrical that he shone most brilliantly. If he was as the Hebrew prophet in his hortatory, declamatory, and denunciatory mood in his midwifery teaching, he was still more like him in the clear vision he had of the future. He saw more immediately and more penetratingly than any man else in his age the physiological developments of obstetrics and gynaecology. It was from experiments and more still from his wonderfully powerful faculty of intuition that Blundell foresaw the possibility, and recommended the performance of division of the Fallopian tubes to prevent the necessity for a second Caesarean section. Here is a quotation[7] giving his directions: "I would advise an incision of an inch in length in the linea alba above the symphysis pubis; I would advise further, that the Fallopian tube on either side should be drawn up to this aperture; and, lastly, I would advise, that a portion of the tube should be removed, an operation easily performed, when the woman would for ever after be sterile." Again,[8] he stated that extirpation of the healthy ovaries, what came afterwards to be called Battey's operation or oöphorectomy, would "probably be found an effectual remedy in the worst cases of dysmenorrhoea, and in bleeding from monthly determination to the inverted womb." By experiments upon rabbits a few hours after delivery he showed the feasibility of the Porro modification of the Caesarean section; three out of four rabbits in which he removed the puerperal uterus recovered, to his great surprise, as he admits. In gynaecology, too, he had foresight which enabled him to view the triumphs of ovariotomy when he had only Lizars's Edinburgh case to enlighten him.[9] He had one or two hard hits at the small diagnostic powers of the surgeons of the day who failed to recognize ovarian cysts; he calls them "the blundering mistakes of some of your revolting and reviling surgeons—of your 'thank-God-I-know-nothing-of-midwifery' men (excuse a Sanskrit adjective!)." It will be noted that he had not enough vision to foresee that the surgeons would come into abdominal surgery also, and work wonders there little if anything short of those achieved by the ovariotomists and gynaecologists; it will likewise be observed that his language was strong enough to dispense with tonic treatment. Finally—for it is impossible to find space for all his advanced views and practice—he not only determined the feasibility of hysterectomy for uterine cancer by experiment, but practised the operation upon the human subject[10]; he used the vaginal route, and naturally enough had some difficulty with the uterine arteries in the broad ligaments, but he had two successes in five cases, which, considering all things, was really rather a wonderful result. These operations were not undertaken until 1828, fourteen years later than the date of which we are writing now, but even at that time they were very remarkable achievements.

This, then, was the young man who came forward a hundred years ago and made his bow as a lecturer on midwifery and physiology in London. Dr. Haighton and he had some formidable rivals to face. There was David D. Davis, the Welshman, M.D. of Glasgow, Fellow of the Royal College of Physicians in Edinburgh, Licentiate of the Royal College of Physicians in London (admitted in June, 1813); he had been appointed "Man-Midwife in Ordinary" to the Queen's (Queen Charlotte's) Lying-in Hospital in the January of this year (1814), and he was to have the honour in a few years of attending the Duchess of Kent at the birth of Her Majesty Queen Victoria. He also had a large private midwifery class meeting at his house, No. 18, Lower Charlotte Street, Bedford Square. His summer session began on Monday, June 6th, at 10 a.m.,

and his notice in the *Medical and Physical Journal* for June, 1814, announced that "a limited number of young gentlemen were admitted as medical house pupils." There was Dr. H. G. Clough, also, calling himself in 1808 "Physician Man-Midwife," and in 1814 "Physician Accoucheur" to the St. Mary-le-Bone General Dispensary, Welbeck Street, Cavendish Square; he, too, published a syllabus of his lectures, running to 124 pages. There was Dr. Samuel Merriman, nephew of the Samuel Merriman whose work, *De Conceptu*, was so highly thought of by William Smellie that he reprinted it in his *Thesaurus Medicus;* he was lecturing in 1814 at the Middlesex Hospital. There were Dr. Clarke and Mr. Clarke also, who read their lectures at the house of Mr. Clarke, No. 10, Upper John Street, Golden Square; there was Dr. Squire, who lectured at his house in Ely Place, Holborn; there was Mr. Joseph Hopkins, who delivered lectures at the Westminster Lying-in Institution every month; and there was Dr. Robert Gooch, "master of precise forcible description," whose hands were always cold, a peculiarity which he somewhat unexpectedly claimed as "an advantage in the examination of the abdomen," and whose lectures were given at St. Bartholomew's Hospital. Here was an array of talent which might well have daunted an older and more experienced man than James Blundell, but with the aid of uncle Haighton to give him a start he boldly faced them all, and has left to posterity what is perhaps the most readable set of lectures on midwifery of the period—readable, memorable, and highly entertaining.

THE MEDICAL USES OF WATERS AND BATHS.

FOUR lectures on "medical hydrology" were delivered recently at the Polyclinic, London, by Dr. R. Fortescue Fox. The refreshing effect of cool drinks and of cooling baths, and the debilitating effects of heat were, he said, typical of the whole action of heat and cold in health and disease. Baths provided a temporary and local climate for any part of the body. The normal body manifested a response or reaction to heat and to cold, with a certain sequence of changes in the circulation, nervous action, respiration, and metabolism. The reaction to cold, which called forth increased heat production, maintained the temperature of warm-blooded animals. Fatigue, starvation, and disease profoundly modified it, but it was capable of education. Through these reactions it was possible by means of heat and cold to modify at will, in whole or in part, the circulation, nervous energy, and metabolism of the body. By acting locally on certain areas of the skin the internal organs related to those areas could be affected.

The art of hydrotherapy in the widest sense, he said, was the medicinal use of heat and cold, and constituted the first part of medical hydrology. Modern hydrotherapy was part of a new movement towards physiotherapy, which in the last half-century had swept over the Continent. The medical mind in England was at present comparatively untouched by it, which partly accounted for the annual and increasing exodus of British invalids to the Continent.

Many local cooling applications could be used with much advantage in fevers and other acute diseases, and for inflamed and injured parts. In addition to their sedative effect on the general circulation, as shown, for example, in cases of haemoptysis and gastric haemorrhage, they had a marked decongestive effect on inflamed areas, contrasting with the congestive effect of heat, by hot air, etc. On the whole, therefore, cold was more appropriate for acute and heat for chronic maladies. In the cooling treatment of fevers too much cold had frequently been employed. The intention was the stimulation of the nerve centres and of the heart. The prevention of fever was wrong. In practice the lower limit of temperature in a bath in fever should seldom pass 65° F. The best indication for cooling baths in fever was not pyrexia, but a flushed skin, dicrotic pulse, and low arterial pressure.

Subthermal baths (98–90° F.) had a marked sedative effect upon the whole nervous system, peripheral and central, and through it on the circulation and nutrition. They therefore had a wide scope in nervous and mental and circulatory affections, in convalescence, debility and old age, and were the most valuable of all medical baths.

Thermal or resolvent baths (98° to 105° F.) were intended to increase the superficial circulation and that of comparatively superficial parts—joints, muscles, fibrous structures, etc.—to increase metabolism, and to diminish the loss of heat. They intensified all tissue reactions in the parts operated upon, stimulated sluggish changes, and promoted absorption. Unless followed by cold applications, they were liable to produce "thermal debility."

Hyperthermal or intensive baths (105° to 120° F.) were used to produce the highly stimulating effect of brief applications of heat. They were a most valuable stimulant in the collapse of febrile cases, and as foot baths in many chronic conditions.

Douches.—Many thermal and subthermal effects could be best induced by the douche, in which the influence of pressure and mechanical stimulation was added to that of heat.

Hot-air and Vapour Baths.—The great principle (often neglected in practice) of cold after heat was illustrated by the baths of the Greeks and Romans, the Slavonic and Northern and Celtic races. In all of these heat was used to make the body tolerant of cold, as in fever, and it was surprising what extreme degrees of cold could be tolerated after application of heat. The best form of cold bath was preceded by heat, and this should always be the practice for old persons and children, for invalids, and in the case of school baths.

Thermal debility, as seen after hot baths, was a condition strictly comparable to that produced by hot moist climates. Beginning with want of fitness, languor, and acceleration of the pulse, it might proceed to heat-stroke or acute cardiac failure. This secondary reaction to heat was the most serious danger of all bath treatment.

Medicinal springs were often to be recommended to those who never otherwise drank water. The *differentia* of the various springs was but imperfectly revealed by chemical analysis. The presence of dissociated ions, of colloidal metals, with an action analogous to that of ferments, and of known and unknown physical properties, such as radio-activity, probably entered into the action of many springs, and in some of the most dilute waters it was probable that free motility of the particles favoured their action.

Waters of natural heat (subthermal, thermal, or hyperthermal) seemed to exert a different action from ordinary hot baths. They should be chosen largely according to their position in the scale of thermality, according as a sedative, stimulant, or intensive effect might be desired.

Sulphur waters presented dilute solutions of sulphides, probably in a colloidal condition and in a form not otherwise available in medicine. Experience seemed to show that in many chronic diseases, such as gout and chronic articular rheumatism, they had an intensive and almost a specific effect, possibly to be explained by their action upon intestinal toxaemia.

Muriated springs brought into the body one of its natural constituents, which was intimately concerned in osmosis. Their helpful action in weak and catarrhal conditions of the gastric and intestinal mucous membranes was assisted by free carbonic acid gas. Applied externally, salt baths, as at Droitwich, provided one of the most powerful forms of cutaneous stimulation, which, when combined with heat, was of great service locally and generally for myositis, fibrositis, gout, rheumatism, and for "scrofulous" and convalescent young people (as at the famous "Liman" cure in Southern Russia).

Effervescing baths (with or without salt) combined two forms of surface stimulation—the thermal effect of gas and the antithermic effect of water, exerted on innumerable shifting and contiguous minute areas of the skin. There resulted an interesting form of gymnastic of the surface circulation, belonging only to these baths. The sedative and stimulant effect upon the heart produced by such baths was among the best attested facts in medical hydrology.

Calcareous or diuretic waters were deservedly coming into increasing vogue. In addition to their stimulating effect upon the gastro-intestinal tract and their use in urinary calculus and gravel, they often relieved gouty states, and especially chronic high arterial tension, by their action as eliminants.

The *choice of spas* should be guided not only by the effect of the waters, but by the climatic character,

altitude, and scale of thermality of the health resort. Some invalids required the warmth and shelter of valleys or forests. Many warm and sedative spas were to be found in the Rhine Valley and in France. In England, Bath and Leamington and Woodhall Spa belonged to this category. Or, again, for other persons the moorland or hillside resort was preferable. To this class belonged Llandrindod, Buxton, Harrogate; and abroad, the spas of the Auvergne, of the Vosges Mountains, and Bohemia. For yet another group of patients the mountain resorts were indicated, such as Gastein, Leukerbad, or the Pyrenean spas. Lastly, a large number of delicate and elderly persons derived great benefit from northern climates, and from such spas as Strathpeffer, Laurvik, and Sandefjord.

The *British health resorts*, as a whole, provided a tonic and invigorating and bracing treatment, well adapted for particular types of constitution, of morbid tendencies, and of conditions of chronic disease.

In *cardio-vascular affections* heat should be used in a very guarded manner. In such affections there was great sensitiveness to temperature and an abnormal liability to thermal debility. Neither waters nor baths could be used in recent rheumatic carditis; but when the active process had subsided eliminative waters were helpful in all cases of acute rheumatism. The temperate douche held an important place in the treatment of rheumatic and other cardiac affections. It should be employed, as at Aix-les-Bains and formerly at Strathpeffer, without pressure and without thermality. The results were often superior to those obtained from the effervescing bath. All the best bath treatments for cardio-vascular disease were obtainable in the British Isles, and too many such cases were sent abroad, often with regrettable results. Cases of arrhythmia, with sudden alternations of high and low arterial pressure, were among those which were best treated near home. Again, if it were best to discourage exercise, a sheltered and sedative spa should be chosen, even at the risk of its being called "relaxing"; but where exercise was admissible a more stimulant and perhaps a northern station might be chosen. Altitude would in any case be avoided. In arthritis the best results were seen in toxic cases affecting few joints and in the arthritis of middle life, especially where cool and bracing treatments were given. In the last stage, with failure of arterial circulation, hyperthermal treatments were, of course, indicated.

Chronic nervous affections in many instances responded readily to bath treatments. It was surprising how old habits of invalidism and neuralgia yielded to the use of cold douches, with or without preliminary heat. The neuroses of the climacteric, insomnia, tachycardia, Graves's disease, could all be treated through the nervous peripheral organ, and cooling hydrotherapy was commonly indicated. In the slighter cases of neurasthenia and psychasthenia the routine use of some well-appointed medical baths near home should especially be recommended. The health resort with its change of scene and occupation might be described as the second degree of hydrological treatment, whilst the sanatorium with change of people remained for more serious cases. The experience of the German alienists had shown that not only Turkish baths and cold douches but athermal baths prolonged sometimes for many hours were of much value in mental affections.

In *old age* the slight failures of circulation and tightening of the arteries, the failure in the function of the skin, the failure of digestion or of elimination, were just those conditions that were best dealt with by gentle and prolonged hydrological treatment in a suitable climate.

It was the claim of medical hydrology that by means of the various uses of waters and baths it was possible to control and mitigate the reactions of acute disease and to promote and correct the imperfect and faulty reactions of chronic disease.

THE late Dr. Thomas Druslyn Griffiths, of Swansea, formerly President of the British Medical Association, left estate valued at £32,646.

THE International Fire Service Council, which has held its executive meetings and several conferences in London at the invitation of the British Fire Prevention Committee, has decided to issue an international Fire Dictionary in three languages.

THE BRITISH MEDICAL ASSOCIATION AND THE MEDICAL PROFESSION.

A CRITICAL REVIEW OF THEIR RELATIONS.

(Continued from vol. i, page 1415.)

VI.

CONTRACT PRACTICE AND THE NATIONAL INSURANCE ACT.

To pass from the question of out-patient departments to a consideration of contract practice is a natural transition. The fact that defects in the control of out-patient departments and the worst features of club practice have in some areas been found to be reciprocally stimulant is quite sufficient by itself to establish a connexion between the two subjects. The true connexion between them, however, is that those who engage in contract practice in any of its many forms and those who carry on the work of out-patient departments have fundamentally the same object in view. Their common aim is to meet the medical needs of persons who, though they do not come within the scope of the Poor Law, are insufficiently well off to pay the fees ordinarily expected by private practitioners.

On the other hand, there is also a fundamental dissimilitude. In contract practice, though in nearly all its forms it shares with out-patient work a philanthropic quality, the desirability of fostering the independence of the working and lower middle classes is never overlooked. From this point of view, indeed, contract practice and out-patient work are essentially antithetical. In the term "out-patient work" we are including for the moment that of free dispensaries, for out-patient departments are a comparatively modern development, and it was by free dispensaries that in the early nineteenth century most of what is now known as out-patient work would appear to have been done.

Stress is laid on this because from a historical point of view the free dispensary may in some degree be regarded as the *fons et origo* of the twentieth century medical man's trouble in connexion with contract practice. His predecessor a hundred years ago was quite as alive to the needs of the poor as he is, and one way in which he endeavoured to provide for them was by taking part in the work of free dispensaries, and later on it was through a derivative of the free dispensary that he sought to stem the rising tide of abuse of medical charities in all its forms.

This was in the Thirties, when the early members of the British Medical Association, after holding an inquiry into the subject, came to the conclusion that the best remedy would be to encourage the existence of institutions which would do their work on much the same lines as free dispensaries, but be supported to a considerable extent by subscriptions from the patients treated; in other words, they favoured the provident dispensary. It was no doubt an excellent idea, and if the provident dispensaries that came into existence had flourished as a class, it is possible that many of the latter-day problems of the medical profession would never have arisen. Unfortunately, however, large ill-managed out-patient departments multiplied simultaneously, and it was difficult for the provident dispensaries to withstand their blighting influence. Consequently, though many of them were fairly prosperous and continue to exist at the present time, they led as a class a somewhat hand-to-mouth existence, and did not succeed in decreasing the evils of hospital abuse. Though this failure in itself may be a matter of minor interest, yet, looking back, it is impossible not to attribute to the trial of the provident dispensary system some responsibility for the growth of contract practice as a whole. It must have helped to confirm in the minds of the working classes the idea that by making quite small monthly or weekly payments they could, without any loss of independence, demand from the medical profession everything they required in the way of treatment.

Furthermore, the system had a direct though bastard offspring in the shape of medical aid institutions, and it was the evils associated with these which finally aroused the medical profession to revolt against contract practice in all its forms. This was in 1894, when several Branches of the British Medical Association voiced the general discontent by passing resolutions to the effect that medical

men who took part in the work of medical aid institutions ought to be deemed unworthy of admission to membership.

In making this statement, we are not overlooking the fact that for many years previously there had been complaints about contract work of other kinds, or that in 1892 the Southern Branch of the British Medical Association in Ireland, in association with the Medical Society of Cork, had commenced a fight—which eventually proved successful—against the local friendly societies. These and some other like events, including a keen altruistic contest at Coventry, were, however, merely in the nature of preliminary hostilities, and it was over medical aid institutions that really commenced the long struggle which our contemporary, the *Lancet*, aptly dubbed "the battle of the clubs."

MEDICAL AID INSTITUTIONS.

The early fights between the medical profession and friendly societies often involved nothing more than a question of terms, while the fights over medical aid institutions invariably involved one of principle; the essential feature of a medical aid institution was that, instead of there being a contract between those who treated and those who were treated, both alike contracted with a third party—namely, one or more laymen who provided treatment through their medical employees and pocketed any balance remaining when those employees had been paid their agreed fee or salary. They were, in short—and are still so far as they continue to exist—essentially commercial enterprises, whose powers for evil were materially increased when the medical men taking part in their operations served as whole-time employees, and were thus completely under self-interested and purely lay control.

Bodies of this general order bearing various titles had become very numerous by the end of the Eighties, and for the most part their sole aim was to pay their medical employees as little as possible and make contracts for treatment with as many members of the public as possible, quite irrespective of their position in the world. Consequently, not only were they gravely interfering with the work of many private practitioners, but they reduced their own medical employees to a condition of ill-paid servitude, which was all the more degrading and objectionable because it entailed the undertaking of work which could not in the circumstances possibly be performed with efficiency.

The earliest attack upon them would seem to have been in the pages of the BRITISH MEDICAL JOURNAL in 1890; it was repeated in 1891, and in the spring of the following year a medical man in the employ of one such institution was brought before the General Medical Council. The charge against him was to the effect that he had practically sold himself to a body of laymen who were trading in medical treatment for profit, and that in the performance of his work he had associated himself with an unqualified practitioner. The General Medical Council did not hold this medical man to have committed any offence of which it was prepared to take cognizance, but it appointed, a few months later, a committee of inquiry into the whole subject of medical aid institutions. This committee reported very unfavourably about them, but the General Medical Council does not seem to have considered that any of the evils shown to exist were of a kind with which it could deal in any very specific fashion. The Council's final verdict on the report of its committee was not delivered until 1894, and it was then that, as already stated, the standard of revolt was raised by numerous Branches of the British Medical Association.

For some time it looked as if little progress was likely to be made, but at length it appears to have been suggested that one feature in medical aid institutions had been more or less entirely overlooked by the General Medical Council. Commercial enterprises of all kinds depend for their success largely on advertisement, and this advertisement in the case of medical aid institutions took the form of more or less open canvassing. This circumstance was pressed on the notice of the General Medical Council, which thereupon adopted the view that connexion with canvassing institutions must be regarded as professionally illegitimate. This fact, coupled with the further fact that in 1900 the Council brought into full operation its previous resolution regarding "covering," put a different complexion on matters, and the war of the Association against medical aid institutions became more effective. It has now become difficult for them to obtain the services of competent practitioners, thanks to the fact that the Association has succeeded in educating the profession as a whole into regarding the conditions in which the work has to be done as equally bad for the patient and for the doctor.

THE FRIENDLY SOCIETIES.

As for other forms of contract practice, the first definite step taken by the Association as a whole was to appoint a subcommittee to confer with the representatives of friendly societies regarding the abuses existing. The conferences commenced in 1898, but were not followed by any material improvement, partly because the friendly societies, believing that they held the medical profession in the hollow of their hand, were totally unwilling to listen to reason—they refused, for instance, even to consider the question of adopting the principle of a wage limit—partly because there was some uncertainty as to what was the best line for the profession to adopt. The latter circumstance was natural, because there was great variety in the character of the complaints made, and precise data as to the conditions prevailing in different parts of the country, and their results were practically entirely lacking. Consequently, after the expression of many different opinions in its pages, the BRITISH MEDICAL JOURNAL, which already in previous years had supplied a great deal of information on the subject, commenced early in 1903 an inquiry of its own, and at the annual meeting in the same year a resolution was passed directing the Council of the Association to undertake a full investigation of the whole matter. Incidentally, it may be remarked that the collection of this information was the first instance of the use of the Divisions of the Association in obtaining the opinion of individual members of the profession.

The work involved was completed in less than a year, and the resulting report included detailed information as to all forms of contract practice then being carried on in different parts of the United Kingdom, and the experience of a very large number of medical men in connexion with it, coupled with a review of the reforms required and of the economic and ethical considerations involved. In other words, it supplied data necessary for the formulation of a policy having for its aim an improvement in the conditions in which those engaged in contract practice did their work.

This report eventually became well known, both in and out of the profession, as the Contract Practice Report of 1905, and its issue in that year marks an epoch in the consideration of the difficulties in question. Shortly afterwards a definite plan of operation was drawn up, and the subsequent resistance offered in various parts of the country to unfair conditions or undesirable forms of contract work became more effective than hitherto.

Nevertheless, it was clear to students of the subject that, despite the fact that better terms for contract work were being obtained, much the best course would be to abolish all existing forms of contract work and substitute for them a public medical service, such as had originally been suggested in connexion with the question of hospital abuse some thirty years previously, and as had also been considered in some detail by the authors of the report on contract practice already mentioned. Consequently, two committees of the Association set to work to elaborate this idea, and eventually formulated a complete scheme for a public medical service. Its basic idea was that medical men in every area should, through the local Division of the British Medical Association, establish and maintain under the control of the profession itself a service which would provide for the needs of all members of the public whose income did not exceed a stated sum; that such persons should have a right to choose any doctor they preferred if he was ready to accept them as his patients; and that every medical man in any given locality should have a right to take part in the work of the service. This, it will be seen, was the same idea as that later on put into practice to some extent in the panel service of the Insurance Act.

THE INSURANCE ACT.

The plan devised was duly circulated for consideration among the Divisions, but before any decision regarding it had been reached by the Association as a whole the National Insurance Bill was introduced into the House of Commons. Inchoate and sketchy as its proposals were, they nevertheless covered in principle all the ground that

it was proposed to cover by the Association's own carefully devised scheme for a public medical service. This being the case, attention was naturally diverted from the latter. Eventually, as every one knows, the bill was passed, and this threw all other questions relating to contract practice into the background. One day it may be necessary again to take them up, but even so the form of these questions is likely to be altered, since the Act in question has had the effect of killing a considerable proportion of the sick clubs which previously existed.

The Act has now been in operation for some eighteen months, and it would be highly interesting to review its history from the time that it was first introduced into the House of Commons from the point of view of the work of the Association and in some other connexions. Apart, however, from the fact that such a task would extend this article beyond any reasonable length, it is highly doubtful whether it could be undertaken with advantage at the present time. Moving events such as those connected with the passage of the National Insurance Act and its coming into operation can hardly be seen in true perspective until a sufficient number of years have elapsed for all keen feeling on the subject to have passed away. There is no objection, however, to drawing attention to a few outstanding points—a few mountain tops amid an intricate maze of minor hills—on which the historian of twenty years hence will certainly seize.

The measure originally proposed in the House of Commons differed from the measure eventually adopted as the National Insurance Act, and the provisional regulations as to the administration of medical benefit presented to Parliament on October 1st, 1912, differed from the substantive medical benefit regulations laid on the table of the House of Commons on December 5th of the same year. The alterations were entirely in favour of the medical profession, and were directly due to the work done by the British Medical Association.

It may at first seem as if the making of these very definite statements were inconsistent with the opinion previously expressed that the time has not yet come when the history of the National Insurance Act can well be written, but there is no real inconsistency, for the statements are not an assessment by ourselves of the result of the Association's work in connexion with the National Insurance Act, but a mere summary of the contents of a document on which the historian of the future will of necessity largely depend for any views that he may formulate. This document is the third section of the third part of the first Report on the Administration of the National Insurance Act, drawn up by the National Insurance Commissioners for England and Wales. Its authors can hardly be accused of any bias in favour of the British Medical Association, so those who feel any conscientious doubt as to whether that Association deserves well of the medical profession in connexion with the National Insurance Act can hardly do better than read the report for themselves.*

Still depending solely upon it as a source of information we may add that, had it not been for the activities of the Association, administration of the medical benefit clauses of the National Insurance Act would have rested in the hands of those old and determined enemies of the medical profession—the great friendly societies; that there would have been no free choice of doctor—the old system of employment of selected doctors by separate societies would still be in existence; and that the utmost annual payment for each insured person to the medical man in charge of him would have been 4s. 6d. only.

The original intentions of the promoters of the Act were, however, so altered under pressure brought to bear upon them by the British Medical Association that the medical profession now has a definite voice in the administration of the Act. On every Local Insurance Committee there must be at least one medical man to every nine laymen, and in addition there must be a Local Medical Committee representative of all practitioners in the locality, and a Panel Committee representative of those who have taken service under the Act. The annual payment for each insured person, instead of being only 4s. 6d. a head, cannot be less than 7s., and may be as much as 7s. 6d., and there is the possibility of obtaining an allowance for mileage. The scope of the work, instead of being just what a friendly society official chooses to make it from time to time, is defined, and when the question arises of whether the services of a medical man shall be retained or ended it is decided not by a mere friendly society official, but by a body formed of two medical men and a lawyer.

Allusion is made in the document in question to many other points of a kindred nature, but those mentioned suffice to prove the truth of the statement that has been made, namely, that, owing to the work done by the British Medical Association, the Insurance Act as originally designed was materially modified in favour of the medical profession.

From the same document the historian of the future will also gather that, despite the fact that the text of the National Insurance Bill was not available until May 9th, 1911, the objections felt towards it by the medical profession had been definitely formulated by June 1st. In other words, within three weeks the promoters of the bill were not merely aware that sundry medical men objected to one or other of its features, but were faced by a series of definite demands made on behalf of what was for the time being, and for many months afterwards, an absolutely united profession. Considering how little attention individual medical men pay, as a rule, to what goes on in the House of Commons, and considering how complex was this particular measure, and how strongly its general aim appealed to many thoughtful men, it would not have been surprising if the objections felt towards some of its clauses had taken no more practical form than mere sporadic grumbling; and it is certainly a remarkable thing that within so short a space of time the features of the Act which were fundamentally objectionable should have been clearly recognized and the demands which ought to be made in respect of them reduced to a few compact sentences. Even when one knows how it was done the feat still remains notable.

It was rendered possible by two circumstances. The organization of the British Medical Association made it feasible to set to work on the very day that Mr. Lloyd George delivered himself of his preliminary statement in regard to the bill to cause meetings to be held in every part of the kingdom, not only of members of the British Medical Association, but of all medical men, whatever the nature of their practice. The second circumstance was of almost equal importance. At all these meetings there were present numbers of medical men who, thanks to the British Medical Journal having for more than a year previously made a regular practice of supplying information on the subject of sickness insurance work and its underlying principles as exemplified in other countries, and to closely allied topics having recently been debated in most of the Divisions of the Association, were thoroughly conversant with the general subject. Consequently the debates from the beginning took a really practical form.

The report also supplies the historian of the future with the information that at the eleventh hour and when the Government was seriously considering which of two possible alternatives should be adopted if the medical profession persisted in the threat not to join the proposed panels, there was evidence of some change of view among medical men, and eventually the Association thought it right to release from their engagements all those who had signed a pledge of abstention from panel work. There is no suggestion in the report that when the Association came to this determination it was leaving a stricken field, but, on the contrary, it is shown that it had gained for the profession advantages so great that they involved the Government in large and unexpected expenditure, and an impression is left that, in the view of the writers of the report, it was only because the greatness of the alterations of this scheme were not fully appreciated that the decision to rescind the engagements was not reached earlier.

More than eighteen months had elapsed since those engagements were first signed, and since then the Association had succeeded little by little in getting the original bill and the regulations so far modified that from the point of view of its immediate effects the general scheme had become one not unacceptable to a majority of those more immediately concerned. It may be said, in short, that this report makes it impossible that, when the history of the Act comes to be written, any view will be taken other

* Report for 1912–13 on the Administration of the National Insurance Act, Part I (Health Insurance). (Cd. 6907. Price 2s. 9d.)

than that the British Medical Association performed in connexion with it a very great service both to the profession and to the public. To underpay the profession or to impose upon it irksome or degrading conditions must always tend to make its work inefficient, and such inefficiency must inevitably have resulted had the Association allowed to pass unmodified a bill which in its original form promised simply to perpetuate all the worst features of the old club system.

There is one other point on which historians will certainly seize, and to which, consequently, it is legitimate to allude. Some of the events connected with the passage of the National Insurance Act exemplify in a remarkable degree two curiously antithetic tendencies in the medical profession. Both are sources of weakness, and both, on searching the records of the British Medical Association and contemporary literature, will be found to be in no wise of modern development. One is an indisposition to recognize that as social systems become more complex, corresponding changes in the conditions in which the medical profession does its work are inevitable. The other is an impatience with the slowness of economic evolution, which evidences itself in a readiness to form what in political circles are known as "caves." Very often such caves form themselves into associations for the promotion of their particular views or of some special interest, and this was the case in connexion with the later developments of the contest under consideration. Some of the associations or societies thus formed have already ceased to exist, and the rest, judging from past history, may be expected to follow suit after frittering away a certain amount of the profession's never excessive financial resources and fighting power.

To complete this article by summing up the present situation in a few words, it may be said that contract practice in the sense in which that term used to be employed is now rapidly expiring, and is being replaced by a system in which the practitioners concerned, instead of having to compete for the patronage of lay managers of clubs and associations, deal with the State itself and do their work on terms fixed by Parliament or by local authorities after consultation with representative committees of practitioners. To this extent the system is sound, and if it is to be allowed to continue permanently, the task that the British Medical Association has before it is to see that the good points of the system are developed to the utmost, and that there shall not be grafted upon it any features or forms of work which would interfere with the interests of private practitioners as a whole, or stunt the progress of scientific medicine, or unduly trammel the freedom of action of those who take part in the operation of the system itself.

(To be continued.)

A PROPOSED BILL RELATING TO INCIPIENT MENTAL DISORDER.

AT the conclusion of the annual meeting of the Medico-Legal Society, held on June 30th at the rooms of the Medical Society of London, 11, Chandos Street, W., a discussion took place on incipient insanity, with particular reference to a bill bearing upon this matter soon to be introduced into the House of Lords. The bill has been drafted by the Medico-Legal Society, in consultation with the British Medical Association and the Medico-Psychological Society. It proposes to legalize the giving of medical treatment in the early stages of mental disease (subject to the consent of the patient) notwithstanding the provisions of Section 315 of the Lunacy Act, 1890, which makes it illegal to exercise restraint over a person who is not a certified lunatic. The authority for treatment in an incipient case (which may be given in an approved house—for example, a mental hospital, general hospital, or private house or institution) is a declaration by a medical practitioner that the patient is suffering from incipient mental disease, and is not suitable for certification as a lunatic or defective under the Mental Deficiency Act, 1913.

The PRESIDENT (Earl RUSSELL) said the bill was intended to deal with the circumstance that it was a very dangerous thing for a medical practitioner or any one else to treat a person on the border-line of insanity. Any one doing so was constantly in danger of prosecution under Section 315 of the Lunacy Act, and the result was that persons who might be saved from becoming actively insane, if treated in time, often were not treated because of this fear of prosecution; they were allowed to go from bad to worse until they reached a certifiable stage, and might be brought under the Lunacy Act and properly treated. The bill was a voluntary one; no person could be detained against his will. The bill might be better if it were compulsory, but it would then have no chance of passing.

Dr. ARMSTRONG-JONES (resident physician at the London County Council Asylum, Claybury), in introducing the discussion, said this bill would be the Magna Charta of every person likely to suffer from nervous stress or breakdown; yet when he so described it in the public press recently he was accused of suggesting that 80 per cent. of the population should be certificated. As a matter of fact, the whole object of the bill was to avoid the stigma of certification. Mental disease was of all diseases the most curable in the early stages, but it was one of the most expensive and difficult to cure when rooted in any family. The bill would make it possible for rich and poor to be treated outside the gates of an asylum; the potentially insane would be saved from the damning certificate. The bill had the sympathy of the Board of Control, and he paid a tribute to the activity in the matter of the Medico-Legal Society, to Mr. Roland Burrows, LL.D., who drafted the bill, and to Sir William Collins.

Dr. F. J. SMITH said he wished to raise what was, perhaps, an academic point—Was there such a thing as incipient insanity? Was it not a condition which had been there practically from birth, though not exhibiting itself at first? He preferred the term used in the bill, "mental disease of recent origin." For persons whose condition did not warrant compulsory detention the bill would be an admirable one. The question arose whether a patient would realize his condition and submit himself voluntarily to treatment; such patients usually resented the idea that it was necessary they should be taken care of.

Dr. ARMSTRONG-JONES, in reply, mentioned the delirium of typhoid fever, pneumonia, or puerperal fever as instances of incipient insanity. These cases were temporary, yet many of the sufferers were sent to asylums. They were only there a short time, but the effect of certification was to damage the people in their careers.

Dr. F. G. CROOKSHANK thought it was a matter of mistaken diagnosis if cases such as those mentioned were sent to asylums. He would hesitate to describe those persons, who were undoubtedly suffering from forms of mental disease, as having "incipient mental disorder." For such cases legal authority to restrain was needed, and that was not provided by the bill. At present every one who dealt with these cases broke the law justifiably by applying physical force for a few days. Without casting stones at the general practitioner, there was a danger that under pressure the general practitioner would apply this bill to persons who should be certified; that might be met by including in the declaration to be signed by the doctor the definite statement that the case was not suitable for certification. He foresaw difficulties, because the declaration in effect authorized another practitioner to receive a patient and give treatment.

The PRESIDENT pointed out that the authority given by a medical practitioner was not necessarily to another practitioner, but to an approved person. It was felt desirable not to use the word "certificate," so that the patient could not be said to have been certified in any sense. The operation of the bill would be under the direction of the Board of Control, whose inspectors would deal with cases which it was thought should be certified.

Dr. ARMSTRONG-JONES emphasized the undesirability of a woman with delirium of puerperal fever being delivered at an asylum; she might be sent under the bill to an approved house or a special ward of a hospital.

Mr. C. WOODWARD thought puerperal insanity a bad case to take for the purposes of the bill; such patients were absolutely insane at the moment

Dr. A. T. SCOTT (late surgeon of Holloway Prison) thought the bill should deal with adolescent cases; in such cases the stigma of insanity was a very real thing

Dr. BERNARD SPILSBURY asked what would be gained by the bill, seeing that it was already possible for a patient to give his consent to voluntary treatment. He thought refusals to undergo treatment would be frequent.

The PRESIDENT replied that the main object of the bill was to avoid a prosecution of the medical practitioner under Section 315, but although the measure was a voluntary one, there was no necessity for a formal consent to treatment. The bill was initiated at a discussion by the Medico-Legal Society, whose council sat later with representatives of the British Medical Association and of the Medico-Psychological Society to pass the draft in its present form. It was proposed to ask Lord Loreburn to introduce the bill in the House of Lords, to explain its objects, and cause it to be read a first time. The bill could not get any further this session, but it was thought useful to place it before the public.

Mr. ROLAND BURROWS said that care had been taken to eliminate from the bill any term used in the Lunacy Act, as its nomenclature had acquired a sinister meaning. The bill declared that if a person was not certifiable he could be treated. It was proposed that this should be done under proper conditions and without harassment to those in charge. Medical practitioners were distrusted by the public in regard to insanity; therefore the aspect of voluntary treatment had been over-emphasized in the bill for the express purpose of allaying apprehension. The bill was based on a Government measure, introduced in 1905, presumably with the approval of the Lunacy Commissioners. The bill laid down no rule as to treatment; it merely provided that a person in whose custody a sufferer was should not be liable to be prosecuted. The form of treatment was a matter for a medical attendant. As to the definition of incipient insanity, he felt that the psychiatrists deserved criticism because they had not agreed amongst themselves what were the standards of sanity or insanity. Dr. Mercier had not been able to take part in the discussions on the draft of the bill, but he sent a criticism, in which he asked: "Who are perfectly sane? Is there anybody except the members of this committee?" The remark illustrated a tendency of the psychiatrists to say that every deviation from the normal was insanity. The law had no regard to anything but objective symptoms.

The discussion then closed.

EPSOM COLLEGE.

SIR HENRY MORRIS, the Treasurer of Epsom College, presided at the annual general meeting of governors on June 26th, at the office of the College in Soho Square. The attendance was much larger than usual, possibly as a result of the correspondence which has taken place in the columns of the BRITISH MEDICAL JOURNAL in reference to the bequest from the late Miss Glenny, which was awarded by the court to the Royal Medical Benevolent Fund.

The proceedings began by the submission of the report of the scrutineers—Dr. F. de Havilland Hall, Colonel Bruce M. Skinner, and Mr. W. A. Propert—on the result of the voting for pensioners and foundation scholars. Two pensioners and three foundation scholars were elected, whilst a further pensioner and another foundation scholar were admitted by the Council subsequently. Details appear in our advertisement columns.

In moving the resolution as to the adoption of the report, the CHAIRMAN drew attention to the salient points contained therein, some of which are mentioned below. In reference to a suggestion which had been made by some persons that the Royal Medical Benevolent Fund and Epsom College ought to have compromised in regard to the bequest of £500 from the late Miss Glenny, he said that the Council of Epsom College was convinced that the testatrix intended the bequest for their charity. This opinion was fortified by the statement in the proof of Mr. Crosse, the solicitor to the testatrix and one of the executors, that the executors were satisfied that the College was entitled to the legacy, that being the institution the testatrix intended to benefit. Moreover, the executors would have been failing in their duty had they not done their best to enable the bequest to reach the destination intended by the donor.

The report of the Council to the governors, which was unanimously adopted, stated that at the present time the foundation and the trustee funds rendered assistance to 50 ordinary pensioners, 9 Pugh pensioners, 10 France pensioners, 16 Da Silva pensioners, 3 Morgan annuitants, 5 Highett pensioners, 1 Cheyne annuitant, 4 Brodie Sewell pensioners, 2 Christie pensioners, 1 Sir Thomas Smith pensioner, 1 Susan Harriette Tait annuitant, and 50 foundation scholars. The report impressed upon those intending to leave money for the Foundation attached to the College the great importance of mentioning the official title of the College, namely "Epsom College." The report referred to the resignation of the Rev. T. N. H. Smith Pearse of the appointment of head master, and stated that the Council wished to express its appreciation of his earnest and sustained efforts to foster the various interests of the College, and to promote its moral tone and good general character. Since the last annual general meeting G. W. Davis had obtained an open scholarship in science at St. Mary's Hospital; L. V. Ardagh had secured an exhibition for classics at Wadham College, Oxford; A. R. Wood had won an exhibition for science at Clare College, Cambridge; and two old Epsomians had gained open scholarships at St. Bartholomew's Hospital in October last, one in science and the other in arts. Eleven boys had passed the whole or a part of the first examination for medical degrees of the University of London; thirteen boys had passed the matriculation examination of the same university, three of them being in the first class; and nine boys had gained the higher certificate of the Oxford and Cambridge schools examination board.

After the adoption of the report and the election of members of the Council and auditors, a vote of thanks to the Chairman for services rendered to the College as treasurer closed the proceedings.

ROYAL MEDICAL BENEVOLENT FUND.

AT the last meeting of the Committee twenty-four cases were considered, and grants amounting to £185 voted to twenty-two of the applicants. The following is a summary of the cases relieved:

M.R.C.S., L.R.C.P., aged 47, who practised at Aysgarth, Yorks, and abroad. After residence abroad, his health broke down and he had to return to England thoroughly incapacitated, and still unable to work. Voted £10 in two instalments.

Widow, aged 65, of L.S.A.Lond., who practised at Ipswich. Five children; three married, but unable to help. Only income £8 per annum from life assurance, and 19s. per week from lodgers. Health not good. Relieved twelve times, £130. Voted £10 in ten instalments.

Daughters, aged 48 and 56, of M.D.Aberd., who practised at Luddenden, Yorks. The eldest is suffering from incurable deafness, and the younger one has very indifferent health. Only income £20 each per annum from investment. Relieved once, £10. Voted, £10.

Widow, aged 58, of L.R.C.P. and S.Edin., who practised at Balham and died in 1913. Invested small capital in furnishing house to receive paying guests, but has lost money. Voted £12 in twelve instalments.

Widow, aged 39, of L.R.C.S. and P.Irel., who practised in Monmouthshire and New South Wales. Engaged as housekeeper at £15 12s. per year, and one of two daughters, aged 10 years, allowed to live with her. The other child adopted by husband's relatives. Asks for assistance towards the education of daughter. Voted £2 and referred to the Guild.

Widow, aged 64, of M.R.C.S.Eng., who practised in Birmingham, Brighton, and Australia. Lost all capital in consequence of husband's long illness eleven years ago. Only settled income £10 per annum, and too old to obtain work. Voted £12 in twelve instalments.

Widow, aged 53, of L.R.C.P. and S.Edin., who practised at Great Yarmouth. One daughter, who used to dispense for her father, but now helps her mother and does other work. Invested capital in boarding house, which has not paid. Voted £12 in twelve instalments.

Widow, aged 46, of L.S.A.Lond., who practised at Leyton. Five daughters, eldest 16 years. No provision made for the widow, and her only income is a small allowance made by her brothers. Voted £2, and referred to the Guild.

M.B., of Aberdeen, aged 55, who practised at Bunbury and in Essex. Suffering from paralysis and quite unable to work. Wife and four daughters, two of whom are at school. Only income £76 per annum from investments and small pension. Voted £5 and referred to the Guild.

Widow, aged 32, of M.R.C.S.Eng., who practised at Keyingham, near Hull. Three children, the eldest 9 years. Only income £12 per annum. Voted £10 in two instalments.

Daughter, aged 43, of L.R.C.P. and S.Edin., who practised at Easdon and Whitley Bay. Obtains a small income by nursing, but has been unable to work for eleven weeks owing to sciatica. Relieved nine times, £60. Voted £5.

Daughter, aged 62, of M.R.C.S.Eng., who practised at Lydney. Means lost through a defaulting trustee, and too old to work. Only income an annuity of £21 from another charity. Relieved seven times, £77. Voted £5.

Widow, aged 56, of M.R.C.S.Eng., who practised at Enfield. Two daughters, one married and the other an invalid. Income only £60 per annum and not well enough to work. Relieved three times, £15. Voted £5.

Widow, aged 49, of L.S.A.Lond., who practised at Leicester. Earns a little by needlework, but cannot obtain sufficient work. Two daughters, each only earning a little, and two boys, ages 12 and 10, at school. Relieved twice, £22. Voted £12 in twelve instalments.

Widow, aged 55, of L.R.C.P. and S.Glasg., who practised at Heaton-on-Tyne. Six children, two of whom are married and unable to assist, and the others only very little. Has two lodgers. Health very unsatisfactory. Relieved ten times, £106. Voted £12 in twelve instalments.

Daughter, aged 50, of M.R.C.S.Eng., who practised at Box. Lives with delicate sister, who also receives a grant from the Fund. Applicant's health very unsatisfactory. Relieved twice, £24. Voted £12 in twelve instalments.

Widow, aged 68, of M.D.Edin. and M.R.C.S.Eng., who practised at Cambridge. Income £25 per annum from friends, and occasionally has a boarder. Relieved four times, £24. Voted £12 in twelve instalments.

Widow, aged 56, of M.R.C.S.Eng., who practised at Wellingborough. No income of own, but acted for a time as housekeeper for relative, who gave home and board in return. The home has now been given up, so she is stranded. Relieved three times, £32. Voted £12 in twelve instalments.

Widow, aged 34, of M.R.C.S.Eng., who practised at Bow, E. Endeavours to make a living by taking in boarders, but not very successfully and is in arrears with rent. Has twin boys, aged 7½ years. Relieved once, £10. Voted £10.

Special emergency grants of £5 each were also made to two cases, these to be given at the discretion of the Honorary Secretary for Cases.

Contributions may be sent to the Honorary Treasurer, Dr. Samuel West, 11, Chandos Street, Cavendish Square, London, W.

LITERARY NOTES.

MR. GEORGE BETHELL, Registrar and Librarian of the Medical Society of London, has sent us a reprint from *The Library Association Record* of May, 1914, of an account of the library under his charge, which was read at a meeting of the Library Association held on January 8th. The Medical Society was, as is well known, founded in 1773 on the initiative of John Coakley Lettsom, who was greatly assisted by John Fothergill. Mr. Bethell traces the growth of the society and its library. The library now contains about 23,000 volumes and a unique collection of printed tracts on medical and allied subjects, also about 500 manuscripts, including a collection of Greek MS. Among the manuscripts is the diary of Dr. John Ward, vicar of Stratford-on-Avon. This diary, says Mr. Bethell, which runs into seventeen volumes, extending from 1648 to 1679, contains much that is interesting, both medically, ecclesiastically, politically, and socially, of that period. Mr. Ward had practised medicine, and his many medical references, especially relating to his visits to London hospitals and the treatment of his parishioners, are of great interest. Possibly the most interesting of all his entries is that relating to the death of Shakespeare. The entry is as follows: "Shakespear, Drayton, and Ben Jhonson had a merry meeting and it seems drank too hard for Shakespear died of a feavour there contracted." This important entry filled in a gap that had long been obscured, regarding the great poet. Mr. Bethell gives a list of the incunabula in the library; among them we note the *Rosa Anglica* of John of Gaddesden (1492). The library has an excellent collection of English medical works of the sixteenth and seventeenth century. Mr. Bethell says that a very important work possessed by the Medical Society is the treatise *De Trinitate Divina* by Servetus. Every original copy of this work, except one, was burned, together with the author, by John Calvin. The copy which escaped the flames, having been secured by D. Collad, one of the judges of Servetus, eventually found its way into the National Library of France. This edition, which is without name of place, printer, or date, was printed in the year 1723 by one Palmer in Swan Alley for Thomas Osborne, bookseller, but before it was completed was seized upon by John Kent, messenger of the press, and Wm. Squire, messenger in ordinary, on May 27th in that year at the instance of Dr. Gibson, Bishop of London, and burnt, with the exception of a very few copies. In this book, says Mr. Bethell, is contained the first account of the circulation of the blood, nearly eighty years before the immortal Harvey published his discovery. This is not quite correct. Servetus only describes the pulmonary circulation, and this description is contained in the *Christianismi Restitutio* published in 1553, the year in which the author perished at the stake. Servetus had written two books on the Trinity some twenty years before.

The death of Francis II of France, the first husband of Mary Queen of Scots, was regarded, as most deaths of important personages were at that time, as due to poison, and one writer, Beaucaire de Péguillon, even charges Ambroise Paré with the crime (*venenum ab Ambrosio, chirurgico Calviano in Regis aurem inditum ferunt*). There was poison in the ear, but it was engendered by sepsis. Francis was born with obstruction of the nose and mouth, due doubtless to adenoid vegetations. His breath was foul, and he was a most unhealthy subject. He died in 1560 of Mary Stuart, says the Duc d'Albe. His young and vigorous wife may have helped to hasten the end, but the true cause is indicated with a coarseness and ferocity characteristic of the time by John Knox, who wrote:

> The potent hand of God from above sent unto us a wonderful and most joyful deliverance; for unhappy Francis, husband to our Sovereign, suddenly perisheth of a rotten ear . . . that deaf ear that never would hear the truth of God.

Francis died of chronic suppurative otitis, as is shown by Dr. Louis Courladon in *Aesculape* for March, 1914, where the case is fully discussed in its historical as well as in its medical aspects.

The problem of infant mortality, like the poor, has always been with us; but it has not always been regarded from the standpoint of the modern statesman and philanthropist. Professor L. Emmett Holt, who has contributed a most interesting article on the history of legislation affecting child welfare to the May number of *The Child*, remarks that the Society of St. Vincent de Paul, in the first half of the seventeenth century, was the first philanthropic body in any European country which attempted to induce public authorities to acknowledge the civil existence of foundlings. "A little later," continues the writer, "Louis XIV recognized the value to the State of these infants, and gradually the idea grew that the foundling not only had a right to life, protection and care, but might be of value to the State." This proposition, which seems self-evident to the present generation, was entirely new to the contemporaries of the Roi Soleil. Up to that time the sentiment which had animated the founders of homes and refugees for abandoned and neglected children had simply been one of pity for the child as an individual, rather than recognition of his rights as a potential citizen; and it is significant of the attitude of the State towards child life that such establishments almost invariably owed their existence to religious orders or private benefactors, seldom, if ever, to State or municipal authorities. "The right of infants to live and the value of infant life as such was not recognized until very modern times," says Professor Holt; and our ancestors took it for granted that a large proportion of children were doomed to die in early childhood. Even doctors were fatalists in this respect; and Professor Holt quotes Black, who published a historical sketch of medicine in the year 1782, as saying that during the latter half of the seventeenth century there were only three physicians in Great Britain who paid any special attention to the diseases peculiar to infancy. In spite of this philosophical acceptance of the inevitable, however, it is mainly owing to the medical profession that the economic value of infant life has at length been recognized at its true worth. The contents of the May number of the *Child* are in themselves sufficient proof of the interest felt in every rank of society for all that concerns the welfare of the nation's children. Such widely divergent subjects as the sun and air cure for delicate and nervous children, and the school journey movement, are dealt with at some length by Miss Kate Emil Behnke and Mr. G. G. Lewis; whilst Dr. Leonard A. Parry writes on the annual loss of life through burns amongst the children of the poor, and Sir Robert Baden-Powell has contributed a short article on the Boy Scouts.

The King of Italy recently received in private audience Dr. Pietro Capparoni, member of the council of the Italian society for the critical study of the history of natural sciences and medicine. He presented His Majesty with the five yearly volumes of the *Rivista di Storia della Medicina*, the official organ of the society.

SATURDAY, JULY 4TH, 1914.

THE PROBLEM OF PROSTITUTION.

At a time when widespread interest is shown in the problems of venereal disease, it is useful, if not pleasant, to be reminded of the social facts on which such diseases mainly depend. Most people are ready to regard prostitution as a fixed and ineradicable necessity of society since a very early stage of human history, when it sometimes had some sort of religious sanction, and one certain to remain to the end of the chapter. Yet prostitution, like other social ills, is not a strict necessity; it depends upon, and is a reflection of, the character and environment of citizens; its methods of operation, as well as its social significance, vary from period to period; and it is capable, if intelligently treated, of vast amelioration, just as it is liable, if ignorantly handled, to develop into a menace to the very existence of society.

The Bureau of Public Health in New York has undertaken an elaborate inquiry into the subject, and two of four reports promised have been issued.[1] Mr. Abraham Flexner, in his report, leads his readers through chapters full of interest, to an intelligent view of the problem presented to him in his investigation of the countries of Western Europe. He shows the peculiarities of the modern state of affairs, and compares the methods by which the different States seek to handle the question. His book is to be heartily commended to those who are sufficientiy interested in social problems to peruse a short and most readable study, which concludes with a useful abstract of the methods adopted in Paris, Berlin, Hamburg, Vienna, and Denmark.

Mr. Flexner started without any special knowledge, and consequently without bias. He has finished as an uncompromising opponent of all the various forms of State regulation. He finds it at every turn opposed to public policy, and possessing no counterbalancing advantages. Regarded from the facet of public order—to which all modern forms of regulation trace their source—it is not justified by success, at least in our present state of social polity; from the point of view of disease—generally regarded as its modern justification—it is worse than a failure. Indeed, it were wonderful if methods devised to deal with public order should also deal effectually with infectious diseases. Moreover, the method adopted for the hygienic examination of prostitutes, if the description approaches the truth, is not only unpleasant, but must be rather a means of spreading than of stopping contagion. They detect only a small proportion of disease, and probably infect more than they detect. Where it is done with modern research methods, women learn to defeat the examination by use of antiseptics. It follows that a prostitute's certificate is useless and misleading, as, indeed, it must be where women entertain a multiplicity of males. Bordels, sometimes supposed necessary for public order and for the protection of decent girls, are a delusion and a snare. They debase and degrade the women who live in them, they breed abnormality and criminality, and become centres of both; where they have been stopped, their abolition has conduced to public order and probably to good health.

Regulation is based on the supposition that male laxity in sex matters is unalterable and ineradicable, and is opposed to that gradual social and hygienic improvement which is the keynote of modern thought. Hygienically it is hopeless, since minors, who do not, or should not, come under the system, are the most dangerous source of infection.

The growing tendency to the abolition of regulation in Europe is, however, constantly opposed by interests of various kinds; the system of morals-police is too full of temptation and difficulty to allow of a high standard of efficiency. Prostitution is admittedly a matter of demand and supply. Each of those can be depressed or stimulated. Each is in fact depressed by education; the supply mainly comes from the lowest social and intellectual strata; two-thirds of professional prostitutes are reckoned to be mentally backward or defective; but whether this defect is congenital may be doubted. Demand, again, is increased by the demoralizing influences of city life, as also is the supply. The supply is also fostered—though not perhaps mainly—by economic influences, such as low wages of girls; in certain walks of life wages are to some extent influenced by what they can "otherwise" get. But the licensed house is the strongest stimulus both to supply and demand. Its authorized presence is a standing lure to the ignorant and inexperienced, to whom it holds out a fancied immunity from disease. The successful existence depends on the constant supply of "new blood," so that the houses form centres of the "white-slave" traffic. In fact the authorized house of prostitution is the worst focus of just those evils which it is in the public interest to suppress. Without bordels, writes one authority, there is no white-slave traffic. The fact that, according to Mr. Flexner, only about one-eighth of all prostitutes in any town are inscribed, makes any system of regulation a delusion as a measure of public health; segregation is equally futile, inasmuch as it fails to segregate.

Mr. Flexner, as a result, is an "abolitionist." He would be glad to see all State control abolished wherever it exists. He admits the inappropriateness of the term "abolition" in countries like Great Britain and the United States of America, where regulation does not exist; but he contends that the word stands for more than a negative policy. No doubt it does in the minds of the leaders of the movement, but it is to be feared that the majority of people are led to believe that all is well so long as we have no return to the Contagious Diseases Acts.

But, in fact, all is not well in "abolitionist" countries. This is now well recognized in England, and is evidently shown by the various inquiries carried out in New York, Chicago, and elsewhere. The facts in New York are given in a report by Mr. Kneeland. It is an unvarnished statement of the forms and methods adopted by commercialized prostitution in New York, and may well cause uneasiness to any man who imagines that State regulation is the only evil. Perhaps the most interesting part of this report is the study of the State Reformatory at Bedford Hills, in which the antecedents and the mentality of prostitutes are considered.

On the whole it appears that the great evils with which we have to contend—social evils, of which disease is a sequence—are commercialization,

[1] Publications of the Bureau of Social Hygiene, New York: *Prostitution in Europe*. By A. Flexner. Introduction by J. D. Rockefeller, jun. 1914. (Demy 8vo, pp. 455; 10 figures. 7s. 6d. net.) *Commercialized Prostitution in New York City*. By G. J. Kneeland. With a supplementary chapter by K. B. Davis. Introduction by J. D. Rockefeller, jun. London: Grant Richards, Ltd. 1915. (Demy 8vo, pp. 346. 7s. 6d. net.)

exploitation, and advertisement. Regulative systems are to be condemned as fostering all these evils; but they exist apart from regulation.

In all attempts to deal with prostitution as such, it must be borne in mind that sexual promiscuity, whether in the man or the woman, constitutes a vice, but not a crime. So long as there is mutual consent, it is only liable to the interference of the law where harm is done to any third person or public order is infringed. But the law should place severe penalties on the third party—male or female—who exploits and profits from the vice of others. All such action may and should be made liable to pains and penalties. The measure of these must be public opinion; and nothing at present is so important as the education of public opinion in this matter of sexual indulgence which directly promotes the lowering of personal responsibilities and family ties, and is also the main cause of the spread of diseases which are continually sapping the vitality, the health, and the reproductive energy of every nation, not only in Europe but throughout the whole world.

MEDICAL FAME.

THERE is scarcely any kind of fame more transitory than that of great doctors. It is a commonplace that men whose ambition, like the wrath of Achilles, has sent millions of men to Hades, are placed on a pinnacle of glory during life, and their names are writ large on the page of history. Politicians who have brought their country to the verge of destruction have a niche in the Temple of Fame. On the other hand, men whose patient labour has been the means of saving innumerable lives, preventing incalculable suffering, and bringing health to nations, arouse little popular enthusiasm. Their names are drowned by the drums and tramplings of conquests.

Balzac said, "The glory of surgeons resembles that of actors, which exists only during their lifetime and passes away with them." It is the glory that attaches to execution as distinct from creation. Not long ago Paul Bourget said that the destiny of men who are only great in the practice of the art of healing is pathetic, as, when they are in turn conquered by death which they have so often vanquished, they truly realize the famous plaint of the dying tyrant, *Qualis artifex pereo!* Although Nero did not deserve the name of artist, his dying exclamation nevertheless remains the symbol of the tragic loss to the world of supreme gifts which die with their possessor. Lasègue, in speaking of Trousseau, referred, with a melancholy which he did not seek to disguise, to "actors, birds of passage like ourselves!" Hippocrates and Galen are but the shadows of great names. The same may be said of Boerhaave, who was so celebrated in his lifetime that it is said a letter sent to him from China with the address "M. Boerhaave, Europe," reached him without delay. Of the Bells, of Dupuytren, of Liston, of Syme, of Graves, of Trousseau, of so many others nearer our own day, whose fame was in all men's mouths during their lifetime, what remains? For a short time their names are remembered, then they are forgotten. The name of "Dr. Abernethy" has survived in legend, not as that of a great teacher of surgery, but as an eccentric character on whom a number of amusing stories has been fathered. Even in their own day men held in the highest honour by their brethren are often not even names to the public. Cheselden was the leading surgeon of his time in this country, yet a man who was so much in the full tide of human existence (to quote Johnson's phrase) as Swift had never heard of him. Cheselden was a friend of Pope, who was his patient, and who wrote:

> I'll do what Mead and Cheselden advise
> To keep these limbs and to preserve these eyes.

In a letter to Pope from Dublin dated February 7th, 1736-37, Swift asks "who this Cheselden is who has so lately sprung up in your favour." Pope answers: "I wondered a little at your quere (*sic*) who Cheselden was. It shows that the truest merit does not travel so far any way as on the wings of poesy; he is the most noted and most deserving man in the whole profession of chirurgery; and has saved thousands of lives by his manner of cutting for the stone." Swift replies rather testily: "How should I know Cheselden? On your side men of fame start up and die before we here (or at least I) know anything of the matter." How many, except surgeons, now know the name of Cheselden? and how many surgeons have any but the vaguest knowledge of him and his work?

When a man's name is attached to a discovery which has revolutionized medical thought it may survive, like that of Harvey. But many, perhaps most, great discoverers, have been known only to a few during their lives, and when they are dead their names are too often forgotten till they are excavated from mouldering records by some Dryasdust in search of matter for a paper. Lister is an exception, but even when he had made his scientific enemies his footstool his name was almost unknown to the public. When he was made a peer people who would doubtless have called themselves educated were heard asking who he was and what he had done to deserve the honour. They would have been ashamed of such ignorance of even a second or third rate actor. One reason for this difference is that the artist of the stage appeals to all, and his name has nothing but pleasant associations. On the other hand, only sick folk are interested in the healing art and its professors, and the name of the doctor is necessarily associated with times of suffering. Another reason is that the actor lives in a glare of publicity even when he is not actually before the footlights. But the "Harley Street physician" of the popular newspaper and the advertising quack have more honour among the mass of the public than the most successful practitioner who does not sacrifice the dignity of his calling to notoriety. The doctor, however, has the satisfaction of knowing that he passes by doing good; as even Carlyle, one of the sternest critics of the profession, said, whoever is in the wrong, he is in the right. And if he has added the smallest stone to the edifice of knowledge he may comfort himself with the thought that, though his name be forgotten, his work lives. In this sense he is impersonally immortal and can say with Ennius:

> Nemo me lacrumis decoret, nec funera fletu
> Faxit: quur? volito vivu' per ora virum.

THE INFLUENCE OF THE OVARIES AND THE UTERUS UPON LACTATION.

TIME was when lactation was supposed to be a phenomenon under the control of the nervous system. This view was upset in 1898, when Ribbert transplanted part of a mamma from a virgin rabbit into a pregnant one, and observed that the transplanted gland developed and secreted milk. In 1906 Lane-Claypon and Starling proved that the fetus *in utero*

developed a hormone that was taken up into the maternal circulation, and was the agent that gives rise to the mammary enlargement and the lactation that characterize pregnancy. Their experiments were repeated and confirmed in 1908 by Foà, who used bovine fetal extracts and animals of different species. But the fetal hormones are not the only factors involved in the growth and activity of the mammary glands. In 1911 von Basch found a similar hormone in placental extract, and proved that its administration to other animals, as well as its action on transplanted portions of mammary gland, was unquestionable.

In the same year two French observers, Bouin and Ancel, showed that the ovarian corpus luteum is the source of a hormone that activates the mammae, whether gestation occurs or not. They argue that in such animals as the rabbit the corpora lutea provide the exciting cause for the growth of the mammary glands during the first part of pregnancy. Proceeding further, they stated in 1912 that the myometrial gland—a structure found in the uterine wall of the pregnant rabbit between the stroma and the muscular layers of the uterus—produces a hormone that further develops the activity of the mammary glands. J. Hammond and F. H. A Marshall,[1] in a paper on the functional correlation between the ovaries, uterus, and mammary glands in the rabbit, have studied the question with particular regard to the pseudo-pregnancy resulting from sterile connexion with vasectomized buck rabbits: experiments were also undertaken to ascertain whether or not the uterus is an essential factor in this mammary growth, by hysterectomy. They find that the development of the corpus luteum of pregnancy (the corpus luteum verum) or of pseudo-pregnancy (the corpus luteum spurium) in the doe rabbit is functionally correlated with the hypertrophy of the mammary glands, as has been shown by Ancel and Bouin and by others. In the pseudo-pregnant rabbits this hypertrophy is followed on about the nineteenth day by a definite secretion of milk, the quantity of which may be temporarily increased by the injection of pituitary extract, just as in normal lactation. This hypertrophy can take place in rabbits from which the uterus has been removed while still immature; the conclusion is that the uterus is not an essential factor in the development of the mammary glands.

It was also noted that the development of the corpora lutea of pseudo-pregnancy is correlated with uterine hypertrophy and hyperaemia, followed by the extravasation of blood; these uterine changes are clearly comparable with those occurring in true pregnancy, and they afford a confirmation of the view that the corpora lutea are a necessary factor in causing and maintaining the raised nutrition of the uterus during the first part of the period of gestation. After about the nineteenth day following sterile connexion the mammary hypertrophy appeared to retrogress, and these changes all took place without any demonstrable activity in the myometrial gland. Whether the corpus luteum does or does not play any part in mammary growth or secretion at the later stages of normal pregnancy is a point that must be left for further investigation; it may be remarked that the period of gestation in the normal rabbit is thirty days.

It is not in rabbits only that pseudo-pregnancy may lead to phenomena suggesting that a litter is about to be produced; Hammond and Marshall record the case of a cat that failed to become pregnant after connexion, yet began to secrete milk four weeks after the last copulation, the secretion continuing for about two weeks subsequently. Even the experimental animals themselves may be deceived as to their presumedly approaching maternity, it would appear. Thus Hill and O'Donoghue record the case of a marsupial cat, *Dasyurus viverrinus*, that was seen to clean out its pouch for the reception of expected young, although it was not pregnant; and one of Hammond and Marshall's rabbits, twenty-eight days after a sterile coitus, plucked fur from its breast and made a nest as if preparing for parturition, while at the same time milk could be expressed from its mammae. Instinct, in fact, is not an infallible guide, and the "provisions of nature," dear to the teleologist, are sometimes irrational.

THE OXFORD OPHTHALMOLOGICAL CONGRESS.

THE Oxford Ophthalmological Congress will take place this year on Thursday and Friday next, July 9th and 10th. The head quarters of the Congress will be at Keble College, where an unofficial dinner will take place on Wednesday evening at 7.30. The Congress will be welcomed by the Master of the Congress, Mr. R. W. Doyne, in the department of human anatomy. On Thursday morning and thereafter addresses will be given by Dr. Casey A. Wood of Chicago, Mr. S. H. Browning of London (sympathetic ophthalmitis), Mr. W. M. Beaumont of Bath (toxaemic iritis), Mr. G. M. Harston of Hong Kong (treatment of trachoma with CO_2), Dr. H. Alexander Brown of Reno, Nevada (trachoma), and by Mr. R. W. Doyne (the pupil under various conditions of illumination, and the movements of the eye in reading). Demonstrations will be given in the Scientific Museum, and operations will be demonstrated at the Eye Hospital by various surgeons. On Friday there will be addresses by Dr. A. Darier of Paris (emergencies in ocular therapeutics), Dr. Wendell Reber of Philadelphia (heterophoria), Mr. G. H. Pooley of Sheffield (local anaesthesia in eye operations), Messrs. J. Jameson Evans and T. Harrison Butler (operations for chronic glaucoma), Lieutenant-Colonel Henry Smith of Amritsar, India, and by Mr. Sydney Stephenson of London (bovine tuberculosis in phlyctenular affections). On Friday afternoon a discussion on the question of compensation in injuries of the eye will be opened by Dr. William Robinson of Sunderland, who will be followed by Dr. Frank Shufflebotham of Newcastle-under-Lyme. The dinner of the Congress will take place in Keble hall on Thursday evening, under the chairmanship of Professor Arthur Thomson, and afterwards a recommendation of the council that an ophthalmological congress shall be held annually out of London will be discussed. Further particulars can be obtained from the Secretary of the Congress, Mr. Sydney Stephenson, 33, Welbeck Street, London, W.

THE STETHOSCOPE AND THE CHEST SOUNDS.

LAËNNEC's invention of the wooden stethoscope is commonly said to have followed on his use of a roll of paper for mediate auscultation in a stout young lady whose modesty he was anxious not to offend. The short wooden stethoscope is still generally used in France, though, as a matter of fact, the use of the stethoscope is not popular among French practitioners or students, who evince a decided preference for direct auscultation. In addition to the objections to this method which many feel owing to the intimate contact it demands, direct auscultation is difficult when the patient is very ill, since it entails his being made to sit up in bed, and grave consequences have followed this practice in cases of typhoid, pneumonia, and advanced cardiac disease. The binaural stethoscope is practically unknown in France, and the phonendoscope is reserved for the differential diagnosis of difficult heart cases in hospital. The objection raised to the use of the stethoscope in France is that it modifies the sounds in transmission, but after all that is

merely a question of habit, for one soon learns to appreciate the significance of the sounds actually heard, and even the wooden instrument is open to the same reproach. The most striking development of the stethoscope in England of late years has been the introduction of a whole series of improvements having for their object to amplify the sounds. These modifications are perhaps mainly intended to assist practitioners whose hearing has become defective, because, with normal acuity, no difficulty is experienced by the trained observer in detecting all that is required for purposes of diagnosis, by the unaided ear, the wooden or the ordinary binaural stethoscope. The value of the amplification of sound thus obtained is a matter as to which great difference of opinion obtains. One elderly practitioner declares that a given instrument is of the greatest value while another does not find that it materially assists his hearing. This divergence of opinion is due to the fact that when dullness of hearing is due to imperfection in the apparatus of transmission—for example, the drum and ossicles—mere increase in the volume of sound, within certain limits, does not appreciably affect the vibrations actually conveyed to the inner ear or sensorium. If, on the other hand, the transmission of vibrations by the middle ear is good, the hardness of hearing being due to dulled perceptivity on the part of the nervous mechanism of the ear, then even the slightest addition to the intensity of the vibrations is of service. There are of course plenty of ways of distinguishing between the two classes of kinds of deafness. For instance, if the subject is unable to hear the ticking of a watch, say at 2 inches from the ear, but perceives it when the watch is placed between the teeth, it is plain, since the sounds transmitted by bone are readily heard, that the middle ear must be at fault. Such a person will probably derive little advantage from apparatus that merely increases the volume of sound. On the other hand, if the apparatus of transmission be intact, then every addition to the intensity of the vibrations, however slight, will be appreciated. It is like ringing a cracked bell: if we pull hard we make more noise; but if the wire be broken no amount of extra pulling is of any avail, even though the bell be whole.

EUGENIC MARRIAGES IN AMERICA.

THE eugenic marriage laws passed by several States of the American Union do not seem to be very successful. In Pennsylvania applications for a marriage licence have to be made on a form drawn up by the State Department of Health; in the application it must be stated, among particulars as to colour, occupation, parentage, and so forth, that neither of the contracting parties is afflicted with a transmissible disease. This law is mild when compared with those passed in some other States; yet although it received the Governor's approval so recently as July 24th, 1913, we learn from the *Boston Medical and Surgical Journal* of April 30th that already it is pronounced to be a failure. After an experience of over eight months the Chief Clerk of the Philadelphia Marriage Licence Bureau says that only one case has arisen in Pennsylvania since the Act came into operation in which an applicant was refused a permit for disabilities included among its provisions. The weakness of the statute in practice lies in the fact that the clerks have no right to refuse a licence as long as the applicants give answers that are technically "satisfactory" to the prescribed questions concerning health and physical condition, even though these answers may be obviously untrue. It is pointed out by the Chief Clerk that the ineffectiveness of the Pennsylvania law is not remarkable, for the same result has been reported in the other States where legislation has been more drastic. "It only goes to prove," he says, "what the eugenic theorists entirely overlook: that when couples make up their minds they are suited to each other, no mere law is going to prevent them from mating." As has often been urged in the BRITISH MEDICAL JOURNAL, human nature is stronger than any Act of Parliament, and love laughs at legal locksmiths. The eugenic marriage law has for the same reasons been a failure in Michigan. In the State of Wisconsin the law would seem to be a farce for a different reason. According to the *Daily Mail* of May 5th, a woman who had worked for several years disguised as a man obtained a medical certificate of good health such as is required by the law, and went through the form of marriage with another woman. The "bridegroom" is said to have been for years a patient of the doctor who signed the certificate, and he never suspected her sex. His examination consisted in taking blood from her arm, possibly for a Wassermann test. Doubtless he acted in perfect good faith, but the incident places the working of the eugenic marriage law in a somewhat ridiculous light.

FREE THROMBI AND BALL-THROMBI IN THE HEART.

JUST a hundred years ago William Wood, of Edinburgh, published the first case, so far as is known, in which a rounded clot of blood was found free in one of the cavities of the heart. The patient, a girl of 15, had suffered from shortness of breath due to cardiac disease for above three years, and at one time had many attacks of sudden dyspnoea and faintness. It was found after death that she had advanced mitral stenosis, and in addition the left auricle contained a firm and spherical clot of blood rather more than 1½ in. in diameter. Down to the year 1913 some thirty-four more instances have been put on record in which the heart contained loose thrombi. These have been recently collected and analysed by Hewitt[1] in an interesting monograph, and discussed in all their aspects. Genuine ball-thrombi and oval thrombi are very rare, as he points out, only five indisputable instances of the one and only one of the other having been described; in the remaining instances the clots may have been detached from the cardiac wall during the examination of the heart, or else they showed signs of recent attachment to the heart wall on some part of their surface, and such cases, he argues, "should be classed as probably loose or free thrombi." All cases of genuine ball or oval thrombi of the heart hitherto reported have been found in the left auricle, and have been associated with marked mitral stenosis and insufficiency. That such clots may act as ball-valves and occlude one of the valvular openings of the heart appears probable, but Hewitt states that it has yet to be demonstrated that this has actually occurred. He concludes that no sign or symptom has so far been described that will enable the occurrence of loose thrombi in the hearts of patients with mitral disease to be diagnosed with any certainty. This point is brought out again in Dr. French's very recent account[2] of the case of a woman who died with mitral stenosis and heart failure. Here there was a rounded mass of old blood clot free in the right ventricle. It was about the size and shape of a human eyeball, and at one pole showed evidence that it had been attached at one time to some point on the ventricular wall, although the detachment must have been complete for some while. This clot was just too large to pass through the pulmonary valve, and had probably produced what might be called a cup-and-ball pulmonary stenosis, becoming moulded into its rounded shape in so doing, and producing cardiac sounds of extreme variability at the base of the heart in accordance, no doubt, with its varying position. It may be noted that at no time was there heard anything sufficiently definite to suggest that there was actual pulmonary stenosis in this case. It is interesting to remark that in only one of Hewitt's 35 cases of loose thrombi in the heart was the clot found in the right

ventricle; in 2 it was in the left ventricle, in 3 it was in the right auricle, and in the remaining 29 it occupied the left auricle.

DOCTORS AND THE DEATH PENALTY.

NOT long ago a popular writer suggested that "death at the hands of the law should be regarded as a major scientific operation and as such entrusted to the medical officer." In some Scandinavian countries the office of surgeon and executioner were occasionally combined, and in our own country doctors have given attention to the best means of helping malefactors to shuffle off this mortal coil by studying the right length of drop required for the purpose and the most effective way of adjusting the noose. In France the instrument with which the capital sentence is carried out, though not invented by Dr. Guillotin, was brought into use again and perfected by him just before the Revolution in which it played so terrible a part. It is often said that he himself was a victim of the guillotine, but this is not true; he died a natural death on March 26th, 1814. In these days of centenaries he escaped commemoration, and this is just as he would have wished, for though he introduced the instrument from motives of humanity, he was not proud of having his name attached to it. A rough form of guillotine had been in use in Italy since the thirteenth century, and was employed in Germany in the Middle Ages and in Scotland and England in the sixteenth and seventeenth centuries. For a hundred years or more it had fallen into disuse, and, according to the *Encyclopaedia Britannica*, Guillotin got his information about the apparatus from the description of an execution that took place at Milan in 1702, contained in an anonymous work, entitled *Voyage historique et politique de Suisse, d'Italie et d'Allemagne*. In an article published in the *Progrès Médical* of April 25th an account of the introduction of the guillotine is given. In 1789, when Guillotin brought forward his proposal, there were two methods of execution —hanging, which was a degrading punishment, and beheading, which was reserved for State criminals and did not dishonour the family. Guillotin's object was to do away with this inequality, and accordingly he proposed that crimes should be punished in the same way, whatever might be the rank of the culprit. He gave a vivid description of the horrible methods of execution "devised by a barbarous feudalism"—the gibbet, the scaffold, the wheel, and the stake—and concluded by proposing decapitation as a uniform method of punishment, mitigating it as far as possible by means of the instrument which bears his name. There was an animated discussion, Guillotin's proposal being strongly opposed by the Abbé Maury, who prophetically pointed out that it would be dangerous to accustom people to the sight of blood. Nevertheless, the proposal was adopted, and Guillotin's name became immortal in a manner by no means to his taste. A ballad of the day celebrates him as follows:

Guillotin
Médecin
Politique
Imagine, un beau matin
Que pendre est inhumain
Et peu patriotique!

And so on. The ballad describes the machine and names it:

La machine
Qui simplement nous tuera
Et que l'on appellera
Guillotine!

But it was not till two and a half years later that, after further discussion, the guillotine came into use. Before it was finally adopted Antoine Louis, General Secretary of the Academy of Surgery, was consulted. His answer, which dealt in an exhaustive manner with the construction of the machine, was read on March 20th, 1792. It was proposed to call the instrument "louisette," after him, but the name "guillotine" stuck to it, to the despair of its unwilling sponsor, who for the rest of his life tried to sink himself into oblivion. The first criminal executed with the guillotine was one Nicolas Jacques Pelletier, who "suffered" on April 25th, 1792, for a highway robbery. The guillotine began its awful career as a "precautionary measure" against enemies of the Republic on August 10th in the same year.

THE ANNUAL SHOW AT THE COLLEGE OF SURGEONS.

THE annual report of the conservator, Professor Keith, of the museum of the College of Surgeons, has been printed, and embodied in it is a list prepared by the pathological curator, Professor S. G. Shattock, of the specimens added to the pathological series since last July. These, together with other specimens added during the year, will be on view from July 2nd to 25th. Dr. Keating, C.M.G., Director of the Government School of Medicine in Cairo, has presented, on behalf of the Egyptian Government, a series of specimens of fusible alloys injected into vessels and ducts to show their branching, prepared by Dr. B. Wahby, Professor of Anatomy in the School of Cairo. They are a revival, but with greater success, of corrosion preparations once familiar in museums, and attracted much attention when displayed last year in the museum of the International Medical Congress. Mr. E. T. Newton, F.R.S., has presented the first "reconstruction model" he ever made. The model in this case illustrates the detailed anatomy of the brain of the common beetle. Microscopic sections are modelled in wax, and the wax plates of a complete set of sections are built up so as to make an enlarged model of the complete embryo or organ submitted to the microscope. Thanks to this reconstructional method, great progress has been made in embryology. The Archaeological Survey of Nubia has presented a collection of second and fourth dynasty Egyptian skulls hitherto not represented in the museum, a sixth cervical vertebra of an ancient Egyptian, with a bronze arrow-head transfixing its body, and tattooed skin from a mummy. There are some instructive radiographs and preparations showing the changes which occur in "Sprengel shoulder," or congenital elevatio of the scapula. Thanks to the energy of the conservator, Dr. Keith, and the interest taken in human anthropology and osteology by other authorities, additions have been made to the collection of ancient British remains, bones of prehistoric flint miners, neolithic and palaeolithic, presented by the Prehistoric Society of East Anglia and by Mrs. Hall, owner of the estate near Weeting in Norfolk, where "Grime's Graves," the flint mines, are situated. Sir James Moody has presented a collection of human remains from an Anglo-Saxon cemetery near Cane Hill Asylum. A series has been added during the past year representing the skeleton of modern English people, showing that certain definite changes have occurred in the physical condition of the people in recent centuries. Many negro and Polynesian skulls have been added, and Mr. Barrington Nash has presented an authentic cast of the skull of Robert Burns. Some skulls and casts of skulls showing neolithic trephining will interest anatomists and archaeologists alike. Dr. T. Wilson Parry has himself experimentally trephined skulls by means of neolithic flakes. Great progress has been made in the cataloguing of the splendid pathological museum, and the descriptive catalogue of the obstetrical instruments has been completed, and a typewritten copy placed in the museum for the use of visitors.

CHILDREN'S COUNTRY HOLIDAYS.

DURING the past few years a very commendable movement has been carried on in various parts of England and Wales having for its object to secure a real country holiday for children who live the year through in crowded parts of populous towns. The undertaking is organized by philan-

thropic agencies and has assumed such dimensions that the children who take part in it may be numbered by tens of thousands. This being so it is obvious that there must be a certain amount of risk from the possible introduction of infectious disease into the country districts unless the greatest care is exercised in the selection of the children to be sent away. It is true that instances in which outbreaks of infectious disease could clearly be traced to the country holiday movement have not been recorded, though this may be due to the vigilance which has hitherto been exercised by the public health officials concerned. With a view to emphasizing the importance of this vigilance the Local Government Board has just issued a memorandum to sanitary authorities in which the principal precautionary measures that can be taken are pointed out. It is suggested that intended arrangements should be communicated as long before as possible to the medical officer of health of the country district concerned. It is expected that such communications will assist the town agency by preventing children being sent to dwellings in the country where they would be exposed to the risk of infection or to insanitary conditions, while the country medical officer of health, in taking precautions against the spread of infectious disease in his district, will be materially assisted by information as to the nature of the inquiries which have been made before the children are sent down and by being put in touch with the persons who are to be responsible for their care and maintenance whilst in the country. Moreover, overcrowding may be avoided if the medical officer of health can have timely information of the houses in his district to which it is intended children shall be sent. Attention is drawn in the memorandum to the necessity for making inquiries to secure that no child shall be sent to the country who is in an infectious condition, or who is in the incubation stage of an infectious disease, or comes from an infected house. Medical officers of health are already overburdened with routine clerical work, but it would not be very much trouble for them to inform the officials of the country holiday organizations whether particular houses from which children are to be sent away are or recently have been infected. In a well-organized public health department this would not entail much trouble.

THE CO-ORDINATION OF AFTER-CARE.

The statistics of most of the sanatoriums for consumption go to prove that a large percentage of their patients leave the institutions in a fit condition to earn their living. In a few instances their former employment is kept open for them, but in the great majority the patients have to find some other means of earning money, commensurate with their powers of work. Employers, as a rule, are not very willing to take on an enfeebled hand, and an unwarranted fear of infection operates to decide others against the engagement of any one who has once been marked as consumptive. By the help of after-care committees these difficulties may be overcome to some extent, but a far wider and more co-ordinated system is required whereby county councils and other local authorities may work together to the same end. This need is emphasized in the latest report of the Kelling Sanatorium in Norfolk, an institution that has been doing excellent and ever-increasing work since its foundation in 1902. In thirteen years the number of beds has been increased from 10 to 95, and a large number of patients are discharged in a fit condition to earn their own living, if only suitable occupation can be found for them. Much has been done by the After-care Committee of the sanatorium to assist patients of both sexes to obtain work, and to observe necessary precautions to prevent relapse, but no co-operation with similar committees in other places has as yet been established, whereby such assistance might be continued and the patient kept under such observation for a sufficiently long period to warrant his classification as a cured or even arrested case. At Kelling many of the patients find opportunities for acquiring some knowledge of country pursuits, such as poultry farming, and are even engaged at a weekly wage to do suitable work about the sanatorium itself. With an average stay of 13.6 weeks it has been found that over 70 per cent. of the patients become capable of work, but the value of such work is soon lost to the community if want of means or unsuitable employment should lead to a further relapse. Hence the need for common action by way of after-care committees throughout the country whereby the consumptive may be enabled to earn his own living instead of dragging out the remainder of his days at other people's expense.

STREET NOISES.

IN the JOURNAL of June 27th reference was made to the increase of noise in the streets owing to the steadily growing volume of traffic that passes through them, and to the maddening concourse of nerve-jarring sounds which assails our ears in consequence. A correspondent lays the blame more on piano organs, brass bands, and other forms of street "music" than on motors, but he reserves, as Mr. Gladstone once said of himself, his "choicest Billingsgate" for the whistling and yelling of boys. There is no doubt that the youths who run down the Strand screeching out "Winnalls!" without any mitigation or remorse of voice, as Malvolio says, are serious nuisances; but after all, the evil is intermittent and its distribution is local. Even the other noises which make us think of Hogarth's picture of the Enraged Musician are not continuous or universal. On the other hand, nowadays the crash of the motor bus and the discordant hooting of the taxi-cab we have with us everywhere. In the West End streets and squares through which people of the so-called smart set, or who wish to be thought so, return from theatres and other entertainments, the snorting of their hooters, their shouts of revelry, and their noisy farewells murder sleep for unhappy dwellers in those neighbourhoods; many of these are people whose days are full of exhausting work, the wear and tear of which can be repaired only by a good night's rest. Still worse is the case of the inmates of the nursing homes sprinkled like satellites around the great centres of medical activity; for many of them broken sleep may make the scale, trembling between life and death, turn the wrong way. In the *Times* of June 29th Sir Henry Morris once more pleads for these victims of the motor horn. He writes in the hope that the new chief of the Local Government Board may find it in his heart to do what Mr. John Burns led the members of a conference held in 1910 to expect that he, in conjunction with Sir Edward Henry, Commissioner of Police, would accomplish—that is, to standardize the sound of hooters, making it uniform in tone and pitch. This would, at any rate, get rid of the horrible discordance which in a literal sense "doth work like madness in the brain." "By this means," says Sir Henry Morris, "and by limiting the hours of night during which motor horns should be allowed to be sounded in the streets of cities and towns, there would be some chance of our obtaining more continuous undisturbed rest than now." Any appeal to the good feeling of the class of motorist of whom we complain would, we fear, be useless; or we should say, again with Malvolio, "Is there no respect of place, persons, nor time in you?" But we would warn them that their disregard of the comfort of others is gradually arousing against them a resentment that may bring them to reason. The public has a right to be protected against the unrestrained selfishness of a small number of wealthy persons, who seem to think the possession of a motor puts them above the law of ordinary humanity. "Fredome," as John Barbour, the old Archdeacon of Aberdeen, says, "is a noble thing," and nowhere is there more real freedom than in this country. It is not freedom, however, but savagery, which makes

a man think he has the right to make as much noise as he likes in public places without regard to any suffering he may thus inflict. And it cannot, we think, be denied that the motor has brought with it a peculiar callousness, which makes those who ride in it indifferent to any inconvenience they may cause to humbler mortals. That dislike of noise is not confined to a few persons of high-strung nerves is sufficiently proved by the fact that the general press is full of complaints on the matter. The question of street noises is one with which it might be difficult for a Legislature faced with so many large issues to deal at present, but in the meantime we should be satisfied with police regulations that would do something to temper the horrors of the hooter to ears made specially sensitive by illness or great strain of work.

PROPOSED SPECIAL FUND.

A correspondent suggests that it might be useful if the purposes to which the proposed Special Fund are to be applied were published in the Journal. These purposes can be ascertained in a general way by a comparison of the Report of Council on the proposed Fund, published on pages 319 and 320 of the Supplement of May 2nd, 1914, and the Report on a Scheme for Organization of the Profession, published in the Supplement of November 1st, 1913. The former report dealt quite generally with the objects of the Fund, stating that it would be devoted "mainly to work which the British Medical Association is precluded by its constitution from undertaking." The report also stated that the Fund is required "as a reserve for the protection of the medical profession in future emergency." The Report of Council, which is at present under the consideration of the Divisions, deliberately refrains from going into detail, it being the intention of the Council to ascertain the opinion of the Divisions as to whether a Fund for these general purposes is desirable, as to how far the Association would be justified in assuming that the profession is prepared to support such a Fund, and what form its constitution should take—that is, Trade Union or Trust—leaving the details to be worked out after the general principles have been established. A reference to the earlier report (Supplement, November 1st, 1913) will give some indication as to the detailed way in which at that time it was proposed to spend the Fund if established, but these details must not be taken as applying to the present proposal, and, in fact, some of them are already out of date.

SCHOOL TEACHERS AND MEDICAL INSPECTION.

A conference between the Medical Inspection Subcommittee of the Medico-Political Committee of the British Medical Association and representatives of the National Union of Teachers will be held on Wednesday evening next at 7 p.m. At this conference the teachers will express their views with regard to the details of school medical inspection which should be undertaken severally by the medical inspector and by members of the teaching staff. It appears that the allocation of duties and responsibilities varies very much in different districts. In some teachers are expected to undertake duties for the proper discharge of which they feel they do not possess the necessary technical knowledge. It would appear that when such duties are imposed upon teachers it is because the local authorities are unwilling to provide a medical officer with a sufficient staff. It is hoped that the conference will result in an understanding upon this and other matters affecting the proper administration of medical inspection of schools.

THE LAWRENCE RESEARCH FUND.

In memory of their father, Sir W. Lawrence, F.R.S., and of their brother, Sir Trevor Lawrence, the Misses L. E. and M. W. Lawrence have presented £4,000 to the Royal Society in trust to devote the interest to the furtherance of research into the cause and cure of disease in man and animals in such manner as the president and council may from time to time determine. Sir William Lawrence (1783–1867), who was apprenticed to John Abernethy and was his demonstrator of anatomy for ten years, became assistant surgeon to St. Bartholomew's Hospital in 1813, and surgeon in 1824. Five years later he succeeded Abernethy as lecturer on surgery. In addition to his work as a general surgeon Lawrence gave special attention to ophthalmology, and published a treatise on diseases of the eye. He became Serjeant-Surgeon to Queen Victoria in 1857, and was created a baronet in the year of his death. He was succeeded in the hereditary honour by his son, Sir Trevor Lawrence, long treasurer to St. Bartholomew's Hospital, and President of the Royal Horticultural Society. After his recent death many plants from his collection of special scientific interest were presented to the Royal Botanic Gardens, Kew.

ROYAL COMMISSION ON VENEREAL DISEASES.

The Royal Commission on Venereal Diseases, appointed on November 1st, 1913, has issued a brief report stating that from the period November 7th to April 6th it has held thirty-two meetings and examined thirty-six witnesses. The branches of the inquiry are so numerous, and in some cases so closely interrelated that the Commissioners have found it impossible to deal with them separately by completing one branch before entering upon another. Their investigations are therefore incomplete, and they propose to take evidence from several Government departments as well as from private individuals able to speak with special knowledge. They expect also to receive statistics which are being prepared by certain hospitals and institutions. The report contains no conclusions or recommendations, but is accompanied by an appendix containing the minutes of evidence taken down to April 6th. Since that date the Commission has sat on eleven days to hear evidence. Abstract reports of the evidence taken at all the meetings of the Commission down to July 4th have been published in our columns.

The Library of the British Medical Association has received from Dr. Jamieson B. Hurry (Reading) a copy of Section xxiii of the *Transactions* of the International Congress of Medicine in London. The section relates to the history of medicine. The general volume, Part II of the Section of Orthopaedics, and the Section of Dermatology were presented a short time ago to the library, but it still needs all of the other sections.

The Irish Medical Schools' and Graduates' Association will hold a lunch at the Grand Hotel, Aberdeen, at 1.15 p.m. on Thursday, July 30th, at which Dr. Douglas will preside. The annual National Temperance League breakfast will be held in Trinity Hall, Union Street, Aberdeen, on the morning of the same day, when Mr. Alexander P. Forrester-Paton, President of the Scottish and Vice-President of the National Temperance League, will be in the chair.

Fifty years have passed since Professor Eugene Koeberlé performed his first ovariotomy in Strassburg. In order to commemorate worthily this anniversary and to perpetuate the memory of the great surgeon, the first on the Continent who successfully followed Clay, Spencer Wells, and Keith in establishing ovariotomy, a committee consisting of his pupils, friends, and admirers in all countries has undertaken to set up in the Civil Hospital, Strassburg, a bronze memorial tablet bearing a portrait. Subscriptions will be received by Dr. Bucher, 2, rue Brulée, Strassburg, Alsace-Lorraine.

Medical Notes in Parliament.

[FROM OUR LOBBY CORRESPONDENT.]

Proceedings on the Finance Bill.—In view of the recent alteration in the programme of the Government, it is necessary to add to the explanations which were made in our leading article of last week on the subject of the Finance Bill. The provisions remain as already explained, but it has been decided, after the passing of the necessary resolutions of the House, that that which we described in our last issue as Finance Bill No. 2, shall be added to the Revenue Bill after that bill has passed through Committee. The procedure which will be taken when that time arrives will be to move that the Revenue Bill be recommitted for the purpose of adding the clauses which previously formed Finance Bill No. 2. As a result of this procedure, there will be two bills instead of three—the present Finance Bill and the Revenue Bill containing the land valuation proposals and the proposals with respect to grants to local authorities.

Budget Schemes: Tuberculosis.—Mr. Worthington Evans asked the Chancellor of the Exchequer in what proportions the £750,000 proposed for the extension of the tuberculosis arrangements to dependants of insured persons, tuberculosis laboratories, and nurses was to be divided amongst the three items mentioned; and whether it was intended to introduce legislation on the subject this session.—Mr. Montagu said: It is proposed that of the sum referred to £400,000 should be allocated to tuberculosis services, £250,000 to nursing, and £100,000 to pathological laboratories.

Dogs Bill.

The Dogs Bill is now dead, and the manner of its death affords interesting illustrations of different methods of parliamentary opposition. On Wednesday, June 24th, Committee A reassembled to continue consideration of the Dogs Bill, but a quorum of the supporters of the measure, as on the previous occasion, was not obtained in the room. Many members who were opposed to it remained outside and declined to come in. After waiting half an hour the Chairman, in announcing the adjournment until Tuesday, June 30th, raised the question whether he should report members who, whilst present in the precincts, declined to attend the committee. The contention of the members who remained outside was that, if a bill enlisted so little interest and enthusiasm amongst a committee of some eighty members that it could not secure the attendance of a quorum of twenty, they were not called upon to make a quorum in order to facilitate its progress. A discussion on the remarks of the Chairman took place in the House of Commons later on, and the Speaker pointed out the difficulties which were involved in any proposals to remove members from a committee, and that, whilst the Committee of Selection could place members on a committee they had no power or authority to remove them. It was also pointed out that what would apply to members who had waited outside in the lobby would apply with more force to those who had not come at all.

On Tuesday, June 30th, there was a large attendance of the Committee, and there had evidently been energetic whipping on both sides. The first amendment which was pressed was one by Dr. Chapple, which he moved with a few remarks only, to insert the word "inoculation" before "experiment." The supporters of the bill were evidently surprised, and as the morning wore on, not a little annoyed, that its opponents declined to take up the time of the Committee by speeches, and many and ingenious were the efforts of Sir Frederick Banbury, Mr. McVeagh, and others to induce them to prolong the discussion. The university members were taunted with not placing their learning at the disposal of the Committee, and the medical members, Dr. Addison and Dr. Chapple, were repeatedly invited to enlighten the darkness of the lay minds, but without avail. The amendments which were moved by the opponents of the bill were all inserted in the first clause, usually by 18 votes to 15 or thereabouts. As it was finally amended, the first clause read as follows: "From and after the passing of this Act it shall be unlawful to perform any inoculation experiment of an unscientific nature calculated to give pain to any dog for any purpose whatsoever, either with or without anaesthetics, and no person or place shall be licensed for the purpose of performing any such experiments." After the clause had been amended so as to make it only apply to inoculation experiments of an unscientific nature, there was obviously not much left of the bill, and on the main question being put that Clause 1 should stand part of the bill, it was negatived by 18 votes to 15. Clause 1 being therefore deleted, and being the only operative and effective clause, Sir Frederick Banbury moved that the Committee do not proceed further with the consideration of the bill. This was agreed to without a division, and the Chairman undertook to report the bill and the resolution of the Committee accordingly to the House.

After Mr. Rawlinson had secured the insertion of the words "an unscientific" before the word "nature," it was proposed by Mr. McVeagh that the Secretary of State for the Home Department should be the tribunal to decide what experiment was of an unscientific nature. Mr. Ellis Griffith, on behalf of the Home Office, declined to undertake the responsibility, and Mr. Scott Dickson, Sir Philip Magnus, and others were variously nominated for the unwelcome office. The defeat of the bill was probably a relief even to some of its supporters amongst the Committee, and it was generally agreed that it is an unfortunate feature of parliamentary proceedings in Committee that bills of this character should delay the proceedings of the Committee on other important measures which are kept waiting.

Milk and Dairies Bill.

Standing Committee B met for consideration of this bill on Thursday, June 25th, and on Monday, June 29th.

At the commencement of the proceedings on June 25th Mr. Herbert Samuel made a preliminary statement and suggested revised wording for various parts of the first and second clauses of the bill to meet the points raised at the previous sitting by Mr. Astor and others to the effect that the keeper of a cow which was found to be giving tuberculous milk, but in which there was no manifest sign of disease, should receive a notice to that effect from the medical officer of health before proceedings were instituted. In regard also to the point which had been raised as to the conditions under which the milk of such cows might be used in the manufacture of products for human consumption under conditions which would render them safe, the President submitted a revised form of Clause I of the bill and agreed to insert other related amendments in the further parts of the bill. The proposals were accepted by Mr. Astor and his friends, and Clause I of the bill was altered so as to read as follows:

1. *Prohibition of Sale of Tuberculous Milk.*—If a person
   (*a*) Sells, or offers or exposes for sale, or suffers to be sold or offered or exposed for sale, for human consumption or for use in the manufacture of products for human consumption; or
   (*b*) Uses or suffers to be used in the manufacture of products for human consumption,

the milk of any cow which has given tuberculous milk, or is suffering from emaciation due to tuberculosis, or from tuberculosis of the udder, or from acute inflammation of the udder, or from any of the diseases specified in the First Schedule to the Act, he shall be guilty of an offence against this Act, if it is proved that he had previously received notice from an officer of a local authority, or that he otherwise knew, or by the exercise of ordinary care could have ascertained, that the cow had given tuberculous milk, or was suffering from any such disease.

In connexion with the words which it will be seen have been inserted in the clause with reference to a first schedule, it was agreed, on an amendment raised by Mr. Bathurst, that it would be better to specify diseases—tuberculosis included—to which the clause would apply in a schedule, as the schedule could subsequently be added to if experience proved it to be necessary, the departmental orders receiving the sanction of Parliament in the ordinary way. In these circumstances that schedule which has hitherto been the first schedule in the bill will now be described as the second, and so on.

On Monday, June 29th, the greater part of the time of the Committee was occupied in a debate on an amendment

raised by Mr. Astor to the effect that dairies should be subject to annual certificates of registration, and that it should be possible to suspend or revoke such certificates if a dairyman had been found guilty of repeated or serious offences against the Act. It was generally contended by Mr. Astor, Mr. Hills, Mr. Courthope, Dr. Addison, and Lord Alexander Thynne, on behalf of the amendment, that it would thus be possible to extend the London system to other large towns on more or less uniform lines. Considerable objection, however, was expressed to the clause by the President of the Local Government Board and many other members, on the ground that it would possibly be harassing to the trade and be difficult to apply in country districts. In addition, also, it was evident that the insertion of the amendment would gravely impede the progress of the bill, and it was ultimately withdrawn.

Paragraph (*b*), Section 1, of Clause 2, which relates to the inspection of dairies and to persons employed in or about them, was amended by the insertion of words providing that the inspection should be by persons duly authorized by the local authority in which the dairy was situate. At the conclusion of the proceedings, Mr. Tyrrell moved an amendment to omit the inspection of "persons employed in or about the dairies," and the discussion on this amendment was not concluded when the Committee adjourned.

Sight Test for Army Commissions.—Mr. F. Hall (Dulwich) asked the Under Secretary of State for War if candidates for commissions in the army were called upon, after passing the necessary entrance examinations, to undergo a test for eyesight; how many persons were rejected for defective eyesight in 1913; and what were the reasons for making a test, which was in the nature of a preliminary qualification, after the candidates had incurred all the expense and labour entailed by the theoretical examinations.—Mr. Tennant said that the answer to the first branch of the question was in the affirmative. The number rejected for defective eyesight in 1913 was twelve. The test could not, in the interests of the service, be dispensed with; but, in order to obviate disappointment, candidates were recommended in the published Regulations to undergo a preliminary medical examination, and, on payment of certain fees, were allowed to present themselves to a military Medical Board for this purpose. In reply to Mr. Bridgeman, he said that he quite realized that the point was whether it was worth their while to prepare for the final examination. That was why there was a regulation permitting a preliminary examination. Sir Henry Craik asked whether the preliminary examination could not be made sufficiently stringent to prevent the trouble and expense of a re-examination afterwards. Mr. Tennant replied that there must be a final examination before an officer was allowed to join. His eyes might change in the interval.

School Playgrounds.—Sir J. D. Rees asked the President of the Board of Education whether notices were recently issued to certain schools threateniug them with compulsory closure unless they made extensive additions to their playgrounds; if so, what were such schools, and under what provisions of law such notices were issued.—Mr. Pease replied as follows:

> The Board of Education frequently call the attention of local education authorities and managers of schools to the importance of providing adeqnate playground space for public elementary schools and to cases in which the playground space is deficient, and where there are no playgrounds at all the Board have, in the interests of the children and their efficient instruction, felt bound to press the local education authority or managers to submit proposals for early improvement of the premises in this respect. In particular, where substantial enlargements or alterations of existing schools are in contemplation with a view to rendering the premises satisfactory for an indefinite period, it is the practice of the Board to point out that the proposals cannot be regarded as satisfactory for prolonged recognition unless adequate playground space is provided. This action is taken because it is obviously undesirable that considerable sums of money should be spent on a school if it cannot thereby be made satisfactory, and it would be unfair to the managers for the Board to countenance such expenditure. The most recent cases are contained in the lists of schools sent to the Derby County Borough Education Authority and the London County Council. In connexion with this matter I may refer the hon. member to Articles 17 and 18 of the Code of Regulations for Public Elementary Schools.

Mr. Hoare asked whether the Board threatened to close any schools on account of the want of playground accommodation.—Mr. Pease said that it was the practice to put pressure on the authorities to provide adequate playground space, because the money provided by the State could not be efficiently spent in connexion with the schools unless there were proper playgrounds.—Mr. Hoare asked whether there was any statutory authority.—Mr. Pease replied that it was his duty to see that the money of the taxpayers was spent in the efficient management of these schools.

Health of Seamen.—The President of the Board of Trade has informed Major Archer-Shee that the question whether, and, if so, in what respect, the Board's medical staff needed to be strengthened would be considered in connexion with the investigation into the mortality of seamen now being held. It was being conducted by Mr. E. G. Moggridge, Mr. E. W. Colvill, Mr. C. Hipwood, Mr. T. F. Jenkins, and Captain A. H. F. Young, of the Board of Trade; Dr. A. Newsholme, C.B., of the Local Government Board; and Dr. T. H. C. Stevenson, of the General Register Office. They were considering the mortality among seamen on British merchant ships as shown in the vital statistics, with a view to reporting what steps were desirable to diminish that mortality and how far such steps would need legislation. They would, if necessary, take evidence.

Stillbirth Interments.—Mr. Harris asked the Home Secretary whether he had considered the desirability of obtaining a return with reference to stillbirth interments similar to that obtained in 1891.—Mr. McKenna replied that it would be a difficult return to collect, and he would not be justified in calling for it unless it were clear that it would serve some definite and useful public purpose. He would consult the other departments concerned.

Swine Fever.—In reply to questions by Mr. Bathurst, the President of the Board of Agriculture has stated that the chief veterinary officer of the Board had long been conducting experiments with a view to finding a preventive or cure for swine fever, but that it was not possible at present to estimate the value of the result obtained. At the present time twelve separate experiments were under observation. Mr. Runciman added that, as he had stated in the debate on the Board's estimates, he was endeavouring to facilitate arrangements for independent research work on swine fever concurrent with that conducted by Sir Stewart Stockman, but not superseding it. Whether Cambridge University or some other institution was the best for this purpose was at present engaging the attention of the Board and the Development Commissioners, but no definite announcement could be made at present. In further reply to Mr. Charles Bathurst, Mr. Runciman supplied the following table:

Period.	Outbreaks Confirmed.	Swine Slaughtered as Diseased or as having been Exposed to Infection.
First 22 weeks of 1914	1,770	17,926
,, ,, 1913	991	14,493
,, ,, 1912	1,437	18,731

THE *Tropical Diseases Bulletin* for April 30th, 1914, for which Colonel W. G. King, I.M.S., C.I.E., Lecturer on Applied Hygiene in the Tropics at King's College, London, is responsible, is devoted to sanitation. Reports on sanitation from Southern Nigeria, Sierra Leone, Uganda, Ceylon, and British Guiana are dealt with, while under the heading "Disease Prevention" malaria, cholera, typhoid fever, kala-azar, yellow fever, plague, guinea-worm, vaccination, house-flies and disease, insects and their destruction, and larvivorous fish are all discussed. A page is devoted to sanitary legislation, and the treatment of waste by rubbish incinerators is also mentioned. Another interesting part of this number deals with sanitary works, and it concludes with some reviews on health in the tropics.

England and Wales.

SHEFFIELD.

Radium.

The fund for the purchase of radium for the voluntary hospitals in Sheffield is now just over £9,000, and a contract for the supply of 500 mg. has been made with the Radium Chemical Company, Pittsburgh, Pa., U.S.A. The radium is purchased subject to measurement as to purity and amount by the National Physical Laboratory, Teddington, and the vendors are liable to a substantial cumulative fine in the event of their failing to supply the radium at the stipulated time of delivery which is fixed, as to one half, for the end of January, and as to the other half for the end of February, 1915. After long and very careful consideration it has been decided to make use of the emanation instead of the radium itself for therapeutical purposes. It was felt, however, that, to begin with, a portion of the radium should be available for direct use, partly as a stand-by in case the emanation should at any time temporarily give out in consequence of an accident during its collection, and partly because hitherto the most suitable method of applying the rays to the surface of the skin has appeared to be by applicators, the radium salt being spread uniformly over their surfaces and fixed with varnish or in some other way. Radium bromide is a freely soluble salt, and 400 mg. will be used for producing the emanation; 100 mg. of radium sulphate, a relatively insoluble and stable salt, will be kept in reserve and for the manufacture of applicators.

The university authorities have provided suitable accommodation for the radium in the university, and the Radium Committee has appointed Dr. E. Marsden of Manchester to be its physicist. He will be given the status of a university teacher, and will be attached to the staff of Dr. Hicks, Professor of Physics. By this arrangement the Radium Committee secure adequate and safe housing accommodation free of charge, while the university will benefit by having access to a supply of radium for teaching and research work under the charge of an expert who should prove a valuable addition to Professor Hicks's staff. After paying for the radium the Committee will have about £2,000 in hand, and this sum, augmented by the proceeds of the sale of the emanation to other than hospital patients, will suffice to defray the expenses of the department for at least five years.

The Lord Mayor, for the time being, has been elected Chairman, and Professor Sinclair White Vice-Chairman, of the Committee. A medical board, selected from the members of the honorary medical staffs of the voluntary hospitals, will be appointed, and all applications for radium emanation will be submitted to it. A full record of the condition of each patient for whom radium is desired, and the result of its employment, will be insisted on. In this way it is hoped to add very considerably to the accumulating data concerning the effects of radium on malignant growths. It is also in contemplation to organize a cancer research department affiliated with the Pathological School of the University.

Alexandra Rose Day.

On Saturday, June 20th, the streets of Sheffield were commandeered by 1,200 ladies, all dressed in white and pink. They embodied the citizens' first attempt to hold a Rose Day, and thanks to the desire of every one to help the hospitals, the favourable weather, the tact of the vendors, and, possibly, the novelty of the scheme in Sheffield their efforts were crowned with unqualified success. Upwards of 400,000 roses, or to be strictly correct, beautiful imitations of the wild rose, were disposed of long before the day was done, and the hospitals will be benefited to the extent of about £1,800. Had it been possible to secure a larger quantity of artificial roses the result would have been even better, but just now the demand throughout the country is enormously in excess of the supply. The Rose Day Committee and Mr. H. H. Bedford, its energetic chairman, are to be congratulated on the success of their endeavour.

MANCHESTER AND DISTRICT.

The Manchester and District Radium Fund.

The inadequate response to the first appeal to the public for a sum of £25,000 to obtain a supply of radium for Manchester and district has led to a further appeal, and a public meeting was held on June 23rd in the Manchester Town Hall, with the Lord Mayor in the chair. A special address on the use of radium in the treatment of disease was given by Dr. Dawson Turner of Edinburgh, who said that radium had been used in the Royal Infirmary of Edinburgh for the last nine years, and since larger supplies had been obtained it had been tested in a great number of cases and he could speak positively regarding its value, which was no longer experimental. It had been proved that when radium was applied to cancer, the cancer cells in many cases underwent degeneration and were no longer able to reproduce themselves in malignant fashion. In these cases the cancer ceased, became quiescent, did not trouble the patient much and might often be entirely removed by a surgical operation, whereas previously it could not have been so removed. In other cases the growth was destroyed and disappeared altogether. To the question "Is radium a cure for cancer?" the answer must for the present be in the negative. Not all the cases yield in the manner described though the majority did, and he thought it possible that with more experience and larger quantities to work with better results might be obtained. Again, though cancer might be removed by radium from one position, it might recur in another. As yet radium applications had been reserved chiefly for those extensive and very serious cases which were beyond a surgical operation, so that radium never had a chance of proving what it could do in the early stages of the disease. One of the most remarkable and beneficial effects of radium was its power to relieve pain, a relief which was not only temporary but often permanent. There was no form of cancer in which radium was so useful as in the internal cancers of women. All observers were agreed on this and so great had been the success attending the employment of radium and the *x* rays in these cases that the surgeons at the great hospital of Freiburg were said to have given up entirely the use of the knife.

Sir William Cobbett, Alderman Holt, Professor Wild, Sir William Milligan, and Sir Ernest Rutherford supported the appeal, while Bishop Welldon suggested that the churches should be asked to help in the matter.

The matter has now been taken up in an energetic way by the Manchester press, and it is announced that Messrs. E. Hulton and Co., the proprietors of the *Daily Dispatch* and associated newspapers, have promised to contribute £1,000, and to receive any contributions sent to them on behalf of the committee. A donation of £100 has also been given by Lord Derby, and the total amount promised towards the required £25,000 is now about £9,000.

The late Mr. Walter Whitehead.

A monument to the late Mr. Walter Whitehead, Surgeon to the Manchester Royal Infirmary, and President of the British Medical Association in 1902, when the annual meeting was held in that city, has been erected at Bury by his brother, Mr. Henry Whitehead, by whom it was formally presented to the town on June 27th. The monument is a clock tower with bronze statuary adornments, and is surrounded by a garden. At the ceremony, on June 27th, Sir Frederick Treves formally opened the gate of the garden and delivered a short address. The town of Bury, he said, had an illustrious history, and was associated with the names of many great men, but, to a certain section of the world's people not only in England but beyond the seas, the name of Bury would be memorable as the birthplace of Walter Whitehead. When, for the first time in his life, Whitehead passed through the gloomy doorway of a hospital he found wards dismal with a squalor that had long been accepted as inevitable, an operating theatre that was as the valley of the shadow of death, a reign of terror among the living, a record of failure among the dead. The introduction of antiseptics by Lord Lister transformed the whole face of surgery. It robbed it of its direst terrors, it increased its possibilities a thousand-fold, and afforded in every direction new opportunities for the saving of

life and the curing of hitherto unapproachable disease. Prominent among the body of eager men who were pressing forward in the great advance was the figure of Walter Whitehead—towering above his fellows, a strong, self-reliant man who knew no fear and who was a supreme master of his art. It was no matter of wonder that, in that time of evolution of surgery, the influence of such a man as Walter Whitehead should have made itself felt, and that his sturdy intellect should have done much to guide newly-acquired powers into right channels, to restrain the rash, and to encourage the timorous. He was himself a type of what a surgeon should be—a skilful operator, a thinker, a man of quick intuition, and wide experience. The operative measures with which his name would ever be associated were characterized by originality, by boldness, by precise scientific reasoning, by a careful and most finished technique. Whitehead was a Lancastrian, and he brought to bear upon the surgery of his time those attributes of mind and body which were distinctive of the county of Peel, Horrocks, Hargreaves, Arkwright, and John Kay. These were the qualities of courage, of unwavering determination, of far-seeing, of broad-mindedness, and, above all, of sound practical common sense, and a perfect mastery of his craft.

At a luncheon given afterwards by the Mayor, the toast of his health was given by Sir William Milligan, who said that Mr. Walter Whitehead's work at the Manchester Royal Infirmary was an inspiration to all younger men.

SMALL-POX IN SALFORD.

A case of small-pox was last week reported in Salford, and it appears that just about the time when the disease would commence the patient, who is a man of about 32 years of age, was in another district, where a number of cases have occurred. Last year about this time several cases occurred in Salford, and the Drinkwater Park Hospital, which was first established as a small-pox hospital but is now used as a sanatorium for tuberculosis, had to be cleared of its tuberculosis cases for about a month. Every possible effort has been made to avoid the necessity for this on the present occasion, and the patient is now in the Cinder Hill Hospital. The case was only discovered rather late, but as the patient had been confined to his room ever since the illness commenced, there have been very few contacts. All of them have been vaccinated afresh and are being kept under observation.

LEEDS.

TEACHING OF DENTISTRY.

A DENTAL department was established in 1905 in connexion with the Leeds Public Dispensary; during the year 1912–13, the last for which statistics are available, the number of new patients was 3,237, and over 1,400 operations were performed. The number of students in attendance during the same period was 27. The staff of the dental department consists of twelve honorary dental surgeons, with a demonstrator, a house-surgeon, a curator, a nurse, and a clerk. The affairs of the department are managed by a Clinical Dental Committee, consisting of the honorary dental surgeons with the chairman of the Dispensary Board. The department has throughout been self-supporting, its funds being derived from students' fees and payments by patients to cover cost of materials. In 1906 the department of dentistry was added to the Faculty of Medicine of the University of Leeds. For some time it has been felt both by the dental surgeons at the dispensary and by members of the University that a closer association between teaching at the University and the dispensary was desirable. A scheme submitted by the dental surgeons and approved by the Dispensary Board has been adopted by the Council of the University, and will come into operation at the beginning of next session. Under this scheme the instruction in the Dental Department will pass under the control of the University, and will have the status of University teaching. The honorary dental surgeons will become members of the staff of the University under the title of clinical dental lecturers, and all future appointments to these lectureships will be made by the University Council. The Dental Committee will take its place among the academic bodies of the University, reporting its proceedings to the Board of the Faculty of Medicine, on which it will be represented. It is believed that the scheme will enable the co-ordination of the theoretical and practical teaching of dentistry to be more completely and more permanently secured.

TUBERCULOSIS CONFERENCE.

The sixth annual conference of the National Association for the Prevention of Consumption and other Forms of Tuberculosis will be held at the university on July 7th and 8th. The subject for discussion on Tuesday morning—the house in relation to tuberculosis—will be introduced by Sir William Younger, Bart., member of the Royal Commission on Housing (Scotland). The discussion at the afternoon session on tuberculosis, especially surgical, in children will be introduced by Mr. Lawford Knaggs, professor of surgery in the university. On Wednesday morning a discussion on domiciliary treatment will be opened by Sir William Osler. The tuberculosis exhibition will be on view during the conference at the Town Hall, and in a museum at the School of Medicine will be exhibited specimens indicating the effect of tuberculosis on human beings and animals. A meeting under the auspices of the Tuberculosis Society will be held in the Town Hall at 7.45 p.m. on Wednesday, July 8th. A discussion on the future of the tuberculosis service will be opened by the President, Dr. Halliday Sutherland. Tuberculosis officers and practitioners specially interested in tuberculosis are invited to attend with a view to joining the society.

Ireland.

[*FROM OUR SPECIAL CORRESPONDENTS.*]

TREATMENT OF TUBERCULOSIS.

LAST week a temporary building, which is to be used as a central dispensary for the treatment of tuberculosis patients from the County of Dublin, was formally opened in the grounds adjoining the Meath Hospital. A more substantial and commodious building is in course of erection. The Committee has arranged for the use of two small wards in the Meath Hospital for the detention of patients under observation. The City Corporation now required the Crooksling Sanatorium altogether for the city patients. From a return of cases dealt with in County Dublin from the appointment of the Committee (July, 1912) up to the end of the last completed Insurance Act period (January 11th, 1914) it appears that 317 persons were recommended by the Committee for sanatorium benefit; 137 male and 75 female insured persons, and 32 male and 72 female dependants on insured persons. Treatment was accepted and received by 141 male and 99 female patients suffering from pulmonary tuberculosis, and by 19 males and 23 female patients suffering from other forms of tuberculous disease. The result of the treatment in the case of patients whose treatment terminated prior to January 11th last, or who had since completed treatment for which they had been recommended before that date, was as follows: Condition on discharge—Fit for work 91, improved 60, not improved 41, worse 6, discharged for breach of rules or left contrary to medical advice 34, died 28. In the case of 77 persons discharged as "fit for work" or "improved," who were among those treated in the earlier operations of the Committee, and who had been kept under observation by the Committee, the following results were recorded: Improvement maintained 43, unimproved 14, returned for treatment 17, died 3. Since January 11th 122 applicants had been recommended for sanatorium benefit. Sir William J. Thompson, Registrar-General, said that experience taught that the great difficulties were the treatment of patients who were in an advanced stage and the discovery of incipient cases. The results of the sanatorium portion of the Act would depend largely upon getting the patients in the early stages of the disease. He felt that the co-operation of the Meath Hospital with the work of this dispensary would be all to the good.

At the last meeting of the Athy Board of Guardians a circular, received by the county council from the Local Government Board, was read. It referred to the urgent necessity of making provision for the proper isolation of advanced cases of tuberculosis, and suggested that the

union fever hospitals in the county should be transferred to the district councils for isolation purposes. Notice of motion was given to consider the matter. The Enniscorthy Board of Guardians have handed over the fever hospitals at Newtownbarry and Oulart to the district council to be used as sanatoriums for the treatment of tuberculosis under the Insurance Act.

St. John Ambulance Brigade.

The St. John Ambulance Brigade annual competitions for the Dublin Challenge Cups and the Irish Women's Ambulance Challenge Cup were held in Lord Iveagh's gardens, Dublin, last week, when the Chief Commissioner of the Brigade, Colonel Sir James R. Andrew Clarke, Bart., C.B., made the annual inspection. There was a large attendance. The members of the brigade, along with the nursing divisions, number about 300 in Ireland. Weekly classes are held for brigade members, including those of the nursing divisions, composed of women, who have the additional advantage of a month's spare time free training at the Mater Hospital. There are fourteen divisions of the brigade in Ireland, including nursing divisions. Accompanying the Chief Commissioner was Mr. Darvil-Smith, secretary, and Assistant-Commissioner Dr. Lumsden, who is in charge of the Irish branch of the brigade. The Dublin Ambulance Challenge Cup, the gift of Lord Iveagh, was again won by the holders, St. James's Gate B. Team. The Irish Women's Challenge Cup was won by the Alexandra College Team. After the competitions were concluded there was a march past to music. Colonel Sir James R. Andrew Clarke, in an encouraging address, after presenting the prizes, urged the members of the brigade to use every endeavour to make and keep themselves efficient and present themselves for examination. The minimum of twelve attendances during the year was the practical means by which the efficiency of the brigade was maintained. He congratulated the Irish contingent on its work.

Individualization in the Treatment of the Insane.

Dr. Graham, the resident medical superintendent, has issued the eighty-fourth annual report of the Belfast District Lunatic Asylum. He once more reviews in a popular way the causation of insanity and the necessity for public education and for such measures as the Mental Deficiency Act; and he is hopeful as to the benefit ultimately to be derived from the study of eugenics, which is showing the necessity for effort to obtain reliable knowledge and to awaken and enlighten the public conscience. He also advocates the establishment of psychopathic wards where the general practitioner could send patients for observation without the necessity for certification, so that remedial measures could be brought to bear at the earliest possible moment. It will take time for the reforms already accomplished to bear their full fruit, but some betterment, he says, is already to be seen. More than two-thirds of the patients have been transferred to Purdysburn Asylum and some 472 are in the Grosvener Road buildings; the villa system is in full operation in the former, and more individualism is possible among the patients; they are also brought more in direct contact with the elemental aspects of Nature, and the impalpable but very real beneficial effect of such surroundings is being experienced daily. The expenditure amounts only to £21 per annum for each patient, and of this £11 is chargeable to the city rates. Dr. Graham refers to the many excellent qualities of Dr. Patrick, the senior assistant, who had been appointed resident medical superintendent of the Omagh District Asylum. The report ends with the inspecter's memorandum, which refers with approval to the principle of individualism which has been established in the villa system, to the general health of the patients, and to the low mortality and high recovery-rate.

Golden Jubilee, Linden Convalescent Home.

Last week the golden jubilee of the Linden Convalescent Home was celebrated at Blackrock, co. Dublin. The home is under the Sisters of Charity, and since its foundation has been much improved. It consists of a handsome, well-appointed house, situate in eight acres of ground; during the past year no fewer than 1,447 patients were treated in the institution, which is non-sectarian. When first established as a home in connexion with St. Vincent's Hospital, it was intended for only 20 patients, but since that time it has been greatly enlarged and is now capable of accommodating 70 convalescents, who come from all the hospitals in Dublin, and indeed from all parts of Ireland. Dr. Wallace Boyce, M.O.H. Blackrock, who is temporarily acting as medical officer to the home, and the Right Hon. Michael Cox, M.D., surgeon to St. Vincent's Hospital, both spoke in the highest terms of the good work done by the institution.

Scotland.

[FROM OUR SPECIAL CORRESPONDENTS.]

Complimentary Dinner to Dr. Brownlee.

Dr. John Brownlee was on June 26th entertained at a complimentary dinner in Glasgow on the occasion of his retirement from the superintendentship of Ruchill Fever Hospital to take up the duties of statistician to the Medical Research Committee in London. There was a representative company of the medical profession in Glasgow. Professor Gibson, in submitting the toast of the evening, said that he, with the knowledge he had of Dr. Brownlee's familiarity with statistical methods, from the knowledge he possessed of the medical facts upon which these statistics were based, would accept without question any statistical results that came forth from the office under Dr. Brownlee's signature. He hoped that a new era of statistical study was beginning. In replying, Dr. Brownlee said he had been for fourteen years a superintendent of hospitals in Glasgow, and believed that the next great advance in medicine must come from fever hospitals. The great bulk, practically, of the scientific work which had been done during the last twenty years in medicine had been done from the point of view of infectious disease. The fever hospitals of the country should realize that advance was to come from them, and the corporations of the country must realize the fact. He had received every consideration from the Corporation of Glasgow; and the Ruchill Hospital possessed an equipment which no other fever hospital in the country had. He had no doubt that the committee in Glasgow would realize that, as it must supply laboratories, it must also supply sufficient men.

The Safeguarding of Edinburgh's Milk Supply.

In the Medical Officer of Health's Report of the City of Edinburgh, to which reference was made last week (p. 1428), a good deal of space is given to the measures which are being taken to ensure a clean and good milk supply. It may be said that from the cow to the consumer's hands the milk is under a certain degree of supervision; there are weak links in the chain of observation, it is true, but the fact remains that the supply of this extremely important article of food is much more fully under control than it was a few years ago. The supervision begins at the byres, and this is perhaps the weakest part of the scheme, for, whilst the cow byres within the city, which number sixty-four and contain more than 2,000 cows, are well watched over, those in the surrounding districts in Midlothian, not to speak of more distant sources of supply in Linlithgow, Dumfries, and Lanarkshire, cannot, of course, be so rigorously looked into. With regard to the city cow byres, there is supervision of both the animals and the premises. There is systematic visitation every four or five weeks by a veterinary inspector, who examines every cow and the condition of the byre. When tuberculosis is suspected, a sample of the milk or expectorate is obtained, and is examined bacteriologically. In 1913 this examination was carried out in 150 cases, with the result that twenty-seven cows were found affected, and were in consequence removed from the byres. There is also frequent inspection of every dairy shop within the city, special attention being paid to the manner in which the milk is stored. There remains, however, the difficult matter of the supplies of milk sent in from outside the city. At present the inspectors have no means of getting at the cows from which the supply comes—in far-off Dumfriesshire, for instance. There are legal powers, however, by which means might be forthcoming. Some years ago (1891) the local authority obtained powers under a Police Act for certain specified officers to visit and inspect premises and animals wherever situated from which a supply of milk was sent to the city,

and Dr. Maxwell Williamson thinks that the time has come when the section in the Act referred to should be put in force, even although this would entail the appointment of one or two additional veterinary inspectors, whose business it would be to devote their whole time to the systematic and periodical visitation of the country premises from which the milk comes and of the cows which supply it. Meantime, the city inspector does the next best thing: he visits the stations, examines the milk vessels in which the supplies arrive, takes samples for bacteriological examination both from the large vats arriving by train and also from the supplies driven into the city by carts, and he takes steps when this examination gives warning of danger to have the particular cow identified and dealt with in whatever part of the country it may be situated. This is good in its way, but it is a delayed method of reaching what is wrong, and much mischief may already have been inflicted. Dr. Maxwell Williamson some time ago made a representation to the local authority suggesting an alteration in the Dairy Regulations which would meet the difficulty arising in connexion with the milk from outside sources; he repeats the suggestion now. It is as follows: That Regulation No. 12 should read:

Every cowkeeper, dairyman, or purveyor of milk *in or beyond* the city shall cause all barrels, butts, cans, or other vessels of whatever kind used to convey, store, or distribute milk, or which contain milk for sale, either wholesale or by retail, and all bungs, bung cloths, lids, straining cloths, and other utensils, to be scalded with boiling water or steam under pressure, immediately *before and after use*, and thereafter to be thoroughly dripped. No person shall employ or allow any boiler, tank, steam chest, or other receptacle used for scalding or washing such utensils and vessels to be employed for any other purpose.

The medical officer also suggests another regulation (No. 13) to follow the above:

Every cowkeeper, dairyman, or purveyor of milk who sends milk to the city, although resident beyond its boundaries, shall cause all barrels, butts, cans, or other vessels of whatever kind used to convey such milk, to be properly secured by means of padlock, seal, or by such other means as will prevent the opening of such vessel during the course of transit.

He also points out that the Local Government Board is now making suggestions similar to these which he submitted in December last. Certainly if veterinary inspectors cannot yet be obtained to make visitations to the byres in the country districts from which the milk comes, Dr. Williamson's less radical changes as shown in the above regulations (Nos. 12 and 13) might very profitably be adopted. Two interesting appendices to the medical officer's report are concerned with the prosecutions for adulterating milk under the Sale of Food and Drugs Act, and with the visitations of the byres and dairies and the resulting withdrawals of licences, etc. In all, 1,022 samples of foodstuffs (of which the great majority were samples of cream and milk) were analysed; there were twenty-five convictions (all in connexion with milk), and £95 in fines were paid. Dr. Williamson states that the invariable practice was to allow "the appeal to the cow," that is, before any proceedings were taken, the result of the city analyst's certificate was communicated to the person in default, and the offer made to visit the byre premises, superintend the milking operations, and take a sample from the mixed milk of the whole herd, on the distinct understanding that if this should, on analysis, show a result approximate to the sample in question, then no prosecution would follow. "It is highly significant," adds Dr. Williamson, "that refusal to entertain this offer was met with in practically every case, the excuses advanced in support of this attitude being of the flimsiest nature."

The Treatment of Pulmonary Tuberculosis.

Dr. Maclean, Superintendent of the Seaforth Sanatorium, Maryburgh, which was built and endowed by Colonel Stewart Mackenzie, of Seaforth, and Mrs. Stewart Mackenzie, in his annual report, refers to the limited usefulness of any single institution, where circumstances result in the treatment in one building of all types of cases, from the very first cases to third stage cases, almost moribund. Owing to the generosity of the founders and managers, the effort has been made, and is continued, to give treatment to all cases recommended for institutional treatment, but, as the Seaforth Sanatorium is practically the only building for the segregation of tuberculous cases in Ross, the great majority of cases admitted have no business whatever in a sanatorium, though very much in need of treatment. Many of them, properly supervised, would do equally well with domiciliary treatment, and many could be only adequately treated in a hospital. An experience of six years has convinced Dr. Maclean of the need of a complete scheme for the treatment of phthisis, and that if any one kind of treatment should not merely show to advantage, but give its legitimate amount of benefit to the patients, there must be a complete system, properly elaborated and conducted in such a way as to give a complete co-ordination dealing with cases of consumption in all conditions and stages. Following the official classification of the disease, out of 52 patients, only 15 were in the first and second stages, which mainly expected to benefit in a sanatorium. Of these 15, only 1 died, while the 14 are now doing work of one kind or another. Of the remainder, over 25 are now dead and 4 died within a week of being sent to the sanatorium.

Correspondence.

REPORT OF THE RADIUM INSTITUTE, LONDON.

Sir,—Pressure of work has prevented us from replying to Mr. Alton's letter on use of capillary glass emanation tubes.[1]

Mr. Alton contradicts himself. In his statement in the report of the Radium Institute for 1913 he describes the capillary tube as "the latest achievement." He now says they were described in the previous report of the Radium Institute—that for 1912.

Upon looking up this report we find the "capillary" tubes there referred to are described as filled with radium sulphate "closely packed." He says, "Further, on account of their small size (they vary from 2 to 4 cm. long, and are no larger than 3 mm. in diameter), they can often be employed in quite small cavities." This is plainly quite another thing to the tubes we describe, and Mr. Alton's claim seems simply based on his peculiar use of the term "capillary." The tubes we use could not be packed with solid radium sulphate by any ingenuity.

Mr. Alton discourteously infers that we actually saw tubes like our own—or apparatus for making the same—in the Radium Institute. We saw neither the one nor the other. In point of fact, no apparatus beyond the gas flame is required in order to make the tubes. It is really difficult to understand what sort of apparatus Mr. Alton can refer to.

Finally, Mr. Alton refers to a lecture by Mr. A. Hayward Pinch before the Medical Society of London on March 9th. Mr. Alton says the use of "platinum needles" was fully discussed on this occasion. As reported in this Journal (March 21st), Mr. Pinch says, "wherever it is possible to bury the tube in a growth to be treated this should be done," and states his preference for a screen of 1 mm. of silver. The word "needle" appears nowhere, either in the report of the lecture or in the subsequent discussion. The technique that is to be inferred, in fact, is quite different in principle from that which we employ, as will be seen in a paper by one of us, which we hope will shortly appear in this Journal.

We have every reason to hope and believe that the method which we have described of securing increased uniformity of illumination by the simultaneous insertion of many radio-active needles, each carrying a very small charge, will, in addition to minimizing the loss due to screening, prove a real advance in the therapeutic application of radio-active substances. No previous record of this method has come to our notice. In its technique the use of capillary tubes, small enough to fit within fine exploring needles, is necessitated—and so far as we are aware, for the first time necessitated—in radio-active therapeutics.—We are, etc.,

J. Joly.
Walter C. Stevenson.

Dublin, June 25th.

MORAL INSANITY.

Sir,—The inquiry made on this subject in your issue of June 20th is one which all who have to do with the treatment of mental disorders have been making for years.

[1] British Medical Journal, June 13th, p. 1329.

Dr. Helen Boyle read a very able paper at the annual meeting of the Medico-Psychological Society on May 19th, bearing on several aspects of the treatment of borderland cases, the discussion of which opened up the vexed question of certification.

The voluntary boarder system breaks down where it is most required—that is, in the great majority of incipient cases who do not recognize their own mental condition, and cannot be persuaded that treatment is necessary; the case in point would be very unlikely to place himself under any treatment that would restrain his actions and protect him from himself. The idea that a court of law should impose an indeterminate sentence upon the man is out of the question and unheard of. If he is insane, let him be treated as such, and not punished by the law.

I cannot see where the difficulty of certifying him comes in; it is said that his mind was affected, and that he was morally insane; and he must have been certified to be admitted to an asylum as stated. If, therefore, after his discharge he again exhibits the same symptoms on which he was originally certified, how can he be said to be uncertifiable? I take great exception to the word "uncertifiable"; it is very misleading, and often a confession of inability on the part of the would-be certifier to elicit mental symptoms that are undoubtedly present.

There is a great deal of nonsense talked about certification; the very word is uttered with bated breath, as if it was a death sentence, whereas in practice it is often simply an aid to treatment; there is no reason why the patient should even know of its existence; it will disappear when its purpose has been served, and the stigma is greatly exaggerated. I do not mean to infer that all cases exhibiting mental symptoms should be certified; on the contrary, I maintain that there are many cases of pronounced insanity in which it may be (and often is) inexpedient and unnecessary to certify; and there are others with very slight, and, may be, temporary mental symptoms where certification is not only expedient, but necessary for the safety and proper treatment of the patient.—I am, etc.,

Lancashire, June 24th. CHARLES T. STREET.

DENTAL SEPSIS.

SIR,—As my practice includes a large number of domestic servants suffering from dental sepsis, I had the following leaflet printed for two reasons:

First, the patient is often nervous in the consulting room, and remembers very vaguely what is said to her; the pamphlet she takes home and reads at leisure. Secondly, much wearisome repetition is spared and considerable time is saved.

I have found the scheme useful, and others may care to adopt it.—I am, etc.,

Northwood, June 5th. O. HILDESHEIM.

DECAYED TEETH ARE DANGEROUS.

Many people don't understand this because the results come on very slowly and it is not easy to see how the bad teeth cause them.

Toothache. Some people with bad teeth never have toothache. Your health suffers just as much from bad teeth whether they ache or not.

What are the Dangers? The chief one is that every time you swallow you take into your body some poison from the bad teeth. *It is just as if you always carried a bit of bad meat about in your mouth.*

The other danger is that you cannot chew thoroughly. So you avoid wholesome food, such as meat and crusts and apples. That is because your gums are tender. People with no teeth can chew with their gums fairly well.

What are the results? Indigestion in one form or another (pain after food, flatulence, constipation, bilious attacks) and Anaemia are two of the most common results. Often there are others such as Neuralgia, Boils, Sore Throats.

Why do you put off going to the Dentist? Either the expense or fear; fear of pain, or fear of gas, or fear of looking ugly; or you are afraid you won't be able to eat properly without teeth.

Gas given by a properly trained person is safer than a railway journey.

Expense is greater the longer you leave it. Doctors' fees as well as dentists' fees, loss of employment through ill health, etc. *It is far more healthy to have no teeth than to have bad ones.* So have the bad ones out now and get the new ones when you can afford it.

MURMURS OF DILATED HEARTS AND THEIR EXPLANATION.

SIR,—Dr. Samuel West, in a communication published in the BRITISH MEDICAL JOURNAL of June 20th, has called attention to the murmurs he has observed in dilated hearts, which are peculiar to the dilated condition. These, he believes, must be due to "eddies set up within the dilated cavities."

To produce such eddies, it seems to me, it is almost necessary to suppose that something of the nature of fibrillation takes place in the ventricular walls, so that the blood becomes locally disturbed by local contraction upon it. One would imagine, however, that the ventricle must be in a state of serious breakdown, analogous to the auricle under fibrillar contraction, before such would occur, and not merely dilated.

It is *a priori* not unlikely that a dilated ventricle having to expel its contents, or a portion of them, through an aortic orifice of fixed dimensions, might produce a murmur analogous to that produced by an undilated ventricle through a stenosed orifice. The relative sizes of orifice and ventricular chamber having varied in either case, the conditions tending to produce a murmur are similar; except that the orifice being undamaged in cases of simple ventricular dilatation, the murmur is more likely to be soft and blowing, as heard by Dr. Samuel West, than harsh and distinct, as in stenosis. The probable distribution of such a murmur does not seem to correspond, however, with that heard by Dr. West.

It should always be remembered in considering these murmurs, that the aortic orifice does not occupy a fixed position during the heart beat. When the aortic valves open a continuous column of blood fills the aorta and ventricle. The pressure of the end of this column on, or near, the apex of the heart keeps it down, so that when the ventricle contracts it is not the apex which goes up, but the base which comes down. Needles plunged perpendicularly through the body wall of an animal into the apex and base of the heart respectively, show that the apex remains fixed, while the base approaches it during systole. In other words, the pull of the contracting ventricle makes the aorta elongate. It is pulled some distance over the blood in the ventricle, like the finger of a glove. Space is found in the aorta for the ventricular blood by the aorta dilating, and by the aorta lengthening. As the circular dilatation recoils it drives on a wave towards the remote arteries, called the pulse. When the ventricle relaxes and allows the aorta to recoil longitudinally, this recoil, like a catapult, drives on a second wave called the dicrotic. To this method of origin of the dicrotic wave I long since called attention in the BRITISH MEDICAL JOURNAL and elsewhere.

Now when the ventricle dilates, it is probable that this up and down movement of the aortic orifice is disturbed, thus introducing an additional factor into the altered conditions under which blood is leaving the ventricle.

The whole problem is very difficult, but Dr. Samuel West's lucid record of his clinical observations is a good start towards its investigation.—I am, etc.

Clyst St. George, Devon, June 27th. D. W. SAMWAYS.

THE BRITISH MEDICAL ASSOCIATION AND THE MEDICAL PROFESSION.

SIR,—In my enforced leisure I have read with avidity and interest the series of articles headed "The British Medical Association and the Medical Profession," and as they are a lucid statement of facts, I hail them with delight, as "The truth should always be set upon a hill."

What "I hae ma doots" about, however, is, even though we admit the work done by the British Medical Association, has the status of the profession as a whole advanced?

I read that a deputation of the Society of Medical Officers of Health told the Chancellor of the Exchequer recently in public that medical officers of health blue-pencilled their reports, otherwise they might be dismissed. Surely this is much worse than signing a false certificate, as the latter only involves money, whereas the former may lead to disaster, even death, for the community! It was no doubt a useful argument, and may go a long way to obtain what they sought, but oh! the price. They should

read what was said by a judge the other day when passing sentence on a member of another profession.

I read that the drug bill in certain areas is too high, and an order goes forth that prescriptions must be curtailed—hey, presto! the thing is done.

I read that referees are being appointed, as the certificates of the ordinary medical attendant are apt to be incorrect, owing to considerations of practice. I remember waxing very wrath with a colleague on an education committee who stated that he could get a doctor to certify anything, but only two days afterwards, in a crowded railway carriage, a professional brother stated that he dare not give an honest certificate in a certain case, as it would ruin his practice in that neighbourhood.

I read—but need I add to the list we all know so well?

I am not writing this to pose as did the pharisee of old, but because I am not satisfied that the disease from which the body politic of the profession is suffering has been correctly diagnosed. In my opinion we are only treating symptoms. We have lost the confidence of the man in the street by our very unprofessional conduct, and the grave harm the Insurance Act is likely to do is that it will emphasize our faults by bringing them more into the limelight. We can only regain that confidence by returning to the paths of rectitude and straightforwardness whatever be the consequences. Let us put aside our jealousies, our anxiety for this world's goods, our tendency to laud ourselves at the expense of our professional brethren, and all the other sins that do so easily beset us, and let us press forward, vying with each other in brotherly love, gentlemanly conduct, strict professional etiquette, and by a long pull, and a strong pull, and a pull all together place the profession in the niche it should occupy.

Remember the chain is only as strong as its weakest link, and that if we do not hang together we shall separately, as unless something radical is done soon, the forty millions, losing their patience, will rise in their wrath and establish a national service.

I should not like my swan song to be—

> Do I sleep? do I dream?
> Or is visions about?
> Is the medical profession a failure?
> Or is the Caucasian played out?

—I am, etc.,

Castle Douglas, June 29th. J. CROMIE.

SIR,—I am a member of the British Medical Association; I am also a consultant on the staff of a hospital. I have read Article V on hospital abuse in last week's JOURNAL. I am reminded of some facts which help to show why the efforts of the Association *in re* hospital abuse have not met with more success than is reported in the said article. For the purpose of checking hospital abuse, whether from the point of view of a patient's economic status or of his complaint, it is often easy to obtain the name of the private doctor, and it involves only a little trouble to communicate with that doctor. For some time I carried out this plan whenever there were suitable indications. So rarely did I receive in return any assistance, or even acknowledgement, that I gave up the experiment. Again, a large number of patients when they come to the hospital present a doctor's letter or visiting card. Some of these request, others require an answer. I cause a note to be sent in all cases. In this case also the acknowledgement is so scanty that further experiment seems useless. The prospect of using out-patient departments for purely consultative purposes only does not seem very bright. It should not be difficult to organize some degree of insurance against hospital abuse on the lines of my experiments, but my experience is not encouraging.—I am, etc.,

June 30th. F.R.C.S.

THE SPECIAL FUND: TRADE UNION OR TRUST?

SIR,—The letters of Drs. Wallace Henry, Garstang, and Raiment in the JOURNAL of June 27th have effectually squashed all Dr. Fothergill's arguments and exposed the futility of his trust scheme. There are some very powerful arguments in favour of trade union methods which they have not used, which it may be well to set out.

1. In Germany the profession was beaten again and again, until its scientific organization (which had been trying to fight) allied itself with a trade union, and handed over to its trade union department the whole of its offensive and defensive policy. From that day the profession in Germany has never lost ground—has hardly, in fact, lost a single point for which it has fought.

2. That only by the formation of trade unions have the working men of this and every other civilized country been able to obtain for themselves decent conditions under which to work.

Unless trade unions are the best offensive and defensive organizations, the working men all over the world who belong to them are fools for their pains. Then there are strong personal financial arguments in favour of a trade union which will appeal to many men.

A trade union such as the National Medical Guild can offer, as the Guild does now, reduced premiums on various insurances—motor, fire, accident, and life. If the Altrincham motion is passed at Aberdeen, and the National Medical Guild affiliated with the British Medical Association, the latter could well afford to reduce its annual subscription to £1 1s. to members of the Guild, as is done by the Royal Automobile Club for its country members.

Then the National Medical Guild, with the increased membership it would obtain (it could even do it now), could act as its own insurer by underwriting the risks. It already offers all medical defence. It will soon be able to invite the medical defence associations to join it, and so make use of their excellently efficient staffs. It could run a medical agency for its members, thus saving them great expense.

For the benefit of those men who look largely at the financial side of the question, it may be well to put this in a tabular form.

Association plus Trust.

	£ s. d.
Subscription to Association	2 2 0
Usual subscription for medical defence ...	0 10 6
Against costs or damages	0 7 6
Calls to be made for Trust Fund, say £2 a year	2 0 0
	5 0 0

Association plus Trade Union.

	£ s. d.
Subscription to Association	2 2 0
Trade Union (National Medical Guild) ...	1 1 0
Calls at £2 per year	2 0 0
	5 3 0

From which should be deducted, if the subscription to the trade union be, as suggested, merged in that to the Association, £1 1s. together with an average saving on motor car, fire, accident and sickness, and new life policies of at least 15 per cent. on an average outlay of, say, £20 a year, £3. I have put both premiums and savings at a low rate, though the savings would be nearer 25 per cent. when the trade union became its own insurer.

	£ s. d.
Total cost to members	5 3 0
Saving on subscription 1 1 0	
,, premiums 3 0 0	
	4 1 0
Actual cost to members including calls	1 2 0

Let me also put in the same way the non-financial advantages offered by the Association *plus* trust, and the Association *plus* trade union.

Association plus Trust.	*Association plus Trade Union.*
1. A fund, not yet arranged for, and not yet collected, which when collected would be liable to attachment and so would be absolutely useless.	1. A fund, not yet collected, but with the machinery for collecting already in order; a fund which could be used for the purposes for which it was raised, and which could not be interfered with by any legal process on the part of our opponents.
2. A fighting force already discredited in the eyes of the public and the profession in general by its failure in the last fight, and its failure after a year and a half to reorganize itself for future fights.	2. A fighting force with all the *élan* of a new organization, and with the prestige in the eyes of the public that has been gained by the successful fights of trade unions in the past.
3. An organization overweighted by the attempt to combine a scientific body with a forward movement, utilizing the same staff for both purposes.	3. An organization formed solely and wholly for fighting, hampered by no other considerations, and with a staff enabled to devote its entire time and energy to offence and defence, and to those points alone.

Dr. Tomkins shows the absolute futility of Dr. Courtenay Lord's suggestion of a referendum. Until

the profession generally is thoroughly educated in the ideals of trade unionism and its possibilities, a referendum would be absolutely unfair. A large number of men know nothing of and have thought nothing of a trade union, and if asked to vote now would vote blindly against anything with such a low down name. Let Dr. Courtenay Lord wait until there is a general knowledge of medical trade unionism and I will welcome his referendum.

I am afraid that the letters of Dr. Fothergill and Dr. Courtenay Lord suggest between them what in the House of Commons would be called a "blocking motion," and what the plain man would call a "red herring." Representatives at the forthcoming meeting must be on their guard against such tactics.—I am, etc.,

Helston, Cornwall, June 26th. MARK TAYLOR, M.D.

SIR,—Dr. Garstang misinterprets the meaning of my communication; but being a thought reader he correctly interprets what was at the back of my head when writing. The question was intended merely to refute the suggestion in a question which Dr. Fothergill asked in a letter which appeared under the heading, "The Special Fund: Trade Union or Trust." Therefore the subject was clear, and it appeared to me that this question succinctly summed up the position. It appeared to me that this was the thin edge of the wedge. I read Dr. Henry's letter in the JOURNAL of June 27th. He says *re* Dr. Fothergill's questions:

"The interesting series of questions which he (Dr. Fothergill) propounds might be of interest were it proposed to turn the whole profession into a trade union *at once;* that is not *at the present time* a question of practical medical politics, however desirable in my opinion such a course would be." The italics are my own.

Some twelve months ago I was conversing with an ardent trade union member of the profession, who remarked: "I should like to see the Medical Association a trade union association because then we could compel all its members to toe the line." Naturally this threw a little light upon the aims of this trade unionist—his ideal; but no trade union association could possibly make the profession "toe the line," because there will always be members outside the Association. It appears to me that Dr. Fothergill is wise in taking a wider view of this movement than the majority of your correspondents.—I am, etc.,

Bedford, June 27th. S. J. ROSS.

CENTRAL COUNCIL ELECTIONS, 1914–15.

SIR,—I have all along held that the disappointments the medical profession have suffered have been due to the *active* interest of the members of the British Medical Association being conspicuous by its absence—for example, only 5 per cent. to 10 per cent. attendance at meetings, many of those present even not having read the subject up before the meeting; abstention from answering queries sent from head office; neglect of voting for elections; neglect to send their opinions to their representatives on the central committees or head office, etc.

The Council is generally blamed, but they and the men on the committees I have found are energetic, painstaking, and anxious to do all they can for the bulk of the profession; they need the active support and personal interest of all the members.

The elections just passed prove my contention to a nicety. Out of twenty areas, only one (Metropolitan Counties Branch) showed more than one nomination, and even here only 991 took the trouble to vote; in the case of one candidate not two-thirds of those who promised to give first place remembered to do so (that is, they forgot all about the election?). There are nearly 3,000 voters in the Metropolitan Counties Branch.

So that, though many notices of the probable difficulties shortly to be faced have been given in the BRITISH MEDICAL JOURNAL, only 991 out of the whole members of the British Medical Association have voted. Either the rest must be quite content with the men on the Council (which appears unlikely in the face of letters to the JOURNAL during the year), or even those complaining have been too apathetic, when the chance arrived to nominate fresh men, to take advantage of it.

No real advance in the unity or strength of the profession as a whole can be made till all the individual members of it (not only of British Medical Association) take a personal active interest in the situations as they arise.

In my opinion, so often expressed, the remedy is whole-time medical organizers.—I am, etc.,

HARDING H. TOMKINS,
Secretary of the Local Medical and Panel Committees, Essex.

London, N.E., June 20th.

A DISCLAIMER.

SIR,—In the course of a speech made by me at Leeds, in November last, and in the press correspondence which ensued thereon in which I dealt with the Insurance Act and the method in which it was being carried out by the medical profession, I felt it my duty to call attention to the conduct of certain doctors in Yorkshire.

It has been pointed out to me that the words I used have been interpreted by certain persons as casting a reflection upon Dr. Walker and Dr. Erhardt, of Crosshills, near Keighley, and I willingly take this opportunity of stating that I did not make, and never intended to make, any imputation upon either of these gentlemen.

I would further wish to state that there is, so far as I am aware, no cause for complaint against either of these two gentlemen, who are carrying out the Act loyally and honestly, and I would desire to express sincere regret that any words of mine could possibly have been thought to be applicable to them.—I am, etc.,

F. HANDEL BOOTH,
Chairman of the Council of the Faculty of Insurance.

London, W.C., July 1st.

ROYAL MEDICAL BENEVOLENT FUND.

SIR,—We do not think it worth while to reply at length to the letter of Messrs. Beale and Co. which appears in your issue of June 27th. They make no further point in it except that Mr. Crosse's proof of evidence was not sent to Sir John Tweedy and Dr. West by order of the Council of Epsom College until a month after Mr. Justice Joyce had delivered judgement. This appears to us immaterial, as Messrs. Beale and Co., who were acting as solicitors to the Fund, admit *they* had seen it. The reason that the Council of Epsom College, at its first meeting after the delivery of the judgement, directed that copies of Mr. Crosse's proof and of the judge's remark as to the impropriety of either party contesting the will under given circumstances, should be forwarded to the officers of the Fund, was to convey to them the impression of the Council that the legacy ought to be handed over to the charity to which the testatrix intended to give it. As a matter of fact, copies of the proof were delivered simultaneously during the hearing of the case to the legal advisers of both parties. Counsel on behalf of the Fund objected to the most important part of this evidence, and the objection was allowed by the judge. This evidence, which Mr. Crosse was ready to give to the court, should have prevented the Fund, in our opinion, from further contesting the will.

Throughout the several columns of the BRITISH MEDICAL JOURNAL of June 13th and 27th occupied by the representatives of the Royal Medical Benevolent Fund in their effort to defend the retention of the legacy by the Fund, there is complete suppression of the facts mentioned by us in your issue of June 20th—namely, that in 1904 Miss Glenny pointed out that the description "British Medical Benevolent Fund" used in her will of 1902 was wrong, and that in 1905 by a codicil she revoked the legacy to the "British Medical Benevolent Fund" and "in lieu thereof" bequeathed the same amount to the "Royal Medical Benevolent Fund." Miss Glenny's last will was executed five years before, and her death took place six months before the British Medical Benevolent Fund changed its name to "Royal," whereas for many years she and her family had subscribed to the Royal Medical Benevolent College.

Of course, if the evidence Mr. Crosse was prepared to give is ignored, there is nothing to point certainly to Epsom College as the intended beneficiary. We submit, however, that his evidence, though inadmissible in law, ought, in fairness, to be received without question. If it were, we still believe that no impartial and competent person could fail to come to the conclusion that Miss Glenny meant the legacy to go to Epsom College. That

Mr. Crosse himself thinks so is certain, for the following appears in his proof:

After seeing this evidence (namely, the books at Epsom College, which showed that the Testatrix and her family had for many years subscribed to the College) I and my Co-Executors were satisfied that Epsom College was entitled to the legacy bequeathed by the Testatrix, that being the institution she intended to benefit.

We do not propose to trouble you further with regard to a matter on which we feel there can be no doubt, and which has already very fully occupied your columns.—We are, etc.,

HENRY MORRIS,
Treasurer.
W. S. CHURCH,
Chairman of the Council.

June 29th.

SIR,—Having read the letters which have appeared in the JOURNAL under the above heading, it is possible to form an unbiassed opinion on the matter under discussion. The following facts appear to have been clearly established.

That £500 was bequeathed by Miss Glenny to a medical charity. In a will dated March 10th, 1902, the money was left to the British Medical Benevolent Fund, 84, Brook Street, Grosvenor Square, W. In a codicil dated 1905 the testatrix revoked the bequest to the British Medical Benevolent Fund, and left a like sum to the Royal Medical Benevolent Fund. In the will dated May, 1907, the same amount is left to a charity again described as the Royal Medical Benevolent Fund.

From the above facts it would appear to any ordinary observer that the testatrix had no intention of leaving the money to the British Medical Benevolent Fund, but to some other charity named in the codicil and subsequent will as the Royal Medical Benevolent Fund. The charity which was named in the will of 1902 was evidently a clerical error.

Mr. Crosse states that he took his instructions down at the dictation of the testatrix, but with regard to this particular bequest he simply wrote down the word "medical" for amplification afterwards. It is quite conceivable that Mr. Crosse left it to his clerk to look up the medical charities, and he fixed on the British Medical Benevolent Fund with its address in Grosvenor Street and this accordingly was entered in the will of 1902. Miss Glenny noticed the mistake, and in the codicil of 1905 revoked her bequest to the British Medical Benevolent Fund. At that date the only Royal Medical Benevolent Fund was the benevolent fund of Epsom College. The Royal Medical Benevolent College—now Epsom College—had received the support of Miss Glenny and her family for many years, and she informed Mr. Crosse that it was her intention to benefit the charity which had been supported by her and her family.

Sir John Tweedy and Dr. Samuel West state in their letter of June 10th that if the will of 1902 had been operative at the time of Miss Glenny's death the legacy would have been paid to the Fund. That is so. But had the will of 1907 become operative prior to 1912, would it have been paid to the Fund then known as the British Medical Benevolent Fund when it was distinctly stated in the codicil of 1905 that the legacy to that Fund was revoked? I trow not.

The Royal Medical Benevolent Fund has legal possession of the legacy. There let it rest. I do not feel it would be right to take any steps, as suggested by Sir James Barr, to compel the Fund to hand the money over to the College. Let those who feel convinced that the legacy was not intended for the Fund and are subscribers to both the Fund and College, withdraw their subscriptions from the former and hand them over to the latter until the amount lost has been made up.—I am, etc.,

Walthamstow, June 28th. STCLAIR B. SHADWELL.

SIR,—I have just returned from a cruise to the North Cape, where happily I was out of reach of even the BRITISH MEDICAL JOURNAL. My letter in your issue of June 6th respecting the legacy of Miss Glenny to the Royal Medical Benevolent Fund seems to have set the cat among the pigeons, as there have been a good many feathers flying about in your subsequent issues. I might now feel content to leave the matter in the hands of Sir Henry Morris and Sir William Church, but there are some observations by Sir John Tweedy, Dr. Samuel West, and Messrs. Beale and Co. which call for a personal rejoinder.

Sir John Tweedy and Dr. West start their letter by stating that mine contains "one fact and many misstatements," but I have again carefully read my letter, and the only inaccuracy which I can find—an inaccuracy which I would have corrected if I had had an opportunity of seeing the proof—is my statement that I had been reading the annual report for 1914 of Epsom College. This should have been 1913; this simple clerical error is corrected by Sir John Tweedy and Dr. Samuel West as follows: "This report has not yet been before the Council of the College, and will not be considered by it until its meeting on June 26th, when it might possibly even be modified." Any tiro could see that it was the report of the council and signed by the Chairman of Council, Sir William Church, for presentation to the annual general meeting of the Governors.

It is very amusing to find these two gentlemen standing on their dignity and informing us that "the Committee of the Fund consists of men of as high standing and reputation as the Council of the College." What has their standing and reputation got to do with the case? It is with facts I wish to deal. To what charity did Miss Glenny intend to leave the £500? The sooner these gentlemen climb down from their exalted perch to the firm foundation of fact the better. I have now had an opportunity of reading the shorthand notes of Messrs. H. H. Tolcher and Co. of the evidence of Mr. Crosse, who made Miss Glenny's wills, and the judgement of Mr. Justice Joyce; also the proof of the evidence which Mr. Crosse was prepared to give if it had not been objected to by counsel for the Royal Medical Benevolent Fund. I am now more convinced than ever that Miss Glenny intended the £500 for the fund of the Royal Medical Benevolent College, and its allocation to the Royal Medical Benevolent Fund may be law, but it is not justice. On a question of equity a lawyer is about the last man I would think of consulting, yet it is behind their lawyers that these exalted personages of the Royal Medical Benevolent Fund screen themselves. How Messrs. Beale and Co. can justify their statement that the inadmissible evidence referred to "was also before the court when the case was heard" is a puzzle to me.

In Miss Glenny's will of 1902 there was a legacy of £500 to the British Medical Benevolent Fund. She afterwards cancelled this legacy, as she told her lawyer that he had made a mistake; that she wished to leave the money to the fund to which she and her family had subscribed for years, but unfortunately the lawyer in drawing up her next will put in Royal Medical Benevolent Fund in place of the fund of the Royal Medical Benevolent College. It is as clear as noonday that she did not intend to benefit the British Medical Benevolent Fund, and there was not then nor for many years afterwards any Royal Medical Benevolent Fund.

Sir John Tweedy and Dr. West tell us that to refund the money to the College "would be to set aside the judgement of the court." Well then, there are plenty of wealthy men on the committee of the Fund; let them pony up the money themselves, smile and look pleasant like any sportsman who had put his money on the wrong horse.—I am, etc.,

Liverpool, June 28th. JAMES BARR.

EVENING DENTISTRY.

SIR,—As a member of the London County Council Education Committee I am constantly coming in contact with both teachers and scholars about to leave school, or just recently gone to work, who are in urgent need of conservative dental treatment. They admit the necessity, but cannot afford to be absent from work.

Are there any dentists on the *Register* who work after 5 o'clock or on Saturday afternoons? There is a great opening for dentists who will work when other people are at leisure. The public is beginning to realize the importance of dental treatment, but it has not realized that prevention is better than cure, and rather than lose work and pay many people prefer to wait till the teeth get bad enough to, in their eyes, justify missing a day's work. When this time is reached there is often no course open to

the dentist but to take out most of the teeth, whereas a timely visit after working hours while stopping was still possible would have saved the necessity for such radical treatment.—I am, etc.,

London, N.W., June 16th. M. SOPHIA JEVONS, M.B., B.S.

DETERIORATION OF DIGITALIS PREPARATIONS.

SIR,—Dr. Symes (BRITISH MEDICAL JOURNAL, June 20th, p. 1343) brings evidence by physiological testing to show that digitalis tinctures are liable to decrease in strength. One of the main conclusions of his paper is that active tinctures deteriorate much more rapidly than weak ones. He finds that in the case of "tinctures initially more than 25 per cent. *above* standard, only half the tinctures he examined after the lapse of one year were within 25 per cent. of standard, and these had lost from 20 to 70 per cent. of their original activity." This to the pharmacist would appear a very marked drop in strength, and it would seem strange that a tincture twelve years old (vide p. 1345) at the time of examination should show a marked drop in strength subsequently during the following year, owing possibly, as he suggests, to "repeated admission of air to the bottles accelerating the deterioration, previously arrested by prolonged non-disturbance."

Arguing on Dr. Symes's findings of a general fall in potency from month to month, one can only imagine that this tincture must have been abnormally, if not impossibly, strong at the outset, especially when one considers that "active tinctures deteriorate more rapidly than weak ones," and the twelve-year-old tincture was decidedly active at that age.

Pharmacists, I have no doubt, are quite prepared to supply tinctures with date of manufacture on the label if necessary, but it must be remembered that digitalis leaves can only be collected during about four months in the year (from now to September), and that the use of stored dried leaves would bring the matter back pretty well *in statu quo*, as many assume marked deterioration in the dried leaf also. If the storage of the dried leaf is to be prohibited, active digitalis tinctures, according to the new findings, would only be obtainable for about six months during the year. As a matter of fact, with regard to making the tincture thrice yearly, as Dr. Symes suggests, I have no doubt the majority of manufacturers make it more often than this.

Mention might, perhaps, have been added of the paper by Halcher and Eggleston (*American Journal of Pharmacy*, May, 1913), who found that the diminution in strength is quite small. They state that digitalis leaves of good quality do not, as a rule, deteriorate, or do so only with extreme slowness—at a rate probably not exceeding 1½ to 2 per cent. per annum. The same holds good, they say, regarding preparations of digitalis containing at least 50 per cent. alcohol (*B.P.* tincture is made with 60 per cent.).

I myself have determined by chemical means a slight general decrease in strength on keeping digitalis tinctures one year, but I have been unable to find the loss of potency so great as Dr. Symes has indicated.

One hesitates to bring up the question of frog variation to confront so extensive a research conducted with every indication of remarkable concordance, but is there not just a possibility that the 1912 frog was less robust and less tolerant than the 1913 descendant so that the latter required a larger M.L.D.—even at exactly the same period of the year? In other words, Is there not a seasonal variation in frogs just as in digitalis leaf? I take it some absolute standard exists to standardize the frogs employed.—I am, etc.,

London, W., June 22nd. W. H. MARTINDALE.

PSYCHO-ANALYSIS.

SIR,—In the JOURNAL for June 27th (p. 1409) the following passage occurs in a review:

> During the last thirty years the use of suggestion in the treatment of disease, either with or more often without hypnotism, has been increasingly employed. It was originated by Breuer, who called the method "Psycho-analysis."

The facts, on the contrary, are that the use of suggestion in the treatment of disease did not originate with Breuer, being in vogue long before his time, that he called the method he originated, which has nothing in common with suggestion, "catharsis," and that the method of "psycho-analysis" was devised by Freud, who gave it this name.

In the preceding number of the JOURNAL a reviewer quotes, without contradicting it, a statement from Dercum's textbook to the effect that Freud ascribes to dreams an important part in the causation of nervous disorders. Freud has never held any such view, and has repeatedly and categorically expressed his opinion that dreams have no function or action whatever except to preserve sleep.

I quote these current examples merely to illustrate the ignorance that prevails concerning the most elementary and easily accessible facts on the subject of psycho-analysis. It is ignorance of this kind that goes far to explain the mediocre value of most criticisms on the subject, and which does not encourage the exponents of psycho-analysis to answer such criticism.—I am, etc.,

London, W., June 26th. ERNEST JONES.

*** The Freudians, having failed to convince the majority of thinking persons, now show a disposition to assume the martyr's crown. "You do not understand," they say; or "We are misunderstood." As a general rule it is safe to conclude that if persons of intelligence do not understand a theory, it is because the theory is founded on confused thinking, and for fine confused feeding there is nothing like a diet of Freudism.

"THEY MANAGE THESE THINGS BETTER IN FRANCE."

SIR,—It may be within the recollection of some of your readers that the campaign of the great Macaura in this country was not only not interfered with, as stated by Mr. Sewill in your issue of June 27th, but actually encouraged in a way that must have given him the greatest satisfaction.

At one of his Albert Hall meetings a military band—I think from one of the Fusilier regiments—was advertised to lend its aid to the great man's demonstrations. Support such as this from the British army may give him hope after the completion of his term in a French gaol to renew his efforts in this country.—I am, etc.,

Warrington, June 28th. J. S. MANSON.

OBITUARY NOTICES.

SIR,—The late Dr. Myrtle, of Harrogate, said that if medical men would take notes and study their own symptoms we would have more chance to make progress in the prevention and treatment of disease; and when I read the obituary notices which appear in the JOURNAL of our fellow members as they fall (many of them in the prime of life), I feel that if some account of their medical history were given, which need not be long, it would add much to the value of such notices. We are anxious to learn what we can from our patients, and in some cases are able to make a *post-mortem* examination; but much more might be learnt when the patients were members of the medical profession. There can be no doubt that clinical observation has been the pioneer in the advances that have, so far, been made in the science and practice of medicine. Antiseptic surgery, or what is sometimes called Listerism, itself was enunciated by Semmelweis in 1846, but it was not till Lister wrote, and taught what *he* had discovered, that the value of the teaching of Semmelweis was appreciated.

I never heard of Semmelweis until Sir William Japp Sinclair published the life of his unfortunate fellow gynaecologist. Had I been taught when a student what Semmelweis had discovered, as I might have been, it might have made me still more cautious in my midwifery practice, and explained all that Lister has taught us as to the healing of wounds.

It is to the medical profession we must look for progress in the treatment and prevention of disease; and having, though too late, learnt the danger that lurks in food, I am glad to see that in the post-graduate course in Edinburgh this year dietetics appears among the subjects to be taught; but why should dietetics be left to the post-graduate course? It ought to be taught not only in the university to medical students, but to every child in our elementary schools, so soon as the profession is at one on

this all-important subject. It might be well if our research scholars had their attention directed to the subject, and gave us the result of their experiments and observations on themselves, for, unless under lock and key, no patient can be trusted when food is the subject of study.—I am, etc.,

Denholm, Hawick, June 24th. JOHN HADDON, M.D.

THE RESPONSIBILITY OF THE SUICIDE.

SIR,—What on earth is one to do with an antagonist like Dr. Leitch? He first paralyses me with an extravagant compliment and then dances round me, brandishing his sporran, or whatever may be the Scottish equivalent of a shillelagh, and invites me to come on. As Dr. Johnson says, Such treatment I did not expect, for I never had a complimentary antagonist before; and, as Mrs. Malaprop says, I am perfectly putrified. Sir, I admit everything. I admit that Dr. Leitch's expectation that I should sooner or later refer to the case of Captain Oates makes that case inapplicable to my argument. I admit that suicide is not suicide if you call it giving life and not taking it. I might have referred to the case of Curtius, but that Dr. Leitch has no doubt expected the reference and so deprived the example of its force. I am powerless, and have no alternative but to yield myself, rescue or no rescue. It is another Bannockburn. *Vae victo!*—I am, etc.,

Parkstone, June 29th. CHAS. A. MERCIER.

Universities and Colleges.

UNIVERSITY OF OXFORD.

Degrees.

THE following degrees have been conferred:

D.M.—H. H. Carleton.
B.M. AND B.CH.—E. W. N. Hobhouse.

Examinations.

The following candidates have been approved at the examinations indicated:

FIRST M.B. (*Organic Chemistry*).—J. P. B. Harold, P. S. Houghton, J. E. B. Morton, M. E. Shaw, G. K. Stone, W. F. Skaite. (*Human Anatomy and Human Physiology*).—C. W. W. Armstrong, G. Cranstoun, J. L. Dunstan, C. K. J. Hamilton, J. F. Haines, R. M. Humphries, R. W. Lush, B. G. von B. Mellé, D. H. Skinner, A. E. Thomas, K. F. D. Waters, C. D. Wood.

SECOND M.B. (*Materia Medica and Pharmacology*).—H. E. A. Boldero, C. J. A. Buckell, R. W. J. A. Cushing, S. C. Dyke, H. S. Jeffries, C. P. Sells, C. P. Symonds. (*Pathology*).—A. O. Ballance, H. E. Bamber, J. D. Balt, H. E. A. Boldero, L. S. Brown, C. J. A. Buckell, C. H. Carlton, F. B. Chavasse, G. Cranstoun, A. W. Dennis, S. C. Dyke, K. M. Dyott, O. H. Gotch, C. H. L. Harper, O. G. Parry-Jones, O. B. Pratt, G. P. Selby, S. W. F. Underhill, H. St. H. Vertue, A. L. Watts, H. A. B. Whitelocke.

SECOND M.B. (*Forensic Medicine and Public Health*).—C. H. Carlton, V. T. Ellwood, F. C. Gladstone, C. H. L. Harper, C. W. B. Littlejohn, G. A. Maling, E. E. Mather, O. G. Parry-Jones, M. O. Raven, G. S. Robinson, G. P. Selby.

SECOND M.B. (*Medicine, Surgery, and Midwifery*).—J. C. Davies, C. Dean, A. W. Dennis, C. W. B. Littlejohn, E. E. Mather, H. M. Pope, M. O. Raven, G. P. Solby, A. B. Thompson.

D.P.H. (*Part I*).—F. S. Carson, G. M. Cogwell, H. B. Gibbins, W. H. Hewlett, J. Inkster, C. F. B. Kebbell, F. G. H. Martin, L. M. Mayers, R. S. Miller, H. W. Parnis, W. R. S. Roberts, A. H. Savage. (*Part II*).—N. A. Coward, H. B. Gibbins, W. Gilmour, J. Inkster, F. J. H. Martin, J. Powell, E. L. N. Rhodes, W. R. S. Roberts, A. H. Savage.

UNIVERSITY OF CAMBRIDGE.

THE following candidates have been approved at the examination indicated:

THIRD M.B. (*Part II: Medicine, Pathology, and Pharmacology*).—S. G. Askey, D. C. G. Ballingall, H. A. Bell, W. G. Bigger, P. R. Boswell, E. C. Bradford, H. P. Dawson, E. L. Dobson, A. T. Edwards, W. B. Gordon, H. Hartridge, F. G. Lescher, R. W. Meller, A. B. Pavey-Smith, D. V. Pickering, S. G. Platts, L. C. Rivett, L. E. S. Sharp, A. C. S. Smith, P. Stocks, C. R. A. Thacker.

UNIVERSITY OF LONDON.

LONDON (ROYAL FREE HOSPITAL) SCHOOL OF MEDICINE FOR WOMEN.

SIR WILMOT HERRINGHAM, Vice-Chancellor of the University of London, distributed the prizes on Monday, June 29th. Mrs. Garrett-Anderson, President of the School, presided.

Mr. Acland, Chairman of Council, in opening the proceedings, said that the school had sustained a severe loss through the death of Miss Cox, who had been Dean for ten years; but that her place had been filled by one well worthy to succeed her. It was perhaps only natural that the Council should consider itself the body which kept the school going; and if there was one member of that body who worked harder than the others it was Miss Brooks, and he was glad to have the opportunity of thanking her for her devotion to the school. The past year had been very successful, and the future looked equally promising. The school at the present moment was developing very fast. A new department for pharmacology was about to be opened; and the school intended to become the largest school of medicine in the University of London.

Sir Wilmot Herringham, in a short address, said that nowadays one heard a great deal about the advance of medicine, but the most remarkable change he had noticed during the course of nearly forty years' practice was the change in the position of the doctors themselves. Not only was the social position of the ordinary medical practitioner greatly improved, but there had been an immense accession of the influence of medicine in the State. No other profession exercised such an immense legitimate influence in legislation as the medical profession. Besides the change in social position, there was a large increase in the number of public employments open to medical men. No one could foretell what would be the outcome of the Insurance Act, but one result of it had been to make doctors, in a certain sense, public officials. There were already a vast number of posts under Government, and there would probably be more, and this fact alone would effect a change in the position of the private practitioner. The increase of specialization had dislocated medicine still further; and it was becoming, particularly in London, as necessary to organize private practice as that in the hospitals. For instance, the present system of nursing institutions was a disgrace to London, and he hoped the time would come when there would be homes where private patients would receive the same amount of care and attention that hospital patients did now. The practice of medicine was very difficult, not so much on the intellectual as on what might be called the emotional side. The successful doctor needed great powers of criticism and great powers of faith, and it was extremely difficult to combine the two. He had to act continually as a sort of magic man in order that his patient might trust him so as to reap the benefit that accrued from faith; and the hardest part of a doctor's work was to make others trust him when he distrusted himself.

UNIVERSITY COLLEGE.

The Committee will shortly proceed to appoint a lecturer and demonstrator in anatomy at a salary of £350. Applications must reach the Secretary of University College on or before July 11th.

UNIVERSITY OF DURHAM.

Degrees.

THE following were among the degrees conferred at a convocation on June 23rd:

M.D.—J. K. J. Haworth, Eva Lumb, R. S. Renton.
M.D. (*for Practitioners of Fifteen Years' Standing*).—W. O. Beddard, W. H. Date, J. Flynn, A. J. Hesterlow, W. M. M. Jackson, J. R. McFerran, E. Maynard, J. J. S. Pillay.
M.S.—J. J. Brown, J. C. Young.
M.B.—C. Armstrong, I. G. Cummings, H. H. Elliot, C. N. Gover, F. W. Harlow, M. H. de J. Harper, C. Jacobs, H. V. Leigh, F. Metcalfe, E. K. Ryan, H. J. Shanley, K. I. S. Smith, J. C. Spence.
B.S.—C. Armstrong, I. G. Cummings, H. H. Elliot, I. D. Evans, C. N. Gover, F. W. Harlow, M. H. de J. Harper, C. Jacobs, H. V. Leigh, F. Metcalfe, H. J. Shanley, K. I. S. Smith, J. C. Spence.
B.HY.—A. H. Wear, S. Worthington.

The following candidates have been approved at the examinations indicated:

SECOND M.B. (*Anatomy and Physiology*).—*W. A. Hewitson, †H. M. Leete, P. V. Anderson, W. Duncan, E. C. Dunlop, M. J. Erdberg, C. G. Irwin, M. C. Joynt, Freda Newman, G. F. Philip, H. I. Sterne Howitt.

THIRD M.B. (*All Subjects*).—†H. Evers, †J. A. Charles, †A. E. Raine, J. F. C. Braine, J. Brumwell, H. C. Broadhurst, G. A. Clark, H. G. B. Dove, J. Horsley, H. G. Sparrow. (*Materia Medica, Pharmacology and Pharmacy, Public Health, Medical Jurisprudence*).—Mary R. Campbell, R. A. Hooper, N. A. Martin, C. D. Newman, W. O. F. Sinclair, A. C. Taylor, R. Welch. (*Pathology and Elementary Bacteriology*).—L. B. Frere, H. K. Graham-Hodgson, J. D. Johnson, D. O. Richards, A. Smirthwaite.

FIRST M.B. (*All Subjects*).—*W. E. M. Wardill, M. W. A. Sandoe, H. Toma. (*Chemistry and Physics*).—J. N. Alexander, A. Angus, D. G. P. Bell, E. F. H. Bell, J. A. G. Brewis, E. D. Charles, H. C. Clifford-Smith, W. A. Freedman, G. A. M. Hall, A. T. Harrison, Mary K. Henegan, R. A. Hickley, G. E. Hyden, W. A. Jaques, R. T. E. Naismith, C. B. Phillips, G. Reed, F. W. Sopwith, L. W. Studdy. (*Elementary Anatomy and Biology*).—E. G. Anderson, I. Girgis, S. E. Goulstine, H. Kamel, R. G. Melrose, G. G. Robertson, T. W. Robertson, G. H. Shanley, A. W. Wilkinson.

* First-class honours. † Second-class honours.

UNIVERSITY OF EDINBURGH.

THE following candidates have been approved at the examination indicated:

FINAL M.B., CH.B.—R. H. Alexander, C. Atkinson, Mary A. H. Baird, R. G. Bannerman, Rachel M. Barclay, *R. C. L. Batchelor, H. W. Bell, J. G. Bell, J. W. Bennett, S. E. Bothell, J. Biggam, H. B. Binks, W. Bird, E. J. Blair, A. B. Brook, H. P. Caithness, A. Cameron, R. E. Cameron, H. E. Collier, A. N. Craig, J. W. Darling, T. M. Davie, W. M. Dickson, C. L. Dold, C. E. Dukes, G. K. Edwards, J. D. Evans, F. B. Eykyn, S. Fenwick, T. C. Findlater, E. Fowler, H. R. Friedrichs, T. A. Fuller, R. E. Gibson, D. J. Glen, A. S. Glynn, H. F. T. Haddow, A. R. Hamilton, N. E. M. H. Hay, J. J. Healy, G. F. P. Heathcote.

Gertrude Herzfeld, J. Hogarth, K. Husain, Florence E. Inglis, B. O. Jarrette, C. P. M. Joubert, P. W. J. Keet, C. G. Lambie, S. J. A. Laubscher, L. Levy, *P. MacCallum, T. M'Fetridge, R. M. Mackay, E. F. W. Mackenzie, E. L. Mackenzie, J. J. R. Mackenzie, I. K. F. MacLeod, Jean M. M'Minn, F. G. Macnaughton, E. Mansfield, V. H. Mason, D. J. Max, B. Mendelssohn, G. Millar, R. W. Miller, E. M. Molesworth, G. T. Mowat, R. M'I. Muir, W. Murdoch, J. C. Neil, H. S. Palmer, C. C. Philip, G. S. Pirie, R. Power, *J. M. Pringle, M. Razakhan, H. A. Bippiner, R. L. Ritchie, H. C. Robins, C. Sand, H. K. Shaw, B. Shires, H. J. Simson, H. C. Sinderson, T. W. Smart, A. H. D. Smith, D. M. Smith, A. S. Taylor, J. S. Taylor, *A. B. Theron, A. R. Thomson, R. O. C. Thomson, R. Thorp, F. E. Tillyard, P. Toit, Janet P. Walton, C. H. Wan, H. D. Welply, H. P. W. White, G. S. Williamson, D. G. Wishart, E. W. N. Wooler, P. C. V. Woudberg, B. E. Wright, G. D. Yates, J. B. Young.

* Passed with distinction.

UNIVERSITY OF GLASGOW.

SUMMER GRADUATION.

THE summer graduation ceremony took place on June 22nd in the Bute Hall. Principal Sir Donald MacAlister presided, and this being his first appearance at a graduation ceremony since his recent severe illness, he received a very cordial greeting. The proceedings were of the usual noisy kind, and after the degrees had been conferred in dumb show, the Principal handed his remarks on the benefactions during the past year to the Press. Among the notable gifts mentioned were the bequest of £5,000 from the late Mr. Weir of Kildonan for the purpose of providing an additional assistant to the Professor of Materia Medica; the bequest of £25,000 by the late Dr. Gavin P. Tennant for the Faculty of Medicine; and the appropriation by the Carnegie Trust of £45,000 for buildings for the accommodation of zoology and arts.

COMMEMORATION.

On June 23rd the University of Glasgow commemorated its pious founders and its benefactors. The opening religious service was followed by a commemoration address on Lord Lister, delivered by Sir Hector C. Cameron. This was followed by an expression of thanks to the Orator by the Chancellor (Lord Rosebery); then came the graduation ceremony, and finally, a banquet in the evening.

UNIVERSITY OF ST. ANDREWS.

THE following candidates have been approved in the subjects indicated:

FIRST M.B., CH.B. (*Botany*).—D. R. Cameron, R. T. Cameron, J. C. Coutts, J. Farquharson, J. Fergusson, Miss J. H. Hodge, J. C. M'Gregor, N. MacVicar, A. H. Nearne, J. K. T. Mills, L. G. Morrison, Miss J. M. Orkney, W. G. Robertson, G. R. Ross, J. Shirlaw, J. N. D. Smith, W. Thomson.

SECOND M.B., CH.B. (*Physiology*).—Annie R. Campbell, F. J. Charlton, Mary J. S. Cuthbert, Kathleen I. David, J. Irvine, J. Kinnear, Mokham C. Madhok, Puthoor V. Paul, Margaret W. Shirlaw, G. Verghese. (*Anatomy*).—Sheila Bridgeford, Kathleen I. David, Mary M. G. Fergnson, D. Fisher, J. Irvine, J. Kinnear, Allister M. MacGillivray, Puthoor V. Paul, Margaret W. Shirlaw, W. P. Starforth, G. Verghese.

THIRD M.B., CH.B. (*Materia Medica*).—Pam N. Bhandari, F. Braid, T. P. Buist, N. B. B. Fleming, Elsie L. Kyle, Flora M. MacDonald, M. M'Gillivray, Mokham C. Madhok, J. L. Paton, Alice Rattray, D. Roger, A. A. B. Scott, J. M. Stalker. (*Medical Jurisprudence and Public Health*).—Margaret A. Alexander, Agnes W. Andrew, Mohan L. Bery, D. Dempster, T. Esterman, Margaret Fairlie, Louise L. Fraser, G. M. Grant, W. S. King, C. B. MacDonald, C. W. Morrison, D. H. Murray, Alistair G. Stevenson, J. H. Taube. (*Pathology*).—F. Braid, T. P. Buist, A. C. Cassells, T. Esterman, N. B. B. Fleming, Elsie L. Kyle, C. B. MacDonald, M. M'Gillivray, Jeannette M. Mansie, J. L. Paton, D. Roger, A. A. B. Scott, J. M. Stalker, W. M. D. S. Strettell.

FINAL.—P. E. B. Barrow, R. H. B. Barrow, J. R. Caldwell, Mabel G. Cowper, A. C. Craighead, Mary L. David, S. W. Kintoul, D. H. Scott, J. Taylor, R. A. Quinn.

D.P.H. (*Part I.*).—G. N. Anderson, J. C. Robertson. (*Part II.*).—G. M. M'Gillivray, D. T. Munro, D. J. Peebles.

Obituary.

ALDERMAN SIR HENRY WM. NEWTON,

NEWCASTLE-UPON-TYNE.

AFTER an illness of brief duration, although to all who were in the habit of casually meeting him it was apparent that he was the subject of an increasing anaemia, Sir Henry Newton succumbed on June 21st to an attack of bronchitis, during which he was attended by Sir Thomas Oliver and Professor Beattie. Although Sir Henry had reached his seventy-second year, his physique and energy until within the last few months were those of a man many years his junior. He was less known in the field of medicine proper than in that of public health, especially from the municipal and administrative points of view. The son of a Newcastle surgeon, Sir Henry Newton was closely identified with all the recent progressive movements of his native city. He received his medical education in the College of Medicine in Newcastle, and qualified in 1863.

At a comparatively early age he evinced a taste and ability for municipal work. Devoting his life to public service, he never forgot that foremost above all things he was a member of the medical profession, and that its claims had the prior call upon his attention. A strong man in the public sense of the term, an admirable debater, and gifted with oratorical powers of no mean order, Sir Henry rapidly rose in the town council of which he had become a member in 1866. In 1877–8 he filled the office of sheriff, and in 1883 he was elected mayor. His year of office as chief magistrate was remarkable, for in August, 1884, the Prince and Princess of Wales visited Newcastle-upon-Tyne to open the Northumberland Docks, to open Jesmond Dene to the public, and to open also the free library of which Sir Henry Newton was chairman. Many of us remember all of these functions were performed in a most successful manner, and in the following year he became an alderman. In 1901–2—the coronation year of the late King Edward—Sir Henry again occupied the civic chair.

In recognition of his services in connexion with the Public Libraries Committee Sir Henry was presented with his portrait in oils. To everything which made for improving the health and social position of the masses he gave his adherence and assistance. For more than thirty years he was Chairman of the Town Moor and Parks Committee; he was since its opening chairman of the Laing Art Gallery and chairman also of the School of Domestic Economy, but the one position which he occupied with greatest distinction, and in which the value of his work will be seen and felt for many years to come, was that of chairman of the Sanitary Committee. In conjunction with Dr. Henry E. Armstrong, late Medical Officer of Health for the city, much pioneer work in public health work was done. For his services Sir Henry received the freedom of the city in 1906, and in 1909 the honour of knighthood from King Edward.

By his death the Corporation of Newcastle-upon-Tyne has lost its oldest member. Sir Henry may not always have seen eye to eye with his colleagues in the Council, but it could never be said of him that he played for popularity.

Suitable magisterial reference to the death of the late alderman was made by Sir George Hare Philipson, Chairman of the Bench.

The funeral was attended by the Lord Mayor of Newcastle and by the city aldermen and councillors, by representatives of the various public bodies with which Sir Henry had been identified, and by large numbers of the public.

To Lady Newton, his second wife, and to the sons and daughters of both families, much sympathy has been expressed in various ways.

THE LATE DR. NEIL OF THE WARNEFORD.

DR. CHAS. A. MERCIER writes: Permit me to lay upon the grave of my friend Dr. Neil a wreath of respect and affection. He belonged to a nation among which I am privileged to count many intimate friends, and he had a full measure of the quality—humour, which we southrons pretend they do not possess, besides others that we cannot pretend to deny to them—thoroughness, sound sense, business ability, and professional skill. I have sent many patients to his care, have often visited them at the Warneford, and can speak from personal knowledge of his unwearied kindness to them, often reciprocated by suspicion and abuse, and of the constant solicitude with which he worked and hoped, even in very unpromising cases. His crowning merit was that he never attempted to divert the purpose of the founder of the Warneford, to afford treatment and care on the most moderate terms—in a large proportion of his cases on charitable terms—to patients of the educated classes. He never angled for patients who could pay high fees, nor did he attempt to substitute an impressive but uncomfortable magnificence for the solid homeliness and comfort of the Warneford. When we think of the number of patients that came under his care, of the atmosphere of tranquillity and goodwill that he maintained around him, and of the help that so many found in reliance on his strong character and sound judgement, we can form some estimate of the good that can be done in a quiet and unobtrusive life. He found his appropriate field of activity; he laboured in it

with unremitting diligence; he won the respect and regard of all around him; his life, if it was unambitious, was useful, fruitful, and happy. Who could wish more to be said of himself?

Medico-Legal.

ALTERATION OF AGREEMENTS.

ABSENCE OF DUE NOTICE.

THE action by Dr. Salter against the London Insurance Committee, which was decided in his favour, as was fully reported last week, page 1437, was carried out on his behalf by the Medical Defence Union. Messrs. Hempsons, the solicitors to the Union, received an intimation from the London Insurance Committee, asking them not to proceed upon the rule by issuing a writ, and stating that the Committee accepted the position, and would restore Dr. Salter's name to the panel at once. Application was accordingly made to the Divisional Court on July 1st for an order for costs as against the Committee, and this was granted. Counsel for the Committee stated that he was instructed to say that the Committee was very glad to reinstate Dr. Salter, but, as an important question of principle was involved, the Committee desired to have it settled by the Court.

PROCEEDINGS UNDER THE APOTHECARIES ACT, 1815.

AT the Bow County Court on June 29th the Society of Apothecaries recovered a penalty of £20 against John Charles Purdue, described as a medical herbalist, of 28, Roscoe Street, Canning Town, for a breach of the Apothecaries Act, 1815, in that he had acted and practised as an apothecary or medical practitioner in attending and medically treating the infant daughter of Arthur Thompson, of 21, Scott Street, Canning Town, whose death in January last was the subject of an inquest conducted by the local coroner. It appeared from the evidence that the child had become ill on Tuesday, January 27th, and was taken by her mother to the defendant's shop, who examined her and said that she was suffering from pneumonia. He further gave the mother medicine for the child and oil to rub her chest with. He was again summoned by the mother to see the child on the same afternoon, and then administered further medicine, also using the stethoscope and taking the child's temperature with a clinical thermometer. The defendant attended the child further on the Wednesday, Thursday, and Friday, on the evening of which day the child died. The defendant was paid the sum of 2s. in respect of his medicine and attendance. It appeared from the medical evidence given at the inquest that the child actually died of meningitis. At the hearing of the case the defendant's counsel endeavoured to argue that he was protected by a statute of Henry VIII, sometimes called the Herbalists Act. The county court judge held that the statute was inapplicable, and that there had been a clear breach of Section 20 of the Apothecaries Act, 1815, and he consequently gave judgement for the Society, with costs on the higher scale.

ALLEGED PERSONATION.

AT the Hampshire Assizes, before Mr. Justice Kennedy, a man aged 60, charged under the name of Hugh Munro McLeod Mackenzie, was convicted on a charge of feloniously, knowingly, and unlawfully giving a false death certificate. The case involved a charge of personation, and evidence was brought to show that the accused was not Hugh Munro McLeod Mackenzie whose name appeared on the *Medical Register*, and that this gentleman resided in South Africa. The accused had obtained the insertion of his name on the panel for Southampton. The prisoner, who was undefended, stated in his own defence that he was named Mackenzie, and a medical practitioner; he did not know Dr. Mackenzie, now in South Africa. The judge said that, judging by the photograph produced, it was hardly possible that the prisoner could have changed so much, and the evidence showed that the accused was not the man registered. After the verdict had been returned it was stated that the accused had formerly practised at Portsmouth, and the allegation that he was personating Dr. Mackenzie residing in South Africa had been brought to the notice of the General Medical Council, but as the accused was then extremely ill no proceedings were taken. The prisoner offered to resign from the panel, but the judge stated that his name would be struck off, and that as he was very ill he would be kept in prison for a month.

DAMAGES AGAINST AN EXTRACTOR OF TEETH.

IN the Rochdale County Court, on June 26th, an action was brought by a young man employed by the corporation against Ada Berry, trading as R. H. Berry, extractor of teeth, for £100 in respect of the alleged negligent extraction of a tooth. The patient was subsequently attended by Dr. Bateman, who, in consequence of recurrent bleeding, advised his admission to the infirmary, where he was treated for a month.

The defendant, who was not legally represented, said, according to the report in the *Manchester Guardian*, that she was taught the business of an extractor of teeth by her brother, who, like herself, was not a qualified dentist. She used a syringe to insert into the gums a preparation she obtained from a chemist, and said it was not possible to insert too much of the fluid. She also gave a powder for the plaintiff's use, and she admitted that she did not know the contents of the powder.

His Honour, in giving judgement, said there had been neglect in the administration of the drug, and that neglect had caused the plaintiff terrible suffering. He gave judgement for £85 and costs.

Medical News.

THE Robert Koch Foundation for combating tuberculosis offers a prize for the best research on the value of various kinds of rays (sun, Roentgen, radium, mesothorium) in the diagnosis and treatment of tuberculosis. The essays, which must be in German and typewritten, should be addressed to the Secretary, Herrn Geh. Sanitätsrat Professor Dr. Schwalbe (Berlin-Charlottenburg, Schluterstr. 53), and should reach him before July 1st, 1915. Each essay should be authenticated by a motto corresponding to one contained in a separate envelope enclosing the author's name. The prize is of the value of £150. The successful essay will be included among the publications of the foundation, but the author will be allowed to publish a short abstract in the *Deutsche medizinische Wochenschrift*.

THE Cremation Society of England, in conjunction with the Blackpool and Fylde Cremation Society and the Manchester Crematorium, Ltd., is organizing an exhibit at the Health Exhibition to be held in connexion with the Congress of the Royal Sanitary Institute at Blackpool (July 4th to 11th). Photographs and plans of the various crematoriums and photographs showing the retentive nature of earth burial will be on view, together with a specimen of cremated ash. There will also be exhibited a working model of the Golder's Green apparatus, by which is demonstrated how cremation is effected by the agency of superheated air only in a retort quite separate from the actual furnace. Mr. G. A. Noble, Secretary, will represent the Cremation Society as delegate at the Congress, and will be in personal attendance at the exhibition to give information. Dr. P. J. R. Bucknill, of Blackpool, will read a paper on cremation, illustrated by diagrams and lantern slides.

THE Council of the Nightingale Fund proposes to offer every year to nurses who have obtained a certificate after three years' training in some recognized school a limited number of scholarships entitling the holders to a year's training at the Household and Social Science Department of King's College for Women in the University of London. The new buildings of this department, now in course of erection on Campden Hill, will contain laboratories in close proximity to the experimental kitchen and laundry, which form a portion of the hostel where the practical arts are taught. Every endeavour will be made to keep in view the object of the course, namely, to equip trained nurses to undertake the responsible administrative and social appointments they are likely to be called on to fill. The value of the scholarships will be adjusted to meet the tuition fees, to provide maintenance during the year, and to compensate in some degree for the salary the year's training will oblige the scholar to forego. The scheme is experimental, and its continuance must depend upon its success.

ON June 23rd Dr. Stovin, until lately Medical Officer of Health, Ilford, was entertained at supper by the members of the Ilford Medical Society. Dr. Ernest Watts, president, who was in the chair, spoke of the cordial relations which had always existed between the M.O.H. and the general practitioners in the district, and of their great appreciation of Dr. Stovin's services to the district. Dr. Carrell, speaking as the member of the society who had longest been in practice in Ilford, said that though differences of opinion had arisen, they had never disturbed the friendly relations between the profession and Dr. Stovin. The president then, on behalf of the society, presented Dr. Stovin with a silver salver, bearing a suitable inscription, and the signatures of thirty-six of his professional brethren in the district. Dr. Stovin, who on rising was warmly cheered, said that he felt deeply this fresh expression of the constant kindness and help he had received from all members of the society. He concluded by proposing the toast of the Ilford Medical Society, which was acknowleged by Dr. Drought. The company separated after the toast of the president had been received with enthusiasm.

THE usual monthly meeting of the Executive Committee of the Medical Sickness, Annuity, and Life Assurance Friendly Society was held at 429, Strand, on June 19th, when Dr. J. Brindley-James was in the chair. The claim account presented showed an improvement over that of

last year, and the proposals received in the first five months of this year constituted a record in the society's experience. The new combined sickness and endowment table with reduced premiums for the first five years has also proved popular with younger members of the profession. The votes for Epsom College were dealt with at this meeting, there being two candidates for Foundation Scholarships who are the sons of deceased members. The widow of a late member was also applying for a pensionership. The society subscribes £105 per annum to the College, and the votes are all used for the dependants of deceased members. During the past few years the sons of several members have been admitted to Epsom College as foundation scholars. Prospectus and all information can be obtained from Mr. Bertram Sutton, Secretary, Medical Sickness and Accident Society, 33, Chancery Lane, London, W.C.

NEARLY every one who is accustomed to pass the greater part of the day away from home, particularly those whose occupations oblige them to spend much of that time going from place to place, has experienced the discomfort of defective or inadequate lavatory accommodation in public places. This want is not peculiar to any one town or district, but is felt in almost every crowded city, both at home and abroad. The New York Bureau of Public Health and Hygiene, realizing the importance of their cleanliness and good management not only for comfort, but also for health, has caused an inspection to be made of the public lavatories in every quarter of that city. The results of this investigation have been published by the Superintendent of the Bureau, Dr. Donald B. Armstrong, in a pamphlet called, *Comfort Stations in New York City*. The inspectors have evidently carried out their task with commendable thoroughness; and the defects in the New York public lavatory system are indicated with no sparing hand. The pamphlet is illustrated with diagrams and photographs, and contains suggestions which might be adopted with equal advantage on either side of the Atlantic.

THE January and February number of *Tumori*, published in Rome, leads off with an article by Izar and Patanè recording a series of complicated experiments devised to free the antigen, used in the meiostagmic reaction for malignant tumours, from all those substances, soluble in ether and methylic alcohol, which do not enter specifically into play in meiostagmic reactions. A second paper deals with synthetic antigens composed of fatty acids and protein substances. Then follows a long paper on a case of tumour of the hypophysis, with comments, sections, and a full bibliography. The next important communication is probably that of Bilancioni and Cipollone on endotheliomata; it contains a detailed account of 14 cases, drawings, and an extensive bibliography. Of the 14 cases, most occurred in young subjects of 8 to 25 years, and were situated for the most part in the nose; the tumours could be separated into two main groups, according to the predominance or otherwise of the fibrous tissue contained therein; a marked feature in all these tumours was the presence of migratory cells. The form of the actual cells of the tumour varied according to their point of origin, whether from the blood vessels or from the neoplastic parenchyma. It is considered that the latter cases mostly arise directly from the endothelial membrane of the blood vessels or lymphatics. From the clinical point of view these tumours are benign, of slow growth, for the most part single and with non-ulcerated surfaces, do not give rise to metastatic growths, and are chiefly of importance from the mechanical effects they may produce.

IN an interesting report on sleeping sickness in Northern Rhodesia to December, 1913, Dr. May, the principal medical officer, shows the extent to which the disease has been met with. *Glossina morsitans* transmitting human trypanosomiasis has been met with outside the confines of the present closed area, for example, by Dr. Ellacombe in the Serenje district to the east of Lake Bangweolo (September, 1912), by Dr. Kinghorn in the Mpika district (May, 1913), by Dr. Ward in the Ndola district (1912–13), and by Dr. MacKnight in the Luana Valley (September, 1913). In April, 1912, the Luangwa Sleeping Sickness Commission moved from Nawalia in the Luangwa Valley to Ngoa (Mpika district) on the Congo-Zambesi watershed with the object of determining what influence climatic conditions have on the transmission of the parasite by *G. morsitans*. Attempts to transmit the human trypanosome by means of *G. morsitans* at laboratory temperature on the Congo-Zambesi plateau during the cold season were invariably unsuccessful, in spite of the fact that 680 flies were used. The developmental cycle of *T. rhodesiense* in *G. morsitans* was found to be influenced in a marked degree by the temperature; high temperatures (75° to 85° F.) favoured the development of the parasite, whilst low temperatures (60° to 70° F.) were unfavourable; the first portion of the developmental cycle could proceed at lower temperatures, but for its completion the higher temperatures were essential apparently. The relative humidity of the atmosphere had no influence on the development of the trypanosome in *G. morsitans*. The object with which this Commission was formed, namely, to establish the responsibility of *G. morsitans* as the carrier of human trypanosomiasis, having therefore been accomplished, the work of the Commission came to an end at Ngoa in August, 1912. Very great credit is due to Dr. Kinghorn and his coworkers, Drs. W. Yorke, A. F. Wallace, and Mr. Ll. Lloyd, for the rapidity and thoroughness with which this work was accomplished.

ONE effect of grafting of an ovary in woman appears to be swelling of the parts around the graft associated with pains, which last for three or four days. At the end of a few weeks the graft is, it appears, completely absorbed, and it seems that cessation of the catamenia is always associated with the shrinking of the graft. In a joint communication, Tuffier, Gery, and Vignes (*Annales de gynéc. et d'obstét.*, February 1914, p. 97) report the appearances in a graft in the body of a woman who, when 41 years of age, underwent subtotal hysterectomy for an enormous soft fibroid. Tuffier grafted one of the ovaries on to the subcutaneous cellular tissue. The usual phenomena, it is implied, occurred. The woman died two years and eight months later, and the graft appeared like a little white lozenge, half an inch in diameter, homogeneous, very hard, and firmly adherent to the surrounding connective tissue. Sections examined under the microscope presented all the appearances of complete sclerotic involution. Authorities do not seem to be agreed as to the merits and effects of grafting an ovary when unavoidably removed from its anatomical attachments in the course of an operation. Tuffier and Vignes published in the same number of the *Annales* an earlier report, which shows that absorption of the graft with cessation of ovarian functions is by no means constant; in one patient a graft was made when subtotal hysterectomy was performed, and a cystic tumour of the graft, as big as a hen's egg, was enucleated from the parietes three years later. The removal of both a woman's ovaries must never be reckoned a trifle, but it is not clear that grafting can neutralize the possible evils of a sudden premature and artificial menopause and that it may not be the cause of special evils as yet unrecognized.

A DINNER of the National Medical Union took place on Saturday, June 27th, at the Café Monico, London. Dr. Greenyer, of Brighton, presided, and about eighty members and guests (including ladies) were present. The toast of "The National Medical Union" was proposed by Dr. Playfair, of Edinburgh, who said that there ought to be no difficulty in obtaining the three or four thousand members necessary to place the union on a sound financial basis. The toast was acknowledged by Drs. Porter, Brassey Brierley, Greenyer, and Carswell. Dr. Porter, who represented the Edinburgh Medical Guild, one of the bodies affiliated to the National Medical Union, spoke earnestly on the subject of the liberty of the medical profession. Dr. Brassey Brierley gave an account of the origin of the National Medical Union, and said that it was necessary to uphold the dignity and honour of the profession by means of a body which was not a trade union. Dr. Greenyer made an amusing speech on the writing on the wall which occurs at feasts. Dr. Carswell congratulated the union on having as guests representatives of other organizations; and the toast of "The Guests" was acknowledged by Dr. F. J. Smith, who dealt with the deleterious effect on the teaching of medical students likely to follow from the present panel system under the Insurance Act. He protested against the apathy shown by the College of Physicians while the Act was being introduced, and expressed a hope that the two Colleges would be roused to display a more decent activity in the future. He felt that a deluge was coming; but he feared that neither of the Colleges, nor even the British Medical Association, was likely to put up an effective umbrella against it. Mr. Adolphe Smith described how he had survived many hundreds of interviews with medical practitioners (panel and non-panel) while in search of information on the working of the Insurance Act for the columns of the *Lancet*. The speeches were alternated with musical contributions by Mrs. Edwin Smith (violin), Miss Metcalf, Dr. Parrett, and Dr. Lavies, and with a sketch by Mr. Chas. Pond. Members of the Guild present in London had, we understand, spent the day in discussion, but no statement of policy was, so far as we are aware, put out for information.

Letters, Notes, and Answers.

ORIGINAL ARTICLES and LETTERS *forwarded for publication are understood to be offered to the* BRITISH MEDICAL JOURNAL *alone unless the contrary be stated.*

MANUSCRIPTS FORWARDED TO THE OFFICE OF THIS JOURNAL CANNOT UNDER ANY CIRCUMSTANCES BE RETURNED.

CORRESPONDENTS not answered are requested to look at the Notices to Correspondents of the following week.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Office, 429, Strand, W.C., on receipt of proof.

TELEGRAPHIC ADDRESS.—The telegraphic address of the EDITOR of the BRITISH MEDICAL JOURNAL is *Aitiology, Westrand, London.* The telegraphic address of the BRITISH MEDICAL JOURNAL is *Articulate, Westrand, London.*

TELEPHONE (National):—

QUERIES.

TREATMENT OF SUNBURN.

MAJOR, R.A.M.C.(T.), asks for a formula for a lotion to apply to sunburns in camp. Ointments have been used in the past, but they are not convenient in camp. He would be glad to hear the experience of any member who has tried sulphate of quinine, as recommended by Hammer, or the bisulphate, as employed by Scherber (Epitome of Current Medical Literature, June 13th, paragraph 346).

INCOME TAX.

Motor Car: Bad or Doubtful Debts.

J. P. J. has deducted one-quarter of the cost of a new motor car and a sum in respect of bad and doubtful debts in calculating his liability; the surveyor of taxes refuses to allow the deductions.

*** "J. P. J." does not say what means of locomotion he formerly employed. If the car was purchased to replace a discarded vehicle the cost is a legitimate professional expense to the extent of the net cost of the vehicle displaced, any excess being an outlay of further capital for which no deduction can be made. The question of the allowance due for bad and doubtful debts is one of some difficulty. The Income Tax Act of 1842 restricted the allowance to bad debts "proved to be such to the satisfaction of the Commissioners," but in 1853 provision was made for the valuing of doubtful debts for the purposes of assessment. Where that allowance is claimed a strict valuation would probably be required, involving considerable trouble, if not expense. Our correspondent may perhaps be able to arrange for his assessment to be calculated on the basis of his cash receipts, and in that case would avoid the necessity of claiming any deduction for either bad or doubtful debts.

SYSTEMIC EFFECT OF BEE STINGS: PROPHYLAXIS.

DR. J. CROMIE (Castle Douglas) writes: I have a patient who is a beekeeper as a hobby; when he began and got stung the part injured swelled up, but he felt no general effects. Now the local effects are trivial, but within five minutes after being stung he collapses with feeble pulse, is very faint, feels tingling all over, vomits, has diarrhoea, urticarial rash, and is quite exhausted, sleeping for about two hours and then waking up all right but tired. Can any one suggest prophylactic treatment, as he does not want to give up his bees?

*** We hope that this question will attract attention. The first suggestion that occurs for the symptoms produced in Dr. Cromie's patient is that they are anaphylactic in nature, but so far as we know this does not take us very far on the way to prophylaxis. There is a good deal also that is obscure about the local reaction to the stings of bees and mosquitos. In some persons the immediate reaction is slight and of short duration, but there is a recurrence, in which the symptoms are often very much more severe, after an interval of about twenty-four hours; there may be three or four more recurrences at about the same interval, but of decreasing severity. It is well known that most beekeepers acquire more or less local immunity after a time, and apparently it is not completely lost during the winter. Whether such pronounced anaphylactic phenomena as Dr. Cromie describes have been recorded before we do not know, nor do we know whether anything of the same kind has been observed in respect of mosquito bites.

ANSWERS.

TREATMENT ON CHRONIC EMPYEMA.

DR. GEORGE WILLETT (Keynsham, Bristol) writes in reply to "Country Doctor": May I suggest the wisdom of making an *x*-ray examination with a view to eliminating the possibility of the pleura containing a foreign body. I once found six inches of rubber drainage-tube in an empyema, and on its removal the sinus immediately closed.

DR. S. J. ROSS (Bedford) writes: I would suggest that he send some of the pus to the Clinical Research Association, of Watergate House, York Buildings, Adelphi, London, requesting them to prepare an autogenous vaccine. I have seen several cases of chronic empyema completely cured by the administration of autogenous vaccines. Of course, the possibility of rib necrosis must be excluded.

THE FLY NUISANCE.

E. M. H. writes: I would recommend "D. H." to try the "Daisy Fly Killer" manufactured by Alfred Somers, Brooklyn, New York, U.S.A. I do not know of any agency in this country. The cost is about one shilling. I found it most efficient in South Africa and India. Full instructions are sent with each tin.

PAIN FOLLOWING ZOSTER.

DR. R. INGLIS DOUGLAS (Strathpeffer Spa) writes: "F.R.C.S." might do worse than try (*a*) the high-frequency electric breeze ten to fifteen minutes daily, afterwards gently rubbing in ichthyol and lanoline ointment for two or three minutes; or (*b*) kataphoresis, using a pledget of lint moistened with chloroform (the lint to be attached to the positive pole). Strathpeffer provides a very pure sulphur water, most suitable for elderly gouty persons. It contains a low percentage of the undesirable salt, NaCl, and a large proportion of sulphur in the form of the more easily digested hydric sulphide. The air and scenery are, of course, unrivalled.

DR. ROSENAU (Kissingen) writes to suggest the Sprudelbaths at Bad Kissingen, which are very rich in free carbonic acid and do not contain a large amount of salt (about 1 per mille fixed ingredients), or the baths at Oenhausen. The galvanic current and blue light treatment may also be advisable.

LETTERS, NOTES, ETC.

WE have received from Mrs. Will, widow of Surgeon Lieutenant-Colonel J. O. Will, R.A.M.C., on whose behalf an appeal was made by Drs. Blomfield, Dick, and Sichel in the JOURNAL of April 18th, a letter expressing her thanks to the many persons who responded.

A WARNING.

MR. MACLEOD YEARSLEY (London, W.) writes: A man, of gentlemanly and plausible address, who consulted me on June 24th, paid his fee by a cheque on the Tottenham Court Road Branch of the London City and Midland Bank. This draft was returned marked "no account," and I am informed that the book from which it was torn was issued by the bank some years ago. It appears further that another doctor besides myself has had a similar experience recently. The man is of medium height, dark, heavily jowled, and wearing a short moustache. He gave the name of "J. Howard Stewart," and his age as 38 and 9 months.

PARTURITION COMPLICATED BY ENTEROCELE.

DR. CATHERINE L. SMITH (North Colliugham, Newark) writes: I was called to a multipara, seven months pregnant. On examining I found a bag of membranes presenting and a hand outside of this bag of membranes. I sent for my partner and examined under chloroform. I was very much puzzled, and thought with the hand presenting that it was a twin pregnancy. On further examination I thought it was a hydrocephalus and punctured, but very little fluid came away. I put my hand into the uterus and brought down a foot; then with very great difficulty I succeeded in delivering a body with an enormous enterocele; this was the supposed bag of membranes which I had punctured. No further difficulties occurred, but I am thankful that the child did not go on to full time.

ON DIATHESIS IN INFANCY:

A PLEA FOR ITS CLOSER STUDY.

[WITH SPECIAL PLATE.]

BY HECTOR CHARLES CAMERON, M.D.,

PHYSICIAN IN CHARGE OF THE CHILDREN'S DEPARTMENT, GUY'S HOSPITAL.

INTRODUCTORY.

PROFESSOR EMMETT HOLT, of New York, in an interesting article published recently, entitled "Infant Mortality, Ancient and Modern," referred to the prejudicial influence which was exerted in England by the growing tendency to encourage lay workers and members of the nursing profession to busy themselves with the doctrines of infant hygiene and the practice of infant dietetics. Professor Holt's words are:

> If in England the measures referred to have been much less successful than in other countries, we must remember that in that country the care and feeding of the infant is generally believed to be the special province of the nurse. The physician is frequently not consulted at all. The effect of this is seen in the undue prominence given to nurses and social visitors.

While we must all admire the energy and devotion with which all over the country educated lay men and women of great intelligence have applied themselves to attack the problems of infantile mortality, it must, I think, be conceded that there is a strong element of truth in Professor Holt's remarks. It is significant that at the present time the National Association for the Prevention of Infant Mortality and for the Welfare of Infancy is petitioning the medical schools and examining bodies that the subject of Infant Hygiene should occupy a definite place in the medical curriculum. The high infant mortality among the poor of our great cities has aroused the compassion and interest of a large section of the educated public; it has left the medical profession, as a whole, comparatively unmoved. And yet it is to the medical profession alone that the country must look for improvement in our present conditions, because medical men alone can bring to the study of the problem the special knowledge, insight, and habit of mind which can conceive and isolate the true nature of the difficulties which confront us daily in dealing either with infantile mortality in general or with any one particular infantile complaint. Especially is this true in the study of infantile dietetic disorders. The lay mind is necessarily apt to start with the assumption that all digestive disturbance proceeds from faults in the composition of the diet, from gross excess, or from a want of cleanliness. No doubt among the very poor the proportion of cases directly attributable to these causes is much higher than among the better to do, and there is a wide field for the instruction of poor mothers in the elementary rules of health and infant hygiene. Yet even among the poor there is abundant evidence that malnutrition and dyspepsia, on breast or on bottle, is not always to be attributed to gross ignorance or culpable carelessness on the part of the mother. The doctor alone is able to detect other causes for disturbance.

Dyspepsia is very frequently the expression of an underlying infection. The infant at birth has but one function highly developed—that of absorbing an amount of food which, relatively to that of the adult, is enormous. A function so highly developed is very readily disturbed, and infections of all sorts and in the most various situations present themselves in the guise of a primary digestive disturbance. Still more interesting is the large group of cases in which dyspepsia is dependent on peculiarities of infantile diathesis, and upon inherited, inborn abnormality of digestion. Among the infants of the well-to-do classes, where the composition and amounts of the diet are well controlled and subject to the most careful scrutiny, and where the hygienic conditions are faultless, digestive disturbances are rarely *ex alimentatione*—from gross assaults upon the digestive powers by an absolutely irrational diet—but arise commonly *ex infectione* or *ex constitutione*.

The suggestion that it is possible to recognize types of individuals whose aspect and whose liability to suffer from a certain train of symptoms marks them off as belonging to a certain diathesis, is not new. Indeed, the conception of diathesis is almost as old as the study of medicine itself. For long it held a foremost place in all medical literature. Later, in the second half of the last century especially, there came a time when it fell into disrepute. These years were marked by great advances in the study of the local disorders of the different parts of the body as the use of the stethoscope grew general, and the methods of physical examination became highly developed. Bright, Addison, Wilks, Virchow, and many others taught the importance of morbid anatomy, and the necessity of interpreting all clinical phenomena in the light of the examination of viscera *post mortem*. Later still the science of bacteriology sprang into being, and profoundly influenced our whole conception of the processes of disease. With more definite knowledge of these processes much of the old-time teaching upon diathesis was found to be no longer tenable, and the very name to a great extent fell into disuse. To-day it again stands in the forefront of interest, both in medicine as a whole, and especially in the study of the disorders of infancy. Although most of the types of diathesis formerly described have been discarded, it is still possible to recognize certain inborn and inherited constitutional anomalies marked by the constant association in the same individual of a wide variety of symptoms and local manifestations. The presence of one set of symptoms often enables us to predict the appearance of others at a later time.

Although we have no sufficient knowledge of the true nature of the constitutional anomaly, we believe that this anomaly accounts for the presence of the local disorder, and that treatment to be successful must be directed not only against any one local manifestation, but must combat the underlying cause—the diathesis itself.

Evidence for the Existence of Certain Diatheses in Infancy.

The evidence of these wide divergences of constitution is very marked in the study of the dietetic disorders of infants. It is universal experience that upon the same diet and under the same hygienic conditions we may meet with one child who thrives and develops perfectly, whilst another becomes rachitic, a third grows anaemic, and a fourth shows a lowering of tolerance to all infective catarrhal processes. So frequently are such variations encountered that we are driven to the conclusion that infants are born with considerable differences in the chemical structure of their several organs and tissues—differences which exert their influence in greater or less degree, according to the character of the diet.

Formerly when a breast-fed infant suffered from severe and persistent dyspepsia, the failure was commonly regarded as evidence of an idiosyncrasy on the part of the mother. It was thought that her milk was of unsuitable composition, or capable in some way of exercising directly a prejudicial effect upon a normal infant. To-day we know that the milk of every woman, not herself the subject of an infective disorder, is equally suitable for the normal infant, and that the composition as well as the amount of the milk is controlled to suit his needs by the varying stimulus of suction. If the milk of one woman causes digestive disturbances, the change to the milk of another is seldom of any avail. The same woman may suckle three or four infants, only one of whom is dyspeptic and fails to thrive. Although one infant may do very badly on the breast, the same breast may yet be safely used for other normal children. Of the three great groups into which infantile dyspepsia is divided, dyspepsia *ex alimentatione*, dyspepsia *ex infectione*, and dyspepsia *ex constitutione*, the last is not only of the greatest interest, it is perhaps also of the greatest frequency. No classification of infantile dyspepsia can be complete which ignores those fundamental distinctions between individual infants. That the same diet may produce a healthy infant in one case, and in another lead steadily to severe illness and even death, forces us to attempt the study of infantile diathesis. It is right that we should have clearly in mind the results of under-feeding (*Inanition*), of over-feeding, and a temporary loss of tolerance for all or some of the constituents of the food (*Dyspepsia*), of a similar but permanent loss of tolerance (*Marasmus*), and of the symptoms of the absorption into the blood stream of certain disintegration products of abnormal

digestion (*Intoxication*). At the same time we should endeavour to appreciate the usual result of imparting to the diet a one-sided character, so that either fat or carbohydrate is present in gross excess, and we should be able to distinguish between a primary digestive disturbance and a disturbance secondary to infection, whether of the bowel wall (*enteral*), or in other parts of the body (*parenteral*).

But we must also be prepared to recognize as a sufficient cause for disturbance the existence of certain constitutional abnormalities, the "exudative diathesis" of Czerny, for example, or extreme neuropathy. The study of the disorders of infancy must concede due prominence to the consideration of the child. The subject is not exhausted by an examination of a variety of diets, by enumerating rules for dilution and dosage, and by insisting on the necessity for cleanliness. If infants could always be fed by rule of thumb, if the whole matter could be dealt with in a few pages of general directions, infant feeding might be left as at present almost outside the medical curriculum, and be regarded as of greater interest to nurses than to medical men.

As knowledge increases it becomes more and more clearly recognized that dyspepsia in infancy is not always, or even usually, accounted for by gross excess in the amount of the diet or gross faults in its composition. It becomes more and more apparent that it is wrong to approach the study of the disorders of infantile digestion in the belief that the child is the constant and unvarying factor, and in the hope that we shall one day find a universal artificial diet applicable under all conditions and to all infants

In spite of the confident statements of those who claim unvarying success with some particular method of feeding —whole milk, for example, or the so-called "humanized" milk—the digestive powers of individual infants are very various. We shall often find it our lot to study the abnormal reactions of particular children to food which may be said to be of perfectly suitable composition, and upon which in our own experience large numbers of infants of similar age have shown uniform and steady progress.

In the study of infantile disorders it is helpful to group together in our minds certain symptoms, certain peculiarities of aspect, certain tendencies and liabilities to particular disturbances, which experience teaches us are apt to occur in infants of a certain type and of a certain inheritance. The frequency with which these groups of symptoms occur in the same individual, either simultaneously or successively, at different times in the course of growth and development encourages the belief that they are only various expressions of an underlying constitutional idiosyncrasy.

The Exudative Diathesis of Czerny.

We owe to Czerny a clear statement of the clinical symptoms of a particular diathesis which is so common that its manifestations in greater or less degree are met with every day in practice and are familiar to all.

In the older medicine a group of symptoms, constantly recurring and of great frequency, was described under the name of "scrofula." Children who showed the scrofulous diathesis were characterized by a certain physical aspect—harsh, dry skin, with a pronounced tendency to certain scaly and lichenoid eruptions, fine silky hair, which grew irregularly beyond the true hairy scalp on to the forehead and over the zygomatic arch, long eyelashes, and a tendency to a further hairy growth on the back of the neck and between the scapulae; chronic catarrhs in various situations were almost constant—nasal catarrh, with a profuse secretion which irritated and infiltrated the upper lip, nasopharyngeal catarrh, bronchial catarrh, phlyctenular conjunctivitis, leucorrhoea, and mucous diarrhoea. As a result of the chronic irritation of the mucous membranes, a secondary glandular enlargement was the rule. Tonsillar overgrowth, adenoid vegetations, hypertrophy of the lymphatic glands and of the lymphoid tissue generally of the whole body were commonly found.

With the discovery of the true nature of the tuberculous infection it became recognized that a large number of scrofulous children were infected with tubercle. In many the enlarged glands became definitely caseous; in others the catarrhal and inflammatory symptoms were combined with diseases of bone clearly of a tuberculous nature or with tuberculides of the skin.

Nevertheless, after the separation of those individuals in whom a tuberculous infection had declared itself, there are still left a very large number of children who would unhesitatingly have been described in former times as of a scrofulous or strumous diathesis. Those children who show the catarrhal and lymphatic changes of the old-time scrofula without evidence of tubercle, have been studied under many names. Virchow borrowed from Thomas White* (1784) the name "inflammatory diathesis"; Henbner, Escherich and others speak of "lymphatismus" and the "lymphatic constitution"; French authors write of "arthritismus" and "neuro-arthritismus," the English authors of "mucous disease" and "status lymphaticus." Czerny, who has traced the diathesis backwards to earliest infancy, where it forms one of the commonest causes of digestive disturbance, impressed by the frequency with which exudative processes occur upon the skin and mucous membrane, has given it the name of the "exudative diathesis." He has emphasized especially that the increased vulnerability of skin and mucous membranes is primary, the lymphatic enlargement secondary.

Symptoms of the Exudative Diathesis in Later Childhood.

The manifestations of the diathesis in infancy are those with which we are immediately concerned. The developments later in childhood and in adult life, though not dissimilar in nature, are more varied in type and must first be described. The subjects of the diathesis are marked by a characteristic appearance (see plate). The child's face is usually plump and rounded and marked by a high colour on the cheeks and on the front of the chin. In these situations a dry, scaly eczema is usual. Seborrhoea of the scalp is common. The hair is often sparse, but growing in wavy curls rather than straight. The frequent catarrhs of nose and pharynx are accompanied by tonsillar and pharyngeal overgrowth and by enlargement of the cervical glands. Otitis media is common and the children are often in consequence deaf. The so-called "geographical tongue" is frequently seen. Bronchial catarrhs and asthma-like attacks are frequent. In some cases the symptoms in childhood persist and a permanent asthmatic tendency may be established. In such cases a history of asthma in the parents or among relatives is frequently obtained. Many asthmatics will be found to have suffered in infancy and childhood from seborrhoea of face and scalp.

In some cases the intestinal mucous membrane shares in the general tendency to catarrhal and exudative inflammation, with the production of chronic enteritis and secondary overgrowth of the intestinal lymphatic tissue. This condition is well described by English authors (Eustace Smith, Gee, etc.) under the name of "mucous disease" or "coeliac disease." In general, restlessness, irritability, and nervousness are marked symptoms, and a violent and passionate fit of crying will often make the examination of a young child difficult.

A further group of symptoms has a close association with the phenomena of anaphylaxis, urticaria, sometimes giant urticaria, transitory oedema or exudation into joints, as well as spasmodic asthma. In other cases difficulties in the digestion and metabolism of fat stand in the foreground. The "cyclical" vomiting of childhood is frequently accompanied by evidence which marks the child out as of this particular diathesis.

Perhaps the most characteristic of all the symptoms is seen in the profound constitutional disturbance which is apt to accompany those apparently slight catarrhs to which, at longer or shorter intervals, the child is usually liable. In some children hardly a week passes during which they do not sicken of an acute feverish attack. At nightfall the temperature may be 104° or 105° F., and the child may present all the appearance of serious disease; and yet the morning finds every symptom gone. If, on the other hand, the infection is more sustained, weeks of high fever may elapse, yet repeated and careful physical examination does not disclose any physical signs of disease. In the severer degrees of the condition numerous

* *A Treatise on Scrofula, commonly called the King's Evil.* By Thomas White, Surgeon to the London Dispensary; 1784.

infections are fatal which would have caused but slight disturbance in a normal child. Pneumonia has a higher mortality; a trivial laryngitis may lead directly to death; in an acute attack of diarrhoea drowsiness may gradually deepen into coma, until death ensues; sometimes sudden heart failure, from fear or other emotion, the subcutaneous injection of antidiphtheritic serum, anaesthesia, or other trivial causes, may seem to be the direct cause of death. Acute infections may cause death with great rapidity, and very early in the course of the disease. A few weeks ago I performed an autopsy on a girl 17 years of age who had fallen down dead in one of the streets of the City. She had not complained of feeling ill. Marked hyperplasia of the thymus and thyroid glands and of all the lymphatic glands of the body was at once apparent. Naked-eye examination discovered no other cause for death, yet careful histological examination by Dr. Johnson showed a very early miliary tuberculosis of the lung. Lastly—as the French authors especially have insisted—arthritis, chorea, endocarditis, and other rheumatic manifestations are most commonly and most typically seen in children who exhibit marked signs of the diathesis.

The symptoms so described embrace a very large number of disorders, not usually regarded as akin. The hypothesis that all are dependent upon an underlying diathesis is founded only upon the observation that groups of such symptoms tend to occur in the same individual. As a rule, in any one individual a particular group of symptoms recurs again and again. In other cases the type of the manifestations changes at different stages in the development of the child. In one child the tendency to pyrexial attacks, nasal or naso-pharyngeal catarrhs, otitis media, tonsillar and adenoid hypertrophy, and enlargement of the cervical glands is most marked. In another digestive disturbances and the antipathy to a diet rich in fat is prominent. In a third urticaria and bronchial catarrh, or true spasmodic asthma, predominates; in a fourth seborrhoea or eczema of skin and scalp. The diathesis is hereditary. Often it occurs in all members of a family, and it will then usually be found that one or other parent has suffered severely in youth in the same way.

The therapeutic measures by which we may hope to control the manifestations of the diathesis are both local and general. In the latter group are a number of well-ascertained dietetic and hygienic regulations.

For my present purpose the chief interest lies in the extension by Czerny and others of the recognition of the diathesis back to the earliest days of life, and the emphasis more recently laid on the part which it plays in the production of digestive disturbances both on breast and on bottle.

Symptoms of the Exudative Diathesis in Infancy.

In early infancy the most common way in which the inheritance shows itself is the complete or relative failure of breast-feeding. The children often show none of the strength, vigour, and firmness of the normal breast-fed baby. From the first they may be meagre, small, and complaining, and persistently dyspeptic. The mother's breasts may be well formed and full of milk, and yet for weeks and even months no improvement takes place. Dyspepsia, with the passage of green stools and vomiting is frequent, and in a breast-fed child should always suggest the existence of this diathesis. In other cases, however, a different picture presents itself. The infant achieves a rapid rise in weight, yet the more rapid the growth the more marked do the other symptoms of the exudative diathesis become. Finkelstein especially has emphasized the tendency for infants who show the diathesis to belong to one or other of these two types—the thin and wasted type, or the fat, pasty and eczematous type.

Cutaneous Symptoms.—Seborrhoea of the scalp is extremely common in the form of a dirty greyish-brown fatty secretion appearing irregularly upon the hairy scalp, which resists all the mother's attempts to remove it. This symptom appears in breast-fed infants suffering from dyspepsia with very great frequency.

A dry eczema of the cheeks and chin is common, especially in thin infants. The skin in these situations is reddened, dry, scaly and rough. In the fat and pasty type an acute irritating eczema is more frequent.

Urticaria papulata is often seen. The minute papules are scattered on the scalp, body, and extremities, but not on the face. They are often present on the soles of the feet. Each crop tends to last two or three days.

Intertrigo occurs readily, in spite of the greatest cleanliness, in the groin and axilla, in the genital folds, or behind the ear.

Symptoms in the Mucous Membranes.—The same vulnerability which appeared in the skin shows itself in the mucous membranes. Naso-pharyngeal catarrh, with accumulation of secretion in the posterior nares and pharyngeal wall, and slight enlargement of the cervical glands, is common. Because the infant lies constantly on his back the anterior nares often remain free from secretion, so that the appearance does not suggest nasal catarrh. The interference with nasal breathing is so great that suckling is rendered difficult. Often this obstruction is the direct cause of weaning, a course to which the mother is inclined because of the coincident dyspepsia. The catarrh often sets in with high fever, loss of appetite, diarrhoea and vomiting, and prostration: a diagnosis of bronchopneumonia is often wrongly made. Examination of the naso-pharynx and the cervical glands makes the diagnosis clear. Laryngitis, bronchitis, and otitis media are frequent complications. The lingua geographica, conjunctivitis, eczematous or phlyctenular, and circular caries of the teeth are seen in later infancy. The mucous membrane of the intestine is also affected. In earliest infancy constipation or dyspeptic green stools are common symptoms. Later follicular colitis, mucous diarrhoea, and threadworms are frequent.

Symptoms of Overgrowth of Lymphoid Tissue. — The spleen, thymus, tonsils, lymphatic glands, and intestinal follicles all show a tendency to an enlargement, which is probably secondary to the chronic irritation in the areas which they drain.

Treatment.—The symptoms of the diathesis are encouraged or controlled largely by the composition of the diet. Especially marked, as a rule, is the ill effect of a fat rich diet, such as cow's milk. Even the breast milk may disagree for this reason. Limitation of the amount of milk and the early substitution in part of carbohydrate food is usually the most successful line of treatment. Without dietetic regulations the local treatment of the various manifestations, the repeated catarrhs, or the lymphoid overgrowth—as, for example, the adenoid enlargement—is often without avail. Over-feeding is especially harmful, and the food should be reduced so that it just covers the physiological needs. As might be expected, the subjects of the diathesis are apt to show a very violent reaction to all infections in which catarrhs are common. Measles and whooping-cough may endanger life.

Illustrative Cases.—The diathesis so described is of such common occurrence that numerous cases might be quoted from among the patients seen upon a single day in the out-patient department of a large hospital. The following case illustrates the association of infantile dyspepsia, seborrhoea, adenoid overgrowth, and asthma.

CASE I.

An infant, 3 months old, suffering from severe seborrhoea of the scalp, was brought to me on December 3rd, 1911. Although nursed on the breast he had suffered severely from dyspepsia almost from the first. At 5 weeks old he had been weaned. He was always sick when cow's milk even in considerable dilution was given. He had had much less dyspepsia upon sweetened condensed milk. The seborrhoea had appeared at 3 weeks. The scalp when seen was completely covered with masses of secretion.

A fat-low carbohydrate-rich diet was ordered, and recovery followed in about six weeks' time. On April 20th, 1914, he was again brought to me. I was told that he was well except for a tendency to suffer from slight scaly eczema of the cheeks and chin, repeated nasal catarrhs, and severe spasmodic attacks of dyspnoea. Two maternal aunts suffered from asthma. He had some tonsillar enlargement and a mass of adenoid vegetations.

Dietetic rules were given. He had been taking large amounts of cow's milk, and a diet predominatingly vegetable and cereal was recommended. The adenoids may have to be removed later. The association between them and the asthma cannot, however, be regarded as cause and effect.

CASE II.

A girl aged 8 was brought to the hospital for growing pains. She had been weaned for failure to thrive at three months although the mother had plenty of milk. She walked and cut her teeth somewhat late. In her third, fifth, and sixth year

she was admitted to hospital for bronchopneumonia, but recovery was always rapid, and pyrexia short-lived. The mother thought that the attacks did not differ from many others which the child had had, and which she had almost grown to neglect. They set in suddenly with burning heat, flush, and dyspnoea. At such times the glands in the neck always enlarged. (In another case with similar history the mother told me that a diagnosis of mumps had been made in the hospital surgery on four separate occasions, and on each she had attempted to obey instructions and carry out isolation of the child.) At 2 years old she had had eczema of the scalp. She had then been fat, but had got thin later. On examination she was seen to be a small child, with sparse, wavy, curly, reddish hair, and dark eyelashes. Fine downy hair grew low down on the forehead, beyond the true hairy scalp and over the cheeks almost like a whisker. There was marked enlargement of tonsils and adenoid overgrowth. The nostrils were pinched and atrophied. The cervical glands were large and palpable, the axillary and inguinal glands smaller, but easily palpable and visible under the thin skin. The face was reddened with rough, dry skin on the cheeks. The tongue showed the condition lingua geographica. The chest was narrow, with little subcutaneous fat. The skin was very white over the chest, and changed to a deeply pigmented colour over the distended abdomen. She complained of abdominal pain at intervals, often had diarrhoea and blood-stained stools. There had been frequent prolapse of the rectum. At one time thread-worms had been seen. Lately she had complained much of joint pains, and a diagnosis of acute rheumatism had been made.

Case III.

The portrait of C. E., aged 5, is selected to show the sparse hair with indeterminate anterior margin, dry eczema of cheeks and scalp, adenoid overgrowth, and enlarged pigmented abdomen. She was brought to the hospital for repeated attacks of diarrhoea and abdominal pain. She had been weaned at 3 months, and had never thrived on the breast, although the attempt had been persisted in. The cervical, inguinal, and axillary glands were palpable. She was subject to repeated pyrexial attacks of short duration, during which she vomited, became drowsy and listless, and felt "burning hot."

Case IV.

A male infant, aged 3 months, admitted to Guy's Hospital under my care. In the surgery the temperature was 105°, and there was marked dyspnoea. Examination showed that the lungs were free from physical signs. The cervical glands were enlarged, and the fauces and pharyngeal wall were reddened and inflamed. The temperature remained high for two days, when recovery took place rapidly. The child had suffered continuously since birth from dyspepsia, and the weight—7 lb.—was less than at birth. Weaning had taken place at 6 weeks, and the diet had since consisted of equal parts of cow's milk and water, with added cane sugar. There was a slight roughness of the skin of the cheeks and forehead. Upon a diet of citrated whole milk the weight rose rapidly, but as the child grew fat the eczema became acute, and spread actively over the cheeks. After four weeks the diet was changed to sweetened condensed milk, when the eczema immediately improved, and the face became quite clear. On three occasions there have been acute paroxysmal attacks of dyspnoea, without pyrexia, which suggest the presence of asthma.

Such cases might be multiplied indefinitely. Czerny has called the disorder the commonest ailment of childhood. I am well aware of the danger of laying too great stress upon such hypothetical conceptions as that of a diathesis the true nature of which is still a subject for speculation, or of allowing explanation by assumed causes to take the place of inquiry into anatomical and clinical facts. I believe, however, that in ignoring this aspect of disease altogether, and in concentrating all attention upon the local phenomena, we commit a serious error. In the large new textbook of children's disease, edited by Batten, Garrod, and Thursfield, I find little mention of the question of diathesis at all, although perhaps no subject has been dealt with so minutely in the recent literature of diseases in children or debated so earnestly at meetings of societies and congresses on the Continent. Speaking of the spasmophilic diathesis, so good an observer as Dr. Leonard Guthrie dismisses the conception somewhat contemptuously as savouring of an extinct medicine.

Neuropathy in Infancy.

A second type of infantile diathesis which is worthy of close study, and which is also the direct cause of much infantile dyspepsia, both in breast-feeding and in artificial feeding, is found in severe neuropathy in infancy. The neuropathic inheritance may show itself from the earliest days of life in an altogether abnormal restlessness and sensitiveness to external stimuli. The neurotic infant is usually meagre and spare. The limbs often show a considerable degree of hypertonus. The abdomen tends to be strongly contracted, so that the recti muscles stand out prominently. Such children sleep badly from the first. When the healthy child sleeps he can be moved from his cot without awakening, and ordinary conversation in the room in which he lies has no power to disturb him. The neuropathic infant sleeps only to wake at the slightest sound. If any one approaches his cot, with a start he is wide awake again. No doubt, when mother as well as child are of neurotic temperament, the condition of the child is aggravated by the atmosphere of his surroundings. His will and his temper suffer no opposition. If food, for example, is given to him on a single occasion to quiet his midnight cry, there is no rest for his mother for many subsequent nights. More than other children, the neuropathic child, in the natural desire of mother and nurse to quiet him, suffers the risk of overfeeding, just as more than other children he tends to receive excessive psychical stimulation. Of all infants, he is in most need of rest; yet, in the hope of coaxing him to quietness, mother and nurse exhaust themselves and him in devising new psychical stimuli. The constant appeal to his senses produces a precocious mental development, but it aggravates the nervous instability and exhaustion. Finally, he can hardly be left alone for a moment, so accustomed has he become to the efforts of those who minister to his sensations. A little tyrant in the house, he may only rest on his daily excursions abroad, when at last he may lie still looking at the clouds, the traffic, or the trees.

Among such infants with a strong neuropathic inheritance dyspepsia is very frequent, even apart from the likelihood that their fretfulness and clamour will lead to overfeeding. In a few cases vomiting may be so marked that all food for a time seems to act as a veritable emetic. In other cases oesophageal or pyloric spasm develops, and it is almost exclusively in infants of this type that we find the development of hypertrophic pyloric stenosis.

Conclusion.

Many other examples of congenital inborn abnormality of constitution might be quoted, but enough has been said to make clear the contention that the problems of infantile dietetic disorders require for their solution all the trained faculties of medical men, and that a close supervision of the amount, composition, and quality of the diet will not avail in a great number of cases to detect the cause or ensure recovery. In infantile disorders, as elsewhere in curative and preventive medicine, the help given by trained, competent, and intelligent nurses and voluntary workers can only be subsidiary to the work of experienced medical men. At the present time, because of the relatively small number of medical men who are interested in the subject or who study it in a rational and broad-minded way, there is some tendency for their place to be usurped by lay workers, who are perhaps more interested but whose lack of training renders them unable to appreciate the complex nature of the problems concerned. The scientific study of the ailments of very young infants is of supreme importance to the State. Progress in this country of the control of infant mortality is hindered not by the apathy of the public or the State, but by the comparative neglect of the profession. To that extent the criticism of Professor Holt is true.

An International Congress on School Hygiene will be held in Brussels in 1915. The following subjects are proposed for discussion: The school building and its equipment; medical inspection in urban and rural schools; the prevention of contagious diseases in school; the teaching of hygiene to teachers, scholars, and parents; school hygiene in its relation to physical education at the different ages of the children; teaching methods, syllabuses, and school equipment in relation to hygiene; school hygiene in its relation to exceptional children; school hygiene with regard to adolescents. The Congress will be held under the patronage of H.M. Albert, King of the Belgians, and under the auspices of the Belgian National Institute of Paedology and of the Belgian Paedo-technical Society. M. J. Cerman, Director-General of Primary Studies at the Department of Science and Art, and Dr. J. Demoor, Rector of the University of Brussels, are Presidents of the Organizing Committee. All communications and inquiries should be addressed to Dr. H. Rulot, secretary-general, 66, rue des Rentiers' Brussels.

FIG. 1.

FIG. 2.

FIG. 1.—Case III of series. Showing disposition of erythematous lesions. Desquamation resulted, as shown in the photograph.

FIG. 2.—Case II of series. Showing disposition of erythematous lesions. The swelling of the affected buttock is well shown in the photograph.

FIG. 3.—Case IV of series. Showing effect of peripheral neuritis, resulting in foot-drop with atrophy of the affected muscles.

CARBON MONOXIDE POISONING IN THE SENGHENYDD EXPLOSION.

[WITH SPECIAL PLATE.]

BY IVOR J. DAVIES, M.D., B.S., M.R.C.P.LOND.,
HONORARY ASSISTANT PHYSICIAN, KING EDWARD HOSPITAL, CARDIFF.

THE Senghenydd explosion happened about 8.10 a.m. on October 14th, 1913, and is the worst disaster in the history of British mining. The number of men killed was 440. The whole of the men working on the eastern side of the mine were brought up safely, almost immediately after the explosion occurred; 18 men only were rescued from the western side, after an exposure to the noxious fumes for twenty hours, and survived. Five died from the effects of burns and injuries sustained whilst following their occupation in close proximity to the shaft, and one man lost his life on the day following the explosion whilst assisting in work at the fire which was raging in the west main level, being killed by a fall of stone. The whole of the remaining men working on the west side were asphyxiated by carbon monoxide gas, many were also burnt and sustained multiple injuries, either as a direct consequence of the explosive blast or from being buried under falls of roof.

AN ACCOUNT OF THE RESCUE OF EIGHTEEN MEN FROM THE BOTTANIC DISTRICT OF THE SENGHENYDD MINE.

The rescue party consisted of representatives from the various colliery companies, the Miners' Federation, the Home Office, and a few of the Senghenydd Colliery officials, with the Rhymney Valley Rescue Brigade in charge of Superintendent Ritto, together with Dr. Dan Thomas, of Bargoed.

The circumstances under which rescue operations into the Bottanic District were rendered possible will be fully explained in a later paragraph. The party entered the No. 1 North Road from the east side of the pit, taking fresh air with them, and found but slight evidences of force and fire along this road.

Four bodies were passed; one, a man of exceptionally fine physique, was found in the middle of the road lying on his back with his hands clasped behind the head, indicating that he assumed a position of repose when first affected by the fumes of afterdamp. There were superficial burns upon the face and hands, and well-marked signs of carbon monoxide poisoning were present. The noxious fumes in this instance must have produced a narcotic effect, for the position was one of ease, and must have been assumed before consciousness was lost.

Two other bodies were found close by, lying in a semi-prone position against a box, and leaning against each other; these also showed typical signs of asphyxia from carbon monoxide. It is interesting to note that a live horse was found on the road.

The narrow entrance to the Bottanic District was now reached, and a dead haulier was found lying doubled up over the back of a tram with his head inwards. There was an extensive scalp wound over the back of the head, and death was due to carbon monoxide poisoning. The position of the body and wound on the head suggest that he was hurled backwards against the side, struck his head, and fell forwards into the tram, and was asphyxiated whilst lying stunned in this position. A little further in, close to the mouth of the narrow airway, was the body of the district fireman, lying in a semi-reclining position with the legs crossed, and head resting on the left hand; the body showed no marks of violence nor of burning, and presented well-marked signs of poisoning by carbon monoxide. The man's lamp was found some yards nearer the pit bottom, in the middle of the road, indicating that after leaving his district, and finding the air insupportable in the No. 1 North Road, he attempted to get back to inform his men, and, when affected by the fumes, dropped his lamp, and tried to crawl back. As will be described later, one of the earliest signs of poisoning by carbon monoxide is that anything carried becomes too heavy, and has to be dropped. The state of this body proves conclusively that comparatively little force entered the district, and also points to the complete absence of fire. The importance of these observations will be fully understood later in connexion with the description of the erythematous lesions found on the bodies of the survivors.

The narrow airway was now reached, and the party proceeded in single file, but it was agreed that a line of communications should be kept from a fixed base, where some of the rescue men remained with their apparatus. The working places were now thoroughly explored in turn, and most of the survivors were found along the main road. The air was fresh up to this point.

Rescue brigades from Porth and Crumlin, in charge of Superintendents Thorne and Wimborne respectively, also rendered valuable assistance in the treatment and transport of the survivors.

The following cases are illustrative of the series of 18, a clinical abstract of which is given below.

CASE I.

(22) He first experienced a sensation of choking, which he attributed to smoke which entered the district, and says that ten minutes later his legs gave way and he lost the use of his feet, and was obliged to crawl on his knees to reach the main road, but before getting there "he felt his head going," and became unconscious, and recollects nothing further until the evening of the following day, after admission to the temporary hospital. When rescued his condition was as follows: Unconscious, foaming at the mouth and nostrils, lying in a reclining position, with his back against the coal face and head dropped forwards. Respiration was greatly laboured and frequent; the pulse was feeble, frequent, and irregular, and there was evidence that he had vomited. The condition of the man was extremely grave, but he gradually revived by the treatment, which will be fully described in another paragraph. He again collapsed into a similar state after being brought to the surface and carried to the temporary hospital, which had been prepared and equipped at short notice for the reception of the survivors under my care.

This patient was almost *in extremis* for twenty-four hours, and his condition constantly varied from that already described to periods of improvement which were only transient. He was conscious at times, but again, as in the case of the pulse and respiration, the state of consciousness varied a good deal, and with the remissions he would doze and become quieter. Throughout the forty-eight hours following the rescue his condition was very critical, and both cardiac and respiratory failure occurred almost hourly. His temperature varied from 99° to 100°.

Owing to marked restlessness his position in bed had to be continually changed. He expectorated frequently an abundant frothy blood-stained material, and there were numerous râles present, indicating acute oedema of the lungs. There was retention of urine, which was drawn off some hours after he was brought into hospital. The urine was dark in colour but contained no blood pigment, but unfortunately a sample was not kept for further examination. The urine afterwards was normal. Oxygen was administered regularly every hour, and at intervals the lower ribs were forcibly compressed bimanually according to the Howard method of artificial respiration. He responded well to stimulation with strychnine and digitalin hypodermically, the former in doses of $\frac{1}{30}$ grain hourly for twelve hours, and with each alternate dose digitalin gr. $\frac{1}{100}$ was combined. The same dose of strychnine was repeated at times when cardiac failure threatened to supervene.

His condition improved in the course of twenty-four hours, but on the following day he relapsed, the temperature became raised and respirations increased, and physical signs of pneumonia appeared. For several weeks afterwards there was irregular pyrexia, varying from 99° to 101°, and the physical signs were those of bronchopneumonia, successive portions of the lungs becoming involved in turn. He ultimately got quite well, but the areas of skin affected by erythema remained anaesthetic for several months, and sensation is still somewhat impaired in those situations.

Erythematous Lesions.—Over the left lower ribs posteriorly were two areas of acute erythema, almost contiguous, one circular and the other oval in shape, involving an area of skin several square inches in extent. These were acutely painful and tender. These areas of erythema were raised and of a cherry-red colour, the hair follicles standing out prominently, as is well shown in the photograph. Complete anaesthesia was present over these areas, and hyperaesthesia as already noted. The colour gradually faded, but was evident for several weeks, and some desquamation resulted, but anaesthesia persisted for months.

CASE II.

J. J. (19), brother to the foregoing. His first symptoms were consequent upon the smoke coming into his working place, and he felt "choked" and giddy, and some minutes later a feeling of weakness came over him, which was felt in the feet, and a sensation as if something was lifting the hair of the scalp. He says that he has no recollection of anything further until the fourth day after the explosion, when he realized what had happened. He was found some distance from his working place, and close to the main haulage road.

He was unconscious and lying in a semi-recumbent position

against the side of the road. He was badly affected by the fumes of after-damp, but to a lesser extent than his brother.

He was revived and conveyed to the temporary hospital, where his condition was found to be as follows: Semi-conscious and extremely restless and irritable, his mental state closely resembling that of cerebral irritation. He constantly shifted from one position to another, but this was partly due to extensive erythematous lesions, which made lying in almost any position uncomfortable.

The erythematous lesions were confined to his back in the following situations:

1. An almost quadrilateral patch of acute erythema in the left infrascapular region and involving an area of skin of about 2 in. in extent.
2. Another on the left buttock triangular in shape with its base over the tuberosity of ischium, and sides extending upwards and forwards to the iliac crest, as shown in the accompanying photograph.
3. Smaller patches in the right infrascapular and lower dorsal regions.

The whole of these erythematous areas possessed characters similar to those already described, and these lesions were evidently very painful, for he groaned repeatedly, and on examination exquisite tenderness was elicited, particularly over the affected buttock.

These areas of skin remained congested for several weeks and anaesthetic for several months.

His general condition is now good, but he still suffers from neurasthenia.

CASE IV.

T. M., aged 18. He was working on the face of the coal at the time, close to the airway, with his father and two brothers, who were afterwards found dead. He accompanied the others in their endeavour to escape along the return road, and remembers distinctly that his father and two brothers were with him when the double parting was reached on the way back. All were now feeling the effects of the after-damp and fell. He attributes the onset of symptoms to the exertion of walking quickly uphill along the incline road, for three-quarters of an hour had now elapsed from the time of the explosion.

When rescued he was seen to be badly affected, and more in a state of collapse than asphyxia. He was revived with difficulty, and conveyed to hospital, where he recovered sufficiently some hours later to be conveyed home. He has no recollection of the rescue party coming to his aid, and only vaguely remembers being conveyed and detained in hospital.

His condition was as follows: There was some degree of collapse, but this had greatly improved on reaching fresh air.

Peripheral Neuritis.—This involved the dorsiflexors of the right foot, giving rise to foot-drop as shown in the photograph. There was also some pain, swelling, and redness of the foot and leg for several days. Anaesthesia of the lower third of the outer side of the right leg and of the whole of the foot and heel was present. This afterwards cleared up upon the sole, but anaesthesia still persists in the other situations, and paralysis remains almost unaltered. Some slight improvement has resulted from massage and electrical treatment of the affected muscles. There is paresis and atrophy of the whole of the right lower limb; the calf measures 2 in. less and the thigh 1 in. less respectively than the corresponding parts of the sound side. Complete reaction of degeneration is present in all the muscles of the right leg, except the gastrocnemius, which gives a partial R.D. The thigh muscles react normally. Loss of tactile sense and anaesthesia persist on the lower half of the outer aspect of the leg, the inner side of the dorsum of the foot in a line with the great toe, and also on the ball of the foot. The foot is usually cold and red, and there is also some vasomotor instability elsewhere. He has complained at times of pain along the sciatic nerve as far as the knee, and occasional shooting pains in the foot and ankle. The knee-jerks are exaggerated, but the plantar response is flexor in type.

Erythematous Lesions.—(1) A well-defined area of acute erythema, quadrilateral in shape, on the right buttock, 5 in. long by 3 in. wide, and extending almost transversely from the tuberosity of the ischium to the great trochanter. The characters were identical with those described in previous cases, and in his case the lesion closely resembled an extensive wheal produced by local injury and attended by considerable pain, swelling, and induration of the part. (2) There was also an oval patch of acute erythema over the right lower ribs in the anterior axillary line. (3) There was another small patch of erythema above the external malleolus.

These lesions progressed in the same manner as in the cases already described.

CLINICAL ABSTRACT OF THE SERIES.

Symptomatology.

General.—Languor, weakness, and an almost irresistible desire to lie down.

Cerebral.—Drowsiness, mental confusion, giddiness, headache (in one case only).

Muscular weakness of the legs was complained of by all, and was in most instances the earliest symptom felt, particularly in the knees. Probably this was but a part of a general asthenia, which first manifested itself in the legs, and was brought out by exertion. In one case the patient says that his head became too heavy for his body, and he was obliged to lie down.

Cardiac symptoms were not complained of in the early stages of poisoning, although subsequently several were in a state of collapse from cardiac enfeeblement.

Respiratory.—Cough was present in some of the cases, but this was probably due to smoke. One complained of a feeling of constriction in the chest, another of suffocation.

Physical Signs.

General.—Some but slightly affected, others suffered from various degrees of collapse.

Cerebral.—Stupor, restlessness, irritability, depression, coma.

Cardiac.—Marked enfeeblement of cardiac action in many and repeated attacks of cardiac failure in one case. The occurrences of remissions and relapses so frequently in this case, made the question of prognosis very difficult. His case (No. 1) was considered as hopeless by most of the medical men present, but he responded well to timely stimulation and inhalation of oxygen, which was given almost continually. The condition and progress of this case have convinced the writer that no case of carbon monoxide poisoning should be regarded as hopeless, for he was almost *in extremis* when brought out of the mine, and after some improvement following the restorative measures applied at the time of rescue, he again collapsed on reaching fresh air and during transport to the temporary hospital a quarter of a mile or so distant from the colliery.

Respiratory.—Acute oedema of the lungs occurred in one case (No. 1). There were three cases of bronchitis and two cases of bronchopneumonia. One of these (No. 1) was prolonged, and attended by considerable constitutional disturbance, whilst the other (No. 3) was of short duration. In both cases the course was subacute for the major part of the illness.

Nervous System.

Ataxy occurred in several patients antecedent to loss of consciousness.

Peripheral neuritis occurred in five cases. In four cases paralysis in the distribution of the external popliteal nerve resulted in foot-drop, and anaesthesia in the area supplied by this nerve. The lesion was on the right side in all, but in one (No. 5) foot-drop was also present on the left side, but cleared up quickly. There was some paresis of the dorsiflexors of the feet in several, but of short duration. In one case (No. 7) the extensor muscles of the forearm were affected, resulting in wrist-drop, but this was also of short duration. The hand on this side was also in a condition of acute erythema with vesiculation, with absolute anaesthesia. This has now resulted in an atrophic condition of the whole hand with ankylosis of the carpometacarpal joint of the thumb in a position of adduction, some atrophy of the thenar eminence and first dorsal interosseous muscle, and the fingers are cold, glossy, and tender. There is anaesthesia of the ball of the thumb and of the four fingers, and also incurving and furrowing of the nails. There is loss of movement in the thumb and index finger. The lesion in this case must have involved many of the terminal twigs of the ulnar and median nerves. The ordinary methods of treatment for cases of peripheral neuritis were adopted.

CUTANEOUS LESIONS.

Acute erythema occurred in nine of the cases. In one case (No. 7) oedema, vesicles, and bullae were associated with the erythema. In several oedema of the part was present, with erythema. In five erythema affected the right buttock only. In three erythema affected the left buttock. In one both buttocks were affected. In several of these cases other parts were also involved. In only one case did the buttock escape.

In seven cases erythema affected the skin over the scapula or immediately below its lower angle, and most commonly over the spine and vertebral borders. In six cases erythematous lesions involved the skin of the chest wall, and in five of these on its posterior aspect inferiorly, whilst in one instance the skin over the pectoral muscles was involved and in another a large area on the front of the thigh was affected. In two cases the skin above the malleoli was affected. In three of the cases a patch of skin below the head of the fibula was affected, and in two paralysis of the dorsiflexors of the foot on that side was associated.

Thus the lesions most commonly involved the buttock, and generally the skin over the tuberosity of the ischium was affected. In other situations the skin over bony prominences was most commonly affected.

Thus pressure must have played a part in the determination of the site of these areas of acute erythema, for most of the survivors were found in a sitting or reclining position. However, the occurrence of acute erythema in situations other than over bony points indicates that pressure was not the cause of these lesions, and the presence of hyperaesthesia with anaesthesia, too, affords strong evidence of the existence of some other factor in the causation of the cutaneous lesions.

Characters.

The patches were raised and of a brilliant cherry red colour, and the hair follicles stood out prominently, and the erythematous condition was attended with considerable pain, which made lying on the affected part impossible.

The affected areas were hot to the touch and very tender, and faded a little on pressure, but, owing to extreme tenderness, only slight pressure could be applied without causing much discomfort. Absolute anaesthesia was present to painful impression. This was strictly confined to these areas for the most part, but in some instances it extended a short distance beyond, but not more than to the extent of an inch in a single instance, in others it was less than this.

Progress.

The colour gradually faded over a period of several weeks, and it did not go through the stages of a bruise. In two cases the areas of erythema are still evident, and the colour can be restored to some extent by rubbing the part. In one case, when this is done, the patch becomes red, and the margins are of a purplish colour.

Many show generalized vasomotor instability, and in some factitious urticaria or dermographism can easily be elicited. In one (No. 7) there is passive congestion of the fingers, which are generally cold. In some desquamation and crusting resulted.

In one (No. 7) definite scarring has taken place, and this involves the subjacent muscles of the thumb. Probably septic infection was responsible for this result. In two others probably scarring will ensue. There is evidence of atrophy in two cases, for the area of skin previously occupied by acute erythema is now depressed below the surrounding parts. In one (No. 7) the acutely erythematous condition of the fingers has been definitely succeeded by atrophic changes as already described.

Hyperaesthesia lasted for several weeks. Anaesthesia was absolute for several months, and in many is still evident.

PATHOLOGY.

The considerations detailed above point to some resemblance between the cutaneous lesions of carbon monoxide poisoning and those belonging to the group of toxic erythemata. In both there is capillary dilatation, serous exudation, and cellular infiltration.

The presence of hyperaesthesia and anaesthesia, so striking in the cases now under consideration, constitute an important difference between the two affections, for they are absent in toxic erythemata.

The scarring and atrophic changes in carbon monoxide poisoning afford a marked difference between the two affections.

The association of anaesthesia with erythema indicates that the cutaneous lesions of carbon monoxide poisoning are of the nature of an angioneurosis, and brought about either directly by anoxyaemia, or indirectly through the circulation of toxins produced by faulty metabolism.

The persistence of the lesions and their results favours the former view, and point to a marked interference with the nutrition of the skin. If the lesions were due to the circulation of toxins, one would expect this to subside soon after the patient recovered from the immediate effects of the gas, and on this supposition the cutaneous lesions should be of brief duration, and clear up completely.

The association of peripheral neuritis with several of the cases favours the view that an angioneurosis is responsible for the condition of carbon monoxide erythema, and it is rather remarkable that in two cases of external popliteal paralysis erythematous patches were present just below the head of the fibula, and almost exactly over the situation of the nerve. The influence of pressure has already been discussed.

The cutaneous lesions of carbon monoxide poisoning were first described by the writer in a communication to the BRITISH MEDICAL JOURNAL of November 1st, 1913. There is no record of any previous observation of these lesions, which, in the writer's opinion, are now fully established as true manifestations of carbon monoxide poisoning. There was no evidence of burns or of any fire having reached the part of the mine where the survivors were found.

TREATMENT OF CARBON MONOXIDE ERYTHEMA.

Lotio calaminae was of some value locally, but relieving pressure such as by a ring pad or cushion enabled the patient to lie down with some degree of comfort.

SYMPTOMS SHOWN BY RESCUERS.

The symptomatology of carbon monoxide poisoning as shown by those engaged in the work of exploration, etc., will now be considered.

General.

A marked feeling of languor and an irresistible desire to rest quite regardless of immediate danger. Those affected wanted to be left alone, and would resent interference, even if directed to their advantage.

Fatigue becomes so acute that almost any muscular action cannot be sustained. One man was obliged to relieve himself of a pocketful of nails, another a hammer, another his cap, for even this seemed too heavy. A colliery manager leading one of the parties, and carrying the canary, when affected by the gas felt his grip upon the wooden cage weaken, and imagined his fingers were swollen. Others complained of faintness, others of exhaustion.

These symptoms were usually brought on by exertion, and were far more evident in those doing hard manual work than in the officials superintending such work. Some relief would ensue from rest, but this would be of a brief duration, and recur immediately work or walking were resumed.

Cerebral.

Tinnitus aurium was one of the earliest symptoms. Headache was general, and first felt at the back of the head, and described by some as amounting to a severe pain. Some complained of a feeling of constriction as if the head were encircled by a band which could be tightened by a screw.

Others said they had a feeling as if the crown of the head was being lifted off, or a sensation of expansion of the head; or a feeling of the head splitting in two. One said that "his head felt double the size." A marked feeling of "throbbing in the temples" was present in many. Headache was delayed in some, and absent in a few. A feeling of contentment or complacency was general even in those suffering from the various subjective sensations described above. Many were fully aware of their dangerous position, but strangely there was no mental distress, and they would lie still, and make no effort to move on to a place of safety. In some the mental state was one of exhilaration, even when prostrated and conscious of extreme danger. Such cases would desire to rest, and would not actively assist any one desirous to help them. All precaution would be abandoned, and one leader of a party carried the canary mechanically, and ceased to take any further notice of its movements. Many said that their sense of humour was increased as in the early stages of alcoholic intoxication, and jokes and pleasantries would be exchanged between the mine officials and the working men.

Many responsible officials who ordinarily possess a keen sense of authority and duty would joke with their subordinates, although fully conscious of doing so, and, indeed, they would mentally reprove themselves for being "childish."

Some were greatly amused at the gasping appearance of others, although fully aware that their own condition was very similar.

Others, again, would exhibit hysterical symptoms, such as immoderate laughter, shouting, or singing, and in this respect one said that the effect in his case was very similar to that produced by nitrous oxide. A mild degree of delirium was produced in some instances, and one of the mine officials when affected became excited on reaching

fresh air, and raised his lower limbs in walking in a manner resembling the "turkey trot."

Some were happy and depressed in turns, others were irresponsible and indifferent as to their language to their superiors. One man in this respect behaved similarly when "gassed" as on another occasion when observed by the writer to be under the influence of alcohol. Giddiness was complained of by many, and several were observed to be ataxic on endeavouring to walk.

Cardiac.

Palpitation was a common and early symptom, and accompanied in many by a very tumultuous action of the heart. Cardiac action would become so forcible that some were obliged to keep the elbow firmly pressed against the left side. The members of one party exploring the mine within a few days of the disaster, and when it was possible that some of the workmen were still living, believed that they could hear knockings, which they attributed to the presence of entombed men, but which were really due to tumultuous heart's action, and which became audible to others.

Another party which suffered in the same way said that they could plainly hear one another's hearts when all were silent in a remote part of the mine. Some stated that palpitation was so acute that they felt compelled to fall, for the heart's action was strained "almost to bursting point." Others described their symptoms as a severe throbbing of the heart.

Respiratory.

Breathlessness was common, and was probably in many cases partly cardiac in origin. Some described this as being asthmatic in character, others as "heavy and deep breathing"; others, again, said their breath was "heavy and gasping."

Muscular.

Weakness of the lower limbs was general, and described by some as a giving-way of the knees; others as a sagging of the knees; others stated that their legs became tremulous and weak; another said that his legs failed to support him and "felt like rubber"; another said "his legs were like whips"; others that their feet became too heavy. One—the official already mentioned, whose gait and behaviour excited some amusement—said that his lower limbs seemed very pliable, and he felt capable of performing almost any acrobatic movement. This was partly due to his mental state of exaltation, but which was maintained by a condition of flaccidity in the lower limbs.

Gastro-intestinal.

Vomiting occurred in some instances and gave relief. This happened in a few cases on reaching fresh air, and was attributed by one to the administration of oxygen.

Sequelae.

Malaise and lassitude were present for days in most cases, and some complained of failure of memory for some time. Those who continually inhaled small quantities of carbon monoxide gas—as, for example, those at work on the bashings—were subject to a cumulative effect, and general failure in health was the result and neurasthenia. It is the opinion, too, of many of the leading mining experts that respiration is permanently affected after such work.

The writer hopes to verify this by further observations of those affected at Senghenydd.

TREATMENT OF AFTER-DAMP POISON.

Preventive.

Miners in each district of the colliery should be subject to discipline and in charge of the district fireman.

When an explosion occurs the fireman should warn all the men to this effect by a recognized signal, such as ringing of an electric bell.

Some districts of the mine may escape the immediate full effects of the explosion, as did the Bottanic district in the Senghenydd disaster. The men should assume comfortable reclining positions on either side of the road, in a place selected by the fireman as being the best situated to obtain the purest air available. The fireman then inspects the roads leading from the district, and ascertains if escape be possible.

We have evidence from the survivors that the fireman in charge of the Bottanic district of the Senghenydd Mine made an attempt to collect his men, and cautioned them not to move until his return. His body was found just inside the narrow airway leading to the district. He was probably overwhelmed by the after-damp ascending No. 1 North Road.

The efforts of the men to escape have been already described, and the onset of symptoms in almost every case followed the exertion of walking quickly up the inclined road. Some also were considerably more excited than others. The party of men was almost wholly overcome by the time the double parting of the district was reached, and most of the bodies were found in groups close to this spot.

It is difficult to explain why eighteen men survived and why eighteen men died, for there were no marked differences of age, general health, and habits. Their respective positions also were somewhat similar, for almost all were found reclining against the side, and in some places the dead and living were mixed together.

The air close to the Mafeking return must have been heavily charged with the deadly fumes of after-damp, for a canary died suddenly here on the following day. Many of the men in endeavouring to escape traversed the road leading to the Mafeking return, and it is possible that some went further than others, and so were worse affected by the vitiated air of this part of the mine. Moreover, the concentration of the men at the double parting of the district must have lessened their ultimate chances to escape.

There is, of course, the question of varying susceptibility to the effects of after-damp poisoning, and this must have been partly responsible for the result.

When escape by the comparatively short route along the No. 1 North Road was impossible, the men would have done wisely to remain in the district rather than to traverse the long and difficult road heavily charged with the fumes round to the main level of the mine.

A supply of oxygen kept in the district would probably have saved the lives of many, for some of the survivors were hardly affected and only in a drowsy state. Inhalation of oxygen would have revived these men, and they could then assist the others. A knowledge of the administration of oxygen could be included in the instruction given to miners in first aid classes which are so well attended in the principality.

Large cylinders of oxygen could be kept in each district, and fitted with several gas bags, which could be filled, and used to resuscitate those affected by the after-damp. Unfortunately the effects of an explosion in many parts of the mine are so immediate and overwhelming that no escape is possible, but districts like the Bottanic in the Senghenydd Mine may escape the full blast and the noxious fumes may only diffuse in slowly, and thus with the aid of oxygen and the precautions already noted many lives may be saved.

Again, miners under such circumstances should drink the cold tea which is their favourite beverage when at work, and unless they have taken food recently they should partake of that in their boxes. The "jacks" and "boxes" found in the Bottanic district in the Senghenydd Mine at the time of the rescue were for the most part full.

Thermos flasks containing hot tea and milk, or hot coffee and milk, would be better than "jacks" containing cold tea.

Summary of Recommendations.

1. The district fireman to be responsible for the safety of the men, and the strictest discipline should be maintained at all times.

2. No man is to leave the district until permitted by the fireman in charge.

3. The fireman with another, or failing him two or three experienced men, are to undertake examination of the air along the roads leading to the district, and they should be careful to avoid over-exertion when carrying out such an inspection.

4. The men in the meantime should assume a position of rest, preferably in a semi-recumbent posture, and should drink their beverages and partake of food if necessary.

5. They should endeavour to keep awake, and those less affected should encourage the others.

6. A supply of oxygen, if available, should be used to restore those already affected by the after-damp. Inhalation of ammonia, too, would be useful.

Curative.

In the treatment of a person suffering from after-damp poisoning, unless removal to fresh air can be carried out immediately, treatment should first be applied on the spot.

The oxygen cylinders attached to the breathing apparatus of the rescue brigade can be utilized, and the air around the patient fortified by an ample supply of the gas. Artificial respiration can be performed at the same time. Inasmuch as most of the survivors in the Senghenydd Mine were found in a sitting position, this was maintained, and artificial respiration performed by the Howard method.

These measures proved to be effective, even in the worst cases suffering from collapse.

Massage and brisk friction of the limbs, too, was useful, and strychnine hypodermically. In less affected cases in which stupor is a feature, vigorous shaking and flipping measures were adopted.

The application of lotio calamiuae seemed to relieve the pain of the erythematous lesions after the patients were removed to hospital.

In many of the explorers who were "gassed" artificial respiration by the Schafer method was best. Oxygen was administered whilst the movements were being performed.

Owing to spasm of the upper limbs (Case 1), erythema, and oedema of the hands (Case 7), burns on the limbs in many others, the Sylvester method of artificial respiration was inapplicable, and this, too, would have hindered the simultaneous administration of oxygen.

As regards transport various means were adopted at Senghenydd. In slightly affected cases they were shouldered out by a helper upon either side, and the boys were carried pick-a-back. In badly affected cases a stretcher was used, but owing to the turns and obstructing timbers in the narrow entrance of the Bottanic district leading to the No. 1 North Road a blanket had to be used.

Ambulance trams for conveying injured or "gassed" miners should be devised for use in collieries. A wheeled support across which a stretcher or blanket could be suspended would be useful as a means of transport from distant parts of the mine. Commonly in ordinary cases of injury occurring in the mine the coal trams are used as a means of transport, but this for obvious reasons is unsatisfactory, and may seriously aggravate such injuries.

The patients should be covered up warmly with blankets or rugs, for on removal from the hot air of the mine to the relatively cold outer air serious collapse is apt to take place, as happened in some of the Senghenydd cases.

A small hospital should be permanently established as near as possible to the colliery.

All men suffering from the effects of after-damp poisoning should be carried, and under no circumstances should be allowed to walk home, for symptoms may be delayed and come on suddenly.

It is important that restorative measures should be carried out as far as possible in the mine itself, for the difference of temperature and pressure at the surface may lead to a relapse, as happened in some of our cases. This is probably due to the sudden liberation of small bubbles of the gas, which might form emboli in the brain and elsewhere.

Rescue Brigade Work.

The rescue brigades equipped with special self-contained apparatus rendered fine service in the work of rescue of exploration.

The first rescue party to arrive was the Rhymney Valley rescue car, with eleven men in charge of Superintendent Kitto, at 10.30 a.m. The nearest rescue station was Porth, ten miles distant, but this brigade did not reach the mine until half an hour later than the first named, owing to trouble with tyres, and to the fact that they were not summoned to the scene of the disaster until 10 a.m., nearly two hours after the explosion; thus valuable time was lost, inasmuch as before their arrival it was impossible to repair the damage done to the water pipes owing to fumes and smoke.

Had a rescue brigade been on the spot the water pipes could have been repaired immediately, and efforts directed against quenching the fire raging in the main west level would have been far more likely to be attended with success than three hours later. Whilst immediate measures were being taken to combat the fire, probably others of the rescue brigade with breathing apparatus might have been able to reach the West York district, and possibly also the Bottanic district, and thus many more lives would have been saved. This view is supported by the following considerations. The districts already mentioned were far more favourably placed for the purposes of rescue than the others.

One man employed in the West York district actually escaped from a point about twenty or thirty yards below the engine on the incline. He was blown down, but uninjured; and as he expressed it, he made a bolt for the shaft, and groped his way out, and fell unconscious close to the bottom of the upcast shaft.

The West York district was explored on the day following the explosion and the air found to be tolerable. Several men had made their way to within twenty yards of safety, and their bodies were recovered on the next day. Most of the others working on the coal face had traversed several hundred yards before being overcome. The positions of these bodies will be fully described in a later paragraph.

One of the bodies found in a group close to the Mafeking return was brought up on the next morning and bore the appearance of not having been long dead. The body was examined by several medical men, and each one formed this opinion independently.

Again, with regard to the Bottanic district, where the eighteen men were eventually rescued, the committee of experts determined that after an examination of No. 1 North Road at 9 a.m. and at 1 p.m. on the day of the explosion, rescue operations in this direction were impossible, owing to the fire having reached the Cross Cut, and dense volumes of smoke were travelling with the air into the road. The road subsequently became impassable, owing to falls, consequent to the burning of timbers supporting the roof.

The falls of the roof just described must have almost completely blocked the road, and thus the amount of smoke travelling up the No. 1 North Road was greatly diminished. Probably this was responsible for the reversal of the air, which maintained life in the Bottanic district and made rescue operations possible. Probably, too, before the falls occurred a large amount of this smoke was diverted into the stables, for the doors here were destroyed as a direct result of the explosion.

The rescue brigades early in the day were desirous of making an effort to reach the men in the Bottanic and West York districts, but permission was not granted, inasmuch as the mining experts believed that such efforts would be attended with certain calamity. The reason stated against making an endeavour to reach the Bottanic district from the east side of the mine was that it was impossible owing to the smoke in the No. 1 North Road.

The Rhymney Valley Rescue Brigade had worked at a fire two years previously, where the smoke was said to be even denser than that at Senghenydd, and the gauges of the apparatus could not be read even by a lamp of a hundred candle power, and a line of communications had to be kept by each man touching the one in front. After this experience this brigade at Senghenydd was prepared to enter the districts already mentioned.

Upon the arrival of Professor Redmayne, His Majesty's Chief Inspector of Mines, and Dr. Atkinson, the Chief Inspector of Mines for Wales, it was decided to examine the east roads leading to the west side, and this was done at 9 p.m. on the same day, with the result that they found the air to be now travelling down the No. 1 North Road, and not in the reverse direction as is normally the case. When this fact was reported it was decided to explore the Bottanic district from the east side of the pit, and the party started at 10 p.m. Their further progress has been elsewhere described.

The matter has been referred to in detail, inasmuch as it is highly probable that had the mine a permanent rescue brigade of its own, equipped with the breathing apparatus, an attempt would have been made much earlier to reach the Bottanic district.

The rescue brigades which came from other places were not acquainted with the mine, and proceeded almost

immediately to attack the fire and repair the water pipes. They were informed that no lives could have possibly escaped the immediate effects of the explosion.

The considerations strongly support the view that each mine should have its own rescue brigade, consisting preferably of men drawn from the ranks of the officials who possess an intimate acquaintance with the workings, which are varied and often complex, as the plan of the Senghenydd Colliery shows.

Rescue brigades for mines should consist of very carefully selected men. They should be in charge of a brigade superintendent qualified by long experience, and capable of instructing the men and maintaining thorough discipline.

It may seem almost unnecessary to suggest that the men should be of good physique, and that medical examination should be done at intervals, and immediately before undertaking any rescue work. However, at Senghenydd a brigade man collapsed whilst taking part in the exploration of No. 1 North stables. The heat was intense and the fumes dense, with the result that one of the men was overcome, and had to be carried out by the others. On subsequent examination it was found that the man suffered from heart disease, and had been unable to work for three weeks, and on the day of the explosion was actually under orders to attend the Cardiff Hospital for special examination. The apparatus was confiscated, but afterwards found by Professor Haldane to be in thorough working order. As a result of this the other brigade men were medically examined, and two more men certified unfit for the work.

The question of temperament, too, is of great importance in the selection of men for rescue brigades in mines. It transpired that whilst the brigades were removing the bodies from the York West district one of the men took fright and ran back. With this single exception the men constituting the various brigades were fearless, and were of great service in the work of rescue and exploration.

If, as already suggested, each mine had a rescue brigade trained and always ready for any emergency, the superintendent in charge would have ample opportunity of knowing his men and rejecting those unfit by temperament as for any other reason. In such a permanently instituted brigade, too, much advantage would be gained from the men becoming well acquainted with one another, which is so necessary for the purpose of discipline and co-ordinated work.

The brigade should have a medical officer to examine the men at intervals and to instruct them in principles of first aid, and it would be a great advantage if he could attend the practices and accustom himself to the use of the apparatus.

The training of rescue brigades should be carried out under conditions which resemble the actual as closely as possible. Arrangements should be made for filling the galleries of rescue stations with a certain percentage of irrespirable gases, such as carbon monoxide and sulphur fumes, and smoke.

The brigades, too, should have frequent practice in the mine itself, and operations could be carried out in the various districts with obstacles here and there to simulate falls of roof. Moreover, all the men should possess a good knowledge of first aid, together with that of the chemistry relating to gases and the administration of oxygen.

Whenever an accident happens in the mine the brigade should be summoned to attend the injured and convey them to the surface.

One of the brigade men at Senghenydd whilst assisting to carry a body slipped and was momentarily stunned. Instead of transferring the wounded man to the stretcher and removing with all speed to fresh air, some of the others ran for help to the base 50 yards away. Had these men possessed an intimate knowledge of first-aid principles, and been accustomed to put this to practice, their first consideration would have been to convey their injured colleague as quickly as possible to fresh air.

In actual operations the men should be thoroughly fresh, and have had a good meal before descending the mine, and should not take alcoholic liquors in any form.

The various brigades should work in shifts, for it is of vital importance that the men should not be exhausted by overwork, as they are then much more prone to be affected by the after-damp and to suffer acutely. One man at Senghenydd collapsed after being at work continuously for twenty-one hours. This was the result of physical exhaustion and not of a defect in the apparatus, which was afterwards found to be in good working order.

Immediately symptoms of poisoning are experienced or observed by others, the man should desist and return to the surface, and afterwards should not resume work until he is pronounced fit by the medical officer of the brigade.

As far as possible a close watch should be kept by all members of the party upon each other for signs of after-damp poisoning, and no one should be allowed to proceed alone to any part of the mine. Should the conditions prevent the brigade working together, then a line of communications should be maintained from a fixed base.

The rescue party should never go without a canary previously noted to be chirpy and lively. The bird, in a cage fitted with a small oxygen cylinder, should be carried by the leader of the party, and kept by the left hand on the corresponding shoulder, where its movements could be constantly observed. The position of the bird is important, inasmuch as carbon monoxide gas is lighter than air, and is uppermost. One exploration party at Senghenydd almost ended disastrously by omitting to observe the above precautions.

The earliest sign noticeable in the bird is a ruffling of the breast feathers; then it becomes unsteady, and assumes a position of roosting, and would remain so until it fell off the perch. The plan adopted by the superintendents of the rescue brigades at Senghenydd, to whom I am indebted for the account of the symptomatology of carbon monoxide poisoning in birds, was to shake the canary off its perch whenever it showed a tendency to adopt a roosting position, and if it failed to rise from the floor of the cage, or would flutter its wings in an attempt to do so, this was sufficient evidence that the bird was affected.

A constant watch should be kept for evidences of early embarrassment in the bird. When a canary was put suddenly into an atmosphere charged with carbon monoxide it fluttered quickly and died, but rescue parties should not wait for this, inasmuch as an atmosphere highly dangerous to life may be reached before the canary actually dies in the way indicated.

Post-mortem Appearances.

The following notes on the *post-mortem* appearances of 400 bodies refer to external appearances for the most part, inasmuch as permission could not be obtained to do any dissections.

Although some of the bodies were not recovered for several months, and were consequently in an advanced state of decomposition, yet typical signs of carbon monoxide poisoning were present in nearly every case.

The face was the part usually examined for the presence of the characteristic coloration, and, if not evident here, a part of the chest would be washed free from coal-dust, or incisions made in the limbs.

The colour in most instances was bright pink, and was evident even in portions of flesh exposed by injury, such as in torn ends of muscles around joints from which the limbs had been blown off. Many of these bodies were not recovered for several months, and yet the typical pink coloration of the exposed part, just described, was still evident. This indicates the firm stability of the compound formed by the union of carbon monoxide with haemoglobin.

In another instance the brain was exposed and lacerated by a compound comminuted fracture of the skull. The meninges and brain substance were bright pink in colour, and no haemorrhages were seen. The cerebral substance showed many small white areas, almost circular in shape, and about the size of a pea. These were probably areas of unaltered brain substance.

The colour of the gums in a large number of bodies closely resembled that of the enamel used in making false teeth, and, until the parts were closely examined, in many cases artificial teeth were believed to be present.

In no instance were false teeth found to be loose, and this points to the absence of convulsions in most instances. In one only was the tongue found to have been bitten.

The tongue in a large number of bodies was swollen in almost the whole of its extent, the tip only remaining

normal in size, and considerable difficulty was experienced in removing false teeth for the purposes of identification.

Superficial burns on exposed parts were common, and in a large number of instances coal dust had been driven into the skin, and had to be scraped off before the typical colouring could be ascertained.

Tattoo marks were very distinct, and the delineations of certain celebrities could be easily made out at almost first glance.

The features of many of the earlier bodies were swollen, and a sanguineous froth exuded from the mouth and nostrils, and showed the typical coloration.

A small pool of blood was found by the side of one body, and was fluid even after the lapse of thirty hours, and of a characteristic bright pink colour.

Fractures and dislocations of almost every possible variety and description were found, and such was the terrible force of the explosion that some bodies were blown to pieces and the limbs of others evulsed at the joints, even the lower limbs being separated in this way without fracture from the hip-joints.

Most of the bodies were found close to the coal faces, and were for the most part in groups, within 100 yards of the working places. The positions were variable, and many were killed whilst actually at work, and just fell over from the position they were in at the time. Thus many were found actually at the coal face on their knees, hauliers beside their trams, and engine men in their seats. Some had tied mufflers round the mouth and nostrils, others their vests or waistcoats; another had plugged his nostrils with cotton-wool.

There were evidences in some instances that boys had been carried by men before both were overcome. Four men had rushed out in one district arm in arm, and had fallen together about 60 yards from the coal face.

Five bodies were found in the No. 1 North Road under a fall, and recovered five weeks after the date of the explosion. They were men working in the Bottanic district, and were seen by the survivors after the explosion happened. One was a master haulier and a man of experience, and probably persuaded four others to accompany him in a bid for safety. These men rushed to their doom, for the No. 1 North Road at the time was heavily charged with after-damp, which entered the narrow passage leading to the Bottanic district, and which convinced the others that escape in this direction was impossible. Inasmuch as there was an equal number of survivors and dead in the district, it is probable that had the five men remained with the others, two at least would have survived. The bodies of these men were greatly mutilated, but one showed unmistakable evidences of carbon monoxide poisoning, and thus the injuries must have happened either after death or whilst he was in an unconscious state from CO asphyxia.

In the West York district four men got within a short distance of the shaft before being overcome, and were at variable distances from the 15 to 100 yards proportionate to their respective strengths. All had fallen forward on their faces, and evidently whilst running. Thus the first body was that of a young man of fine physique, and the fourth that of a boy. Ten others had traversed 600 yards before becoming unconscious on the main road close to the Mafeking return. These were in groups of three, and appeared to have sat together and to have gone off to sleep. Two were on opposite sides of a rail, and appeared to have been leaning against each other. The body of the district overman was about 10 yards in front of this group and out-bye to the Mafeking return, whilst the others were in an in-bye position. He had fallen forward on his face, and it is probable that he was leading this group of men to safety, and, being a man of considerable experience and sound judgement, knew that the critical point along the road would be near the Mafeking return, which conveyed the air from this district towards the upcast shaft. He halted his men in-bye to this point, and decided to make a test of his own life, and his fellows were to follow if the glimmer of his lamp was seen to be receding, or that he was to shout to the others. This view is held by his old friends, and is highly probable, for he was a man of fine physique, and could have got as far as the four mentioned above, for these, too, had travelled from the coal face, and several of the group of nine might have reached a near point to the shaft as well. Thus, amidst the gloom and horror of a terrible disaster, there were evidences of heroism of the finest description.

I am particularly indebted to Dr. Phillip James, the doctor of the colliery, for much valuable information, and to many of the colliery officials for their courtesy and help.

Presidential Addresses

METROPOLITAN COUNTIES BRANCH.

SOME OBSERVATIONS ON MODERN VASCULAR PROBLEMS.

By FRED. J. SMITH, M.D., F.R.C.P.,
Physician, London Hospital.

SOME two or three years ago Dr. James Mackenzie delivered a lecture in which he stated that physicians had been in the habit of making two fundamental errors in their teaching of the pathology of cardiac disorders; and my first object is to show that these errors existed only in his own mind, and arose from his ignorance of the teaching (at any rate at the London Hospital) of cardiology, and from his lack of appreciation of the lessons conveyed by the literature of the subject.

His first statement was that we physicians had taught that a valvular bruit heard in the heart invariably meant the commencement of a condition certain to grow worse, was always an omen of dreadful things to come—was, in fact, the handwriting on the wall of a fate from which none of the possessors of a bruit could ever hope to escape. I take this opportunity, belated though it be, of flatly contradicting such a pernicious error of statement.

Evidently Dr. Mackenzie had never had the advantage of hearing the late Sir Andrew Clark speak on the subject. I well know that Clark was constantly teaching that bruits were not always to be looked upon as such dreadful portents, for he had collected (and I believe published) a large number of cases in which in the course of routine examination he had found valvular murmurs without any signs whatever of cardiac insufficiency, cases which he labelled "murmurs without heart disease," and against which he warned us especially to be on our guard lest we should frighten some poor soul into a serious illness. Nor could Dr. Mackenzie have heard of Sutton's teaching. I had the good fortune to be his house-physician, and many is the time I have heard him say, "Gentlemen, it is my good fortune to be a little deaf, so that I cannot always hear these murmurs of which you speak"; and we who knew him were always proud to admit that Sutton with his one ear could hear more than we could with our two, by which we meant that his clinical knowledge could see much farther into the case than our stethoscopes could take us.

These two instances are quite sufficient to show Dr. Mackenzie's ignorance of the teaching of his time, and as an old pupil of these great masters of medicine I must confess to some little soreness at hearing a specialist express in public a disregard for, and ignorance of, their teaching.

The second error of which Dr. Mackenzie accused us has as little foundation in fact as had the first. Dr. Mackenzie says that as he reads books on cardiac disease it would appear that it was taught that back pressure caused heart failure. Having evolved this absurd piece of topsy-turveydom, he then proceeded to hold us up to ridicule for having taught it, and in very grave language to inform us that the horse drew the cart and not the cart the horse—an observation of which I do not believe that any modern physician can be asserted to be ignorant.

I have now relieved my mind of a portion of the indignation I have felt at the publication of these statements, which are not only absurd and incorrect in themselves but unjust to the memory of my dead teachers, and must proceed to express my admiration for the extreme beauty

and precision with which modern cardiology has solved the minute details of many problems connected with the heart. It has laid bare even before our eyes the exact why and wherefore of irregularities of beat, of tachycardia and bradycardia, of many forms of anomalous rhythm, of venous pulsation, of dicrotism, of pulsus alternans, etc., and no doubt has led many to a much clearer understanding of these phenomena; but I beg leave to doubt whether this showing up of the individual trees instead of a wood is a sight which it is always advisable to put before the eyes of medical students. Each modern discovery in the science of medicine—bacilli in the sputum of phthisis, eosinophiles in the blood of the hosts of parasites, and now heart-block and auricular fibrillation in heart disease—is apt to be used as a short cut by students to enable them to dispense with detailed examination of patients by the eye, the hand, and the ear; and, indeed, in relation to my present subject, the magic words, "heart-block," "auricular fibrillation," "excessive or high blood pressure," are quite sufficient to conjure with, without any silly inquiries into shortness of breath, indigestion, diminution of urine, oedema of feet, ascites, etc., let alone a general inquiry into the patient's feelings.

It is true that by electric and other cardiograms a very pretty picture of the heart's working can be obtained, and that by a careful analysis, which must be almost microscopic in accuracy, of the picture thus produced, and by then throwing the picture on to a screen, it is possible to make visible to a large class a great deal of what we formerly had to learn by frequent and prolonged personal observation at the bedside, and which then was not always easy to convey to our pupils. This is, no doubt, a tremendous advantage, and we owe it entirely to modern methods; but as one who has had considerable experience, not only as a teacher but as an examiner, I must again repeat that I think it a mistake to allow a student thus to substitute pictorial representation for bedside observation. Such pictures and their analyses are of the utmost value to men who are already qualified, to those who by observation and clinical experience have obtained some knowledge of the efficiency or otherwise of a patient's heart, and have learnt to observe the symptoms of dis-ease, as Sutton used to spell it in his lectures on pathology. But I have often been brought to feel in the examination room that pictures, macroscopic and microscopic, weights and measures, can be abused as well as used, and that in the hands of students the former is very likely to be their fate; so much has this been the case in my experience that I have been driven to the firm conviction that it would be a good thing if the teaching of advanced medicine of a "university type" (to use the well-known words of the University Commission) were reserved entirely for a post-graduate course to come in between the final examination and a licence to practise, and to be made compulsory for all students before they are allowed to treat patients on their own responsibility. This is the very best time in a student's career for him to appreciate such teaching, just the time when he wants to compare bedside with laboratory work, so that he can take the best of both.

Blood Pressure.

Let me illustrate what I mean by a few remarks on blood pressure. Early in his career the student learns from his physiology teacher that there is such a thing, and he probably sees many beautiful instruments, and perhaps experiments, by which it and its variations are measured. Pharmacology teaches him how it can be increased or diminished by drugs; in the wards cases of cerebral haemorrhage make a great impression on him by reason of their fatality and sad results other than death. He finds in all probability that in all the cases of cerebral haemorrhage blood pressure is high—above, say, 150—and by a short and easy process of reasoning he is led by a specious short cut to say, If I find a patient, therefore, with a blood pressure of over 150 or 160, I must try and bring this down with drugs, that I may rescue the patient from a threatened apoplexy.

What a host of fallacies are here within a line or two of print! It is really difficult to mention, let alone to discuss them all.

The first that springs to my mind is the utter and absolute blank ignorance of us all—including the keenest physiological and pharmacological intellects—as to the intricate causes operating through a whole life which have led eventually to this high pressure; and then, again, the same ignorance as to the special purpose that it serves, and has probably for years served, in the economy of the individual—it must have served some good purpose and have been an efficient instrument to that end, or otherwise the life of the individual would long ago have terminated in death or disease; indeed, we have learnt by clinical, not by laboratory experience, that if we lower such pressures in robust individuals by drugs, we are very likely to produce a condition of depression which is only to be relieved by allowing the pressure to rise again to what, for the individual, has become the normal, however widely this may differ from our ideal normal.

Again, let me ask you to think what you know about the means that may be used to bring down and to keep down—there's the rub—any pressure above the normal. We have, of course, the whole group of nitrites—most valuable drugs—to use on an emergency; we have many preparations of iodine and of thyroid gland substance, but so far as I know the effect of all these is but temporary and ceases very soon after cessation of medication, and assuredly no one can be persuaded to continue to be a lifelong drug taker, especially when the drugs make him feel rather worse than better. Exercise, we are told, increases the blood pressure, but obesity that arises from inactivity is, I believe, just as great an infliction as the high blood pressure, not to mention the dyspepsia likely to arise from the same mode of life. Attention to diet and the administration of purgatives may do some good, provided, again, we do not make life a burden, but only the specialist—and he with less reason than most—claims to understand the precise article of diet that is causing the high pressure. The most usual rule is to cut off that article most desired by the patient—a rule, perhaps, not so empirical as might be thought.

As a third point worthy of notice let me ask you, collectively, what do you know of two things—(*a*) the direct effect of the nitrites upon all organs other than the blood vessels, and (*b*) the effect of the lowered pressure upon these same organs? An honest answer would, I think, be, Nothing at all; and yet unless your practice be guided by clinical experience you will often be tempted into trying to reduce blood pressure by their means. What would you think of a skilled watchmaker who took a dirty dinner-fork with which to fish out of a very valuable and complicated watch a grain of dirt? Not much, I trow; and yet I wonder whether the nitrites are a much more delicate instrument when thrust into the exceedingly delicate mechanism of the human body.

Another point. Let me draw your attention to the final argument in the mind of the man with the sphygmomanometer, "If I don't lower this pressure the arteries which I know are diseased will burst." I suppose there is no escape from the ultimate term of this argument; arteries cannot stand the pressure in them or they would not burst. This, I suppose, must be true, but who knows the condition of every millimetre of every artery? It needs but very little experience in the *post-mortem* room to convince anybody that diseased and thickened radials may exist with perfectly healthy arteries of the brain and of the heart, and, *per contra*, that diseased coronaries may exist alone or diseased cerebral vessels; and, with all these doubtful factors, who knows whether he will do more harm than good by reducing or attempting to reduce blood pressure? May it not be that a good pressure in the coronaries is really essential to cardiac efficiency? may it not equally be true that the same pressure is required for the nutrition of cerebral nerve centres? and may we not be on the horns of a dilemma, either one of which has a disaster for a final term? I personally hold very strong views that it may be so, and when called upon to treat such a case I prefer, if I can, to try to do as little harm as possible—to treat symptoms rather than physical conditions, to help my patient rather than science, for which purpose I have found that mercury and potassium iodide are as good as anything and better than direct vascular alteratives; if syphilis be, as it too often is, at the bottom of the trouble, we are giving a specific remedy, adapted to go to root causes, and if syphilis be not an antecedent factor these

drugs, possibly combined with a little digitalis, still seem very useful, though I admit I do not know precisely why.

Auricular Fibrillation and Heart-block.

My address seems to be rather of the nature of a melancholy jeremiad: "Things are wrong; let us not try to put them right lest we make them worse." So I would like in conclusion to turn to what I consider are the real triumphs of modern cardiology, so that I may finish on a more cheerful note, though I may possibly be giving more credit to modern investigaters than they would claim for themselves.

As I understand the matter, cardiac disorders may broadly be divided into two classes: those of which muscular inefficiency is the essential basis and those of which a nervous trouble is the real foundation; symptoms and physical signs alone would scarcely appear to be quite sufficient absolutely to determine with precision which is the prevailing factor, though the determination of this factor is absolutely necessary for really effective and rational treatment—perhaps I should say for the really satisfactory management of the patient and his troubles.

I am led to believe that by a careful study of multiple cardiograms and vasculograms it is possible to determine with absolute precision whether a muscular or a nervous fault requires to be remedied, if remedy be available. This achievement I hold to be a pearl of great price, an invaluable addition to our knowledge, and I would that every medical man should know of it, and even every student, so long as it will not be misunderstood by him and will not lead him into slackness of observation and indifference to the tales of woe poured into his ears by sufferers.

Even this achievement has, however, at present its disabilities; the instruments required to obtain the ——grams are expensive, their application requires considerable skill and experience, and the interpretation of the ——grams themselves is not always easy. May we hope that before long a good deal of this trouble will disappear and that we shall be able to apply the principles to our poorer patients as to our richer ones, who can demand the services of specialists already?

Meantime let us not despair; let us remember what I have always learnt and always taught—that bruits and irregularities of rhythm, faintings and other evidences of cardiac inefficiency, in the young at any rate, are not always of ominous significance, and especially let us remember what specialists would have us forget—that in the vast majority of cases brought to us for an opinion as to cardiac capacity, it is quite possible to form a correct estimate from general experience combined with careful observation of the individual.

WORCESTERSHIRE AND HEREFORDSHIRE BRANCH.

HOW TO INCREASE THE USEFULNESS OF THE BRITISH MEDICAL ASSOCIATION.

BY

JOHN LIONEL STRETTON, L.R.C.P., M.R.C.S.,

Senior Surgeon, Kidderminster Infirmary and Children's Hospital.

VARIOUS suggestions have been put forward with the object of improving the position of the British Medical Association, of enhancing its prestige, and increasing its usefulness. The Plymouth Division has given notice of a motion "That it is desirable for the future that the British Medical Association should confine its policy to promoting the scientific and social welfare of the medical profession by leaving all medico-political work to be done by some other body formed for such purpose and registered as a 'Trade Union,'" and the Brighton Division recommends "That the British Medical Association be transformed into a Federation for other medical bodies formed to safeguard the interests of one or more sections of the medical profession, while allowing all such bodies to continue their separate existence." These and other resolutions tend to show that there is some dissatisfaction with the Association in its present condition.

To us in Worcestershire the state of affairs is particularly disquieting, because we pride ourselves on the fact that our city was the birthplace of the Association. I think that many of our members who have openly expressed their dissatisfaction have failed to realize the magnitude of the debt they owe to the Association. If it be admitted that the fight over the Insurance Bill was not so well conducted as it might have been, there can be no doubt that but for the action of the Association the position of the panel doctors would have been very much worse than it is at the present time.

It is true that the six cardinal points were not all secured. Of these, the wage limit always appeared to me of great importance; and although I am assured by some of the panel practitioners that the loss of it is of no moment, I regret that it was not embodied in the bill. The free choice of doctor, which was supposed to be granted, is by no means secured, and the representation of the profession on the Insurance Committees is totally inadequate. The only point really gained was the increase in the financial offer of the Chancellor of the Exchequer. The advance from 6s. to 9s. was enough to satisfy a large majority of the profession that the work would be sufficiently remunerative to justify them in accepting service, in spite of the refusal to concede their other demands. It was this decision which prevented the Association from insisting upon further concessions, and, though we may think that it was a mistake, we should in common justice accept the responsibility and not try to blame the Association.

The dispensing of medicines by the chemists was never contested, although I have on several occasions expressed the opinion that it was a matter of the utmost importance. It has already given rise to difficulties, and will always be a source of trouble and annoyance. Viewed from the lowest standpoint, as a commercial transaction, is it possible that a doctor would provide his patient with inferior medicine? I say without fear of contradiction that his object must always be to get rid of those who consult him in the shortest possible time, and the cheapest way to do this is to prescribe the medicine which he considers best. If he dispenses it himself he has the advantage of knowing that the actual drugs he orders are put into the bottle, and, further, that their quality is satisfactory.

In carrying out the campaign a vast amount of gratuitous work was performed by a body of men who have received scant recognition of the services they rendered or the sacrifices they made. Also a large amount of money was expended by the Association, and this must have temporarily crippled its financial position.

Is it fair, now that the first battle has been fought, to say that no fight was put up? Is it fair to decline a membership which would assist in discharging the bill, or to grumble at a small increase in the subscription to aid in strengthening our depleted finances?

It appears to me that, instead of resigning membership ourselves, it is the duty of each one of us to use our best efforts to obtain reinforcements for the Association by inducing those to join who have hitherto held aloof. For my own town, I am happy to be able to state that since the passing of the Insurance Act I have secured the adherence of the only two practitioners who were outside our fold, so that we now represent a united family.

The suggestion of a federation has some attraction for me. To join up the various bodies which safeguard our interests would have distinct advantages. One annual payment would save us the trouble, and possible neglect, of multiple subscriptions; there would be a considerable saving of expense, and the linking together of our scattered forces would strengthen all of them.

To confine the Association to scientific work would, I think, be a mistake. It has a very large membership; it is the acknowledged mouthpiece of the profession; and, as such, it is the only body at present capable of representing us. It would be a long time before any new organization could occupy such an influential position.

With regard to a "trade union," there is much to be said on both sides. The idea is repugnant to the professional sense of some of our members, contrary to the traditions which are their pride, and ill accords with their conception of the honour and dignity of our great calling. With all this feeling I agree, but I cannot shut my eyes to the fact that the great cause of weakness in our ranks is our individualism.

Every member forms his own opinion, often from insufficient or incorrect data. He cannot—it would generally be more correct to say will not—attend meetings; he sits at home in his armchair; he may read some portion of his JOURNAL; he listens to fragments of information conveyed to him through various channels; he draws his conclusions for or against the men who have spent their time and toil in investigations; and nothing will dissuade him from the opinion—frequently more or less prejudiced—at which he has arrived. Would a trade union convert him? I have an idea that he might guard his diagnosis with his resignation.

There are, however, other reasons which indicate the desirability of such a change. Legal difficulties in dealing with our funds, and in other matters, would be overcome. It is a question which requires consideration; but of this I am confident, be the result what it may: we shall never secure victory until we adopt the principle that the minority must give way to the majority; nay, more, that they must loyally support them. We all have a right to our opinions, and when convinced of their truth it behoves us to use every effort to secure their general adoption. But when we find that a majority of our profession decide against us we undoubtedly ought to fall in with that majority, until we can convert them to the view which we believe to be correct.

From these remarks it is obvious that I consider it the duty of every member of the profession to attend our meetings, when he will thoroughly understand all the important matters which are discussed and be able to give his valuable advice. I freely admit, and I join heartily in the complaint, that at present the profession is called to attend far too many meetings. The overlapping of the Medical and Panel Committees is deplorable. We have done our best to obviate it, but as yet their separate existence is a necessity.

The number of the Association meetings, now that we have recovered from the preliminary consideration of the Insurance Bill, is not excessive. It is necessary for us to discuss a considerable number of medico-political questions. This side of our work has grown, and I see little probability of its decrease. It depends to some extent upon the decision as to our future constitution.

I do not think anything is to be gained by resolutions which declare "that the working of the medical clauses of the National Insurance Act by members of the profession is derogatory to the profession and against the public interest." The Act has become law. The financial arrangements appear to be satisfactory to the large majority of the profession, and it only remains for us to endeavour to remove abuses and introduce improvements into the service. Much of this work will probably fall upon the Medical and Panel Committees, but it is probable that some of it will still be referred to our Divisional meetings.

For the past three or four years the medico-political work has been sufficient to occupy the whole of our attention in this Division, and it has not been possible to hold any scientific meetings. Apart from the Insurance Act there are still some outstanding problems of a medico-political nature which urgently require solution, and these ought to receive early consideration in order that they may be satisfactorily and finally settled.

Medical aid institutions demand our attention. It may not be possible to do away with them, but it should not be difficult to reform them. If such a desirable result is to be attained, they must be approached in a spirit of fairness. No compromise can be effected if both sides remain obdurate. In Kidderminster we have succeeded in effecting a settlement. The Medical Aid Association has agreed to our suggestions that there should be no canvassing, and that no money shall be funded. All the proceeds in excess of expenditure are handed over to the medical officer, with the exception of a small reserve fund, which is necessary in case of an epidemic. We accepted a wage limit of £150 a year. I have been told that this is a disgrace to us. This accusation is a sample of what I consider unfair conduct. The Medical Aid Committee could fairly retort that many of our members are attending friendly societies, where there is no wage limit at all. I consider that it was a great point to gain the recognition of any wage limit, and to have fixed it at £150 is but little in excess of the demand of the British Medical Association in one of the cardinal points.

We should also take up the question of fees for life insurance examinations. Half a crown is inadequate remuneration for any form of report; 5s. should be a minimum fee for industrial cases. Ordinary cases, where the amount insured is £100 or less, may be examined for half a guinea, but above that amount a minimum fee of a guinea should always be demanded. It is not right that any insurance company should settle the fee to be paid to us without having previously consulted and come to an agreement with us. We ought, further, to secure an undertaking that our reports should not be communicated to another office. At the present time, if proposals are made to several offices, after one examination has been made and reported the other companies are able to obtain copies of that report without any payment, and the profession is thereby robbed of the fees which ought to be paid by each office for a report.

In order to have some chance of coping successfully with the enormous amount of necessary work and the number and complexity of the scientific and other questions constantly arising for consideration it would seem desirable to establish some time-saving method of procedure, on the principle of division of labour. My own feeling is that it would be a wise arrangement to confine the work of our Divisions to medico-political matters. The Branches could then devote their attention to the scientific side. To confine the scientific work to the Branches would have the great advantage of securing a wider interchange of views. We are always liable to become limited in our outlook and restricted in our opinions. What Worcester practises may be very good; it is not necessarily the best. Hereford, Malvern, or Kidderminster might have some criticism to offer. It is not certain that their suggestions would be an improvement, but their criticism, whether of the destructive or of the constructive order, might lead to further investigation, to the mutual benefit of the practitioners concerned and to the great advantage of the suffering public.

Clinical meetings and visits to operating theatres where the different methods can be compared are all useful. Such a system is now in vogue in America, and has spread in this country. On the Continent it has been developed to the extent of inviting groups of surgeons from one country to visit and conduct operations in another.

Let us now consider our own Branch more particularly. From the account of the year's work read by our Secretary, it will have been gathered that I have acted to a large extent on the principle which I have advocated. I was fortunate in securing some of my distinguished friends to come and address us. The attendance at the meetings, I think, justified my attempt, and I feel satisfied that all who were present obtained some useful information. I do not claim that the session was ideal, for although the presence of an eminent member of the profession is calculated to attract men to a meeting it does not follow that the subject to be discussed or the information to be gained is the most useful to the majority who attend.

As I have already stated, I think an interchange of views between our different towns would be useful, and papers on general subjects connected with everyday work would be distinctly helpful. Take, for instance, disease in the abdomen, which is so frequently occurring and offering puzzles of the greatest complexity—conditions with which I am often brought into contact, and which I view from the dual position of a surgeon and a general practitioner. A meeting devoted to a discussion of this matter should be useful to all of us. If our new President approves, and if it is thought sufficiently interesting to justify giving up one meeting to it, I shall be pleased to open the discussion.

There are many controversial subjects agitating the minds, not only of the profession, but also of the laity. Among our members there are, no doubt, some who could offer us papers, and many with divergent views which would lead to an illuminating discussion. May I enumerate some interesting subjects we might consider? such as the antiquity of man, his original organization, and the probable length of his tail; the approximate date of his appearance; whether the mummy of Rameses II, which is preserved in the museum at Cairo, is anywhere near the period of man's first appearance; or whether his

sojourn on the earth extends to thousands or to millions of years.

Then there are the still more interesting possibilities of the future, viewed from the evolutionary standpoint. Will the sense of smell, which is already on the wane, disappear? And will it be replaced by some other sense which the exigencies of the time may demand? With the rapid changes in our modes of progression will the present form of legs continue to be necessary, or will they eventually give place to some more useful extremities, such, for instance, as wings? Will the position of the eyes be maintained, or may it become advisable for one of them to find a place on the top of our heads to save us from destruction by ginger-beer bottles and other refuse discharged from our airships? Will the appendix remain, or will future surgeons be deprived of much of their work by its disappearance? And what will be the fate of the so-called cesspool—the large intestine? Does the crusade against the teeth indicate that they, too, must give way to some more satisfactory arrangement? Or is the present-day doctrine an illusion—that all disease is due to pyorrhœa, and that the only chance for our salvation is to submit to the wholesale extraction of our teeth?

Are we nearing the period when the population of the world will overtake the possible food supply? Is the solution of this problem to be found in the increased fixation of nitrogen? If so, is it probable that the vast quantity of that material which exists in the air will ever be utilized?

Some, considering such queries as these to be too speculative and not of much use for practical purposes, might prefer to discuss the possibility of improving our methods of diagnosis. Take, for instance, such a common disease as rheumatic fever. Is it always possible to distinguish it from other fevers? As a concrete example, may I quote a case which came under my observation? A lady had an abortion in the second month. The fetus was expelled in its membranes; not satisfied that all the placental tissue was away, I dilated and cleared out the uterus. Everything went well until the sixth day, when I found headache, pains, swelling and effusion in the right knee, urticarious rash, and a temperature of 103°. If I had not cleared the uterus out myself, and had my naked finger in it—I defy anyone to be certain in a rubber glove—I should have regarded it as septic. On inquiry, I learnt that she had had an attack of rheumatic fever three or four years previously, followed by chorea. This attack pursued the usual course; there was a relapse and ultimately a recovery. I was naturally anxious, and if there had been any means of establishing a certain diagnosis it would have been a great advantage.

Again, can a rash be certainly pronounced scarlet fever, and can enteric fever be diagnosed with certainty, even in the presence of a positive Widal reaction?

Drugs offer various problems, on which some members could doubtless enlighten us. Is it an advantage to have the multitude of new remedies which come into fashion only to be superseded by others? Are not some of the old remedies now discarded superior to the new?

Another fertile topic which occurs to me is the treatment of tuberculosis, with which many problems are connected. The advantages—and may I say the disadvantages?—of sanatoriums and of tuberculin injections; the suggestion of a fleet of motor cars to drive the sufferers about; the preventive measures and regulations, which demand all sorts of safeguards and inspections, cleaning and whitewashing, while they neglect the examination of the milkmen and bakers—people who may be suffering from phthisis and coughing and spitting all over our foods. My own suggestion, made many years ago, is that every one who assists in our food distribution should be subject to periodical examination, and, if found to be suffering from a communicable disease, prohibited from such occupation.

The treatment of the insane gives rise to another group of questions. Is it desirable to shut them up in asylums? Once in, should they ever be allowed at large? Should they be kept lingering on in their miserable existence at an enormous cost to the State? Should they be permitted to propagate?

Then there is the larger question of eugenics, with the rival claims of heredity and environment. This subject is very much in the foreground at the present time, and its adequate treatment, in view of the investigations now being carried on, offers scope for diligent study and serious discussion, opening out a whole series of problems directly or indirectly connected with it, and all of immense and far-reaching practical importance for the present and future welfare of our own country and the world at large. Other questions worthy of discussion are the right to die and —may I add?—the qualifications to live, the falling birth-rate, whether due to physical degeneration, to the carrying out into practice of the Malthusian doctrine, or to other causes.

Other suitable matters for discussion, offering a wide and varied field of choice, are the control of venereal diseases, teetotalism and the regulation of the drink traffic, vaccination and the notification of diseases, the sale of patent medicines, the control of bone-setters, quacks, and Christian scientists, and the disposal of the dead. We might enlarge our field by discussing the present day medical education, the advisability of a one portal entrance, the benefit of special qualifications, and the advantage or disadvantage of a State medical service. The hospitals question is also worthy of attention, and the all-important nurse demands our earnest consideration—whether a State registration of nurses would be preferable to the present chaotic position, which allows any female to don a uniform and palm herself off as the finished article.

There are also innumerable cases of interest constantly occurring, the recording of which would add largely to our store of knowledge and so increase our usefulness. Indeed, it is sad to think of the loss we annually sustain through the neglect to report them.

With all this material for discussion, I predict for my successor a very busy session. Out of the many and varied subjects suggested he can offer ample scope to all the members of the Branch to display their special knowledge and attainments and so enlighten the whole body.

STAFFORDSHIRE BRANCH.

RECENT LEGISLATION AND THE MEDICAL PROFESSION.*

By JOHN RUSSELL, M.A., M.B.,
Honorary Physician to the North Staffordshire Infirmary.

I PROPOSE in this address to discuss the tendencies of present State legislation, its effects on the profession, and the fitness of the present organization of the profession to cope with the duties required of it. This I cannot hope to overtake fully in the short time at my disposal. I can only touch on the points which have struck me personally, from my own experience, as being of importance.

The tendency of present legislation is for the State to concern itself with the health of the individual. The productive power of the State depends on the efficiency of its units, and that again depends on a full, free, and complete development and use of the healthy functions of life. Is it any wonder, then, that the State has become alive to the necessity of concerning itself with, and making itself responsible for, the health of the individual units of which it is composed? The wonder is that it did not become alive to this necessity ages ago. This involves a certain amount of compulsion, a thing always considered repulsive to a British subject. We have heard it argued over vaccination, and we have had the conscientious objector introduced to an extent which is a positive danger to the community. Well, there is a Nemesis waiting. Again, recently in this neighbourhood we have had a newspaper correspondence about temperance legislation, and the opponents of any restriction on the sale of alcohol have been quoting with much jubilation Bishop Magee, who in a memorable address said he would rather see Britain free than compulsorily sober. Much, I grant, can be said in favour of the development of habits of self-restraint, and self-responsibility may do much to evolve a higher grade of character, but my experience tells me that the individual cannot be accepted as the arbiter of his own health, and an outside authority must be called in with power to act. How often does it happen that a man apparently in perfect health on coming to a physician to be examined for life insurance is found

* Delivered at the annual meeting of the Branch, June 25th, 1914.

to be suffering from an insidious malady which is sapping his life! Is it not the case that sometimes a physician is called in to help, it may be, a young wife with a young and tender family, and with every prospect of a happy and useful life, but who, unfortunately, by hereditary taint or a combination of circumstances has developed an inveterate taste for alcohol? How useless is he without the power of compulsion! Much as I admire the feeling that a man's house is his castle, I feel strongly that, so far as the public health is concerned, this feeling is effete, and that the day is coming when, just as we have compulsory education, school inspection, and examination of workshops, we shall have compulsory examination of each individual as regards, not only his personal health, but the conditions under which he lives in his own home, and that the State will enforce the treatment of diseased conditions, the segregation of degenerate types, the prevention of marriage of unsuitables, and the breeding of inefficients. This may seem Utopian, but is it not necessary for efficiency, and therefore a thing to be striven for? Much has been done in the past by legislation and the efforts of our public health authorities. Let us look for a moment at some figures given by Dr. Newsholme, the Medical Officer to the Local Government Board, in his last report for 1912–13. He states that,

comparing the experience of 1912 with the average experience of 1891–1900, the rate of infant mortality has declined 38 per cent., the death-rate from measles 16 per cent., from scarlet fever 66 per cent., from whooping-cough 40 per cent., from diphtheria and croup 57 per cent., from tuberculosis (all forms) 32 per cent., and from pulmonary tuberculosis 25 per cent. The comparison for the following diseases can only be carried to the year 1911. Between 1891–1900 and 1911 the death-rate from puerperal diseases had fallen 28 per cent., from pneumonia 15 per cent., and from bronchitis 45 per cent. The death-rate from all causes has declined 27 per cent. between 1891–1900 and 1912.

Very instructive also are the figures he gives showing the gradual diminution in the standardized death-rates per 1,000 for the quinquennial periods from 1871–5 to 1906–10—20.9, 19.8, 18.7, 18.5, 17.6, 16.0, 14.4; and in 1912 it fell still further to 13.3, the lowest death-rate yet recorded. This shows how much has been done, but on a succeeding page of Dr. Newsholme's report certain statistics are given which make us pause and ponder how much has yet to be done. They are statistics by Dr. Stevenson of infant mortality in the chief occupations and groups of occupations.

Among the families of army officers in 1911 the infant mortality per 1,000 births was only 44, of naval officers and solicitors 41, of medical practitioners 39, and the rate of infant mortality of the middle classes generally was only 61 per cent. of the total mortality of the country among legitimate infants. These figures, as Dr. Stevenson remarks, "show how little of our present infant mortality is essentially inevitable." With these figures must be compared the average rate of infant mortality among artisans of 113, among miners of 160, among unskilled labourers of 152, and among agricultural labourers of 97 per 1,000 births.

These figures are a striking and sad indictment of the conditions which obtain among the industrial classes and the inefficient steps taken by the State to combat them. Quite as striking and damnatory is the evidence obtained by considering the inefficiency caused by venereal diseases and intemperance. The foul race-sapping ravages caused thereby do not stand out luminously in mortality tables. They are to be found in the private records in the physician's room. There no uncertain tale is unfolded of the deprivation to the State caused by these two diseases. There is an old aphorism that "a man is as old as his arteries." How much arterio-sclerosis can be laid at the door of syphilis and chronic alcoholism? Edgren, a Swedish doctor, states that 20 per cent. is due to syphilis and 25 per cent. to alcohol. These two diseases, then, between them are responsible for nearly half the cases. Thanks to the movement started at the International Congress in August last by Sir Malcolm Morris, the State is wakening to its responsibility, and as the result of the labours of the Commission now sitting it is not too much to hope that beneficial legislation will follow. Many doctors are a little sceptical as to the effects of legislation, and are very suspicious of any interference by a lay authority, lest there be a limitation of their liberty and sphere of influence. We need, however, only look at the effects produced by the tinkering, half-hearted measures already introduced to cope with the havoc arising from the white plague—tuberculosis—to be convinced that good must result and the welfare of the community advanced.

The attitude of the profession to recent legislation is to me a matter of grave concern and is fraught with issues of the greatest importance. The introduction of the principle of compulsory insurance against sickness and disability has always appeared to me to be a necessity if the working classes are to receive efficient treatment, and the present Act, however imperfect it may be and however unfair some of its clauses may appear, was welcomed by me from the first as a step in the right direction. As time goes on my opinion of its utility is strengthened, especially when I consider the contemplated extensions and the opportunities they will afford for scientific work. Many of the sturdy objectors to the Act I have always honoured because, however misguided they were in my opinion, they were, I felt, conscientious. It might not be altogether futile, even in this late period of the world's history, to consider the guiding principles of human conduct laid down by Aristotle in his *Ethics* some 300 years B.C. In studying this treatise what would strike our statesmen most would be the largeness and benevolence of his conceptions. This is most apparent when he speaks of the Supreme Good, the End of Ends which every one must strive to attain. This he considers to be happiness, not, however, of self alone, but the happiness also of a man's family and countrymen. Starting out from the point of view of the individual citizen he thus arrives at the same end as that proposed by political science—the happiness of the community. He says that every artist, every professional man—the painter, the musician and such like—has his peculiar business to do, and the good of each artist is in doing his business well and appropriately. The full position he states thus: "Happiness, or the highest good of a human being, consists in the working of the soul, and in a course of action, pursuant to reason and conformable to virtue, throughout the whole continuance of life." Aristotle thus offers two guiding principles of supreme importance—the happiness and well-being of the community, and the due performance of the work we have to do. Compared with modern times is the advice offered different, or are the ἀρχαί, the beginnings to which ethical philosophy points and from which the conduct it enjoins is derived, not one and the same? In the admirable address given by Sir William Ramsay as President to the British Association in 1911, he laid down principles which it would be well for us as a profession to consider earnestly and follow resolutely. I shall quote but one sentence:

I plead for recognition of the fact that progress in science does not only consist in accumulating information which may be put to practical use, but in developing a spirit of prevision, in taking thought for the morrow, in attempting to forecast the future, not by vague surmise, but by orderly marshalling of facts, and by deducing from them their logical outcome; and chiefly in endeavouring to control conditions which may be utilized for the lasting good of our people.

The first thing we as a profession have to do is to recognize that we are an integral part of a machine which the State has set up to promote the health of the industrial classes, and that if we fail in our duty the work of that machine is useless. If an army has to take the field the first thing to be thought of is a commanding officer who by his experience, knowledge, and organizing power can command the confidence of every unit of every arm of the force he has to lead. Then there has to be a head quarters staff, composed of officers, each representing and intimately acquainted with one particular arm of the service, who can assist their chief in co-ordinating the work and making one effective whole. Further than that, there is an important point: We must be concerned with the efficiency of each unit, each individual fighting unit, and that is complex, depending on training, *moral*, and equipment. Is it not strange that in the beginning of this enlightened twentieth century we should have in this country, which boasts of being in the vanguard of civilization and humanism, a Minister of War, a First Lord of the Admiralty, a President of the Board of Trade, a President of the Local Government Board, a President of the Board of Agriculture and Fisheries, a President of the Board of Education, and above all a Chancellor of the Exchequer, and yet we have not a Minister of Public Health? And

what is the result? We have a number of disjointed overlapping services without any co-ordination. We have the Poor Law service, which curiously enough is concerned with vaccination; we have a public health service which concerns itself with sanitation and infectious diseases, and yet is not responsible for tuberculosis and syphilis; we have factory surgeons concerned with the health of the worker and the conditions under which he works; we have the school medical officer concerned with that most important factor, the health of the young, and the conditions of school life; we have our voluntary hospitals well equipped and staffed for the investigation and treatment of special cases, but in a position of splendid isolation, and not linked up as they should be with the general practitioner; and then, finally, we have private practice, whether it be consulting or general, panel or non-panel. All these divisions or arms have their uses. What is wanted is co-ordination to banish the chaos and inefficiency which at present exist. We want a statesman who will utilize to the utmost the forces at present in existence to combat disease. I sometimes think that in our desire to make fresh scientific conquests we neglect to apply to its fullest and at the earliest newly acquired scientific knowledge. Take, for example, the epoch-making discoveries of Ehrlich. They were not made yesterday, and yet to-day is the treatment resulting therefrom available to the great masses of the people? We must have a Minister of Public Health with a head quarters staff, composed of men representing all the different arms of that multifarious army which is concerned with the health of the nation and has to combat disease and disability.

We now come to consider the efficiency of the units this army is composed of. I said this efficiency depended on three factors—training, *moral*, and equipment. I need say nothing to emphasize the importance of training, but I should like to protest strongly against a present tendency to narrow the scope of medical education and to confine it to strictly scientific study, without the broadening influence of a classical education and the general culture appertaining thereto. With regard to the second factor, which I have called morale, this in a military sense is regarded as especially meaning discipline and confidence, but I wish to consider the moral condition as wider and to include what Aristotle speaks of when he says that the good of each artist consists in doing his business well, the complete and full performance of his function. At the present time there is considerable agitation about the excessive sickness experienced by approved societies under the Insurance Act. Much of this is being attributed to malingering, and the fault is laid at the doctor's door—in fact, to hear some laymen talk, one would think it was entirely due to malingering, and that sloppy methods and want of backbone shown by the panel doctors are the sole causes of the financial ruin staring many approved societies in the face. To understand how misleading such an idea is one has only to consider the many factors which contribute to excessive sickness claims. I do not wish in any way to minimize the evils of malingering and the extent to which it obtains. Whether it exists to a greater or a less extent, the question is, Are we as a profession doing our best to prevent it? Those who were present at a conference with the Commissioners recently will agree with me that a very serious charge was made against the profession, and a very strong case made out against, not the profession as a whole, but certain members who do not exercise sufficient care in the granting of certificates of disability. Members of my Division may remember that twelve months ago I was a vehement opponent of the form of sickness certificate which insisted on a statement of the cause of illness. Ideally I still think that the simple statement that an insured person is unable to work should be sufficient, but my practical experience during the last year of the slipshod way some of my colleagues give out certificates has shown me conclusively that the demands of approved societies are in this respect natural and just, and that the only businesslike way is for medical practitioners to state as accurately as they can the cause of illness for the guidance of the societies which are financially liable. Now an objection is raised that at first in many cases a diagnosis is impossible. True, but let us give a provisional diagnosis and not be ashamed to alter it afterwards. One great advantage of having to state the cause of illness is that it stimulates the making of a diagnosis. A grievous and lamentable tendency, especially among the overworked doctors in industrial neighbourhoods, is to let things slide and not bother about a diagnosis, buoyed by the hope that Nature in her resourceful way will in the end bring about the cure. What we want is a stirring up of clinical interest. All else will follow—accurate diagnosis and accurate determination of the period of disability. What is the cause of this lack of clinical interest and how can we best kindle it? Surely most of us start with a serious interest in our work. We have it instilled into us in our universities and hospitals, by our professors and teachers; it is fostered in the brief period we are residents in hospitals, by intimate association with our colleagues, and it may be by the helpful supervision of the honorary staff; chemical and bacteriological laboratories are at our disposal to lead us to an accurate diagnosis, and hygienic surroundings and careful nursing to help us in treatment. What, then, happens when many have to go out and earn their livelihood by general practice, it matters not among what class of the community? Each becomes a detached unit, there is no longer any co-ordination with colleagues, each has to plough a lonely furrow, without help of laboratory, and treatment is often ineffective owing to insanitary conditions and lack of careful nursing. Many practitioners manage to survive the ordeal, and maintain in spite of all these adverse influences a scientific interest in the work of their profession; but is it a wonder that a man here and there, whose resistance may have been lowered to some extent either by ill health or the social conditions he may have been compulsorily exposed to, gradually loses interest in his work? Now it should be, and I believe is, the object of our Association to see that there is nothing in our professional work which tends to produce this lethargy, but rather that everything should kindle and fan the flame of scientific interest and activity. How, then, is this best to be done? I say by the full and complete equipment of every practitioner, so that he is in a position to combat disease with every known resource at his disposal, and further by complete and intimate association and co-ordination with his colleagues.

This leads me to consider the present equipment of the general practitioner. I have already spoken about the excessive sickness claims experienced by approved societies, and I said that there were several important factors apart from malingering which probably account for the great bulk of the excess. I should like now to allude to one or two of those factors, particularly those which may be considered as being connected with equipment. A very interesting and instructive paper in the *New Statesman* recently showed how Germany deals with excessive sickness; it was written by an investigator who has been spending some months in Germany going from one Krankenkasse to another and finding out how Germany has met the difficulties which now face our Commissioners. What has struck me most particularly in this article is that the findings of a layman belonging to a class of the community which many of my colleagues look upon, wrongfully I think, with suspicion, tally so closely with the ideas many of us have held for a long time. He shows how Germany has for a long time recognized that the excess of sickness payment is in the bulk due to real excess of sickness, and that the only way to meet this is not by a reduction or refusal of benefits, but by extending and improving medical attendance and benefit. What has happened in this country? The bill started by proclaiming that adequate treatment should be given in sickness to all the industrial classes; the Act finished by offering only such treatment as an average practitioner could give. As a result the insured person is debarred from many of the more modern methods of treatment, and if he is suffering from any malady requiring the treatment of a specialist he has to pay for it or gain access to some of our voluntary institutions. This access is not gained easily; it may involve ten, twelve or even more weeks' waiting and a corresponding drain on the approved society's funds. At the present moment at the London Hospital there are 867 urgent cases on the waiting list. Provision must be made for these cases, and our hospitals must not have their usefulness curtailed by the hand-to-mouth existence they have at present to endure, when many of their important officials, who could be much more profitably employed, have most of their time occupied purely in begging. We have

thus in this country a limitation of effort which destroys efficiency and necessarily increases the duration of illness. In Germany there is no limitation. Absolute dependence is not placed on the diagnosis and treatment of the panel doctor, a second opinion is offered and paid for. In each district there is a list of consultants and specialists at the disposal of the insured, and their services are paid for by the State. I cannot tell exactly the scale of remuneration of these, but it is stated by this anonymous investigator that the general average of the figures he had obtained in different centres pointed to a payment for consultant and specialist services of about 40 per cent. of that paid in the aggregate to the general practitioner. Specialist services are available for diseases of the eye, ears, and throat; dental treatment is given and provision is made for *x*-ray examinations and massage. Nothing is excluded in Germany. If any appliance is required to make an insured person efficient it is obtainable, within a certain limit of cost, including such things as trusses, artificial limbs, and spectacles. The relation to hospitals is interesting. Some centres, like Munich, depend largely for a second opinion and special treatment on institutions, while others, like Dresden, prefer specialists. The striking point is that there is no such thing as a waiting list, and treatment can be obtained without delay or unnecessary expenditure of sickness benefit. It is, however, paid for. The Krankenkassen pay for every patient they send to hospital an average of 2s. 6d. a day. Last year the Munich organization, with 183,000 members, paid to hospitals £49,326. In this same article specimen statistics are given of the cost per member for doctors (both general practitioner and consultants or specialists), for institutional treatment (including hospitals and convalescent homes), and for medicines and appliances, and two of these I will quote as representative.

	Doctors.		Institutions.		Medicines, etc.	
	Cost per Member.	Percentage of Total Expenditure.	Cost per Member.	Percentage of Total Expenditure.	Cost per Member.	Percentage of Total Expenditure.
	s. d.		s. d.		s. d.	
Dresden ...	8 2½	18.45	5 7	15.73	4 8½	13.21
Munich ...	6 11½	15.10	8 2½	17.88	4 2	9.13

This shows that the German Krankenkassen are paying from 11s. 6d. to 19s. 4d. a member for what Mr. Lloyd George is trying to get for 9s.

It is evident, however, that our statesmen are becoming alive to the deficiency of our equipment, and a grant of a million and a quarter has already been voted to remedy the evil. Particularly gratifying is it that a certain proportion of this sum is to be devoted to a supplying of laboratory facilities to assist the busy practitioner in accurate diagnosis and the more modern methods of treatment. No one can over-estimate the value of modern laboratory methods in assisting diagnosis and treatment. That this is being generally recognized is shown by the final report of the Departmental Committee on Tuberculosis, which recommends a general extension throughout the United Kingdom of clinical laboratories for the better diagnosis and treatment of disease.

Dr. Newsholme is no less emphatic in his last report when he states that "in order that a satisfactory medical service may be secured throughout the country facilities for work similar to that now being done in hospitals will need to be offered to medical practitioners generally." To see the extension of this work in modern times it is only necessary to glance at the reports of this work in our large and best equipped hospitals. In Guy's Hospital 5,326 specimens were examined during 1911, and in St. Bartholomew's 5,117. In the latter case Dr. Gordon gives the following analysis:

(*a*) Bacteriological	2,176
(*b*) Vaccines made	280
(*c*) Wassermann's test	928
(*d*) Cytological examinations (blood count, pleural effusion, cerebro-spinal fluid, urinary sediments) ...	427
(*e*) Chemical examinations (test meals, faeces for occult blood, etc.) ...	450
(*f*) Sections of morbid tissues	856

The above work is additional to a large amount of pathological work done in the hospital wards (over 700 beds).

These figures were given in reply to a special letter sent out to hospitals by Dr. Newsholme; and Dr. Gordon in his report further states that the number of specimens actually examined in 1911 would have been doubled had the total number been examined in which such investigation was practicable.

Such an extension of pathological work is not invariable in the hospitals throughout the country; many of those remote from large centres of population and unconnected with medical schools are especially inadequate. It is to be hoped that in this new further movement for the establishment of laboratories our large voluntary hospitals will be utilized. It will be a means of correlating the work of the hospital with the work of the general practitioner, and the financial aid thus obtained will help to raise the standard of those hospitals which for lack of means have hitherto been unable to maintain fully-equipped pathological departments. It is suggested that these State-aided laboratory centres should be only in connexion with our universities, but in a district like this, with over a quarter of a million of inhabitants, and with a populous surrounding district, surely it is better to have our own laboratory. This is, fortunately, rendered feasible by the generosity of the present President of our infirmary, who has recently equipped a first-class pathological department, which, with a full and complete staff, will be able to meet every requirement of the whole district. I hope the time will soon come when there will be an amalgamation of the efforts in this direction by the public health authorities, the voluntary hospitals, and now also the Insurance Commissioners; and we shall have the establishment of laboratories at Hartshill which will be not only complete in the way I have already described, but which will be able to carry out valuable independent research in the industrial diseases connected with our staple industries.

Times are critical, and we want earnest combined effort to stem the tide and secure for the medical profession the honoured position it has always held in the past. Detractors we have many, but I am convinced that the same spirit animates the bulk of the profession as was so eloquently expressed in the inaugural address to the International Congress in London in 1881 by Sir James Paget, a man whose life has been an inspiration to many. With his words I conclude:

"We had better not compete where wealth is the highest evidence of success. We can compete with the world in the nobler ambition of being counted among the learned and the good, who strive to make the future better and happier than the past, and to this we shall attain if we will remind ourselves that, as in every pursuit of knowledge, there is the charm of novelty, and in every attainment of truth utility, so in every use of it there may be charity. I do not mean only the charity which is in hospital or in the service of the poor, great as is the privilege of our calling in that we may be its chief ministers, but that wider charity which is practised in a constant sympathy and gentleness, in patience and self-devotion. And it is surely fair to hold that, as in every search for knowledge we may strengthen our intellectual power, so in every practical employment of it we may, if we will, improve our moral nature; we may obey the whole law of Christian love, we may illustrate the highest induction of scientific philanthropy. Let us, then, resolve to devote ourselves to the promotion of the science, art, and charity of medicine. Let this resolve be to us as a vow of brotherhood, and may God help us in our work."

THE late Dr. B. H. Mumby, Medical Superintendent of Portsmouth Lunatic Asylum, left estate valued at £13,020.

Two Chinamen were convicted at the Thames Police Court recently for unlawfully selling opium. The prosecutions were instituted by the Pharmaceutical Society. It appeared that in the first case the defendant kept a boarding house; the society's inspector purchased a 4 oz. tin of opium for 18s. 6d. The defence was that the opium was kept for the proprietor's private consumption, and that the sale was made without his knowledge; a fine of 20s. and 2s. costs were imposed. In the second case the inspector purchased a tin of opium for which he tendered £1 and received 1s. change. The defence was that the defendant had not asked for money, and that the inspector had left the £1. In this case the magistrate fined the defendant £5 and 2 guineas costs.

REPORT ON TUBERCULOUS MILK IN EDINBURGH.

By A. PHILP MITCHELL, Ch.M., M.D., F.R.C.S.,
ERNEST HART MEMORIAL SCHOLAR, FORMERLY MCCUNN SCHOLAR IN SURGERY AND BRITISH MEDICAL RESEARCH SCHOLAR.
(From the Royal College of Physicians Laboratory, Edinburgh.)

THE results of the bacteriological examination of a large series of unselected cases of tuberculosis of the cervical lymph glands published in the BRITISH MEDICAL JOURNAL last January (p. 125) showed conclusively that the bovine type of tubercle bacillus plays a significant part in the causation of this disease affecting children in Edinburgh and district.

Being thus furnished with an index of the frequency of the bovine infection in children, it was natural to inquire to what extent the milk supply of the same area was infected with tubercle bacilli. The Edinburgh milk supply had not been satisfactorily investigated in this particular.

Examination of Milk in Edinburgh.

A systematic examination of the milk supply was commenced in November, 1913, the results of which I desire to state briefly.

As in all large towns, Edinburgh derives its milk supply from two sources, dairy byres within the city boundary and milk imported from country byres. The latter is the more important, because at the present time almost two-thirds of the total amount of the milk consumed in the city is derived from country byres, and is conveyed to town by road or rail. Roughly speaking, the quantity of milk reaching Edinburgh daily from the country is about 10,000 gallons, as against 6,000 gallons supplied from the city byres.

Practically all milk imported from the country byres reaches the consumers through the milk shops, which number fully 400. Whereas the great bulk of milk produced in the city byres is conveyed direct by van to the consumers, a comparatively small quantity reaches them through the milk shops. Hence milk as sold in Edinburgh milk shops is largely produced in country byres.

The milk was collected in the following way: Samples of mixed milk were obtained from the milk shops in each municipal ward. They were collected in the morning in sterilized pitchers and brought immediately to the Royal College of Physicians Laboratory. A pint of milk was bought from each milk shop. After allowing the milk to sediment during the day in a sterilized separation funnel in the ice chamber the sediment was withdrawn and centrifugalized in the evening. The cream and supernatant milk were then poured off, and the deposit (mixed with a small quantity of cream and milk, generally about 5 c.cm.) was inoculated into two guinea-pigs. As far as possible guinea-pigs of medium weight were employed. In testing each sample the inoculations were made subcutaneously into the groin and intraperitoneally. It is highly important to employ two animals for each test, as may be judged by the fact that of the 82 tuberculous samples, only 36 produced generalized tuberculosis in both of the experimental animals. The animals were allowed to live at least three weeks.

Samples of mixed milk to the number of 406, collected from the same number of milk shops, were tested in the manner described; 82 samples (20 per cent.) were found to contain tubercle bacilli. The table shows the prevalence of tuberculous milk in each municipal ward.

It may be safely assumed that the results of these investigations indicate that a considerable number of the cows in country byres contributing to the Edinburgh milk supply are giving tuberculous milk. It is unfortunate that it was not possible to trace the milk to its source, and that I am unable to record the condition of the cows or of the herds which supplied the milk. If the administrative arrangements in regard to milk sent to Edinburgh from country byres had been adequate, the majority of the infected animals might have been eliminated from the herd supplying tuberculous milk.

It is a noteworthy fact that one country byre frequently supplies several milk shops in the same street. When such a byre is sending tuberculous milk to the city it is possible that, in some instances, tuberculous samples may be obtained from each shop supplied. No doubt this affects the percentage to a certain extent in a systematic examination of milk samples from milk shops only. However, we cannot well fall back upon this explanation when we come to consider the prevalence of tuberculosis amongst dairy cows in Scotland. It is only since the coming into operation of the Tuberculosis Order on May 1st, 1913, that reliable statistics on this point have been forthcoming. Of the 1,249 slaughtered cows in Scotland during the first year's operation of the order, fully 370 were notified in the six counties (Dumfries, Kirkcudbright, Wigtown, Lanark, Linlithgow, and Midlothian) which are large contributors to the daily milk supply of Edinburgh. It is evident that the number of cows supplying tuberculous milk in Scotland is by no means small, and that the milk supplied from the country to all Scottish towns must frequently contain tubercle bacilli. Furthermore, these figures, I consider, harmonize with the high percentage of tuberculous contamination which I have found in country milk as sold in the Edinburgh milk shops.

Samples of Mixed Milk collected from Edinburgh Milk Shops (November, 1913, to May, 1914).

* Average percentage for city.

With such a milk supply as that of Edinburgh, which yields tubercle bacilli in 20 per cent. of the samples examined, the legislative measures required to render this supply pure are far-reaching.

The Control of Bovine Tuberculosis.

In the light of present knowledge bovine tuberculosis can no longer be considered a negligible factor in respect to the spread of tuberculosis amongst children, more especially since unsterilized cow's milk in Scotland is a vehicle by which tubercle bacilli must very frequently be introduced into the bodies of children.

The control of bovine tuberculosis is undoubtedly a large undertaking, but I am convinced that important results would follow from local authorities being compelled to provide for a regular and adequate system of veterinary inspection by full-time officers, the frequent bacteriological and experimental testing of samples of milk and milk products by skilled bacteriologists, and the destruction of all cows which show evidence of udder tuberculosis, or which are clinically tuberculous.

While a number of towns such as Manchester, Liverpool, Birmingham, Sheffield, and Leeds have realized the necessity for taking steps to deal with this problem, very little has been attempted by local authorities in Scotland to prevent tubercle-infected milk from reaching the public—

in fact, sometimes the actual regulations enforced being considerably less than those set forth on paper. For example, the Edinburgh local authority has had the power under the Municipal and Police (Amendment) Act since 1891 for the medical officer of health or a veterinary inspector to enter any byre or cowshed wherever situated if the milk produced therein is being sent for sale within the city, to examine any cow kept therein for the supply of milk, and to take samples of milk. Such important powers as regards the country supply of milk to the city have, I regret to say, scarcely been exercised at all by the said local authority. It is clear that for the proper exercise of these powers a sufficient staff of veterinary inspectors is necessary.

General Conclusions.

The high incidence of tubercle bacilli in milk imported to Edinburgh from country districts clearly points to the necessity of measures more stringent than those at present enforced being taken to prevent tubercle-infected milk reaching the public.

The danger from infected milk in Edinburgh cannot be regarded as other than serious. The fact that the supply of milk from country byres, which yield almost two-thirds of the total amount of milk consumed daily in the city, and of which there is practically no veterinary inspection, is increasing annually, strongly emphasizes the necessity for radical changes. It is a question which must be taken up and dealt with by the local authority. The only way to safeguard the public against this danger is, without further delay, to grapple with the existing inadequate supervision of the milk supplied to Edinburgh from rural districts. The existing local powers should be exercised to their full extent and a sufficient staff of veterinary inspectors established. But veterinary inspection cannot do everything. A systematic bacteriological examination combined with experimental testing (by inoculation of animals) of milk samples carried out uninterruptedly year after year is indispensable—such samples to be collected not only from milkshops and milk vans, but at railway stations. Bacteriological methods and veterinary inspection must go hand in hand, the former serving as a guide and also a check upon the latter.

It must be borne in mind, however, that no purely local effort will suffice to eradicate bovine tuberculosis. The provision of legislation for the whole country is very desirable in view of the inadequacy of the powers at present vested in Scottish local authorities to ensure a pure milk supply. Additional and more stringent regulations will have to be drawn up and applied so as to exclude the recognizably tuberculous cow from the milk supply, whether the seat of the disease is in the udder or elsewhere. Means must be provided for tracing diseased milk back to its source and stopping the source of such milk. These requirements can only be secured by the universal compulsory inspection of dairy cows by full-time veterinary inspectors, assisted by experienced bacteriologists provided with adequate laboratories. It is unfortunate that such demands are not fully met in the Milk and Dairies (Scotland) Bill now being considered by Parliament. Efforts should be made to have these incorporated in the bill.

Until the proper legislative measures are obtained it is advisable for the public to boil all milk consumed in their families.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

APPENDICULAR GRAFTING.

In 1911 Lexer[1] made use of the appendix to repair the deficiency occurring in the urethra as the result of excision of a stricture. Streissler[2] in the same year used the appendix to restore the urethra in a case of hypospadias, and more recently Babcock[3] transplanted the right ureter into the appendix in a case of carcinoma of the bladder.

In October, 1913, I saw a boy, aged 11, who had on the previous day been walking along a railing. He had slipped and, falling astride the railing, had bruised the perineum. When I saw him any bruising that may have occurred was masked by extravasation of urine. I opened freely into the tissues of both groins, and then performed suprapubic cystotomy and passed a rubber catheter from behind forwards. Two days afterwards the temperature reached 105° F., and he was in a very critical condition. Extensive sloughing of the tissues in the perineum and groins took place, with loss of the perineal portion of the urethra. The sloughs separated slowly and cicatrization finally obliterated the perineal urethra. All urine was discharged through the suprapubic opening. In November I attempted to reconstitute the urethra over a catheter. The wound broke down, urine was discharged from the perineum for some time, but gradually the wound closed and the urethra was again obliterated, all urine being discharged suprapubically.

In March, 1914, I made another attempt to reconstitute the urethra and again failed. Further attempts of a similar nature I considered to be unwarranted, and I thought it better that all urine should be passed suprapubically until the perineal tissues were healed, and then to attempt grafting the saphenous vein into the deficiency.

On May 29th I again dissected out the proximal and distal portions of the urethra in the perineum and removed as much scar tissue as possible. I then resected a portion of the saphenous vein, but finding its calibre much too small for my purpose, I opened the abdomen and removed the appendix. It seemed quite healthy, but contained a threadworm. It was impossible to remove the serous coat, so I scarified it thoroughly with a scalpel, and then removed about half an inch of its distal end. The graft finally prepared was over an inch in length. I passed a rubber catheter through the penile portion of the urethra and then threaded the appendix on it. The point of the catheter was then passed on into the bladder. It was now quite easy to unite the mucous membranes of urethra and appendix at either end, and, that being accomplished, the wound was closed.

On June 3rd the catheter came out (it had been stitched in with catgut) and another catheter was passed under an anaesthetic and stitched in.

On June 8th the catheter was left out, the perineal wound was healed, and all urine since that date has been passed naturally. The boy is now walking about and micturates freely and normally without discomfort.

In conclusion, I would point out that Axhausen's experiments on transplantation of mucous membranes show definitely the value of autoplastic as opposed to homoplastic or heteroplastic grafts. The biochemical properties of the individual are so diverse, and anaphylaxis is of such potency in the subsequent fate of grafted mucous membranes, that it would seem imperative to rely only upon autoplasty.

HOUR-GLASS CONTRACTION OF UTERUS AFTER PITUITARY EXTRACT.

I received an urgent message on June 28th to see a healthy multipara (aged 35 and at full term), as she had a profuse "show," and her "waters had come away"; I was assured that she had had no pains.

I found the patient had lost a fair amount of blood, which was slowly oozing; the os was dilated to the extent of two fingers, and the presentation was a normal vertex. The membranes had ruptured. There was no placenta praevia.

As the bleeding continued and no pains supervened, I applied a tight binder, and administered 1 c.cm. of pituitary (infundibular) extract hypodermically. Pains came on immediately, the haemorrhage ceased, and two hours afterwards the child was born. An hour and a half after the birth of the child I decided, after several futile attempts to express the placenta, to introduce my hand into the uterus, as I strongly suspected hour-glass contraction. I discovered, well above the cervix uteri, a typical constriction, which embraced the umbilical cord so tightly that I had some difficulty in slowly dilating it digitally and liberating the imprisoned placenta, which was found detached and normally situated in the upper segment of the "hour-glass." The amount of blood lost *post partum* was not abnormal.

I had only once before used pituitary extract, and that was in a case of severe *post-partum* haemorrhage, when

the results were excellent. I have always avoided it in normal labours (it is occasionally recommended as a time-saver), as it has seemed to me—theoretically, at any rate—that the risks must be the same as those of ergot given before the completion of the third stage. The case here recorded would appear to show that at least the production of hour-glass contraction is a potentiality shared by both these useful drugs.

WEST HAM UNION INFIRMARY.

A CASE OF EXTRAORDINARY SHORTNESS OF THE SMALL INTESTINE.

(By J. C. MUIR, M.D., Medical Superintendent.)

A GIRL, aged 15, was admitted on December 27th, 1913, with a history of abdominal pain for three weeks, referred mostly to the right lower abdomen. She was fairly well nourished and the other organs were normal. The abdomen was full, rather resistant, and very slightly tender, but nothing definitely abnormal could be detected. There was some gurgling and the caecum was thought to be distended. She remained under observation for some weeks. The bowels were somewhat stubborn, but with aperients and enemas almost daily actions were obtained which were of normal character.

On February 9th a very definite swelling was found in the lower abdomen, consisting obviously of distended coils of gut, with visible peristalsis and marked gurgling on palpation. There was evidently a partial obstruction of some part of the intestine.

Operation.

On February 12th, under open ether, the abdomen was opened to the right of the middle line, below the umbilicus. The swelling was found to consist of very adherent and tangled coils of ileum in its lowest part, causing considerable obstruction of the lumen near the ileo-caecal valve. The ileum was greatly distended, being fully as large as the large gut, and its peritoneal coat was much thickened, and had a milky appearance. There was, in fact, a chronic peritonitis, not confined to but most marked over the lower ileum. Here and there were small milky tubercles, but the appearances were not those of ordinary tuberculous peritonitis. The tangled portion could be isolated, and was resected. This was considered preferable to any form of short-circuiting, which would have left the tangled and distended coils untouched. In view of subsequent events it does not seem likely that short-circuiting would have met with any greater success. The anastomosis (end-to-end) was made with some difficulty, as there was only an inch or two of ileum left above the ileo-caecal valve, and it could not be brought fully outside the abdomen. The appendix was normal, except that it contained two small stercoliths.

After-History.

The patient was very collapsed afterwards, but rallied well in the next few days. There was evidently some failure of technique on my part, for a fortnight later she had to be anaesthetized, and a large collection of foul pus was evacuated from the abdomen and a tube inserted. The anastomosis, however, must have held, for no faeces ever escaped. From this date onwards the temperature was normal. The abscess healed rapidly and was closed a fortnight before death. From the date of the operation, however, she had intractable diarrhoea, from three to five or six loose stools daily, and, with some temperary rallies, she wasted progressively. The abdomen seemed normal, and no disease was detected in other organs. She died on April 26th, some ten weeks from the date of operation.

It is necessary to lay stress on the length of gut removed. When uncoiled after removal there appeared to be some 4 ft. of it. My colleague, who assisted me, estimated it at less than this. It will be generally agreed that the tendency of the surgeon is not to minimize the length of gut which he removes. In view of what followed the point is of some importance.

Post-mortem Examination.

There was extreme wasting and chronic peritonitis, with extensive adhesions, but no enlarged glands or other evidence of tubercle. There was marked thickening of the peritoneal layer of some parts of the intestine, especially of the large intestine from the splenic flexure down to the rectum. A portion of this was examined microscopically for evidence of tubercle, but the pathologist's report was negative. The anastomosis was sound and admitted two fingers. A point of minor interest is that one layer of the celluloid thread used was still quite unabsorbed; the other was not seen.

The small intestine was removed *in toto* from pylorus to caecum and measured only 17 in. It ran in one S-shaped curve, passing from the caecum a little to the left of the middle line before turning back to form the curve of the duodenum. It was normal in appearance, texture, and calibre, all the abnormally thickened and dilated part having been removed. Except for some old pleural adhesions, the other organs were normal.

REMARKS.

The cause of death was only too obvious—namely, insufficient digestive and absorptive surface in the small intestine. Allowing 4 ft. for the part removed, the total length was well under 6 ft. It is true that the part removed was not actually measured, but 4 ft. was the most liberal estimate amongst those who saw it, at a time when there was no suspicion of the unfortunate state of affairs. Even allowing—which I do not admit—that it may have been a little more, the total length still remains extraordinarily small. A standard textbook of anatomy gives 15½ ft. as the extreme limit of variation downwards.

I must admit freely that the condition was not noticed at the time of operation. I assumed, perhaps unjustifiably, that there was plenty of small intestine above, knowing that I was not more than 2 or 3 ft. (as estimated before uncoiling) from the ileo-caecal valve, and I only pulled down enough to get a healthy part for anastomosis. The presence of chronic peritonitis and adhesions did not, of course, make examination particularly easy. The failure of observation was thus, though disastrous, perhaps pardonable.

Reports of Societies.

ROYAL SOCIETY OF MEDICINE.

ANNUAL MEETING.

THE annual meeting of the society was held on July 7th, under the chairmanship of the president, Sir FRANCIS CHAMPNEYS. The annual report of the council recalled the various activities of the society during the year, to most or all of which our columns have borne witness from time to time. The report stated that the subcommittee of the Finance and General Purposes Committee had given careful consideration to the possibilities of effecting economies in the expenditure of the society. The report of the honorary treasurers showed that the balance of income and expenditure was not altogether satisfactory; the ordinary expenditure had risen from £10,742 to £12,292, and the total was raised by the extraordinary expenditure to £13,255. The income had amounted to £12,451, and fell short of the expenditure by nearly £804. The extraordinary expenditure included that on "at homes," and on the reception of the International Medical Congress, amounting together to about £347. The income, though it had fallen short of the expenditure, had exceeded that of the previous year by £1,664.

The statement of assets and liabilities showed that the

financial position of the society was quite sound, but as it was believed that its work could be made more effective if it could command a larger income, Dr. ROBERT HUTCHISON moved a resolution to raise the subscription of Fellows residing within a radius of four miles of the society's house to four guineas. The number of Fellows present was small, but this proposal led to considerable discussion, and finally a resolution was adopted instructing the council to consider in what way the subscription could be raised, and to report how the increased money should be spent.

The report of the honorary librarians showed that the total number of books and pamphlets added during the year was 3,675. The use of the Allchin room, where readers, if they so desire, can have books they are engaged upon left undisturbed for unlimited periods if not required by other Fellows, had been much appreciated.

The number of Fellows of the society is now 2,854, of whom 1,016 are country members and 264 foreign; in addition there are 859 members, including 504 country and 130 foreign.

The PRESIDENT, in a brief address, said that the society had in response to a request of the Privy Council been able to give advice with regard to the proposal to establish an international health bureau at Jerusalem, and he believed that as Government departments realized the command the society had of expert opinion, such requests for advice would become more frequent. He referred with regret to the resignation of the editor of the *Proceedings*, Dr. Nachbar, who had been appointed medical superintendent of St. George's Hospital, and went on to discuss the large amount of matter which was received from various sections for publication. Sir Francis Champneys said that he considered that some of the sections held too many meetings, or at any rate sought to obtain too many papers, for the holding of meetings for discussion only was not open to criticism. He suggested that a rule should be made by all sections that a paper should not be accepted for reading until it had been placed in the hands of the committee of the section. In conclusion he thanked the officers of the society for the support they had given him during his two years of office, and expressed his confidence that the welfare of the society would be safe in the hands of his successor, Dr. Frederick Taylor.

A vote of thanks to Sir Francis Champneys, proposed by Sir WILLIAM CHURCH, and seconded by Sir RICKMAN GODLEE, was carried by acclamation.

MR. A. BOWES ELLIOTT, F.R.C.S., of Abergele, North Wales, has presented to the library of the Royal College of Surgeons the medical log of the *Lord Stanley*, slaver, kept by his grandfather, Christopher Bowes, who was surgeon to the ship. The final pages bear two official notes. The first is the surgeon's: "Custom House, St. George, Grenada. I, Christopher Bowes, Surgeon of the ship *Lord Stanley*, George Farquhar, Master, from the Coast of Africa, do swear that the foregoing is a just and true journal, kept by me during this present voyage, to the best of my belief.—(Signed) Christopher Bowes. Sworn before me the 14th of August, 1792.—George Ferguson, Clk." The second note reads: "Custom House, Port of St. George, Grenada. These are to Certify, that the foregoing is a true Copy of the Original Journal delivered in and sworn to. Given under our Hands and Seals of Office, the 5th of September, 1792. George Ferguson, Collr., J. Williams, Compr." The total number of slaves on board, when the ship started on June 21st, was 389, namely: "Men" 214, "men boys" 67, "boys" 10, "women" 68, "women girls" 24, "girls" 6; from this total of 389 were deducted 3 deaths in port and 2 men sent ashore, one being lame in his arm and one, a "man boy," affected with epilepsy. According to the calendar and tables in the log, the voyage took thirteen days, and there was one death every day. There was clearly a great deal of sickness, but the notes are very brief, covering no more than fourteen pages. "The boy No. 1 was attacked with pains in the bowels, with diarrhoea," "The man No. 18, senseless this morning, at 10 a.m. died," are samples of the entries. It is not surprising, therefore, that Sir Ronald Ross, who has read through the log, admits that it cannot be decided what the slaves were suffering from; but quite possibly many had tried to poison themselves on being captured, for Africans are experts at poisoning. An epidemic similar to summer diarrhoea is also probable.

Reviews.

MANSON'S "TROPICAL DISEASES."

THE fifth edition of Sir PATRICK MANSON'S *Tropical Diseases*[1] is welcome, and will be eagerly read by many. Rivals have sprung up since the early days when the work reigned supreme, but it still holds its place amongst these younger and vigorous offshoots. There is, we believe, room at the present day for an English standard work on tropical medicine by many authors, and if Sir Patrick Manson could see his way to making his work the basis of this, then it would keep his name and his work, and incidentally his teaching, green for many a year to come. Knowledge has advanced so much in recent years that it is impossible for any one man, however gifted, to keep completely up to date in the many diverse subjects that are now classed under the heading of tropical medicine. It has been said, not without truth, that a work on tropical medicine begins to be out of date even before it is published. A perusal of the pages of the *Tropical Diseases Bulletin* will certainly show what an enormous number of papers are now being written on tropical subjects, though at the same time it must be admitted that the vast bulk of them contain nothing new. Most of the papers of the present day are really a rehash of old work with little or nothing new added. In this way the subject is cumbered, and it becomes more difficult to extract the wheat from the chaff.

In the present edition the text with the index is increased by only 61 pages. There are some completely new chapters—namely, one on phlebotomus fever and one on rat-bite disease. The latter, of course, is not strictly a tropical disease, and the same may be said of pellagra, but as they are uncommon and occur in the tropics it is well that they should be discussed in books on tropical medicine. In addition to these chapters new matter on other diseases is incorporated in the text as it existed in the fourth edition, published in 1909, less important material finding a place in footnotes or in small print. The number of coloured diagrams has been increased, and we notice new photographs and new black-and-white sketches throughout the pages of the manual. These, of course, add to the value of the work and make the reading of the text a much greater pleasure. The difficulty of combining the scientific with the clinical aspect of the different diseases has now become a serious problem for the writer of any handbook of tropical medicine. Castellani and Chalmers in their well-known manual separated the two, and the plan has its advantages.

As Sir Patrick Manson says in his preface, the prevention and treatment of tropical diseases have not been neglected in recent years, and more than one investigation has had most gratifying results. The treatment of yaws and relapsing fever by salvarsan bears out this statement, and the substitution of emetine for crude ipecacuanha is, as the author observes, a very useful advance in the treatment of amoebic dysentery and amoebiasis generally. There are many problems in tropical medicine still requiring solution, however, and very often as new work is being completed on one subject new ideas are gained about another. Verruga peruana is an example in point. Oroya fever and the verruga condition, till now always spoken of as phases of the same disease, have recently been shown by Strong and his fellow workers to be two quite distinct diseases. If this conclusion be accepted, as we believe it should, many interesting and new problems arise for solution. Ulcerating granuloma is another disease requiring further research; it is mentioned briefly in the present work, but Wise's most recent observations on the parasite-like bodies found in the lesions are not discussed. We wish that Sir Patrick Manson could be persuaded to rewrite the chapter on filariasis. No one can be more competent to bring out all the points of the story. Another section which is rapidly gaining in importance and upon which much work has recently been done is that of tropical skin diseases.

---

[1] *Tropical Diseases: A Manual of the Diseases of Warm Climates.* By Sir Patrick Manson, G.C.M.G., M.D., LL.D.Aberd. Fifth edition, revised throughout and enlarged. London: Cassell and Co., Limited. 1914. (Crown 8vo, pp. 957; 239 figures. 12s. 6d. net.)

For the use of students a good general sound account is what is required, and this is what Sir Patrick Manson's book provides. Long may it do so, and long may coming generations of students enjoy a perusal of its pages.

I.K. (IMMUNKÖRPER) TREATMENT.

THE introduction of a new method of treatment, dependent for its success on the skill and knowledge with which it is employed, too often meets with early condemnation by those who use it without these qualifications. Many times has the premature vauntiug of an idea, sound in itself, led to indiscriminate application and failure. Then it is only after years of patient observation that the original plan takes its fitting place. Among the patient workers whose original ideas are gradually obtaining recognition, the name of Dr. Carl Spengler of Davos stands prominent. His views, founded on laborious experiment, have been scouted by some other workers, who maintain that they are not correct in theory and are ineffective in practice; but others, who have given perhaps closer attention to them, hold a very different opinion. Of these latter may be classed Dr. W. E. M. ARMSTRONG, who has himself studied in Dr. Spengler's laboratory, and has by no means been blinded by the enthusiasm that sometimes warps the judgement of the pupils of a masterful teacher. He has lately published a small book [2] which we can commend to every one who really wishes to understand the system of treatment that has been somewhat enigmatically designated as "I.K."

These mystic letters imply nothing more than "immune bodies." The principles of immunization by active and passive means are generally accepted. In the one case the tissues of the patient are stimulated to generate their own antibodies, while in the other the antibodies are prepared in the tissues of another animal and injected ready-made into the patient. This latter method, of which the antitoxic treatment of diphtheria is the best known example, has the advantage that it produces less constitutional disturbance in a body which has already been severely poisoned by the virus which it is sought to neutralize.

Dr. Spengler's researches have led him to the conclusion that a far larger proportion of the so-called protective substances are present in the red corpuscles than in any of the other constituents of the blood, and hence he has prepared his immunizing solution from the blood of highly immunized animals without separation of any of its component parts. This solution he believes to contain a very large proportion of immune bodies, and by means of them he maintains that a lytic effect can be produced upon the bacteria, as well as an antitoxic effect upon the poison which is produced during their disintegration.

A striking phenomenon has been observed with respect to the relative effects of high and low degrees of dilution. The action of the I.K. solution seems to increase in power with the amount of dilution even to the almost inconceivable extent of a thousand billion times. It must be added that competent observers have not been able to endorse this observation, although it has been vouched for by many skilled workers. Polyvalency has also been claimed for it, and this is believed to be due to the constant presence in blood of immune substances against all forms of pathogenic bacteria. Apart from clinical evidence of its activity, the microscope has served to show that active lysis takes place within a short time of administration. The changes in the bacilli can be made manifest by a method of staining whereby the granules in each bacillus appear black, the body of the micro-organism retaining the red colour. The breaking up of the bacillus under the influence of I.K. can thus be watched. Dr. Spengler has designated the disintegrated granules *Splitter*. It is further claimed that the presence of the antitoxin can be microscopically identified.

As regards the practical application of the method in cases of tuberculosis of the lungs, it would appear that beneficial effects appear at once, but do not last long. They are renewed with every fresh injection, and the progress towards recovery is fairly steady. It is obvious that no hard and fast lines can be laid down for practical guidance in routine work. In every case the operator must feel his way. The use of the I.K. treatment should not be attempted by any one who has not fully grasped the ideas on which its employment is founded. It would seem that the intelligent use of dilution appropriate to each case must be an important factor in the attainment of success, and in the compact and clearly descriptive account which Dr. Armstrong has put before the profession the whole subject will be found to be dealt with in the spirit of the impartial investigator, not too severely critical of doubtful points nor over-enthusiastic as to successes already achieved.

[2] *I.K. Therapy, with Special Reference to Tuberculosis.* By W. E. M. Armstrong, M.A., M.D.Dubl. London: H. K. Lewis. 1914. (Demy 8vo, pp. 93. 5s. net.)

CEREBELLAR LOCALIZATION.

As long ago as 1876 Nothnagel remarked that the vermis and the two lobes of the cerebellum must have different functions, and similar observations have frequently been made by physiologists since that time. But the cerebellar functions do not lend themselves very readily to experimental investigation. From the experimental point of view they consist almost entirely in disturbances of equilibration and the co-ordination of muscular movements; and when the cerebellar lesion is small these disturbances may be transient, and for that reason easily missed. For these causes the part played by the cerebellum in the normal processes of life has always remained a little obscure; the duties assigned to it have never seemed adequate to its size and complicated structure. Recently, however, it has been very carefully studied in France, and an attempt to localize the representation of definite muscular groups in definite portions of the cerebellum has been made by ANDRÉ-THOMAS and DURUPT,[3] working in Dejerine's laboratory at the Salpêtrière. It is generally agreed that the limbs are represented by centres of co-ordination in each cerebellar hemisphere of the same side, and that the head, neck, and trunk are similarly represented in the vermis. As for the methods of experiment employed, it has always been found that excitation of the cerebellar cortex or nuclei yields ambiguous results; some hold that the cerebellum is directly excitable, others that it is not, and in any case the facility with which the excitation spreads from one part to another makes the exact interpretation of results impossible. It is quite otherwise, however, with ablation experiments, in which definite portions of the cerebellum are removed or destroyed, while the animal (a dog or monkey) is under the influence of a general anaesthetic. This, therefore, is the method of experiment adopted by these authors. They found that minute lesions of definite parts of the cortex of the cerebellar lobes produced functional disturbances in certain muscle-groups of one limb; more extended lesions would affect the whole limb, while extensive lesions affected both limbs on the same side. These functional disturbances are not paralyses; they are divided into four separate groups. First is dysmetria, a disorder of active movement; the initial impulse is unduly strong, the movement is too rapidly made and arrested too late, with the result that the objective is overpassed. Second comes passiveness; in given directions the affected limbs can be placed in various unnatural attitudes, which the animal makes no attempt to correct. Thirdly, if the limbs are moved in directions opposite to those in which passiveness is shown, the reaction is immediate and excessive. And fourthly, the affected limbs cease to react to various normal modes of excitation. In a word, localized cerebellar lesions cause anisosthenia, or perturbation of the equilibrium between antagonistic muscles. For each segment of a limb, and for each articulation, there seems to be a cerebellar centre for each direction in which movement may occur—for flexion and extension, for abduction and adduction, for rotation inwards and outwards, to quote examples. In normal circumstances the centre presiding over, say, flexion is counterbalanced by the centre for extension; the two work together in antagonism, with the result that any desired degree of flexion or extension can be smoothly obtained. When one of these centres is injured by experiment or disease, the equilibrium between the two is upset, with the results indicated above. Probably the many cerebellar centres of direction are closely connected with one

[3] *Localisations Cérébelleuses.* Par André-Thomas et A. Durupt. Paris: Vigot Frères. 1914. (Med. 8vo, pp. 101; 94 figures. Fr. 6.)

another, so that the matter is not quite so simple as this; in addition it must be remembered that the cerebrum has a very powerful controlling influence over movements of all sorts, and it appears that it can compensate satisfactorily for losses of co-ordination caused by the smaller cerebellar lesions. But if the cerebral activity is deviated or preoccupied by such things as fear or external interests that deflect the attention, evidences of the cerebellar lesion reappear; and if the lesion is too extensive, this compensation can never be complete. If successive injuries are inflicted on the cerebellum of an experimental animal, compensation is each time impaired anew. The disturbances due to the first injury are aggravated by the second; compensation for the second lesion is less satisfactory than that succeeding the first.

THOUGHTS OF A PHYSICIAN.

AMONG the *Main Issues* discussed by Dr. STEEVES in his little collection of essays[4] are toleration, the child, courage, letter writing, sickness and health, gratitude, egotism, and the book collector. All are written with a delicate literary artistry which makes them charming to read and are informed with many wholesome and suggestive ideas. He pleads for a more rational and considerate treatment of children than they often receive from thoughtless parents. He truly says that children are often punished for a physical disability when they are really suffering from a disease which only the chance visit of the physician reveals. The truth is strongly impressed on those of us who remember the treatment meted out by ignorant teachers to little ones whose apparent stupidity and inattention were caused by nasal obstruction and adenoid vegetations. What a step forward was made by Meyer when he "gazed on the Pacific" of a throat packed with these little growths! We can remember one of the greatest English physicians of the day denouncing the whole thing as quackery; he would not look for himself because they had been brought to his notice by "specialists," whom he regarded as the pariahs of the profession. In speaking of appearances, Dr. Steeves has some wise words to say to persons whose belief in their own judgement of character leads them astray by unwarranted trust in a plausible manner. In an essay on letter writing, Dr. Steeves strongly condemns the lack of training in the use of their own tongue by boys at our public schools, the results of which are seen in young men who can write good Latin and Greek verse and cannot express themselves in decent English. Mr. Balfour said the other day that he had never been taught English at all. This is one of those things they do better in France, and the consequence is that every Frenchman of any education can write his language well, and among literary men there is a much higher standard of style than English writers possess. Sickness, says Dr. Steeves, rightly understood, has a moral lesson. "Many a man can remember how some attack of illness in the case of his friend has resulted in a complete change of character." On the other hand, this comforting doctrine must not be pushed too far; Weir Mitchell held that the influence of pain on the character was the reverse of good. Speaking of choice in literature, Dr. Steeves is very sound in his preference for the English classics, and he evidently pities the state of mind of those who airily pronounce Dickens and Thackeray "quite out of date." This is largely an affectation on the part of people nurtured on the unwholesome literary diet of which there is so much at the present day. We cannot follow Dr. Steeves through all the subjects of which he treats with such sanity of outlook presented with so much literary grace. We can only recommend the book warmly to readers who prefer good sense, the fruit of ripe scholarship and practical experience as a physician, to sensuality naked and unashamed, or, what is worse, tricked out with the Coan garment which by half hiding indecency makes it more alluring.

NOTES ON BOOKS.

THOSE who are called upon only occasionally to do necropsies and students about to commence their duties in the *post-mortem* room will find *A Handbook for the Post-mortem Room*,[5] by Dr. A. G. GIBSON, extremely useful. All the directions are given clearly, and there is a complete absence of irrelevant matter. The tendency to write in one place in terms of the metric system and in another in those of the English system is confusing and objectionable, but this is so commonly done that it cannot be said to detract from the general usefulness of the work.

In his small booklet on *Holidays*[6] Dr. C. D. MUSGROVE has put together much sound advice that should profit both the man in the street and paterfamilias to read before the holidays are due. It contains eighteen chapters, in which are considered the various types of holiday that may fall to the lot of each one of us, the ways in which they may be spent most profitably, and the dangers to which the incautious holiday-maker is exposed. Admirable common-sense rules for the avoidance of these dangers, so often underestimated, are given, while at the same time the possibilities of enjoyment often missed are pointed out. Dr. Musgrove's book makes a most seasonable appearance; it is well written, full of sound advice, and may be cordially recommended to the attention of the public.

The last published volume of *Guy's Hospital Reports*[7] has already been referred to on two occasions in the BRITISH MEDICAL JOURNAL. One of these references was in an article entitled "Wilksiana," which appeared in the JOURNAL of April 25th, 1914, p. 933; the other was to a note on Mr. William Wales's "List of Books by Guy's Men in the Wills Library, Guy's Hospital," in our issue of May 9th, 1914, p. 1028. In the scientific part there is a paper by J. Fawcett and H. Rippmann on carcinoma of the bladder associated with gall stones, based on 47 cases, brief notes of which are given in an appendix. Notes from the Throat and Ear Department: Enucleation of the tonsil (56 cases); acute suppuration of the frontal sinus or ethmoidal cells which caused suppuration in the orbit (4 cases); and cold paraffin wax injection for the rectification of depressed bridge of the nose (3 cases), are contributed by W. M. Mollison, A. M. Zamorra, and A. H. Todd. Under a special heading, "Neurological Studies," edited by Dr. A. F. Hertz, are notes on the etiology and treatment of sciatica by the editor; four cases of cerebellar ataxia in children, by Mr. E. S. Taylor; a case of polioencephalomyelitis associated with optic neuritis and myocarditis, by Drs. Hertz, W. Johnson, and H. T. Depree; progressive muscular atrophy associated with primary muscular dystrophy in the second generation, by Drs. Hertz and W. Johnson, who also record two cases of bilateral atrophy of the face; and ten consecutive cases treated by hypnotism, by Mr. F. G. L. Scott; Dr. E. P. Poulton reviews the state of knowledge in regard to creatinine and creatine. Drs. Lauriston Shaw and Herbert French report a case of splenomegalic polycythaemia or erythraemia; Dr. Hertz and Mr. W. E. Digby record a case of recovery from a duodenal ulcer produced by a burn; Dr. E. L. Kennaway contributes some notes on the excretion of acetone bodies; Mr. W. E. Tanner gives the results of a study of 440 cases of inguinal hernia; and Dr. A. Read Wilson discusses parasyphilis of the nervous system, with special reference to some of its rarer manifestations. The volume contains several well executed illustrations.

Dr. MAJOR GREENWOOD has contributed to the *City of London Illustrated* a historical poem on London of which he has been good enough to send us a reprint. It opens with the following invocation:

> O London, City of my earliest dreams!
> Home of my fathers, ancient Capital
> Of Britain's empire!

In thirty-one rhymed stanzas of nine lines he gives a sketch of the history of London and winds up by an appeal to the patriotism of its citizens to be—

> As stout of heart, as strong in enterprise,
> As was that London, whose remains we see.

As Dr. Major Greenwood truly says, "great and greater London" should beware of dissensions. The reprint is illustrated by two maps, one about 1658 and the other of the stile or steelyard from Van Wyngard's plan made for Philip II of Spain. The date given for the latter must be wrong.

THE BRITISH MEDICAL ASSOCIATION AND THE MEDICAL PROFESSION.

A CRITICAL REVIEW OF THEIR RELATIONS.

(Continued from page 27.)

VII.

ETHICS.

ETHICAL considerations underlay so many of the doings of the Association described in previous articles, and consciously or unconsciously influence so largely the actions of every medical man in the course of his daily labours, that it is worth while to devote a little space to a sketch of the work that the Association has done in this connexion. It will perhaps be more convenient to begin, so to speak, at the end of the story—that is to say, by describing the more recent actions of the Association in regard to ethics.

For the last ten years or so an Ethical Committee has been one of the essential portions of the Association's central mechanism, for though its members are appointed from year to year, the body itself is one of the standing committees of the Association under its existing constitution. It is called the Central Ethical Committee, because its primary duty is to act as a kind of reference committee in respect of all questions of an ethical character brought under the notice of the Council; in fact, though the Council reserves the right to hold an inquiry of its own should it think fit to do so, the Central Ethical Committee may be regarded as a court of appeal in respect of decisions by like bodies which form part of the local organization of the Association throughout the country. The fact that it has been found necessary to form a subcommittee to deal with cases which cannot await meetings of the full Committee, and that during the last ten years decisions have been reached on nearly a thousand points, afford sufficient evidence of the utility of the work done by the Association through this Committee for the medical profession at large.

Furthermore, this Committee is in some degree an initiating body, and with the approval of the Representative Body of the Association has completed several highly successful pieces of work of a somewhat different order from that above mentioned. Some years ago, for instance, it drew up a code of rules for the guidance of medical men who in the course of their duty are obliged to interview, and perhaps examine, persons in charge of other practitioners. Such events have long been common in connexion with the operation of the Workmen's Compensation Act, and owing to tuberculosis campaigns and the growth of school medical work occur now with yearly increasing frequency. The code clearly defines the rights and duties of all medical men concerned in such events, and thus makes it easier to avoid giving unintentional offence.

Perhaps an even more important piece of work done by the Central Ethical Committee some two years ago was to draw up a set of rules for the conduct of inquiries whenever there arises a dispute between medical men or any allegation of breach of professional good conduct. In drafting this document the Central Ethical Committee had primarily in view the desirability of meeting the needs of Branches and Divisions of the Association, but the work done involved what is in effect a practical expression of the general principles which should underlie any inquiries of the kind. These rules of court, as they may be called, are invaluable, for it is obvious that any inquiries regarding breaches of ethics should be conducted on lines to which no ethical exception can possibly be taken, and nothing equivalent to these rules exists elsewhere.

These rules were circulated throughout the Divisions of the Association, and have been adopted by most of them. They make it impossible that any case can be judged on *ex parte* evidence; ensure that all pertinent facts shall be duly considered; that no one having a direct interest in the question at issue shall have a seat on the inquiry committee; and give all those who do not agree with any decision that may be reached, and who are directly interested therein, a right of appeal. Any two medical men, for instance, who did not agree upon some point could refer the question for settlement—first, to the Ethical Committee of the Division to which they belong, then to the Ethical Committee of the Branch Council, next to the Central Ethical Committee, and finally, if desired, to the Council itself. It is, of course, very rare for such a series of inquiries to be held, because as a rule those concerned are ready to bow to the opinion of colleagues in their immediate neighbourhood if these have been in a position to consider matters on sound lines.

As already indicated, most Divisions are now in this position, so that there are now some 200 courts of honour, as they may be called, scattered throughout the country. That they should be so numerous, and that their procedure should be uniform is a very great advantage; it means that in practically every locality there is at hand a body whose dicta disputants can accept without loss of dignity; this makes for prompt settlement of disputes and consequent absence of bitterness.

Before the reconstitution of the British Medical Association in 1902 the number of these courts was much smaller, for there were only the Branch Councils to form them. Such Councils always paid a considerable amount of attention to ethical questions, but it was not until the Nineties that to do so became one of their formal duties. The immediate cause of this was a resolution passed by one of the Sections into which the work of the Annual Meeting was divided in 1895; an Ethical Section was held at this meeting for the first time, and among a series of resolutions passed was one to the effect that it would be expedient for every Branch to constitute its Executive Council into an Ethical Committee. The suggestion met with general approval, and was adopted by the Council. A further suggestion was that the Central Council should itself form an Ethical Committee to receive and report upon such matters as might be referred from the Branches or arise in any other way. This suggestion also seems to have been generally approved, and in effect to have been met, by adding the words "and ethical" to the title of an already existing committee, namely, the General Practitioners Committee. The latter was first constituted in 1893, and would appear to have been a kind of omnibus committee. Even before its title was expanded, it had been dealing with questions of an ethical character, and it was especially active in regard to questions of contract practice. It was, indeed, the fact that this committee found reason to regard much of the contract practice then in existence as ethically unsound that started the campaign against medical aid institutions on lines more effective than those which had previously been pursued.

So far as the term "ethical" is concerned, this committee had at least two predecessors at various times in the history of the Association. They were, however, special, not standing committees, and were appointed with a view to seeing whether they could evolve anything in the nature of a comprehensive code of medical ethics. As no final report from either of them seems to be extant, it may be supposed that both came to the same conclusion as that tacitly reached at much later dates by the General Medical Council and the Central Ethical Committee of the Association itself. It is to the effect that, as a general rule, every case involving ethical considerations should be judged on its own merits. The principles of ethics, as the founder of the Association, Sir Charles Hastings, pointed out, "exist in every well-governed mind and are identical in all circumstances, however variously they may be applied"; but in medical work circumstances tend so much to differ—minutely, it is true, yet materially—that only in a limited number of connexions is it useful or desirable to reduce general ethical principles to statutory rules. The belief that this view probably prevailed among the majority of members in early as well as recent years is further supported by the fact that in the Seventies the Association declined the offer of an ethical code which had been drawn up by a member, and did so despite the fact that this code was admittedly well conceived so far as concerned the indicated circumstances for the application of each of its rules.

It is also of interest to note that the Association—though, as already indicated, it took into consideration the desirability of a code of ethics being drawn up—never in its corporate capacity seems to have felt the lack of a code. It applied general principles and came to definite conclusions promptly on many occasions in the first fifty as well as later years of its existence, and proved itself a

fearless upholder of its views. An instance in point may be quoted from the year 1850 when it expelled one of its leading members because he persisted in meeting in consultation a man who had been shown to have obtained a diploma from one of the colleges by the presentation of false certificates. In the same decade, moreover, a still more prominent member—who had taken to practices which the Association at the time regarded as *contra bonos mores*—escaped a like fate only by timely resignation.

No one, indeed, who scans the newspapers published in the middle sixty or seventy years of last century can feel any doubt as to the need of the existence of a body holding strong views on ethical subjects, or can fail to feel some gratitude to the Association for what it has done in this connexion. Apart from blatant self-advertisement and almost undisguised connexion with admitted quacks and patent medicine vendors, quarrels between medical men not infrequently pursued lines which fortunately have no counterpart at the present day. As was said by a speaker at the annual meeting of 1859, "Every month produced scenes of contention in the courts of justice for which the profession had to blush." Many circumstances at that period favoured the prevalence of a low standard of ethics, and though the evils were recognized and numerous efforts made to stem them, the balance of force was on the wrong side for many years. In the earlier of these years one potent influence was that there was practically no admitted kinship between different departments of medicine. The ill-feeling between them, especially in London, was notorious; it was expressed at times in unmitigated terms, and would seem to have been perfectly sincere. There is evidence that improvement in this respect occurred towards the time when the first Medical Act came into view, but the disease broke out again with renewed vigour, though in a somewhat different form, a few years later, when specialism first began to arise.

Allusion to this factor has already been made in previous articles, but we mention it again because it was the hope of being able to eliminate its effect that directly originated one of the Association's most characteristic features. Those who shared the work of founding the Association proved themselves something more than skilled clinicians, for though at that date State medicine had yet to be born and pathology was still in its infancy, they obviously believed in preventive medicine, and showed themselves able to recognize the causes of a disease as well as its symptoms. They realized, in short, that one cause, at any rate, of the existing lack of that "harmony and good feeling which should ever characterize a liberal profession"* was that a medical life tended on the whole to be an isolated life, or in other words, that the circumstances of ordinary practice tended to keep medical men apart rather than bring them together.

This was the point on which those who took part in the foundation of the Association seized, and they determined that as far as possible its evil influence should be eliminated. Consequently they endeavoured to ensure that members of the Association should foregather at least once a year in circumstances likely to promote "friendly intercourse and free communication"* by devising the special features of an annual meeting of the Association.

Now, it is not uncommon for a Superior Person who has been present at a congress of one kind or another scornfully to describe it as having been "merely a picnic," but though the term could not be used by any reasonable person in speaking of any meeting whatever of the Association, it was nevertheless intended from the beginning that something of the spirit of a picnic should exist at its annual gatherings.

From the beginning of time—Association time—these meetings have been held in the middle of a July or August week, and lasted practically to its end; and, again from the beginning of time, they have always included a certain amount of business proper, a certain amount of science, and a certain amount of purely social intercourse. In the earliest years of all, the scientific work was limited to listening to a review by the President for the year of the scientific occurrences in the previous twelve months. A little later on persons were chosen to deliver addresses in medicine, surgery, and obstetrics; then came discussions on topics connected with these three subjects; and finally, as membership of the Association increased, the Sections multiplied to the number common in recent years. It is true that the amount of work now done in these Sections and the interest taken in their proceedings tend to make the annual meeting a very much more strenuous period than formerly, and that thanks to the importance the Association has acquired in the public estimation, the social doings now have a civic as well as a private character; but so far as ordinary members of the Association are concerned present-day meetings, in respect of length and division of time, are similar to those held fifty or more years ago.

They play, in short, exactly the part and produce exactly the results that those who originated them intended they should, and it is impossible to believe that any one who has ever seriously considered the subject will doubt for a moment that quite apart from their scientific results these gatherings of the British Medical Association, like the more frequent meetings of its Divisions and Branches, have been and always must be of immense moral value to the medical profession.

Any self-analyst must know that it is exceedingly easy to conceive an intense dislike for a person with whom one is merely acquainted by sight or by hearsay, or through the expression of his views in writing, or reports of what he has said at some public gathering; and the same self-analyst must also know that there are very few people in regard to whom it is easy to feel thoroughly vicious once one has met them on neutral ground. Practitioner A, for instance, sees B from time to time and is repelled by his appearance; he hears something about C which prejudices him against him; reads the paper of D and regards him as very ill-informed; hears of E expressing views which he regards as abominable; while into the hands of F passes a patient whom he would have wished to retain, and G in some professional connexion fails to exhibit the courtesy which A considers his due. There are, in short, a hundred ways in which ill-feeling or dislike may arise, only to soften or entirely disappear when the individuals concerned are brought into contact with one another on neutral ground. They then find either that their previous impression was entirely mistaken, or that, after all, there is something likeable about the man. There must be hundreds of members of the Association who have gone through an experience of this kind at an annual or other meeting of the Association, and not a few who date from an Association meeting a very warm friendship.

This is a fact which would make the annual meetings of the Association, as also its Divisional and Branch meetings, of high value even if no real work whatever were ever done at them. They bring together medical men of every kind, enable them to hear one another's views, to meet on informal terms. They thus produce a spirit of camaraderie which would otherwise not exist and create an atmosphere or moral medium which is highly favourable to the growth and maintenance of a high standard of medical ethics.

It is to these circumstances that may be attributed a proportion of the great improvement a study of the records of the Association and of independent sources of information shows undoubtedly to have occurred. Furthermore, seeing that the annual gatherings of the Association as a whole will continue, and that the meetings of its Divisions and Branches are likely to be more frequent than ever in the future, and that there now exists the mechanism for dealing with questions of ethics which has been described at the beginning of this article, there would appear to be no fear whatever that ethical standards will ever fall below their present level. They may, indeed, be expected to rise; for while in the past there has never been anything academic in the actions of the Association in regard to ethical matters, it is now in a better position than ever to ensure that when it pronounces decisions consequences shall follow them.

Finally, it may be said that while the records of the Association prove that many medical offenders against ethical principles have found reason to recognize that they cannot flout the opinions of their colleagues with impunity, they show, also, that the Association is entitled to gratitude from the profession for its readiness to defend medical men against whom ill-founded ethical charges have been brought by lay individuals or bodies. On several occasions

* Phrases used in the original prospectus of the Association.

the Association has spent large sums of money in their defence, and on others has been successful by other means in securing them the justice previously withheld.

The Association, in short, has not only helped to raise ethical standards, but has also endeavoured to enforce them on all parties concerned.

(To be continued.)

RESEARCH DEFENCE SOCIETY.

THE annual meeting of the Research Defence Society was held in the rooms of the Royal Society of Medicine on June 30th; Lord LAMINGTON, who was recently elected President, was in the chair, and there was a large attendance, which included many ladies. Among those present were Sir James Reid, Sir John Tweedy, Professor Cushny, Sir David Ferrier, and Sir Wilmot Herringham. Expressions of regret for inability to be present were received from, among others, Mr. Arthur Balfour, Mr. Waldorf Astor, M.P., Lord Rayleigh, Sir John Brunner, Lord Hugh Cecil, Lord Cromer, and Sir Francis Darwin.

Reports.

The report of the committee stated that since last June many new members and associates had joined the society; and the number of names on its books was now above 5,000. They had lost, by death, many good friends—among them the late President, Sir David Gill, who in March, 1912, succeeded the first President, Lord Cromer. The work of the society during the year had included arrangements in connexion with more than 100 meetings, lantern lectures, or debates. Lectures on subjects associated with the work of the society have been given at many public schools—Eton, Winchester, Rugby, Charterhouse, Westminster, St. Paul's, and elsewhere. On several of these occasions moving pictures had been shown. The plan for a permanent bureau and exhibition in London, in one of the principal thoroughfares, had been postponed in favour of a temporary bureau now in one town, now in another. Temporary bureaux had been opened in Southampton, Bournemouth, Hastings, Bexhill, and Hull, with very satisfactory results. At several important exhibitions, in London and elsewhere, stalls had been arranged. The opinion was expressed that the opposition to all experiments on animals was losing ground among educated people, in spite of the unceasing efforts of the antivivisection societies to make their cause popular.

The Treasurer's report showed a considerable increase in subscriptions and donations. By donation of £10 or more during the past year, the society had gained many new members.

Lord KNUTSFORD, in moving the adoption of the reports, thanked Lord Lamington for accepting the presidency, a post in which, owing to his knowledge and experience, he was eminently well qualified to succeed the two distinguished men who had preceded him. Every year of the society members grew more determined to make the truth better known to the general public. It was usually rather difficult to get at the truth of statements made by antivivisectionists, as when particulars were sought for it was generally found that the alleged incident had occurred in some out-of-the-way place, and the time was last century, or even before Christ. He referred to an antivivisectionist meeting which was very poorly attended and very well reported; but he said it was now known that that report had been paid for at advertisement rates. At another similar meeting each member of the audience had been bribed to attend by the offer of ninepence a head and a free ride in a brake.

President's Address.

Lord LAMINGTON said that the society was really a protecting guard for science, in its noblest form, against those who were led by their emotions rather than by their reason. Its desire was to reduce human and animal suffering, and on no account to encourage any practice which could possibly tend to permit callousness or indifference to the pain suffered by others. The whole question of cruelty to animals should be considered in relation to the question, How far it might be brutalizing to the human mind. Taking this as a standard, the antivivisectionists should have large reserves of kindly feeling toward their fellow beings: but experience, unhappily, proved that the language they used was calculated to wound most deeply the feelings of those engaged in work for the benefit of humanity. The cruelty which pervaded the animal world perplexed many minds, but he was honestly convinced that it was not physical pain that caused the greatest amount of suffering to animals; it was when their instinct of self-preservation took alarm that they suffered. Any one who had seen wounded wild animals must have noticed how, when unalarmed, they appeared indifferent to their wounds. It was only when their instinct of self-preservation was aroused and they became aware of their disablement that they seemed to suffer. Even amongst mankind, uncivilized races did not feel pain in anything like the same degree that civilized people did. Only 5 per cent. of all the experiments made involved an operation. These experiments were made under anaesthesia, and in many of them the animal was killed under the anaesthetic; 95 per cent. of the experiments were inoculations or of the nature of inoculations. The antivivisectionist would exclaim, "But think of the suffering caused to animals by such inoculations as that of cancer!" He (Lord Lamington) could only say that he had seen guinea-pigs infected with cancer and moving about and feeding apparently without any pain or discomfort. It should be remembered that a special condition was attached to certificates under the Act, enjoining that any animal which was in severe pain, likely to endure after an experiment, should be killed, even though the object of the experiment had not been attained. If persons who had any doubt on this matter read the report of the Royal Commission, they would be convinced that any actual pain caused was infinitesimal. Let this be compared with any of the operations which took place on any ordinary farm—the mutilation of cows and pigs, the extraction of teeth, neurectomy, which were all frequently done without any anaesthetic whatever. There were some antivivisectionists who affirmed that nothing had been gained from scientific research, whereas it was by the help of experiments on animals that the whole science of physiology had been advanced. In the same way the true character of many diseases had been discovered. It was to experiments on animals that almost every important remedy which had come into use in the last forty or more years was due—for example, diphtheria antitoxin, thyroid extract, cocaine, chloral, phenacetin, adrenalin, salvarsan, and many more—and experiments on animals had helped towards the discovery of the protective treatments against rabies, cholera, plague, Malta fever, and typhoid fever. By such discoveries as these, the efficiency and health of the nation had been promoted, workers in dangerous trades had been safeguarded, and protection had been given to the man on foreign service. In the animal world live-stock had been benefited in the contest against infectious illnesses, and a great advance had been made towards the curative treatment of the bacterial and parasitic diseases of the higher animals. He did not wish to attack the antivivisectionists, and the chief business of their Research Defence Society was not mere fighting. It was the quiet steady education of public opinion as to the true character and method of experiments on animals in this country, and the great advantages which these experiments gave not only to human life, but to the life and health of the higher domestic animals. He denied altogether that men were not entitled to make experiments on animals to protect themselves from diseases, and he was convinced it was by the mercy of God that human science and research had done so much already to alleviate the sufferings of humanity.

A vote of thanks to the President for his address was carried, on the motion of General Sir REGINALD TALBOT, seconded by Dr. SANDWITH, in the absence of the Bishop of North Queensland, from whom a letter was read. Dr. Sandwith said that the most satisfactory feature of the society's work was the success of the numerous branches established in big cities. He paid a tribute to the work of Mr. Stephen Paget.

Cinematographic Demonstration.

After the meeting Mr. STEPHEN PAGET showed moving pictures of the cholera vibrio, the bacillus of typhoid fever, spirochaetes in the blood of a fowl, agglutination

of spirochaetes, Leishman bodies (kala-azar), *Trypanosoma gambiense* (sleeping sickness), the mechanism of phagocytosis, and the mosquito. The disease caused by these parasites was explained and the mode of their action in producing infection was shown. The part played by animal research in these discoveries and the power of controlling disease thereby attained was made clear.

Nova et Vetera.

A SYRIAN BOOK OF MEDICINE.

SYRIA probably first got its knowledge of medicine from Egypt, which by merchant caravans and military expeditions carried civilization into Western Asia. When the Sassanian King, Sapor I (A.D. 240–273) founded Gundhê Shâhhûr (Gondisapor) he took thither Greek physicians who introduced the medicine of Hippocrates into the East. Before the close of the third century of the Christian era the writings of Greek physicians and philosophers were being translated into Syriac. Dr. Wallis Budge has recently published the text of the great Syriac Book of Medicines, edited from a manuscript in his possession and has added an English translation.[1]

The work is in three sections, the first of which consists of lectures translated from Greek into Syriac by a Syrian physician who may have been attached to one of the great medical schools which existed at Edessa (Urfa), Âmid (Diarbekir) and Nisibis in the early centuries of the Christian era. Neither the name of the author nor that of the translator is given and some of the lectures are missing. The system of medicine expounded is fundamentally that of Hippocrates, whose actual words are quoted in several places. The author regarded disease as the result of natural causes, and lays great stress on a knowledge of symptoms and on prognosis, diagnosis, etiology, and diet. He insists on the importance of suitable food, in health as well as in disease, and strongly condemns overeating and overdrinking. In most diseases he advocates the use of purging and bleeding. The enema was in frequent use, and fomentations, poultices, and baths were largely employed. Suitable food, a cool, airy dwelling-place, proper clothing, water from a swiftly running stream, absence of all mental and physical fatigue, and sufficient sleep are recommended as means of health. The prescriptions given number nearly 1,000. Many of them are attributed to Galen, Dioscorides, and others of the older physicians, while many are of Egyptian, Persian, and Indian origin. They resemble in form those found in the Ebers Papyrus. Throughout, the author insists on the independence of the art of healing and its freedom from magic and priestcraft.

In the second section astrology comes on the scene; this was evidently introduced into the manuscript by another author or compiler whose mind was held in bondage by omens, portents, spells, divinations and planetary forecasts. The third section contains 400 prescriptions composed by ignorant and superstitious men; they have, however, a value of their own as illustrating the folklore of a part of Mesopotamia and preserving a number of popular beliefs and legends about birds, animals, magic roots, and so forth—parallels to which may be found in mediaeval Bestiaries. Many of the diseases mentioned Dr. Wallis Budge has been unable to identify, and for a number of the names he has found no exact English equivalents. This difficulty is one that is met by every student of ancient medical literature in which the description of symptoms is so vague that the diseases resemble nothing known to modern nosology. The Syriac text is edited from an MS. copied at Dr. Budge's own expense; he thinks it was written in the twelfth century. During the short examination of the original which he was permitted to make, he found nothing to indicate when, where, and by whom it had been written. Its size and general appearance suggest that it had been copied in some monastery at or near the Tigris. He thinks the parts missing probably contained theories or statements not acceptable to the monks; the later chapters, dealing with the organs of reproduction and their diseases, may have been torn out as unsuitable and unnecessary for ascetics.

We need not follow the writer of the first or Hippocratic section through the exposition of his theories, which are familiar to all students of old medical literature, and which have left a deep impress visible to this day in popular pathology. A few points may, however, be noted. A chapter is devoted to the strangles, a dangerous disease which would appear to have included tonsillitis, post-pharyngeal abscess, ulceration of the gums and tongue, and, possibly, diphtheria. The treatment of that, as of a great many other conditions, consists in getting rid of excess of chyme, which forms the nourishment of the abscesses. Insufflations of powders, gargles, and so forth are mentioned, and amputation of the uvula was performed in certain cases. Innumerable remedies for toothache are recommended, including one or two by means of which the teeth were loosened and extracted without pain. In speaking of the stomach and its diseases, the author has something to say as to the evil effects of intemperance. The "abominable lust" for drink in men is said to be due to the noxious salt or bilious chyme collected in the coats of the belly. Some men, we are told, crave for foul drinks, just as they do for foul meats, and in others the longing is so unquenchable that they drink themselves to death. Men have been known to eat the vipers called "danpasdês," because they produce thirst, and others drink wine wherein a viper of this class has been drowned." In regard to diseases of the liver and digestion the author makes the prudent remark that "we must never assign causes to a disease unless we are certain of our facts, and we must never misread symptoms."

Nothing need be said as to the section which deals with divination, forecasts, omens, the influence of the planets and the signs of the zodiac on the characters and dispositions of men and human affairs in general. The third section contains prescriptions representing a belief some traces of which still survive, for instance, among people who carry about potatoes as a preventive of rheumatism. The good which a man derives from carrying about with him the heart or some other part of the eagle, vulture, hawk, white falcon, falcon, partridge, hare, crab, frog, ox, fox, bear, weasel, hedgehog, pelican, black crow, besides a number of magical roots, are fully set forth. A useful hint to candidates for official appointments may be found in the following recommendation:

> If a man wishes to stand well with the governing powers, let him cause the head of a crow to be hung up over him, and if he wishes to stand well with his neighbours let him cause the heart, eye, and skin of a wolf to be hung up over him.

The reader who is not an Oriental scholar may get a good idea of the contents of the *Syriac Book of Medicines* from the very learned and interesting introduction contributed by Dr. Wallis Budge. A particularly interesting part of this introduction is that dealing with medicine among the Egyptians, Greeks, and Syrians. The Egyptians were the founders of the chief systems which were, with modifications, in use throughout Greece, Arabia, Syria, and many other parts of Western Asia down to the Middle Ages. He refers to the medical papyri preserved in the museums of London, Berlin, Leipzig, and Philadelphia. The London (eighteenth dynasty) was first described by Birch, who pointed out that some of the prescriptions contained therein are said to date from the time of King Khufu, the builder of the first pyramid. Dr. Budge thinks it may be assumed that a large part of the contents of these papyri is taken from older ones, and is the work of physicians who flourished under the ancient and middle empires. According to tradition, the Egyptians in the earlier centuries of dynastic civilization were familiar with the use of plants as medicines. The number of vegetable medicines used by them was very great, among them being aloes, dates, figs, opium, and hyoscyamus. Many of the ingredients were of animal origin—lizard's dung; the blood, fat, dung, semen and testicles of the ass; bat's blood; the blood, dung, and vulva of the dog; the fat, dung, and uterus of the cat; the dung of

[1] *Syrian Anatomy, Pathology and Therapeutics; or the Book of Medicines.* By E. A. Wallis Budge, M.A., Litt.D., Keeper of the Egyptian and Assyrian Antiquities in the British Museum. Published under the direction of the Royal Society of Literature of the United Kingdom. Vol. i, Introduction, Syriac Text. Vol. ii, English Translation and Text. Humphrey Milford, Oxford University Press, London, New York, Toronto, Melbourne, and Bombay. 1913. (42s. net.)

crocodile and of antelope, and so forth. Our own ancestors used ingredients just as nauseous. In one of his letters we find Martin Luther complaining that the medicine, a mixture of garlic and horse-dung which his wife had recommended to him, did him no good. Metallic preparations, such as oxide of zinc, lead, and copper, sulphate of iron, and so on, were also used by the Egyptians. Medicines were given in the form of ointment, liniments, plasters, poultices, pills, tablets, boluses, tinctures, decoctions, extracts, juices, and powders. Inhalation was used, and the beneficial effects of massage were well known.

In all periods of Egyptian history, medicine and magic went hand in hand, the incantation probably being looked upon as the more important of the two. A rigid conservatism prevented the development of medicine into a scientific system. In the treatment of disease the Egyptians were satisfied to be guided by the wisdom of their ancestors; they made no experiments, and went on using prescriptions that had served for hundreds, if not thousands, of years. This was probably due to the fact that the prescriptions had become, as it were, sacred formularies. If the patient died and it was proved that the treatment had been in accordance with that sanctioned by custom, the physician was held blameless. If otherwise, he was liable to be called to account.

How far, says Dr. Budge, the knowledge of Egyptian medicine penetrated into Eastern Mesopotamia is unknown, but in the seventh century before Christ the prescriptions inscribed in cuneiform on tablets from the Royal Library at Nineveh show many points of resemblance with those of Egypt. The Assyrians derived a great deal of their medical knowledge from the Babylonians. Very few fragments of medical tablets have come down from the time of Khammurabi, about B.C. 1950. But magical texts of that period have been unearthed in Lower Babylonia. Dr. Budge thinks it impossible that a nation so highly civilized as the Babylonians had no system of medicine, and equally impossible that the Sumerians before them had none. In the prescriptions found on Assyrian tablets, many of the names of plants or medical preparations are Sumerian, and these, he thinks, can only have come to the Assyrian scribes who copied the tablets for the royal library from Babylonian or Sumerian originals. According to Dr. Morris Jastrow[2] the medical texts in the great library of clay tablets gathered by King Ashurbanapal of Assyria (668-626 B.C.) numbered about 800. He says that the treatment of disease as revealed in these tablets goes back to at least 2000 B.C.

Dr. Wallis Budge is entitled to the special gratitude of all scholars and students of medical history. His book is a monument of learning, the building of which has evidently been a labour of love.

SEVENTEENTH INTERNATIONAL CONGRESS OF MEDICINE, LONDON, 1913.

A FINAL meeting of the Organizing Committee of the International Congress of Medicine in London last year was held in the rooms of the Medical Society of London on Tuesday afternoon, July 7th. The President, Sir THOMAS BARLOW, was in the chair, and nineteen other members were present. The minutes of the last meeting were read by the Honorary General Secretary, Sir WILMOT HERRINGHAM, and confirmed, and the report of the Finance Committee was presented by Mr. G. H. MAKINS, C.B., as follows:

Report of the Finance Committee.

A subscription list towards the general expenses of the Congress was opened on November 20th, 1910, and this list continued open until the date of the meeting in August, 1913.

Subscriptions thereto were received from 1,613 individual members of the profession. Contributions were also generously made by the Royal College of Physicians of London, the Society of Apothecaries of London, the Royal College of Physicians of Edinburgh, the Royal College of Surgeons of Edinburgh, the Proprietors of *The Lancet*, the Worshipful Companies of Merchant Taylors, Goldsmiths, Clothworkers, and Salters, and also by Lady MacCormac and Lady Butlin. The total sum of £5,418 5s. 7d. received from these sources was further augmented by £2,834 4s. 4d., the profit derived from the Congress Exhibition, and a sum of £195 3s. 11d. accruing from various sources, such as the sale of materials temporarily employed in the organization of the Central Office and Museum and the interest on money placed upon deposit with the bankers. To the above sums remains to be added £6,494 11s. 9d. received in membership fees. Thus in all a grand total of £14,942 5s. 7d. was obtained.

An estimate of probable receipts and expenditure submitted by the honorary treasurers to the Finance Committee at an early date proved practically accurate as far as the expenses of organization and the various sources of income are concerned. With regard, however, to the matter of entertainment, it was noted that the Reception Committee undertook only a single evening conversazione, and that as on previous occasions the Executive Committee was largely indebted to the generosity of private individuals and public bodies for the highly successful social gatherings which took place. Mention of the various public bodies who gave invaluable help, both in affording accommodation for the meetings of the sections and in the exercise of hospitality, has already been made in the preface to the general volume of the *Transactions*.

The estimate assumed further that, as on previous occasions, the sum received by payment of fees by members would suffice to meet the expenses of printing, publishing, and distributing the volumes of the *Transactions* of the congress.

When, however, the great mass of material afforded by the original papers and the discussions thereon came into the hands of the editors a provisional estimate was asked for from the publishers as to the cost of printing and distribution. From that estimate, as submitted to the Finance Committee, it appeared obvious that the balance lying to the credit of the honorary treasurers would prove insufficient for the purpose for which it had been reserved. This insufficiency depended not only on the great mass of material to be printed, but also on the heavy cost to be entailed by the distribution of the volumes to members, so large a proportion of whom either reside on the Continent, in America, or in the Dominions beyond the Seas.

The Finance Committee therefore decided to make an appeal to the officers of each section and subsection, and thus endeavour to raise from each an additional sum proportionate to the size of the section or subsection concerned, and to the expense incurred in printing and distributing its volume of the *Transactions*. The ready help afforded by all the sections (excepting those of orthopaedics and dermatology, from whom no contributions have been received) towards meeting the expected deficiency, resulted in the collection of £646 0s. 6d.

In consequence, however, of editorial curtailment of some of the papers and discussions, and the unexpected receipt of a sum of £347 0s. 7d. by sales of the *Transactions* (up to date), the publishers' provisional estimate proved to have been excessive, with the result that the honorary treasurers found themselves with a balance of £337 19s. 8d. at the bank, as well as with a credit balance with the publishers of £59 2s. 4d. Since the sum realized by the special appeal was subscribed for the exclusive object of completing the *Transactions*, the Finance Committee decided that the balance of the money should be returned to the respective donors in proportion to the amount subscribed, and this decision has already been carried into effect.

It may be noticed that in spite of considerable curtailment, the volumes of *Transactions* extend to the formidable total of twelve thousand four hundred and ninety-eight pages. The Finance Committee wishes to draw special attention to the remarkable promptitude and success with which this great undertaking has been carried out by the editorial secretaries of sections and the Editorial Committee, and also to the excellence with which the volumes, printed in three languages, have been produced, in a space of little more than six months, by the Oxford Press.

Now that all expenditure has been met, a sum of £49 1s. 2d. lies in the hands of the treasurers, which may still be slightly augmented by the sale of further copies of the *Transactions*, and it remains for the General Committee to decide what shall be done with the eventual balance.

The report was adopted and it was resolved:

1. That it be left to the officers of the Congress to decide how the eventual balance from the general funds shall be disposed of.
2. That the Royal Society of Medicine be asked to deposit the minute books and other records of the Congress in their library.

On the motion of Mr. D'ARCY POWER, seconded by the HONORARY GENERAL SECRETARY, a large committee was appointed, with power to add to its numbers, to serve as a National Committee of Great Britain and Ireland for the purposes of International Congresses of Medicine. Sir Thomas Barlow was elected president of this committee, and Dr. Clive Riviere, 19, Queen Anne Street, W., and Mr. H. J. Paterson, 9, Upper Wimpole Street, W., were appointed secretaries.

In bringing the meeting to an end, and finally winding up the business of the congress in London, the CHAIRMAN said that it would only be right to give expression to the feeling of gratitude to all who had taken part in the work of organizing the congress, and especially perhaps to the

[2] *Proceedings of the Royal Society of Medicine*, March, 1914.

younger members who had worked so actively and harmoniously in promoting the success of the sections.

In the evening the President gave a reception, which was numerously attended, at the Royal College of Physicians, to meet the members of the committee of the congress. The guests were received by Sir Thomas and Lady Barlow. The Harveian librarian, Dr. Norman Moore, had arranged an exhibition of early editions, fine bindings, and other books of interest, including manuscripts of Harvey and Sydenham, in the library, and a part of the small, but very interesting, collection of plate in the possession of the College was on view. A loan exhibition of water-colour and pencil drawings and etchings was displayed in the large library. During the evening Mr. Stephen Paget gave in the theatre a series of cinematograph exhibitions of films illustrating the life of micro-organisms, lent by Pathé Frères, and in the library the Westminster Glee Singers delighted the company with a number of songs.

LITERARY NOTES.

THE first number of the *Aberdeen University Review* has already been noticed in the BRITISH MEDICAL JOURNAL (November 22nd, 1913). The February and June numbers complete the first volume. They maintain the high standard set by the first number. The February number contains an interesting account of the University Library, by Mr. P. J. Anderson. Mr. Reynold A. Nicholson contributes an article on Omar Khayyam, and Professor Selbie discusses the uniqueness of the Old Testament. In the June number Professor Henry Cowan writes on the tomb of the founder of Marischal College; Sir Henry Craik, M.P., contributes reminiscences of Glasgow College, and Mr. James D. Symon throws interesting sidelights on the mediaeval student.

Writing in the *Glasgow Herald* of June 26th, on the address on Lister delivered by Sir Hector Cameron before the University of Glasgow on June 23rd, Mr. Alex. F. Morrison makes an interesting reference to the school days of the great reformer of surgery. Joseph Lister as a boy attended a Quaker school of which Mr. Binns was principal. Mr. Morrison says his father, Dr. Morrison, the late rector of Glasgow University, after graduating at Aberdeen, was appointed a classical master under Mr. Binns. Among his pupils was Joseph Lister, who was only a year or two younger than himself. Lister was described by Dr. Morrison as a bright, clever boy, and an insatiable student.

> Not content with the work prescribed for the day, he would read far ahead of his class-fellows; and my father has often told me that he had frequently to rise of a morning before six o'clock in order to keep abreast of his ardent pupil.

In Lister the child was father of the man.

Mr. Stephen Paget contributes to the *Cornhill Magazine* for July the first part of an article entitled "The Parent's Assistant." He urges parents to confess their own faults to their children. One act of confession, he says, will avail more between them and their offspring than many acts of correction:—

> I have long forgotten innumerable occasions when my father was right and I was wrong; but I remember clearly an occasion when he said that he had been wrong, and I right: though it is open to doubt whether he was. More than thirty-five years ago, on a Sunday evening, in Munich, I was aching all over to escape from the hotel dinner to the opera. He utterly disapproved of Sunday theatre-going; but he said, *I leave it to you to decide.* Early next morning, he came to my bedroom, and said that he had been thinking it over carefully, and that he thought, on the whole, as I was so fond of music, that I had done right in going. I am not likely to forget him thus humbling himself to me.

Mr. Paget goes on to tell a story of Darwin, on the authority of Sir Francis Darwin, who says:

> He had a horror of drinking, and constantly warned his boys that any one might be led into drinking too much. I remember, in my innocence as a small boy, asking him if he had ever been tipsy, and he answered very gravely that he was ashamed to say he had once drunk too much at Cambridge. I was much impressed, so that I know now the place where the question was asked.

These, says Mr. Paget, are the impressions which endure when other impressions, most deep for a time, have long faded off the surface of memory. This seems to us a hard saying, especially in these days, when the respect of children for their parents is becoming an extinct tradition. The fathers who have borne the white lily of a blameless life, like Sir James Paget or Charles Darwin, must be few, and for most of us confession to our children, besides being a painful ordeal, might have results the reverse of edifying. The normal child looks on his father as a model of perfection, and it would be dangerous to show him the imperfection of the model. *Decipit exemplar vitiis imitabile.*

The first of a series of articles on the physical conditions of the Jewish race by Mr. Israel Cohen appears in *Knowledge* for June. After showing that the Jewish type has not undergone any appreciable alteration in Europe during the last two thousand years, he goes into detail as to the favourable position in which Jews stand with regard to mortality in general. The physiological characteristics of the Jew, he says, are not due to any organic peculiarities of a racial origin, but to social, historic, and economic causes. Having dwelt for nearly two thousand years in towns, and for the greater period in the most insalubrious and congested quarters, and having been subjected to every kind of persecution in his struggle for existence, he possesses a constitution that combines a poor muscular development with a highly developed nervous system. His average height in Eastern Europe is 5 ft. 3 or 4 in., whilst that of the Jewish immigrant in the United States is 5 ft. 5 in.; but the native Jews, both of New York and London, are taller than their foreign parents—a fact which demonstrated how susceptible is the physique of the Jew to the influence of environment. The inferiority of the Eastern Jew in chest development is still more striking. Among healthy and normally developed people the girth of the chest equals or even exceeds half the stature; but this proportion is far from common among the Jewish masses of Russia, who present a larger percentage of military recruits with deficient chest measurement than any other subject people of the Czar.

We have received from Messrs. Appleton and Co., publishers of *Jungle Days*, by Arley Munson, M.D., extracts from a letter from the authoress, in which she takes exception to certain remarks on her use of Indian vernacular words, in the review of her book published in the BRITISH MEDICAL JOURNAL of April 4th. The word *lambādi* has the accent on the second syllable, and cannot be confused with "Lombardy," in which the accent is on the first syllable. *Dacoity* is the act of robbery, the robber is a *dacoit* or *daku*. The Hunterian transliteration, *dakaiti* and *dakait*, represents more exactly the pronunciation of the words, at least in Upper India. There are many tribes in India, of which the *Maghiya Doms* are perhaps the best known, the members of which live by crime, and bring up their children to gain a living in the same way. The children of such tribes, unless they happen to fall into the hands of a mission, have no chance of becoming anything but criminals. But any man may become a *dacoit*, either as his permanent profession or as a casual amateur. Standard works on the subject are H. H. Wilson's *Glossary of British India* and the *Glossary of Anglo-Indian Words* by Yule and Burnell, both of which Dr. Arley Munson might consult with advantage, if she thinks of making any changes in a second edition. The words *Raja* and *Rani* are usually translated as King and Queen, and in many cases rightly so. But there has been no Indian ruler for over half a century who has had any claim to be an independent sovereign. The last was the titular Emperor of Delhi, Bahadur Shah, a very old man, who was deposed after the Mutiny, of which he was the nominal figurehead. But the Mogul Empire had been a mere shadow and the Emperor a puppet in the hands of the Marathas long before he came in contact with the British. The last surviving Indian who could claim to have been a king was the late Maharaja Dulip Sinh, who as a child nominally reigned for a few years in the Punjab. And the last Indian who was *de facto* a king and exercised full sovereign powers was Dulip's father, Ranjit Sinh, the Lion of Lahore, who died on June 27th, 1839. Upper Burma, under King Thibaw, was independent up to 1885, but it was then quite outside British India. The title "Maharaja" or "Raja" may now mean anything from the ruler of a great state, such as Kashmir, in a position little removed from independence, to a title about equivalent to an English knighthood, bestowed as a personal distinction for charitable donations or for municipal services. When Kipling speaks of a petty hill chief as a king we suppose that the title was used as a joke, a literal translation of the word *Raja*.

British Medical Journal.

SATURDAY, JULY 11TH, 1914.

A TRADE UNION?

THE opinion that the medical profession in these islands is in need of a reserve fund to meet large emergencies is, we believe, held by practically all its members. Those who oppose the intention of the British Medical Association to set up such a fund do not, so far as we have been able to ascertain, question the need; but they consider that the moment is not opportune, and that the men whose principles and sense of professional honour would compel them to subscribe to such a fund are sick of seeing the keen and conscientious paying to fight the battles of the slackers and the commercial-minded.

Modern legislation, however, has a knack of moving with disconcerting suddenness and rapidity, and we have had recent experience that politicians with reputations at stake will not be very punctilious as to the means they use to attain an end they believe to be good. Let us, then, assume that a reserve fund is necessary, and, greatly daring, put aside doubts as to whether the majority of the profession will contribute to such a reserve fund, in order to consider the question of its administration, which, as our correspondence columns bear witness, arouses great differences of opinion. We cannot hope to compose these differences, but it seems worth while to make an attempt to discover their nature.

The difference of opinion rests mainly if not solely on the safeguarding of a fund if raised. Clearly it would be absurd to raise such a fund if it was to be drained by the first litigious malcontent or escheated to the Charity Commissioners.

There are certain things the Association wishes to do for the profession which it cannot do, and never will be able to do directly. It cannot, according to Mr. Colquhoun Dill's opinion of May 28th, 1913, regulate the terms on which medical practitioners are to carry on their practice or provide compensation for those who might suffer pecuniarily through supporting the action of the Association in this direction. It cannot do these things, because any such action to be effectual must involve interference with individuals in carrying on their practice; any regulations made must, in fact, be "in restraint of trade," and actionable wrongs to individuals would be almost certain to result. In the case supposed, damages and costs would be payable out of the special fund, "and unless the Association could establish the entire separation of the special fund from its general funds, the latter funds might be made liable also." Mr. Dill went on to advise that if the Association desired "to adopt a policy involving the regulation of the mode in which medical men are to conduct their practice," its best course would be "to form a separate society and register it as a trade union." This has been accepted as conclusive by some of our correspondents, and, having regard to Mr. Dill's eminence as a lawyer, especially in this particular branch of the law, it would certainly seem so until we look at the condition he regards as necessary, turn back to an earlier opinion of his as to a trust fund, and finally consider the degree of protection to a fund afforded by the Trade Union Acts. The condition he mentions is that the Association should keep control of the separate society, which is to be registered as a trade union, by taking power to appoint its officers or governing body. He states that the rules of the society through which this control might be retained "would require very careful consideration," but appears to hold that the plan would be feasible. As to a trust fund, the opinion given by Mr. Dill on March 6th, 1912, was to the effect that there was no objection to the Association acting as administrator or trustee of a fund raised by voluntary subscriptions, forming no part of the funds of the Association, and bearing its own expenses of administration. He held that in so acting the Association would not commit any breach in the conditions of the licence of the Board of Trade, and that neither that Board nor any member of the Association could restrain it from so acting.

The positions are sharply contrasted: on the one hand the Association can in law raise and administer a voluntary fund which it would hold in trust for certain purposes; on the other, it is asked to promote the establishment of a separate society registered as a trade union, and try to retain control of it by requiring it to adopt special regulations. Here we pass from questions of law to a question of policy. Legal opinion has taken us as far as it can or would consider itself competent to lead. The final decision, as must always happen, rests with the client. "The Association might keep control of such a society." So much is law, and we have no doubt good law, but could it? That is a question of politics. Would the members of "a separate society," even though that society were founded by the British Medical Association, certainly consent always to agree that the Association should keep control? We already have the answer, for many of the most eager trade unionists are already demanding that the Association should hand over all or practically all its medico-political activities to the "separate society" registered "as a trade union."

That this result is foreseen by those who are in favour of placing the collection and administration of a special fund in the hands of a trade union is apparent from motions of which notice has been given for the Annual Representative Meeting at Aberdeen a fortnight hence. The Plymouth Division, for example, will ask the Representative Body to say that it is desirable that for the future the British Medical Association should confine its policy to promoting the scientific and social welfare of the medical profession by leaving all medico-political work to be done by some other body formed for such purpose and registered as a "trade union." It is perhaps as well that the effect of the proposal should be thus plainly stated, for it may be doubted whether all the results of the adoption of trade unionism, as they must affect the Association, have been fully appreciated by the majority of members. The motion means that the Association is asked to abandon work which it was founded to do, which the articles, now in course of publication, on the British Medical Association and the medical profession, show it has always done, and has done more fully and effectually since its last reorganization. It is a negation of the principles of those who brought about that reorganization, and would mean the abolition of many of the most active standing committees of the Association. Not only would the work of the Insurance Act Committee have to be handed over to the

trade union, but also the ethical work of the Association, and much, if not all, of its medico-political work. Much of the work now done by the Public Health and Hospitals Committees would go also. What the position of the Irish and Scottish Committees would be it may be difficult to say, but apparently most, if not all, the work they are doing and propose to do more effectively in the future would be taken away from them. It seems quite clear that such a revolution is not in the interests of the Association as a corporate body. Whether it would be to the interest of the profession at large thus to curtail its activities is a matter which calls for very careful and unbiassed consideration. Great risk must always attend panicky legislation. By strenuous work through three or four generations the members of the Association have built up for it a reputation with the public, with Parliament, and with Governments as the mouthpiece in medico-political matters of the whole profession, which it would be folly lightly to throw away.

The Association is asked to make this very serious sacrifice because, so it is alleged, it is the only way in which the proposed fund can be safeguarded. To say that it is the only way implies that it is a sure way. This is a legal question, and the answer of the courts and of legal experts is not so clear and confident as some of the advocates of a trade union for the medical profession would have us believe. There seems, however, no doubt that the officers of a trade union can be sued; it is as to the position of a union itself that legal opinion is doubtful. Mr. Schloesser, the joint author of a legal handbook on the position of trade unions,[1] says, in a book addressed to the general public[2]: "By the Trade Disputes Act, 1906, the unions, as such, are protected from this class of action [in respect to the procurement of breaches of contract] when there is a trade dispute. . . . The courts, in addition, have been expressly restrained by statute from interfering in domestic inter-union affairs. This latter restriction has, however, been systematically whittled down by judicial decision, and a new tendency has recently developed, which has tended to hold trade unions to be as a whole corporate bodies rather than voluntary associations, and to make them corporately liable to be sued in their registered name and corporately restricted to specific powers given them by the Legislature. It is, therefore, somewhat difficult to say to-day how far a trade union remains in the eyes of the law, as it is in fact, a purely 'voluntary' association."

The decision of the Council recommending the Representative Body that the collection and administration of the special fund should be placed in the hands of a trade union was reached by a narrow majority in a small meeting, and does not seem to be wholly consistent with subsequent action extending the organization of the Association for medico-political purposes by the establishment of Irish and Scottish offices with whole-time medical secretaries for national business; and by the appointment of an Assistant Medical Secretary attached to the central office. This extension has been made in accordance with the instructions of the Representative Body, which at its annual meeting last year rejected a proposal to form a union of medical practitioners registered under the Trade Union Acts for such members of the Association and other practitioners as might desire to join such a union.

It is, we believe, now admitted by the advocates of a trade union that a society so registered would have no more power of obtaining recruits than the Association, and could possess greater power to retain a dissatisfied member only through a threat to withdraw benefits, or, frankly, by intimidation.

MODERN VIEWS OF THE SCROFULOUS DIATHESIS.

Although almost driven out of the curriculum of the schools, the conception of "diathesis" as a factor in the production of functional disorder, leading to organic disease, has not by any means died out; it continues to be useful in the attempt to understand certain conditions or types of constitution which we are compelled to believe are of importance in etiology. For example, the train of symptoms and physical changes which have been from early times recognized as indicative of the "scrofulous" type have not been entirely explained by the fact that they are usually associated with the presence of the tubercle bacillus. What other influences are at work to start the infant at the breast upon his scrofulous way? The answer to such a question has not been fully sought for and little attention was paid to it until recently. In an interesting paper on diathesis in infancy, published in this issue (p. 53), Dr. H. C. Cameron has brought forward many interesting points for consideration and has shown that a more careful study of the problems are needed before the vague explanation of a diathetic cause is resorted to. One infant at the breast may fail utterly to digest and absorb breast milk which may have proved perfectly digestible and nourishing to another. The cause of the dyspepsia must therefore be sought in the composition of the recipient organs rather than in that of the breast milk. Such an infant presents some abnormality of constitution and this would probably be found to be chemical in nature. Hence a much more elaborate investigation into the chemical composition of the tissues and organs of infants who have died from scrofulosis set up by digestive irregularity is needed before the causation of the familiar train of symptoms can be rationally explained.

It is somewhat remarkable that even in the latest works upon the subject this question of infantile dyspepsia is little mentioned, and its treatment left, as heretofore, to the unscientific guidance of mothers and nurses. Dr. Cameron relates many cases in which marked scrofulous changes, and especially the sequences of catarrhal affections which led Czerny to give the name of "exudative diathesis" to the well known condition, had followed upon imperfect digestion of breast milk. Such cases must occur in every practice amongst the poorer classes, and might probably be treated at an earlier stage with greater success if the underlying causes of the dyspepsia were more fully understood.

Doubtless other influences than dyspepsia may affect the course of the catarrhal affections of the mucous membranes and of the skin, which in their turn lead to glandular enlargement and anaemia. The liability to infection by pathogenic organisms is not very great in early infancy, but the stability of the infantile nervous system may be a very considerable factor. The irritable child, rendered more irritable by digestive troubles, is too often mismanaged by nurse or mother, who lavish attentions upon it when sleep is the great desideratum. The study of the dyspepsia of infants may thus afford an explanation of the scrofulous diathesis and the subsequent

[1] *The Legal Position of Trade Unions.* By Henry H. Schloesser and W. Smith Clarke, Barristers-at-Law. London: King and Son.

[2] *Trade Unionism.* By Henry H. Schloesser, Barrister-at-Law. London: Methuen. 1913.

occurrence of the developed disease may be obviated. For the present, however, whether described as an exudative diathesis or as scrofulosis, the disease is all too prevalent, and the appearance of a second edition of Professor Cornet's work on the subject,[1] of which a good translation has been made by Dr. J. E. Bullock of St. Leonards, should stimulate inquiry into the debatable points to which we have called attention. Dr. Cornet's researches have extended over many years, but it does not appear that he has attacked the problem of the causation of infantile dyspepsia. In an early chapter he agrees that the nourishment in the first year has a great influence on the genesis of scrofulosis, and he also records his belief that the exudative diathesis depends upon chemical processes produced by latent defects in the composition of the body, but he does not lay so much stress upon these points as upon others. He appears to hold that the presence of the tubercle bacillus, human or bovine, will explain the vast majority of cases; but he also recognizes a pyogenic form occurring alone or in combination with tubercle.

Dr. Cornet enters into every aspect of the known disease in all its stages. The information that he gives is culled from the experiences of ten years of personal research and from references to the researches of others, of which the bibliography alone extends to seventy-five pages. The translator has carried out his work with great judgement, and the book in its English dress is as interesting to read as it is exhaustive of its subject. A considerable section is devoted to therapeutics, and a vast amount of information is conveyed in plain terms indicating the bad as well as the good points of most of the accepted methods.

JOSEPH CHAMBERLAIN.

THE statesman for whose death the whole British Empire is now in mourning was interested throughout his public life in all questions affecting the social welfare and the health of the people, and we may be allowed, in the name of the medical profession, to pay a special tribute to the foresight and breadth of view which enabled him so well to understand the intimate connexion between successful colonization of the tropics and the problems of disease. Before him politicians had treated public health questions as of little importance, because unlikely to influence votes, and the colonies had by many been looked upon as an indifferent parent regards his offspring—troublesome dependents to be turned adrift to shift for themselves as soon as possible. Mr. Chamberlain took a larger view, and recognized that the Mother Country had duties towards the vast territories it had taken under its government or protection.

He served his apprenticeship to public health work in Birmingham, and while Mayor of that city (1873-76) followed a policy which showed that he had already grasped the broad principles of sanitation which were afterwards to be developed on a wider stage. His first objective was the acquisition of the business of the gas companies by the municipality in order that the large profits he foresaw would accrue might be devoted to the improvement of the sanitary condition of the town; it was at that time imperfectly provided with drains, and few, if any, of the smaller houses had waterclosets, the "pan system" being almost universal. His second great scheme was to buy up the waterworks; at that time many surface wells, generally polluted, were still in use, and, in fact, constituted the main source of supply of the drinking water used by the working classes. He hoped by gaining control of the water to lower the charges, and thus to facilitate the closure of wells and the wider introduction of the use of tap water. The last act which marked his mayoralty was the construction of Corporation Street, by which a wide avenue was driven through a congested part of the city, and a large area of slum property cleared away. Although the financial results of this scheme have up to the present not realized his sanguine expectations, there can be no doubt of the improvement thus effected in the sanitary condition of the city. Mr. Chamberlain's interest in the housing question never failed, and in 1907 he accepted the vice-presidency of the Birmingham and District Housing Reform Association, which has done so much for the provision of better dwellings for the working classes. In the management of municipal affairs he displayed the same foresight, the wide and penetrating glance which distinguished him at the Colonial Office, and made him second only to the great Lord Chatham as a builder of the British Empire.

While to many politicians place is an end in itself, to Mr. Chamberlain it was of value as affording opportunities of carrying out schemes which he believed to be for the welfare of the nation and the empire. In his own phrase, he thought imperially, and therefore when he was given a choice of office he deliberately selected one that then seemed of lesser honour and importance than others which he might have claimed, because in the post of Colonial Secretary he saw the chance of realizing his dream of consolidating the empire. He perceived that a knowledge of the health conditions of the tropics was the first step towards delivering them from the diseases which paralysed the working capacity of the natives and interfered disastrously both with efficient administration and with trade. The greatness of the man is shown in his readiness to be guided by the counsels of advisers whom he could trust. Sir Patrick Manson for some years had been urging the need of instruction and research in tropical diseases, but his voice was as that of one crying in the wilderness till he gained the ear of Mr. Chamberlain. The energetic action of the Secretary of State for the Colonies quickly brought the scheme suggested to him to fulfilment. Schools of tropical medicine were founded in London and Liverpool; both, from small beginnings, have grown into flourishing institutions, which have sent out large numbers of men to do battle successfully against the diseases peculiar to the tropics and have done much by investigations in the native haunts of these diseases to solve the problems of tropical hygiene.

A brief account of the part played by Mr. Chamberlain in the initiation and prosecution of the campaign against tropical disease was given in the BRITISH MEDICAL JOURNAL of February 7th, 1914, and at the annual meeting of the British Medical Association in Birmingham in 1911 he was unanimously elected an honorary member "in recognition of his eminent services in promoting the systematic study of tropical diseases." Without the stimulating power of Mr. Chamberlain this work, which is of the highest importance to the prosperity of the empire, could never have been accomplished, and his active sympathy was a constant encouragement to the workers. It was a work which was very near his heart, and we have good reason to know that there was nothing in his career of which he was more proud than he was of

[1] *Scrofulosis.* By Professor Dr. G. Cornet. Translated from the second German edition by J. E. Bullock, M.D. London: John Bale, Sons, and Danielsson, Ltd. 1914. (Roy. 8vo, pp. 526. 15s. net.)

the success of his efforts to promote the study of tropical diseases and to help in freeing these gardens of the Hesperides from the dragons which kept watch over the treasures they contain.

There may be differences of opinion as to Mr. Chamberlain's activity in other directions; there can be none as to the results of what he did for the health of the tropics. It is significant of the indifference of the public to matters of health which lie at the foundation of national prosperity that this, which is the most enduring monument of his fame, has been passed over in silence by the general press. Of those who paid tributes to his memory in Parliament, only Lord Crewe referred to the impulse given by him to the study and practice of tropical medicine. It is sad that his death should have followed at so short an interval the commemoration of his services to the London School of Tropical Medicine, to which reference was made in the Journal of June 27th. It is comforting to all who recognize in him one of the foremost political leaders of his day to learn that he passed away peacefully, the light of his intellect undimmed till within a few hours of the end. Mr. Chamberlain was in the habit of saying that the greatest affliction of old age was the failure of the mental powers which it so often brings with it; this he was mercifully spared.

THE UNIVERSITY OF LONDON.

The affairs of the University of London are still in a state of suspense. In reply to a question by the representative of the university in Parliament (Sir Philip Magnus), the President of the Board of Education said recently that the Government did not contemplate the creation of a new university in London distinct and separate from that which now exists, as an ambiguous phrase used in his speech on the estimates had led some to think. The Government contemplated the reconstitution of the university, but, before taking any steps, would await the report of the Departmental Committee. Sir Philip Magnus then asked whether this Committee would report before the close of the present session. Mr. Pease replied that the Committee was not yet in a position to say by what date it would complete its report, but added that he did not expect it would be ready for submission before the close of the session. It will be remembered that part of the scheme in contemplation is to give the university appropriate buildings of its own, and that three sites have been spoken of—Somerset House; a site on the south side of the river adjoining the new County Hall, the building of which has been so long arrested by labour difficulties; and a site near the British Museum, where it was hoped that a university quarter might grow up. In this matter of the sites a certain negative amount of progress has been made, for the Prime Minister has informed the Chancellor of the University that the Government cannot approve the diversion of Somerset House from its present purposes. The Senate at its last meeting decided to inform the Government that, having considered various sites suggested for the head quarters of the university, it is of opinion that it is undesirable to proceed further with the consideration of this matter unless and until the Treasury intimates its willingness to provide accommodation more suitable in situation, more convenient in character, and on terms not less advantageous as regards tenure than those attached to the present occupation at South Kensington. The Senate, therefore, would seem to have stepped aside, at any rate for the present, and the next move lies with the Departmental Committee, but there is no indication of when this move will be made.

THE THIRD INTERNATIONAL OPIUM CONFERENCE.

The third International Opium Conference assembled at the Palace of the Counts at the Hague on Monday, June 15th, and rose on Thursday, June 25th. Thirty powers were represented, as compared with twelve which took part in the first Conference of 1911–12, when the Convention was drafted, and twenty-four at the second Conference in July, 1913. Mr. Loudon, the Minister for Foreign Affairs of the Netherlands, as Honorary President, opened the proceedings, summarizing the present position of the signature and ratification of the Convention, and Mr. Cremer was again elected President. Sir William Collins and Mr. Max Müller for the third time acted as plenipotentiaries for Great Britain. From the reports published in the Dutch papers and references to the *protocole de clôture* which have appeared it is evident that very substantial progress has been achieved. Of the thirty-four powers which were invited by the original twelve signatory powers to co-operate, thirty-two have now agreed to do so, and have signed the Convention. Turkey and Servia, we understand, alone remain aloof. Some ten of the forty-four signatory powers have gone further, and have ratified the Convention, and the gratifying announcement was made at the Conference by the British delegates that Great Britain, too, is now ready to take this step. A resolution was passed by the Conference unanimously inviting the Foreign Minister of the Netherlands to address an urgent and respectful request to those signatory powers which have not yet either ratified the Convention or announced their intention of doing so, requesting them to deposit their ratifications with as little delay as possible in order that the Convention may be put into force at the earliest possible moment. The Conference then proceeded to discuss the problem which had been propounded for its consideration by a resolution passed by the second Conference—namely, whether it is possible for the Convention to be put into force without waiting for signature of the Convention by every one of the forty-six powers which were either original participants or had been invited to sign. The Conference appears to have decided that it is possible for the Convention to be put into force notwithstanding the non-signature, up to the present, of Turkey and Servia. A rumour has reached us that one or two powers, and especially Germany, were indisposed to support this view. We cannot understand how this rumour can be correct, as the reports of the two previous Conferences clearly show that it has been all along regarded as not improbable that the state of affairs now disclosed might come about, and that the representatives of Germany had clearly stated that in their opinion the omission of one or two powers to sign the Convention ought not to compromise its coming into force nor preclude the signatory powers from going forward without them. By a further resolution the Conference decided that if by December 31st, 1914, all the signatory powers shall not have deposited their ratifications it shall be lawful for those signatory powers which shall have then deposited their ratifications to put the Convention into force; and that powers subsequently ratifying shall be at liberty to do the same. A special protocol for the use of such powers is to be opened forthwith at the Hague. It is clear that the abstention of any power which is a large producer of opium or manufacturer of morphine or cocaine might not a little impair the efficiency of such partial putting in force of the Convention, unless indeed some means were devised by the contracting powers which would effectually neutralize the abstention of others. Doubtless the best result would be to obtain ratification by all the signatory powers and then by the terms of Article 24 of the Convention the coming into force would take place automatically three months later. In view

of the great measure of success which has hitherto been attained, it seems incredible that any power which has signed the Convention can hesitate much longer to proceed to ratification; and the good offices of the Netherlands Foreign Office, under the able leadership of Mr. Loudon, may be relied upon to promote this consummation. The *procès-verbal* of the third Conference has not yet been published; we shall await its issue, which will doubtless clear up some of the points that at present remain obscure.

DEATHS AFTER SALVARSAN.

ANY doubts as to the causes of death in fatalities after salvarsan injection will be dispelled by a perusal of an able analysis of the published cases by Dr. Carl Schindler.[1] The symptoms in practically every case recorded are strikingly similar—headache, vomiting, restlessness in the first twenty-four hours, a few hours of apparent recovery, and then relapse, leading to coma and death on the fourth day. The *post-mortem* appearances of the brain, kidneys, and other organs do not differ in any important detail. It is clear from the results of Professor Heinz-Erlangen, Hoppe and Schreiber, and others, who introduced large doses of arsenic directly into the circulation in animals, that both salvarsan and arsenic are vascular poisons, acting directly on the blood vessel wall, the blood itself, and the vaso-constrictor centre, producing a circulatory stasis, or local thrombosis and their associated symptoms. Theories which attribute catastrophes to impurities in the solvent, alcoholism in the patient, injudicious selection of cases, or technical errors in the administration must be abandoned. Death from salvarsan is nothing less than death from acute paralysis of the circulation by arsenic. Though these views may not meet with much opposition, the suggested means for the avoidance of the evil will not be accepted as a panacea. The author would have us confine ourselves to intramuscular injections in all cases, and makes the statement that aqueous intramuscular injections have only twice caused death, and oily suspensions no fatalities whatever, while intravenous injections have proved fatal ten times with 0.5 gram, eight times with 0.4 gram, and eight times with 0.3 gram. This is somewhat misleading, for the enormous majority of injections are intravenous. That deaths may occur even with the intramuscular method is admitted, but the disabling, painful infiltrations, abscesses, and necroses which so frequently resulted, and which led very early in the history of the drug to legal proceedings in Berlin, are not sufficiently emphasized. No exception need be taken to the estimate of a minimum, with oily suspensions of 3 per cent. necroses (Yoha), and with aqueous solutions 5 per cent. (Ehrlich), 7 per cent. (Wechselmann), or 10 per cent. (Blaschko); but Schindler claims that his results with injections by Yoha's method are as perfect as those of the authorities who inject intravenously. He is careful to add, however, that he does not consider it necessary to obtain a negative Wassermann reaction in refractory later cases. He has not solved the problem, but he has stated his case very reasonably, and if he does not convince every reader, he has at any rate added a very valuable contribution to the study of one of the most important medical and economic questions of the day.

THE DETERMINATION OF SEXUAL CHARACTERS.

CASES have been recorded in birds in which the plumage of one-half of the body was male in character, that of the other half female; and in these instances a testis has been found on the male side of the body, an ovary on the female side. This state of affairs has been met with in the chaffinch, the bullfinch and the pheasant, and has been taken to prove the influence of the nervous system upon the secondary characters of sex. Thus Bond[1] has recently described the skin of a Chinese pheasant of the white-ringed Formosan variety. On the left side it showed the plumage, speaking generally, and the spur of the male bird, though the wing primaries and the coverts were of the female type. The right leg showed only the rudiment of a spur, such as is found in the normal hen pheasant. The bones of the left tarsus and phalanges were longer and thicker than the corresponding bones in the right leg. The tail feathers were especially interesting; the outer half of each feather assumed the male type of plumage, while the female colouring and pattern appeared on the inner or more covered half. Bond gives further details and a most interesting discussion of the explanation this very anomalous case of hermaphroditism seems to demand. Instances have been described in which unilateral castration in stags or fallow deer has been followed by abnormal or unequal development of the antlers. Marshall and Hammond[2] have investigated the influence of castration on the growth of the horns in Herdwick sheep, a breed with horned rams and hornless ewes. Their results support the hormone theory rather than the nervous theory of the relation between the sexual glands and the secondary sexual characters. They found that removal of the testes from Herdwick ram lambs arrested further growth of the horns forthwith, at any stage of development. Unilateral castration did not stop the growth of the horns, nor did it affect their symmetry, though their development appeared to be retarded. Removal of the testes alone without the epididymides inhibited horn growth in just the same way as ordinary castration, in which both organs are removed together.

THE MEASUREMENT OF FIRE-DAMP.

A NEW fire-damp indicator and alarm, described by some of those present as heralding the day of comparative safety in mines, was demonstrated before a company of scientists and mining engineers, under the chairmanship of Lord Ninian Crichton-Stuart, M.P., at the Hotel Cecil on June 26th. With this apparatus, the invention of Mr. Alfred Williams, the presence even of negligible quantities of methane (light carburetted hydrogen), of which fire-damp chiefly consists, can, it is said, be detected, and it has the great merit of becoming more sensitive as the danger-point is approached. Professor Silvanus Thompson, who has made a thorough investigation of this methanometer, said that it was based upon the property of platinum black to rise in temperature in an atmosphere containing fire-damp. When installed in the working of a mine, it not only warned the miner that there was fire-damp in the atmosphere, but also informed him of the exact percentage present. A thermo-electrical method of measurement was employed, and when the platinum black was acted upon by the methane, a galvanometer caused an indicator to traverse a scale, marked out from a fraction of 1 per cent. up to and beyond the inflammable percentages. Unfortunately, when cold, platinum black was insensitive to the small percentages, and therefore the means had to be provided for a slight preliminary electrical heating, so that the substance was maintained at its highest degree of sensitiveness. The essential part of the instrument was a torch-like arrangement, to be held in the hand, or passed up into crevices and cavities; this was attached by wires to a box containing the indicator dial, which was instantly responsive to changes in the volume of gas present. Professor Thompson said that instruments could be left in any part of the mine, and arranged so as to give a signal, audible or visible, on the percentage of fire-damp rising to 1½ or 2, or to that 2½ which was regarded as indicative of danger. It had the further advantage, he said, that it could be used for recording, day by day, the

[2] F. H. A. Marshall and J. Hammond, *Journal of Physiology*, London, 1914, xlviii, 171.

percentage of fire-damp present, and these continuous records could be compared with the barometric records, when it would be observed to what extent they rose and fell together. The result would be, not only to enable the ventilation of mines to be improved, but also quite possibly to afford means of ascertaining the likelihood of outbursts of fire-damp which at present were as little predictable as earthquakes. The president of the Miners' Federation, Mr. R. Smillie, suggested that the apparatus might also be made in a small compass, so that each workman could carry with him his own indicator. Not the least advantage of the methanometer was that at last the miner would be able to carry a sufficient light without fear of dangerous gases, and thus he would be warned in time of the perils of falling roof and sides, and saved also from nystagmus, which was largely the consequence of the dim safety-lamp illumination hitherto permissible. There would now be no objection to the brilliant portable electric light in mines, as the inspectors would have a far more satisfactory means of testing for fire-damp than the "safety" flame afforded them. This application of platinum black seems to have other utilities, for Mr. J. Erskine-Murray, D.Sc., stated that he had tested the sensitivity of the instrument for the vapours of benzene, methylated spirit, and petrol, all of which had an appreciable effect, so that the meter would be of service in garages and other places where there was liability to petrol leakage. It would even be possible to tell whether a man had lately visited the bar, and in medicine it seemed to offer a means of regulating precisely the administration of ether as an anaesthetic. A demonstration of the instrument was given with gas supplied from a fiery mine in Glamorganshire.

MEDICAL TERMS IN THE NEW ENGLISH DICTIONARY.

THE present part[1] of the *New English* or *Oxford Dictionary* is not lacking in medical terms, all of them defined, classified historically, and supplied with abundant illustrative quotations with the skill, completeness, and appropriateness which we have come to expect from Sir James A. H. Murray and his company of learned coadjutors. The difficulty is to select from among the many interesting medical words those which are outstanding. There is *trepan*, "a surgical instrument, in the form of a crown-saw, for cutting out small pieces of bone, especially from the skull"; it is not to be confused with the other *trepan*, "a word of obscure and low origin," meaning a person who entraps or decoys others into actions or positions which may be to his advantage and to their ruin or loss. Sir James Murray gets his first illustrative quotation of the surgical use of trepan, both substantive and verb, out of Lanfranc's *Chirurgery* written about 1400; and among the many later ones we note an example from the self-revealing Mr. Pepys's *Diary* to the effect that "Prince Rupert is . . . so bad that he do now yield to be trepanned." The word takes origin in the French *trépan*, a borer, the mediaeval Latin *trepanum*, a crown-saw, and the Greek τρύπανον, a borer. Near to it in the *Dictionary* is *trephine*, about the origin of which Sir James quotes Woodhall (*Viaticum*) its inventor, writing in 1639: "The Trafine . . . an instrument of my owne composing . . . although it may be said to be a derivative or Epitomy of or from the Trapan . . . I thought fit to put the name of a Trafine upon it (*a tribus finibus*) from the three ends thereof." In this case the French *trépbine* is derived from the English word. It is "an improved form of trepan with a transverse handle, and a removable or adjustable sharp steel centre-pin which is fixed upon the bone to steady the movement in operating." Trepan and trephine have both their following of attendant words, such as *trepanation*, *trepanner*, *trepanize*, *trephination*, and *trephining*. Then, again, there is *trauma*, not yet fully naturalized, from the Greek, and meaning both a wound or external injury and also the condition caused by this. The adjective *traumatic* means, as every medical man knows, "of, pertaining to, or caused by a wound, abrasion, or external injury," but how many are aware of the fact that it once meant "for the cure of wounds. a vulnerary"? *Traumaticin* has a modern ring about it, but, as a matter of fact, there is an illustrative quotation from Dunglison's *Medical Lexicon*, published in 1857, namely, "A name given by Eulenberg to a solution of gutta-percha in chloroform, which is applied externally in various chronic cutaneous diseases." There are also the derived words, *traumatism*, *traumatize*, *traumatol* (the trade name of an iodo-orthocresol), and *traumatropism*, meaning "a peculiar growth or curvature of an organism, especially a plant, resulting from a wound," and therefore more botanical than medical. Further, there are the combination forms, including *traumato-* in their structure: There is thus *traumatocace* (traumatic gangrene), *traumatocomium* (a hospital for the wounded), *traumatology* (the scientific description of wounds), *traumatonesis* (suture of wounds), *traumatopnoea* (the passage of air through a wound in the thorax during respiration), and *traumatopyra* (traumatic fever). Travail, in all its many meanings, is fruitfully illustrated, and full attention is paid to its obstetric use. Not only is its literal significance shown by examples, such as the sentence in Malory's *Arthur* (1470–85), "She bygaune to travaille fast of her child," but the figurative employment is also illustrated, as in such seventeenth century quotations, mostly with a theological bearing, as Milton's "Let her cast her abortive spawne without the danger of this travailling and throbbing kingdome," and T. Wall's "travelling with the pangs of a false zeal, they fall in labour of a monstrous Reformation." It is a curious fact that theological controversy in the seventeenth century seemed to find a perverted sort of delight in violent obstetric imagery. It is worth while remembering that *travel* (to make a journey) originally was the same word as *travail*, and meant (although doing so no longer) to torment, to distress, to toil, and to suffer the pains of parturition. Perhaps the most interesting medical term in this part of the *Dictionary* is *treacle*, coming as it does from the Greek word for the antidote against a venomous bite; but reference has already been made to it under *therapeutics*,[2] and no further notice need be taken of it here, save to say that the medical man who is interested in such matters will find a rich feast in the illustrative quotations. One may ask how many well-read people know that *churl's* or *poor man's treacle* is garlic, and that *Englishman's treacle* is water germander; perhaps one does not wish them generally to know that *treacle-carrier* is a contemptuous term for an itinerant quack doctor or medical practitioner. Medical words, in fact, abound in this fasciculus, such as *tramort* (old word for a corpse), *transanimate* (new suggested usage, not found here, is to express the act of resuscitating a stillborn infant), *trans-condyloid* and many other *trans's* of all sorts and combinations; *transfusion*, *trapezoid*, *trapezium*, *trapezius*, *treatment* (with this spiteful quotation, "many are even rendered incurable by the treatment of inconsiderate physicians"), *trematode*, and all the medical terms beginning with *tri-* and with *tria*—no small host. It is a wonderful dictionary, and can be read like a book—more pleasantly than some books.

[1] *A New English Dictionary on Historical Principles.* Edited by Sir James A. H. Murray. Traik-Trinity. (Vol. x.) Oxford: At the Clarendon Press. . . . Humphrey Milford. July 1st, 1914. (Price 5s.)

THE INTERNATIONAL CONFERENCE ON THE BLIND.

THE International Conference on the Blind, held in London from June 18th to the 24th, was a distinct success. Large numbers of teachers of the blind and of those interested in the organizations that deal with the education and work of the blind met in London for consultation; there

[2] BRITISH MEDICAL JOURNAL, April 13th, 1912, p. 856.

were representatives from the Colonies, the United States, and many Continental countries. Most of the papers contributed dealt with purely technical matters; but there were two of considerable medical interest. The passing of the Mental Deficiency Act has brought under renewed consideration the relation of the mentally defective blind to the existing blind institutions. Teaching in the blind schools is quite a different matter from teaching in the ordinary schools; the number of the blind is small, there are many schools, and it follows that there is much more individual teaching in these schools than can be arranged for in any ordinary school. This makes the difficulty of the mentally deficient much less urgent in the blind schools, for they neither prevent the progress of the more acute, nor are they hurt by the activity of their betters. After much discussion it was agreed to memorialize the Board of Control recommending the establishment of a few schools for the mentally defective blind so arranged as to cover large areas of the country. It was felt that such a scheme would provide better for these children than a number of very small local centres. A paper was read by Mr. Bishop Harman on the education of the high myopes. His chief point was that the conference, as representative of teachers of the blind and of blind interests, had no part in the teaching of high myopes, for the children were not blind, nor was there any necessary expectation that they would become blind; he therefore urged that educationally these children, and the special classes necessary for them, should be attached to the elementary schools, as was the practice in London, and not to the blind schools, as had been done in some parts of the country, from considerations of convenience. To judge from the expressions of approval made by the listeners, and the remarks of subsequent speakers, there was a general agreement with the recommendation.

SAINT MARY RONCEVALL AND CHARING CROSS.

UNDER the title *Historical Sketches of Old Charing* Dr. James Galloway has reissued in book form his essays on "The Hospital and Chapel of Saint Mary Roncevall" and "Eleanor of Castile, Queen of England, and the Monuments Erected in her Memory." The book, which is printed by John Bale, Sons, and Danielsson, Ltd., on special paper, with fourteen full page plates, is published and sold for the benefit of Charing Cross Hospital (price 10s. 6d. net). A long review of the first article, which was originally privately printed as a pamphlet under the title *The Story of Saint Mary Roncevall*, was published with illustrations in the BRITISH MEDICAL JOURNAL of January 4th, 1908 (p. 35), and a note on the second appeared in our issue of January 10th, 1910 (p. 98). The historical value of the essays fully warrants their publication in a more permanent form. Dr. Galloway has given the results of painstaking research in a way which makes them eminently readable. Special value is given to the story of Saint Mary Roncevall by the fact that Dr. Galloway has sought first hand information on many points from living sources; hence his work is not disfigured by the absurd blunders often met with in writers about mediaeval ecclesiastical matters. As we said in reviewing the pamphlet, to Dr. Galloway it has clearly been a labour of love to trace out the history of the old convent at Charing which was an offshoot or "cell" of the priory established by Charlemagne in memory of his nephew Roland, who fell with the other Paladins in the pass of Roncesvalles in 778. The community of Saint Mary Roncevall appears to have first established itself in England in 1229 under the patronage of William Marshall, Earl of Pembroke, eldest son of the great William Marshall, *Rector regis et regni*, Protector of the King after the death of John, from whom Richard Coeur de Lion, when disarmed by him in fair fight, was once fain to beg his life. William Marshall gave them all his houses at "Cherring and the curtilages adjoining," besides lands in other places. In the village of Charing the brethren built a convent, a chapel, and a hospital for the sick. Of the work of this hospital unfortunately there is no record. Nothing more is heard of the brethren for many years. In 1290 Eleanor of Castile, wife of Edward I, died at Harby, near Lincoln, and the King, in memory of her, had a sculptured cross erected at every place where her body rested in the course of its conveyance to Westminster. The cross at Charing was completed in 1294. The community reached the height of its prosperity in this country in the second quarter of the fourteenth century. The convent at Charing was its head quarters, and it had large estates in various parts of the suburbs, besides property at Canterbury, Oxford, and elsewhere. In 1349 came the Black Death, which by sweeping away vast numbers of the clergy paved the way for far-reaching changes in Church and State. The story is told by Cardinal Gasquet and the late Canon Jessopp. The Charing Cross community suffered very severely, and its affairs were thrown into confusion. After various vicissitudes it shared the fate of the religious houses dissolved by Henry VIII. Its death warrant was signed in 1544. The site with the "sumptuous palace" built with the stones of the old convent by Henry Howard Earl of Northampton passed through various hands till it became Northumberland House, with the gateway surmounted by the lion of the Percys, so familiar to Londoners of a past generation. This has now in turn given place to Northumberland Avenue. Charing Cross Hospital is connected with Saint Mary Roncevall only by the fact that on its foundation by Dr. Benjamin Golding in 1823 it was first housed in Villiers Street, on the northern boundary of what was once the property of the priory. Of the crosses in memory of Queen Eleanor, which were really shrines built on consecrated ground, only three remain—at Geddington, Northampton, and Waltham. The one now standing at Charing Cross is a modern reproduction of the old shrine, designed and erected by the late Mr. Edward Barry. Once more we congratulate Dr. Galloway on the result of his labours, and we hope that as a historian he will be a substantial benefactor to the hospital with which he is so honourably connected as a physician.

Medical Notes in Parliament.

[FROM OUR LOBBY CORRESPONDENT.]

Finance Bill (Budget Scheme).

Laboratories.

IN reply to Mr. Chancellor, the Chancellor of the Exchequer said that the amount of the sum of £250,000 to be applied this year to tuberculosis, nursing, and pathological laboratories which would be expended on pathological laboratories, was £50,000.

Mr. Chancellor asked if the work to be carried on in the pathological laboratories to be provided for in this year's Finance Bill would include experiments on living animals.—Mr. Lloyd George replied that, as he had stated on May 14th, the proposed grant was in respect of laboratories to be used primarily for purposes of diagnosis and not of research.

Mr. Catheart Wason asked whether it was to be understood that "these research committees" would not be entitled to make experiments on living animals.—Mr. Lloyd George replied that that was not a matter which came within his department.

Treatment of Tuberculosis.

Mr. Astor asked whether the money to be provided under the Finance Bill for the treatment of dependants of insured persons suffering from tuberculosis in districts where no arrangements had been made for their treatment, with the aid of the Hobhouse Grant, would cover the whole cost of the treatment of such persons; and, if not, what proportion of the cost would be provided under the Finance Bill and from what source the balance would be derived.—Mr. Lloyd George replied that a statement would be made shortly, giving particulars of the admini-

stration of the proposed grant for tuberculosis referred to in his speech on introducing the Budget.

Sick Nursing Grants.

Dr. Chapple asked the Chancellor of the Exchequer whether he had received a communication from the Scottish National Conference of Friendly Societies urging that the administration of the grants for sick nursing, tuberculosis, and pathological laboratories should not be separated from the present administrators of medical benefit.—Mr. Lloyd George replied that he had received a deputation on the subject, which was engaging the careful attention of the Government.

Milk and Dairies Bills.

England.

THE consideration of the English bill was continued on Thursday, July 2nd. The amendment by Mr. Tyrrell to omit the inspection of persons employed in or about dairies was negatived after discussion without a division.

In response to Mr. Glyn-Jones, Mr. Herbert Samuel promised to submit an amendment at the next meeting of the Committee making it clear that it would be possible in the course of inspection to take milk from a particular cow or even from a particular teat.

An interesting and long discussion took place on the question of the manipulation of milk by various processes of addition or abstraction. In regard to colouring matters, Mr. Bathurst stated that in different parts of the country fashions prevailed in regard to the colour of milk, and that milk dealers took the precaution of seeing that the colour of the milk accorded with the prevailing fashion. Ultimately, as an addition to the prohibitions in Clause 2, a paragraph (*d*) was added forbidding the abstraction from milk of butter fat or any other constituent. Further, the regulations were made to cover the cases of milk which had been artificially treated. As the result of the morning's discussion, a considerable number of alterations were made in the first section of Clause 2.

On Monday, July 6th, the Committee was continued, and a great part of the time was occupied by an amendment brought forward by Mr. Astor, Dr. Addison, Mr. Hills, Mr. Bathurst, and others, and supported by members belonging to different parties, to enable regulations to be made for dealing with so-called "certified milk." Some apprehension was expressed by various members as to the effect of the proposed amendment upon small shopkeepers, and, as a result of the discussion, the amendment was given a more restricted scope than in its original form, and was accepted by the Committee without a division.

After a further paragraph had been added to the clause as brought forward by Mr. Samuel with regard to the inspection of individual cows, the remainder of the time of the Committee was occupied in a discussion as to the procedure to be adopted in connexion with the issue of Orders under the bill. It will be seen, therefore, as a result of the sittings up to the present, only two clauses of the bill have been gone through, but these are in many respects the fundamental clauses, and it is anticipated that after Clause 2 is added much more rapid progress will be made. Indeed, it is possible that one of the few important questions leading to prolonged debate that remains is that which relates to the authorities which will be called upon to administer the Act.

At the present time Clause 2 of the bill stands as follows:

2. *Extension of Power to make Orders respecting Milk and Dairies.*—(1) The purposes for which general and special orders with respect to milk and dairies, hereinafter referred to as Milk and Dairies Orders, may be made by the Local Government Board under section thirty-four of the Contagious Diseases (Animals) Act, 1878, as amended by the Contagious Diseases (Animals) Act, 1886, shall include the following purposes:

(*a*) The registration with local authorities of all dairies.

(*b*) The inspection of dairies and persons employed in or about dairies.

(*c*) The prevention of danger to health from the sale for human consumption or from the use in the manufacture of products for human consumption of infected, contaminated, or dirty milk.

(*d*) The prohibition of the addition of colouring matter and the prohibition or regulation of the addition of skimmed or separated milk, or water, or any other substance, to milk intended for sale for human consumption, or the abstraction therefrom of butter fat or any other constituent, and the prohibition or regulation of the sale for human consumption of milk to which such an addition or from which such abstraction has been made or which has been otherwise artificially treated.

(*e*) The regulation of the cooling, conveyance, and distribution of milk intended for sale for human consumption or for use in the manufacture of products for human consumption.

(*f*) The labelling, marking, or identification of churns, vessels, and other receptacles of milk for sale for human consumption or used for the conveyance of such milk.

(*g*) Authorizing the use in connexion with the sale of milk of the term "certified milk," prescribing the conditions subject to which milk may be sold under such designation, and prohibiting the use of such term or designation in connecting with the sale of milk in respect of which the prescribed conditions are not complied with.

(2) A Milk and Dairies Order with respect to the inspection of cattle in a dairy may authorize the person making the inspection to require any cow to be milked in his presence and to take samples of the milk, and to require that the milk from any particular teat shall be kept separate and separate samples thereof furnished.

(3) If any person is guilty of a contravention of or non-compliance with the provisions of any Milk and Dairies Order, he shall be guilty of an offence against this Act.

(4) Milk and Dairies Orders shall be made by the Local Government Board with the concurrence of the Board of Agriculture and Fisheries, and shall have effect as if enacted in this Act.

(5) All Milk and Dairies Orders shall be laid before each House of Parliament as soon as may be after they are made; and if an Address is presented to His Majesty by either House of Parliament within the next subsequent forty days on which that House has sat next after the Order is laid before it praying that the Order may be annulled, it shall thenceforth be void, but without prejudice to the validity of anything previously done thereunder, or to the making of a new Order.

The Rules Publication Act, 1893, shall apply to any such Order as if it was a statutory rule within the meaning of Section 1 of that Act.

Scotland.

The bill for Scotland, unlike its English companion, has had a smooth and rapid passage through Committee. It has been subject to few alterations; the chief relate to the restriction of the rights of invasion by urban authorities into rural districts, and the imposition of duties in accordance with the general terms of the Act in such cases upon the rural authorities.

Apart from the amendments, however, made in Committee, three new clauses have been added to the bill and should be quoted in full. They are as follows:—

Inspection of Premises Other than Dairies.—It shall be lawful for the local authority to authorise the medical officer of health, the sanitary inspector, or any other officer, to inspect from time to time, and to examine the cattle in, any premises from which the occupier sells milk only in small quantities and for their own consumption to persons in his employment, or to neighbours, notwithstanding that such occupier is not a dairyman within the meaning of this Act, and such occupier and persons in his employment shall give all reasonable facilities and assistance to such officers for such inspection and examination.

Dairymen to Notify Disease, etc.—Every dairyman who has in his dairy any cow which appears to be suffering from any sore on the teats accompanied by suppuration or bleeding, or from any disease liable to infect or contaminate the milk, or any cow which to his knowledge is giving tuberculous milk, shall forthwith give written notice thereof to the local authority stating the situation of the dairy.

Intimation of Inspection.—Where any official of a local authority proposes to inspect any dairy in the district of another local authority or to examine the cattle in such dairy under powers contained in this or any other Act he shall give intimation by the readiest means available to the medical officer of health of the second-named district of the intention to make the said inspection or examination so that, if circumstances permit, the medical officer of health, sanitary inspector, or veterinary inspector, of the second-named district may be present at such inspection or examination.

Treatment of Tuberculosis.—Mr. Astor asked the President of the Local Government Board the number of general voluntary hospitals in London which had made arrangements with local authorities or Insurance Committees for treating tuberculous cases, the number of beds so made available, and whether all these institutions received payment for treating these insured persons.—Mr. Herbert Samuel said that he understood that arrangements were at present in force between the London Insurance Committee and three general hospitals under which twenty-eight beds were occupied by insured persons at the beginning of the present month, while arrangements were

pending with a fourth hospital. Arrangements were also in force between the Committee and three consumption hospitals under which seventy beds were occupied by insured persons at the date above mentioned. The London County Council proposed to make arrangements for the treatment of tuberculous cases in seven general hospitals and three consumption hospitals in London, and hoped to obtain 160 beds at these institutions during the next twelve months. The Middlesex and Surrey County Councils had each arranged for the use of beds at two general or consumption hospitals in London, and on March 31st last Middlesex was using eleven beds and Surrey thirteen beds in these hospitals. He understood that in all cases payment was or would be made by the Insurance Committee or the county council for all beds occupied under the arrangements specified. In reply to Mr. Astor the President of the Local Government Board stated that provision for the free examination of sputum is made in the tuberculosis schemes of forty-two county councils and sixty-six county borough councils, namely:

County Councils.—Bedford, Berkshire, Buckingham, Cheshire, Cornwall, Cumberland, Derby, Devon, Dorset, Durham, Ely (Isle of), Essex, Gloucester, Hereford, Hertford, Huntingdon, Kent, Lancashire, Leicester, Lincoln (parts of Holland, Kesteven, Lindsey), Middlesex, Northampton, Northumberland, Nottingham, Peterborough (Soke of), Salop, Somerset, Southampton, Stafford, Suffolk East, Suffolk West, Surrey, Sussex East, Sussex West, Warwick, Westmorland, Wiltshire, Worcester, Yorkshire (East Riding, West Riding).

County Borough Councils.—Barnsley, Bath, Birkenhead, Birmingham, Blackburn, Blackpool, Bolton, Bootle, Bournemouth, Bradford, Brighton, Bristol, Burnley, Burton-on-Trent, Bury, Carlisle, Chester, Coventry, Croydon, Derby, Dewsbury, Dudley, Eastbourne, Gloucester, Halifax, Hastings, Huddersfield, Ipswich, Kingston-on-Hull, Leeds, Leicester, Lincoln, Liverpool, Manchester, Middlesbrough, Newcastle, Northampton, Norwich, Nottingham, Oldham, Plymouth, Portsmouth, Preston, Reading, Rochdale, Rotherham, St. Helens, Salford, Sheffield, Smethwick, Southampton, Southend-on-Sea, Southport, South Shields, Stockport, Stoke-on-Trent, Sunderland, Tynemouth, Wallasey, Warrington, West Bromwich, West Ham, Wigan, Wolverhampton, Worcester, York.

Captain Faber asked whether, at the Gibcrack Sanatorium at East Harringfield, Chelmsford, it had been the custom to send patients back to their own homes when they were beyond recovery, and if so, whether he proposed to take any action in the matter so that disease might not be spread by the practice. Mr. W. Benn replied that the treatment appropriate for a case of tuberculosis varied according to the condition of the patient. It was not desirable that a patient should be retained in an institution intended to provide treatment other than that required in that particular case. Under the arrangements made by Insurance Committees, however, other forms of treatment were available for insured persons discharged from institutions. Lord Charles Beresford asked the Chancellor of the Exchequer if he was aware that at the Cripples' Hospital and College at Alton 95 per cent. of the cripples were cured who would otherwise succumb or be cripples for life; and whether, looking to the amount of good that this hospital did, he would give a State grant to the hospital and also create hospitals of a similar character throughout the country. Mr. Lloyd George replied as follows: I am well aware of the brilliant work carried on at the hospital referred to by the noble lord. The general question of hospital accommodation is now receiving the attention of His Majesty's Government, and meantime I fear I can make no statement.

Infant Mortality and Stillbirths.—In reply to Mr. Pike Pease, the President of the Local Government Board said that the rate of infant mortality in the United Kingdom in 1913 was 108 deaths under 1 year of age per 1,000 births registered. The proportion of stillbirths could not be stated, as they were not registrable, and information in regard to them was obtainable only for areas which had adopted the Notification of Births Act, 1907. These areas did not in all cases tabulate the information, but it might be stated that during 1912 the stillbirths notified under this Act in the county of London numbered 2,593. This amounted to 2.4 per cent. of the total births notified, and to 0.57 per 1,000 of the estimated population at the middle of the year.

Physique of School Children.—In reply to Mr. Astor, the President of the Board of Education said that of the 200 reports of school medical officers for the year ending December 31st last so far received and scrutinized, twelve contained a reference to the injurious effect of work out of school hours on the physique and general condition of children. Further reference to the subject would be found in the last two annual reports of the Board's chief medical officer. In reply to Sir Harry Verney, Mr. Pease said that the Board had not regarded the weighing and measuring of children as essential to the performance of the minimum statutory duty of a local education authority; but had always included the child's height and weight in the "model" inspection schedule, since it was held that no child could be considered properly examined medically so long as the medical officer remained in ignorance of its height and weight. In assessing the grant the Board had, therefore, felt bound to take this circumstance into consideration. The Board did not regard provision for the periodic weighing and measuring of children with the view to the collection of anthropometric data as an essential part of an efficient school medical service. In reply to Mr. Leif Jones, who raised the question of the establishment of a proper medical standard and medical inspection, Mr. Pease said that the Board was putting pressure in that direction and was endeavouring to secure proper regard to the heights and weights of school children.

Education Grants.—Sir Philip Magnus asked the President of the Board of Education in what way and to what special purposes of technical education it was proposed to allocate the sum of £100,000, being part of the sum of £560,000 to be given to higher education; and how he proposed to dispose of the sum of £395,000 in assisting secondary education.—Mr. Pease said that he was not in a position to state the precise method in which the sum of £100,000 would be distributed in aid of technical education, but it was intended to apply a substantial portion of it to increasing the grants-in-aid of larger institutions doing advanced and highly organized work, and thereby to raise the proportion which the present grants bore to the cost of that work. Supplementary regulations were in preparation for the purpose. As regards secondary schools, it was proposed to make substantial increases in the grants given under the existing regulations, which would be modified accordingly. It was hoped that draft regulations would soon be ready for that process of consultation and discussion with authorities and bodies concerned, which was desirable preliminary to their issue.

Tenure of Medical Officers of Health.—Sir Philip Magnus asked the President of the Local Government Board what steps, if any, he had been able to take to remove the pressing disabilities of medical officers of health as regards insecurity of tenure, absence of any scheme of superannuation, and inability to obtain payment of travelling expenses in discharge of their duties, which were brought under his notice by the deputation which he and the Chancellor of the Exchequer and the President of the Board of Education recently received; and whether the position of sanitary inspectors, as regards some of their disabilities, was likely to be improved.—Mr Herbert Lewis replied that he could say no more at the present moment than that the matter was engaging the close attention of the President of the Board.

Opium Traffic in China.—In reply to Mr. Theodore Taylor, the Secretary of State for Foreign Affairs said: Manchuria, Shansi, and Szechuan were closed to the import of Indian opium on September 11th, 1911; Chihli and Kuangsi on March 1st, 1913; Anhui, Hunan and Shantung on June 15th, 1913; Fukien on May 1st, 1914; Hupeh on June 1st, 1914; and Chekiang and Honan on June 10th, 1914. He understood from reports received that strong measures were being taken in most provinces to check the production and illicit consumption of opium in China. There remained, however, seven provinces in respect of which evidence of the cessation of production had not yet been forthcoming, and which had consequently not yet been included amongst the provinces into which the importation of Indian opium was prohibited, though no opium was imported into four of them.

Canada.

[FROM OUR SPECIAL CORRESPONDENTS.]

SIR THOMAS RODDICK AND DOMINION REGISTRATION.

THE announcement that the honour of knighthood has been conferred upon Dr. T. G. Roddick has been received with particular pleasure. The name of Sir Thomas Roddick will always be remembered in the annals of Canadian medicine, for through his untiring efforts, continued for nearly twenty years, difficulties were overcome and a new era was commenced in the practice of medicine in the Dominion. A year ago Dominion medical registration became an accomplished fact. Before that a man was able to practise only in the province in which he received his medical degree; in some cases he could not cross a stream to exercise his calling, even in an emergency, if by chance that stream were the dividing line between two provinces. Now, if a man so wishes, he may take the examinations of the Medical Council of Canada, and thus be enabled to practise in any part of the Dominion—with the exception of the province of British Columbia—without further examination. Sir Thomas Roddick is indeed to be congratulated upon the successful attainment of a worthy object.

The second annual meeting of the Medical Council of Canada took place at Ottawa on June 16th and 17th. With the exception of Dr. McKechnie of Vancouver, Dr. W. Bapty of Victoria, and Dr. Jenkins of Prince Edward Island, all the members were in attendance. A new member was introduced, Dr. E. Braithwaite of Edmonton, appointed in the place of the late Dr. Kennedy of Macleod, Alberta. The resignation of Sir Thomas Roddick from the presidency was received with much reluctance and deep regret on the part of the entire Council. As a mark of esteem Sir Thomas was elected honorary president for life with a seat on the executive committee, so that he will still be associated with the Council. The new president is Dr. R. S. Thornton of Deloraine, Manitoba, who has been an active and able worker in the interests of Dominion medical registration. The vice-president is Dr. R. J. Gibson of Sault Ste. Marie, Ontario. Dr. R. W. Powell of Ottawa was re-elected registrar; Mr. F. H. Chrysler, K.C., was appointed general counsel; and Mr. G. L. Blatch was appointed auditor. The examinations this year will be held at Montreal on October 13th, and, for the convenience of western applicants, examinations will be held also at Winnipeg on June 15th, 1915.

The diploma of the Council—L.M.C.C. (*honoris causâ*)—was conferred upon the Hon. Dr. W. J. Roche, Minister of the Interior.

THE DEAN OF THE MEDICAL FACULTY, MCGILL UNIVERSITY.

Dr. H. S. Birkett has been appointed dean of the faculty of medicine at McGill University in succession to Dr. Frank J. Shepherd, who has filled the position so ably for the past six years, and who, full of honours, is now retiring from his professional engagements. Dr. Birkett graduated from McGill University in 1886 with highest honours. He joined the staff of the university in 1889, entered the service of the Montreal General Hospital in 1891, and in 1899 became laryngologist and otologist to the Royal Victoria Hospital. In 1895 he was appointed professor of laryngology and otology in McGill University. Dr. Birkett is well known throughout this Continent, and is held in the highest esteem; he is an excellent organizer, and his appointment as dean meets with general approval.

MANITOBA MEDICAL ASSOCIATION.

The seventh annual meeting of the Manitoba Medical Association was held in the medical library of the University of Manitoba, Winnipeg, on June 2nd, 3rd, and 4th, under the presidency of Dr. Jasper Halpenny. It was attended by a number of members and some fifty visitors, and Dr. Halpenny and those who assisted him so ably are much to be congratulated upon the success of the meetings. At the opening session the chair was taken by Dr. O. Bjornson. The president gave an address on medical education, in the course of which he said that as so many students put themselves through college by working during the vacations in any capacity that offered, he was of opinion that it would be an unnecessary waste of time for such students to take an arts course before entering upon the study of medicine. Nevertheless, he thought that before long the University of Manitoba would require a student to take at least two years in arts before beginning his medical studies. He thought that during the first two years in medicine too much time was devoted to anatomy, and that during the fourth and fifth years the tendency to specialize was becoming too great. After graduation, he advised that from one to three years should be spent in hospital work before going into practice.

The presidential address was followed by a paper on laparotomy (non-obstetrical) during pregnancy, by Dr. Archibald Maclaren of St. Paul, Minnesota, who cited the results of 35 cases in the St. Paul hospitals; the address provoked an interesting discussion. Dr. S. J. S. Pierce spoke on the subject of antityphoid vaccination. In view of the prevalence of typhoid fever at certain times of the year, a resolution was passed urging all physicians to introduce antityphoid vaccination in private practice, and to enforce compulsory inoculation wherever large gangs of men are forced to work under unfavourable conditions. Dr. Edith Brown, Dean of the Medical College, Punjab, India, gave a short address on medical work in India. On June 3rd a clinical meeting was held at the Winnipeg General Hospital, after which members motored to Assiniboine Park for luncheon. Several interesting addresses were given in the afternoon of Wednesday and Thursday, and clinics were again held at the General Hospital on Thursday morning.

The incoming president is Dr. H. A. Gordon of Portage La Prairie, and the honorary secretary is Dr. R. B. Mitchell of Winnipeg.

GAS POISONING.

Of late a large number of cases of poisoning by illuminating gas have been reported. The matter has been taken up by the Royal Society of Canada, and will be brought to the notice of Parliament in order that something may be done to prevent the adulteration of gas by carbon monoxide. At a recent meeting of the Royal Society a committee was appointed to inquire into the subject. The members of the committee are Sir Thomas Roddick, Dr. R. F. Ruttan of McGill University, Dr. Mackenzie of Toronto, and Dr. G. Prent Girdwood of Montreal. The committee is now collecting statistics of the cases which have occurred during the past five years.

THE PREVENTION OF TUBERCULOSIS.

A series of post-graduate courses in the diagnosis of tuberculosis was commenced at the Bruchési Institute, Montreal, on June 2nd last. The courses, given under the direction of Professor S. A. Knopf, of New York, continue for fifteen days, and the members of each are limited to six; the fee is $15. In last year's report of the Royal Edward Institute it is stated that 2,570 persons attended the clinics during the year; of these, 625 were found to be non-tuberculous, and this is held to show that the efforts which are being made to reach patients while they are still in the first stages of consumption are bearing fruit. An open-air school was opened in December, 1912; this was the first school of its kind in the province of Quebec, and the second in Canada. It has proved most successful and has been well attended. On very cold days in winter, when the temperature is below zero, the ordinary school work gives place to story-telling. A summer camp was also held last year during the months of July and August, and will be held again this summer.

PRISON CONDITIONS IN CANADA.

In August, 1913, a Commission was appointed to enquire into the state and management of the Kingston penitentiary and the report of this commission has now been published. The regulations of the penitentiary are based on the Act of 1834, which states "Whereas if many offenders convicted of crime were ordered to solitary imprisonment accompanied by well-regulated labour and religious instruction, it might be a means. . . . of reforming the individual," etc. The terms of this Act appear to have been rather too rigorously adhered to and solitary imprisonment has always been a conspicuous feature of the discipline. The conditions of labour, particularly stone breaking, were found to be bad and the system to be conducive to moroseness, there being nothing to break the monotony. The Commissioners

regretted that little attempt was made to educate the illiterate and criticized the treatment of the insane prisoners. They considered the buildings in which such prisoners are housed unsuitable and condemned the punishments inflicted. They recommend that a competent alienist should be employed by the Government, and that suitable permanent arrangements should be made for the care of the insane. In Western Canada the provincial governments take care of the criminal insane, and the Commissioners consider that this might be arranged in Eastern Canada, although such action might meet with some disfavour; a separate institution might be provided for such defectives. The practice of "cellular feeding" and certain punishments still in vogue in the prison were also condemned by the Commissioners, who recommend that prisoners should be classified; that first offenders should be sent to reformatories and only the older and more hardened prisoners sent to the State prison; and that prisoners should be given healthful, interesting, and profitable work, which would enable them to gain an honest livelihood when they went into the world again. It is recommended also that prisoners should be paid for their labour, and that their wages should go towards the maintenance of their families. The Commissioners strongly recommend the establishment of a penitentiary commission of three members to organize the prisons, make regulations for their management, and select the officers, who would be held responsible for results. In Toronto improvements are to be made. The present gaol is to be closed in November, 1915. A new central police station will be built, which will contain police head quarters, men's, women's, and children's courts, and cells for transfers on remand. Upon commitment, all prisoners will be removed to one of the several institutions—men's industrial farm, women's industrial farm, central prison, juvenile home, or insane detention home.

THE NEW ROYAL COLUMBIAN HOSPITAL.

The new Royal Columbian Hospital at New Westminster, British Columbia, was formally opened in May. The building is four stories and contains accommodation for over two hundred patients. The hospital was first established in 1862.

LICENCE TO PRACTISE IN ALBERTA.

The autumn examinations for licence to practise in Alberta will be held at the University of Alberta, commencing on September 15th. The examination fee is $50 and applications, with matriculation certificate and graduation diploma, should be sent to the Registrar, University of Alberta, Edmonton South, Alberta, on or before August 15th next.

Ireland.

[*FROM OUR SPECIAL CORRESPONDENTS.*]

THE HOUSING PROBLEM.

LAST week an Inspector of the Local Government Board held an inquiry in Dublin into the application made by the City Council for sanction for loans for clearing insanitary areas, erection of artisans' dwellings, etc. The scheme was one for clearing four areas in the city already condemned as insanitary. The cost of the scheme was nearly £300,000, and provided for the erection of 800, 98, and 180 dwellings, having from four to two rooms each. The cost in three of the areas was approximately £175,000, £27,000, and £39,000 respectively. The scheme was opposed on the ground that the rents to be charged—7s. to 3s. 6d.—were higher than could be paid by the class of people for whom the houses are intended, and that as a consequence the rents would have to be lowered, with a consequent deficit to be made up by an increase of the rates, which are already about 11s. in the £.

The Corporation's total expenditure on housing schemes up to the present has been £350,000, with a total burden on the ratepayers of £10,000 a year. The ratepayers and civic reformers were ably represented on the inquiry, and their objections to the proposed schemes were radical and far-reaching. They urged that the schemes perpetuated overcrowding, that they were piecemeal and unmethodical, fitting into no plan of civic development, that they would be a further burden on the rates, and finally that the whole problem could be solved efficiently and far more cheaply on different lines. They did not object to the clearing of the insanitary areas, but to their immediate repopulation on a scale of still injurious density; they protested against large expenditure on schemes which will create new slum problems for a new generation of citizens. The recent Departmental Committee's report recommended the removal of a considerable part of the slum population to cheap houses on virgin soil in the outskirts of the city. The Corporation's schemes ignored this recommendation and did not meet the arguments—social and economic—on which it was based. Sir Charles Cameron, in his evidence, said he would like to see half the houses in the city rebuilt. He totally disagreed with the suggestion to build the new houses on the outskirts of the city; there were no such waste places in English and Scottish cities as there were in Dublin, and if these waste spaces were allowed to remain the city would become a desert. Referring to one of the particular districts under consideration, he said, in all such areas the death-rate was always high, but that it did not depend so much upon the fact that people lived in one room as on their extreme poverty.

The Inspector made an order in regard to three of the areas, giving the Corporation power to acquire and clear them, but leaving open the ultimate use to which the sites might be put. He refused the order in the case of the fourth scheme.

Last week Mr. Henry Murphy, Local Government Board Inspector, held an inquiry, at Fermoy, into the application of the Urban Council for a loan of £4,580 to to erect twenty cottages under the Housing of the Working Classes Acts. Evidence was given of the great necessity for the erection of the houses. At least 100 houses would be necessary. The inspector said he would make his report as soon as possible.

ISOLATION HOSPITAL FOR NEWRY PORT.

At a meeting of the Newry Port Sanitary Authority last week it was decided to ask the town surveyor to prepare a plan and estimate of costs for the provision of an isolation hospital for sea-borne cases of infectious disease on Rough Island, about four miles from Newry.

Scotland.

[*FROM OUR SPECIAL CORRESPONDENTS.*]

OBJECTIONS TO A PROPOSED TUBERCULOSIS HOSPITAL.

MR. C. E. GREEN of Liberton has published in the *Scotsman* newspaper for July 2nd the correspondence which has passed between him and Mr. Walter Macgregor, Secretary to the Longmore Hospital for Incurables, Edinburgh, regarding the proposed transference of the phthisis and tuberculous cases from the hospital in the city to the Liberton Cottage Hospital, or rather to an extension of it, in ground purchased at Stenhouse. Mr. Green stated that this ground is contiguous to five dairies, and that whilst the nearest one (with 35 cows) is within a hundred yards, two others are within two hundred yards, and the remaining two not further away than four hundred yards. Furthermore, the Alnwick Hill filter beds (covering many acres), which play so important a part in the water supply of Edinburgh, are only 500 yards distant, and are frequented by gulls and water fowl which roam over the surrounding lands; the filter beds drain into a burn which runs through a corner of the hospital grounds. Dr. Guthrie's industrial school with its many boys is also close at hand. Mr. Macgregor in his reply referred to the fact that adequate precautions are now taken to prevent the spread of tuberculosis from one person to another, to the ease with which tubercle bacilli are killed by fresh air and sunlight, and to the mode of construction of the Liberton Cottage Hospital. It is doubtful, however, whether these statements will reassure public opinion in Liberton which has been somewhat shaken by the proposal, and one awaits a more authoritative pronouncement from one or other of the medical officers who have to do with the city and county to allay anxiety. A good deal of publicity has recently been given to investigations regarding tubercle bacilli in the milk

upply of Edinburgh which comes from farms in the country round about; and it is not easy, after having educated the public up to a high standard of dread regarding the transference of tuberculosis by sputum, by infected cows, and the like, to get people to accept the assurance that what seems to the ordinary mind to be a dangerous arrangement is really a safeguarded plan. It is argued that there must be other pieces of land available not in the immediate vicinity of five dairies. Liberton, as its name is believed to signify, was in old days the village of lepers, but it was not then in touch with the city of Edinburgh, which clung very much to the sides of the rocky ridge running from the castle to Holyrood, and, needless to add, there were then no Alnwick Hill filter beds

England and Wales.

MANCHESTER AND DISTRICT.

SMALL-POX IN LANCASHIRE.

IT is satisfactory to find that so far no further case of small-pox has been notified in Salford since the single case reported last week. Accommodation having been found for this case in the Cinder Hill Hospital, it has not been necessary to remove the patients suffering from tuberculosis from the Drinkwater Park Hospital, which was erected primarily as a small-pox hospital but is at present being used as a sanatorium for tuberculosis. At both Oldham and Rochdale, however, several fresh cases have been discovered, and a feeling of great disquietude has arisen as to the source of one of the cases. It appears that the small-pox cases at the Marland Hospital are located in a pavilion adjoining the pavilions used for other infectious diseases, and a child of about 8 years of age, after being in the scarlet fever wards for about three weeks, was then found to have contracted small-pox, from which it has died; the inference is that in some way or other the child had contracted the disease while in the hospital. The Marland Hospital was originally a workhouse, and was converted by the Rochdale Corporation into a fever hospital about twenty-eight years ago. At that time it was well isolated from all other buildings, and with the approval of the Local Government Board cases of small-pox were treated, as well as other infectious diseases. Numerous houses have since been built in the neighbourhood, and the Corporation had made repeated attempts to get separate provision for the small-pox cases, the latest idea being to combine with various other local authorities to obtain a joint small-pox hospital. Unfortunately that had not been accomplished when the present outbreak began, and the idea that small-pox may be airborne over considerable distances has now led to a public meeting of protest, at which a resolution was passed strongly protesting against further use of the Marland Hospital for small-pox, and expressing the opinion that two of the cases at least could only have been infected from the hospital itself. Up to the present there have been in all 16 cases in the Rochdale district, 11 of which arose in Milnrow; 9 of the cases have been treated in the Marland Hospital.

MANCHESTER ROYAL INFIRMARY.

At the last meeting of the board of management of the Manchester Royal Infirmary it was stated that the donations towards the £25,000 required for the Central Branch now amounted to nearly £22,000, no less than £1,264 having been received since the previous meeting. Special reference was made by the chairman, Sir Wm. Cobbett, to the sum of £1,000 received from Mr. Oswald Stoll to name a bed at the Central Branch the "Ardwick Empire Bed." The chairman said that the donation promised by Mr. Stoll had nearly been fulfilled by a series of annual matinées, and he was pleased to state that Mr. Stoll had agreed to promote further similar efforts to raise an additional sum of £1,000 for the Central Branch.

THE SMOKE NUISANCE IN MANCHESTER.

Some time ago the Manchester City Council appointed an "Air Pollution Advisory Committee" to make a full investigation into the smoke nuisance, and the work has been divided into four departments, subcommittees being appointed to deal with the legal and administrative aspects and with engineering, chemical and statistical questions. In various parts of the city the chemical committee has already placed a number of soot-gauges and the statistical committee has decided to follow in the main the methods of inquiry adopted by the Industrial Research Department of the University of Pittsburgh. Circulars will be sent out to a number of hospitals and to representative trades, hotels and private persons, asking a considerable number of questions, the aim being to find out the loss and damage from smoke suffered by traders and manufacturers, by hospitals, offices and hotels, and in household and in private life. The questions cover a very wide field, information being asked, for example, as to the yearly average cost for the cleaning of garments, washing of collars, cuffs, shirts and handkerchiefs, and the damage done directly or indirectly to articles of clothing through wear and tear from excessive washing. There is a long series of questions as to the damage done by smoke to plants in gardens within the city, the cost of air-purifying appliances, the depreciation of shop goods of various kinds, and the cost of painting and decorating made necessary by the state of the atmosphere. Further questions are directed towards making a comparison with the experience in other towns and districts. A number of questions are addressed specially to women, who are asked to mention any extra expenditure on articles such as hats, gloves, curtains, etc., and in each case an estimate is requested of the extra amount added to the cost of running the household owing to the smoky condition of the air. There can hardly be any doubt that the economic cost of the smoke nuisance in Manchester alone must amount to hundreds of thousands of pounds a year, and only by proving this by statistics, so far as statistics can be obtained, will the public be roused to demand a remedy.

LONDON.

TREATMENT OF TUBERCULOSIS.

The Local Government Board and the Scheme for Uninsured Persons.

THE London County Council has received a letter from the Local Government Board commenting on the scheme for the residential treatment of tuberculosis approved by the Council on May 26th (BRITISH MEDICAL JOURNAL, May 30th, p. 1206). The Board stated that, in consequence of the refusal of the London County Council to bear any part of the cost of treating insured persons, it understood that the London Insurance Committee did not propose to arrange for residential accommodation through the County Council. There were clearly many advantages in dealing with insured and uninsured persons by one scheme, and the Board greatly regretted that the County Council had not been prepared, as the councils of other great towns had been, to undertake to provide the accommodation necessary for the whole community, subject to the condition that half the annual cost, after deducting receipts from the Insurance Committee and other sources, would be met out of grants from the Local Government Board. The Board had some doubt whether the proposals of the Council in regard to the selection of cases for residential treatment would prove satisfactory in actual working. While the Board took no exception to the establishment of the proposed honorary advisory board, it considered that instead of authorizing this board to appoint medical referees to examine selected cases for residential treatment, the Council would have been well advised to appoint a clinical tuberculosis officer, whose duties would have included advising the Council in the selection of cases for residential treatment. The Board did not consider that the proposed system of payment by fee per case would be a desirable part of a permanent arrangement. Presumably the number of cases normally referred to the medical referees would only be a small proportion of the whole; otherwise the expenditure for this purpose would be unduly high. The Board, however, would not object to these proposals on the understanding that they were reviewed at the end of twelve months, and that should experience show they were not satisfactory or economical, some other machinery for selecting cases were adopted. It was important that no action should be taken which might debar persons in

need of treatment from obtaining it, and if any charge were made it should only be in cases in which there was clear evidence that a contribution towards the cost might be expected. It did not appear to the Board that any obligation could be imposed on medical practitioners who recommended cases for residential treatment to investigate and advise as to the financial circumstances of the patients.

Subject to these comments the Board approved generally of the proposals of the Council as regards adults, on the understanding that the provision of beds at present proposed was to be regarded as an instalment only of what would ultimately be required. The Board was in communication with the Board of Education in regard to the proposals for the treatment of children. It would be necessary for the institutions in which beds were retained by the Council to be approved by the Board for the treatment of tuberculosis if such approval had not already been given.

Correspondence.

SPECIAL FUND: TRADE UNION OR TRUST?

SIR,—In that part of the Annual Report of Council which deals with the proposed special fund members are referred to an appendix containing a report adopted by a majority of the Council in favour of the establishment of the fund on trade union lines. May I ask a few questions about this report? How many members of Council were present when it was voted upon? I am told 21 out of a possible 52. How many voted in favour of the report? Was it 11? How many voted against? Was it 8, and 2 not voting? I think we are entitled to have these details when we are dealing with a matter which may involve the destruction of the Association as now constituted.

The report is of the baldest possible nature. It hardly discusses any of the difficulties of the trade union proposals, and practically relies for its recommendation of the trade union method upon the statement that there is the "fullest legal protection possible to funds" under a trade union. The discussion which has taken place in the JOURNAL shows that there is room for much doubt as to the value of this "fullest legal protection," but I do not propose to deal with this aspect of the question. We are surely entitled to know why the Council has changed its mind since July of last year, when (see Supplementary Report of Council, pages 16–18 of SUPPLEMENT, BRITISH MEDICAL JOURNAL, July 5th, 1913) it submitted to the Divisions the most careful analysis of the situation I have yet seen, and ended up by recommending *against* the adoption of the trade union method of organizing the profession.

These arguments were endorsed by the Representative Meeting of July last year by a majority of over 2 to 1, and I think it is due not only to the members of the Association but to the reputation of the Council for consistency that we should be told why the Council has changed its mind. Such an explanation would, of course, entail an attempt by the Council to refute the arguments it adduced in the report to which I have alluded.

This report is so much to the point that I venture to ask you to append to this letter a rather lengthy extract from it. I would, however, urge all who are interested in the subject to read the whole of the report. It seems to me that most of those who have written on the subject recently have ignored or forgotten it. If members will only take the trouble to think this subject out I believe they will come to the conclusion that it is time we stopped wasting our time in pursuing a delusion which, owing to the fact that the Council does not seem to know its own mind, is at the present time unsettling many of our members whose time would be much better occupied in putting their energies into the work of an association which already includes a considerable majority of the working members of the profession instead of talking about the institution or encouragement of another body which must be a rival to the Association, and whose alleged advantages are at present very much "in the air." I think that there is at present a danger of some of us dropping the substance to grasp at the shadow.—I am, etc.,

Newport, Mon., July 6th. W. J. GREER.

*** Our correspondent's information as to the numbers present and voting is correct. The vote was reached after a motion to adjourn had been defeated, and after an amendment proposing that the three appendices to the Committee's report should be submitted to the Representative Body and Divisions without any expression of opinion thereon, had also been rejected.

Extract from Supplementary Report of Council, EMENT, BRITISH MEDICAL JOURNAL, July 5th, 1913.

14. But if such a trade union were formed could it be put and kept under the control of the Association, being used simply as a means of protecting certain voluntary funds raised for particular purposes outside the powers of the Association, and be run alongside the Association without the risk of becoming a serious rival to that body? The difficulties of such a course would be great. It is probable that, as advised by counsel, a trade union could be formed whose governing body could be nominated by the Association or its Council, but it would be impossible to ensure that at some future time the rules of the union would not be altered in a manner which resulted in its connexion with the Association being dissolved. Such a union, if successfully floated by the efforts of the Association, might induce large numbers of practitioners to join, and would undoubtedly attract mainly those practitioners engaged in insurance and other contract work. The tendency might be that those practitioners would join the union, but not the Association, and the time would probably come when the union would decline to be controlled by an Association largely composed of practitioners who did not subscribe to the union, were not specially interested in its objects, and many of whom might even be antagonistic to it. In addition, the encouragement of such a union by the Association would be looked upon by many as a confession of the inability of the Association to promote the interests of the profession as a whole, an object which has always been put in the forefront of the Association's claims on the support of the profession.

15. This latter point is of such importance that it deserves close examination. Is it a fact that the Association has failed to safeguard and promote the interests of the profession as a whole? Up to the passing of the Insurance Act most practitioners were probably of opinion that considering the comparative youth of the Association as a fighting machine, and particularly in view of the smallness of the subscription, the Association had done a very great deal for the profession. It is certain that it had gradually acquired the reputation of being the only representative organization of the profession, and as such was consulted by the Government. In December last Parliament, the press, and the public, looked upon the British Medical Association as a very strong organization indeed, equal to any of the trade unions. Dissatisfaction with the constitution of the Association, and the demand for the establishment of a medical trade union have undoubtedly received a strong impetus from the breakdown of the resistance of the profession in January last. But it may very seriously be questioned whether the form of the organization of the profession had anything to do with that failure. Trade unions after all depend mainly on the loyalty of their members, and loyalty is a sentiment which differs greatly in strength in different people. A few will go to the stake for it, but in most people its strength largely depends on social and economic conditions. In a strike workmen often disobey their trade unions when they are either compelled to give in by privation or are convinced that they have obtained all they are likely to get by the strike. In the same way it is obvious that large numbers of the medical profession in January last came to the conclusion either that the profession could not successfully resist the Government or that the terms offered by the Government were good enough to be given a trial. It is extremely doubtful whether these practitioners could have been induced to refrain from putting their names on the panel by any imaginable form of organization. Even if the Association had been a trade union offering financial support to its members who declined to accept service under the Act, it is probable that the non-members, together with those members who were never very strong in their resistance, and those who were convinced that the Act would be beneficial to them, would have been sufficiently numerous to provide a service in many parts of the country.

16. It is open to serious doubt whether trade unionism as a form of organization is suitable for the medical or, indeed, any profession. The strength of a trade union lies mainly in the following facts: (*a*) Its members generally work together in large groups, and it has never

been found possible, for example, to form an effective trade union among agricultural labourers or other scattered workers. It is much easier to bring moral suasion to bear on a man who works in a mine or in a workshop, and whose comfort, if not his daily bread, depends on his making common case with his fellows, than on one whose work must always remain largely an individual affair. (*b*) Another great source of strength to a trade union lies in the benefits which it gives to its members; the facts that a member loses all claim to these benefits if he leaves the union, and that he can be expelled from the union for disloyalty, undoubtedly go far to explain the adherence of trade unionists to their union, often in the face of great temptation. It is doubtful whether this resource is available to the medical profession. The subscription to a medical trade union which professed to give benefits equivalent to those given by a trade union (out of work pay, strike pay, accident pay, death benefit) would have to be very considerable, and there is no evidence that members of the medical profession are willing to pay such subscriptions. Investigations into subscriptions paid by several trade unions show that the amounts paid by each member vary from one-fiftieth to one-eightieth of the workman's total income, and as was shown in a leading article in the BRITISH MEDICAL JOURNAL of April 5th, 1913, members of the London Society of Compositors, whose average weekly wage may perhaps be stated to be 45s. per week, recently for a considerable period paid a subscription of 2s. 6d. per week—that is to say, one-eighteenth of their total income.

(*c*) The final resort of the trade union, if unable to secure its objects by negotiation, is to proclaim a strike and call its members out. This weapon is not available to the medical profession, and the same remark applies to many of the most effective methods of the trade unions, which depend on what is euphemistically called "moral suasion." Not only are they not available, but they are repugnant to the great majority of the profession.

17. The Council is of opinion that the subject should be most carefully considered by the Divisions in all its bearings, in view of the discussion which will take place at the Annual Representative Meeting. There is no doubt that there is something superficially attractive about the idea of a trade union, which has appealed very strongly to the members of a profession smarting under a sense of defeat and ready to snatch at any course which seems to offer a guarantee against the repetition of such a collapse as recently occurred. The Council has arrived at the conclusion that the formation of a medical trade union offers no such guarantee.

18. Quite recently a further possible course has been suggested to the Council. It may be said to be an inversion of 5 (*b*) in the report quoted above—namely, to form an entirely new limited company, with no licence from the Board of Trade, and with the widest possible powers, and to put all the property of the present Association into trust, to be used for the purposes for which it was raised. It has been suggested that in this way the new Association would have all the advantages of increased powers (though always, of course, within the limitations of what is possible to a limited company) and single subscription and one membership, and there would be no danger of forming bodies that might grow into powerful rivals. There would be only one trust, instead of many. The trust funds could be used, subject, of course, to the consent of the trustees, as long as they lasted, for the purpose for which they were originally raised, and as they would receive no additions, would in time be exhausted. The Council, in conjunction with the legal advisers of the Association, is considering the feasibility of the procedure.

MEDICAL FAME.

SIR,—Your very interesting editorial, "Medical Fame"[1] is illustrated by the many whose names are imperishable, and by others whose names are being overshadowed by oblivion. I would supplement your list with some names of Irishmen whose genius and skill promoted the science of medicine, but whose names find no place in modern medical literature, if we except an occasional allusive reference in von Ziemssen's *Cyclopaedia of Practical Medicine*. Our American friends are taking much credit for aspirating the lateral sinuses and perforating the corpus callosum, and Baron Dupuytren's operation on the cerebrum still lives in memory; but how few remember O'Halloran's incision of the corpus callosum in 1750! We puncture the spinal cord, examine the cerebro-spinal fluid for diagnostic purposes, and produce analgesia by injecting analgesics, but forget the splendid monograph of the brothers Griffen, which appeared one hundred years ago—a monograph worthy of von Ziemssen's eulogy. Waller's paper on diapedesis, which gave us the first true picture of the pathology of inflammation, remains unnoticed by the present generation. Little's wonderful operation on the arch of the aorta, which he successfully performed in Sligo Infirmary, has ceased to be referred to in works on surgery. Currie's introduction of the clinical thermometer is unrecognized, and Wunderlich is credited with the idea. But the overlooking of the great works done by the Higginses of Sligo is the most remarkable neglect of the age. "Holmes and Semmelweis" is the title of an editorial in the May number of the *Interstate Medical Journal* in which the writer properly ascribes much honour to both the scientists and refers to the statue erected by the Hungarians to Semmelweis both as a patriot and a scientist. But no mention is made of that distinguished scientist, William Higgins, who first announced the law of multiple proportions, and as long ago as 1802 demonstrated the antiseptic properties of chlorinated lime, and some ten years later induced his friend, Dr. Labatt to adopt its use in midwifery. About twelve years later Labatt introduced chlorinated lime solution into the Rotunda Hospital, but owing to the way the preparation was used by nurses knowing nothing of the principle of antiseptics its use was discontinued. Antiseptics came to be discredited and disused, just as was Boynton's theory of 1830–40. Of Bryan Higgins space does not admit of even a list of his many and valuable works. I may, however, say that in ethylic bodies he foretold that an anaesthetic would be discovered. May I supplement my list of distinguished Irishmen by a few quotations from a quaint old writer of the mediaeval period, Lanfrank? "If a sinew has been cut . . . it is good that you sew together the ends of the sinews . . . with the sewing of the skin," and on bleeding, or rather on the control of it, he writes: "He cut the skin above the vain and twined the vain in his hands and bound the end of a vain with a thred."—I am, etc.,

Dublin, July 4th. GEORGE FOY.

INFECTION OF CHILDREN WITH THE BOVINE TUBERCLE BACILLUS.

SIR,—I beg to submit for kind publication in your paper a few reflections occasioned by Dr. Mitchell's article on the danger to children of tuberculous milk.[1] It gives me great pleasure to render to British science and to Dr. Mitchell the homage due to his work for its scientific exactness and far-reaching conclusions.

The authority of Koch, which proclaims the non-transmission of bovine tuberculosis to human beings, has for too long proved a fatal illusion to consumers, has excused administrative indifference, and has encouraged frauds in every country. Dr. Mitchell's work proves definitely, following as it does that of Nocard and Arloing in France, of Tubinger and Jensen, of Behring in Germany, and others, that bovine tuberculosis can be transmitted to human beings. It confirms, also, the researches of Bang, Gehrmann, Evans, and Moussu, as to the presence of bacilli in the milk of tuberculous cows, even when their udders are quite unaffected, and although they do not present in appearance any clinical symptom apart from the tuberculin reaction. It further justifies the interest occasioned by the conclusions of the works of Calmette and Vallée, which establish that tuberculosis—in the case of young subjects at least—is most often transmitted through the intestines, and that of all the modes of infection the penetration of bacilli to the level of the intestines is the one which realizes the most rapidly and surely tuberculization of the ganglions annexed to the lungs. In short, we are specially happy in France in recognizing that all the remedies recommended by Dr. Mitchell are also those which our scientists and congresses have insistently asked for.

However, there is one remedy which my honoured *confrère* has perhaps not sufficiently developed, and regarding which, with your kind permission, I would like to bring forward some more precise data. I allude to the sterilization of milk.

It is very evident, alas! that we shall have to wait many years yet before administrative measures help to stem the

[1] BRITISH MEDICAL JOURNAL, July 4th, p. 31.

[1] BRITISH MEDICAL JOURNAL, January 17th, 1914, p. 125.

danger by increasing the number of veterinary inspectors so as to obtain rigorous control of all milch cows. Consequently the popularization of healthy milks free from pathogenic germs becomes the only practical means at our disposal for protecting the population, and particularly the children, from tuberculous infection.

I certainly agree with Dr. Mitchell when he recommends the use of sterilized milk for children, but—and the matter is of paramount importance—it is necessary to take the precaution of teaching the public, and even the doctors, what sterilization ought to be if it is to be really efficacious. Now, if the results of sterilization are excellent when it is carried out immediately, it has been demonstrated that when it takes place long after milking it does not possess the same advantages; that is why the sterilization of milk at home by the mothers after fifteen, twenty-four, or forty-eight hours, as happens in large towns, becomes an illusory and insufficient precaution, because such sterilization is incapable of purifying a milk which is already polluted, contaminated, and altered, not only by bacteria, but also by their toxins. In France Variot and many others have given numerous proofs of the dangers of this belated sterilization. - - -

Consequently, if we wish to fight satisfactorily against the danger so plainly shown by Dr. Mitchell, we must not content ourselves with proclaiming the necessity for sterilization, but on the other hand we must advocate the industrial sterilization immediately after milking. Above all, it is necessary that the doctors, the true educators of the public, should have the courage and honesty to give, after careful research and experiments, their true opinion of milks offered for consumption, as did Dr. Mitchell. This is their right and their duty. Just as they should point out the existence of contaminated milk such as that of Edinburgh, so should they testify publicly to the quality of commercial milks which have given them satisfaction. The increasing popularity of industrially produced sterilized milk in France, where it has saved so many children's lives, is due to the courage of Variot and his pupils.

I beg to bring to the notice of English doctors the work which I had the honour of presenting to the Académie de Médecine de Paris on January 27th, 1914, on the alimentary and therapeutic value of condensed milk for infant feeding. From my experiments, which fresh study has confirmed, and taking into consideration only facts registered during nearly three years' work in connexion with about one hundred children examined to date, it results that all the children nourished exclusively on condensed milk, even from their birth, have shown in weight and height a growth equal or superior to that of normal children. At no time during the first two or three years, in the course of which they have taken no other milk either alone during the first few months or with other food from the time of weaning, have these children shown any signs of digestive, osseous, or circulatory trouble. On the other hand, certain children nourished on other milks who were suffering from serious digestive derangements (vomiting, diarrhoea, etc.) and retarded development, when fed on condensed milk were quite able to tolerate it, and thanks to this properly administered diet recovered their health.

Further, in cases of serious infantile diarrhoea, instead of giving the children a hydric diet for too long, or vegetable bouillon which is deprived of all nutritive value, I have successfully given them condensed milk not diluted with boiled water in these instances, but with rice water, the astringent properties of which are well known. In these particular cases condensed milk, besides being a suitable food, constitutes an effective medicine.

These experiments show that condensed milk is a food entirely free from danger and of a distinct nutritive and therapeutic value to children. It should therefore be placed side by side with sterilized milk, which is so valuable when mothers' milk is lacking. Further, owing to its easy preservation, small volume, and reasonable selling price, it shows real advantages over sterilized milk. Its use should therefore obviously be adopted in large towns, and doctors will only do themselves honour in recommending it to mothers. In my opinion, there is no better remedy for avoiding the spread of tuberculosis amongst children.—I am, etc.,

DR. LASSABLIÈRE,
Chef de Laboratoire à la Faculté de Médecine de Paris.

Paris, April 29th.

SOCIETY FOR TUBERCULOSIS MEDICAL OFFICERS.

SIR,—The purposes of a society such as that proposed for medical officers of the tuberculosis service are, we may take it, two-fold. It primarily, by corporate action, looks after the interests of its members, and secondarily provides a meeting place for men engaged in the same work for discussion.

As your correspondents have pointed out, there is in existence a tuberculosis society. So far, however, its excellent work seems to have been confined to the consideration of tuberculosis problems more from the purely medical aspect. At present there are thirty tuberculosis medical officers members or Fellows of the Society of Medical Officers of Health. It has been suggested that they form themselves, as in the case of the school medical officers, into a group or branch of this society. The formation of such a group would obviate the danger—pointed out by Dr. Thompson Campbell—of the creation of separate societies. The constitution of the Society of Medical Officers of Health provides for the formation of as many district or county branches as may be necessary. The existing organization, likewise, provides every facility for a working basis. It is most desirable that all the branches of the Public Health Service should be brought together as much as possible; it would be to the interests of all concerned.

I suggest that the existing Tuberculosis Society take over the tuberculosis medical officer members of the Society of Medical Officers of Health and, if necessary, alter its constitution to meet the altered conditions. It might be named the Society of Tuberculosis Medical Officers, and a definite group arrangement be made with the Society of Medical Officers of Health. I trust that negotiations may be opened on such lines.

Meantime, the evident thing for all tuberculosis medical officers to do is to become members of either the Tuberculosis Society or the Society of Medical Officers of Health, pending any such proposed arrangements. The honorary secretary of the former is Dr. W. O. Pitt, 42, Upper Walthamstow Road, Walthamstow, Essex. The offices of the latter are at 1, Upper Montague Street Russell Square, W.C.—I am, etc.,

S. NICOL GALBRAITH,
T.M.O., Lambeth.

London, S.W., June 23rd.

THE ROYAL MEDICAL BENEVOLENT FUND.

SIR,—We have no intention of becoming parties to the retrial by newspaper correspondence of an issue which has been determined by a judge of the High Court; but we do desire to add a few last words on the dispute which has unhappily arisen between the Royal Medical Benevolent Fund and Epsom College respecting the Glenny legacy.

1. Much use—we might almost say sinister use—has been made of an incidental remark of the judge towards the end of the hearing of the case—namely, "If either of you people know, either by inadmissible evidence or otherwise, that the legacy was intended for the other you ought not to contest it." In the opinion therein expressed we unreservedly concur. Neither before nor during the hearing of the case did the committee of the Fund, or, so far as we know, any member of the committee, know of any evidence, "inadmissible or otherwise," respecting the intention of the testatrix which was not in the possession of the court when Mr. Justice Joyce delivered judgement in favour of the Fund.

2. We confidently rely on our letter of June 13th, and the letters of Messrs. Beale of that date and of June 27th, for a complete vindication of the good faith of the committee of the Fund, and of its sincere endeavour to effect an amicable settlement either by conference or by a joint friendly application to the court, or (privately) by the appointment of an arbitrator.—We are, etc.,

JOHN TWEEDY,
President.
SAMUEL WEST,
Treasurer.

July 7th.

THE twenty-fifth anniversary of the opening of the Johns Hopkins Hospital, Baltimore, will be celebrated with appropriate rites in the first week of October. Addresses will be delivered by a number of well-known teachers and clinicians.

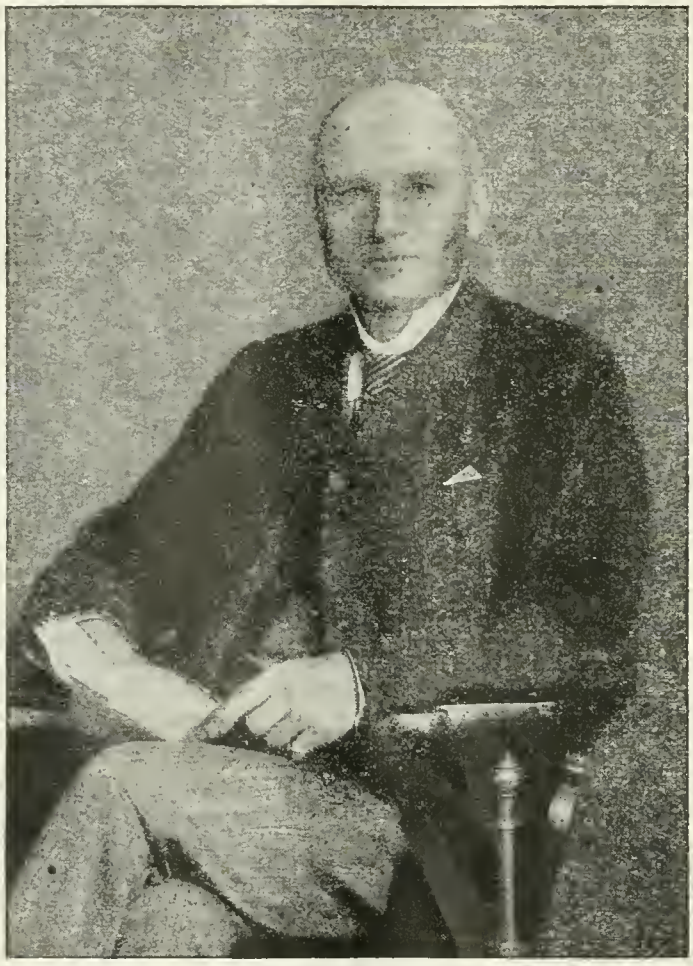
Obituary.

CHARLES VACHELL, M.D.Lond.,

CONSULTING PHYSICIAN TO THE CARDIFF INFIRMARY.

By the death of Dr. Charles Vachell Cardiff has lost one of its foremost medical men and one of its most public-spirited citizens.

Charles Tanfield Vachell was born at Cardiff in 1848. He was the eldest son of the late John William Vachell and grandson of Alderman Charles Vachell (Mayor of Cardiff in 1849 and 1855). His forbears had been settled in Berkshire for some centuries. He was educated at Hereford Cathedral School, and after matriculating in the University of London he entered King's College in 1865. He took the degree of M.B. in 1870, and graduated M.D. in 1874. In that year he became house-surgeon at the Cardiff Infirmary; in 1879 he was appointed medical officer to out-patients. In 1882 he was promoted to the position of full surgeon, and, strange as this custom may now appear, to that of physician in 1886. For some years, and up to the time of his death, he was consulting physician to the Infirmary, now known as King Edward VII Hospital.



CHARLES VACHELL.

He was a most accomplished practitioner, and throughout his life rendered distinguished service to the hospital.

In the affairs of the British Medical Association he always took a warm and active interest. He had been president of the South Wales and Monmouthshire Branch and of the Cardiff Division, and was foremost in the controversies aroused by the Insurance Act. He was a frequent contributor of papers to the Cardiff Medical Society, of which he had been president, and until recently took an active interest in the discussions. Hanging on the walls of the Society's rooms is a series of photographs illustrating some of Dr. Vachell's pioneer work in the surgery of the thyroid.

For many years he enjoyed an extensive and lucrative practice, and he was justly regarded by a large circle of patients as a steadfast friend and trusted adviser. He was one of the founders of the Cardiff Provident Dispensary.

The wide range of his interests and tastes was very notable. For many years he was an active officer in the Glamorgan Artillery Volunteers: he attained the rank of Surgeon-Lieutenant-Colonel, and was awarded the V.D. decoration after twenty-two years' service. For ten years he was honorary secretary of the Cardiff Naturalists' Society, and on three occasions filled with distinction the post of president. He was a great lover of natural history, and possessed a wide knowledge of botany. Associated for many years with the old Cardiff Museum, he did yeoman service in securing the location of the National Museum of Wales in Cardiff; he was a member of the court of governors, the council, and of various committees of the Welsh Museum from the start. He was a J.P. for the counties of Cardiff and Glamorgan. In politics he was an ardent Conservative. For a long period a worshipper at St. John's Church, Cardiff, he had for some years discharged the duties of churchwarden with general satisfaction.

His striking characteristics were an unbounded and infective enthusiasm, inexhaustible capacity for work, and great kindness, sympathy, and generosity. He was a man of strong personality and striking presence. His was essentially a full life. His skilful, devoted, and kindly services to the poor, his readiness at all times to help his colleagues with his wise counsel, and his unswerving loyalty will always cause him to be remembered with affection and esteem.

In 1887 he married Winifred, the daughter of the Rev. J. W. Evans, Rector of Cossey, Norfolk, and he is survived by his widow, a son, and two daughters.

His funeral on Monday, July 6th, was attended by a large number of his colleagues and friends, and afforded a striking testimony to the universal respect and affection entertained for him.

H. COOPER ROSE, M.D. St. Andrews,

HAMPSTEAD.

Dr. H. Cooper Rose, who practised in Hampstead for over forty years, died on July 1st at the age of 83. He was born at Wootton-under-Edge, Gloucestershire, and received his medical education at the medical school of Middlesex Hospital, where he gained high honours. He took the diplomas of M.R.C.S.Eng. and L.S.A. in 1853, and graduated M.D. at the University of St. Andrews in the following year. After residing a short time in Devonshire, he settled in Hampstead in 1855. He was appointed medical officer to the Soldiers' Daughters' Home, Hampstead, in 1860, and earned the love of the children, and the high esteem of the committee and staff. He became one of the surgeons of the Hampstead Provident Dispensary in 1866, retained that position for many years, and was appointed consulting surgeon on his retirement. He was a Fellow of the Royal Medical and Chirurgical Society and a member of its council in 1886–7, a Fellow of the Pathological Society, and a member of its council in 1873–4, and a Fellow also of the Obstetrical Society, serving on its council in 1875–6. In addition he was a Fellow of the Linnean, the Geological, the Royal Geographical, and the Zoological societies. He became a member of the British Medical Association at an early stage of his career, and was a member of the Central Council from 1870 to 1877. He was also a member of the

Council of the St. Andrews University Graduates' Council from 1870 until recently.

During his long life in Hampstead Dr. Cooper Rose took an active and generous part in almost every work of public interest or importance in the district. He was a member of the Hampstead Vestry for many years, and first chairman of its Sanitary Committee. In 1869 he originated the Hampstead Literary and Scientific Society, which had the advantage of listening to addresses by Sir Richard Owen, Dr. Edwin Lankester, and many others, including Dr. Rose himself. He was a Conservative in politics, was a member of the Conservative Association when Hampstead formed part of the constituency of Middlesex, and when Hampstead became a separate borough took an active part in its Conservative Association and in the Constitutional Club then established. In 1888 he was called to the Bar, and his knowledge of law helped him materially in his public work. He joined the Hampstead Rifle Volunteers, and served for six years as a private and for eight as a medical officer; in 1869 he joined the Royal East Middlesex Militia as surgeon-major, retiring at the end of fifteen years' service, retaining his military title and the right to wear the uniform. He was also for some years divisional surgeon to the Hampstead police. Dr. Rose's health broke down in 1895, and in that year he retired from practice and from his public work in Hampstead.

We regret to announce the death of Dr. FRANK PORTER NEWELL, Fellow and member of the Council of the Royal College of Surgeons in Ireland, which took place after a somewhat prolonged illness on June 24th, at his residence in Dublin. Dr. Newell was an articled apprentice to the late Sir George Porter, Bart., studied at the Meath Hospital, and graduated in the University of Dublin. When qualified, he acted as house-surgeon and resident medical officer of the Meath Hospital and County Dublin Infirmary for the unusual period of nine years. Subsequently he was appointed medical officer of the Castle Street Dispensary, and served in that capacity down to the time of his death. He was kind and sympathetic to the poor of his district, and a good and loyal friend. His death will be much regretted by his patients and many others.

DR. JOHN GAREY, an ex-member of the Town Council of Glasgow, died in a private nursing home in Glasgow on June 19th, after an operation. He was a native of Ayrshire, and became M.R.C.S.Eng. in 1880. Thirty years ago he began practice in the southern suburbs of Glasgow, and always took a keen interest in public affairs. In 1891 he was returned to Glasgow Town Council, and continued a valued member for a period of fourteen years. He was a J.P. for Glasgow, and was well known as a keen bowler and draught player. He was the first president, and for many years secretary, of the Hampden Bowling Club, Glasgow, and also for many years president of the Scottish Draughts Association. He is survived by his widow and two daughters.

DR. MURDOCK ALEXANDER LINDSAY, the young Professor of Pathology at Dalhousie University, Halifax, lost his life in the terrible disaster which befell the ss. *Empress of Ireland* on May 29th. Dr. Lindsay was on his way to England to be married. He was in his 32nd year. He was born in Halifax and educated at the academy there; he took the B.Sc. degree and his first two years in medicine at Dalhousie; the following three years he spent at the University of Edinburgh, where he took the degrees of M.B., Ch.B., in 1908. After spending some time in the hospitals of Edinburgh, Liverpool, Leeds, and Birmingham, he returned to his native city in 1911. He was appointed Pathologist at the Victoria General Hospital and Professor of Pathology and Bacteriology in the newly-established Faculty of Medicine at Dalhousie University. The esteem in which Dr. Lindsay was held was shown on the occasion of his funeral, which was one of the largest in Halifax for many years.

The Services.

INDIAN MEDICAL SERVICE.

THE following circular has been issued:

GOVERNMENT OF INDIA: ARMY DEPARTMENT.

MEDICAL DEPARTMENT.
Attendance. Simla, 14th April, 1914.

To the Director, Medical Services in India.

Sir,—I am directed to say that the Government of India have had under consideration the question of introducing a more definite reciprocity between the civil and military medical services than that at present existing as a result of the Orders promulgated in India Army Circulars, Clause 189, dated the 31st October, 1881. They have now decided that all medical officers, assistant and subassistant surgeons in military employ shall, when called upon to do so, render their services to civil departments gratuitously, and that similarly all such servants of Government in civil employ, including purely civil assistant and subassistant surgeons, shall perform, without payment, duties required of them on the military side in cases of necessity. Cases in which such officers, assistant or subassistant surgeons are called on to perform any specially arduous duty outside their own immediate work will be dealt with under the provisions of Finance Department Resolution No. 249-E.A., dated 15th July, 1912.—I am, Sir, your most obedient servant,

(Sd.) W. R. BIRDWOOD, Major-General,
Secretary to the Government of India.

Copy of the above, together with a copy of the Indian Army Circular referred to, forwarded to—

The Home Department.
The Foreign and Political Department.
The Finance Department.
The Public Works Department.
The Department of Revenue and Agriculture.
The Department of Commerce and Industry.
The Department of Education.
The Railway Department (Railway Board).
The Financial Adviser, Military Finance.
The Director-General, Indian Medical Service.
The Chief of the General Staff.
The Adjutant-General in India.
The Quartermaster-General in India.
The Military Secretary to His Excellency the Commander-in-Chief.
The Director-General of Ordnance in India.
The Director-General of Military Works.
The Director, Royal Indian Marine.
The Military Accountant-General.
The Controller of Military Supply Accounts.
The Controller of Military Accounts, 1st (Peshawar), 2nd (Rawalpindi), 3rd (Lahore), 4th (Quetta), 5th (Mhow), 6th (Poona), 7th (Meerut), 8th (Lucknow), 9th (Secunderabad), Burma, Divisions.
The Examiner of Accounts, Military Works.

(Sd.) A. W. CHITTY, Major,
Assistant Secretary to the Government of India.

ARMY CIRCULAR.

MILITARY DEPARTMENT.

MEDICAL DEPARTMENT.
Attendance. Simla, the 31st October, 1881.

CLAUSE 189.

Medical Officers of the British and Indian Services bound to give their Professional Services without Remuneration when required by proper authority in the interests of Government.

Officers of the Army Medical Department and of the Indian Medical Service are not entitled to extra remuneration for the performance of any duty prescribed by regulation which may be required of them by proper authority in the interests of Government.

If the services of a medical officer, in military employ, are temporarily needed for Government purposes in other departments, they are to be asked for through the military authorities, and no fee for such special or extra duty is admissible.

Similarly, in cases of emergency, military authorities are entitled to apply officially to local heads of departments for the gratuitous services of medical officers in civil employ.

It will be observed that the Army Circular of October 31st, 1881—Clause 189—referred to officers of the Army Medical Department (now Royal Army Medical Corps) and of the Indian Medical Service, that is, to commissioned officers only.

The Order of April 14th, 1914, extends the scope of the Army Circular of 1881 to the Indian Civil Subordinate Medical Departments—to include all assistant and subassistant surgeons, and also to all civil assistant surgeons and subassistant surgeons—that is, purely civil officers who have no connexion with the army.

The Army Circular of 1881, though not generally known, has apparently worked without friction, and is in itself a proper order, and its extension to all Government medical servants, of whatever grade, seems to be without objection. But the new Government of India Order (April 14th,

1914) is so loosely worded—as has often, unfortunately, been the case with Orders affecting medical officers—that an immediate explanatory and supplemental order would seem to be necessary.

The words most open to criticism are "when called upon to do so." Called upon by whom? The Order does not say, and as it stands it would be open to any Government servant in civil employ to call upon any military medical officer or subordinate to render medical assistance, and similarly any military officer could requisition the services of a civil medical officer or subordinate.

The old Army Circular of 1881 limited the services to be rendered to "duties prescribed by regulations," and the requisitioning authority to "proper authority in the interests of Government." Probably the new Government of India Order implies such duties "prescribed by regulation" and "in the interests of Government," and means that a "proper authority" should requisition the services of the medical officers, civil or military, of any grade. But if so, why does not the Order say so? It is only too well known how these loosely worded orders are constantly interpreted against the officers affected by them. "When in doubt, give it against the officer" was once the instructions of a Government financial authority to his office.

In the case of an Order like that under notice which may be assumed to impose extra duties, without remuneration, on medical officers of all grades, both military and civil, it should be distinctly laid down by whom the requisition is to be made, that the duties are such as are prescribed by regulation, and that they are in the interests of Government; a mere reference to an old Army Circular issued thirty-three years ago and not to be found in *Army Regulations, India, vol. vi, Medical*, of which we have the edition of 1904 before us, is not satisfactory.

For years past it has been a matter of astonishment that the Government of India should fail to see the too frequently irritating nature of orders and of the wording of orders issued in the Medical Department. We wonder if the successive Directors-General have always been consulted as to the wording of orders. We understand that *Army Regulations, India*, are periodically republished and that each fresh edition contains all the changes and new orders made since the previous issue. In the copy for 1904 we do not find the substance of Army Circular of October 31st, 1881, which is surprising if it was then in force—that is, in 1904, ten years ago. The only reference to the subject is in paragraph 45, which says that medical officers in military and civil employment may be assigned temporary civil and military duties, respectively, as an extra charge, with the concurrence of the local Government and the general officer commanding.

THE INDIAN MEDICAL SERVICE.

I.M.S. (India) writes: I feel I cannot allow the letter signed "V. P. Gonsalves," published in the BRITISH MEDICAL JOURNAL of May 30th, p. 1218, to go unanswered, as it appears to me to be quite misleading in many particulars. When the writer says that "the names of a few competent officers are given, and it is apparently contended that the record of their work is a proof of the high quality of the work of the whole service," one really wonders whether Mr. Gonsalves is as ignorant of the enormous amount of work that has been and is being done by the members of the Indian Medical Service, or of the number of eminent and highly qualified men who have been and are at present in the service, as this sentence would lead one to suppose. If so, it would be as well if he were to study the past records of the Indian Medical Service and glance at the qualifications and records of the men at present serving before he rushes into print with such statements.

Again, when he talks about the higher grades of the Civil Department being reserved for military doctors, to those who do not know the real condition of affairs it would appear that the Indian Medical Service was purely a military service and that if a doctor was required for some special appointment in the Civil Department one would be sent direct from military employ without any reference to his special qualifications. The real facts of the case are that a considerable percentage of the service is in constant civil employ, and a large proportion of men join with the sole idea of getting a civil appointment. Although every man *must do* at least two years in military service, yet as soon as there are vacancies after this, he will, if he wishes it, be posted to civil employ, and, except in the case of grave military emergency, remain there for the rest of his service, if his work is satisfactory. In the case of the professors at the various medical colleges these are not even liable for recall to military service. I think to call such men military doctors is, to say the least of it, a terminological inexactitude.

The duties of the ordinary civil surgeon are very numerous and varied, and many people, so far from contending that the years spent in military and civil employ prior to being appointed to a professorial chair are wasted, and unsuit a man for such appointments, hold that they form a most valuable training and make a man a far better and broader-minded specialist than he would otherwise have been.

That mistakes have been made in the past, and may again be made in the future in the selection of the best and most suitable men for the professorships, no one will deny; nor that such anomalies as Mr. Gonsalves mentions have occurred in the past, but there is such a strong feeling against it that it is most improbable that it will ever occur again. On the other hand, is there any system by which such mistakes can always be avoided? Can it be said of any hospital in the world that the staff is the best and most efficient that could possibly be selected?

What I do affirm and what I am sure that any disinterested person who knows India and the India Medical Service will agree with me in affirming is, that as far as medical and surgical qualifications and the special experience necessary for the professorial posts are concerned, the service can furnish as good, if not better men, than could be obtained from any other sources.

I would further point out that a large majority of the Indian Medical Service have gained valuable experience by holding resident hospital appointments at home before coming into the service, and thereafter when on leave many of them engage in special courses in the subjects in which they specialize.

The candidates for the professorial appointments are, moreover, as a rule selected from those men who have gained further valuable experience by holding one or other of the posts of resident surgeon, or resident physician, to one or other of the more important hospitals out here, which practically entails the charge of the patients and the performance of nearly all the emergency operations, etc., in the absence of the professor, and very often the charge of the out-patient department as well. After holding a post of this kind for two years or more, they will then, as vacancies occur, and if considered suitable, be appointed to act for the professors when these take leave, and usually they will so act on several occasions before being appointed permanently to such a post. It will thus be seen that in nearly all cases there is very ample opportunity of judging how far any man is fitted for any post of this kind before he actually obtains it. Would this be the case to the same extent with any other system?

The only feasible alternative would be to obtain men direct from home to fill these appointments; and with their entire ignorance of the country, its special diseases, the language and inhabitants, they would be at an immense disadvantage, to say nothing of the difficulties that would arise in providing men to act for them when sick or on leave. Moreover, if really highly qualified and experienced men are to be obtained, the salaries would be prohibitive, and even then it is, I think, highly doubtful if the work would be as efficiently performed as at present, owing to the numerous disabilities under which such men would be working.

When one sees the ease with which the numbers of Indian students who go to England nowadays from the Indian medical schools gain diplomas after only a few months' study, it does not seem as if there was much wrong with the teaching they have received out here.

Again, the writer asks, "Why is this system not adopted by other countries or native states?" The reply appears to me to be perfectly simple—namely, that there is no other country or native state in which precisely the same conditions exist as in India. I feel that I have already trespassed too far on your valuable space, so will refrain from going into this matter any further now.

Universities and Colleges.

UNIVERSITY OF LONDON.

MEETING OF THE SENATE.

A MEETING of the Senate was held on June 17th, under the chairmanship of the Vice-Chancellor, Sir Wilmot Herringham, who was re-elected Vice-Chancellor for the year 1914-15.

Site for the University.

A letter was read from the Secretary to the Prime Minister intimating that the Government could not contemplate the diversion of Somerset House from its present purposes. It was resolved:

That the Vice-Chancellor be requested to inform His Majesty's Government that the Senate, having considered various sites which have been suggested for the head quarters of the University, are of opinion that it is undesirable to proceed further with such consideration unless and until His Majesty's Treasury intimate their willingness to provide accommodation more suitable in situation, more convenient in character, and on terms not less advantageous as regards tenure, etc., than those attaching to the present occupation at South Kensington.

Recognition of Teachers.

Mr. William W. C. Topley was recognized as a teacher of pathology at Charing Cross Hospital Medical School.

Appointments.

Professor Arthur W. Crossley, Ph.D., D.Sc., F.R.S., was appointed to the University Chair of Chemistry tenable at King's College.

It was reported that the Principal had appointed Professor F. Womack (St. Bartholomew's Hospital) as examiner in physics at the first examination for medical degrees to be held in July, 1914, in place of Mr. A. O. Rankine.

Anthropological Research.

The thanks of the Senate were accorded to Dr. Robert Mond for a donation of £250 for the purpose of enabling Dr. B. Malinowski to carry out investigations on tribes in New Guinea, and the title of "Research Student of the University of London" was conferred on Dr. Malinowski in this connexion.

Board of Studies in Pharmacology.

A board of studies in pharmacology was constituted for the remainder of 1914 as follows:

(a) Teachers of the University: Dr. A. J. Clark (Guy's Hospital Medical School), Professor A. R. Cushny (University College), Professor W. E. Dixon (King's College), Dr. W. J. Fenton (Charing Cross Hospital Medical School and Hospital for Consumption), Dr. O. F. F. Grunbaum (London Hospital Medical College), Dr. P. Hamill (St. Bartholomew's Hospital Medical School), Dr. R. H. Miller (St. Mary's Hospital Medical School), Dr. F. Ransom (London School of Medicine for Women), Dr. R. A. Young (Middlesex Hospital Medical School and Hospital for Consumption). *(b) Other Persons:* Dr. H. H. Dale; (the person, if any, who, not being a teacher of the University, is for the time being a staff examiner of the University in Pharmacology). *(c) Whether Teachers of the University or other Persons:* The chairmen of the Boards of Intermediate Medical Studies, Advanced Medical Studies, Studies in Physiology, Studies in Human Anatomy and Morphology.

It was resolved that the board be deemed to be within the purview of the Faculty of Medicine.

Grant to the University of London Club.

It was resolved that a grant of £100 be made for the year 1914–15 to the University of London Club on condition that the club shall be put, free of charge, at the disposal of the university for official purposes upon the request of the Vice-Chancellor or Principal.

Donation from Committee of International Congress of Medicine.

The thanks of the Senate for a donation of £100 were accorded to the Committee of the seventeenth International Congress of Medicine which met in the university buildings in 1913.

Appointment of Representative.

Dr. R. H. Cole was reappointed Governor of the Slough Grammar School.

Regulations for M.B., B.S. Examinations.

The Senate has resolved that in and after the session 1915–16 the regulations for the M.B., B.S. examination for internal and external students be amended as follows:

By the substitution for the words "Eye, Ear, and Throat," of the words "Eye, Ear, Throat, and Skin" in Section (11) of the syllabus in surgery.

Chairman of Committees.

Sir Alfred Pearce Gould, K.C.V.O., M.S., F.R.C.S., has been appointed Chairman of the Graham Legacy Committee, and Dr. F. Taylor Chairman of the Committee of Medical Members of the Senate.

Paul Philip Reitlinger Prize.

The Paul Philip Reitlinger prize (£30 in 1914 and £40 in 1915) will be awarded annually on December 3rd, provided there is a candidate (who must be an undergraduate or graduate of not more than five years' standing) of sufficient merit. In 1914 and biennially thereafter the prize will be awarded for the best essay embodying the result of some research work on the medical subject carried out by the candidate. In 1915 and biennially thereafter the prize will be awarded for the essay on a literary, historical, or philosophical subject. Essays must reach the Principal of the university not later than October 1st in the year of award.

UNIVERSITY OF MANCHESTER.

Degree Day.

THE Degree day ceremony, on Saturday, July 4th, attracted a large audience, the Whitworth Hall being literally packed. In his opening statement, the Vice-Chancellor (Professor Weiss) made special reference to the resignation of his predecessor, Sir Alfred Hopkinson, who had witnessed during his term of office a steady growth and development of the university. Reference was also made to the loss which the university had sustained by the death of Mr. E. J. Broadfield. There had been a considerable increase in the number of the students, and the Vice-Chancellor regarded it as particularly gratifying to find that the entry of students to the medical school was greater than it had been for many years past. This increase in the number of students imposed a difficult task on the university—to find the necessary accommodation for lectures and laboratory work the Council had sanctioned the erection of a new building for the Arts Department, which it was estimated would cost about £30,000; to meet this the university would have to depend on the generosity of its friends and the citizens of Manchester. In addition to a large number of degrees in all the faculties, the following honorary degrees were conferred: LL.D., Mrs. Lees of Oldham; Doctor of Letters, Professor Fenillerat of Rennes, and Professor Gonner of Liverpool; Doctor of Science, Professor Bragg of Leeds and Mr. J. E. Stead; Master of Arts, Mr. W. F. Cotterill of Salford; Master of Technical Science, Mr. Charles Day of Manchester.

Examination Results.

The following candidates have been approved at the examinations indicated:

FIRST M.B., CH.B. *(Part III, Organic Chemistry and Bio-Chemistry).*—N. Abdoh, T. H. Almond, May Ashburner, Sybil Bailey, H. Bradshaw, Mary G. Cardwell, H. J. Chronnell, T. Colley, S. E. Critchley, Elizabeth C. Davies, H. Dickie, E. B. A. Edleston, P. Fildes, G. H. W. Gough, F. L. Heap, F. S. Horrocks, Fahim Isaac, A. W. Kirkham, J. H. Lees, J. Mills, T. O'Brien, Kathleen O'Donnell, E. Pigott, H. J. Porter, A. R. Redfern, L. Samuels, A. G. Saunders, L. J. Schwartz, V. T. Smith, J. T. Walker, Marie Wardman, Ethel D. Willis.

THIRD M.B.—G. S. Bate, H. W. Bennett, H. Chadwick, W. Christopher, R. Colley, Eva L. Glasier, Alice M. A. Holt, R. L. Newell, F. C. Ormerod, J. A. Panton, Nesta H. Perry, Dorothy Potts, C. R. Sandiford, W. Stansfield. *(Pharmacology and Therapeutics).*—J. H. Albinson. *(Hygiene).*—J. D. Byrd.

FINAL *(Forensic Medicine and Toxicology).*—J. C. Bramwell, *A. T. Gibb, E. Granger, W. Halliwell, *J. G. McKinlay, H. M. von Mengershausen, J. F. C. O'Meara, F. G. Prestwich, J. Rigby, C. G. Todd, F. Vause, L. Walton, R. Willan. *(Obstetrics).*—W. S. Booth, G. B. Horrocks, K. Maximus. *(Medicine).*—W. S. Booth, G. B. Horrocks, K. Maximus. *(Surgery).*—G. B. Horrocks.

FINAL *(All Subjects).*—†Lily Allan, B. Browning, F. Chadwick, J. W. Craw, H. C. Duffy, C. W. Fort, **D. T. Harris, J. R. Jagger, †O. M. de Jong, E. A. Linell, Kate K. May, A. S. Paterson, *J. R. B. Russell, J. R. Slack, E. H. Walker.

* Passed with distinction in one or more subjects.
† Second-class honours.

UNIVERSITY OF SHEFFIELD.

THE following candidates have been approved at the examinations indicated:

FIRST M.B., CH.B.—J. N. Gale, J. V. Mainprize, R. H. B. Mathews, J. Ryan, Alice White, Ethel White.

SECOND M.B., CH.B.—Mary Andrews, F. G. E. Hill, Florence E. Millard.

FINAL.—W. B. Allen, G. F. Stones, J. R. Turner, D. C. Turnbull C. H. Wilson.

D.P.H.—J. R. McGregor, E. T. K. Walker, P. D. Warburton.

* Second-class honours.

UNIVERSITY OF EDINBURGH.

Honorary Degrees.

AMONGST those who received the honorary degree of LL.D. at the graduation ceremonial on July 3rd were Byrom Bramwell, M.D., Consulting Physician to the Royal Infirmary, and Frederick Walker Mott, M.D., Pathologist to the London County Asylums.

The Dean of the Faculty of Laws (Professor James MacKintosh), in presenting Dr. Byrom Bramwell, Consulting Physician to the Royal Infirmary, said: Fortune has not acted blindly in putting in the van of the honorary graduates in law the distinguished physician whose commanding presence so well fits him for the part, and whose brilliant reputation, built up in our midst, has added fresh lustre to the Edinburgh Medical School. After Dr. Bramwell quitted our class-rooms, laden with student honours, he garnered a wide knowledge of medicine in five years of busy general practice, followed by five years of fruitful hospital work at Newcastle and on the teaching staff of the Durham College of Medicine. Returning to Edinburgh in 1880, he conducted extra-mural classes with gratifying success, while the remarkable gifts he displayed in the clinical wards of the Royal Infirmary soon made his name known all over the medical world as a great clinician and carried him into the front rank as a consulting physician. Perhaps his most salient characteristics were a rare acumen in diagnosis and a sympathetic attitude to every advance in medical thought and practice, which made him a pioneer in introducing many of the newer methods of treatment. His contributions to medical literature, as diverse in subject as they are striking in volume, are highly prized as scholarly records of keen observation and extensive experience. Successive editions of his valuable textbooks and fresh series of his clinical reports have served to revive for many a practitioner the impressions and inspiration first caught from the author's lips in the crowded wards. Many generations of former students will be gratified to learn that the Senatus has shown its appreciation of Dr. Bramwell's high deserts and the distinguished services he has rendered by admitting him a doctor in the sister Faculty of Law.

In presenting Dr. Mott, Pathologist to the London County Asylums, he said: It is my privilege to present next an acknowledged leader and guide of medical opinion in the great and growing department of psychiatry, one who is held in equal honour on both sides of the Border. A graduate of London with the highest distinction, Dr. Mott served a long apprenticeship to general medicine as physician to Charing

Cross Hospital, and was elected a Fellow of the Royal Society in 1897 in recognition of his valuable researches on the comparative anatomy and physiology of the brain and spinal cord. For the past seventeen years he has held the post of pathologist to the London County Asylums, and has devoted his energies to a department which he has made peculiarly his own—the pathology of the brain and mental disease. To take but a few examples of his original investigations in this field, he has demonstrated that syphilis is the essential cause of general paralysis of the insane and locomotor ataxy: he was the first to describe the changes in the brain produced by sleeping sickness; and he has elaborated from statistics and pedigrees an instructive study of the influence of heredity in relation to epilepsy, feeble-mindedness, and insanity. The results of these and many other researches in neuro-pathology, Dr. Mott has presented with fullness and clearness in standard textbooks and special journals, while he has delighted many a professional gathering by luminous addresses like the Morison lectures delivered in this city. Nor must I omit to mention his strenuous exertions in connexion with the establishment of the Maudsley Hospital for the study and treatment of incipient insanity. Many honours have rewarded Dr. Mott's outstanding services in forwarding the scientific study of mental disease and in alleviating the unhappy lot of its victims, and the university would fain add its tribute of admiration and esteem by enrolling him among its honorary graduates.

Degrees.

The following candidates have been approved at the examination indicated:

FIRST M.B. (*Physics*).—R. F. Balmain, W. E. Coutts, E. D. D. Dick, son, W. J. Dunn, H. A. E. Kirby, V. L. P. Hayes, L. A. Lawrence, J. B. Liggins, F. P. MacGillivray, Mary P. Mair, W. J. Manson, I. Platzky, H. S. Plowman, B. Pyman, J. Reid, D. G. Robertson-W. G. Robson, E. O. Ruddock, T. A. Seller, J. K. Son, G. A. Sinclair, H. G. Smith, M. R. Zada, W. L. Zeeman. (*Chemistry*).—B. Cheifitz, Anna G. Christie, W. J. Dunlop, D. N. Dutt, M. H. A. Fletcher, D. T. P. Gay, R. T. Halliwell, V. L. P. Hayes, H. P. D. Helm, S. S. Horwitz, W. G. Hughes, L. A. Lawrence, Anne L. MacDonald, J. E. B. Miller, J. K. Mitchell, J. K. Murray, J. J. van Niekerk, J. Robinson, E. O. Ruddock, J. Sharp, Eliza J. Stuart, J. Tulloch.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

ELECTIONS TO THE COUNCIL.

No fewer than 1,048 Fellows sent in their voting papers for the election of members of Council on July 2nd; 11 voting papers arrived too late, and out of the 1,037 votes that were counted, 3 were pronounced invalid. Only six Fellows voted personally. This was the largest poll ever recorded at the Council elections.

The result was as follows:

Candidates.	Votes.	Plumpers.
WILLIAM THORBURN (Fellow 1886, Manchester)	534	53
CHARLES ALFRED BALLANCE, M.V.O. (Fellow 1882)	434	5
WILLIAM MCADAM ECCLES (Fellow 1892)	351	23
JAMES STANLEY NEWTON BOYD (Fellow 1881)	337	14
CHARLES RYALL (Fellow 1896)	304	13

Mr. Ballance, who had retired from the Council in rotation, was re-elected, and Messrs. Thorburn, Eccles, Stanley Boyd, and Ryall were elected Members of Council.

The remaining nine candidates were not elected:

Candidates.	Votes.	Plumpers.
John Bowring Lawford (Fellow 1885) ...	256	5
Thomas Horrocks Openshaw, C.M.G. (Fellow 1886)	245	30
Walter George Spencer (Fellow 1887) ...	238	2
Raymond Johnson (Fellow 1888) ...	218	7
Frédéric Francois Burghard (Fellow 1889)	204	4
Francis James Steward (Fellow 1898) ...	177	25
Herbert Stringfellow Pendlebury (Fellow 1897)	106	9
Thomas Herbert Kellock (Fellow 1891) ...	99	0
Percival Macleod Yearsley (Fellow 1895)..	90	2

Mr. Willmott H. Evans and Mr. J. E. T. Frazer acted as scrutineers.

The result of the poll was announced just before 7 p.m. by the President, Sir Rickman J. Godlee, Bart., who presided at the election.

CONJOINT BOARD IN IRELAND.

THE following candidates have been approved at the examination indicated:

FINAL COLLEGES.—R. M. Alcorn, R. A. Austin, R. J. Brookes, F. Byrne, W. P. Cooney, T. N. Enright, A. B. Foott, S. H. Good, C. W. Joynt, J. Lanigan, A. Merrin, W. J. J. Mulcahy, C. Murray, J. J. O'Connell, H. V. O'Donoghue, L. S. O'Grady, G. M. C. Powell, N. A. K. Sparrow, M. Shipsey, F. M. D. Taylor, J. J. Walsh.

Public Health AND POOR LAW MEDICAL SERVICES.

POOR LAW MEDICAL OFFICERS' ASSOCIATION OF ENGLAND AND WALES.

THE annual meeting of this association took place on Thursday, July 2nd, at Burnley.

The Mayor (Alderman J. S. Kay), in welcoming the members in the Council Chamber of the Town Hall, spoke of the unfortunate dispute which had been going on in Burnley for some eighteen months between the Poor Law medical officers and the Poor Law authorities. He held no brief for either party, but trusted that the dispute might come to an end speedily. If as Mayor he could be of any assistance at any time in bringing about a settlement, he would be pleased to render that assistance. Surgeon-General Evatt, the President, in returning thanks for the reception, said that he also regretted there should be friction at Burnley, and the Council of the association agreed with the Mayor most thoroughly. It was surprising that a town that had done so much by providing an institution so admirable as the Poor Law Hospital he had had the pleasure of inspecting should allow friction over a matter which must be capable of being settled. If it was possible for the Mayor to help, the association would be glad to have his assistance. The Mayor said he hoped the meeting might be a happy augury for a settlement.

Dr. Bird, Honorary Secretary of the Burnley Division of the British Medical Association, who also welcomed the meeting, said that the Division was doing everything in its power to settle the dispute.

The Mayor then withdrew, and the minutes of the last annual meeting were read, confirmed and signed by the chairman. The annual report of the Council and its report on the Poor Law Institutions Order (see JOURNAL, June 6th, p. 1271) were unanimously received and adopted, and a copy of the latter was directed to be sent to the Local Government Board. The balance sheet for the year was, after some discussion, unanimously approved. Surgeon-General Evatt, president, and Dr. Major Greenwood, honorary secretary, were re-elected to those offices by acclamation. Dr. Napper was re-elected treasurer, and Dr. Withers Green auditor. Dr. Balding was also re-elected chairman of council. The following were elected members of council for 1914–15: Dr. Holder (Hull), Dr. Gidley-Moore (Fyfield), Dr. Lloyd Brown (Tunbridge Wells), Dr. Withers Green (London), Dr. George Jackson (Plymouth), Dr. Drury (Halifax), Dr. C. Biddle (Merthyr Tydfil), Dr. Thackray Parsons (London), Dr. W. Brown (Bristol), and Dr. Agnew (Burnley).

Recent Legislation affecting the Duties of Poor Law Medical Officers.

Mr. C. E. Bygrave, Clerk to the Blackburn Guardians, said that the Poor Law Medical Service had been considerably affected by recent legislation and Departmental Orders. Upon the passing of the Insurance Act it was anticipated that the duties of district medical officers would be considerably lessened as a direct result of the Act. But relieving officers in the Blackburn Union stated that they found on the whole no appreciable difference in the issue of medical orders, as distinct from ordinary orders for relief, and they gave the following reasons—that the migratory population, usually the unemployed and unemployable, were uninsured, that was, not in benefit, and that the members of the resident population who were out of benefit were apt to seek the assistance of the district medical officers upon the occurrence of the slightest need, as apparently his or her insured brother or sister was in the habit of doing. Where insured persons had no medical card, it was easier to obtain the services of the district medical officers than those of the ordinary doctor. The total number of persons in the Blackburn Union who were being attended by district medical officers on December 12th, 1913, was 117, and the number attended on December 12th, 1911, was 93. The diminution in the number of persons in receipt of out-relief between 1910 and 1911 was mainly due to the removal of old age pensioners from the outdoor relief list. The cases of midwifery were undoubtedly fewer, but in some, though the mother was in receipt of maternity benefit, it had been found necessary to effect removal to the workhouse infirmary. In the workhouse infirmary the maternity cases were also fewer in number. The need for institutional medical treatment did not seem

to be diminished as a result of the Insurance Act. The Local Government Board had expressed the opinion that medical officers should assist insured persons in the workhouse who applied for certificates enabling them to recover from their approved societies the amount of the benefits which accrued during their treatment in the workhouse infirmaries. Mr. Bygrave, however, expressed the opinion that all that the workhouse medical officer could be called upon to supply was the certificate which required the medical officer to certify in writing the sickness of the inmate or the cause of his attendance on him. He was unable to agree with the statement that the duties of the medical officers had largely increased in consequence of the new Institutions Order. The question of remuneration of workhouse medical officers for attending and giving evidence at inquests held on workhouse premises appeared to him to require putting on a more satisfactory basis. The Old Age Pensions Act had caused a large diminution in the number of old persons in the receipt of out-relief, but the recipients of the pensions were still entitled to the services of the district medical officers. There seemed to be a consensus of opinion of the need for a standard curriculum and examination for Poor Law nurses, and schemes were in course of preparation with this object. This would obviously mean an increase rather than a decrease in the duties of workhouse medical officers. The proposals to appoint whole-time district medical officers were not likely to mature; he had had some experience in a sparsely populated rural union, but large in point of area, and he could not bring himself to believe that the proposals would be seriously considered as being suitable for such a union, and even if the position of medical officers and health and district medical officers were combined, the salary offered for the joint posts would not be likely to attract competent men: there was a difficulty in obtaining men for whole-time appointments except for the more important posts.

In the discussion which ensued, the Secretary said that old age pensioners had largely increased the work of the Poor Law medical officers. The old people remained outside the workhouse, and had to be attended by the doctor outside. Dr. Parsons (Fulham), speaking of the effect of the Insurance Act on institutional treatment, said the Act had distinctly reduced the number of maternity cases at Fulham, but had caused very little diminution in other cases.

Dr. Holder (Hull) complained that a medical officer was sent into a district without a hope of getting promotion for what he did. No one went to see whether they did their duty or not, except the relieving officer, and he did not report. There was never any recognition of their service.

(To be continued.)

Medical News.

IT is announced that the Parliamentary Committee on Proprietary Medicines will meet shortly to consider a draft report prepared by the chairman, Sir Henry Norman.

THE *Light Car* (1d.) for this week (July 8th) is a special doctors' issue, and contains a series of illustrated articles on various types of light cars considered to be specially suitable for medical men.

ON the occasion of his leaving Sheffield to take up a position under the Board of Education, Dr. Ralph Williams, medical officer to the Sheffield Education Authority, was presented by the medical staff of the schools with a silver cigar-box, a set of Kipling's works, and a suit-case, as a token of their esteem.

THE steamship *Orvieto* of the Orient Line, which left the Thames on July 3rd, carried a large number of members of the British Association, who are journeying to Australia for the annual congress there. Among them were Sir Edward and Lady Schäfer, Sir Oliver and Lady Lodge, Professor Symington, Mr. C. J. Bond of Leicester, Dr. F. A. Dixey of Oxford, Professor E. A. Minchin, and Dr. H. W. Marett Tims.

THE War Office Committee appointed to inquire into the relations of the British Red Cross Society and the St. John Ambulance Association has begun its inquiry. The Chairman is Sir Walter Lawrence, G.C.I.E. The Red Cross Association is represented by Mr. Ridsdale, Chairman of the Executive Committee, and Sir Anthony Bowlby, C.M.G.; the St. John Association by Sir James Andrew Clark, C.B., and Lord Herbert Scott; and the St. Andrews Association (Scotland) by Sir George Beatson, K.C.B. The other members are: General Sir Edmond Elles, Chairman of the Territorial Forces Association; Colonel Streatfeild, Chairman Kent Territorial Force Association; and Mr. R. H. Brade, C.B., and Surgeon-General Macpherson, C.M.G., nominated by the War Office.

WHILE holding an inquiry recently at the City Coroner's Court, Dr. F. J. Waldo drew the attention of the jury to the formalin chamber in which the body had been preserved. It was, he believed, the only one in the United Kingdom, although the system was in use in Belgium and at various places along the Mediterranean coast. He found that the features of bodies, especially those taken from the river, became more recognizable after they had been exposed to the formaldehyde fumes (1 in 40) for a few days in the chamber. He added that the London County Council had power under the Public Health (London) Act, 1891, to build and equip with preserving apparatus two mortuaries for use by London coroners, but had taken no steps in this direction.

THE occasion of a garden party, given by Dr. G. H. Davy in the grounds of the Newland Orphan Homes to members of the East York and North Lincoln Branch of the British Medical Association, was taken to present Dr. John Divine with a silver salver and a cheque for £45. The salver bore the following inscription: "This tray, together with a cheque for £45, was presented to Dr. John Divine by his medical colleagues in recognition of the services he rendered as honorary secretary of the Hull Local Medical and Panel Committees, 1913-14." Dr. Milburn, prior to the presentation, referred to the hard and strenuous work Dr. Divine had done in connexion with the work of these committees. Out of eighty-four doctors on the panel list in Hull upwards of eighty had subscribed to the testimonial. Dr. Davy, in making the presentation, expressed his high appreciation of the services rendered by Dr. Divine, who duly acknowledged the gift.

SIR ARCHIBALD GEIKIE, as chairman of a local committee which has raised £2,000 for the maintenance of the educational museum established by the late Sir Jonathan Hutchinson at Haslemere, is appealing to the general public for an additional sum of £6,000 or £8,000. Subscriptions may be sent to Miss Rose Jackson, Downcourt, Haslemere. The site, building, and contents have been presented to the public by the trustees under Sir Jonathan Hutchinson's will. In collecting and displaying the specimens he worked upon a definite plan, arranging them in series to show in chronological succession the stages in the history of plant and animal life upon the globe. By an original and ingenious arrangement he was able to indicate the broad sequence of events in the history of man from the Stone Age to the present day. The museum is visited every year by some ten thousand persons of all classes, and schools are brought from considerable distances to study its contents and to hear the curator's explanations.

THE Board of Education, acting under the Mental Deficiency Act, 1913, has issued regulations governing the notification of mentally deficient children. The Local Education Authority will, as a rule, be moved by the certifying officer, who will be the school medical officer of the authority or such other duly qualified medical practitioner as the authority may nominate for the purpose. If a Local Education Authority is in doubt as to whether a child is or is not capable of receiving benefit or instruction in a special school or class under the Elementary Education (Defective and Epileptic Children) Act, 1899, it may refer the question to the Board of Education, otherwise it will notify the case to the local authority under the Mental Deficiency Act. The Local Education Authority must further notify to the local authority under the Mental Deficiency Act any mentally defective child who, on or before attaining the age of 16, is about to be withdrawn or discharged from a special school or class. Further, the Local Education Authority may call for a special report from any teacher of the school the child has been attending. With regard to any blind or deaf children the Local Education Authority may propose to notify, it is required to furnish the Board of Education with a copy of the report of the certifying officer, and if the child is already attending a special school, with a report by the head teacher on the child's progress.

MAJOR LEONARD DARWIN, who delivered the presidential address at the annual meeting of the Eugenics Education Society, on July 2nd, chose as his subject the segregation of the criminal. He said that while improvement in environment would no doubt cause a diminution in crime, there would be a remnant of habitual criminals whose strong natural tendencies, being subject to the laws

of natural inheritance, would infallibly tend to reappear in their descendants. To lessen their fertility, therefore, seemed within the scope of eugenic reform. The aim of the social reformer was, wherever it was possible, to remove the bad environment; but the eugenist should at the same time strive to strengthen the innate characters of the individuals composing the coming generations. That result might be obtained by selective breeding. Courage had been claimed as a marked characteristic of the criminal; but those who studied the habitual criminal would find few qualities in him to admire. The object should be to pick out those who were endowed to a very exceptional extent with natural qualities which facilitated the adoption of a life of crime; and having selected a class f the criminal community whose progeny the nation of the future could well do without, the next question was how to prevent that progeny from coming into existence. The only method now possible within the region of practical politics in England was the detention or segregation of those criminals during the period of their fertility. The eugenist condemned the existing system whereby the habitual criminal was subjected to numerous short imprisonments, because it not only did not tend to lessen the number of his progeny, but was likely to increase his racial productivity by giving it from time to time renewed vigour. Social reformers, who recognized the immense importance of environment, ought to be the first to condemn the practice of letting loose thousands of unreformed criminals into our slums, where their influence might be likened to that of animals carrying the germs of disease. Much would have to be done before the machinery established under the Mental Deficiency Act would produce the best results; no trustworthy estimate could be formed of the number of criminals who would be dealt with under its provisions. Sooner or later inquiry must be made as to whether some steps ought not to be taken with regard to the remainder of the habitual criminal population. A desirable reform which eugenists should endeavour to promote would be the amendment of the Prevention of Crimes Act so that it might be made more readily applicable to the man of many minor offences.

IT has already been announced in the JOURNAL that the International Congress of Neurology, Psychiatry, and Psychology will be held at Bern in September (7th to 12th). The official programme has now been issued. The congress will be presided over by the President of the Swiss Republic. Dr. P. Dubois, of Bern, is President of the Organizing Committee; the Vice-Presidents are Dr. P. L. Ladame of Geneva, Professor C. von Monakow of Zurich, and Dr. R. Bing, *Privatdocent* of Neurology at Basel. The members of the International Committee for Great Britain are Drs. Barham, C. Hubert Bond, Byrom Bramwell, William Brown, W. R. Dawson, Sir Bryan Donkin, Sir David Ferrier, Dr. E. Goodall, Dr. Bernard Hart, Sir Victor Horsley, Mr. W. McDougall, Drs. John Macpherson, F. W. Mott, David Orr, George M. Robertson, Risien Russell, Mr. Alex. F. Shand, Professor C. S. Sherrington, Dr. R. Percy Smith, Sir George Savage, Dr. C. Spearman, Professor James Sully, Dr. W. H. B. Stoddart, Dr. John Turner, and Dr. S. A. Kinnier Wilson. In the Section of Neurology papers on regeneration in the nervous system will be read by Professors Alzheimer, of Breslau, and Ramon y Cajal of Madrid; on reflex paths in the medulla and cord by Professor Sherrington, Professor Pierre Marie and Dr. Foix of Paris; on tabes and general paralysis in relation to the *Spirochaeta pallida*, by Professor Ehrlich; and on Ehrlich's salvarsan in the treatment of syphilitic nervous and mental diseases by Professor Crocq of Brussels. In the Section of Psychiatry papers will be read on the pathogenesis and treatment of phobias by Professor Bechterew of St. Petersburg; on senile mental diseases, by Professor Redlich of Vienna, and Dr. Anglade of Bordeaux; and on the rôle of the defensive ferments in pathology, by Professor Abderhalden, of Halle, Professor Binswanger of Jena, and Dr. Lampe of Munich. In the Section of Psychology papers on psychological heredity will be read by Dr. Mott and Dr. Ladame; and on the biological bases of psychology, by Professor Petzoldt of Charlottenburg. Among other communications promised are papers on the surgical treatment of epilepsy by Professor T. Kocher; on epilepsy and cerebral tumour by Dr. Aldren Turner (Section of Neurology); and the treatment of temporary forms of intellectual disorder by Dr. Nathan Raw (Section of Psychiatry). Particulars as to hotel accommodation, excursions and so forth, can be obtained from the Secretary of the Congress, Dr. Schnyder, 31, rue Monbijou, Bern, to whom all communications relative to the Congress should be addressed.

Letters, Notes, and Answers.

☞ *Queries, answers, and communications relating to subjects to which special departments of the* BRITISH MEDICAL JOURNAL *are devoted will be found under their respective headings.*

QUERIES.

J. E. H. P. asks for advice in the treatment of the following case: G. M., roadman, aged 54, has a patch of discoloration on the skin on the front of the right leg. It is dark blue or violet in colour, shading off to brown at the edges, and there is some peeling of the epidermis. It measures 5½ by 4 in. This dates from an operation for right inguinal hernia three years last March. He got thrombosis of the right femoral vein, otherwise is quite healthy and has no varicose veins. He goes about his work, and I have dressed the patch every fortnight with Unna's paste, which relieves it, but it neither gets better nor worse.

SEA-BATHING AND SKIN IRRITATION.

F. J. W. would be grateful for advice in the treatment of a patient who, as a boy, revelled in sea-bathing. Of late years (he has turned fifty) he has taken to it again, as opportunity offers. He finds, however, that after about two days' consecutive bathing he has to give it up, owing to intolerable itching of the legs below the knee, worse at night. They present a bright erythematous appearance, with a slight branny desquamation later. What ointment or oily preparation, it must not be expensive, will best meet the case and enable him to continue to enjoy sea-bathing?

POISONOUS PIGMENTS IN CRAYONS.

DR. W. B. DRUMMOND (Edinburgh) writes: Are the pigments used for colouring crayons for school use of a poisonous nature, and is there any risk of their affecting the health of children using them? Free-arm drawing with coloured chalks is becoming a very common "lesson" for young children in elementary schools. Naturally a good deal of chalk dust must float about and be inhaled. Naturally, also, children will sometimes clean their fingers by the primitive method which Kipps adopted to stanch his wound. It seems to me, therefore, that the nature of the colours in coloured chalks must be of some importance from the hygienic point of view. An educational firm, to which I wrote, replied, "Our chalks are prepared with pigments, and not aniline dyes." The nature of the pigments is not stated, but as some of the best and most common pigments are compounds of arsenic, mercury, and lead, the question arises whether chalks for use by children should not be coloured with aniline dyes if white chalk will not serve the purpose. Some time ago you published some cases of lead poisoning in children, apparently due to paint being conveyed to the mouth in the manner suggested above.

LETTERS, NOTES, ETC.

IN announcing last week the issue in English by C. Reichert, of Vienna, of an abridged catalogue of microscopes and accessory apparatus, the address of the London agents, H. F. Angus and Co., 83, Wigmore Street, W., was incorrectly given.

FRESH AIR AND PNEUMONIA.

DR. ARTHUR J. MATHISON (London, N.) writes: Dr. Bain, in the JOURNAL of June 13th, writing of the treatment of pneumonia by quinine and calomel, puts it on an equality with that recommended by me and used with complete success recently by Dr. Manasseh in Syria. Looking back to Dr. Arnold's letter, which appeared in July, 1913, I find he claimed that he had treated pneumonia for eighteen years, with a mortality of under 5 per cent., on the purgative and quinine plan chiefly. On the other hand, with the potassium iodide and creosote treatment, Dr. Manasseh in Syria and I in London have no mortality, if we except a case in which I was called the day before the death of the patient, an old lady who had been ill for about five days. Others have sent glowing reports. I put it to Dr. Bain that 4 or 5 per cent. of all the cases of pneumonia in one year only in the United Kingdom constitutes a tremendous and appalling difference. I was under the impression that the profession was practically united on the subject of fresh air in this disease. But fresh air alone, I fancy, would not come out well in statistics.

A Lecture
ON
SOME PROBLEMS IN CARDIAC PHYSIOLOGY.

DELIVERED BEFORE THE UNIVERSITY OF LONDON, JUNE 18TH, 1914.

BY A. F. STANLEY KENT, M.A.OXON.,

HENRY OVERTON WILLS PROFESSOR OF PHYSIOLOGY IN THE UNIVERSITY OF BRISTOL.

[WITH SPECIAL PLATE.]

BEFORE 1892 it was impossible to explain the action of the mammalian heart on the comparatively simple lines found adequate in the case of the heart of the frog, owing to the fact that any muscular connexion between auricle and ventricle in the mammal was absolutely denied.

In 1892 it was shown that this idea was erroneous, and that muscular connexion between auricle and ventricle did as a fact exist. In the following years the details of the connexion were worked out by various observers, and the band of tissue is now familiar to every one as the auriculo-ventricular bundle.

As is often the case with new knowledge, it was some time before the existence of the auriculo-ventricular bundle was used in explaining symptoms presented by clinical cases. Within the last few years, however, its importance has been fully recognized and its presence has been generally referred to in explaining certain forms of cardiac irregularity.

Certain difficulties have arisen in connexion with these explanations from time to time, and some observers have doubted whether the case really is as simple as it appears. Clinical experience and experimental results have sometimes thrown doubt on the explanation put forward.

The difficulties are of the following kind: Cases have occurred in which—if the published records are to be trusted—an interruption of the normal rhythm of the heart has been observed, although the auriculo-ventricular bundle has proved to be intact, and cases of normal rhythm have occurred in which the bundle was subsequently found to be destroyed. Many of these difficulties may be capable of solution. Some of them, however, appear to be insoluble.

So long ago as 1892 I described[1] the existence of additional muscular connexion between the auricle and ventricle in the right lateral wall of the heart, and although this observation excited little attention at the time, it lived in the memory of some workers in cardiac physiology, and was sometimes glanced at as likely to afford a possible explanation of puzzling experimental results.

My own work on the heart was unavoidably interrupted, and it is only within the last three or four years that I have been able to return to it.

The position of the problem was then found to be as described. The presence of the auriculo-ventricular bundle was acknowledged, and it was regarded as the one and only path of muscular conduction between auricle and ventricle; and yet it was not adequate to explain the facts found clinically and experimentally.

The problems which presented themselves for solution, therefore, were the following:

1. Do there exist anatomical paths of muscular connexion between auricle and ventricle other than the auriculo-ventricular bundle?

2. If such additional paths exist, what are their number, situation, structure, and connexions?

3. Are such paths—provided they exist—capable of forming a physiological connexion between the auricle and the ventricle?

It appeared best to carry out the histological part of an investigation of this kind upon human material, as the labour involved would in any case be very great, and the whole of the work would have had to be repeated had other material been used. Such a selection made the work more difficult, as it is always troublesome to obtain human material sufficiently fresh to make good preparations. This and other difficulties were ultimately surmounted, however, and a minute examination of the whole of the auriculo-ventricular connexion was commenced.

The method adopted was as follows: The whole of the auriculo-ventricular ring of the heart was divided up into blocks, and each block in turn was cut into sections. The sections were floated on to glass, stained, mounted, and examined. The stains found most generally useful were the connective-tissue stain of Mallory, Heidenhain's iron haematoxylin, haematoxylin and safranin, and various modifications of the silver impregnation method.

Stress should be laid on the fact that in the systematic examination of the ring every section in the series was stained and examined. In some researches it has appeared that not every section, but every alternate section, or even every third or fourth, has been examined. If it is desired to exclude once for all the possibility of the existence of any extra connexion, it is obviously necessary that every section shall be examined.

Many of the original series of sections have been repeated, sometimes again and again, for the purpose of confirming, or of correcting, the earlier results.

Some of the more important conclusions are the following:

1. *Neuro-Muscular Structures.*[2]

There exist in the heart, in the neighbourhood of the auriculo-ventricular groove on the left side of the organ, neuro-muscular structures whose constituents are partly nervous and partly muscular, and these have connexions with the nervous structures of the groove and with the muscular tissue of auricle and of ventricle.

2. *Nodal Tissue.*[3]

There exists in the right lateral wall of the heart a mass of hitherto undescribed nodal tissue.

3. *Muscular Connexions.*[4]

In association with No. 2 there exists at least one muscular path between auricle and ventricle along which impulses can pass, and which is able to keep the chambers in physiological association, even when the auriculo-ventricular bundle has been cut.

4. *Paths of Physiological Conduction.*[5]

Experimental results have been obtained which completely bear out the anatomical fact of the existence of an additional muscular path between auricle and ventricle.

1. NEURO-MUSCULAR STRUCTURES.

The neuro-muscular structures can be described best by referring to the appearances which are found successively when a series of sections is examined. The structures lie in the connective tissue at the base of the auricle or ventricle. The first indication of their presence is the appearance of a few nerve fibres of small size amongst the connective tissue bundles. A few sections further on it is seen that the number of fibres has increased, and soon connective tissue is seen to be arranged round the group and to be forming a sheath for it.

As the series of sections is followed, the group of fibres becomes larger, and may attain a diameter of 170 μ. It now appears as a well developed bundle of fibres, surrounded by a well-formed capsule of connective tissue, inside which a definite and large lymph space can often be distinguished.

If the bundle be followed further it will be seen that its constituents are changing. Instead of the nervous fibres forming the only kind of tissue present, there are now more darkly staining fibres which can be recognized as muscle, very similar to the fibres of the neighbouring auricle or ventricle. Some, however, have different characters, appear at first sight to be tubular, and prove on closer examination to be composed of more or less structureless protoplasm in the centre, with striation and indication of sarcostyles at the periphery. These fibres bear some resemblance to the fibres of Purkinje found elsewhere in the heart.

The amount of muscle in the bundle gradually increases, and may become large, whilst at some part of its course muscle fibres are given off from the bundle and become connected with the neighbouring auricular tissue. In other situations some of the nerve fibres may be seen

* Being contributions to a study of the relations which exist between the various chambers of the mammalian heart.

to leave the bundle, and, apparently, to become connected with nervous structures lying in the connective tissue of the groove. Throughout their course these bundles are provided with a rich supply of blood vessels.

The complete organ then presents itself as a spindle-shaped mass, commencing with a few nerve fibres of small size, increasing to a bundle of, perhaps, 170 μ in diameter and somewhat resembling a nerve trunk, and richly supplied with blood. Soon muscle appears amongst the nerve fibres, assumes considerable proportions, and ultimately becomes connected with neighbouring muscular masses. The nerve fibres also appear to become connected with neighbouring nervous masses. The bundle is contained in a connective sheath in which lymph spaces may be seen.

2. Nodal Tissue.

This—the second structure to be described—is found in a different part of the heart wall. It is found in the auricular wall at a point almost on the extreme right lateral aspect of the heart, slightly towards the posterior surface. Amongst the bundles of auricular muscle in this situation will be observed a more circumscribed mass, partly surrounded by fibrous connective tissue, and in free communication with the rest of the auricular muscle.

The mass may be nearly circular in outline, or it may be distinctly olive-shaped. In either case it is seen to consist of an outer part which is similar to normal muscle, and a central portion which shows modifications of the kind usually associated with nodal tissue. The tissue stains differently, its fibres are often exceedingly fine and show rich branching, and the cross striation is not very easily seen. The blood supply is rich.

3. Muscular Connexion.

Associated with the presence of this nodal tissue is the existence of a muscular path leading from the auricle to the ventricle and forming a channel along which impulses are able to travel. This path is found at the lower part of the mass of nodal tissue, and is formed by the passage of strands of ventricular fibres derived from two or three different layers of the ventricular wall upwards and outwards until they come into association with the tissue of the node. Thus the node is as it were interposed in the course of the muscular path between auricle and ventricle, and any impulse passing from auricle to ventricle would necessarily pass through the tissue of the node.

The need for such an arrangement is apparent when the physiological conditions are considered. For, as suggested in 1892,[1] the interposition of the fine fibres of the node with their altered character results in a slowing of the rate at which the impulse travels, and thus the pause between the auricular and the ventricular contraction is brought about.

4. Experimental Results.

That the existence of such a channel of communication between the auricle and the ventricle will render necessary important alterations in our ideas of the mechanism of the co-ordination of the action of these chambers is obvious. For if, contrary to preconceived ideas, the auriculo-ventricular bundle is not as a matter of fact the sole muscular path along which impulses may pass from auricle to ventricle, its destruction does not necessarily involve the interruption of such passage, and clinical cases and experimental results—hitherto difficult of interpretation—become intelligible.

Direct experimental results are therefore of especial interest, and the following experiments, amongst others, have been carried out:

In the exposed heart of the mammal the bundle has been cut and electro-cardiograms have been taken subsequently. These showed that the rhythm between auricle and ventricle persisted.

The experiments performed by Flack and Leonard Hill showed that there existed in the right lateral region of the heart a mechanism which in certain circumstances was capable of affecting the auriculo-ventricular rhythm.

More recently I have carried out the following experiments, directed especially to the clearing up of the question. The method adopted was simple. In the beating heart of the mammal a thin knife was passed through the right ventricle, near the groove, and brought out in such a way as to sever completely the auricles from the ventricles with the exception of a strip of tissue at the right side of the heart. Under these conditions it is found that beats arising spontaneously in the right auricle pass through to the ventricle, and evoke ventricular beats, and, after the heart has ceased to beat spontaneously, beats excited artificially in the auricle still pass through to the ventricle and give rise to ventricular beats.

Since under these conditions the only tissue connecting the auricle to the ventricle is the strip at the right side of the heart, and the histological part of the inquiry has already shown that an anatomical connexion exists in this situation, it is impossible to avoid the conclusion that in this right lateral auriculo-ventricular junction there exists a muscular path capable of transmitting impulses and of co-ordinating the action of the chambers of the heart.

Further, since, as has been shown, the muscular path is completed by the interposition of a mass of nodal tissue, through which the impulses must pass, it is clear that the conditions here are similar to those found in the case of the auriculo-ventricular bundle, and that the auriculo-ventricular pause may be explained on similar lines—that is, as being due to the passage of the impulse over tissue modified histologically and physiologically, with a resulting delay in conduction.

It is clear that the above considerations must exercise a considerable influence upon the nature of our explanation of cardiac action.

(The lecture was illustrated by numerous lantern slides, drawings, photographs and preparations.)

THE *Yellow Fever Bulletin*, vol. iii, No. 2, contains a paper on experiments and observations on yellow fever, by Scott Macfie and Johnston, which is of some importance because it claims to confirm, practically for the first time, observations made by Seidelin, who as long ago as 1909 described a parasite for yellow fever. Since that time Agramonte, Schilling, Guiteras and others have criticized this so-called parasite, and the general opinion amongst experts at the present day is that these bodies are not parasitic in their nature. Many of the criticisms levelled against them have laid special stress upon the very dissimilar appearance of the bodies as depicted in coloured plates, and haematologists have regarded them as well known artefacts often seen in blood examinations. Scott Macfie and Johnston, who both belong to the West African Medical Staff, and worked at the Medical Research Institute, Yaba, near Lagos, S. Nigeria, go further, and claim that during the course of an epidemic of yellow fever they found bodies similar to those described by Seidelin in the blood of guinea-pigs, dogs, and rats, and propound the theory that these animals carry the parasite of yellow fever, and that man is infected from them by way of the mosquito. A careful study of their work is not convincing, and a coloured plate does not serve to remove hesitation felt in accepting so momentous a conclusion as they would draw. It seems rash to say, for example, that the bodies in Figs. 1, 7, and 14 of the coloured plate are the same bodies or in any way similar to those represented in Figs. 9 and 10, and equally does this statement apply to the bodies found in the animal's blood. Figs. 20, 25, and 39 may be and possibly are piroplasmata, but it is difficult to see how they can be held to have any connexion with, for example, Fig. 35, or with the bodies depicted as coming from the human cases. As regards the animal's blood, bodies similar to some of those depicted may be seen in guinea-pigs that have never been out of England. Many more control experiments appear to be necessary, and before the results can be accepted they must be confirmed by competent protozoologists or helminthologists in England or the States. As already said, those who have most closely studied the bodies described by Seidelin do not consider that they are parasitic in nature.

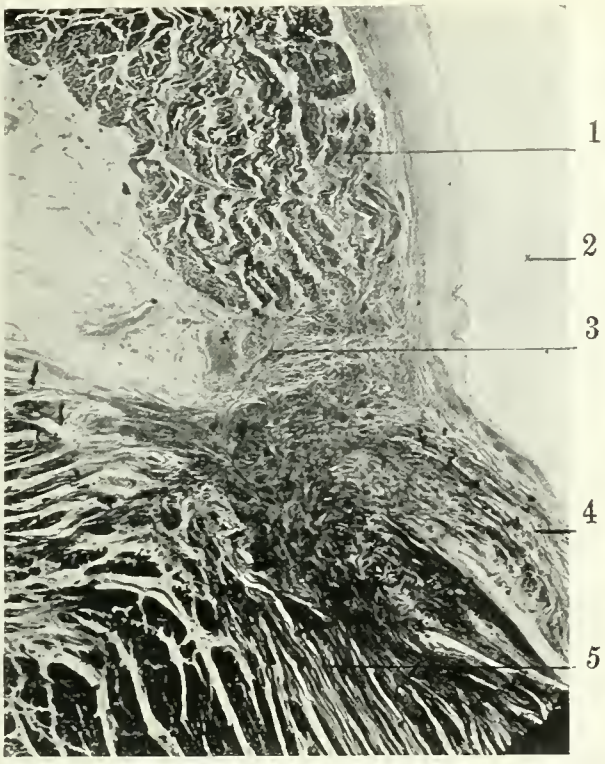

Fig. 1.—*Auriculo-ventricular Junction.* (Heart of adult man.) Shows auriculo-ventricular junction at position G of diagram (left side of heart). The neuro-muscular structure appears as a cylindrical body enclosed in a connective tissue sheath. It has been cut transversely. The darker portions at the upper part of the bundle are muscular fibres. 1, Left auricle; 2, cavity of left auricle; 3, neuro-muscular structure; 4, valve; 5, left ventricle. ×17.

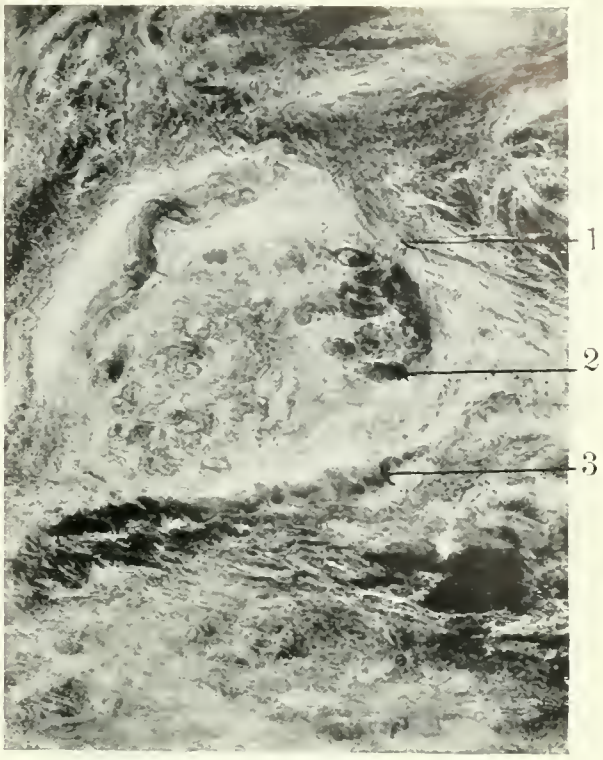

Fig. 2.—*Neuro-muscular Structure.* (Heart of adult man.) Neuro-muscular structure from position G in diagram (left side of heart). The cylindrical body is seen here under a higher magnification, and its constituent parts are more distinct. The darker portions towards the periphery are muscular tissue, some of the fibres being cut transversely and some longitudinally. The nervous tissue is situated towards the centre of the bundle. 1, Connective tissue; 2, muscular fibres; 3, connective tissue sheath. × 174.

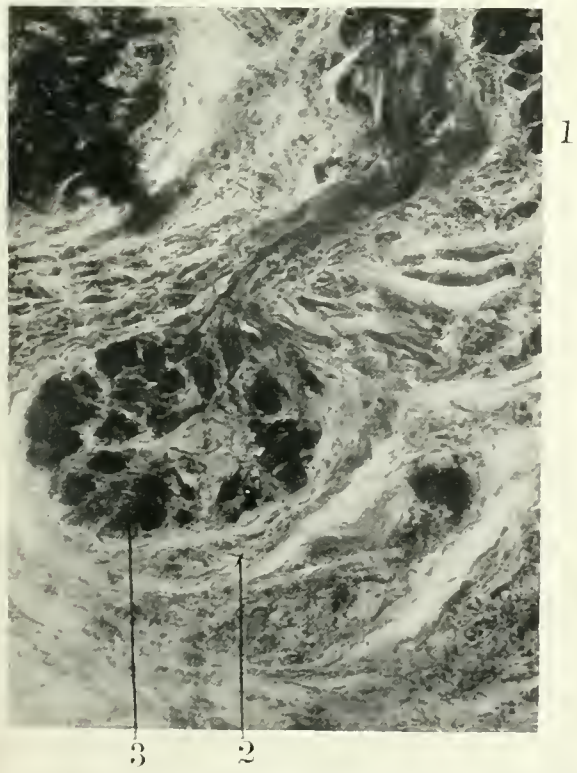

Fig. 3.—*Muscular Fibres of Neuro-muscular Structure.* (Heart of adult man.) Section taken from position G in the diagram. The muscular fibres of the neuro-muscular structure are shown streaming away to become continuous with the auricular muscle. 1, Muscular fibres of auricle; 2, connective tissue sheath; 3, muscle fibres. × 412.

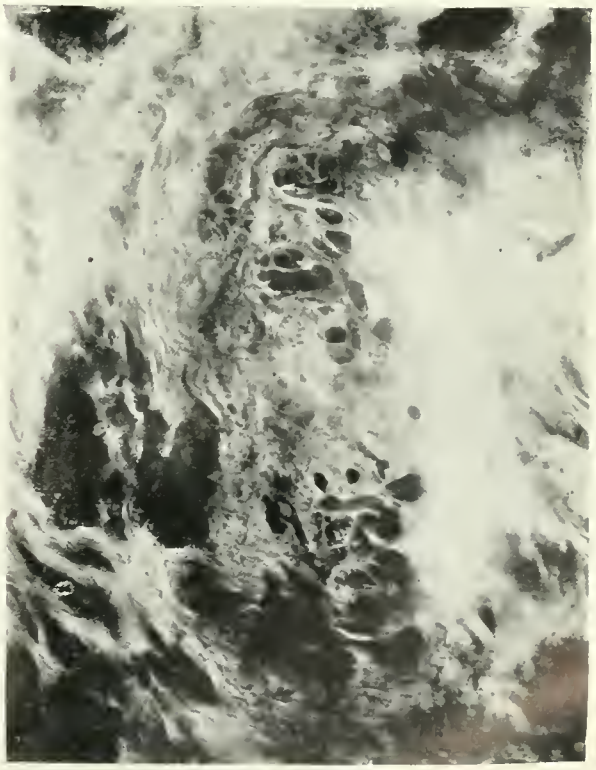

Fig. 4.—*Arborization of Muscular Fibres.* (Heart of adult man.) The section is taken from the neighbourhood of the letter G in the diagram. It shows spiral muscular fibres terminating as an arborization in a mass of fibrous connective tissue. × 336.

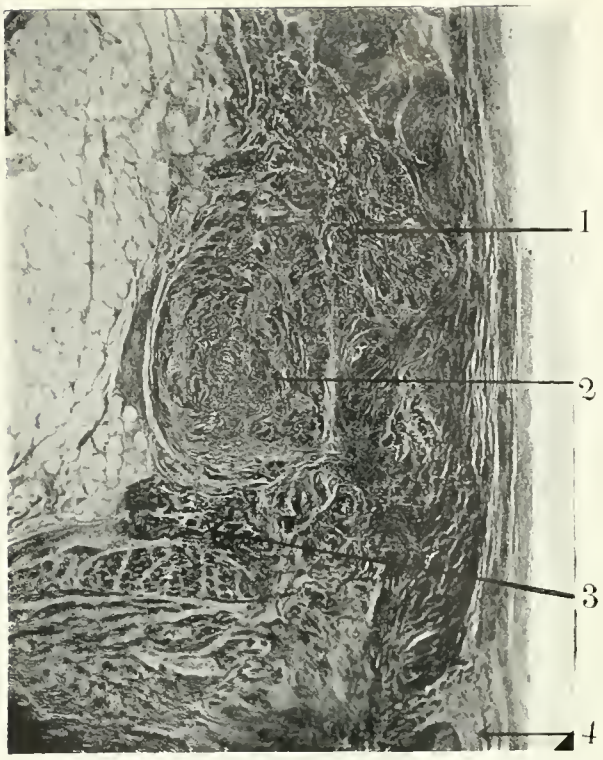

Fig. 5.—*Right Lateral Node.* (Heart of man.) The section is taken from the position c in the diagram (right side of heart). It shows at the upper part the muscle of the right auricle continuous with the muscular tissue of the node ("right lateral node"). The central portion of the node is composed of modified ("nodal") tissue. At the lower part of the node this modified tissue is in close association with the muscular tissue of the right ventricle. 1, Auricle; 2, node; 3, ventricle; 4 valve. × 50.

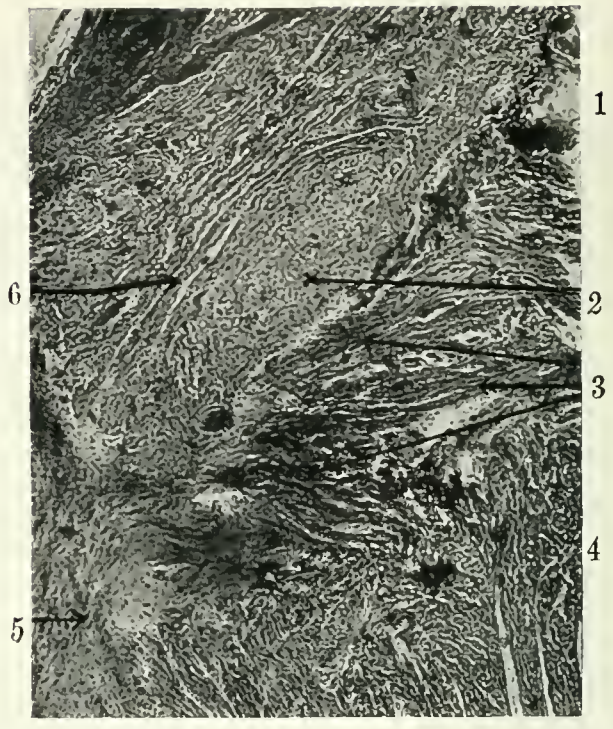

Fig. 6.—*Right Lateral Auriculo-ventricular Junction.* (Heart of man.) The section is taken from the position c in the diagram (right side of the heart). At the upper part is shown the muscle of the right auricle continuous with the muscle of the right lateral node. The central part of the node is composed of modified ("nodal") tissue. The lower part of the node is continuous with fibres of the right ventricle derived from three sources, thus forming the "right lateral auriculo-ventricular junction." 1, Auricle; 2, nodal tissue; 3, ventricular muscle; 4, ventricle; 5, base of valve; 6, auricular muscle. × 76.

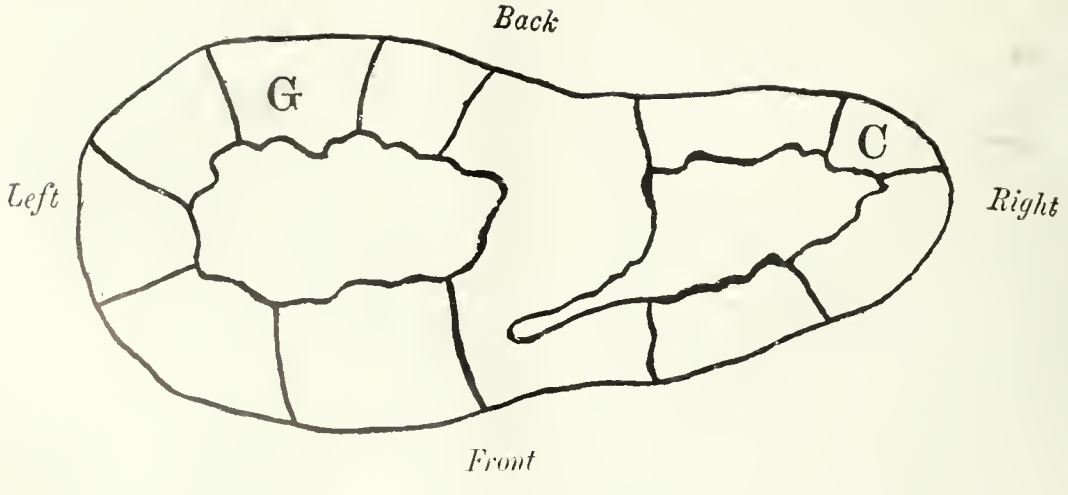

Diagram of base of heart of man, looking upwards, after the apical part of the ventricles has been cut away. Neuro-muscular structures are found at G. The right lateral auriculo-ventricular junction and node are found at C.

THE CAUSATION, PREVENTION, AND CURE OF GOITRE, ENDEMIC AND EXOPHTHALMIC.

BY RUPERT FARRANT, F.R.C.S.,
SURGICAL REGISTRAR TO THE WESTMINSTER HOSPITAL.

[WITH SPECIAL PLATE.]

IN an article published in the *Proceedings of the Royal Society of Medicine*, February, 1914,[15] it was shown that the toxaemias could be divided into three groups according to their action on the thyroid. In the first group were those that had no effect on the gland, in the second those that caused a colloid hyperplasia, and in the third those that caused a complete or acute hyperplasia. It was found that the microscopical appearances of the colloid hyperplasia were indistinguishable from those seen in endemic goitre, whilst the microscopical appearances of complete hyperplasia were indistinguishable from those seen in exophthalmic goitre. No definite signs of hyperthyroidism were observed in cases affected with a single toxaemia. Neither were they seen in guinea-pigs after inoculation with two acute toxaemias—the second being injected before recovery was complete from the first. But hyperthyroidism, as judged by the occurrence of exophthalmos, was found in a man in whom an acute toxaemia had supervened on a chronic. The case was one in which miliary tuberculosis had developed on chronic. It was also found when a subacute toxaemia had supervened on a chronic. Ten out of 12 cases of cirrhosis of the liver presented exophthalmos. It had also been described in chronic interstitial nephritis, which may be regarded as a chronic toxaemia liable to exacerbations. As death occurred in these cases soon after the occurrence of hyperthyroidism, a complete picture was obtained of the toxaemias causing extreme thyroid hyperplasia and the thyroid hyperplasia causing signs of hyperthyroidism.

These examples serve to bridge over the gap between the thyroid changes found *post mortem* and the thyroid changes and hyperthyroidism found clinically in either endemic or exophthalmic goitre.

The object of this paper is to record observations made on 85 cases of goitre (exclusive of simple hyperthyroidism) between 1909 and 1914 as to the relationship between toxaemias and diseases of the thyroid; to prove that cases in which the thyroid is diseased the causatory micro-organism or toxaemia can be determined; to show that in this way not only can diseases of the thyroid be cured, but also prevented.

CAUSATION.

It is proposed, for the sake of convenience, to subdivide the micro-organisms and toxaemias into four groups, according to their situation; they are usually in the mouth, nose, lung, or intestine.

The Mouth.

Pyorrhoea and dental caries are associated with micro-organisms of all kinds; some, such as the streptococcus, staphylococcus, and pneumococcus, can at once be eliminated, as they have no effect upon the thyroid. Any change must, then, necessarily be determined by some other infection. Observations were made at Mr. Landon Whitehouse's dental clinic in 1909 on cases that attended for teeth extraction. Signs of hyperthyroidism were found in about 7 per cent. of cases. Bacteriological examination of the teeth was made in too small a number for the causatory organisms to be determined. The cases were mostly females between the ages of 17 and 30. The history given was that of nervousness, with falling out of the hair and moistness of the palms of the hands, slight loss of weight. Examination revealed a fine moist skin, fine glistening hair, tremor, tachycardia of about 110, perhaps slight prominence of one or both eyes, with or without general fullness or enlargement of the thyroid. No one of these signs was sufficiently prominent for any gross thyroid lesion to be suspected, but taken together they showed a typical picture of hyperthyroidism. Cases of dental caries frequently do not attend until they are suffering from one of the secondary results, as chlorosis, dyspepsia, or osteo-arthritis. Observations were therefore extended to such cases. An exactly similar condition was found in a few of the early cases of dyspepsia, in a large proportion of the early cases of osteo-arthritis, and in some cases of chlorosis.

This association of hyperthyroidism and chlorosis was first described by Chvostek; he thought it was a forme fruste of exophthalmic goitre. The symptoms of hyperthyroidism in these cases thus pass unnoticed, as they are masked by the other more prominent effects of the toxaemia. There is one exception, that is, when the case comes to the ophthalmic surgeon with unilateral exophthalmos. Any one of the symptoms of hyperthyroidism may become more prominent than the others. It may affect the hair, skin, vasomotor or central nervous system; the cases being diagnosed and treated for this one symptom, thus alopecia, hyperidrosis, urticaria scripta, tachycardia, and hysteria. Examination has shown that in some of the cases so affected the other signs of hyperthyroidism are to be found.

CASE I.—M. L., female, 33. A case with carious teeth, pyorrhoea, dyspepsia, and commencing pains in her joints associated with hyperthyroidism, the most prominent symptom of which was unilateral exophthalmos (Fig. 1). There was some slight fullness of the thyroid.

Fig. 2 shows the diminution of the exophthalmos after ten weeks; no treatment or drug of any kind was given, and she continued her work (Mr. Brooksbank James's case).

The relation between the pyorrhoea and hyperthyroidism is not merely a coincidence, but is that of cause and effect, as the following shows. After teeth extraction, for the first week there is some increase of symptoms; they then rapidly clear up for two or three months, but it is usually six months before they disappear entirely.

CASE II.—M. W., female, 32. A similar case, but with slight bilateral exophthalmos; refused to have her teeth removed. She was treated for one year with the following drugs: Iron, arsenic, nux vomica, belladonna, and aloin, without improvement. Her teeth were then put in order; the hyperthyroidism disappeared in six weeks.

An attempt was made to follow these cases over a period of five years—letters were written to 10 cases, no answers were received from 9 whose teeth had been removed; the tenth, who had refused to have her teeth removed, came up for examination; the signs of hyperthyroidism had increased, she had unilateral exophthalmos, marked tremor, and a pulse of 120.

The occurrence of some nervous shock causes an exacerbation of the symptoms, especially those connected with the nervous system.

CASE III.—M. M., female, 23. Carious teeth, dyspepsia (for which gastro-jejunostomy had been performed), associated with hyperthyroidism. Her teeth were removed, but her father died a few days later, and she developed typical exophthalmic goitre. This subsided in a few months. She then nursed her brother, who died, and she again developed exophthalmic goitre, which again subsided after some months.

A second toxaemia acting on a gland that is already in a condition of complete hyperplasia from infection of the teeth causes an enlargement of the gland, with an exacerbation of the symptoms, the degree of which varies with the intensity and duration of the toxaemia. The symptoms may continue for one to two months after the infection has to all appearances ceased.

CASE IV (Dr. Purves Stewart's case) (Fig. 3).—A. L., male, 30. He had had bad teeth since a child, a persistent cough three years, with slight haemoptysis two years ago. Eighteen months ago he had had a bad attack of influenza. He stated that he had always been nervous; he first noticed palpitation two to three years ago. Following the influenza his eyes became prominent, he lost weight, and became weak and tremulous. Examination revealed acute exophthalmic goitre accompanied by sleeplessness, delirium and mania, persistent vomiting, and diarrhoea. Amyotonia was so marked that it was first thought to be a case of myasthenia gravis. His mouth was foul from pyorrhoea; the nasal septum was deviated, but there was no evidence of tuberculosis.

In this case the effect of toxaemias on the thyroid appeared to be, from the history, that the pyorrhoea organism caused a condition of hyperthyroidism. The deviated septum rendered him liable to recurring nasal infection; the intermittent toxaemia from this (? *B. catarrhalis*) caused a further thyroid change; the last acute attack of this toxaemia led to the development of exophthalmic goitre. The later history of this patient will be noted under the heading "Cure" (p. 111).

The Nose and Nasal Sinuses.

The nose is one of the sites for acute, subacute and chronic infections. Amongst the micro-organisms that cause them are: *B. catarrhalis*, Friedländer's bacillus, *B. influenzae*, pneumococcus, staphylococcus, streptococcus. Of these, the last three can be eliminated. Of the others *B. catarrhalis* was found from inoculation of guinea-pigs to cause a complete hyperplasia. The rest were not so injected, but as they nearly always occur in symbiotic combination with *B. catarrhalis* these infections may be regarded as having such an action—if not from their own power, from the fact that *catarrhalis* is present.

In a normal nose in a normal individual an infection with a common or "influenzal" cold would cause a transient thyroid hyperplasia. The gland would involute to normal soon after the subsidence of the toxaemia. But if the patient were already in a condition of hyperthyroidism from any other cause the fresh stimulus from the *B. catarrhalis* would lead to an exacerbation of the hyperthyroidism. The nose may be abnormal, there may be some deformity leading to chronic infection and thickening or atrophy of the mucous membrane, polypi may be present, or chronic sinusitis—conditions likely to cause a chronic or constantly recurring toxaemia. In these, if *B. catarrhalis* was present, thyroid hyperplasia with hyperthyroidism would occur, as has just been described in cases of pyorrhoea. It, however, should be remembered that the nose is generally sterile, and that an original infecting micro-organism frequently dies out in the presence of an excessive number of pyogenic organisms.

The association of exophthalmic goitre with nasal infections has been described by Hack,[1] Semon,[2] and Scanes Spicer.[3]

The following examples serve to illustrate the occurrence of hyperthyroidism and exophthalmic goitre from these causes:

CASE V (Fig. 4).—F. H., male, 24. Thirteen months ago was quite well, and weighed over 12 st.; four months later he noticed an enlargement of his neck and other symptoms of exophthalmic goitre; these steadily increased despite all drugs and antithyroid treatment. (Fig. 4 shows his condition on admission to hospital; he weighed 7 st. 4 lb.)

For some years he had drunk water from a goitre-producing well without noticing any thyroid enlargement. Thirteen months ago he began to work with lime, the dust from which caused a chronic nasal irritation. Examination showed that he had ulceration of the middle turbinals with opacity of his antra. There was only a slight nasal discharge, a swab from which showed no growth on culture. An extension of his infection occurred with pharyngitis, laryngitis, and some crepitations at his right apex. He lost 9 lb. in eight days and died. A *post-mortem* examination was refused. Thyroid hyperplasia was caused by the well water, and the exophthalmic goitre from the fresh toxaemia acting upon this.

CASE VI (Fig. 5).—M. J., female, 36. Three years ago the symptoms of hyperthyroidism had developed with exophthalmos. Her neck enlarged six months ago, and she lost 14 lb. in weight. She stated that she had had bad teeth for some years, and a chronic nasal discharge. Examination showed a mild type of exophthalmic goitre associated with pyorrhoea and chronic rhinitis, with perforation of the septal cartilage. Hyperthyroidism was caused by the teeth infection and exophthalmic goitre by the sequence of a chronic nasal infection.

CASE VII.—M. B., female, 31. For eighteen months she had noticed the gradual onset of the symptoms of exophthalmic goitre. She had had bad teeth for some years, and constantly recurring colds. Examination showed pyorrhoea, a deflected nasal septum, with chronic hypertrophic rhinitis.

CASE VIII.—M. C., female, 39. A case of similar nature, but exophthalmic goitre developed after chronic sinusitis.

Lung.

The common infection found in the lung is that due to *B. tuberculosis*. In my last paper it was shown that its action on the thyroid varies with the degree of the infection; miliary tuberculosis causes a complete hyperplasia, whilst the chronic causes a colloid hyperplasia. The thyroid changes occurring in a case of tuberculosis can be arranged in a circle which passes through the stages of both complete and colloid hyperplasia to a final condition of fibrosis. The vertical diameter of this circle is dependent on the extent of the infection. At one stage tuberculosis is associated with complete hyperplasia, during which stage signs of hyperthyroidism may become evident.

The onset of exophthalmos has been described following the onset of miliary or chronic tuberculosis, and the condition of the thyroid ratified *post mortem*. Dufour[4] has described two cases of exophthalmic goitre in association with tuberculosis. Holles made observations on 33 cases of exophthalmic goitre, and concluded that the majority were tuberculous in origin. Similar cases have been also described by Poncet and Lincke.

The following examples serve to illustrate these points clinically:

CASE IX.—C. F., male, 39. Had early chronic phthisis; exophthalmos was noted temporarily following the development of fresh foci.

CASE X.—F. S., female, 22. Developed whooping-cough two years previously, which was followed by phthisis which was said to have been cured. Latterly she had noticed a fullness of her neck, which she thought was getting bigger. Examination showed that there was tenderness and slight enlargement of the thyroid. Pyorrhoea was present, and signs of tuberculosis at the right apex, with tubercle bacilli present in the sputum.

CASE XI.—B. S., female, 43. Presented a mild type of exophthalmic goitre, associated with pyorrhoea and chronic phthisis. From her history she appeared to have developed symptoms of hyperthyroidism from pyorrhoea, the supervention of phthisis caused an exacerbation which gradually developed into exophthalmic goitre.

Intestine.

The intestine may be the site of all kinds of micro-organisms and be the medium through which various poisons are absorbed. The toxic products may be divided into two main groups—(*a*) material derived from the decomposition of the intestinal contents from the action of the putrefactive anaërobes; (*b*) toxins directly derived from the micro-organisms infecting the tract.

(*a*) Decomposition of the intestinal contents occurs especially when any obstruction is present in the tract. A toxaemia becomes evident in cases of either acute or chronic intestinal obstruction and in the more subtle cases of intestinal stasis. Observations made on the thyroids obtained *post mortem* from cases of acute and chronic intestinal obstruction have revealed no signs of hyperplasia. Neither has hyperthyroidism been observed in cases of intestinal stasis nor have cases of hyperthyroidism shown signs of intestinal stasis, in fact the reverse—frequent action of the bowels or diarrhoea—is a common symptom. Many thyroids have been obtained from cases in which intestinal stasis was present, but it is considered advisable to defer their consideration until a later paper on another subject. It is concluded that there is no evidence to show that products of the intestinal putrefaction have any action on the thyroid.

(*b*) The micro-organisms infecting the intestinal tract. McCarrison[5] in his last paper has shown that some organism living in the alimentary canal of an infected individual gives rise to thyroid enlargement. He produced goitre in goats by giving them water contaminated with the faeces of goitrous people and by feeding them with cultures of the organisms grown on agar. He obtained the same results by using the faeces of non-goitrous people.

The Micro-organisms Present in Faeces.

The micro-organisms may be divided into two groups, the aërobic and the anaërobic. The true anaërobic have not been examined beyond the *B. aërogenes capsulatus*, which appears to have no action on the thyroid.

Of the aërobic, the pneumococcus, streptococcus, and staphylococcus can be eliminated as having no action on the gland. There is left the *typho-coli* series which may be subdivided into the *B. typhosus*, *B. enteritidis*, and the *B. coli* groups. It is proposed to trace these from the *B. typhosus* towards the *B. coli*. Infection with *B. typhosus* does not cause a thyroid hyperplasia. The result of infection with *B. alcaligenes* has not been examined. *B. dysenteriae* causes a complete or acute hyperplasia, judged from the effect of inoculation of Flexner's and Shiga's bacilli into guinea-pigs and from asylum dysentery in man. Of the *enteritidis* group, Gaertner's bacillus as found in infantile diarrhoea causes a complete hyperplasia. These two groups can be dismissed as being causatory agents in the production of endemic goitre, as they are not present in the faeces of goitrous individuals. It is possible to conceive, however, that when they are present in combination with other micro-organisms they might be concerned in causing thyroid changes and hyperthyroidism. The *B. coli* group is still left. Typical *B. coli* can be

eliminated as it is a normal inhabitant of the intestinal tract of normal individuals.*

The Effect of Water on the Coli Group.

A good deal of discussion has arisen as to what is a normal *B. coli*. In this work the normal *B. coli* is regarded as being one that is a Gram-negative, feebly motile, non-spore-bearing bacillus, that coagulates and acidifies milk and produces indol; that forms acid and gas from glucose, lactose, dulcite, maltose, and mannite, but not from sucrose.

Whipple[7] in 1903 found that the type of *B. coli* changes if it be kept under abnormal conditions. Horrocks[8] found that *B. coli* kept in unsterilized well and tap waters develops a delayed action on milk and neutral red, and but feebly produces indol. Penfold showed that bacteria of the colon-typhoid group can produce a mutant. Houston[6] found that in filtered water typical *B. coli* are outnumbered by the atypical. This he ascribed to the mutation of *B. coli*. Clemesha,[10] however, thought this finding was due rather to the extinction of some forms, and rapid growth of others. This is as it may be. Yet these data are sufficiently striking to suggest that a bacteriological examination be made of the water supply in goitrous districts, and that a like examination be made of the faeces of goitrous persons coming from these districts. The presence of the mutants of *B. coli* in either would suggest that *B. coli* had somewhere been placed under abnormal conditions.

Bacteriological Examination of the Water.

Opportunity for examination of a large series has been, for obvious reasons, limited. Samples have been obtained from surface wells in Wiltshire, Bucks, and Herts. The following organisms were grown:

1. *Wiltshire.*—Water obtained from a surface well in a chalk district. From a sample normal *B. coli* and two mutants were isolated. Of the mutants, one had a negative action on dulcite, the other a diminished action on all the sugars with the exception of dulcite, which was increased.

2. *Bucks.*—Two varieties of colonies appeared, the one wavy the other circular. The former constituted 92 per cent., and had no action on dulcite and sucrose; the latter constituted 8 per cent., and caused no changes in dulcite, but altered sucrose with acid and gas formation.

3. *Herts.*—Two types of colonies grew; one produced acid and gas with all the sugars, the other no gas with lactose.

Etiology of Endemic Goitre.

It is proposed now to consider the etiology of endemic goitre from the point of view of infection with the *B. coli* group.

The number of cases among people who have always lived in London is small. It appears that goitre rapidly diminished in London after the closure of the wells and the establishment of a pure water supply. Still London has an advantage that the cases seen come from all over the world. Those examined have come from places as far apart as Cashmere, Central India, Australia, South and West Africa, and various parts of England. The character of the water supplied to these individuals has varied from 48 per cent. of hardness to snow or rain water. The strata over which it has flowed has varied from chalk, granite, clay, and limestone. One can eliminate both the chemical constituents and the soil as being direct causatory agents of endemic goitre.

Contamination of Water and its Consideration as a Culture Medium.

Goitre is common in the valleys of mountainous districts. Inquiry shows that the water supply in these districts is of surface origin, and so liable to surface pollution. Usually it neither passes through filtering beds nor stands in volume. The two great safeguards in the removal of surface contamination and its consequent micro-organisms are absent. The same applies to surface wells and springs. Rain-water, though in the first instance pure, soon reeks with micro-organisms from the methods adopted in its collection, and the barrels and tanks in which it is kept. Water derived from snow is also open to surface contamination, and, as shown by Houston, micro-organisms survive longer in water at lower than higher temperatures. Thus in all these instances inquiry shows that there are factors present which render the water liable to contamination, and that they may also tend to the development of, or the prolongation of the life of micro-organisms derived from such contamination.

Examination of Faeces.

(*a*) *Normal Faeces.*—Clemesha in India examined 46 samples of normal human faeces and 25 samples of cow dung, including about 3,500 different colonies isolated by various methods. McConkey made similar examinations in England. They divided the organisms into four groups, and the following table shows the percentages obtained:—

	McConkey.	Clemesha.
Sucrose− Dulcite−	34 ...	53.2
Sucrose− Dulcite+	38 ...	17.4
Sucrose+ Dulcite+	15 ...	6.8
Sucrose+ Dulcite−	12 ...	22.2

Under 5 per cent. were Glucose+ Lactose−.

(*b*) *Faeces of Goitrous Patients.*—Bacteriological examination of the faeces of cases of endemic goitre have been made; in one case McConkey's B.S.A. plates were used, in the others Conradi-Drigalski's agar plates. One case had left the goitrous district nine years.

B. coli and the following varieties were found:—

1. Negative to sucrose and dulcite.
2. Were negative to sucrose but positive to dulcite (*B. coli*).
3. Were positive to sucrose and dulcite.
4. Were positive to sucrose and negative to dulcite.

The percentages in which 1, 3, and 4 were present was excessive. They occurred up to 100 per cent. and the total exclusion of normal *B. coli*.

5. Merely decolorized sucrose, and produced no indol (*B. coliformis*).
6. Produced acid and gas with sucrose, the acid being++.
7. Had a negative action to litmus milk, lactose, sucrose, and dulcite, but were positive to glucose, maltose, and mannite (*B. paracoli*).
8. Caused acid but no gas in sucrose, lactose, maltose and mannite, and had no action on sucrose or dulcite.
9. Had a diminished action on all the sugars, with the exception of dulcite, which was increased.
10. Had no action on sucrose or lactose.

The percentages of these atypical forms varied up to 86 per cent. It may be said that water containing members of the *B. coli* group has been supplied to individuals; these individuals became goitrous, and mutants of *B. coli* have been isolated from their faeces. The mutants found in the faeces were not necessarily the same as those found in the water.

If there is any causatory relation between infection with atypical members of the *B. coli* group and goitre formation, it should be possible to experimentally make an exact reproduction of the series of events. Evidence might also be forthcoming that the organism is specific to the individual in whose faeces it occurred.

Fixation of the Complement.

Blood has been examined for fixation of the complement in three cases of endemic goitre, in which the following organisms were isolated from the faeces: (1) Normal *B. coli*, (2) those positive to sucrose, (3) those negative to dulcite, (4) those negative to dulcite, and produced no gas with glucose, lactose, maltose, and mannite. It was found that there was no fixation of the complement.

This was only to be expected, as the condition is an apyrexial toxaemia. No confirmation can be derived from the complement fixation test.

Experimental Production of Goitre.—These and other experiments will be published in detail later.

Transmutation of B. coli.

A typical healthy strain of *B. coli* with normal sugar reactions was inoculated into distilled and tap water containing various amounts of broth and into water containing various salt solutions. The sugar reactions are being taken at the end of every week for the occurrence of mutation.

* I am sorry that Major McCarrison was misquoted in my last paper. He wishes me to correct this. Instead of colif rm bacillus causes endemic goitre in the Gilgit Valley, the passage should read, vaccines of coliform bacillus, staphylococcus, etc., have been used with success in the treatment of goitre.

Pathogenicity and Action on the Thyroid of Typical and Atypical B. coli.

Guinea-pigs were used in these experiments, as Eyre[11] found that *B. coli* was a normal inhabitant of the guinea-pig intestine.

Septicaemia.

Three guinea-pigs received intraperitoneal inoculation with typical *B. coli* and three with *B. coliformis* to cause a septicaemia. The thyroids showed an acute haemorrhagic hyperplasia.

Toxaemia Subacute.

Eighteen guinea-pigs were divided into three groups and fed respectively with bread and milk contaminated with fresh cultures of typical *B. coli*, *B. paracoli*, and *B. coliformis*. The guinea-pigs died. The order of the pathogenicity of the cultures appeared to be—*B. paracoli*, *B. coliformis*, *B. coli*. Those fed with *B. paracoli* survived on an average 10.8 days. Those fed with *B. coliformis* survived on an average 12.6 days. Those fed with *B. coli* survived on an average 16 days. The thyroids showed a varying degree of hyperplasia from a complete to a colloid hyperplasia. Those that survived the longest showed the colloid hyperplasia indistinguishable from that seen in endemic goitre. The glands appeared enlarged, but as they are small in guinea-pigs no reliable observations on this point can be made.

Chronic Toxaemia.

A similar number of guinea-pigs were fed in an exactly similar manner except that they received smaller doses of the cultures given every alternate day. Three died from each group at the end of ten days, and others were killed at periods varying from the nineteenth to the thirty-second day. The thyroids appeared to be enlarged, and were microscopically indistinguishable from endemic goitre. The amount of colloid formed varied with the organisms: with *B. coli* it was slight; with *B. paracoli* it was more apparent; whilst with *B. coliformis* it filled all the interstitial spaces. The vesicles were packed and surrounded with colloid. In one, cysts filled with colloid were present.

It is concluded that these micro-organisms are pathogenic to guinea-pigs in the following order: *Paracoli*, *coliformis*, and *coli*. An acute toxaemia, either from intraperitoneal inoculation or by feeding with large doses of broth cultures, causes the thyroid to undergo a complete hyperplasia. A chronic toxaemia causes a change similar, both microscopically and macroscopically, to endemic goitre, which is most marked with *B. coliformis*. The proportion of cell hyperplasia to excessive colloid formation is found to vary in each individual guinea-pig and with the degree of the toxaemia. Endemic goitre can be artificially induced in guinea-pigs. The complete cycle, commencing with water contamination and the presence of the mutants of *B. coli* to goitre formation, can be performed in the laboratory.

It is concluded that endemic goitre, whether it occurs in isolated habitations or in goitrous districts, is caused in man by the chronic ingestion of organisms of the *B. coli* group.

B. coli are washed away from surface droppings and contaminate surface waters, and unless means are taken to get rid of them they become ingested by man. The *coli*, being placed under abnormal conditions either in the water or in the upper part of the intestinal tract, undergo mutation. The mutants are present in the faeces of individuals affected with endemic goitre, and when once lodged there may remain for many years. The pathogenicity of the mutants appears to vary; some members cause a colloid hyperplasia of the thyroid with enlargement and no signs of hyperthyroidism. It is possible to conceive that some of the varieties may produce a toxin capable of further stimulating the thyroid to a condition of complete hyperplasia accompanied by signs of hyperthyroidism. At present no further attempt has been made to separate them, as there are some hundred varieties. The amount of thyroid change varies with the degree of infection.

The following may be taken as an example of the induction of endemic goitre:

CASE XII.—G. F., female, 13. At the age of 10 she went to reside in a goitre district and drank well water for seven months. She then returned to London; eighteen months later she noticed an enlargement of her neck. She was seen a year later and found to have a general enlargement of the thyroid with an adenoma of the right lobe. The mutants isolated from the faeces had negative reactions to litmus milk, lactose, sucrose, and dulcite.

The Effect of other Toxaemias acting on a Thyroid already in a Condition of Endemic Goitre.

Pyorrhoea.—The thyroids in cases in which pyorrhoea coexisted with endemic goitre were softer and more vascular than that seen in endemic goitre alone. Signs of hyperthyroidism were present up to a forme fruste of exophthalmic goitre. Cases of this type were described by F. V. Muller[12]:

CASE XIII. *B. catarrhalis.*—M. W., female, 12. Had drunk water from a well and developed goitre, as had her grandmother and sister. *B. coliformis* was isolated from her faeces. She had a deviated septum and was constantly catching colds. The thyroid was soft and evenly enlarged, and there were some signs of hyperthyroidism. Whilst under observation she caught several colds. After each of these there was an exacerbation of the symptoms of thyroid excess, which subsided about a month after each attack.

CASE XIV. *An Acute and a Chronic Toxaemia supervening on Endemic Goitre.*—C. G., female, 39. Resided in a goitre district in the Himalayas from the age of 18 to 31. Her teeth were removed for caries when she was 32. She developed whooping-cough when 36½. Her neck enlarged about the age of 30, accompanied with slight symptoms of hyperthyroidism. After whooping-cough the hyperthyroidism increased and she developed exophthalmic goitre. Seen a year later, the thyroid presented an adenoma of the right lobe and isthmus, the symptoms of exophthalmic goitre had largely subsided, pulse 96. In this case endemic goitre caused an enlargement of the thyroid; the pyorrhoea, slight hyperthyroidism: the temporary acute toxaemia of whooping-cough caused exophthalmic goitre, which gradually subsided after its termination.

In a similar way other toxaemias or combination of toxaemias can be considered, the chronic toxaemias causing a colloid hyperplasia and the subacute a complete hyperplasia with signs of excessive secretion. Thus small encapsulated adenomata were found in a case of actinomycosis seven months after infection. An adenoma occurred in one case a year after the combination of rheumatic fever and mumps.

Formation of Adenomata.

In my last paper it was noticed that colloid hyperplasia is found in two other conditions besides chronic toxaemias—namely, during the involution of either the acute or chronic toxaemias. They are not generally found during the involution following a single acute toxaemia. They are typically found in the late stages of exophthalmic goitre, that is, following a combination of subacute toxaemias. Masses of colloid are formed from the hypertrophied tissue which become encapsuled to form adenomata. Adenomata after the involution of the chronic toxaemias is typically seen in the late stages of endemic goitre.

PREVENTION.

It is proposed to separate the diseases of the thyroid into two groups: (*a*) Those in which the most prominent feature is hyperthyroidism (exophthalmic goitre type): (*b*) those in which the most prominent feature is thyroid enlargement (endemic goitre type). The methods adopted in preventing these will be considered separately.

The prevention of exophthalmic goitre depends entirely on the recognition of the first stage—the early condition of hyperthyroidism. The presence of this is usually marked by the occurrence of nervousness, followed by falling out of the hair, sweating, and slight loss of weight; examination reveals all the signs of exophthalmic goitre in a minor degree; its detection necessitates examination of the skin, hair, and sweat glands, of the muscular tone, the sympathetic nervous, and the cardio-vascular system. The cases are to be found amongst those diagnosed as pyorrhoea, dyspepsia, early osteo-arthritis, chronic rhinitis, tuberculosis, cirrhosis of the liver, and chronic interstitial nephritis, the last two being of interest rather than of importance. In these cases the infection and its results are more prominent than the signs of thyroid excess. The cases are also to be found amongst the following, in which one symptom of thyroid excess is more prominent than the other: Hyperidrosis, alopecia, urticaria scripta, tachycardia, myocarditis, hysteria, any exophthalmia. These cases come under notice, not onl

in general practice, but also in the special departments. When a diagnosis is made, the case becomes a bacteriological study; both the nature and the focus of the infecting micro-organisms are to be found. A methodical examination should be undertaken, the history of any past illnesses elicited, and the date of onset of each noted.

Reference to a previous paper will determine whether any of these have an effect on the thyroid. The date of the onset of the symptom of thyroid excess should be compared with the date of the occurrence of the toxaemias. In this way a connexion between the causatory toxaemia and the hyperthyroidism can often be elicited. An examination of the mouth, nose, lungs, etc., must be carried out for the site of the infection, and swabs and cultures to find the causatory micro-organisms. In those cases in which the micro-organisms have been constantly swallowed a bacteriological examination of the faeces should be made to find if the organisms have become indigenous in the intestine. When the causatory micro-organism and its site has been determined, means should be undertaken for its removal. Some minor surgical operation, such as teeth extraction, submucous resection of the nasal septum, removal of the nasal polypi, suffice to cure the condition, accompanied in appropriate cases with intestinal antiseptics such as thymol. In the cases that have been so treated the symptoms entirely disappeared in about six months; no intestinal antiseptics were used, as it was necessary to determine the exact connexion between the toxaemia and the hyperthyroidism without the intervention of drugs. It may be as well to state that because carious teeth or a deviated septum happen to be present it is not sufficient to at once ascribe the cause to them. Only about 7 per cent. of cases of dental caries exhibit such symptoms. With a deflected septum there must be a very definite history of constantly recurring infection. It is also as well to remember that owing to the general vaso-dilatation all the mucous surfaces are flushed. Enlarged tonsils are but an effect, a part of the disease.

The following example shows the benefit of prevention:

CASE XV.—N. B., female, aged 33, was seen with signs of early exophthalmic goitre, including double exophthalmos in association with pyorrhoea and carious teeth and frequent nasal infection. Six months after the removal of her teeth no signs of hyperthyroidism were present. Her sister, aged 38, gave a history of an exactly similar condition, but after an acute attack of influenza she developed exophthalmic goitre which after eight years terminated into myxoedema. When seen, her primary infecting foci were still present. (Fig. 6.)

Though there are several combinations of chronic toxaemias that can cause thyroid enlargement, endemic goitre is the only one that can be prevented. After the experiments already outlined dealing with the etiology of this condition have been completed, it is proposed to put forward a definite plan for the collection, storage, and purification of water in endemic goitre districts and on the notification of goitrous wells, the object of which will be the removal of *B. coli*, typical and atypical, from these water supplies, either by filters, prolonged storage, or the use of antiseptics. As these micro-organisms belong to the *typho-coli* series, precautions should be taken similar to those adopted in the prevention of typhoid fever or any other water-borne disease.

CURE.

The cases will again be divided into two groups: (*a*) Those associated with signs of excessive secretion; (*b*) those only associated simply with enlargement of the gland.

In group (*a*) are those cases that have advanced beyond the stage of hyperthyroidism to that of the formes frustes and of typical exophthalmic goitre. The question arises, Can the gland retrace its steps after the removal of the causatory toxaemias and involute to normal, and can those organs that have been affected by the excessive secretion do the same? When a comparison is made between the microscopical appearances of a normal gland and those of exophthalmic goitre one is struck by the enormous cell increase that has taken place. In the solidification of the vesicles there are nearly ten times as many cells per vesicle; the vesicles themselves are also increased in number, so that when the gland is doubled in size the secreting area is increased some forty times. Involution to normal thus necessitates a reduction in the secreting cells to $\frac{1}{40}$. It may be deduced from the length of time taken for the symptoms of thyroid excess to disappear in the cases of simple hyperthyroidism that complete involution of the gland and the disappearance of the symptoms in exophthalmic goitre would take over six months. Any incidental toxaemia acting as a fresh stimulus would lead to a recurrence, the extent and duration of which would depend on the intensity and duration of the toxaemia. Observations have been made on cases following the removal of the infecting agent.

As far as possible, the patients while in hospital did not rest in bed—they got up early in the morning and did ward work, no medicinal or other treatment was given, so that any improvement could only be accounted for by the removal of the toxaemia. The cases were first examined along the following lines:

(*a*) Gland changes: Alteration in the pituitary fossa (*x* ray), hyperplasia of the tonsil, post-sterno-mastoid glands, thymus, and spleen were noted with any alteration in the blood. The neck was measured, and the consistency of the thyroid observed especially for the presence of adenomata, cysts, and other signs of commencing degeneration.

(*b*) The presence and degree of the signs of thyroid excess.

(*c*) The site, and if possible the nature, of the infecting micro-organisms.

From (*a*) an estimate was made of the reaction of the ductless glands to the toxaemia, and whether the thyroid had commenced to involute by a process of degeneration.

From (*b*) an estimate of the degree of hypersecretion.

From (*c*) the causatory agent was determined.

The treatment adopted and the results obtained necessarily varied with the nature and the situation of the infecting micro-organisms. The most striking results were obtained in the very acute cases in which the infecting process could be completely removed. The following examples demonstrate the results obtained from removal of the infection in the four common situations.

Teeth.

The toxaemia derived from the source has but a preliminary action. It serves as a basis for the action of another to cause exophthalmic goitre. Only one example will be given, as it was discussed under prevention.

CASE IV (Fig. 7).—A. L., male, 30. Hyperthyroidism was present for three years, associated with pyorrhoea. Following an acute infection in his nose, to which he was rendered liable by a badly deviated septum, exophthalmic goitre developed, accompanied with acute mania; pulse 130, respirations 36, and extreme myasthenia. He was treated with all the usual medicinal remedies without avail, and given up as moriturus. His mouth was put in order, and twenty-one teeth removed under gas and oxygen. Five days later he became quiet, and slept, and his three attendants were no longer needed. After fourteen days he had put on 23 lb. in weight, and at the end of three months he had put on 34½ lb.; pulse 108; exophthalmos had disappeared and the thyroid had diminished 1½ in. It was realized that the onset of any fresh toxaemia before involution was completed would cause a recurrence and probable death; but owing to myocardial degeneration it was thought inadvisable to attempt to prevent such by an operation on his nose or to diminish the effect that such could have by removal of a portion of his thyroid. It was hoped that complete involution would take place before the onset of a toxaemia. Four months later he developed another acute nasal infection, his symptoms rapidly recurred, and he died in another hospital despite all medicinal measures.

Nasal Cases.

Cauterization of the nose became the standard treatment for exophthalmic goitre after Hack, Frankel, Semon, and Spicer recorded cases cured by the removal of nasal polypi and other nasal affections. This soon dropped into disrepute, as the majority of cases are not nasal in origin.

CASE XVI.—E. L., female, 27. Gave a history of the symptoms of hyperthyroidism for some years associated with carious teeth, and constantly recurring colds. Three months ago she had developed a very bad cold which lasted for a month, when exophthalmic goitre occurred. Examination showed a soft enlargement of thyroid, an adenoma in the left lobe, with an average degree of symptoms; pulse 120. The teeth were carious, and right nasal septum and inferior turbinals were adherent. The adhesions were divided and the teeth removed; the symptoms cleared up with the exception of the adenoma in the left lobe, which was subsequently removed by operation. It had undergone cystic degeneration.

CASE XVII (Figs. 8 and 9).—L. C., female, 26. Gave a four years' history of exophthalmic goitre. She had drunk water from a goitrous well, and had carious teeth and a chronic cold. The thyroid was but little enlarged, pulse (?) 160, marked exophthalmos, weight 8½ lb. She was kept in bed until her condition had subsided from the last nasal infection, her teeth were then removed and a submucous resection performed. In nine weeks she weighed 105 lb., the tachycardia and exophthalmos were only present during excitement.

CASE VI (Fig. 10).—M. J., female, 36. Three years' history of hyperthyroidism in association with carious teeth. Her thyroid had enlarged six months previously. Examination: A firm, hard enlargement of the thyroid with well-marked exophthalmic goitre, pulse 150, double exophthalmos, weight 87 lb. Her nose presented a black slough surrounding a perforation of the septal cartilage and chronic rhinitis. Her teeth were removed and the nose treated with nasal antiseptics. In four weeks her neck had diminished 1¼ in. At the end of fourteen weeks she weighed 124 lb., and the exophthalmos was not noticeable. During the involution an adenoma developed in the left lobe of her thyroid. Her heart was left in a condition of some myocardial degeneration with dilatation, and a pulse of 110.

In the nasal cases for the most part the toxaemia is not always present, but constantly recurs. Removal of the basal toxaemia causes the symptoms of exophthalmic goitre to subside. After-operations can with safety be performed on the nose to prevent the recurrence of the nasal infection and consequent exophthalmic goitre.

Lung.

The association of tuberculosis with hyperthyroidism and exophthalmic goitre has led some observers (Hollos) to believe that the great majority are tuberculous in origin. He reported 28 cases that he had treated with I.K. with recovery in 10.

From the microscopic appearances of the thyroids obtained from cases dead of tuberculosis it is concluded that only for a period of a few years is the gland in a hyperactive condition. It is only during this time that exophthalmic goitre is liable to develop.

In the early cases hyperthyroidism may be a transient phase which disappears perhaps to return after an exacerbation of the tuberculosis or the onset of another toxaemia. Observations have been made on five cases of typical exophthalmic goitre associated with chronic tuberculosis of the lungs. They were of a mild type with the exception of one case, which is quoted below. The basal toxaemia in four was pyorrhoea. The cases were observed for over a year, during which time the symptoms partially subsided, and the gland underwent degeneration with the formation of adenomata.

CASE XVIII.—M. R. F., female, 22. Gave a history of constant colds and haemoptysis at 17, followed by exophthalmic goitre. Examination showed a pulsating thyroid, pulse 156, double exophthalmos, weight 115 lb., steadily decreasing. The nasal septum was deviated, and the mucous membrane in a condition of chronic rhinitis. Tuberculosis was present in the right apex. Partial thyroidectomy was performed under Crile's anoci-association. At the end of a month there was a great reduction in symptoms, but she had lost a further 9 lb. in weight. She was sent to the seaside, and her symptoms cleared up *pari passu* with the tuberculosis.

The indications for treatment of exophthalmic goitre associated with phthisis appear to depend on the extent of the infection, the degree of hyperthyroidism, and the condition of the gland. In the first stage, when the condition is transient, the treatment should be directed to the tuberculous focus. The same line also may be adopted in chronic phthisis; the symptoms subside with the cure of the infection or upon fibrosis of the gland. In the more acute variety the treatment will depend on the coexisting toxaemia. In all cases this should be removed or prevented. Sometimes it is not feasible, as in the above case, when prevention involves a serious operation on the nose. Here it seemed preferable to remove half the thyroid first, and then to complete the cure by sanatorium treatment.

Before recommending treatment with tuberculin, it is advisable to note the effects of vaccines on a normal gland. Mention of this will be made in a paper on the normal stimulus.

Intestinal.

Hyperthyroidism and exophthalmic goitre, caused by the association of a toxaemia with that derived from the presence of coliform organisms in the intestine, are cured by removal of the source of the toxaemias.

The simplest of these is when endemic goitre is associated with carious teeth. Removal of the teeth and the administration of an intestinal antiseptic cause a rapid disappearance of the thyroid enlargement and the symptom of hyperthyroidism.

CASE XIX.—Female, 24 (Figs. 11 and 12). Drank well water from a goitre-producing well until 2½ years ago. She had had carious teeth for some years. Examination showed a soft even enlargement of the thyroid, medium type of exophthalmic goitre. Double exophthalmos, pulse 92. A mutant of *B. coli* was isolated from the faeces which decolorized litmus, sucrose, and produced no indol. Many carious teeth were present. After teeth extraction and the administration of thymol the neck diminished 1 in., the pulse became 78, and exophthalmos was not noticeable, and she increased 8 lb. in weight in a fortnight. The mutant of *B. coli* was not found after seventeen days' treatment, three days from the last dose of thymol.

CASE XX.—A. F., female, 25, was in a condition of hyperthyroidism from endemic goitre and carious teeth; exophthalmic goitre developed after an attack of influenza and pleurisy. She was treated for two years with drugs and *x* rays without effect. Examination showed a soft even enlargement of the thyroid, pulse 120, and marked unilateral exophthalmos. The carious teeth and inferior turbinals were removed and thymol administered. In six months she increased 25 lb. in weight; the exophthalmos was only present on excitement and her pulse rate was 84. An adenoma developed in the right lobe during involution.

Enlargement of the Thyroid without Signs of Excessive Secretion.

This group may be subdivided into three. (*a*) Those caused from the ingestion of the atypical forms of *B. coli* (endemic goitre). (*b*) Those caused by the combined effect of two toxaemias other than atypical *B. coli* that are capable of inducing a colloid hyperplasia. (*c*) During the involution following either the acute or chronic toxaemias.

(*a*) *Endemic Goitre.*—The history of the case is of great help in making a diagnosis. Every toxaemia from birth upwards and their date of onset should be noted. The character of the water supply should be ascertained both in the district in which the patient was born and in the districts where they have afterwards resided, with the dates and the time of onset of the thyroid enlargement. In this way the cases may be placed into groups according to their cause. A routine examination should then be made. A sample of the water should if possible be subjected to a bacteriological examination and the different members of the *B. coli* group isolated. The faeces are similarly examined and the causatory organism determined. Before treatment is commenced a careful examination of the gland should be made for the presence of adenomata and cysts. A preliminary purge is given (castor oil should not be used), thymol gr. x in cachets is administered two to three times a day for fourteen days; after a three days' interval it is repeated for another fourteen days. A week later the faeces are again examined. If the organism is still present another course of thymol is necessary. (Fats and oils must not be given within two to three hours of taking thymol.) Under this treatment the organisms are killed, the gland rapidly diminishes in size. The following may be taken as an example of the sixteen cases treated.

CASE XXI.—G. F., female. The paracolon and the *B. lactis aerogenes* were isolated from the faeces. Twelve days after treatment with thymol her neck had diminished 1 in.; at the end of eight weeks it was of normal size, having diminished 2 in. She had previously been treated for six months with syr. ferri iodidi with only a ¼ in. diminution.

The action of vaccines and their use in the treatment of endemic goitre will be discussed in a later paper on the normal stimulus.

Group (*b*). After the nature of the toxaemias has been determined they should be removed, though for the most part they have ceased to act before the cases are seen.

Group (*c*) consists of adenomata and cysts that have developed in the course of involution. If the cause be still present it should be removed; often it has ceased to act long before the cases are seen, though from the history the causatory agent may be determined even twenty or thirty years after its onset.

The question arises—Up to what point can thyroid affections be cured by removal of the cause?

Enlargements of the thyroid, whether of the exophthalmic or endemic type, entirely subside after removal of

the cause, providing this is done before the development of adenomata or cysts. Glands containing these will subside as a whole, but the adenomata or cysts are left. The administration of iodine may cause a slight diminution in their size, but they have not disappeared even after eighteen months' treatment. Cysts and adenomata should be treated along the usual surgical lines.

The symptoms of excessive secretion at first rapidly diminish after removal of the cause, and then more slowly *pari passu* with the diminution in the size of the gland. Any excitement will for the moment bring these symptoms again into evidence. If the disease has progressed so far that the various organs have become degenerated, only partial recovery can be made. The patient may be left with a dilated heart, permanent albuminuria or glycosuria, or with some weakness of the nervous system, either central, peripheral, or sympathetic, leading to feeble mentality, paralysis of a nerve, or some vasomotor disturbance. These require appropriate treatment.

Acute Exophthalmic Goitre.

These cases arise from the effect of a toxaemia acting on a gland that is already hypertrophied and has led to hyperthyroidism or typical exophthalmic goitre. The added stimulus gives rise to an acute exacerbation which may rapidly lead to death. Treatment is a matter of difficulty, as the five cases quoted show. Medicinal measures may prove unavailing, removal of the toxaemia may be impracticable, and any attempt to remove a portion of the gland may prove fatal.

CASE IV.—A. L., male, 30, developed an acute *catarrhalis* infection before involution was complete from exophthalmic goitre and died in a few weeks despite all medical remedies.

CASE V.—F. H., male, 30. An extension of a *catarrhalis* infection on exophthalmic goitre caused death in five days despite medical remedies.

CASE XXII.—S. L., female, 28. Developed an acute *catarrhalis* infection on medium type exophthalmic goitre and went rapidly down hill. An attempt to remove half the thyroid under Crile's anaesthesia proved fatal.

CASE XXIII.—V. D., female, 25. Developed acute exophthalmic goitre on endemic goitre and teeth infection. She lost 26 lb. in weight, but recovered under medicinal treatment after appearing moriturus for some weeks. She now exhibits the combination of myxoedema and degeneration of various organs from exophthalmic goitre.

CASE XXIV.—M. R., female, 51. An acute exophthalmic goitre developed from the effect of acute *catarrhalis* on exophthalmic goitre from chronic *catarrhalis* and teeth infection. Recovery after partial thyroidectomy under Crile's anaesthesia.

Such cases can only be treated on their own merits.

CONCLUSIONS AND SUMMARY.

Endemic goitre is caused by the toxins from the atypical forms of *B. coli*. The mutants are usually conveyed by water. They become indigenous in the intestine, and different mutants of *B. coli* are to be found in the faeces of cases of endemic goitre. The mutants are but rarely present in the faeces of normal individuals or in the faeces of individuals goitrous from other causes. It is possible to conceive circumstances which place the *B. coli* under abnormal conditions in the intestine itself, and lead to mutation and the temporary appearance of mutants in the faeces of normal individuals.

The mutants set up an apyrexial toxaemia, which stimulates the thyroid, so leading to a colloid hyperplasia and eventually to enlargement of the gland.

The whole process can be imitated in the laboratory, and endemic goitre induced in guinea-pigs by feeding with small doses of the mutants.

The supervention of a fresh toxaemia whilst the gland is in a hyperactive state causes a complete hyperplasia, with absorption of colloid and signs of hyperthyroidism up to a condition of exophthalmic goitre. This is dependent on the intensity and duration of the fresh toxaemia.

Endemic goitre is preventable by the avoidance of water contamination and by the sterilization of contaminated water.

It can be cured by the administration of intestinal antiseptics, the gland returns to normal, providing no degeneration has taken place. The gland as a whole involutes to normal, but the adenomata or cysts are left.

A condition similar to endemic goitre can be caused by other toxaemias capable of inducing a colloid hyperplasia.

Exophthalmic Goitre.

Exophthalmic goitre is due to a combination of toxaemias of an intensity sufficient to cause a hyperplasia with absorption of the colloid material. One acts during a period sufficient to give rise to a complete hyperplasia associated perhaps with slightly marked signs of hyperthyroidism without necessarily any glandular enlargement. The supervention of another infection stimulates the gland, which usually enlarges, and the signs of hyperthyroidism become very evident; the case develops into one of typical exophthalmic goitre. A nervous shock may lead to the diagnosis by suddenly bringing into evidence the symptoms of hyperthyroidism, especially those connected with the nervous system.

The severity and duration of exophthalmic goitre is dependent on the intensity and duration of the toxaemias. If they be of short duration the disease will disappear in a few months.

Exophthalmic goitre can be prevented by the detection of the early cases of hyperthyroidism and the consequent removal of the basal toxaemia.

Exophthalmic goitre can be cured if the causatory agents be removed before degeneration has occurred either in the gland or in those organs that are affected by the hypersecretion.

When degeneration has taken place in the thyroid, removal of the toxaemias causes involution to take place only in the hypertrophied portion; the adenomata and cysts are left. These require appropriate surgical treatment, as they to a certain extent keep up the symptoms of thyroid excess. Surgical treatment without removal of the cause is followed by recurrence unless so much of the gland substance has been removed that hypersecretion is impossible. Degeneration in the other organs partially recovers after involution of the thyroid; appropriate treatment is necessary for those that remain. Acute cases of exophthalmic goitre may present themselves in which surgical treatment is the only means of saving them, though the risk of death under the anaesthetic perhaps precludes operation.

As our knowledge of toxaemia is limited, so necessarily must be that of exophthalmic goitre.

The bacteriological work was done in the Westminster Hospital Laboratory, and I am much indebted to Dr. Braxton Hicks and Mr. Chopping for the care which they have taken over the work. I am also much indebted to Mr. Spencer for giving me the opportunity of making observations on clinical material.

ANOCI-ASSOCIATION IN THE PREVENTION OF SHOCK AND POST-OPERATIVE DISCOMFORTS:

AN EXPERIENCE OF 113 CASES.

BY

H. B. BUTLER, F.R.C.S.E., AND E. W. SHEAF, M.C.CANTAB.,

ASSISTANT SURGEONS, ROYAL SURREY COUNTY HOSPITAL, GUILDFORD.

CRILE'S theory of shock is that it is due to the exhaustion of the vasomotor centres in the medulla and cord, the most important factors in the production of surgical shock being fear, pain, and anaesthetic poisoning. In operations done by ordinary methods these three factors are not sufficiently eliminated, and the operation is followed by a fall in blood pressure and definite changes in the cells of the central nervous system.

Ether and chloroform prevent feeling and movement, but they do not prevent the reception of stimuli and the discharge of nervous energy. Theoretically, nitrous oxide

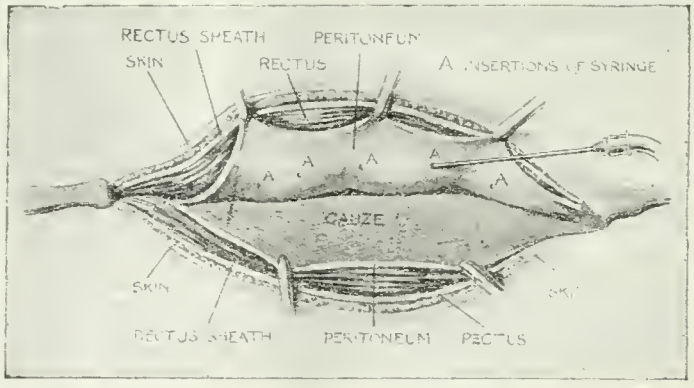
should diminish shock, for it acts by preventing oxidization, and presumably oxidization is a process in the fatigue changes of the nerve cells. Experiments showed that an equal injury produces three times as much change in the nerve cells under ether as under nitrous oxide.

Exhaustion can be produced by injury, sleeplessness, and fear. Tearing produces far more shock than clean cutting, and rough handling and strong traction on peritoneal-covered viscera is especially liable to produce shock, which can be avoided by gentle manipulation.

Stimulants, such as strychnine and alcohol, produce exhaustion changes in brain cells; it is therefore as rational to treat the exhaustion of strychnine poisoning with trauma as to treat the exhaustion of trauma with strychnine. To advise the use of stimulants for the treatment of shock is as foolish as to advise a man who is almost bankrupt to increase his expenditure. Morphine and other sedatives are conservative of energy, and are therefore of use against shock.

Crile's principle is to prevent the consumption of the stored energy of the brain cells before, during, and after surgical operations by preventing the brain from receiving painful and disquieting stimuli. He calls this anoci-association, meaning the exclusion of all harmful associations or stimuli.

Two other theories of shock are those of Yandell Henderson and of Rendle Short. Yandell Henderson believes that painful stimuli reflexly induce deep breathing, so that the carbon dioxide in the blood is reduced below the normal (acapnia). When the painful stimuli cease, this reflex cause of deep breathing is no longer present, and the normal stimulus produced by carbon dioxide is so diminished that respiration becomes very shallow, and the absorption of oxygen is insufficient. Although this may be a factor in shock, an experiment of Crile's shows that its importance cannot be great. Two dogs, A and B, were taken, and it was arranged so that the blood of A circulated through the brain of B, and conversely. A was injured and its brain cells showed typical shock changes, while the brain cells of B remained normal. Rendle Short, moreover, found by experiment that acapnia was not present in five cases of surgical shock observed by him. Rendle Short's theory is that reflex contraction of the arteries follows stimulation of pressor nerve fibres; plasma is consequently squeezed from the capillaries with resulting oligaemia.



This figure is to show the method of injecting the peritoneum. It is held up by forceps, and the needle is inserted very obliquely just under the surface, the only difficult part of the technique.

The merits of these theories do not affect the present question, because Crile's practical suggestions for prevention of shock serve in all, as the authors of the acapnia and oligaemia theories both put painful stimuli as the first link in the chain of events, and this link is broken by anoci-association.

In September, 1913, Gray[1] of Aberdeen described his technique of giving omnopon before an operation, and using local anaesthesia with novocain, ether being only used when required to keep the patient quiet. The method is on the same lines as Crile's, but it does not cut off noci-associations so thoroughly.

Chaldecott and Bryan[2] obtained extremely satisfactory results in twelve severe operations. Gas and oxygen were used; they had less post-operative vomiting than in our cases, but apparently more trouble when the peritoneum was handled.

We believe that Sir Berkeley Moynihan was the first surgeon to use Crile's methods of anoci-association in this country, and his opinion of their importance may be gauged from his remarks in his Address in Surgery at the Annual Meeting of the British Medical Association at Brighton (1913), when he ranked the work of Crile and its effects on surgery with the discoveries of Lister and Morton.[3]

In our work from July 19th, 1913, to April 30th, 1914, we have followed Crile's methods of anoci-association as closely as possible.

List of Operations Performed.

Appendicectomy ...	57	Amputations through thigh	2
Prostatectomy ...	5	Radical cure, hernia	10
Gastro-enterostomy	5	Strangulated hernia	2
Hysterectomy ...	7	Exploration of kidney	1
Perforated duodenal ulcer	3	Castration ...	1
Colostomy ...	4	Hallux valgus ...	1
Gall stones ...	6	Radical cure, hydrocele	3
Explorations of abdomen	4	Radical cure, varicocele	2
Ovariotomy and appendix	4	Perineorrhaphy ...	1
Ventrifixation ...	2	Glands in neck ...	2
Nephropexy ...	2	Removal of semilunar cartilage ...	1
Excision of knee ...	1	Plating and wiring operations for fractures	8
Amputations of breast	4		
Thyroidectomy ...	5		

After the preliminary injection of scopolamine $\frac{1}{150}$ grain and morphine $\frac{1}{6}$ grain (average doses) one hour before operation, unconsciousness is in most cases induced and maintained by ether given by the open method. In a few early cases the anaesthetist had such a prejudice in favour of chloroform that he could not resist giving it during a part of the operation. Very little inhalation anaesthetic is usually required, generally about one third of the usual amount, and the patient sleeps comfortably without giving any anxiety. When unconsciousness has been produced, the skin is infiltrated with a 1 in 400 solution of novocain; during the incision the deeper layers are treated in the same way as they are exposed.

If the infiltration is thorough no stimuli reach the brain, and the lightest possible ether administration is needed, sufficient only to keep the patient quietly asleep, for the cut does not wake him. In other words, the infiltration anaesthesia, aided by the scopolamine and morphine, should be sufficient by itself to cut off all impressions of physical pain, the inhalation anaesthetic being solely used to eliminate mental anxiety, and in such quantity only as is sufficient to keep the patient from knowing that an operation is proceeding, and oblivious to any distressing sights or sounds.

In abdominal operations, after the peritoneal cavity has been opened, a wet gauze pad is packed into the incision and the peritoneal edges are everted and freely injected with a solution of quinine hydrochloride and urea (5 per cent. of each in normal saline), large blebs being formed all round the peritoneal incision. An area should be infiltrated which will generously include all the parts which will subsequently be traversed by stitches. One or two ounces of the solution, according to the length of the incision, are used at this stage.

In spite of the lightness of the ether anaesthesia, there is no rigidity of the abdominal wall and no trouble with extrusion of the viscera, and the hand can gently explore the abdomen with ease. It is a great advantage to operate on patients under such favourable circumstances. Throughout the longest operation the patient's condition rarely gives the least anxiety to either anaesthetist or surgeon, the only difficulty for the anaesthetist being to keep his very light anaesthetic even. Patients have often moved and occasionally talked during the operation; one young lady woke up while the rectus sheath was being stitched and said, "Was it the appendix?" She added that she felt quite comfortable, and a little more ether sent her to sleep again. One marked advantage of the method is the uniform ease with which the peritoneum is sewn up. It

pulls up easily, and the intestines fall back into the abdomen; usually no packing is required.

The injection, of course, adds to the duration of the operation, but, when once accustomed to it, it can rarely add more than five, or at the most ten, minutes. Part of this time is regained by the ease of operating, and in any case it is of no consequence, for the patient's condition is improved by it. There has been, however, one exception to this: An elderly woman of very poor fibre, weakened by six months of haemorrhage, needed panhysterectomy. The anaesthetist was, for some reason, unable to keep the airway clear, and from the start she took the anaesthetic badly. She was deeply cyanosed and strained all through the operation, which was long and difficult. She suffered severely from shock and never picked up, dying on the fourth day. She was the only patient that suffered any degree of shock.

When the operation is over, there is a quick and comfortable recovery; usually no pain at all is complained of, sickness is reduced to a minimum, and the patient usually sleeps well from the first night onwards.

Another marked effect, probably due to the scopolamine, is that, though patients may talk sensibly just before and soon after the operation, they frequently have no recollection of what has happened during most of that day when questioned afterwards, and it is a great advantage to have no unpleasant memories.

Ward and Home Sisters, who started by being sceptical, are now quite convinced of the advantages of anoci-association, and declare that such patients are no trouble after operation.

In two amputations through the thigh in old people, in addition to the usual novocain infiltration, the sciatic nerve was injected with quinine and urea, and there was no shock and practically no after-pain.

One girl of 17 years had a large one-sided goitre, which caused great pain and dyspnoea. The operation for removal was conducted without the slightest anxiety, and recovery was normal and rapid. The patient was subsequently operated upon by another surgeon for enucleation of the tonsils, and died under the anaesthetic. At the *post-mortem* examination status lymphaticus was found. It seems possible that it was anoci-association which saved her from disaster on the occasion of the first operation.

We have had no trouble in the healing of wounds, but there is no doubt that the infiltration must increase the chances of sepsis; and the method should therefore not be used unless the surgeon is sure of himself and his surroundings. Crile has pointed out that it is inadmissible to infiltrate tissues which are the seat of either acute inflammation or cancer.

The comfort of the patient and his pleased surprise at the absence of discomfort would repay the trouble entailed, even if the operation mortality were not lowered. Crile's mortality has diminished from 40 to 8 per 1,000 since he has used anoci-association.

RADICAL CURE OF INGUINAL HERNIA.

BY

JOHN O'CONOR, M.A., M.D.UNIV. DUB.,

SENIOR MEDICAL OFFICER, BRITISH HOSPITAL, BUENOS AIRES.

IT is not with any desire for innovation that I wish to invite attention to a method which I have lately devised, for I feel certain that any surgeon, like myself, who has performed a thousand hernial operations, must frequently have been struck by the difficulty of preventing the fibres of the inner shelf of Poupart's ligament splitting when inserting the necessary approximation sutures. It is obvious that such splitting must act detrimentally by weakening the first and principal line of defence. In order to avoid it I have tried various forms of needles, but found little difference in result, except that on two occasions, when using sharp curved ones, I wounded the external iliac vein (Chopart amputation of the foot followed in one, no penalty in the other).

The operation which I am about to describe has for its object the elimination of such "regrettable incidents," and the fulfilment of the anatomical conditions which form the basis of such thorough procedures as that of Halsted and Bassini.

As to the skin incision, I should recommend every one not to forget Mr. Lockwood's advice, that in order to find the correct line it is essential to begin by invaginating the scrotum with the finger into the external ring. I have seen this elementary precaution often omitted, the inguinal canal missed altogether, and a fumbling excision made into the femoral region. I employ a long incision, extending from the level of the pubic spine to a point about one inch below and internal to the anterior superior iliac spine. The superficial epigastric and superior external pudic vessels are seized with forceps, divided between, and ligated, and the aponeurosis of the external oblique thoroughly exposed. The intercolumnar fibres of the external ring are then snipped with scissors, and with the handle of the scalpel the aponeurosis is split, parallel to its fibres, to the upper limit of the incision. The divided aponeurotic "leaves" are next seized on each side by pressure forceps, which act as tractors, and considerably facilitate the thorough separation of the former, by blunt dissector, from the underlying structures. I wish to lay

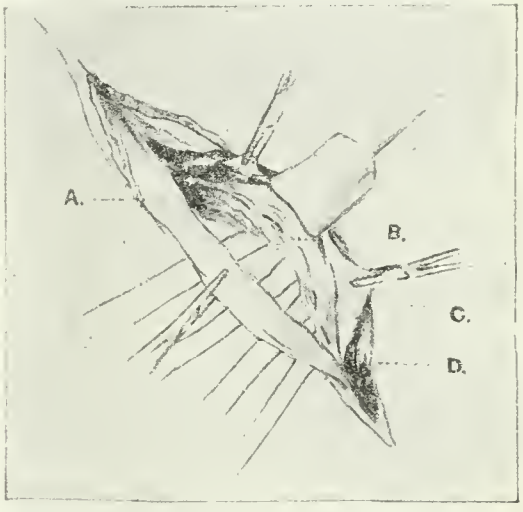

Fig. 1.—A, Poupart's ligament. B, Conjoined tendon. C, Aponeurosis of the external oblique. D, Cord retracted inwards and lying superficial to external oblique.

particular stress on the necessity of thoroughly executing this manœuvre at this stage in order to prevent subsequent anatomical obfuscation, and the avoidance of what I have occasionally witnessed in clinics—the suturing of something to anything.

Once the inner shelf of Poupart is brought into clear perspective, and the fibres of Gimbernat can be readily felt, on the outer side, and the conjoint tendon with the rectus sheath exposed, on the inner, it becomes a very simple matter to free and isolate the cord, and to distinguish, separate, incise, and remove the hernial sac, and to suture the opening flush with the peritoneal cavity.

This completed, the cord is raised up and placed well out of range of injury behind the two tractor forceps attached to the edge of the internal leaf of the divided aponeurosis (Fig. 1).

I now come to the principal part in this operation. The external leaf is drawn firmly downwards and outwards by tractor forceps until the inner shelf of Poupart's ligament comes well into view. Taking this exposed shelf as level, a curved hernia needle is passed from without inwards right through the reflected aponeurosis—the lower one embracing in transit some fibres of Gimbernat's ligament (Fig. 2)—passed across the floor of Hesselbach's triangle, and made to emerge through the substance of the conjoint tendon. The needle is now threaded with strong catgut, one end grasped by an assistant, and the needle withdrawn. The unthreaded needle is again similarly introduced about half an inch above the former, and a mattress suture completed. Three more similar ones are inserted through the above level, and sufficient room is left at the upper angle for the passage of the cord (Fig. 1).

When these four sutures are tied (Fig. 3), the anatomy of the part is considerably transformed, the inner shelf of Poupart's ligament being firmly approximated to the conjoint tendon. Hesselbach's triangle is completely obliterated. In some patients, with ill-developed or flabby conjoint tendons, I have obtained benefit by passing the

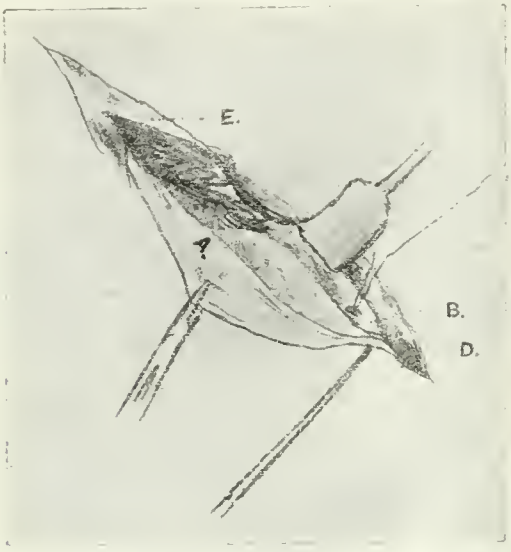

Fig. 2. Insertion of first stitch through Gimbernat's ligament and conjoined tendon. A, Poupart's ligament. B, Conjoined tendon. D, Cord retracted inwards. E, External oblique.

hernia needle further inwards through the adjoining sheath of the rectus, so as to afford a good purchase for the loop of the mattress suture.

Finally, the two aponeurotic leaves are united by a continuous catgut suture, and in doing this I make it a rule to insert the point of the needle deep enough to catch hold of underlying muscle in order that no intermuscular dead space may be left. The cord, of course, is left, as in Halsted's operation, superficial to the external oblique.

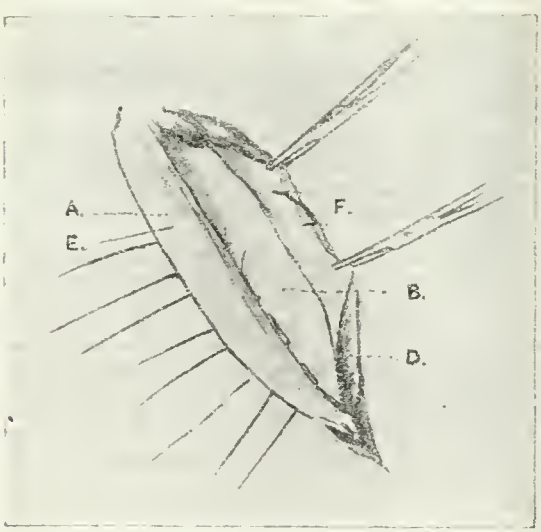

Fig. 3. A, Poupart's ligament (lower shelf). B, Conjoined tendon. D, Cord retracted inwards. E, External oblique—external leaf. F, External oblique—internal leaf.

I find this makes an extremely firm barrier, and is equally useful for the radical cure of oblique or direct hernia.

It is obvious that this operation only differs from that of others in the manner of introduction of deep sutures, but I am convinced the modification is important, in that it affords a simple and absolutely safe method of approximating somewhat delicate tissue in a rather dangerous zone.

I wish to acknowledge my indebtedness to my friend Dr. K. Macfarlane Walker for drawings.

A CASE OF URAEMIA WITH AN UNUSUAL DEGREE OF UREA RETENTION.

BY

H. B. DAY, M.D., M.R.C.P.,

PHYSICIAN, KASR EL AINI HOSPITAL, CAIRO,

AND

W. H. WILSON, M.D.,

PROFESSOR OF PHYSIOLOGY, EGYPTIAN GOVERNMENT SCHOOL OF MEDICINE.

I.—*Clinical Note by Dr. H. B. Day.*

An Egyptian fireman, aged 36, was admitted to hospital to undergo treatment for scabies in the skin section. He did not complain of any urinary symptoms, but the routine examination of urine revealed a high degree of albuminuria, varying from 0.275 to 0.225 per cent. The specific gravity was low—1008—and the reaction acid. The patient was put on milk diet, and discharged in ten days cured of his scabies.

A month later (January 5th, 1914) he was readmitted to the medical wards for oedema of the feet and eyelids with some cough of ten days' duration. The urine was now found to be alkaline in reaction, with a deposit of pus and phosphates. Albumin was present to the same degree as before; the specific gravity was 1010. The bladder was sounded, with a negative result, and the patient was treated for nephritis and cystitis.

A fortnight later the patient's condition caused uneasiness, although all the oedema had disappeared. He had become weak and apathetic, with a fixed staring expression, though responding readily to questions. The amount of urine averaged 1,000 c.cm. a day, but continued of the same low density. In spite of active treatment, the patient became gradually weaker and less responsive. A week later (January 28th) chattering movements of the jaws set in, the tendon reflexes were exaggerated, clonus being easily elicited. The pupils were equal and moderately contracted. The urine showed no further alteration in composition and quantity.

Lumbar puncture was performed and a free flow of clear fluid obtained. No albumin was present (nitric acid test), but the quantity of urea was found by Doremus's ureometer to amount to the extraordinary percentage of 0.75, whereas the normal is 0.03 to 0.04. I was naturally sceptical of such a reading, and repeated the estimation twice again, but with a similar result. I therefore requested Dr. W. H. Wilson to estimate the amount of urea present in the blood. He kindly took samples on two occasions and also collected material at the necropsy. His report forms the second part of this paper.

In spite of rectal injections of saline and cupping to the loins, the patient rapidly grew worse and died three days later (January 31st).

Necropsy.

Dr. A. R. Ferguson, Professor of Pathology, made the necropsy and reported as follows:

"The left ventricle was hypertrophied, the right dilated. The lungs were congested and the liver enlarged, but of normal appearance. The brain showed a recent small patch of subdural haemorrhage on the left side; the ventricles were somewhat dilated and the cerebro-spinal fluid excessive in amount. The bladder was thin-walled and pouched, showing several areas of haemorrhage in the mucous membrane, both old and recent. There were signs of bilharziosis around the opening of the urethra, but no stricture was present. The openings of the ureters in the bladder were lax and patent, but the ureters themselves were dilated. Both kidneys were largely destroyed by pyonephrosis. The residual renal tissue showed acute inflammation."

II.—*Note by Dr. W. H. Wilson.*

At the request of Dr. Day an estimation of the urea content of the blood was made. I also examined the blood and cerebro-spinal fluid obtained *post mortem*, and kindly supplied by Professor A. R. Ferguson.

The method employed was that described by Barcroft,[1] with slight modifications, the apparatus, however, being different. For the samples of which larger quantities were available (*c*, *d*, *e*, *f*), the dried alcoholic extracts were taken up in 20 per cent. NaOH, and decomposed with hypobromite of sodium in an apparatus of the Dupré type; the usual corrections for temperature and pressure were

made; 354 mm.³ of nitrogen were taken to represent 1 mg. of urea. The evaporation of the alcoholic extract was carried out at a temperature varying between 58° and 62° C.

	Urea per cent.
(*a*) 84 c.mm. blood taken 2 days before death ...	0.67
(*b*) 112 c.mm. blood taken 3 hours before death... (This blood was taken from the finger. There being no oedema, the blood was unmixed with serous fluid.)	0.67
(*c*) Blood from the right side of the heart (chiefly serum)	0.738
(*d*) Serum obtained by centrifuging (*c*):	
First sample	0.745
Second sample	0.74
(*e*) Thick blood from vena cava inf. (chiefly corpuscles)	0.53
(*f*) Cerebro-spinal fluid from lateral ventricle:	
First sample	0.85
Second sample	0.84

(*c*) consisted of blood from the right auricle and large veins of the head and neck. Most of the corpuscles had separated out by sedimentation. The specific gravity was only 1037.

(*d*) was quite free from corpuscles and haemoglobin. Its specific gravity was 1036. Proteins 10.5 per cent. (approximately). The high specific gravity is partly explained by the excess of urea (to the extent of 0.0025), partly by the excess of protein.

(*e*) This was obtained from the inferior vena cava at the point of entrance of the left renal vein. It was very thick, resembling a magma of corpuscles. The specific gravity was not determined accurately; it was, however, over 1080.

(*f*) This was faintly cloudy; the specific gravity was unusually high, being 1020. It contained 0.25 per cent. protein.

In the case of the smaller samples—namely, (*a*) and (*b*) and the second determinations of (*d*) and (*f*)—the apparatus used for the hypobromite decomposition was a modification of a "micro-nitrometer" shown by me at a meeting of the Physiological Society, June, 1912. (No description of this apparatus has yet been published.) The method of extraction was similar to that used with the other samples. The percentage of urea found in the cerebro-spinal fluid by Dr. Day four days before death was approximately 0.75 per cent. Probably the actual amount was a little less than this, as it was determined by direct estimation in the Doremus ureometer.

The points of interest in the above results are:

(*a*) The large percentage of urea.
(*b*) The fact that the cerebro-spinal fluid obtained *post-mortem* contained more urea than the serum.
(*c*) That the red blood corpuscles contained a considerable amount of urea.

As regards the first point, the greatest amount of urea present in the blood in uraemia that I find recorded in the literature at my disposal is 0.585 per cent. found by von Jaksch.[2] Widal and Javal[3] record 4 cases in which the amount varied between 0.3 and 0.5 per cent. In the case of a woman who died in Kasr el Aini Hospital two years ago the nitrogen given off from the alcoholic extract of the blood corresponded to 0.66 per cent. of urea. The blood in this case contained a considerable amount of bile pigment and probably also bile salts; the actual amount of urea was therefore no doubt less than 0.66 per cent. The maximum amount I have found in other cases is 0.4 per cent.

As regards the second point, Widal and Froin[4] state that the urea content of the cerebro-spinal fluid is the same as that of the blood plasma; they record one case in which the percentage of urea was 0.448 in both fluids. In a case of uraemia recently examined, I found 0.337 per cent. in the blood serum and 0.316 per cent. in the cerebro-spinal fluid. In the case which is the subject of this note, Dr. Day found 0.75 per cent. of urea in the cerebro-spinal fluid, the figure being identical with that found in the blood serum *post mortem*. In regard to the *post-mortem* material, the serum contained 0.1 per cent. less urea than the cerebro spinal fluid, namely, 0.745 per cent. as compared with 0.85 per cent. In view of the high specific gravity of the cerebro-spinal fluid obtained *post mortem*, a possible explanation would seem to be that some concentration of the fluid took place during the twenty-four hours which elapsed after death before the autopsy was performed.

In regard to the third point, it is generally stated that the urea of the blood is normally contained entirely in the plasma. Some figures given by Barcroft[5] show this; I have also found it to hold good for blood containing as much as 0.09 per cent. of urea. On the other hand, Hedin[6] has shown that in blood to which urea has been artificially added the permeability of the corpuscles to urea is almost complete. In the case under discussion the blood corpuscles undoubtedly contained a considerable percentage of urea. In fluid (*e*), consisting mainly of corpuscles, there was 0.53 per cent. of urea, which is far more than could be accounted for by the small amount of plasma present. The blood taken shortly before death contained 0.67 per cent. of urea, while the serum (*d*) contained 0.745 per cent. Assuming that the ratio of corpuscles to plasma was the normal—namely, 40 to 60—the distribution of urea in the blood would be 0.447 parts in the serum and 0.223 in the corpuscles, giving a percentage of 0.557 in the red blood corpuscles, which is in close agreement with the amount actually determined in the magma of corpuscles (*d*).

The discrepancy between what is known of normal blood, the corpuscular content of urea in this case, and the permeability of the corpuscles to urea as determined by Hedin and others, is probably to be accounted for by the fact that Hedin was working with urea solutions of much higher concentration than are ever found in the blood. It is at least possible that the intrusion of urea into the corpuscles is dependent on a concentration of urea in the plasma much above the normal.

A fact of considerable interest in this case is that the blood contained apparently less than the normal amount of uric acid, certainly no more; whereas in two other cases of uraemia recently examined (in which the urea content of the serum was respectively 0.33 per cent. and 0.25 per cent.) the amount of uric acid was greatly in excess of the normal, being present to the extent of approximately 0.02 per cent. in the first of these two cases. (Both these cases were under Dr. Day's care, to whom I am indebted for the material.) Whether this fact is connected with the difference in pathological conditions present in these three cases is worthy of further investigation.

The case here detailed was one of hydronephrosis with a somewhat acute secondary inflammation of the remaining kidney substance following septic infection of the urinary tract, whereas the condition of the other two was that of contracted granular kidney with a toxic exacerbation shown by considerable albuminuria.

A fact which may also be related to the lack of uric acid in the blood was that coma was completely absent in this case of latent uraemia at the time when a specimen of blood was taken a few hours before death. In the other two patients convulsions and coma had developed, yet in the first case the serum contained no less than 0.75 per cent. of urea as compared with 0.25 and 0.33 per cent. in the latter two. I had no opportunity of personally examining the urine in either case.

The determination of the presence and a rough estimate of the amount of uric acid in the blood was made by the phosphomolybdic acid reaction with an alkaline solution of the dried alcoholic extract. The estimate was formed by comparison with a solution of uric acid of known strength treated in the same way. It is here assumed that the substance present in the blood which gave the reaction was uric acid. It may be mentioned that the only other substances present in the urine (and so conceivably present in the blood) that give this reaction are the aromatic sulphates.

DR. LÉON LABBÉ, Senator for the Orne, has again been elected Chairman of the inter-parliamentary group of members of the French Legislature (Senate and Chamber of Deputies).

AT the annual meeting of the American College of Surgeons, held in Philadelphia on June 22nd, a movement was set on foot for the establishment of a permanent home of surgery in Washington, for which an endowment fund of £100,000 will be required. More than £20,000 was promised by those present within an hour. The college has now a membership of 3,200, having admitted 1,000 surgeons to fellowship at the meeting.

LATENT DYSENTERY, OR DYSENTERY CARRIERS IN SARAWAK, BORNEO.

BY

W. LEDINGHAM CHRISTIE, M.D., F.R.C.S.ENG.,

MEDICAL OFFICER, THE BORNEO COMPANY'S HOSPITALS.

EVERYBODY understands by the use of the word "dysentery" that patients have loose stools, with blood and mucus, but my experience in Sarawak is that many people, white or native, may become thin, pale, wasted and weak with what is practically dysentery, without having loose stools or blood or mucus. In such cases I have found abundant amoebae of the *histolytica* type; and when these were cleared out by a few injections of emetine, with saline treatment, the condition of debility, pallor, and wasting disappeared.

The more one searches the more prevalent does one find this condition of amoebiasis. In imported Tamils I have found amoebae in 100 per cent. of the cases. In other batches 80 per cent. were infested with them, and some have developed acute dysentery and died after arrival, thus proving that the amoebae were pathogenic.

Of Javanese in hospital, not admitted for dysentery, I have found 25.4 per cent. with amoebae; and in a new batch of 16, just imported, 56 per cent. had amoebae and 43 per cent. had ankylostomiasis.

Among Malays examined (only three to date) amoebae were found in all, yet they showed no signs of dysentery. It is true that ankylostomiasis was also present. There is a suspicion that Malays who live by the river, and drink its water, into which of course all their sewage runs, are infected with amoebae, ankylostomiasis, and filaria. Research is being made into their condition.

It is very probable, however, that much of the debility, invaliding, anaemia, and "fever" put down to malaria, which is rare here, is due to the septic, irritated condition of the colon in patients infested with amoebae who show no signs of blood or mucus in their stools till they reach an advanced stage of ulceration.

The following statistics from our laboratory may prove this contention:

During nine months since August, 1913, of 554 cases admitted to Sejijak Hospital, 65 were dysentery carriers and 19 others had the usual signs of the disease. Thus there were 12 per cent. of carriers of latent dysentery and 3.4 per cent. of actual cases.

100 Unselected Cases (April and May, 1914) of all kinds.

Amoebae were found in	34 per cent.
Trichomonas in	13 ,,
Ankylostomiasis in	40 ,,
Round worm in	24 ,,
Whip worm in	44 ,,

Analysis by Nationalities of 100 Consecutive Selected Cases admitted to Sejijak Hospital during May, 1914.

Nationality.	Amoebae Found.	Amoebae not Found.	Total.	Percentage Found.
Javanese	16	47	63	25.4
Tamils	11	2	13	84.6
Chinese	2	12	14	14.0
Dyaks	0	2	2	—
Malays	3	0	3	100.0
Europeans ...	2	3	5	40.0
Total	34	66	100	34.0

In none of these cases was dysentery suspected, nor was blood found. Of the three Malays who complained of pain in the stomach, not only was amoeba found, but trichomonas and ankylostoma as well. In one case *Filaria nocturna* was in the blood at the same time.

Sarawak is nevertheless a healthy country. The reasons are no doubt: (1) The large rainfall (220 in. last year); (2) the cool monsoon breeze; (3) the reduction of malaria by rubber-planting and clearing; (4) the infrequency of cholera, enteric fever, and small-pox; (5) the absence of trypanosomiasis and plague. The temperature also rarely rises above 90 F., and is usually 78° to 80° in the shade. Although the thermometer may reach over 100° in the sun, heat-stroke is rare. For the equatorial region, therefore, Sarawak may be considered one of the healthiest places, in spite of amoebiasis. Although the death-rate is low, I have found Europeans and natives feeling "rotten," as they call it, or suffering from neurasthenia, who became fit soon after the amoebae were cleared from the colon and the resulting colitis and septic state had been cleared up. It used to be common for patients to attribute everything to a "touch of fever" and to take quinine; but I have found that calomel and saline are much more effective.

The actual death-rate of our hospitals only reached 3 per cent. on all cases, and the three deaths we had out of 33 cases of acute dysentery were due to the fact that the estates were caught by surprise and the cases came in a dying state. After we got emetine and cases in the first stage we had no deaths.

Conclusions.

1. That 30 per cent. or 40 per cent. of the entire population are dysentery carriers.
2. That the examination of them early and treatment with saline clears the colon of amoebae and prevents dysentery.
3. That much invaliding and debility are due to latent dysentery.
4. That the amoeba is of one type and cannot safely be pronounced non-pathogenic at any time.
5. That emetine is most valuable in obstinate latent cases, and is essential in dangerous, acute, amoebic dysenteries, robbing them of their terrors.

THREE CASES OF INFECTIVE ARTHRITIS TREATED BY SPECIFIC METHODS.

BY

D. W. CARMALT JONES, M.D., F.R.C.P.,

PHYSICIAN TO WESTMINSTER HOSPITAL.

ACUTE arthritis is a common disorder, but it is not always traced to a definite local infection of the joints. Infections of joints due to the *Bacillus tuberculosis* and the gonococcus are of frequent occurrence, and cases of pneumococcal and streptococcal infection are occasionally met with. In many other forms of arthritis infection of some kind is suspected and probable, but it is often difficult to demonstrate conclusively the presence of any organism. In the following cases a bacteriological diagnosis was made with certainty, and beneficial results were obtained in each of them by specific therapy. The term "bacteriological" is here used to include the diagnosis of syphilis.

There are three methods by which a bacteriological diagnosis may be made in any case of infection: the first is the recovery of infective organisms from the lesion; the second is the recovery of such organisms from a site remote from the lesion, but so situated that the connexion between the two sites is clear; and the third is by means of "reactions," by which is meant the demonstration in the patient's blood of bodies which have a recognized bearing on some organism of known infective properties. The cases here reported illustrate each of these methods.

CASE I.—*Staphylococcus.*

Parlourmaid, aged 42. The patient had been long subject to slight rheumatic pains in many joints, especially the right knee, and had had one severe attack of rheumatism in this joint six years before. In January, 1914, while suffering from slight pain in the right knee, she was out of doors in rainy weather; during the following week this joint became very painful and was much swollen, and three weeks later she was admitted to Westminster Hospital.

On admission the joint was very swollen, and so painful and tender that the patient had had no sleep for three nights. The joint was much distended and was held in a semiflexed position; it was punctured and some opalescent fluid was withdrawn, which contained numerous leucocytes and yielded a pure culture of *Staphylococcus aureus*. The joint was aspirated and emptied as far as possible. An autogenous vaccine was prepared; the patient was inoculated, and in due course extension, massage and passive movements were employed. The result was very satisfactory and ended in complete recovery.

There were some points of interest in connexion with this case. There was no history of trauma nor any

evidence of abrasion of the skin, and the patient did not appear to be suffering from septicaemia, as there were no abscesses elsewhere and the general condition was good. There was, however, the scar of an old operation for osteomyelitis on the tibia immediately below the joint; this operation had been performed thirty years before, and the question arises whether the joint could have been infected from this source. The joint infection was not virulent, and there was no tendency to point; the fluid aspirated was very thin pus, and recovery was complete even in so vulnerable a structure as the knee-joint. It seems probable, therefore, that the infection was of a very mild character, due only to an attenuated organism. Thirty years is a very long period for organisms to persist in the body without giving rise to symptoms, but in this connexion a case reported by Mr. Tubby and Dr. Braxton Hicks is of interest.[1] Their patient had an attack of suppurative osteitis from which the *Bacillus typhosus* was recovered thirteen years after an attack of enteric fever. In such a case independent infection is most improbable, since the *Bacillus typhosus* is of comparatively infrequent occurrence. If, then, an organism can be proved to have survived within the body for thirteen years, there is no obvious reason why it should not continue to survive for thirty.

CASE II.—*Streptococcus.*

Male, aged 40, under the care of Dr. T. A. Durrant, was seen on the recommendation of Dr. Luff. Dr. Durrant reported that the patient was suddenly taken ill with sore throat, a temperature of 102°, and symptoms of influenza, which were followed on the second day by pain and redness in the metatarsal joints of the right foot, and on the third day by swelling and redness of the left ankle, and stiffness and pain in the right shoulder. There was persistent variable temperature for seventeen days, and a fall by lysis succeeded by periphlebitic pain and thickening along the course of the left saphenous vein.

Cultures were made from the blood, the throat, the faeces, and the urine. The throat was still inflamed, and many organisms were obtained from it, with a preponderance of streptococci. The faeces showed numerous cocci in the film, and streptococci were obtained in unusual number on culture. The urine yielded a diphtheroid bacillus, but no streptococci. The blood: About 6 c.cm. were withdrawn from a vein and distributed among six broth tubes, each of which yielded streptococci. A vaccine was prepared from the blood culture, and Dr. Durrant reports that there was rapid diminution of objective conditions from the use of the first inoculation, and the patient made a complete recovery.

This case is an instance of the isolation of pathogenic organisms from a site remote from the lesion. Since they were obtained from the blood, which is normally a sterile fluid, there was strong presumptive evidence that they came from the same source as those causing the symptoms of which the patient complained: the blood is the most satisfactory site from which to obtain organisms in such cases. In the event of the blood being sterile, other sites have to be investigated: for instance, in a case of arthritis, the presence of gonococci in a urethral discharge is strong presumptive evidence that the joint infection is also gonococcal. Similarly, a pneumococcal or typhoid arthritis may be inferred when the joint condition supervenes on pneumonia or enteric fever, in which the specific organisms have been demonstrated. In the present instance, if the blood culture had been negative, it would have been worth while to attempt inoculation with the streptococcus from the faeces, but since this organism is commonly present in stools there would have been greater risk of failure; this applies with still greater force to those obtained from the throat. The case is especially interesting because it is very rare to obtain a positive blood culture from a patient in whom arthritic symptoms predominate.

CASE III.—*Syphilis.*

Male, aged 35, under the care of Dr. Hildesheim, of Northwood, was admitted at his request into Westminster Hospital. The symptoms were not primarily those of arthritis. The patient had worked in many parts of the world, especially in the tropics, and had undergone much hardship; he had been invalided from the Johannesburg mines with the diagnosis of phthisis, but tubercle bacilli had not been found in the sputum. He had recently been invalided from the West Coast of Africa with persistent headache, great depression, and serious loss of weight. About the time of his admission to hospital he developed a sudden painful swelling of the right knee, which was distended with fluid; it was not hot, nor inflamed in the ordinary sense, but so painful as to prevent sleep. It was not acutely tender, and some degree of passive movement was permitted. Extensive pathological observations were made by Dr. Braxton Hicks to exclude malaria and other tropical diseases, with negative results; the blood, however, gave a positive Wassermann reaction, confirming a diagnosis of syphilis provisionally made on clinical grounds by Dr. Hildesheim. Injections of salvarsan were given with immediate relief of the symptoms in the right knee. There was some recurrence in a day or two, but this was followed by rapid improvement, and on leaving the hospital the patient, though far from recovered in general health, was able to walk in comfort.

Syphilitic arthritis of the type here described is not very common. Fournier[2] describes a type similar to acute rheumatism, chiefly affecting the knee, in secondary syphilis, and also painful joints without physical signs of disorder, and painless hydrarthrosis. Adami and Nicholls[3] describe serous synovitis in secondary syphilis, and state that it occurs occasionally in the tertiary stage. This patient had no knowledge of infection; he stated that he had not been exposed to risk for more than a year, and he showed no other secondary symptoms, so that the lesion was probably tertiary.

In this case the diagnosis was made by a reaction, and improvement followed treatment. It should be noted that the specific diagnosis of syphilis is not comparable to the diagnosis of bacterial infections by agglutination, bacteriolytic or opsonic tests, nor is treatment by salvarsan comparable to inoculation with vaccines or serums. It was long held to be an axiom that while bacteria could be cultivated and their infections treated by methods intended to raise the patients' resistance to them, no drugs capable of oral or subcutaneous administration had any bearing on them, but, on the other hand, the protozoa could not be cultivated, while many of them were susceptible to treatment by drugs. That is still largely true, but recently it has been possible to cultivate a few of the protozoa, and Professor Morgenroth has made observations which show that an organic salt of copper has a definite effect on the pneumococcus in the tissues.[4] The Wassermann reaction depends on a fortunate accident, but all observers agree that it has high specific value in syphilis; it differs from the antibacterial blood tests in this, that the "positive reaction" disappears with successful treatment, whereas in recovery from bacterial infections, whether spontaneous or induced, the reaction, which is evidence of resistance, becomes for a time intensified; the reason is that the treatment by salvarsan is the application of a specific poison to the invading organism, and not a stimulus to the body to produce antibodies.

These cases all show the value of accurate bacteriological diagnosis in specific treatment, which is otherwise purely empirical, and has then no advantages over other empirical treatment. Where vaccine-therapy is employed without such a diagnosis, which often cannot be made, it is necessary to make a guess at the infecting organism, and though such guesses are fairly often successful, they are necessarily attended by very many failures. The essentials of success in vaccine-therapy are three—the employment of the right organism, the use of suitable doses, and, thirdly, the power of the patient's tissues to respond to the stimulus of the inoculation. The last can never be guaranteed, but accurate bacteriological diagnosis secures the first of the three essentials.

The prognosis in staphylococcal and streptococcal arthritis is not very good, and frequently ends in permanent damage, more or less serious, so that complete recovery is to be looked upon as a very fortunate result.

THE *Australasian Medical Gazette* states that South Australia was the first State in Australia to erect a crematorium. The crematorium attached to the West Terrace Cemetery was built in 1901 by a number of private persons interested in cremation, as opposed, on sanitary grounds, to earth interment. The structure, which cost about £2,000, was erected on land allotted by the Government. The crematorium had been erected a long time before it was first utilized, and in 1903 the promoters handed it over to the Government. The first cremation was that of the body of a Sikh, on May 4th, 1903. The first white man cremated was the late Dr. Shand, of Port Elliot, on October 30th, 1903. So far there have been 63 cremations at West Terrace, 13 of them in the past twelve months.

PNEUMOCOCCIC ARTHRITIS FOLLOWING ACUTE PNEUMONIA.

BY

W. SILVERWOOD RICHARDSON, F.R.C.S.EDIN.,

ASSISTANT SURGEON TO THE ROYAL VICTORIA AND WEST HANTS HOSPITAL, BOURNEMOUTH.

CASES of pneumococcic infection of a joint following acute pneumonia are rare, and the literature on the subject is certainly not voluminous. For these reasons the following notes may prove of interest.

The older writers on the complications of pneumonia mention "rheumatic joints" as sometimes following this disease. Quain and Osler both record the fact that arthritis may follow an acute attack of pneumonia. Stickler, of Philadelphia, collected records of 11,846 cases of pneumouia from various clincs, and found joint complications in about 800, that is, about 14 per cent. He does not indicate whether any suppurative forms occurred. In the Epitome of the issue of the BRITISH MEDICAL JOURNAL for June 13th, 1914, Buckley is quoted (No. 339) as collecting 172 records of pneumococcic arthritis, and as having reported a case of his own in the *Annals of Surgery*. The shoulder-joint was involved in a child 11 months old, and the trouble supervened upon left lobar pneumonia.

The notes of my own case are as follows:

History.

A male, aged 49, spent his 50th birthday in a nursing home convalescing from pneumococcic infection of the left ankle-joint following an attack of acute lobar pneumonia. He was a slim Frenchman who did not seem to be a good subject for pneumonia; he had had a previous attack three and a half years before when in East Africa, and had never felt well since.

When 25 years old he injured his left ankle-joint, and was unable to walk for several weeks. He sprained it again a few days before his present illness.

Condition when First Seen.

He was first seen on April 8th, 1910; he was then suffering from indefinite symptoms—namely, pyrexia (temperature 104°), chilliness, and rapid pulse (110) and respiration (30). He had been in contact with a bad case of influenza, and it was thought that perhaps he had contracted the disease. Next day physical signs pointed to pneumonia at the base of the left lung; he was very ill, but the attack followed the usual course, and the temperature fell by crisis on the seventh day. During the attack he complained of pain in the left ankle-joint, but there was no swelling or redness.

On the evening of the seventh day the temperature ran up to 101°, and the pulse was 108; he felt ill, and complained of great pain in the left ankle-joint, which was slightly swollen, red, and hot; the pain was lulled by local fomentation and aspirin, but he had a restless night.

In the morning (April 16th) the swelling had increased, and by the afternoon had reached nearly up to the knee-joint. The temperature was 104°, the pulse 120, and respirations 20. I decided to operate.

Operation.

Light chloroform anaesthesia was induced, and an incision made three-quarters of an inch behind the internal malleolus. A pair of dressing forceps was pushed through the incision in the direction of the posterior part of the ankle-joint, and several ounces of creamy pus escaped. A counter-opening was made behind the external malleolus, and a drainage tube inserted. The incisions were extended upwards on either side of the leg through the oedematous tissue, and the wounds and joint freely irrigated with 1 in 40 carbolic. The leg was dressed with sterile gauze.

After-History.

He passed a fairly comfortable night, and at 8 a.m. on April 17th the pulse was 98 and temperature 99°. He expressed himself as feeling much better and more comfortable. The inflammation had ceased to spread; there was, however, still a good deal of oedema round the ankle; this was most marked in front. The wound was irrigated with 1 in 60 carbolic and hydrogen peroxide twice daily and dressed as before.

On April 18th an incision was made into the oedema, in front of the ankle-joint, and more creamy pus came away. The wounds were irrigated and dressed as before; they looked more healthy. The growth obtained from the pus in an agar tube was pure pneumococci; an autogenous vaccine was prepared and 3 million injected on April 19th. Small doses (3 million) of vaccine were given every four days—five doses in all.

The patient made continuous progress and was able to get out of bed on May 12th. He left the home on June 13th.

Passive movement and gentle massage were used daily for three weeks after leaving the home. Passive movements of the joint were begun as soon as the joint wound had healed.

The patient was able to move his joint freely and walked only with a slight limp.

I heard from him a short time ago; he was big game shooting in East Africa; his health was excellent and his joint gave him no trouble.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

ARTIFICIAL PNEUMOTHORAX AND SWIMMING.

THOSE who have followed the details of the recent Thames tragedy, wherein William Mitchell was drowned while attempting to save the life of Sir Denis Anson, may be interested to know a fact about the former which rendered his gallant attempt more hazardous and his heroism more striking than is generally known. William Mitchell was the subject of an artificial pneumothorax.

He came under my care in January of this year with extensive tuberculous infiltration of the right lung reaching to its base, but with a clear left lung. I produced an artificial pneumothorax on February 2nd, and extended it on subsequent occasions till the right lung was completely collapsed, under a pressure of about +12 to 14 cm. of water, save for some adhesions on the inner anterior surface of the apex. Under this treatment his general condition improved, cough and expectoration ceased; he was able to return to work about Easter, and might ultimately have recovered completely. He continued at work, returning for refills every four or five weeks. He received his ninth and last injection of nitrogen gas on June 12th, and left with an intrapleural pressure of +14 to 18 cm. of water and his heart displaced 1 in. outside the left nipple line; this pressure must have fallen to near atmospheric pressure by the time of his death. His left lung was clear and unembarrassed, and he could undertake moderate exertions, such as those entailed in his employment, without any discomfort; he was, however, somewhat dyspnoeic on more severe exertion, and was well aware of this disability. That the presence of a pneumothorax must have greatly handicapped him in his gallant attempt there is no room to doubt—it is only when this fact and his knowledge of it is realized that the bravery of the act appears at its full value.

London, W. CLIVE RIVIERE.

FRACTURE OF A FLOATING RIB IN A NONAGENARIAN.

ON April 11th last, whilst watering the indoor plants, and proceeding from the landing down a flight of only three narrow steps to reach a back window, holding the watering-pot in one hand and the handle of the opening door in the other, I slipped and fell heavily on my back, the edge of a stair evidently coming in contact with the right side just above the sacrum.

My servants helped me up. Great pain supervened on motion, and I feared fractured rib; but deep inhalation did not increase the pain, whence I knew that the ribs encasing the lungs were all right.

I remained in bed the next day, and felt a painful jolting on moving my body. The following day I get up, supported by a belladonna plaster and belt around the injured part. Whilst sitting up I remained quite easy; the pain on moving and turning sides in bed, with the bone jolting, gradually lessened. At the end of three weeks I had quite recovered, and could bear pressure well on the injured part, which on examination disclosed a callus about two inches from the point of the upper floating rib. I never before heard of such a fracture, and the fact that I was born in 1821 adds interest to the fact that bony union occurred in three weeks.

Dulverton. JOHN B. COLLYNS, M.R.C.S. and L.A.C.

AT the annual meeting of the American Medical Association, held at Atlantic City, June 23rd to 26th, Dr. William Louis Rodman, Professor of Surgery in the Medico-Chirurgical College of Philadelphia, was elected President. The next meeting of the association will be held in San Francisco in June, 1915.

THE United States District Judge of the Southern District of Iowa has (says the *Medical Record*) declared unconstitutional, and therefore null and void, the law passed by the last General Assembly of Iowa providing for the sterilization of certain criminals. This decision is based on the ground that the penalty is in violation of the constitution which provides that cruel and unusual punishment should not be inflicted.

Reviews.

GREEK AND ROMAN MEDICINE.

DR. JAMES SANDS ELLIOTT, editor of the *New Zealand Medical Journal*, not long ago visited the south-eastern part of Europe, and his professional interest was naturally aroused by the sight of the places associated with so many men whose names are written on the scroll of medical fame. As the outcome of his pilgrimage to the ancient schools and shrines of healing he has written a book[1] in which his aim has been to give "a general outline of the most important stages in the advancement of the healing art in the two empires to which modern civilization is most deeply indebted." He says the subject has been much neglected, except, as one gathers, by German writers like Baas, Sprengel, and Puschmann. This statement is somewhat remarkable in view of the amount of work in the elucidation of medical history done by Daremberg in France; by De Renzi in Italy; and by Payne, Withington, Clifford Allbutt, Norman Moore, and D'Arcy Power in this country. It must, however, be admitted that medical practitioners are too often indifferent to the history of the development of their art. The "practical" man would say he is too busy with the actual to waste time on the past. But the story of the past is not all mere antiquarianism. It holds in it many lessons for the present. The fanciful notions of disease on which the older medicine was based, though scientifically dead, still hold sway over the public mind and find expression in popular language; a doctor who wishes to inspire confidence must know the old pathology in terms of which the patient speaks of his own case. The superstitious of to-day are the medical teachings of yesterday, and may again be reinstated as accepted doctrine. The variations of medical opinion as to the infectivity of tuberculosis, even within the past hundred years, should teach us prudence in prematurely discarding old doctrines as obsolete. In medicine, as in theology, the maxim *quod semper, quod ubique, quod ab omnibus*, if not to be taken as infallible should not be lightly discarded. The history of medical thought is, therefore, worthy of study for the light it throws on the present and on the direction in which progress is likely to be made.

Dr. Elliott's first chapter is devoted to early Roman medicine. It might be thought that this chapter would be like the famous one about snakes in Iceland, as Pliny says that for 600 years the Roman people were without doctors. He does not, however, say that they were without medicine. To the *atrox animus* of Cato the Elder physicians were hateful, because they were mostly Greeks, and he thought the supple-backed and unscrupulous foreigner would undermine the republic. So far from disbelieving in physic, the great Censor practised it in his own household, and even wrote a guide to domestic medicine, from which it would seem that he put as much trust in cabbage—that "windy vegetable," as the Scottish farmer called it when asked by the Duchess of Gordon if he would have some—as some moderns place in nuts. Cato also set fractures to the music of meaningless charms. If, however, the Romans were content to leave the practice of medicine largely to Greeks, who were often freedmen, they had the elements of a sound notion of sewerage, as the Cloaca Maxima remains to testify.

In the second chapter Dr. Elliott gives an account of early Greek medicine. Due honour is paid to Hippocrates, in regard to whom the curious fact is mentioned that in the island of Cos, with which his name is so intimately associated, the memory of his fame as the Father of Medicine seems to have perished, and he is worshipped as one of the numerous saints of the Greek Church. In speaking of the great school at Alexandria, Dr. Elliott repeats the usual story that the library was destroyed when the city was taken by the Caliph Omar in 641. Gibbon showed that there was no good evidence for this story, and modern scholars, we believe, are agreed in regarding it as a myth.

Dr. Elliott gives a good account of the state of the medical profession and the social rank of its practitioners at the beginning of the Empire. Julius Caesar bestowed the privileges of Roman citizenship on all medical practitioners in the city. Quackery was rampant, and there was much trafficking in poisons. Dr. Elliott gives considerable attention to Celsus, of whom he says that "his practice was not general, but restricted to his friends and dependants." This recalls Goldsmith's remark and Topham Beauclerk's unkind suggestion that he should change his plan and practise among his enemies. Celsus was a patrician, and would therefore probably have thought medical practice beneath his dignity. Perhaps, however, he may have practised the art for art's sake, as Peter the Great operated on his lieges, and a great peer of the eighteenth century took every opportunity of bleeding his friends. Celsus's treatise, *De Medicina*, was probably a compilation intended, not for physicians, but for the instruction of educated laymen.

Dr. Elliott devotes a whole chapter to Galen, a general survey of whose works is given. The decline of medicine in the later Roman and Byzantine period is clearly traced. There is a chapter on the influence of Christianity and altruism on the healing art. In another, gymnasia and baths are dealt with, and the book closes with a particularly interesting review of sanitation, including water supply, drainage, and the disposal of the dead. There is a brief appendix on fees in ancient times.

Dr. Elliott has covered the period of which he writes as completely as is possible within the short compass of 160 pages. His style runs easily in a clear stream to which the famous description of the Thames, "though gentle, yet not dull," might well be applied, and he does not weary the reader with discussions of fantastic theories. The book is a readable summary of the subject of which it treats, and as such may be recommended to those who wish to know the main outlines of medical history, but have no time for the study of more comprehensive treatises.

PHONASTHENIA.

THE hygiene of the voice is a subject that cannot be conveniently included and adequately discussed in a systematic work dealing generally with diseases of the throat. The large number of pamphlets and monographs testify to the fact that the subject lends to separate treatment; and to these Dr. IMHOFER'S monograph on *Phonasthenie*,[2] fatigue of the voice, is a valuable addition. It is divided into five chapters. The first is introductory and historical, and in it he passes in review the work of the pioneers and urges the necessity of drawing attention to phonasthenia and its treatment. The next three chapters are devoted respectively to the varieties and clinical aspects, to statistics and etiology, and to the diagnosis and prognosis of phonasthenia. The fifth and concluding chapter discusses the treatment of the condition, which includes prophylaxis, local and general treatment; this is, perhaps, the most important chapter from the standpoint of the practitioner. Under "prophylaxis" stress is laid upon the importance of local and general medical examination of the student prior to commencing a course of singing lessons and also upon the necessity of the teachers themselves having a knowledge of the causes and indications of phonasthenia. The teaching of elocution in schools and universities is also discussed. The local treatment naturally includes that of chronic tonsillitis. The author, we gather, is not in favour of tonsillectomy nor even tonsillotomy in the treatment of the voice affections under consideration, but counsels conservative measures. The chapter concludes with a description of suitable vocal exercises which are exemplified in plates. Appended to the monograph is an excellent bibliography which will be of service to those engaged in research. Although so much has been written concerning the use and abuse of the voice the subject is still one of doubt and controversy, and those who wish to pursue the matter further will find in Dr. Imhofer's monograph a judicious summary of the present position of the question.

[2] *Die Ermüdung der Stimme (Phonasthenie).* Von Dr. R. Imhofer. Würzburg: C. Kabitzsch. 1913. (Roy. 8vo, pp. 138; 2 Beilagen. Mk. 5.)

A little book on *How to Breathe, Speak, and Sing*,[3] contains the substance of lectures delivered from time to time by Mr. ROBERT STEPHENSON at various centres in London. The author's object has been to set forth the main features of the old Italian method of voice production in relation more particularly to the study of the speaking voice, and to show that, whether for singing or elocution, the same preliminary training is necessary. A series of progressive exercises designed for the student are given at the end of some of the chapters. These, in the experience of the author as a teacher, if performed with intelligence and perseverance, will do much to remove vocal troubles. The collection of vocal exercises with piano accompaniment at the end of the book, together with the chapter dealing with the old Italian method, will be found to be of more interest to the vocalist than to the student of the speaking voice, though the latter is strongly advised to bear in mind the dictum of Morell Mackenzie, "that singing might with advantage be taught as an aid to elocution."

GUNSHOT INJURIES.

COLONEL LAGARDE, of the United States Army Medical Corps, gives in his monograph on *Gunshot Injuries*[4] a thoroughly up to date review of the position of the military surgeon in respect of this important department of his work. That it is merely a department, and not the whole of his professional realm, has been but lately recognized, a fact which has had important effects on military medical administration, and led to much unnecessary and embittered controversy. For many years—in fact, for generations—the military medical officer was called a surgeon, and through the tyranny of nomenclature he was looked on by military men as such, at least primarily, and by the layman almost exclusively. As a matter of fact, military surgery — that is, the surgery of wilfully inflicted injuries—concerns the military medical officer of the army, in times of peace, less than it does his civilian brother. To him the opportunity of treating gunshot injuries comes only in war, an incident not frequent even in the British army, and one which is rare in the history of other services. The great war which closed at Appomattox Court House in April, 1865, provided the medical service of the United States with a storehouse of experience, of which its members made good use, and which, as Colonel Lagarde says in his preface, furnished in the *Medical and Surgical History of the War* a book of reference for the medical profession the world over. When next the United States engaged in war on the grand scale thirty years and more had elapsed, years which saw the introduction of the small calibre high velocity bullet on the side of the destructive agency, and of the aseptic system on that of the healer.

Colonel Lagarde has, throughout his useful work, contrasted the effects of the old weapon with those of the new, the successes of the new treatment with the failures of the old. On the whole it may be said that not only have wounds become less destructive, but that the skill of the surgeon has far more than kept pace with the advance in armament. Wounds which in the old days were inevitably fatal are now readily amenable to treatment, and, even more important from the point of view of the individual soldier, injuries which at one time entailed grievous mutilation, produce in these days only transitory disablement.

Many instances might be quoted, but none, perhaps, is more typical of the advance made than injury of the knee-joint. Thus, in the Civil War, when primary amputation was the rule, only 46 per cent. of all such cases recovered, and these at the price of the loss of a limb. In the Santiago campaign of 1898 none died, and only 19 per cent. were disabled for further service.

An interesting account is given of the various weapons in use in different armies, the initial velocity developed, and other more or less mechanical details. The theory of the production of explosive effects is fully discussed, and the true cause of these—namely, the transference of the remaining velocity of the bullet to the particles of tissue which obstruct its passage—elucidated.

With reference to the new pointed bullet, introduced first into the German army, but later into other armies—most importantly, at the present moment, that of Turkey—the author is of the opinion that "it requires no prophet to predict that the war wounds of the future will be much more grave. Body wounds will be uniformly more fatal; injury to bone will be more extensive and prone to suppuration. The humane character of the reduced bullet wounds so happily noted in recent wars will be less frequent." This is not in accordance with the observations of Birrell and Cousergue, who had the opportunity of studying the effects of this missile in the late Balkan war.

A short chapter on skiagraphy gives a good idea of the difficulties attending the use of this essential means of diagnosis in the field. Colonel Lagarde considers that the apparatus is not needed in advance of the stationary hospitals on the lines of communication. Much must depend on the nature of the campaign. In savage warfare, where transport is hard to obtain and convoys need elaborate protection, probably even this position would be too far advanced.

This book may be confidently recommended to any one requiring a handy manual on gunshot wounds. It does not contain much that is new or original, but it is accurate and reliable. The illustrations are excellent.

TEXTBOOKS OF HYGIENE.

IT is a noticeable fact that among the earliest writers on hygiene, who treated the subject from a practical standpoint, were the professors of military hygiene at the British Army Medical School, beginning with De Chaumont and E. A. Parkes and followed by Colonel Lane Notter and Colonel R. H. Firth. The tradition was maintained by Colonel A. M. DAVIES in 1894, when he published *A Handbook of Hygiene*.[5] In the preparation of the fourth edition now issued Colonel C. H. MELVILLE has collaborated. Although the authors are well known as intimately connected with the Army Medical Service, so that their writings might be expected to refer almost exclusively to army conditions, it is eloquent testimony to the broadness of the science of hygiene that they have produced a work which is of very general application, and which should prove invaluable to those who are engaged in the teaching of hygiene or in sanitary administration. The general arrangement is excellent, and the volume can be thoroughly recommended not only as a textbook for students but as a reliable work of reference for practitioners. As an instance of the carefulness with which the latest edition has been brought up to date, it may be noted that on page 425 reference is made to Maple's damp-proofing machine, which can be used for inserting a damp-proof course in existing walls. It cuts a seam through the wall, whether of brick or stone, ½ in. deep, in which is inserted lead sheeting covered with bitumen and asphalt, the seam is then made perfect externally with Portland cement. The character of the detailed information contained in the work, and of its extent, may be gathered when it is stated that there are tables showing the average stature and average weight at all ages of the general population of Great Britain. The chest girth of males from 10 years of age to 50 is also given, together with the height and weight of London schoolboys and girls from 5 to 13 years. In the chapter on water and water supply there is included a very instructive table taken from the sixth report of the Rivers Pollution Commissioners, showing the composition of spring and deep well water. There is not, however, any very definite statement in this chapter as to what constitutes a pure drinking water, though it must be admitted the definition is not easy. In the chapter on food and dieting the authors give expression to views on the use of chemical preservatives for milk which are quite in accordance with those of other observers. The exact quantity of boric acid, salicylic acid, formaldehyde, etc., that must be ingested in order to bring about injurious effects are, they admit, not known; but they consider it is reasonable that their use at all should be prohibited unless it can be shown

[3] *How to Breathe, Speak, and Sing.* By R. Stephenson, B.A.Cantab. London: Jarrold and Sons. 1914. (Cr. 8vo, pp. 121; illustrated. 1s. 6d. net.)

[4] *Gunshot Injuries: How They are Inflicted, Their Complications and Treatment.* By Colonel L. A. Lagarde, United States Army Medical Corps (Retired). London: J. Bale, Sons, and Danielsson, Ltd. 1914. (Med. 8vo, pp. 407; 160 figures. 18s. net.)

[5] *A Handbook of Hygiene.* By A. M. Davies. Fourth edition. Revised and enlarged by A. M. Davies, D.P.H., and C. H. Melville, M.B., D.P.H. London: C. Griffin and Co., Limited. 1913. (Fcap. 8vo, pp. 730. 10s. 6d. net.)

that they are absolutely necessary, which can hardly be the case when it is well known that leading dairy companies distribute milk over very large areas without using preservatives, and that untreated butter can be brought from Australia in good condition. It only remains to add that the authors have conspicuously succeeded in producing a work the aim of which was to digest essential information "into as small a compass as seemed advisable without sacrificing clearness, and at the same time to omit nothing of real importance."

Although public health administration in the United States of America is only of comparatively recent date, there is gradually growing up in that country a literature on the subject of no mean order. Among the latest additions is a handbook[6] for health officers and practitioners of medicine, by Dr. FLETCHER GARDNER, Health Commissioner of Monroe County, Indiana, and Dr. J. PERSONS SIMONDS, Professor of Preventive Medicine and Bacteriology in the University of Texas. The first part is concerned with epidemiology, which is dealt with in a masterly manner, and quite in accordance with the most recent scientific research. The second part, upon general sanitation, could only have been written by public health officers actually connected with the sanitary service. The four essentials for an efficient public service are, in the opinion of the authors: adequate training of the officials; full time duty; a proper remuneration for work that is full of responsibility and sometimes dangerous, and a tenure of office dependent only on the proper discharge of duties. With respect to the last it is pointed out that it should not be possible to remove a sanitarian because he has made some politician put his filthy tenements or his dirty dairy into proper condition. Removals should be possible only upon charges properly brought before a Civil Service board or a court. It appears that in the State of Indiana there is a single health officer or health commissioner who may seek advice within or without the ranks of the profession or of his State Board, but within his delegated powers he is supreme and only liable for an unreasonable use of his office. Experience has shown that this system works well, for within his area he has co-ordinate authority with the State Board of Health, and an order from him is just as binding for the condemnation of an insanitary schoolhouse or the settlement of a moot point in sanitation. The chapter on milk contains an interesting account of the rules regulating the sanitation of dairies and the sale of milk in Indiana, and it is of interest to note that they were first adopted by the Indiana State Dairy Association and represent only the standard which practical dairymen are willing should be required. Many of the rules are very similar to some of the regulations made under the Dairies, Cowsheds, and Milkshops Order in this country, though it is noticeable that the milkers are not required to cleanse their hands before milking nor are the udders or flanks of the cows required to be kept clean. Although the administrative methods described differ in some material respects from those in vogue elsewhere, there is evidence of a completeness of procedure which might very well be copied. For example, when discussing the question of the isolation of infectious diseases it is recommended that dogs, cats, birds, or other pets should not on any account be allowed to remain in an infected house, for it is pointed out that their hair, fur, or feathers make them excellent carriers of infection from house to house, and in the case of cats and dogs, mingling with others of their kind, make possible that infection may overspread a city in which every human being has complied with the law. We can cordially recommend the work to all practical sanitarians who are anxious not only to make themselves acquainted with public health administration in other countries, but also to add to the efficiency of their own methods.

In the report of the Royal Sanitary Institute for 1913 it is stated that 655 candidates presented themselves for examination for the certificate of inspectors of nuisances, and that of this number 302 were certified competent as regards their sanitary knowledge to discharge the duties of inspectors of nuisances. This proportion of unsuccessful candidates appears to be about normal, for since the examination was established in 1877, of 16,000 candidates examined, only about 8,000 have satisfied the examiners. Those who fail to pass the examination cannot attribute their failure to a lack of suitable textbooks on the special subjects with which the examination is concerned. The most popular, perhaps, is *Practical Sanitation*,[7] by Dr. GEORGE REID, a work which was evolved in the first instance from a course of lectures delivered by Dr. Reid in 1890. Since the publication of the first edition in 1892, a new edition has been required almost annually. The arrangement of the seventeenth edition follows very much on the lines of the first, although there is evidence in it of a very thorough revision, for it presents in a very clear and intelligible form present-day views. There are many subjects which it is necessary for an inspector thoroughly to understand, but a knowledge of which from his previous education it may be difficult for him to acquire. Some of these are particularly well explained by Dr. Reid. Especially is this the case in the chapter on water, which contains a very lucid account of the sources of supply, and in that on ventilation and warming, the various methods of which are admirably discussed. Throughout the work there is evidence of a thorough practical knowledge of the subjects dealt with and of ability on the part of the author to impart that knowledge to others. It seems a pity, however, that there should be continued in this textbook the diagram, on p. 168, of what is essentially a large pit-privy, so arranged that ashes and dry refuse can be put, and are advised by the author to be put, on to the excreta. On the previous page there is shown a pail closet fairly well arranged, so that it seems a pity to give sanction to another form of closet which ought not to be perpetuated.

The fifth edition of the *Sanitary Inspector's Handbook*[8] has been revised with very great care. Mr. ALBERT TAYLOR, who is himself a sanitary inspector, apparently appreciates the value of detailed information, and a busy inspector will find his work very considerably lessened by referring to this book. For example, a more or less detailed specification is given of house drainage work. In the chapter on traps there are excellent descriptions and drawings of these devices for preventing the escape of drain or sewer air, and the author correctly states why some are good and others are bad. He points out, too, quite properly, that the water seal of a trap should be about one and a half to two inches deep, but he does not indicate what is the meaning of the term "seal" either in the letterpress or in the illustrations, nor does he explain the best way to measure the seal in a fixed trap. In view of the great difference of opinion among experts as to the value of the intercepting trap on drains, it is of interest to have the views on the subject of an inspector with an experience such as that of Mr. Taylor. He considers that these intercepting traps are an absolute necessity where the drains pass under a building or in connexion with houses having internal sanitary conveniences, but that they can be dispensed with in smaller houses, such as those built in terraces where the water closets, etc., are situated outside the building and in the open air. He expresses the opinion that in a well-regulated household an intercepting trap does not get blocked up. Mr. Taylor's handbook is a work which no sanitary inspector who desires to carry out his duties efficiently can afford to be without.

NOTES ON BOOKS.

MR. FITZWILLIAMS'S *Edinburgh University Medical Year Book*,[9] of which two earlier issues have appeared, is to be regarded as a handy reference book for old Edinburgh graduates in medicine scattered all over the world. It gives them a directory of graduates arranged alphabetically and geographically; it furnishes them with details of the post-graduate teaching which is now going on; it

[6] *Practical Sanitation: A Handbook for Health Officers and Practitioners of Medicine.* By F. Gardner, M.D., Captain Medical Corps, Indiana National Guard, etc., and J. P. Simonds, B.A., M.D., Professor of Preventive Medicine and Bacteriology, Medical Department, University of Texas. London: H. Kimpton; Glasgow: A. Stenhouse. 1914. (Med. 8vo, pp. 403: 37 figures. 18s. net.)

[7] *Practical Sanitation: A Handbook for Sanitary Inspectors and others Interested in Sanitation.* By G. Reid, M.D., D.P.H. Seventeenth edition, revised. London: C. Griffin and Co., Ltd. 1913. (Cr. 8vo, pp. 365. 6s. net.)

[8] *The Sanitary Inspector's Handbook.* By A. Taylor. Fifth edition. London: H. K. Lewis. 1914. (Cr. 8vo, pp. 640; 89 figures. 6s. net.)

[9] *Edinburgh University Medical Year Book, 1913.* By D. C. L. FitzWilliams, M.D., Ch.M., F.R.C.S.Edin., F.R.C.S.Eng. Edinburgh: The Darien Press. 1913. (Demy 8vo, pp. 250; 17 illustrations.)

tells them of the present arrangements for undergraduates and of the prizes and scholarships to be won by them; it keeps them informed of changes in the professoriate; it lets them know about the university clubs both in Edinburgh and in various parts of the world; and it has a rather short list of births, marriages, and deaths. The present issue has a sort of circular letter from the editor, giving various items of news, such as may interest the old Edinburgh man wherever he may be, and the Dean of the Medical Faculty supplies a report. There are some good photographs of the old and new university quadrangles, of the infirmary, of the library in the union, of the interior of the women students' union, and of the athletic field and pavilion. There are also photographs of Lord Lister in 1869, when he became Professor of Clinical Surgery, and in 1877, when he left for London; of the late Professor Annandale and the late Dr. George Gibson, of the new Professor (Lorrain Smith), of Professor Caird, and of the infirmary residents in 1855. Altogether the book in some, if not in all its parts can hardly fail to interest every Edinburgh graduate whose thoughts still tend to turn sometimes to the old smoke-wreathed city in which he spent some four or five happy years of student life with periodically recurring times of anxiety, when professional examinations loomed large and spectre-like on the horizon.

The fact that the humanizing of dogma proceeds *pari passu* with that of society has been expressed by reversing the statement that God made man in His own image. Of this fact Dr. WHITE'S *Forgiveness and Suffering*[10] is a striking example. "God is love," says Dr. White. "We must take God down off any pedestal on which love cannot stand. Such pedestals are of our own making." He goes on to say that the only love of which we have any knowledge involves the necessity of suffering in so far as it meets with disappointment or rebuff. Hence the sin of the creature, man, involves the suffering of his Creator; and this, in Dr. White's opinion, constitutes the true signification of the Atonement. The divine patience of Christ under the suffering inflicted upon Him by sinners is a revelation of the otherwise unmanifest and inscrutable suffering of Divinity itself from a similar or, rather, from the same cause. This is a beautiful thought, and, conceding certain premisses, which, however, many of us will probably be unable to concede, it is a perfectly justifiable conclusion. The author shows that he is able to hold his own with all comers in the theological field. But we cannot quite follow him when he goes on to say that forgiveness is necessarily dependent on the penitence of the offender and to describe as "free" a forgiveness limited in such a way. There is surely a more sublime form of forgiveness, to which, nevertheless, mere human nature can and does attain—that which understands the perversity which neither desires nor seeks pardon.

Caravanning is in the ascendant nowadays, patronized on the one hand by the long-haired hatless seeker after health, on the other by numberless sensible but hardy people who want a refreshing holiday. Mrs. CHESSER'S *The House on Wheels*[11] supplies a brief account of a seven weeks' tour through Sussex and Kent in a large caravan while she was working on behalf of the Women's Imperial Health Association. She has much good and elementary advice to offer the would-be caravanner, not dwelling overlong on the pleasures of the road, not making too little of the troubles that are sure to beset the beginner—indeed, there is something of the domestic pessimist in many of her comments. The book may be commended to anybody who thinks of taking up caravanning as a pastime.

FORCIBLE FEEDING.

THE Forcible Feeding (Medical Men) Protest Committee on July 7th sent to the Home Secretary a memorial signed by seventy-three medical practitioners, stating their reasons for objecting to the operation of forcible feeding as carried out in His Majesty's prisons, in the following terms:

1. It is an operation performed upon prisoners without obtaining their consent. In view of your statement that it is the invariable practice to obtain the consent of prisoners to an operation, we shall be glad if you will inform us why this practice has been departed from in the case of forcible feeding.

2. Forcible feeding is being employed as a punishment and as a deterrent. On April 2nd, 1913, you assured the House that it would not be your intention to use the power of forcible feeding in the case of ordinary offences, such as window-breaking, obstruction, and so forth, but only in the case of repeated offences and real danger to the public, thereby reserving it for selected prisoners. On March 18th, 1913, you stated that the knowledge "that the medical officers would forcibly feed prisoners had a considerable effect upon the majority of them"—illustrating the effect of this punishment, if not its object.[1]

3. Forcible feeding is being inflicted, not only in the case of repeated offences and real danger to the public, as you informed the House, but on prisoners who have never been convicted or even tried, and who are therefore innocent in the eyes of the law.

4. Forcible feeding as carried out in His Majesty's prisons is a system of torture based upon violence, and depending for its success upon the infliction of pain. It has caused grave bodily injury in many instances, and it always leads to serious impairment of health.

5. As registered medical practitioners we hold that it is against the best interests of the profession that medical officers should be called upon to carry out a method of treatment which is a punishment intended to have a "considerable effect" upon other prisoners.

The memorial concluded by requesting Mr. McKenna to receive a deputation at an early date. To this Mr. McKenna replied as follows:

The petition appears to be based on the allegation that forcible feeding is being employed as a punishment and as a deterrent. The Secretary of State desires me to say that there is no truth whatever in this allegation, and that nothing that he has ever said affords any justification for it.

Forcible feeding has been used only where it is the medical treatment necessary to preserve the lives of prisoners who have refused to take food. It has been used for no other purpose.

The prisoners who are now being forcibly fed include the two women who burned a hotel at Felixstowe; the woman who burned the pavilion at Kew Gardens; the woman who burned Lady White's house at Englefield Green, and who attacked the Rokeby Venus in the National Gallery; two women who damaged pictures in the Royal Academy; one who attempted to destroy an antiquity in the British Museum; and two who were found in possession of explosives, one of them on the occasion of the King's visit to Nottingham.

The Secretary of State assumes that the petitioners do not desire that these women should be allowed to starve themselves to death in prison, and that what they ask for is their release. This would mean that the women would be set at liberty, with the practical certainty that within a week or two they will burn more houses, destroy more works of art, and commit further outrages.

In these circumstances the Secretary of State feels that it would be inconsistent with his duty to the public to grant the immediate release of the offenders; but if the petitioners, out of their medical experience and skill, can suggest any practical method other than forcible feeding by which the life and health of prisoners who persistently starve themselves and who ought not to be released may be preserved, Mr. McKenna will be only too happy to consider it.

As this letter did not state whether the Home Secretary would receive a deputation, a further application was made, and Mr. McKenna consented to receive a deputation from the Protest Committee on July 15th.

The deputation, consisting of Dr. McIntosh (Chairman), Dr. Haden Guest, Sir Victor Horsley, Mr. C. Mansell Moullin, Mr. Frank Moxon, and Dr. H. Schütze, attended at Mr. McKenna's room in the House of Commons on July 15th. On the ground of the undesirability of prisoners' names being published, Mr. McKenna decided that the proceedings must be private, and that neither newspaper reporters nor the deputation's own shorthand writer could be admitted, though he had arranged for an official reporter to be present in order that he should keep control over any report that might be sent for publication. The deputation therefore declined to proceed, stating (according to an announcement issued afterwards) that its position in the matter of forcible feeding was one of grave public responsibility, and claiming the right to be heard in public, especially as the names of the prisoners had already been published. The members of the deputation express their readiness to place their views before the Home Secretary at some future time, should he reconsider his refusal to permit the proceedings to be reported.

Subsequently the committee issued excerpts from the speeches which its members had intended to deliver.

[10] *Forgiveness and Suffering: A Study of Christian Belief.* By D. White, M.D. Cambridge: The University Press. 1913. (Demy 8vo, pp. 143. 3s. net.)

[11] *The House on Wheels.* By E. Sloan Chesser, M.B. London: Chapman and Hall, Ltd. 1914. (Cr. 8vo, pp. 150; 21 illustrations. 2s. net.)

[1] On May 21st Mr. Wedgwood asked the Home Secretary under what law or regulation the consent of a prisoner had to be obtained before an operation could be performed by the prison or other doctors. Mr. McKenna replied that there was no express provision of the law, and no regulation requiring the consent of a prisoner; but it was the invariable practice to obtain prisoner's consent before a surgical operation was performed in prison.

THE ROYAL NAVAL HOSPITAL, CHATHAM.

A PARTY, including a number of deans and other teachers in medical schools, was conducted over the Royal Naval Hospital at Chatham on July 14th by Sir Arthur May, K.C.B., Medical Director-General, R.N., and Surgeon-General A. J. J. Johnston.

This great naval hospital was built between the years 1900 and 1905, and was opened on June 6th, 1905, by his late Majesty King Edward VII. It is situated on Chatham Hill, 223 ft. above sea-level; the geological formation of the land is light loamy soil, about 3 ft. in depth, resting on a permeable chalk bed. The total area enclosed is 39 acres.

The buildings, which were erected at a cost of nearly £800,000, are of red brick with stone dressings, and are fitted with all modern requirements. The hospital, which consists of a general hospital and an infectious division, is constructed on the pavilion system; the pavilions of the general hospital, which run north and south, are connected by a main corridor 900 ft. in length, running in a direction east to west. The general disposition of the buildings is shown in the block plan (Fig. 1).

The administrative block (Fig. 2) occupies the front central part of the site. It has a large entrance hall, connected by a corridor with the main corridor of the hospital. In this block are situated all the offices and also the admission and out-patient rooms, the *x*-ray room, the ophthalmic room, the library, and telephone and board rooms. Above the entrance hall are the laboratory, research rooms, and the pathological museum.

At the back of the main hospital building is situated the steam laundry and laundry store rooms, the engine and boiler house, dynamo rooms, a water tower and plant for the softening of water, the mortuary, sheds for the motor and steam ambulances, and carpenter's and blacksmith's shops.

On an oval site in front of the main building is the church, and beyond this the official residences of the officers, and the quarters for the sick berth staff.

The hospital and grounds are lighted by electricity supplied by generators driven by current supplied by the Gillingham Corporation. There is also stand-by plant for generating electricity in case of a breakdown in the Gillingham supply. The amount of current used is large, as there are over 3,200 incandescent lamps and 70 to 80 electric sterilizers, motors, radiators, etc., as well as an electric kitchen in the sick officers' quarters, where the whole of the cooking is done by electricity.

The food for the general hospital is prepared in a central kitchen and distributed to the various parts of the hospital in closed heated trolleys.

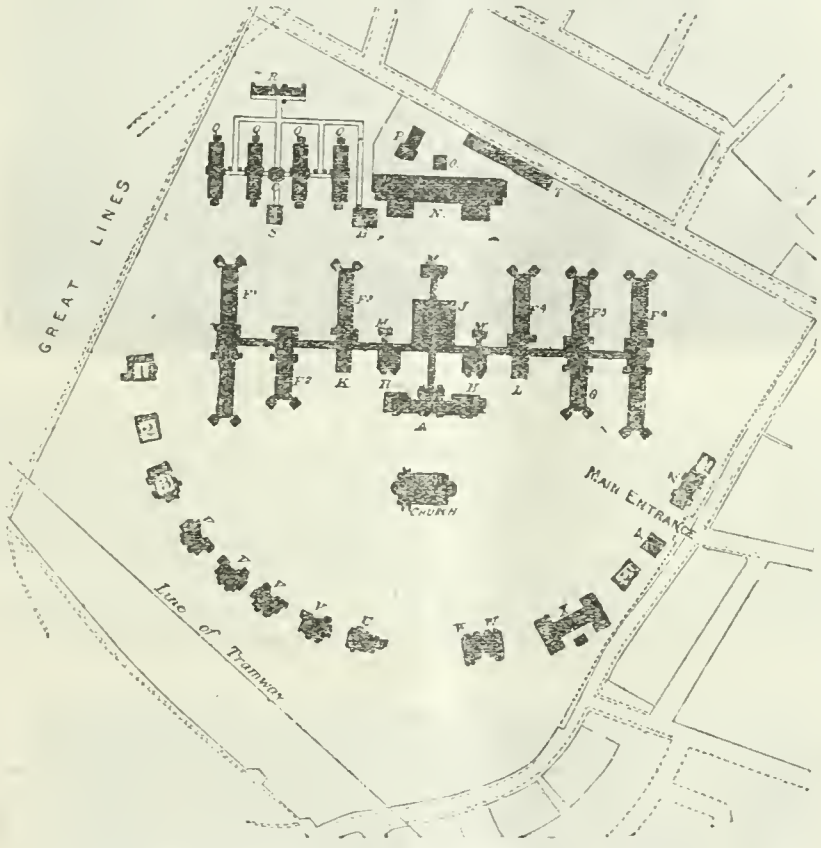

Fig. 1.—Block plan of hospital and annexes. A, Administrative block; F^1 and F^6, double pavilions; F^2, F^3, F^4, F^5, pavilions; G, officers' pavilion; H, H, day and dining rooms; J, kitchen and store; K, dispensary; L, operating room; M, latrines; N, laundries and engine-house; O, water tower; P, mortuary; Q, infectious wards; R, infectious officers' wards; S, infectious receiving and discharge rooms; T, coal pound; U, Principal Medical Officer's residence; V, officers' residences; W, W, steward's and dispenser's houses; X, sick berth attendants' quarters; Y, police lodge; Z, married attendants' quarters; B, infectious kitchen; C, stairs; 1, matron's cottage; 2, dispenser and assistant dispenser; 3, sisters; 4, butler; 5, H. W. M., clerk.

The wards are heated by steam radiators and fires, the remainder of the hospital by steam generated in the boiler house and distributed to the various parts of the hospital by pipes. A small portion of the heating system is worked on the pressure system.

There is telephonic communication between all parts of the hospital and the various residences, and in addition the hospital is in direct communication with the Dockyard, Naval and Marine Barracks, and the municipal telephone system.

PAVILIONS AND WARDS.

There are nine pavilions of which one is for sick officers. Each pavilion contains two floors, the upper wards being reached by electric lifts and stairs from the main corridor. Sanitary towers project from the ends of each pavilion; they contain on the one side lavatory basins and w.c.'s and on the other a sink room and a fire emergency staircase. Each ward contains twenty-eight beds and has its own bathroom, kitchen, and separation cabin with separate sanitary tower. The general arrangement of a ward and its annexes is shown in the sketch plan (Fig. 3).

The walls are covered with enamel paint and all corners and angles rounded; the floors of pitch pine with secret nailing are polished. At the end of each ward and communicating with it is a verandah for cases which are unable to go to the grounds. In the photograph reproduced in Fig. 4, showing the south end of one of the pavilions, the two sanitary towers are well seen, and between them the verandahs, that on the ground floor having steps leading into the grounds. The wards are heated by steam radiators and fires. Each pavilion has a basement for stores, both for hospital service and service afloat; a very large amount of stores, including surgical instruments, drugs, and surgical dressings, is always retained for emergencies, the provision of each ship of the various classes being stacked in a bay. In the basements are also a sterilizing room, the barber's shop, plant for the manufacture of aërated waters and a calorifer for the supply of hot water for baths and washing.

The whole area of the buildings is concreted and a damp course is provided throughout.

Each long ward (Figs. 3 and 5) contains twenty-eight beds, and the separation cabins two beds. The number of beds and equipment is as follows:

Peace.		*War.*	
General hospital ...	497	General hospital ...	770
Infectious division ...	102	Infectious division ...	156
Total	599	Total	926

Beds and equipment are kept in store to supply material for this war complement.

In peace time the hospital is divided into three sections: Medical, with 169 beds, Surgical with 328 beds, and Infectious with 102 beds.

The number treated during the year 1913 in the three sections were:

Medical	1,595
Surgical	2,746
Infectious	164
Total	4,505

In the medical division (four pavilions on the west side) special wards are appropriated for the treatment of mental disease and of tuberculosis.

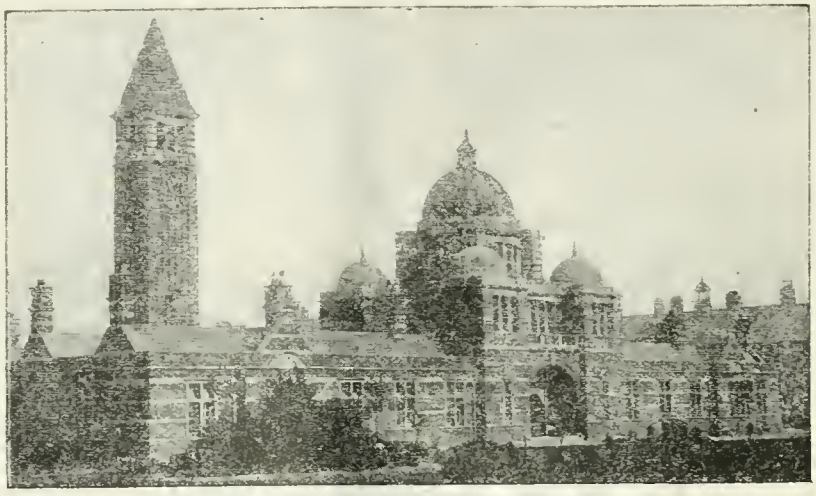

Fig. 2.—Administration block and water tower.
(Photograph by Vernon E. Hancock, Gillingham.)

The Tubercle Ward.

Special provision is made for the treatment of cases of tuberculosis. When a man suspected of this disease is received, he is placed in a general ward, where a careful examination of the physical signs is made. The expectoration is repeatedly examined for tubercle bacilli; if they are found the patient is transferred to the tubercle ward and given the option of being brought forward for survey and invalided on the first occasion, or of remaining under treatment for a period not exceeding three months, so that he may be discharged in as good a physical condition as possible.

The special ward for such cases is freely ventilated by the usual ward ventilation, and the windows are kept open day and night, except during gales of wind. The temperature is taken three times a day, and if in spite of the radiators it falls below 50° F. fires are lighted. The diet is also increased, and the patients more warmly clad.

The usual remedies are given as requisite, cod-liver oil and malt being found especially useful. Tuberculin is offered to all suitable cases, but it is not forced upon them. The results appear to be satisfactory. If the patient has a normal temperature, is in fairly good health, and is not suffering from constipation, the treatment begins with an injection of 0.00002 c.cm. PTO. On the day of injection he is kept in bed, the temperature being carefully recorded and any increase of signs or symptoms is watched for. If all goes well, he is given a larger dose in three or four days, and, if no excessive reaction occurs, the dose is gradually increased on each occasion. The full dose aimed at can never be obtained owing to the short stay in hospital, and, as a rule, the patient only reaches the dose of 0.05. In serious cases of mixed infection an autogenous vaccine is made in the laboratory and has been used with good results.

In the summer months patients confined to bed are, in favourable weather, removed into the open air and placed on an adjacent plot of ground. All patients allowed up are encouraged to be in the open air as much as possible, some of them being wheeled about in chairs. They are not allowed to attend church or entertainments. They are required always to carry a pocket flask; all spitting-pots are thoroughly cleaned out in a flushing-pan, and then placed in a solution of 1 in 20 carbolic for half an hour; they are then boiled for twenty to thirty minutes in the sterilizer and dried. All refuse and unused food supplied to the ward is burned. Health lectures specially directed to prevent the spread of the disease are delivered by the Deputy-Surgeon-General once a month in the ward.

The total number of cases of tuberculosis treated during the year 1913 was 74.

Surgical Division.

In the surgical division (five pavilions on the east side

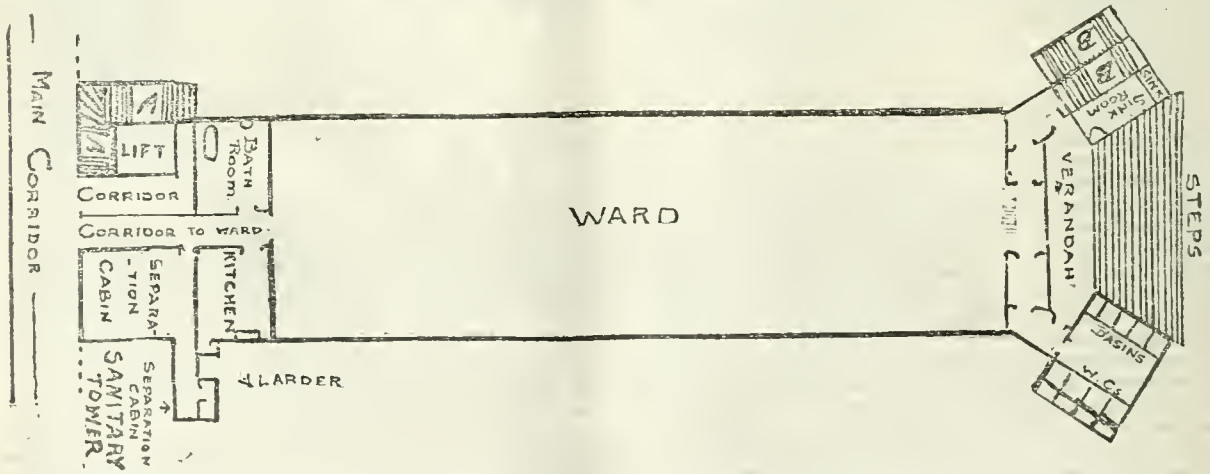

Fig 3.—Sketch plan of a ward and annexes. The dimensions are as follows:—*Ward:* 120 ft. by 28 ft. 6 in. by 14 ft.; cubic capacity, 47,880 c.ft. *Bathroom:* 10 ft. by 8 ft. 5 in. by 14 ft.; cubic capacity, 1,178½ c.ft. *Kitchen:* 14 ft. by 12 ft. by 14 ft.; cubic capacity, 2,352 c.ft. *Separation cabin:* 20 ft. by 12 ft. 6 in. by 14 ft.; cubic capacity, 3,500 c.ft. The cubic capacity in the wards is equal to 1,710 c.ft. per bed. A, Stair; B, fire stairs.

the wards always contain a large proportion of accident cases. There are special wards for eye and ear and venereal diseases, and a separate ward for cases under salvarsan treatment where 229 patients were so treated during the past six months.

There are two operating theatres constructed on modern principles with tiled walls and terrazzo floors. The lighting, natural and artificial, is excellent. The theatres are efficiently equipped, and have electrical sterilizers, a steam-distilling apparatus, and a separate steam sterilizing

room for surgical dressings. Each theatre is provided with an anaesthetic room, instrument room, and dressing room for the surgical staff.

The number of operations performed during the year 1913 was 859, exclusive of dental cases. The operations most frequently performed were for the radical cure of hernia, for haemorrhoids, appendicectomy, for varicocele and hydrocele, and the various operations required in the treatment of injuries, including the plating of fractures.

Both in the general surgical wards and those allotted to aseptic cases variety, it was stated, is always to be found, whilst the venereal wards afford a wide field for the study of that class of disease.

Dental Department.

The hospital also contains a dental department. The dental room, entered from the main corridor, is spacious, and is fitted with all the latest requirements for the use of the dental surgeon. There is an electric engine, pump-chair, fountain-spittoon, electric kettle and sterilizer, and dental cabinet.

It is the duty of the dental surgeon, who is a civilian, to attend to all marines attached to the Chatham Division, numbering about 4,000, both from barracks and from His Majesty's ships. Each marine undergoes an annual dental inspection, and all unfit cases attend for treatment. This rule applies also to the sick berth staff of the hospital. In addition all patients in the hospital are treated when necessary.

The individual patients in 1913 numbered 2,768, and in addition eight cases of fractured mandible and several cases of empyema of the antrum were treated. The number of fillings for the year was 1,230, of extractions under anaesthetics 2,255, without 319, and of scalings 331.

THE INFECTIOUS DIVISION.

The infectious division, which is really a detached hospital, is situated in the north-west corner of the grounds within an enclosed area of $2\frac{3}{4}$ acres. A double fence runs between it and the general hospital enclosing a neutral zone 8 yards in width.

The administrative block on the south boundary contains on the one side of the entrance offices for the medical officer and ward-master, and on the other a receiving room opening from the porch, and a bathroom opening from the receiving room and into a dressing room, and not communicating with the main corridor. The dressing room leads into the baggage room and both lead into the main corridor. Thus cases entering the porch of the hospital pass through the receiving room and are bathed and dressed in fresh clothes before going into the hospital proper. The doors of these rooms are wide enough to allow cots to be taken through them. Any part of the hospital can be reached by raised covered corridors with open sides.

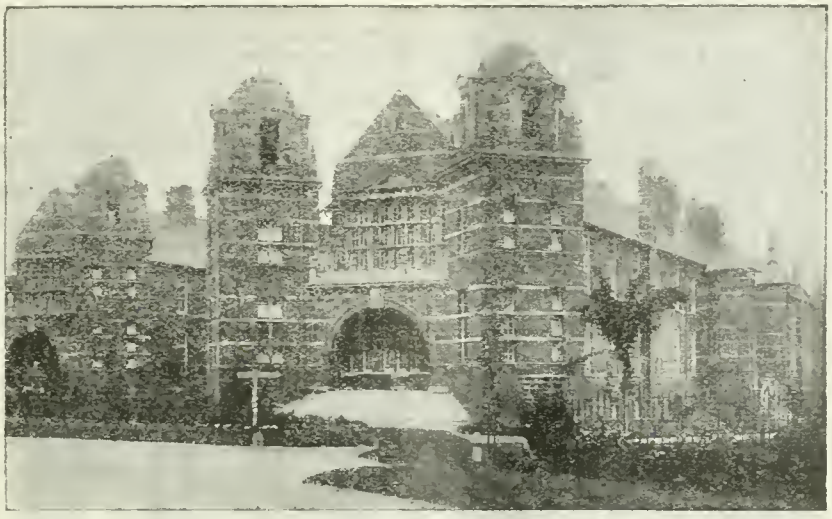

Fig. 4.—South end of one of the pavilions, showing sanitary towers and verandah between.
(*Photograph by Thornton Bros., New Brompton.*)

There are four pavilions, the two outer of one story and the two central of two stories. The upper wards are reached by a spiral staircase over the central corridor. To pass from one pavilion to the other, or between the upper wards, it is necessary to go into the open air. There are two wards on each floor, north and south, and between them are the entrance passage, bathroom, kitchen, and linen-press. These serve for both north and south wards, so that only one disease can be treated in each of the one-story pavilions and two in the double central ones. A sanitary tower is built off each end of the pavilion. Between the pavilions are cabins and lavatories for the sick-berth staff—four cabins on the ground floor and four on the upper.

The officers' block to the north of the pavilions consists of two small wards for one case each, and two larger wards for two cases each. All the wards are on the ground floor. In the centre is the bathroom, and between each single and double ward is a kitchen serving both wards. At the end of the block is a cabin for the sick berth staff.

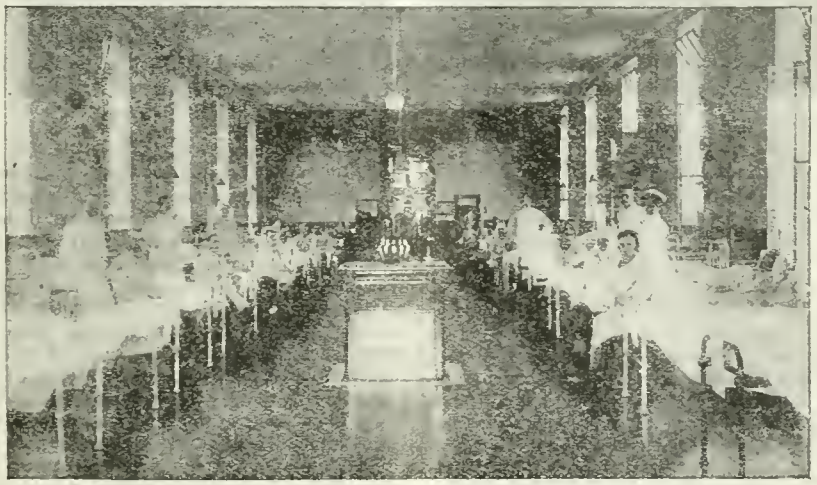

Fig. 5.—A surgical ward.
(*Photograph by Vernon E. Hancock, Gillingham.*)

In another block are the surgeons' quarters, ward-master's cabin, baggage room, and operating room. In the north-eastern corner is an incinerator on a detached site. The kitchen is in the south-eastern corner. There is no doorway from it into the infectious hospital, food being passed through by means of sliding glass windows opening from a covered way.

The staff of the infectious division are four weeks on duty, and have one week leave, or six hours for every twenty-four hours on duty. The staff have a common mess room over the surgeons' quarters. One ward-master sleeps in the sick berth staff quarters, and is employed on day duty only. The stewards and attendants mess and sleep in the division, and are not allowed out of the enclosure. A "zymotic runner" is attached to the medical duty cabin for messages and outside work.

The total number of infectious cases admitted during the year 1913 was 164, and were distributed as follows:

Chicken-pox	2
Measles	15
Rubella	25
Scarlet fever	42
Mumps	52
Enteric fever	25
Erysipelas	3

Laboratory.

The laboratory is situated above the central hall of the administrative block. It is lighted by full length windows on all sides, and large windows round the domed roof (seen in Fig. 2). Opening from it are three rooms, one used as a pathological museum, one as a room for any special research, and one for the storing of media, and an office. The equipment is practically complete for any chemical, pathological, or microscopical examination; it includes hot and cool incubators, hot air and steam sterilizers, an autoclave, large and small centrifuges, freezing and paraffin microtomes, and all the necessary apparatus for water and food analysis (Fig. 6). The work done consists of all the microscopical and chemical examinations for the wards, as well as all the water, milk, and food analyses required in the hospital, ships, and establishments under the Nore Command.

All vaccines required are made in the laboratory. A large part of the work is concerned with Wassermann reactions for the diagnosis and the control of the treatment of syphilities serving in the Nore Division. Between 70 and 100 such tests are done weekly. The systematic examination of suspected and contact cases with a view to isolating carriers of diphtheria, enteric, and cerebro-spinal fevers, also give a good deal of work to the laboratory staff.

Fig. 6.—Laboratory.

Men belonging to the sick berth staff may be trained in the laboratory, and if successful in the examination at the end of the course are entitled to a special badge and extra pay if employed in a service laboratory.

Training of Medical Officers.

Voluntary courses of instruction of about six weeks' duration are held at the hospital twice in the year, for the benefit of medical officers of the ships in port and naval establishments. The course includes the study and practice of bacteriology, clinical pathology, skiagraphy, and hospital administration. Provision is also made twice a year for a short course of lectures and practical work in the laboratory on clinical haematology and microscopy for the convenience of those medical officers who feel they would like to revise their knowledge of these subjects and keep it up to date.

Training of Sick Berth Staff.

The training of the nursing staff of the Royal Navy is one of the most important functions of the hospital. The men are recruited between the ages of 18 and 22, and, after passing a physical and educational test, go straight to the hospital, where they undergo a year's training as probationary Sick Berth Attendants. The instruction is given by the medical officers of the hospital, the Royal Naval Nursing Sisters, specially picked and qualified sick berth stewards, and the dispensers of the hospital. In addition to purely professional training, Swedish and service drills are taught by the instructors of the Naval Barracks, where each man has also to pass out in swimming.

General nursing in the wards is, of course, the most important part of the training. First aid and the management of the emergencies of medicine and surgery are very carefully taught, as at times in the absence of a medical officer in a service like the navy, a well-trained man may be of invaluable assistance. All men are taught practical dispensing, since at sea any sick berth rating may have to be the ship's dispenser.

A full course of sick-room cookery is given by a qualified lady cook, and there is a practical examination at its termination.

The full course comprises the following subjects:

(1) Reading, (2) arithmetic, (3) writing, (4) anatomy and physiology, (5) first aid, (6) bandaging and dressing, (7) operation cases—preparation and subsequent treatment, (8) surgical instruments, (9) general nursing, (10) dispensing, (11) management of wards and sick berths, (12) compiling accounts, (13) cooking for the sick, (14) disinfection, (15) stretcher drill, (16) rough signs of common diseases.

Before being rated as a qualified sick berth attendant, a probationer has to satisfy two medical officers that he is competent in the above subjects. If he fails to pass this examination he is either put back for three or six months, or discharged as unsuitable for a sick berth rating.

The training of probationers was first instituted at Chatham in April, 1912, and exactly 100 men have undergone instruction since that date. At the present time there are forty-four men going through the course.

After becoming a sick berth attendant, the man is still given various courses and lectures if he is stationed at a hospital, and has to pass further examinations for each step in promotion. Men may also specially qualify in the operation theatres, or in massage or as laboratory attendants. Besides the sick berth naval ratings proper a number of members of the St. John Ambulance Corps attend hospital for short courses of training in nursing and hospital work from the naval point of view. These men join the Royal Naval Auxiliary Sick Berth Reserve. Since May, 1912, the number of these men who have attended at Chatham has been 175.

The whole arrangement and supervision of the training work of the hospital is looked after by a medical officer especially appointed for that duty.

Medical Staff.

The following is the medical staff of the hospital:

Surgeon-General: In sole charge.

Deputy-Surgeon-General: In charge of Medical Division, Zymotic Hospital, Sick Officers Medical.

Senior Fleet Surgeon (Operating Surgeon): In charge of Senior Surgical Section, Sick Officers Surgical, and Operating Theatres.

Junior Fleet Surgeon (Operating Surgeon): In charge of Junior Surgical Section, Eye and Ear Department, Surgical Instruments for Hospital Service, and Resident Families.

Staff Surgeon 1: Anaesthetist and Radiographer; Massage Department.

Staff Surgeon 2: Acnte Medical Wards and Tubercle Ward.
Surgeon: General Medical Wards and Zymotics.
Surgeon: Minor Surgical Wards and Salvarsan and Venereal.
Surgeon: Minor Surgical Wards and Venereal.
Surgeon: In charge of Laboratory and Instructor to Probationers' Sick Berth Attendants.
Surgeon: Venereal Ward.

NURSING STAFF.

The following is the nursing establishment:

Nursing Sisters.	
Head Sister	1
Superintending Sister	1
Nursing Sisters (two on leave)	11
Sick Berth Staff.	
Chief Sick Berth Stewards	11
Sick Berth Stewards	37
Second Sick Berth Stewards	24
Sick Berth Attendants	69
	141
Second Sick Berth Stewards (for mobilization)	26
Total	167

CONGRESS OF THE ROYAL SANITARY INSTITUTE.

WHEN the Council of the Royal Sanitary Institute accepted the invitation of the Corporation of Blackpool to hold the twenty-ninth congress of the institute in that town it was confidently expected that a successful meeting would result, and that anticipation has been fully realized. The opening meeting on July 6th was addressed by the President of the Congress, the EARL OF DERBY, who referred to the great improvement that had taken place in recent years in the health of the British soldier. With this improvement, he said, the social status of the soldier had gone up, for every day that he was in the army he was learning more and more of self-respect, and that self-respect did not leave him when he went back into civil life. Formerly the army had been looked upon as a disseminator of disease, but it might now be regarded as a missioner of health.

In the Section of Sanitary Science and Preventive Medicine, the President, Professor SHERIDAN DELÉPINE, discussed in his address the question of the relation of the State and local authorities to the promotion of medical research. Although he deplored the small amount of assistance in this direction given by the State he considered that most creditable work had already been done by the small band of men and women who were engaged in it.

Dr. JAMES NIXON opened a discussion in this Section upon the effect of the National Insurance Act upon public health administration. Although more than one speaker during the discussion referred to the overlapping which was likely to take place in the future work of the Local Insurance Committees and in that of the local health authority, there appeared to be a general consensus of opinion that, on the whole, the Act would have a favourable influence as regards public health administration.

The Conference of Medical Officers of Health was well attended, and in his presidential address Dr. PHILIP BOOBBYER spoke with concern of the lack of uniformity in the allocation of administrative control of public health departments. In some districts he stated the medical officer had more or less complete control of the department, while in others his control was very incomplete.

A discussion upon the standard of habitable houses, introduced by Dr. A. B. DUNN, the medical officer of health of the Doncaster Rural District, elicited divergent opinions as to the need for a parlour in the house of the working man, as to the propriety of giving him a fixed bath, and as to whether it was desirable to erect cottages with two bedrooms or with three.

Dr. T. E. FRANCIS, M.O.H. Llanelly, advocated the carrying out of town planning in small districts by by-law, instead of having recourse to the more elaborate machinery of the Housing, Town Planning, etc., Act, 1909.

A long and animated discussion took place in connexion with the administrative control of diphtheria. Dr. A. B. MACMASTER of Crewe referred to many difficulties which had to be overcome in dealing with this disease. Dr. E. H. SNELL of Coventry brought forward figures with the object of showing that the incidence of diphtheria was much less in those towns or districts in which institutional isolation was not carried out than it was where this system was adopted. The feeling of the meeting appeared to be that it was prudent to continue the advocacy of hospital isolation of diphtheria.

Dr. C. KILLICK MILLARD of Leicester put before the conference his views as to the method of dealing with small-pox. He maintained that the partial system of vaccination now being practised resulted in the occurrence of cases of modified small-pox, so that the present generation of medical practitioners, with little or no opportunity ever of seeing a case of the disease, allowed mild cases to pass by unrecognized. He was not supported by any one present at the conference in his suggestion to carry out general vaccination only in epidemic periods.

Dr. F. G. BUSHNELL raised the question of the appointment of a Minister of Health, and persuaded the conference to ask the council of the institute to consider the matter.

The attendance at the congress was very good, numbering nearly 1,000 persons. The sectional meetings were all well attended. On one day the aggregate number attending all these meetings at one time was nearly 700. The winter gardens, in the Indian Court, where the Mayor gave a reception on one evening, were the subject of admiration on the part of many members, and the magnificent scale on which the entertainments in the town are carried out amazed all those who had no previous knowledge of Blackpool.

ROYAL COMMISSION ON VENEREAL DISEASES.

THE following is the official report issued to the press by the Secretary of the Commission:

At the forty-fourth meeting of the Royal Commission, evidence was given by Mr. J. E. R. McDonagh, one of the surgeons at the Lock Hospital, and by Dr. Parker, representing the State Medical Service Association.

Medical Education: Importance of Early Diagnosis.

Mr. McDonagh said that at the present time the education of medical students in regard to venereal disease was quite inadequate, and it was very important, in his opinion, that compulsory clinical education of students in venereal disease should be adopted. He considered that widespread clinical experience would render public laboratories for the carrying out of bacteriological and other methods of diagnosing syphilis superfluous. The important thing in dealing with syphilis was to treat cases at the earliest possible moment, and these early cases could be diagnosed with greater certainty by clinical than by pathological methods. A negative Wassermann reaction in early syphilis did not exclude the disease, and if treatment were deferred until the reaction became positive, the golden opportunity of cure was lost however energetic the treatment might be. Syphilitic sores, moreover, frequently existed in which spirochaetes could not be found. Mr. McDonagh was of opinion that syphilitic nervous lesions were steadily on the increase, and he considered that the spasmodic administration of salvarsan commonly practised in this country was likely to lead to a further increase. This spasmodic administration of the drug, moreover, gave a false sense of security, and therefore rendered patients a greater danger to the community. He advocated enlargement of the Lock Hospital. The number of patients attending the hospital was steadily increasing. Mr. McDonagh thought that medical research had been very insufficiently supported by the Government, and that much more might be done in this direction; he suggested that it might be an advantage if payment were only made for results.

Proposals as to a State Medical Service.

Dr. Parker maintained that by the establishment of a State Medical Service many difficulties now connected with the treatment of venereal diseases could be overcome. It was essential that treatment should be efficient and confidential, and in the last resort compulsory, and that

the medical officers of health should be in touch with all cases of venereal disease. Efficient treatment would be procurable for the whole State service, and would be open to all sufferers. The treatment would be confidential, there would be no special service of medical practitioners set aside for dealing exclusively with venereal diseases, by consulting whom patients would at once declare to the world at large the nature of their complaint. The size of the State Medical Service, its large and manifold functions, its large and specialized staffs, would render it impossible for the public to suspect the reasons which led the patient to ask advice. The treatment of venereal disease would be but a part of the preventive and curative treatment offered to all sufferers alike under a State Medical Service. No action whatever would be taken on the part of any public authority as long as a patient attended regularly and carried out the instructions of his doctor; but in the event of his failing to do so, he would be proceeded against as a public danger, in the same way as is done in the case of ordinary infectious diseases. Dr. Parker considered the difficult question of notification would be solved under a State Medical Service. Notification in the sense of a notice sent by a private practitioner to the M.O.H. would become unnecessary, for all patients attending a State doctor would be registered with the history and nature of their complaint, and to those persons the M.O.H., who would represent but another part of the same service, would have daily access. In the event of there being a body of private practitioners outside the service there should be notification of venereal disease either by name or number, and the M.O.H. would satisfy himself that the necessary treatment was being carried out by the patient. If this were not so, the name of the patient would be declared and he would be transferred to the charge of the State Medical Service. In order to obtain reliable statistics as to the fatal results of venereal diseases and their sequelae, it might be advisable to have a dual system of death certification—one for the purposes of the State Medical Department, giving the fullest details as to the primary and secondary causes of death, and the other avoiding all facts which might cast a slur on the memory of the dead, to be handed to the relatives of the deceased.

Evidence of Head Masters.

At the forty-fifth meeting the head masters of Eton and Rugby appeared before the Commission.

They considered that the ideal was that boys should be instructed in matters relating to sex by their parents, but their experience showed that that method was not likely at the present moment to be successful to the extent that was desirable. Instruction at school should be given with much caution, and it should be the special responsibility of the head master to give it or to see that it was given. A propaganda based solely on hygienic principles would not bring in the chivalrous appeal which was necessary, and was not likely to succeed. At the same time, hard exercise, hard work, wholesome society, and moderation in diet and drinking were of great use as safeguards against indulgence.

Administrative Methods in Italy.

At the same meeting Dr. Santoliquido, formerly Director-General of the Public Health Department in Italy, gave an account of the administrative methods adopted with regard to venereal diseases in that country.

The Royal Dental Hospital has received a grant of £1,000 from the executors of the late Sir William Dunn.

A memorial tablet to Dr. Francis Julius Le Moyne, "the pioneer cremationist of the United States," was formally presented by the Cremation Association of America to the Washington and Jefferson College, Washington, Pennsylvania, on June 23rd. Dr. Le Moyne was born in 1798 and died in 1879. The first crematorium in the United States was built in 1875 and used for the first time in the following year, when the body of Baron de Palm was burnt. Dr. Le Moyne was the object of much misrepresentation, being accused among other things of being the founder of a new religion in which the burning of the body after death was a mystic rite. He went on preaching the doctrine of cremation on sanitary grounds, however, and gained a considerable following.

THE BRITISH MEDICAL ASSOCIATION AND THE MEDICAL PROFESSION.

A CRITICAL REVIEW OF THEIR RELATIONS.

(Concluded from page 79.)

VIII.

THE SERVICES.

Commonly associated with a right conception of ethical principles and an instinct for their application is the quality known as *esprit de corps*, and the catholicity in this respect of the British Medical Association is well exemplified by the work that it has done on behalf of the medical departments of the Royal Navy, the Army, the Indian Medical Service, the West African Medical Service, and the Colonial Medical Service as a whole. On many occasions the Association has proved itself in no wise less anxious to promote the interests of medical men in all these services than those of the independent practitioners who form the majority of its members.

It began to work for them within twenty years of the date of its foundation, and after the annual meeting of 1850 it grew to regard protection of their special interests as one of the duties that it must habitually perform. It had already at that date made representations to Parliament as to the propriety of army surgeons not being overlooked when military honours were to be bestowed by the Crown, and the meeting in question gave orders for the presentation of a formal memorial on the subject.

The defects in the administration of the Army Medical Department at the time were very numerous, and it is not quite certain why the Association chose this particular point for its first attack. Possibly it was due to the fact that not long previously George James Guthrie, then one of the leading surgeons in London, had declined the honour of Companionship of the Bath.* The ground of his refusal was that it was proposed to place him on the civil division of this order, and he claimed that if he were entitled to the honour at all, it was the military C.B. that he should receive. As a young man he had served for ten or twelve years as an army surgeon, but, in common with numerous other medical officers who served with distinction in the Peninsular campaign, or later on in the early Indian wars, he had received no reward beyond mention in dispatches. Even mention in dispatches was at the time an innovation as far as army surgeons were concerned, for despite the fact that the death-rate among them from wounds and disease was—as now—proportionately quite as high as among other officers, and that a surgeon habitually accompanied storming parties, the tendency was to regard him as a kind of camp follower who ought to be content if he got his rations and his pay. Other officers got special pensions for wounds; a medical officer was regarded by some as a mere civilian, not entitled to such pensions. It was, in fact, only due to the friendship existing between Wellington and his principal medical officer, McGrigor, that mention in dispatches was first accorded to surgeons. After making representations to Wellington as to the unfair treatment of army surgeons, McGrigor convinced him that they should, at all events, be mentioned in dispatches, by adducing the fact that whereas ordinary officers remained in the trenches only for eight hours at a stretch, surgeons had to remain in them for twenty-four.

After the presentation of the memorial of 1850 the Association seems to have taken no further action for some years, but it renewed its attack on the War Office and Admiralty with great vigour in 1857, and from this date onwards the records relating to attention paid to the subject both by the Central Council, by the Branches, and

* As illustrative of the times, as also of some points mentioned in earlier articles, it may be mentioned that Guthrie entered the army as a surgeon in 1801, when barely aged 16. He retired from it when still under 30, and, after a period of study at St. Bartholomew's and elsewhere, he opened an infirmary, which afterwards became the Royal Westminster Ophthalmic Hospital. He also gave lectures on surgery, and eventually became president of the Royal College of Surgeons. He was not, as might be supposed, an unqualified man when he joined the army, but a member of the English College of Surgeons. At that time this college made special arrangements for those who intended to enter either the navy or army or the medical service of the Honourable East India Company. It allowed them to pay only half the ordinary fees for their examination and diploma, but took care to exact from them the remainder if eventually they left the army and began to practise within its sphere of influence.

by the JOURNAL are so numerous that it is not possible to do more than refer to a few items only.

The work of the Association in 1857 seems to have been largely instigated by the occurrences during the Crimean campaign and Indian mutiny, and the memorial that it presented to the Government was of a much more comprehensive kind than the first. The claim made was that the medical departments both of the army and navy should be thoroughly reorganized and the conditions attaching to the employment of medical men in these services entirely altered. None but regularly educated medical men should ever be engaged, and once they were commissioned they should enjoy absolute equality with other officers. In particular, they should have like authority over those serving under them, and be equally well off in respect of retiring pensions, reception of honorary distinctions, and other rewards for good service.

The Medical Service of the Army.

The presentation of this memorial was followed by the issue in 1858 of a Royal Warrant and new Army Medical Regulations, which materially improved the position of the medical men in question—at all events, on paper. The resulting peace did not, however, remain long undisturbed. The Royal Warrant and the Regulations of 1859 had done much more than place on a firm footing the system of competitive examination for admission introduced a few months earlier, and provide for young medical officers a special education at Netley. They had raised the Army Medical Department from a subordinate position to one of relative independence and power. This fact was bitterly resented by combatant officers of all ranks, and they showed a strong disposition to endeavour to neutralize the effects of the change as much as possible, and largely succeeded.

This being the case, the Association first lodged protests with the War Office, and then, finding that no result followed, started in 1864 a definite campaign with the object of securing that there should be compliance in all respects with the terms and spirit of the warrant and regulations mentioned. The crusade took the same form as those which have been described in earlier articles. A deputation was sent to the Secretary of State for War, petitions were sent to Parliament, and endeavours made to secure the co-operation of various persons of influence. The work done was by no means ineffective so far as immediate results were concerned. In other words, the Government caused an inquiry to be held, and subsequently a fresh warrant was issued, and later on, as the pressure of the Association continued, a good many other warrants. There was never, however, any great improvement of a permanent character, for though each warrant in its turn purported to make concessions, and did in fact do so, each was followed sooner or later by the issue of general orders, or War Office circulars or memoranda, which overrode or explained away some one or other of the provisions made at earlier dates.

Matters went on like this for many years, and meantime the Secretary of State for War in the early Seventies took an unhappy course, which has since been followed with equally unhappy results by more than one Minister of the Government. He took into his counsel a private medical friend who was not in a position to gauge the feeling of the profession, and issued a new warrant introducing a system which the British Medical Association, through its JOURNAL, described from the beginning as doomed to failure.

The army medical regulations of 1859 had left the old regimental system practically untouched, while the new warrant, besides substituting a short term medical service for life employment, established a system which was neither departmental nor regimental. All surgeons were classed either as administrative or executive officers, but the unified corps which some of them were supposed to form practically did not exist, and the regiments to which others were attached declined to recognize them any longer as their fellows. In short, nearly all such advantages as an army surgeon had previously enjoyed were abrogated by this warrant.

In effect an army surgeon was no longer either a civilian or a soldier; his relative rank brought no advantage; his promotion was blocked; his retiring terms were bad; he might be forced to keep a horse but was not certain to receive forage allowance; he had no mess room of his own and if attached to a regiment he had no definite right in the mess room of its officers; his time was liable to be entirely occupied by returns, and except as a possible witness he played no part on boards even when they dealt with strictly medical subjects. When he worked in hospitals it was under the command of a combatant officer, and he had no authority over his own orderlies. Furthermore, the system was as bad for the army as a whole as for the surgeons. Soldiers sent to hospital were grouped according to the regiments from which they came; one of the medical officers attached to that regiment was in charge of them, and as these were constantly being changed or might be told off for some other work, a sick or wounded soldier was liable to be treated by several different medical men in succession.

Naturally it was not long before the Association took steps to remedy matters. First it drew up a complete statement of all the evils which existed and presented this document to the Secretary of State at an interview. The proceedings were long, and the reporter's account of the beginning of the speech made in reply to the deputation is worth quoting:

> What the deputation was asking for the whole of the services were asking for—a better system of promotion, better arrangements for retiring, and increased allowances. . . . The medical officers of the army were very fortunate in having a civil power of magnitude and influence like this Association to represent their interest in deputations, and this was what other parts of the army had not. The advantage of being thus represented was very great.

A little later a few new concessions were made; but it was not until the end of the Seventies that any permanent improvement was effected, and meantime there had been a definite trial of strength between the Association and the War Office. The former continued to press for abolition of the existing hybrid system, and the latter publicly declined to take any further step towards meeting its views. In fact, the warfare was so open that just before the Government found itself obliged to give way, a semi-official attack on the Association was made in the *Army and Navy Gazette*, on the ground that it had seriously injured the army by depriving it of medical officers.

The net outcome was that at the end of 1879 a new set of army regulations unified the so-called Army Hospital Corps with the Army Medical Department, abolished the remains of the old regimental system, ousted combatant officers from the control of hospitals, provided for the performance of nursing duties by trained men directly under the command of the surgeons they assisted, and improved the position of the latter in many other ways. This was a real victory, but the Association was still not satisfied.

The new code did not offer any encouragement to medical officers to continue to be earnest students of their profession, and opened the door for the reintroduction of appointment by nomination instead of by competitive examination, and to both of these drawbacks the Association strongly objected.

Consequently at the beginning of the Eighties the war was recommenced; the more direct aim of the Association now was to get established a completely unified service—an Army Medical Corps—and to secure for its officers substantive, not merely relative rank, the advantages of which had become more shadowy than ever. Opponents of the latter change declared that it was ridiculous for medical men to want military titles, while the Association held that the military mind was so constituted as to make them essential. A medical man working in the army should not have to depend solely on the force of his personality for the position he occupied among other officers and the influence he exercised over the men, but would always have to do so until he possessed the only thing that either officers or men really understood, namely, substantive rank.

The fight over this particular question reached its height about 1887, when the Director-General for the time being attended an annual meeting of the Association, and after stating that the public services were greatly indebted to it for what it had been doing, endeavoured to dissuade it from insisting on this particular claim. Though the Director-General was supported by one or two other senior officers who were present the Association was not fully convinced that he was right, and therefore decided

to address personal inquiries as to their views on the point to all medical officers in the army at home and abroad. It received about 800 answers, and having analysed them decided to continue to press for this particular reform.

The work then done resulted in the appointment of a departmental committee, which, at the beginning of the Nineties, among other recommendations, suggested that the question of substantive rank should be settled by the accordance of a composite title, half military, half professional, to all ranks. Due effect was given to this suggestion, but the Army Medical Service was still merely a "department," and there was reason to believe that the rank accorded was not regarded either by the War Office itself or the army as a whole as placing medical officers on equal terms with other officers. The "camp follower" conception still prevailed.

Consequently the Association returned to the charge, and the following five or six years proved a very strenuous period, despite the fact that the Government well recognized the strength of the forces arrayed against it. The Association was fighting for several minor improvements, among them being the limitation of a tour of foreign service to five years and greater facilities in the matter of exchanges. But its principal object was to get the Army Medical Service transformed from a unified department into a corps such as that formed by the Royal Engineers, and eventually it got its way, the intention of the Government to create the Royal Army Medical Corps and accord its officers ordinary military titles being announced by Lord Lansdowne in 1898.

Some four years later—after the South African war—some alterations in the internal organization of the corps were seen to be necessary, and the work then done eventually led to the service being provided with its existing attractive qualities. We use the term "eventually" because some of the modifications originally proposed were of a kind materially different to those finally adopted, and we are betraying what is now simply a *secret de Polichinelle* if we say that some of the features to which the corps owes its present popularity were introduced at the instance of the Association.

The Medical Service R.N.

Since the reconstitution of the British Medical Association on its present basis attention to the interests of medical men in the navy, the army, and the Indian Medical Service has been the duty of a special committee, the Naval and Military Committee. Another standing committee, formerly named the Colonial (now the Dominions) Committee, has among its duties that of performing a corresponding task in respect of those who belong to the various medical services of Crown colonies, including the West African Medical Staff.

Both the committees have done a very great deal of useful work, but have been enabled to perform it with great quietness, thanks to the fact that the Government departments concerned in their operations have for many years past realized the strength that these committees have behind them. As a consequence it has become almost a routine practice for these committees to be informed when changes are in view, and it is only when any representations that they think it necessary to make fail in their object that disputes between the Association and the Government reach the surface. The circumstances that led to this useful state of affairs have, in the case of the War Office, already been described, and those relating to the other services are of a corresponding order.

The Association began to fight for medical officers in the navy at the same date as it began to fight for those belonging to the army, and within a few years it began to fight also for medical men in the employment of the Indian Government. The campaigns undertaken on their behalf were equally determined, but only a very cursory account can be given of them, since the fighting required was as a rule of a somewhat different character and does not lend itself to brief description. In its contest with the War Office the Association had to deal not only with the natural objection of nearly all Governments towards making any alteration of system which would mean spending more money, and the dull conservatism which prevented recognition of the need of any progress at all, but also with a very strong class feeling, which from beginning to end of the contest was perhaps the chief stumbling-block.

The latter influence also played a part at one time in the affairs of the navy, but it began to fade out when, in the early Sixties, admission by nomination was abolished, and seems to have been entirely extinct within fifteen years or so. Meantime a great fight had been going on over questions of pay, study leave, relative rank, allowances, the right of naval medical officers to occupy their time as they pleased on shore, and terms of retirement. Terms of peace were arranged in 1875, when, after a series of memorials and deputations, the Admiralty issued a new warrant dealing with the medical department of the navy. This made a variety of concessions, but the most important of them was, perhaps, that which accorded ward-room rank and ward-room privileges to all medical officers, whatever their seniority. The extent of the victory will be best gauged, perhaps, by the following extract from a letter published in the JOURNAL in the year mentioned:

> One can now conscientiously advise any medical man to enter the service. A young man now enters the service with befitting rank, exceptionally good pay, and every requisite to make him feel that he is in the position of a gentleman. One word in conclusion as to the part played by the Association and your JOURNAL throughout the struggle. We all feel that had it not been for the powerful assistance we derived from our professional brethren who so kindly espoused our cause and made their voice heard, we might long have remained unemancipated, and it is to be hoped that naval medical officers will never forget what is due to the British Medical Association for what it has done during the eventful years 1874–1875.

There were several other letters of the same type, but this will suffice to show that at that time naval medical officers considered they had reason to be satisfied with their position. At later dates various causes of discontent arose, and led to the Association having to bring its influence to bear on several occasions. The most recent of these occurred not many years ago when the Admiralty showed a strong disposition to burke the findings of a commission appointed to consider the affairs of its naval department. Effect, however, was given to most of these some two years ago by the issue of regulations which secured for naval medical officers increased pay and many of the advantages already enjoyed by their fellows in the army. The changes have not succeeded so far in restoring to the medical service of the Royal Navy the popularity which it at one time enjoyed, but it is fair to say that the Admiralty seems disposed to show goodwill in the matter, and the Association has recently been asked for suggestions. These it has now made, and they will certainly—if put into operation—alter the present somewhat unhappy condition of affairs.

The Indian Medical Service.

In the difficulties of the Indian Medical Service class influences have never played any part. Officers belonging to it have always enjoyed an excellent position, and the Government of India has not failed to express its high opinion of the work done by the service. Nevertheless, there have been plenty of occasions when the support of the Association has been eminently necessary.

At one time, for instance, it seemed not improbable that a serious attempt would be made to abolish the service altogether, or make it a kind of appendage to the medical department of the British army; at another, in the early Eighties, a Viceroy proposed by a stroke of the pen to abolish about two-thirds of all the prizes of the department; and again, in the Nineties, a good deal of activity was required to secure for officers of this service just compensation for the loss entailed on them by the fall in exchange values and the gradually increasing expense of Indian life. There has, in short, been plenty for the Association to do in connexion with this service, and its task, unfortunately, is by no means ended.

It may be added that during the last few years the Government has exhibited an unhappy tendency to interfere in various pettifogging fashions with the private affairs, and many of the privileges previously enjoyed by the service, and the prospects offered by it are much less satisfactory than they used to be. It is impossible to discuss this question fully here. It may be stated, however, that there is a movement in favour of displacing

officers of the Indian Medical Service from many of the positions and appointments which have helped to make it attractive. In consequence of this state of things the Association has presented a memorandum and tendered evidence to the Royal Commission on the Public Services in India now sitting.

Colonial Services.

Though the amount of work that the Association has had to do on behalf of medical men in the employ of the colonial Governments is relatively small, it is nevertheless of considerable importance. The Colonial Committee mentioned as having been instituted as one of the standing committees of the British Medical Association after its reconstitution in 1902 was not the first of its race, for at earlier periods the Association had from time to time appointed committees to deal with questions arising in the colonies. Those relating to colonial Branches and their formation and rules were the care of the Council itself, but occasionally when action had to be taken on behalf of individual medical men it was thought desirable to hand over the work to special committees. In the Nineties, for instance, the Association was occupied for a very long time in endeavouring to secure justice for a medical man who had been badly treated by the Government of one of the West Indian islands, and in respect of its labours received the thanks of the West Indian Alliance, as also of a body in this country entitled the Civil Rights Defence Committee.

Again, in the same decade there reached the Association information pointing to the conclusion that the whole system of administration of the medical affairs of the colonies and protectorates scattered along the West Coast of Africa required thorough overhauling, and this led to its appointing a committee to take the matter in hand. The work done resulted in the drawing up of a scheme for the establishment of a unified medical department for West Africa, and on the invitation of the Secretary of State for the Colonies this was submitted to him and became the foundation of the organization now known as the West African Medical Staff. For a few years this service prospered, but some five or six years ago grave causes of discontent arose, and eventually led to the Association making a successful effort to secure the appointment of a commission of inquiry. The net outcome was an extensive reorganization of the service, coupled with the appointment of an advisory board such as was already in existence in connexion with the army and navy. At the present moment it may be said that the affairs of this service are causing some anxiety, but it is to be hoped that the statesman-like views on medical subjects which have usually been taken by the Colonial Office since the time when the late Mr. Joseph Chamberlain was at its head will again prevail. Should they not, the Association will undoubtedly again take the matter up vigorously.

Conclusions.

To sum up, the existence of the Association and its readiness to expend labour, time and money in the interests of all medical men alike, have undoubtedly been of much value to all those who belong to the various services. Apart from the fact that individuals and isolated bodies of medical men are always handicapped when attempting to defend their own interests unsupported by their fellows, it is commonly difficult, if not dangerous, for those serving any of the great Government departments to take any overt action at all. This consideration underlay a communication made last year by a distinguished member of one of the services which contained the following passage:

> The younger members of the profession do not, perhaps, entirely realize the very great importance of supporting an institution which may prove in emergencies their only practical and reliable safeguard against injuries, if not absolute ruin. Without it many would be helpless and powerless, as want of money, want of time, or the peculiar constitution of their work, may forbid the invocation of the law. It was, for instance, owing chiefly to the action of the Association that the Army Medical Service attained its present honourable and useful position. There are numerous similar instances. No one can see the blows that fate may have in store, and the wise man is he who endeavours to protect himself. There are few forms of insurance more reliable than the British Medical Association.

IX.
SOME NOTES IN CONCLUSION.

To the subjects considered in the previous articles more space has been devoted than was intended, and references to other features of the Association's work will necessarily be brief. Many, indeed, it will be impossible even to mention.

Ship Surgeons.

Despite the wandering life led by ship surgeons the records of the Association show that their interests have been by no means overlooked. The work done on their behalf appears to have been begun early in the Eighties, when, after a discussion on the subject in the JOURNAL, a deputation from the Association waited on the President of the Board of Trade to press upon him the unfavourable conditions in which ship surgeons did their work. They were less well paid than stewards and other subordinates of that kind; were given the worst cabins themselves, and any accommodation nominally placed at their disposition for the performance of their duties was liable to be taken away from them at a moment's notice, if not habitually used for some other purpose; they were not given any real assistance in looking after the sick, had no definite authority in sanitary matters, and were totally dependent on the goodwill first of the captain under whom they served, next of the owners who employed them.

The remarks of this deputation had application more particularly to medical officers in charge of emigrant ships, and the President of the Board of Trade promised that in a forthcoming Shipping Act should be introduced clauses calculated to place surgeons in a more favourable position to perform their duties on board ship, and to force shipping companies to exercise greater care in their selection of suitable persons. In the same decade the Association was also moving for the appointment at the Board of Trade of a regular medical department, and so far as ship surgeons in charge of emigrants were concerned some improvement was at length effected.

During the last ten years the subject has never for long been left on one side, and as one result of the attention paid to it several shipping companies mainly engaged in passenger trade have during the last few years put their medical officers in a better position than formerly in regard to the receipt of fees from passengers, and other points. Furthermore, the view held by the Association, that medical men can rarely with propriety undertake charge of a vessel during a voyage by way of a holiday and in return for nominal pay only, seems to be making headway. A more important circumstance still is that a special subcommittee that the Association appointed a year or two ago to consider matters has successfully completed arrangements which will ensure that constant information as to what is going on in the shipping world shall be duly received, and ship surgeons feel that they have at their back a strong organization.

Prison Surgeons.

In 1878 the Association co-operated with the Irish Medical Association in work on behalf of medical officers in charge of prisons in Ireland, and in the early Nineties began to be active in the cause of the prison medical service as a whole. The work done included the submission to the Government of a memorandum which pointed out that for various reasons the attractions of the service, which had never been excessive, had gradually diminished; the rate of promotion among prison surgeons was unduly slow; pension terms were unfavourable; and distinctions were drawn in respect of salaries between governors and medical officers which could not be justified by anything in the character of their respective work or qualifications. The suggestions made were to the effect that convict and local prison services should be amalgamated, a medical element introduced into the Prison Commission, prison surgeons be regarded as eligible for appointments as inspectors and governors, and that when a prison medical officer was not a whole-time employee the rate of his pay should not be determined by the average resident population of the prison of which he was in charge. Some effect would appear to have been given to these suggestions, but much room for improvement remains, and consequently it is possible that the Association may have to take the matter up again.

LUNACY.

The first definite action by the Association in respect of lunacy would appear to have been taken as far back as 1864, when the Government was urged to alter the wording of a bill regarding prisoners presumed to be of unsound mind in such fashion as to make it possible for holders of the Apothecaries licence as well as other qualified medical men to sign certificates in respect of them, and to provide also for the payment of prison surgeons called upon to perform this duty. Its more important work in this connexion does not seem to have been commenced until the Seventies, and after this, and especially in the Eighties, it was frequently very busy indeed.

Its main aims at various dates would seem to have been to get improvements effected in the position of alienism as a study and field of work, and secure facilities for the treatment of persons not actually insane, but deemed to be in danger of becoming so unless taken in hand and effectively treated forthwith; to secure a certain measure of protection for medical men who in the course of their official or other work had to examine the mental condition of individuals and report thereon; to protect owners of private asylums who in the Eighties were threatened with practical confiscation of their property; and to safeguard the position of medical men who without keeping asylums wished to receive from time to time persons of defective intellect as resident patients. Its work regarding treatment of cases of threatened insanity dates back to 1896.

The records also show that the Association, which at a relatively early date pressed for an adequate system of superannuation for all resident medical officers of county and other public asylums, began to point out a few years ago the great advantages that would accrue if co-ordination were established between such institutions, service in one being allowed to count towards promotion in another, and greater facilities for marriage being offered to senior assistant medical officers. A little time ago a body having objects of this kind in view came into existence, and the Association has agreed to co-operate with it.

An allied subject in which the records of the Association show it to have been very active is that of inebriety and narcomania. It has always been a strong advocate of temperance as distinct from total abstention, and in 1875 it began to agitate for the passage of a legislative measure which should make it possible to submit chronic inebriates to measures of a medical kind instead of dealing with them simply through the operation of the criminal law. One outcome was the holding of a departmental inquiry, and this was eventually followed by the passage of the first Inebriates Act and subsequent amending bills.

VACCINATION.

The work that the Association, in the early years of its existence, did on the subject of vaccination has already been mentioned in previous articles; it may be added that the records show that in no decade has its attention ever been diverted from the subject. The passage of the first Vaccination Act, which provided for gratuitous vaccination out of public funds, was largely due to the report published by the Association a year or two previously, and the Association obtained establishment of the principle of compulsion by the Act of 1853. In 1871 it succeeded in inducing the House of Lords to throw out a clause in a proposed Act which abolished multiple penalties for neglect or refusal of vaccination, and in 1874 it was active in connexion with a bill by which the duties of guardians in relation to enforcing the Vaccination Act were regulated. In 1880 it was successful in inducing the President of the Local Government Board to refrain from proceeding with a measure which would have greatly lessened the legal risks involved by the omission of parents to get their children vaccinated.

It was equally active in connexion with later measures, and besides habitually fighting to maintain the claims of public vaccinators to proper payment and security of tenure of office, issued in 1902, for the information of the general public, a pamphlet containing reprints of a series of articles setting forth the real truth about vaccination. This proved so useful that a revised edition was published in 1905. The records also show that on several occasions the Association made monetary contributions to the funds of the Jennerian Society.

QUACKERY.

The subject of quackery early attracted the attention of the Association, and led to the appointment of more than one special committee to study the question. At one time and another somewhat wild statements seem to have been made, but considered opinion on the subject in early days may be summed up in two sentences: (1) Though by no process of law could credulity and love of self-drugging be abolished, and though the Government was perhaps entitled to take advantage of the sale of secret remedies for the purposes of revenue, it could and should strew the path of the quack with many more stumbling-blocks than he had at present to encounter. (2) Medical men themselves could do a great deal to stem the tide of quackery by demonstrating its irrationality by popular lectures and the like, and by pointing out in the course of their daily work among the public the dangers of indulgence in secret remedies.

Early views, in short, were much to the same effect as recent views. As for what has happened meanwhile, it cannot, unfortunately, be said that quackery has been stamped out, but the position is on the whole less unfavourable than it was formerly. In the first place, the reform described in earlier articles and the strong attitude taken up by the Association on ethical questions went a long way towards abolishing one of the graver evils with which the earlier members of the Association had to contend—namely, the active participation of many members of the profession in quackery of one kind and another. In the second place, a very shrewd blow was struck when the BRITISH MEDICAL JOURNAL began to analyse and record in its columns the composition and true cost of numbers of secret remedies. The articles enabled medical men when discussing self-drugging with their patients to speak *ex cathedra;* and the subsequent republication by the Association of most of the articles in two books, placed on sale at a popular price, served to drive the lessons home. Also useful proved the agitation against massage establishments and public exhibitions of hypnotism, started by the Association in the Nineties, and its exposure at various dates of some of the more blatant quacks.

ANNUAL MEETINGS.

Study of the records of the Association relating to annual meetings shows that, though additions have been made, those now held faithfully reproduce the features of the earliest gatherings. Some of the work originally done at the general meetings is now transacted separately by the Representatives, and the report of Council is taken as read; but the presidential address is still delivered as part of the general meeting, and its contents are commonly closely akin to the retrospective addresses that the early presidents had to deliver on their installation. The formal addresses in medicine and surgery are of the same kind as those which began to be added to the agenda at a relatively early date, and the papers read by many openers of discussions are on all-fours with those summaries of existing knowledge on various subjects which the pioneers of the Association desired to be prepared from time to time.

The chief new feature, in fact, is that the reading of scientific papers by ordinary members is no longer mixed up with other business, but takes place at sectional meetings. Even these are now of old standing, though it was only little by little that the work done at them reached its present importance. Apart from the individual value of the papers, these sectional meetings help to fulfil those scientific aims which, though they existed at the beginning could not be attained except through the imperfect medium of the annual volume of *Transactions*. In other words, they enable members to club their knowledge, collate their experiences, and exchange views, and thus help the Association steadily to increase the breadth and firmness of the foundations on which medical practice ought to rest.

Over and above their merits in this respect, it is clear that the gradual increase in their popularity has facilitated progress in the science and art of medicine in a way not apparently foreseen by those who started them. In the audience at a meeting of an ordinary medical society specialists of one kind and another tend to predominate, but the reverse is the case at the annual meetings. At these the general practitioner is present in his hundreds, and such gatherings therefore afford a quite unrivalled

opportunity to those who have a new gospel to preach or valuable results to record.

This is a point of importance, because, when all is said and done it is the general practitioner, not the consultant, who in the long run decides what line of treatment shall be followed in any given class of case. For this reason it is of great value to all men possessed of original minds to be able to bring to bear upon their contemporaries the magic of the spoken word. It may turn into believers in the treatment described and into active supporters of the man who advocates it hundreds who might not read a paper on the subject, or, who having read it, would still maintain an attitude of passive resistance.

Nor is the benefit of the scientific meetings of the Association by any means confined to those who have new gospels to preach. There must be many an ordinary consultant of conservative mind whose success is in some measure due to the accident of his having attended a meeting of the Association, and either by his mere personality or the making of a few sensible remarks convinced some general practitioner present that he was likely to be helpful in a given class of case. Furthermore it is to be remembered that the general body of consultants includes a very large number of specialists, and study of the history of the Association leaves no doubt that progress in many of the special departments of medicine has been materially assisted by its annual meetings and in other ways. Frank acknowledgement of this fact has been made from time to time, and the records show that a statement of this order —which was especially striking because carefully supported by the deduction of a long series of facts—was quite recently made on behalf of ophthalmologists in particular. The speaker ended his remarks in the following words:

> If I interpret these records correctly, it is obvious that the Association has, through the medium of its annual meetings and its weekly journal, ever at hand, done great service to ophthalmology, and it is right that honour should be given where honour is due.
>
> I have always felt that the Association has never yet had the credit due to it for the stimulus it has afforded to the study of clinical and scientific medicine, and I am glad to have this opportunity of acknowledging my personal indebtedness.
>
> Almost every privilege which our branch of the profession possesses to-day is due to the British Medical Association, and every member should be a loyal and active supporter of it.

Finally, it should be added that much of what has been said in the foregoing paragraphs—and especially the remarks concerning the value of sectional meetings as mediums for the collation of experiences and exchange of views—applies equally well to the scientific meetings that the Branches and Divisions of the Association hold from time to time, and it is satisfactory to be able to note that the records show that these are increasing in numbers of late years.

Collective Investigation.

The records show that from time to time the Association has engaged in collective investigations. The report on vaccination mentioned in the article on State Medicine was based on work of this order, undertaken in consequence of the success of a previous collective investigation relating to the epidemiology, pathology, symptomatology, and therapeutics of influenza. The Therapeutic Committee of the Association, which now works as a subcommittee of the Science Committee, also at a later date used this method in its investigation of the effect of new drugs. Perhaps, however, the most important collective investigations carried on by the Association were those conducted in the Eighties under a committee bearing that title. Among the subjects that it took up were pneumonia, puerperal pyrexia, chorea, acute rheumatism, phthisis, albuminuria in healthy persons, the habits of inebriates and of the aged, and the geographical distribution of rickets and urinary calculus. At somewhat later dates investigations of a corresponding kind were made in regard to mental defects among school children, dental caries, on the eyesight of railway employees, on anaesthetics, and on some other subjects.

These inquiries exercised an influence on the afterwork of the Association, and some of the reports in which they resulted were of a very valuable character. The inquiry on pneumonia, for instance, seems to have suggested for the first time that a contagious form must exist; while that on chorea established the frequency with which "rheumatism" figured in the history of choreic patients. The report on phthisis again materially modified medical opinion as to its etiology. Previous to its appearance only a small minority of medical men in England appear to have really believed that phthisis was a communicable disorder. It exercised equal effect on Continental opinion and was frequently quoted in foreign medical literature of the time. The report on the most recent collective investigation—namely, on the operative treatment of fractures—likewise attracted great attention from the profession both at home and abroad.

Branches Beyond the Seas.

In most of the Dominions and Colonies in which Branches of the British Medical Association exist the medical profession now enjoys statutory recognition, but this was not commonly the case when they were first established, and not infrequent recognition of the assistance that the British Medical Association has rendered to members in distant lands, in this and other connexions, is to be found in its records. These show that the Association comparatively early after the passage of the first Medical Act of 1858 began to endeavour to obtain corresponding advantages for members working in British territory but far away from the United Kingdom, and that later on, when it had obtained influence with the Colonial Office, it was frequently able to do other useful work on behalf of medical men in various Crown and other Colonies. In 1893, for instance, it secured prompt reversal of an order requiring medical men in Jamaica to notify cases of infectious disease under a penalty, but without a fee for performance of this duty.

The records of the Dominions Committee of the Association, which is in charge of all matters arising beyond the seas, indicate that there are still British territories in which statutory recognition for qualified medical men has to be obtained, and that during the last few years it has again been busy in such connexions. They indicate also that even when statutory recognition has been obtained the existence of a Branch greatly strengthens the position of medical men working in the Crown Colonies.

The Branches in the Dominions enjoy a large measure of autonomy, but the records show that delegates from these Branches never fail to receive a very warm welcome at annual general meetings of the Association, and that maintenance of the connexion between them and the parent body is considered by both parties to be of not less importance than in earlier days.

Pure Science.

About the beginning of the sixth decade of its existence there seems to have arisen a cry to the effect that the Association ought to abandon a great deal of the work on which it was engaged and confine itself to its original and only object, this being it was alleged, the promotion of science. The cry rested upon a misapprehension. The objects for which the Association was established were briefly summarized in its Memorandum of Association (1874), which is still operative, as "the promotion of medical and the allied sciences, and the maintenance of the honour and interests of the medical profession." The two limbs of this definition are not to be read, and were never intended to be read, as antithetical. It is clear that the two were regarded as being really one. While some subjects were more cherished by certain of the founders and early adherents of the Association than by others, all alike regarded the material and scientific interests of the medical profession as inseparably bound up together. After initiating reform work, they began to offer monetary prizes for competition among those prepared to take up the study of certain subjects;* and, when funds began to accumulate, a decision was reached that each year a definite sum should be set aside for the purpose of making grants to persons desirous of undertaking researches on subjects connected more or less directly with the institutes of medicine. The net result has therefore been that the Association now not only has its own research scholars, but can rightly claim a share in

* The first of these was "The investigation of the sources of the common continued fevers of Great Britain and Ireland, and the ascertaining of the circumstances which favour the diffusion of these diseases, and also those circumstances which may have a tendency to render them communicable from one person to another."

many of the scientific achievements which have won world-wide renown for some of those who now practise medicine in this country, or have done so during recent years. An examination of the records of the committees which have had charge of the work of the Association in this direction, shows that very few well-known names do not figure in the list of those who at one time and another have received financial assistance from the Association in the work on which they were engaged. In fact, to go no further back than 1874, the Association appears to have spent approximately £30,000 on strictly scientific objects.

One or two of the prizes awarded by the Association in early years have been allowed to drop, but others have taken their places, and are equally helpful in encouraging scientific study, and the foundation of a library in 1887 was a further step in the right direction.

This library originated in a collection of books sent for review to the British Medical Journal, and additions to it are constantly being made from this source, as also by purchase and by gifts from authors and others. The great utility of the library to members was further increased a few years ago by arrangements being made to allow of members borrowing books for perusal at their own homes. It should be added that during the last few years over 7,000 books, of which the library possessed duplicates, have been presented to Divisional libraries both at home and abroad on application.

The records also show that in the Seventies the Association began to take up vigorously the cause of those who find it necessary to perform experiments on animals in pursuit of knowledge. On more than one occasion it paid the expenses of individuals forced to defend themselves from attacks in this connexion, and did so much work through its Journal and otherwise that it seems to have come to be regarded as the chief opponent of anti-vivisectionist views. It performed a further service of the same kind in 1907 and 1908, when it reproduced the essence of the evidence given before the late Royal Commission on Vivisection, with the object of furnishing members of the Association with material for upholding the truth when discussing vivisection with their patients and others.

The "Journal."

The ambitions of the founders of the Association in regard to work of a scientific character, and the means by which they proposed to fulfil them, are at the present time best represented by the sectional work of annual meetings, the scientific meetings held from time to time by many Divisions, and by the publication of its Journal.

As for the Journal, it may in some degree be regarded as the begetter of the Association, for it was the amount of support accorded by provincial practitioners to a medical publication in which Sir Charles Hastings and his friends were interested that led the former to conclude that there was room for an association of provincial medical men. The original subscription to the Association (one guinea) was intended to cover the cost of the Association's annual volume of *Transactions*. As a rule, this sum more than sufficed, and it was out of the balance left that grants towards the expenses of Branches began to be made as these were formed, and that the present financial possessions of the Association gradually accumulated.

Although this annual publication of the Association bore the title *Transactions*, it was not on all-fours with the transactions nowadays published by societies. It is true that each volume supplied an account of the annual meeting preceding its publication, but it was made up of classified papers especially written for inclusion therein. This first publication of the Association was, in short, an annual magazine, and when about the end of the Forties there was substituted for it a weekly journal the change was not so great as it might at first seem.

The original Journal was quite small, but little by little fresh features were added until at length it began to assume its present general form, the excellence of which led to its being adopted as a model by some other medical publications. So far, however, none seems to have attempted—consistently and week by week—to cover with equal completeness the whole territory formed by the numerous fields into which the work of the medical profession is now subdivided.

The Supplement, which was first issued in 1904, is devoted more particularly to the business or medico-political side of the Association's work, and keeps members in touch with what is being done by outside bodies whose aims have a bearing thereon; the Epitome, which had its birth in 1890, mirrors the scientific work which is being done abroad; and the Journal itself, though extended in respect of number of pages, still falls into parts, each of which fulfils its original purpose. The first pages are devoted to considered communications on clinical topics, and the pathological, bacteriological, chemical, psychological, and other scientific subjects which are of direct importance to medical men who desire to keep themselves abreast of the times; the next to brief records of interesting points observed in general practice and to accounts of hospital work. The pith of the work done by various societies is recorded in the next pages, and then come reviews of new publications; information as to new instruments and drugs; literary notes, written chiefly from the standpoint of medicine; articles on the history of medicine, to which more importance is now rightly attached than formerly; and others on various subjects which from time to time become of special interest—motoring questions, the incidence of taxation on medical men, the work of benevolent societies, and the like.

The middle pages are given up to a few leaders, one of which is usually a summary of recent knowledge on some particular subject such as the fathers of the Association used yearly to order to be prepared, and short comments on current events. Next come, so long as Parliament is sitting, notes on its doings in connexion with subjects of medical interest; communications from special correspondents at home and abroad; correspondence between individuals; records of the lives of deceased colleagues; and of cases of medico-ethical or medico-legal interest. Finally, after some special sections of varying number, there is a column or two of news and informal notes and queries. The latter reach the Journal in great numbers every week, but unless they are considered to be of general interest they are dealt with in communications sent by post to those concerned.

The Journal, in short, covers very fully the whole of the objects of a scientific character definitely included in the aims of the Association when it was first founded, and, taken as a whole, supplies so much reading matter each week that probably many members devote their attention merely to the particular section which happens to interest them individually. In view of the preoccupations of many medical men this fact is comprehensible, but nevertheless regrettable, because medicine in many respects advances so rapidly, that a man who has not read papers on some particular subject for a long time is liable, when he does so, to find their statements difficult to follow. Many, however, read their Journal steadily week by week, and the following statement by one of them, which is to be found in a recent record, goes far towards supporting what has just been said:

> It is almost needless to refer to the immense amount of information the Journal contains. To any one whose duty it is to know what is being done on the most advanced lines in every branch of work the Journal is invaluable. It is hard to see what the profession would do without it, especially those members who are not in immediate touch with the great centres of work. Moreover, it brings the reader into personal contact with the leaders of thought. Nothing could be more inspiring to a scientific thinker than the records of the ideas of the most advanced specialists of the modern world, so fully and ably reported in recent numbers.

The Final Question.

The first of these articles[1] pointed out that it could only be said to be the duty of every eligible medical man to seek election to the Association unless an answer favourable to that assertion were forthcoming to each of seven specific questions. This was found to be the case in respect of the first five questions, and the answer to the sixth—which inquired as to the past history of the Association in respect of work for the medical profession—is completed by the foregoing note. That answer leaves unrecorded very many useful pieces of work performed by the Association—for instance, its parentage of the Royal Medical Benevolent Fund, and the assistance it gave to Epsom College and in the foundation of the Medical

[1] British Medical Journal, May 30th, 1914, p. 1190.

Sickness Society; its advocacy of the claims of medical men engaged in duties connected with the law courts; its defence of factory surgeons, and its successful attack on the barrack school system. Nevertheless, it suffices to render superfluous any detailed consideration of the seventh and last question. It is clear, in short, that benefit must accrue from the continued existence and further increase of the activities and resources of an Association which has rendered to the medical profession, to science, and to the public at large services such as those described in this series of articles. Consequently, no further reference to this question is required beyond that to be found in the leader on p. 140.

THE TERCENTENARY OF THE UNIVERSITY OF GRONINGEN.

FROM June 29th to July 4th the town of Groningen gave itself up to joyful celebration of the 300th anniversary of its university. Some account of this charming old town of North Holland was given in our report of the proceedings of the International Congress of Physiologists held there last September. The town is closely identified with the university of which its citizens are justly proud, and from Queen Wilhelmina down to the humblest peasant there was willing participation in the celebrations. Of the five universities of which Holland boasts, the two at Amsterdam, one municipal founded in 1877, the other Calvinistic dating from 1880, are of recent growth; the other three—Leyden, Groningen, and Utrecht—are royal universities of ancient foundation. Leyden is the oldest, dating from 1575, when after the memorable siege its citizens nobly chose the grant of a university from the victorious William the Silent rather than the alternative of a remission of taxation. Utrecht dates from 1636 and Groningen this year commemorates the 300th anniversary of its birth. While described as a Royal University and welcoming most loyally the gracious presence at its function of the Queen of the Netherlands and her consort, we were reminded that the citizens of Groningen traced the origin of their university, not to royal favour, but to their own energy and self-sacrifice. North Holland, indeed, is the home of democracy, and unconquered Friesland claims that her people alone of the Germanic tribes have preserved the same name and occupied the same region since Tacitus wrote his annals. Approaching Groningen from the "oozy rim" of the Zuyder Zee, the traveller passes through the rich pastoral country, with big cattle, sheep and horses, and apart from the university it is an agricultural town of 80,000 inhabitants. While it was perhaps more famous in the thirteenth century as a member of the Hanseatic League the enterprise of its citizens and the culture diffused by its learning have preserved it from the stagnation which neighbouring towns have suffered by the diversion of the great channels of European trade. The Gothic tower of St. Martin's is a landmark far and wide; the Groote Markt affords an animated scene when on market day it is recruited by the peasantry from the surrounding countryside, laden with rich produce of their intensive cultivation. The Stadhuis, rebuilt is 1787 in classic style, is the emblem and abode of its active and democratic municipality.

It is, however, the university, with its 70 professors and 550 students (of whom 140 are women, and 200 belong to the medical faculty), with its magnificent museums, laboratories, hospitals, botanical gardens, and last, but not least, its new central offices (rebuilt in 1909, after the fire of 1906), which gives animation, distinction, and world-wide fame to this old town of North Holland. Hither came some 100 delegates on Monday, June 29th, from the universities of Europe, America, India, and Australia, to offer their salutations on her 300th birthday to their sister of Groningen. They were received with abundant hospitality and unaffected friendliness by the curators and senate, as well as by the kindly hosts and hostesses who placed their homes at the disposal of the delegates from afar.

Like the other royal universities, Groningen is governed by a body of five curators. Jonkheer Geertsema, the Commissary of the Queen, is the president of this body, and received the visitors with the greatest courtesy. The Burgomeister, Jonkheer Tjarda van Starkenborgh Stachouwer, and his family vied with the President in maintaining the reputation of Groningen for Batavian hospitality. They were well supported by the other curators—Jonkheers Binnerts, Lohman, and Homan—who received their guests in the aula of the university on the evening of June 29th. The Rector Magnificus for this eventful year is Professor Hamburger, whose marvellous physiological laboratory is the most modern and well-equipped in Europe; he was assisted in all the arrangements by the ever-tactful Dr. Nijhoff, as well as by the energetic secretary, Dr. B. ten Bruggen Cate, and his gracious wife, a niece of the artist Mesdag.

Tuesday morning (June 30th) was devoted to visiting the laboratories, museums, hospitals, and other interesting buildings of Groningen, and at 2 p.m. the academic assembly met in the Nieuwe Kerk to hear orations by the President and the Rector, and to receive numerous addresses of felicitation from the delegates of other universities. A strict limitation of speeches, both in number and time, had been wisely prescribed, and was for the most part observed. A brilliant Latin address, spoken extempore by Professor Th. F. Zielinsky of St. Petersburg, was especially enjoyed, while a lighter note was touched by the improvised and impassioned address of the representative of the Roumanian University of Jassy.

Great Britain sent representatives from London, Oxford, Cambridge, Birmingham, Liverpool, Leeds, Manchester, Sheffield, Aberdeen, Edinburgh, St. Andrews, Glasgow, Cardiff, and Dublin. Among the British delegates were Lord Reay, Sir E. A. Schäfer, Sir William Collins, Professors Hills, Leedham Green, E. W. Hobson, R. Caton, S. J. Hickson, Kirsopp Lake, H. R. Dean, G. A. Smith, J. Mackinnon, J. Fergusson, Mr. Lynn Thomas, and Dr. D. J. Coffey. Professor George Adam Smith made a brief and appropriate speech on behalf of all the British universities.

In the evening a banquet was given to some 350 guests by the curators and senate of the university. The toast of the guests given by the Minister for Agriculture was acknowledged by Lord Reay, better known as Mackay in Holland, and by Professor Roethe. The former remarked on the value of such international amenities among universities, adding that Jeremy Bentham, who had inspired the University of London, had also coined the word "international," and that the Metropolitan University by its external side spread its influence all over the world. Professor Blanchard, the parasitologist of Paris, worthily proposed the State of Groningen, which was replied to in perfect French by the burgomeister. A gala performance at the Cabaret, which the Prince of the Netherlands honoured by his presence, closed a well-filled day.

On Wednesday, July 1st, at 10.30 the Nieuwe Kerk was again thronged. Queen Wilhelmina and her consort occupied the royal pew, and Her Majesty read a gracious address after having received the degree of Doctor of Netherlands History. Among other recipients of honorary degrees were Sir E. A. Schäfer, Dr. Hickson, Professor Paterson of McGill University, Professor Zielinsky, Mr. Andrew Carnegie, and Lord Reay. There were more addresses and some songs to the accompaniment of the organ, and then a solemn procession was formed of curators, senators, professors, and delegates, who marched in glorious array beneath a blazing sun to the town hall.

A small party of twenty was entertained at lunch by President Geertsema to have the honour of meeting the Queen. The two representatives of London University were included in the party, and were accorded the privilege of an interview with Her Majesty. After this came the turn of the students, who in the costumes of 1648 enacted a pageant in the "Groote Markt," representing the Peace of Münster. The evening was devoted to a musical soiréo given by the Senate in the theatre. Thus terminated the official ceremony of the tercentenary, the rest of the week being given up to water parties and excursions. The weather was radiantly fine throughout the celebration, and Groningen's guests parted with reluctance from their kindly hosts, loaded with memories of regal hospitality and full of admiration of her people's university, at once so ancient and so modern.

LITERARY NOTES.

It is intended that in the future the *St. Bartholomew's Hospital Reports* shall be published in three parts each year; the first two parts containing scientific and clinical papers, the remaining part the hospital statistics, etc. It is hoped that these parts will appear in July, December, and March of each year. The first part will be issued at the end of the present month.

The *British Review* for July contains among various other matter—political, poetical and critical—two papers of special interest to medical readers. Mr. K. L. Kenrick presents the case against eugenics in a vigorous style. In another article "Medicus" discusses the various ways of starting in practice and the conditions for success. Speaking of the Insurance Act, he says it has undoubtedly played great havoc in many practices, but on the other hand it has been the means of increasing and in some cases doubling and trebling the incomes of some doctors. He thinks, however, that the Act has been "the means of ruining good and scientific work." He says:

> For a man with few or no ideals except to make money, the prospects of the medical profession never were so good as they are at the present time; but for the man who has ideals, the rise is as slow, or rather slower than it ever was.

He concludes with the comforting reflection that the prospects of a general practitioner are about as good as they ever were, for fewer men are entering the profession.

Mr. Wilfred Whitten ("John o' London") in his *Londoner's London* (Methuen and Co.) says that Lombard Street has other than banking associations. In Plough Court was born Alexander Pope. Of the poet's boyhood in Lombard Street nothing is known, but Mr. Whitten finds a trace of it in his mocking verses, "To Mr. John Moore, Author of the Celebrated Worm Powder." Moore was a quack doctor living in Abchurch Lane, which leads from Lombard Street into Cannon Street. His "learned Friend of Abchurch Lane," Pope calls him. "John Moore's Worm Powders" were very extensively advertised in the newspapers, with testimonials written in plainer language than would be tolerated to-day. Pope asks Moore to remember that "all humankind are worms":

> O Learned Friend of Abchurch Lane,
> Who sett'st our entrails free;
> Vain is thy art, thy powder vain,
> Since worm shall e'en eat thee.

When Moore died in 1737 the *Gentleman's Magazine* gracefully remarked that he would now "verify Mr. Pope's witty observation"—in the last line of the epigram quoted.

The connexion between the breast feeding of infants and racial decay may at first sight not appear very close; but the loss, whether real or artificially induced, of the mammalian instinct in the women of a nation is not to be lightly disregarded by those interested in the preservation of national health and prosperity. The decline of breast feeding amongst modern mothers forms the subject of an interesting article by Mr. Harold K. Waller which appeared in the June number of *The Child*. In it the author discusses the reasons for this decline and the means of checking an evil which threatens to prove a source of serious danger to the future welfare of the race. "There is a tendency," remarks Mr. Waller, "to consider lactation as an unstable phenomenon, and the privilege accompaniment to robust physique, associated with the type of intellect that is erroneously considered somewhat low in the scale of culture." Public opinion, moreover, especially of late years, tends to regard lactation as an additional burden upon the mother, and one that can be dispensed with without endangering the health of either mother or child. The fallacies upon which such theories are founded are exposed by Mr. Waller, who proves that the successful rearing of children at the breast is by no means so difficult or complicated a matter as it is often asserted to be, and that it is, in fact, far less troublesome and dangerous than artificial feeding upon patent foods. Much, of course, depends upon the patience of the mother and the formation of good habits in the child; but these being once acquired, there is no reason why, in the majority of cases, a healthy woman should not provide her child with that natural food for which, as yet, no satisfactory substitute has been found. The June number of *The Child* also contains articles by Dr. A. Gilmour on school dentistry, and by Dr. Edward F. M. Neave on squint in childhood; whilst Dr. G. de Swietochowski gives some valuable advice as to the prevention and treatment of spinal deformities; and Miss Alice Ravenhill has contributed a short account of the health of children in the public schools of British Columbia.

The *Year Book of Open-Air Schools and Children's Sanatoria*, which will shortly be issued by Messrs. John Bale, Sons, and Danielsson, Limited, under the editorship of Dr. T. N. Kelynack, is a companion volume to *The Tuberculosis Year Book and Sanatoria Annual*. It is intended to be the authoritative directory and guide on open-air education and all matters relating thereto. It will be a reference work for the information of medical, educational, and other leaders engaged in the conduct of State, private, philanthropic, and national schemes for the betterment of child life, and particularly of tuberculous, tuberculously disposed, convalescent, delicate, and other children requiring special medico-educational consideration and care. It will contain editorial reviews, original communications, critical surveys, accounts of open-air education schemes, descriptions of open-air schools and children's sanatoriums, particulars of national associations, societies, and other bodies, reviews and notices of books, records and reports, and much else of practical service.

Among the writings left by Swedenborg is a section of his *Regnum Animale* which deals with the brain anatomically, physiologically, and philosophically. A part of this had been translated and prepared for publication by Professor Rudolf Leonard Tafel, who published one volume in 1882 and a second in 1887; but he died in 1893 before he could complete the work. Dr. Max Neuburger, Professor of the History of Medicine in the University of Vienna, communicated to the meeting of the Association of German Scientists and Medical Practitioners, which met at Hamburg in 1901, a paper on Swedenborg's investigations on the physiology of the brain, laying stress, as Tafel had done before him, on their scientific value. Soon afterwards he placed himself in communication with the Swedish Legation in Vienna, to which he expressed his regret that the manuscript of Swedenborg's work on the brain had not been published. This was submitted to the Minister for Foreign Affairs in Stockholm, who laid it before Professor Gustaf Retzius of the Royal Academy of Sciences, where the Swedenborg MSS. were kept. In *Notes and Queries* of October 15th, 1913, Mr. Charles Higham stated that a cursory examination by Professor Retzius of the manuscripts which treat of the brain and nervous system convinced him that a sufficiently thorough examination would take more time and work than he could devote to them, and the task was postponed. In August of 1902, however, Professor Retzius fortunately met Mr. Stroh, and at the ordinary meeting of the Royal Academy of Sciences in the following December a committee, consisting of Professors C. Lovén, A. G. Nathorst, S. E. Henschen, and S. Arrhenius, with Mr. Stroh, was appointed "to examine all the manuscripts of Swedenborg, and present a report thereon to the Academy, stating whether and to what extent they ought to be published." In the following April a favourable report was presented by the committee, and the printing of a selected number of volumes was decided upon. The plan was to print some three or four volumes, but it developed later into a decision that Swedenborg's physical philosophy of 1710–34 should be represented by seven volumes and his anatomical and physiological works by three. Of these *Opera quaedam aut Inedita aut Obsoleta*, the first three volumes have already appeared under the general editorship of Mr. Stroh, with a preface by Professor Retzius (who also defrayed the cost of publishing the three volumes), and introductory matter by Professors Nathorst and Arrhenius. Arrangements—literary and financial—have been made for the publication of the other volumes. Mr. Stroh's work will also include the collection of documents relating to Swedenborg.

British Medical Journal.

SATURDAY, JULY 18TH, 1914.

IMPENDING DEVELOPMENTS IN NATIONAL INSURANCE.

MEDICAL attention is at present very largely directed to the question of the disposal of the various grants promised in connexion with the Budget. The Chancellor of the Exchequer has indicated that certain of these grants will definitely go to the authorities who administer the Public Health Acts, and that others will definitely go to the authorities who administer the Insurance Acts, but the destination of others is left in suspense. Included in the grants that will go to the insurance authorities are those devoted to the provision of referees and consultants, and also the grants for clinics. Included in the grants the destination of which is undecided are those which relate to laboratories and nursing. The Chancellor indicated that they lay midway between public health and insurance, and that their final disposal was open to discussion. It is important that the medical profession should have clear views on the subject, and should express its views at the earliest possible moment.

The Insurance Act has been accused of tending to commercialize the profession; were it to have this effect the result would be disastrous to the profession, and must eventually destroy the efficiency of the work it does for the public. That the risk exists will not be denied, but we believe there is much to be said for the view that the grants which are still in doubt, if now properly allocated, would tend to bring the profession more closely into touch with science than it has ever been before. There is, however, a risk that a mistake may now be made and the new work sent along the wrong road.

Throughout the country there are numerous provincial hospitals established in towns which are natural centres, and therefore convenient to the medical profession and its patients in the several localities. These should, wherever practicable, be made the centres of activity each for its own area. To establish there the clinics, or most of them, would be in the natural line of development, and it would be equally natural for the referee-consultants to make the hospital their head quarters. In most such hospitals *x*-ray apparatus, electrical appliances, and the rest of the modern armamentarium for the diagnosis and treatment of disease, including, in very many instances, clinical laboratories, are already provided and only need development. It seems obvious that the clinical laboratories required by the Budget proposals should be situated on the same premises, and be in the closest possible relation with the clinics; the two should in fact be part of one scheme. That being so, it seems clear that laboratories situated in municipal buildings, perhaps a mile or two away from the hospitals, would not only be less convenient than laboratories placed at the hospitals, but necessarily less efficient because removed from the influence of the clinical hospitals and the atmosphere they create. The laboratory and the clinic should, in fact, be inseparable. It appears to follow that throughout the country generally the laboratory and the clinic should be under the same administration locally and centrally. Now the administration of the clinic is to be part of the administration of the Insurance Act; so also, therefore, ought to be the administration of the laboratory, or at least the insurance authorities should have the predominant voice. It would be very awkward to have one part of the combined laboratory and clinic managed by a town council, and the other part managed by an Insurance Committee. This consideration points to the propriety of the clinical laboratories being placed in the hands of the Insurance Committees, which will control the clinics, rather than of the public health authorities. To this end a committee of the British Medical Association has suggested that the control should be vested in a joint committee consisting of representatives of the Insurance Committee, the Local Medical Committee, the local hospitals, and the County Council. If there should be any insuperable obstacle in the way of setting up such a new authority as that suggested, the same object might be attained by the appointment of a subcommittee of the Insurance Committee, with, perhaps, additional members co-opted from the other bodies mentioned, for clearly in any case some method of co-ordination will have to be found.

Local laboratories could not always have, in respect of staff and appliances, an equipment sufficient for all purposes—that is to say, difficult cases must occur in which consultation between laboratory workers will be desirable. The local laboratories should therefore be grouped in relation to great medical teaching centres, where there is a school possessing institutes of pathology and bacteriology. Each such centre, which it may be hoped will receive a great impetus as a result of the allocation of the "Research Penny," should have attached to it a convenient group of local laboratories, and it would not be difficult to specify the particular functions that should be performed centrally as distinguished from locally. In all cases the staff of the local laboratories should be placed in direct relation with the staff of the nearest central laboratory, and the growth of provincial universities during this generation facilitates such an arrangement. One important consideration here is that if the body vested with local control were the Insurance Committee it would always contain a representation of the medical profession.

As regards great cities the position is somewhat different. The hospitals in great provincial cities with several hundred thousand inhabitants are seldom so distributed through the area as to make them convenient centres for clinics. In so far as a great hospital in such a city is the centre for medical men of a given district it ought to be so used, but it will probably be necessary in addition to provide clinics here and there in the thickly populated outskirts of the city to suit such members of the profession and their patients as live too far away to make it practicable for them to use the large institutions.

Coming now to the question of the nursing grant, of which the destination was also left open in the Chancellor's speech, the question of control as between the Public Health authorities and the Insurance authorities seems capable of only one reply. Insurance Committees must contain medical practitioners to the extent of at least 10 per cent. of the total membership, and they must also in every case include at least four women. Public Health authorities have very seldom any such representation

either of doctors or women, and where a member of the public health authority happens to be a doctor he is there by the accident of local election, and not by right of statute or because he is a doctor, as is the case with Insurance Committees. Nursing is clearly a part of adequate medical service, and should be administered by the authority responsible for that service.

It is true that at present the Insurance Committees have responsibility only for about a third of the population, but we cannot shut our eyes to the probability that a demand will arise for the extension of the scheme of national insurance to the dependants of the insured. Whether we think this will happen soon or late, we must not lose sight of the possibility, for it makes it all the more important that development should follow the right lines now, at the beginning. If dependants of insured persons were to be brought in, the total proportion of persons under the charge of Insurance Committees would be raised to not less than four-fifths of the whole population of the country, and the remaining one-fifth would be largely made up of those who are so well off as to be quite outside any necessity for such insurance. In so far as nursing functions come in any way under the provisions of the Public Health Act, they are confined to cases of infectious diseases; under the Insurance Act there is no such limitation. For these reasons it is in the interests of the public and of the medical profession that the nursing grant should go, not to the public health authorities, but to the insurance authorities.

The Insurance Act is specially related to the treatment of individuals, whilst the Public Health Acts are specially related to preventive measures applied to communities—mainly measures to deal with environment, water supply, drainage, housing, and the like. The general character of the membership of the two authorities cannot but have close relation to the functions which they are separately to perform. Incidentally in this connexion reference may be made to another point, to which some weight should be attached. In the Insurance Committees an attempt has been made to interest the representatives of the approved societies directly in the working of the Act, and it does not seem politic that these persons should be asked to give their services only when the dry detail work of registration and routine administration is under consideration, and that when work of vital interest affecting every member is to be dealt with it should be proposed to hand it over to some other authority. Such a course would inevitably tend to deter representatives of the societies from taking their legitimate share in determining the policy of the Committees in larger issues.

The prospect opened up by the establishment of medical centres at the hospitals which already exist in connexion with nearly every considerable town throughout the country is very attractive. It indicates how readily the profession, aided by the post-graduate instruction for which so remarkable a demand has arisen within the last decade, may keep itself in close touch with the practical developments of medical science and teaching.

PAST, PRESENT, AND FUTURE.

THE series of articles on the relation of the British Medical Association to the medical profession is brought to a close in this issue. Their preparation has involved no inconsiderable amount of historical research, but the expenditure of time and space has been justified, for despite inevitable shortcomings the articles as a whole may be regarded as constituting what a writer of the late Georgian period—that in which the Association had its birth—would have called a conspectus of the work of the Association since the date of its foundation to the present time.

The study on which the articles were based was commenced with the object of seeing how far the work hitherto done by the Association for the medical profession justified the contention that all members of the medical profession ought to join its ranks, and we have received assurance from keen supporters of the Association, who believed they were already well acquainted with its history, that the articles have shown to them that the Association has done much more than they had hitherto realized. This is all the more satisfactory because in no single instance has any of the crusades mentioned been exhaustively described, and to much that has been done in other directions no allusion has been made.

It is inevitable that the extent to which different parts of the Association's work appeal to individuals should vary with their preoccupations, but the value of no institution having objects at all comparable to those of the Association can ever be judged from any single standpoint, nor should any one who desires to form a sound opinion as to its potentialities allow himself to be influenced either by its success on one particular occasion or by its failure on another. It is by its whole history that it should be judged, and this history must have endured for a period sufficiently long to allow general conclusions to be drawn.

This is the consideration that gives value to the comprehensive sketch of the work of the Association that has now been supplied. The period that it covers is long, and the forms of work described numerous. Summed up it shows that the history of the Association has been one of persistent effort in a multiplicity of directions during eighty-two years, and it is impossible to doubt that the sketch justifies the conclusion that the Association has been remarkably successful in fulfilling the aims with which it was founded.

In regard to those aims, it has sometimes been assumed that they were mainly scientific, but this, as pointed out in the course of one of the articles, is an incomplete conception. The promotion of science, so far as the meaning of that term in 1832 is truly comparable with its meaning at the present day, was one of the main objects the founders of the Association had in view, but they fully realized that only by simultaneous promotion of the social, moral, and financial interests of the medical profession could it ever be attained. Consequently, the Association from the very commencement found itself involved in struggles not essentially dissimilar from those which have attracted so much attention during recent years.

Considering the small beginnings from which it sprang and the immensity of the forces with which it had to contend—not least of which was apathy of politicians, the public, and even the profession itself—as also the great variety of its undertakings, it would not have been remarkable if the impetus with which the Association started had been exhausted comparatively early in its career. But so far from this being the case, it continued to grow in strength and numbers—if not from year to year, yet steadily from decade to decade[1]—in a fashion for which we can find no analogy in institutions connected with other professions.

From time to time, under the influence of waves of feeling, there have been secessions, but as a rule the majority of these wandering sheep have returned to

[1] See JOURNAL, March 14th, 1914, p. 600.

the fold, and the progress of the Association has never seriously been checked.

One reason for its success is to be found, perhaps, in the fact that it has always been thoroughly catholic in its sympathies, and that in its history there is an absence—curiously complete—of any exhibition of jealousy in regard to other medical bodies. It has always been ready to place its machinery at the disposition of blocks of men having special interests, whether scientific or reformative, and on several occasions has even helped to establish and maintain societies or associations formed solely of such men. Some of these bodies have subsequently decided to throw in their lot with the Association, and of those that preserve their identity the majority are still largely dependent on the co-operation of the Association when they desire to influence the general public.

There is room, indeed, for believing that at times the Association has gone somewhat too far in the direction indicated, since the moral and financial strength of the profession, as a whole, is so far limited that none of it can safely be wasted by dissemination over too many separate pieces of machinery. Nevertheless the fact remains that neither this facultative source of weakness nor any internal or external difficulty, numerous as they have been, has sufficed to retard the progress of the Association. Consequently, it has now attained a position of so much importance in the eyes of the general public, as well as of the profession, that prompt notice is taken of any resolutions bearing on the relations of the medical profession to the general public that are passed by the Association as a whole, or by the sections into which its scientific work is divided.

This means that the Association is now in a position to voice the opinions of the profession in a fashion that secures due attention, and side by side with this may be placed the assured fact that not merely boards of guardians and local authorities, but the Government and its various departments now recognize that the Association is a force that must be reckoned with whenever matters of special concern to the medical profession are in question. They realize that while they can count on the assistance of the Association in the promotion of any project having for its object the safeguarding of the public welfare, the progress of science, or improvement in the application of medical art to the relief of individual cases of suffering and disease, it will not suffer the interests of the medical profession to be wantonly set aside, and that if individual medical men are bullied or treated unfairly effective resistance is to be expected.

The fact that these statements can truthfully be made would in itself be sufficient to show that a great gain for medicine has been achieved by the Association, even if the long tale of successful work both for science and for practitioners of every class set forth in the articles under consideration could not have been told.

The Association, in short, is fully entitled to look back with satisfaction on its past and to look forward with confidence to its future. It is not, of course, implied that the Association has always been successful; but its mistakes serve as signposts of what must be avoided by those who have the interests of progress at heart, and its failures have usually paved the way to success. It is not difficult, for instance, for a careful student of its history to detect times at which those then working for reform or any other object were, as the sequel showed, unduly elated, but it is equally easy to detect times when they were unduly depressed. Indeed, the latter greatly outnumber the former, and, looking at them in the light of after-events, it is clear that these failures were often more apparent than real.

The Association, for instance, has caused to be drafted dozens of bills, and only a few of them have ever been debated in the House of Commons; but it would be a great mistake to suppose that the drafting of these bills was labour lost. The drafting was accompanied by much discussion and preceded by continuous agitation, and the two together helped to form the solid opinion which eventually resulted in the desired reforms being obtained either by modifications of the draft bills or by some other more or less closely allied means. It is to be remembered that legislation hardly ever initiates reforms; usually it merely ratifies them. In other words, only in exceptional instances does legislation step in advance of public opinion, and on its success in guiding public opinion the Association may justly congratulate itself.

This statement of the impressions left by the past history of the Association may be completed by saying that it is impossible to rise from its study without being uplifted by a renewed sense of the value of *esprit de corps* and experiencing a feeling of profound admiration for many of the men who at one time and another have played a leading part in its affairs. Their labours, as a rule, have been wholly altruistic, and no small proportion of them have been persons whose prominence either as practitioners or in other ways has been so considerable as to make it difficult to understand how they found it possible to devote so much energy and time to Association work. A good and recent example of such men is the late Sir Henry Butlin, not long ago president of the Association and for many years its treasurer.

It is, in fact, not solely to unremitting effort that the success of the Association must be attributed. It has also been due to an unfailing supply of men of high ability ready to play a leading part in its work, coupled with the willingness of others of not less ability to sink their identity and take a place in the ranks. A further source of strength has been the possession of a JOURNAL which—besides fulfilling the scientific and other requirements described in the ninth article of the series—is conducted on a semi-independent footing, and aims at promoting the Association's objects by keeping the medical profession in touch with the views of the public at large and by getting a hold over the latter through never advocating the claims of medical men otherwise than temperately.

As for the future, one warning note has to be sounded. The number and strength of the forces with which the Association has to contend are not lessening, and in the interests of individuals and large numbers thereof, it may at any time become very desirable that its successes should be achieved with greater rapidity than has sometimes been the case in the past.

This is one reason why all medical men practising in the British Isles or in British territory beyond the seas may rightly be urged to join its ranks, for obviously its driving strength must depend on the justness of its claim to speak in the name of the whole profession; and this, again, must largely be determined by the numbers of those known to be ranged behind its leaders. It is true, of course, that not all members of the medical profession benefit equally by the work of the Association, but it is quite inevitable that all should benefit more or less. Consequently a simile recently used by Mr. Crooks in speaking of trade unionism must certainly be regarded as having some application to members of

the medical profession likewise. A man, he said, who benefited by the work of a union but did not contribute to its support was like a man who stole a wreath from a cemetery and thus won a prize at a flower show.

THE DRUG FUND AND EXCESSIVE PRESCRIBING.

Sufficient information is now available with regard to the drug fund under the Insurance Act to show that in probably the majority of areas the sum of 1s. 6d., or at any rate 2s., has proved adequate to provide a proper supply of drugs and appliances, but in numerous other areas, especially those containing a large industrial population, these sums have not been sufficient to pay the chemists' bills in full, and unless the Government comes to their assistance a large number of chemists in these areas will have to submit to their bills being discounted, in some cases to the extent of over 20 per cent. of the total. It is hardly a matter of surprise that this fact has been seized on as supplying an argument first against the panel system, and secondly in favour of either a State Medical Service or a system in which the approved societies would control the medical service. An article on the subject in a recent issue of the *Scotsman* begins by stating that "the panel system is nowhere more vulnerable than through the administration of the drug fund," and after stating that the sum of 1s. 6d. is "known to be appreciably greater than the charges experienced by the friendly societies in the past," the writer goes on to argue that excessive prescribing by the panel doctors, leading to the necessity of discounting the chemists' bills, is a matter which ought to be dealt with firmly and strictly by the Panel Committees, and ends with the warning, "The panel system is a compromise, and it has the defects of its origin. It is far removed from perfection, and many of its faults are obvious, but it is far preferable to either of the rival schemes which have been suggested to replace it. If at the close of the provisional three years it is decided that it cannot survive, one of the principal reasons given will probably be that the guardians of the drug fund, the panel doctors and chemists, were weighed in the administrative balance and found wanting."

While it is impossible to deny that there is reason and force in this warning, yet the writer of the article hardly lays sufficient stress on two important facts—first, that under the regulations the Pharmaceutical Committee is not authorized to deal with excessive prescribing, except by reporting to the Panel Committee, which is then compelled to investigate the question; and, secondly, that the Panel Committee may, if it so chooses, investigate the question of over-prescribing either by individual practitioners or by the panel generally, without waiting for definite complaints from the Pharmaceutical Committee, though it would have to depend for detailed information on statistics furnished by that Committee. As the Insurance Committee can only deal with the matter on the report of the Panel Committee, the whole responsibility for preventing excessive prescribing practically rests on the Panel Committee, and in so far as any Panel Committee fails in this duty, so far will it be furnishing potent arguments to the opponents of the present system, whether it be the ordinary capitation system or the system of payment by attendance in use in Manchester and Salford, where the chemists are suffering, perhaps, more than anywhere else.

On Wednesday last Mr. Masterman, Chairman of the Joint Committee of Insurance Commissioners, received a deputation from the Pharmaceutical Society, and his reply is published in full in the Supplement, page 71. The report reached us too late to permit of its full consideration, but it will be observed that Mr. Masterman recognized the responsibilities of the Panel Committees, and said that if the machinery of the Act was exhausted by the Pharmaceutical Committees everywhere without result, a new situation would have arisen with which the Commissioners and the Government would have to deal. He asserted that there were great discrepancies between the cost of prescriptions, not only in areas similar in character, but as between individual doctors in those areas, and concluded by stating that he considered the time had come to make a thorough examination of the drug tariff, and that for this purpose he proposed to appoint a small departmental committee.

The duty of recommending that a fellow practitioner guilty of over-prescribing should be penalized is undoubtedly an invidious and odious task, but it seems probable that if the duty be not shouldered by the Panel Committee some alternative will be suggested. It might, for example, be proposed to establish some sort of joint committee containing representatives of the Panel Committee, the Pharmaceutical Committee, and the Insurance Committee to deal with this particular duty, which the Act as it stands leaves to the medical profession to discharge. This is not an alternative the profession could view with satisfaction; it would take out of its hands a matter of strictly professional concern, and would be a confession of failure. An alternative scheme which, early this year, we were given to understand found favour with some members of the Unionist party who have given special attention to national insurance, was to treat the 9s. as a single payment which must be made to cover the cost of medical attendance and drugs, the pharmacists having a definite guarantee of at least 1s. 6d. a head without deductions, any adverse balance being met out of the medical share of the 9s. The argument was that this plan would most effectually arouse the Panel Committee to suppress excessive or over-costly prescribing, since any failure would at once automatically affect the receipts of every panel practitioner. We are not aware that this proposal has yet been officially put forward, but that it commends itself to some politicians we have no doubt.

Both proposals neglect an aspect of the question which is of the first importance, and on it we must join issue with those who favour either. The matter is crudely put by the writer in the *Scotsman* when he says: "Panel Committees throughout the country should make it clear to their practitioners that the fund if properly used can meet all its liabilities." We must emphatically protest against any definition of excessive prescribing which involves the assumption that if the prescribing in any area has cost more than 2s. for each insured person in a year, it must therefore be regarded as excessive prescribing. What if this amount be insufficient in a particular area to provide proper medicines for the large number of patients requiring treatment? Must the practitioners stint their patients simply in order to eke out an insufficient fund? Will they be held guilty of excessive prescribing simply because the drug fund together with the floating 6d. is insufficient to meet the chemists' bills in full? It is quite a false analogy to say that we must cut our coat according to our cloth, for to do anything analogous to this, when

human lives are at stake, would be to become accessories to inefficient medical treatment. That this is no imaginary danger is shown by reports from numerous industrial areas where there is a large proportion of female labour in factories and mills. It is now acknowledged that the amount of sickness among women workers has been greatly underestimated, and even though the total drug fund for the whole country may possibly prove to have been sufficient, there is good reason for believing that in the industrial areas with numerous women workers the local drug fund is not sufficient. This came out very markedly in the report published in the JOURNAL some months ago, showing the position of the drug funds for all the insurance areas of Lancashire for the year 1913. In nine towns—Blackburn, Bolton, Burnley, Manchester, Preston, Rochdale, Salford, Stockport, and Wigan—the average cost of drugs for each insured person for the year was over 2s., varying from 2s. 0½d. in Rochdale to 3s. 2½d. in Manchester. It is significant that in all these towns there is an unusual proportion of female labour in factories and mills, and as a result there is normally a high average sickness incidence as compared with the country generally. It is from these towns, where the chemists' bills have not been paid in full, that the cry about over-prescribing has come. Would the Panel Committees in these towns be justified in taking the suggestion of the *Scotsman* and making "it clear to their practitioners that the drug fund, if properly used, can meet all its liabilities," or that practitioners in these towns, if the cost for drugs they order exceeds 2s., are guilty of excessive prescribing? Or, to put it in another way, would the practitioners there be doing justice to their patients if, knowing that the 2s. was insufficient, they at once, simply to eke out the drug fund or to show their compassion for the chemists, began to stint their patients of medicines which they ought to have? Contrast the towns named with Blackpool, where the average cost of drugs for each insured person was only 1s. 6¾d., Bootle 1s. 6d., Southport 1s. 6½d., Barrow 1s. 8½d., and Liverpool 1s. 9d.; no one of these towns can compare with those in the first list in respect of the amount of female labour in factories and mills. An equally significant fact was reported[1] from Salford, where a number of panel practitioners have been charged with over-prescribing. The cost of drugs for the year in Salford worked out at 2s. 7¾d. in respect of each insured person, but even if all those practitioners who are alleged to have prescribed excessively were cut out, the cost of the prescribing of the remaining practitioners, against whom there is no charge whatever, would work out at considerably over 2s. for each insured person. The explanation given for this is that there is a very high proportion of women workers in Salford, and it seems clear that the consequent high sickness incidence requires more than 2s. to provide a proper supply of medicines.

The moral of all this is, not that the total of the drug fund for the whole country is too small—whether that is so or not can only be determined when full statistics for every area are published—but that, if it is not too small, its distribution is in need of adjustment. To accuse any practitioner of excessive prescribing often carries with it a suggestion of unworthy ulterior motives, and except in flagrant cases Panel Committees will naturally shrink from penalization; but there is a danger that the warnings issued by various Panel Committees may even result in a cheap under-prescribing which would be infinitely worse than any over-prescribing.

[1] JOURNAL for July 4th, SUPPLEMENT, p. 27.

NATIONAL COUNCIL FOR COMBATING VENEREAL DISEASE.

DURING the last few weeks conferences have been held, under the presidency of Sir Thomas Barlow, with a view to the formation of a national council for combating venereal diseases. Those present at such conferences included Sir Rickman Godlee, Sir Francis Champneys, the Bishop of Southwark, Major Leonard Darwin, Sir Clifford Allbutt, Sir William Osler, Sir Henry Morris, Sir A. Pearce Gould, Sir Wilmot Herringham, Mr. Charters Symonds, and others. It has now been decided to form a National Council consisting of representatives of the medical profession and the public. In order to carry this out a circular letter is about to be issued stating the objects of the movement and its method of organization, and inviting recipients to join the council. It may be added that this movement is in no small degree the outcome of two years' work carried out by a committee appointed by the Royal Society of Medicine in conjunction with the Eugenics Education Society.

THE NEW "BRITISH PHARMACOPOEIA."

AT its meeting on July 13th the Executive Committee of the General Medical Council formally adopted as *The British Pharmacopoeia, 1914*, the completed draft submitted by the Pharmacopoeia Committee. It was resolved that copies, in advance of publication, should be made accessible to the public for inspection at the offices of the Council in London, Edinburgh, and Dublin on Monday, August 10th, at 10 a.m., and thereafter from 10 a.m. to 4 p.m. The official publication of the new *British Pharmacopoeia* will be made by notice in the *Gazette* on Friday, October 9th, on which day copies will be on sale by the publishers, Messrs. Constable and Co., Limited, 10, Orange Street, Leicester Square, W.C. The price has not yet been settled by the Treasury.

MEDICINE AND THE WOMEN OF INDIA.

SINCE the Countess of Dufferin, nearly thirty years ago, originated the scheme for the medical treatment of women in India which bears her name, medical matters, and women's hospitals in particular, have been the subject of much attention from the wives of all the Viceroys who have since governed India. Each of them has in turn held the office of Lady Patroness of the Dufferin Fund, and has devoted much time and attention to its management. Lady Minto, the wife of Lord Hardinge's predecessor in office, started a fund for the provision of nurses for Europeans in remote mofussil stations, where trained nurses, under ordinary circumstances, cannot be got. Lady Hardinge, who died last week in a nursing home in London after an operation, was, in her turn, patroness of the Dufferin Fund and of the Minto Nursing Fund. But the two chief developments which will render her name memorable in India are the reorganization, in 1913, of the Women's Medical Service, under the Central Committee of the Dufferin Fund, and the inception of the scheme for the foundation of a special medical school and hospital for the training of female medical students, the Queen Mary Medical College and Hospital for Women at Delhi, as a memorial of the Royal visit to India and of the great Delhi durbar of December, 1911. By the first the medical women employed under the Dufferin Fund, though they did not get all they asked for, obtained more liberal terms of service than before. The second is still in the initiatory stage, but will be carried out within the next few years, and should prove an advance in the medical treatment of women in India second only to the Dufferin scheme itself. Few will dispute that it is better that the medical education of female students in India should be conducted in separate schools rather than along with male students. Lady Hardinge, who was

the daughter of the first Lord Alington, was born in 1868, and married the Hon. Charles Hardinge, who was then attached to the embassy at Constantinople, in 1890. On his appointment in 1910 to be Viceroy of India he was created Baron Hardinge of Penshurst in Kent. In January, 1911, the King bestowed on Lady Hardinge the Imperial Order of the Crown of India, and in December, 1911, the medal of the first class of the order of Kaisar-i-Hind. She accompanied the Viceroy in the State entry into Delhi on December 23rd, 1912, when his life was attempted by means of a bomb thrown from the upper floor of one of the houses in the Chaudui Chauk. Though the Viceroy was severely wounded, and the chuprasi behind him was killed, Lady Hardinge was unhurt. Her courage on this occasion, and her devotion to her husband during the slow process of recovery, were the subject of general admiration in India; and on April 21st, 1913, she was presented with a congratulatory memorial to which over three million Indian women had subscribed.

"CHIROPRACTIC."

MILTON tells us that when his *Tetrachordon* was first offered for sale people said,

> Bless us, what a word on
> A title page is this!

Many readers may feel moved to a like exclamation when they see the word at the head of this article. And they may ask, what is "chiropractic"? We ourselves first saw it in a list of "drugless healers" enumerated in a bill for the regulation of medical practice in California, which we read in the *Pacific Medical Journal* not very long ago. Taken at its face value it would mean nothing more than treatment with the hand. But from the *Canadian Journal of Medicine and Surgery* for May we gather that a fuller definition is given in a pamphlet recently distributed in Toronto. According to that authority, doctors of "chiropractic" treat disease with "no medicine, no surgery, no osteopathy." Disease is said to be caused by "displaced vertebrae in the spine." Health results from the free flow of the "life current" from the brain, the dynamo, through the spinal cord and spinal nerves to all parts of the body. If the vertebrae of the spine become displaced and impinge on the spinal nerves, shutting off the life current from wherever the nerves lead to, the result is disease. When consulted by a patient, a doctor of chiropractic adjusts a displaced vertebra, relieves pressure on the nerves so as to permit the life current to flow once more through the nerves; health is thus again established. A chiropractor, therefore, is a sort of electrician, who makes it his business to discover defects in the wiring of a human machine, and to remedy them by adjusting displaced vertebrae. Take a case of abscess in the groin, the chiropractic method of cure is to adjust the displaced vertebrae impinging on the nerves which supply the lymphatics of the groin. After the necessary adjustment has been made, the life current flows once more from the dynamo; the bubo is cured. If the disease to be dealt with is a psoas abscess, a quinsy, an empyema, it is equally curable, for the pathology is always the same. It is as simple as lying. Asthma, appendicitis, anaemia, bladder trouble, bronchitis, Bright's disease, biliousness, cancer, catarrh, constipation, convulsions, deafness, diabetes, diarrhoea, diphtheria, epilepsy, eruptions, eye trouble, female diseases, fevers, and a number of other diseases—*pourquoi s'arrêter en si beau chemin?*—are all cured by the same procedure. The chiropractic art would therefore seem to be sufficiently simple in theory. All that has to be done is to identify the vertebra the displacement of which causes, say, epilepsy, or the one responsible, say, for cancer of the intestine, then adjust it, and hey presto cockalorum! the disease is cured. But how is one to discover the errant vertebra? And is the "adjustment" quite so simple a matter as it would appear? The system seems to be symbolized in Dogberry's instructions to the watch. The "chiropractic" operator is to "comprehend all vagrom" vertebrae, and bid them go to their places. If any refractory bone will not do so, "take no note of him, but let him go; and presently call the rest of the watch together, and, thank God, you are rid of the knave." It is claimed for "chiropractic" that it differs from osteopathy. The difference seems to be like that between tweedledum and tweedledee. What difference there may be is in favour of osteopathy. The results of an impartial investigation of osteopathy—which is a system of curing "subluxations" of bones, thickened ligaments, and contractured muscles by manipulation—by Dr. Alexander Bryce were published in the BRITISH MEDICAL JOURNAL of September 3rd, 1910. It is, as he says, a system of one idea, and that, we venture to add, to a large extent a wrong one. This was to be expected in view of the utterly inadequate training given in the eight schools of osteopathy in the United States. An account of these schools was given to the Governor of New York by Mr. Abraham Flexner, who has personally inspected them all. His statement, which was published in the *Journal of the American Medical Association* of June 6th, shows the worthlessness of the educational and scientific claims of osteopathy. We know nothing of the schools—if any such there be—where "chiropractic" is taught, but, to judge from the doctrine on which it is said to be founded, we think it may safely be assumed that the knowledge imparted there can have no scientific value.

THE CHEAP COUNTRY COTTAGE.

AT the Surveyors' Institution in Westminster there have lately been on exhibition some two hundred designs for labourers' cottages, brought together with the idea of making a practical contribution to the rural housing problem: seven have obtained prizes in a competition organized by *Concrete and Constructional Engineering*. One of the conditions of the scheme was that the cost of each cottage, exclusive of building profit, sanitary equipment, drainage, and water supply, should not exceed £125; and another that the design should be suitable for execution mainly in some form of concrete, instead of wholly in brick, tile, slate, or stone. This latter condition has at least the merit of requiring great simplicity of external form, and of severely limiting the opportunities for fretful picturesqueness. The rooms for which provision was made included generally a central apartment, answering the purpose of living room and kitchen, and, either on the ground floor or in an upper story, three bedrooms, the largest having, in practically all the designs, a cube of more than 1,000 feet. Both the first and the second prize designs were for one-story cottages, in the first instance isolated, and in the second built in a row. In many of the designs the scullery or wash-house contained a bath, usually in a rather cramped area; in one case the space provided for this purpose could not have had a width of more than 20 in., so that adult immersion would be somewhat difficult. It is a gain, however, to have any sort of bathing accommodation in a £125 cottage, and some venturesome architects even provided a separate bathroom. All the designs appeared to provide for a watercloset, but in some comments by the organizers of the exhibition we notice a suggestion that, in view of the expense (which is disproportionate to that of the main building) of providing a watercloset in country districts, housing reformers might consider whether a detached earth-closet would not meet the requirements of health and sanitation. The height of the rooms in a country cottage is another point upon which the rules appertaining to a town building might be relaxed, as country folk ought to be able to get a plentiful supply of fresh air without special architectural provision for it. In the design which

won the first prize the rooms had a uniform height of 8 ft., which is lower than what is considered the minimum for a town dwelling. This design also was for a flat-roofed cottage, and the windows were so placed that each room would get the direct sun during some hours of the day. The exhibition has performed the service of bringing to light the ideas of architects upon this special problem, and in the main the designs were to the purpose, although here and there one noticed various ornaments and accessories, rather reminiscent of that cottage with the double coach-house, at which

> The Devil did grin, for his darling sin
> Is pride that apes humility.

TUBERCULOSIS IN IRELAND.

"IRELAND enjoys the unique distinction of being the first division of the United Kingdom to apply the principle of notification to tuberculosis by means of an Act of Parliament." So writes[1] Sir John Moore, who, of all Irish medical authorities, is best qualified to criticize the workings of that Act. Notification, from his point of view, must be compulsory if it is to be effective either for statistical accuracy or for combating the disease in all its stages. As applied to Ireland the Act is only permissive, and it would appear that very little advantage has hitherto been taken of the means which it affords for tracing out and dealing with cases of consumption which are a recognized danger to those about them. Not only is there no compulsion, but even permission to deal with tuberculosis is limited to cases of the disease as it affects the lungs, and of these only such cases as are manifestly discharging bacilli, or are living in insanitary conditions, or are liable to handle foodstuffs. Other forms of tuberculosis are ignored, and the pulmonary disease in its early and curable stages is disregarded. It would thus appear that although first in the field, Ireland lags far behind as regards effective notification, and the need for extension of the powers of the Local Government Board in Ireland is clearly indicated. Government action, as is usually the case, has only been taken after many years of voluntary effort have shown the need for it. A voluntary association was formed in Dublin in 1892 to spread knowledge amongst local authorities, and a hospital for treatment of tuberculosis was opened in 1896. The foundation of the Women's National Health Association of Ireland by Lady Aberdeen carried knowledge and enthusiasm into all parts. Under its auspices sanatoriums have been built and are largely used by local authorities and county councils, who prefer to use the beds thus provided rather than incur capital expenditure in new buildings of their own. A grant from the Insurance authorities renders these institutions available also for beneficiaries under the Insurance Act. But in Ireland, as in many other countries, the provision of beds falls short of the requirements. The death-rate has steadily fallen since the year 1894, but the case incidence remains high. Domiciliary treatment becomes more or less illusory when the conditions of the domicile are incompatible with health. Power is needed to deal with the home as well as with the patient, but no such power has as yet been given, and the appointment of well-qualified county medical officers of health would seem to be the first step to be taken in the direction of domestic hygiene. The segregation of the advanced case is as urgently called for in Ireland as elsewhere, but there are only three institutions in the country into which dying cases are received. The statistics of recent years show a high percentage of deaths in workhouse infirmaries, and this is probably due to the more extended use of these institutions for advanced cases of consumption. In them, at any rate, effective isolation can be enforced. Statistical evidence, founded on notification, is manifestly misleading. The number of cases notified in certain areas falls far short of the number of deaths registered under the heading of tuberculous disease. The information afforded by death registration would seem to prove that in Ireland the female cases preponderate, and among these the highest mortality is amongst the younger patients, whereas in the case of the males the deaths are more numerous in the later years of the susceptible period between 15 and 35. Sir John Moore summarizes his conclusions under several headings, the most important of which relate to the compulsory extension of notification, the appointment of whole-time county officers of health and the cleansing of the home of the consumptive before he is permitted to return to it after treatment in hospital or sanatorium. These points, amongst several others, he rightly regards as essential if the crusade against tuberculosis in Ireland is to succeed.

SCHOOL CHILDREN AND QUACKERY.

THE schoolmaster—and still more, perhaps, the schoolmistress—is abroad at the present day. Children are, in the name of morality and hygiene, initiated in the mysteries of reproduction. The simple explanation of the cabbage stock or the gooseberry bush as the source of babies has been replaced by demonstrations on the sexual system of plants, and the mysteries of the doctor's bag have been dissipated by the light of science which has invaded the modern nursery. Whether this early distribution of the fruits of the tree of knowledge is for good or for evil we do not propose to discuss here; that will be seen only when the young generation now at school has risen to its full stature and is confronted with the problems of life. Another effort in the direction of opening the mind of the child to questions which have hitherto been left for adults to settle in their own way is a plan of systematic education in the evils and dangers of quackery. We learn from the *Journal of the American Medical Association* that in the high schools of La Fayette, Indiana, an effort is being made to instruct the pupils as to the methods of vendors of quack remedies. The idea of this novel addition to the school curriculum, the conception of which belongs to Professor Pierson of the Department of Physiology, is to prevent the influence of fraudulent pretensions on the human mind by teaching the infant Hercules to strangle the snakes of quackery in the cradle. Pupils are invited to bring to school all newspaper advertisements of patent medicines and "quack" doctors. The iniquity of these advertisements and the absurdity of the claims put forward on behalf of quack preparations are then explained to them. These demonstrations have, it is said, been received with great enthusiasm, and we can well believe that they are a welcome relief from the routine of school studies. Combined, as it would seem they are, with instruction in physiology, they can scarcely fail to sow the seeds of a knowledge of the nature of disease and of the processes of cure that will later bear fruit in protecting men and women—who, as the poet says, are but children of a larger growth—from becoming the bondslaves of credulity and superstition. On the other hand, the teaching must be carefully adapted to the young mind so as to give enlightenment without engendering morbid introspectiveness in the matter of health. In many minds the revelations of the folly and wickedness of quackery would arouse a perverted curiosity, the results of which might be mischievous. And in the most favourable conditions too much must not be expected from such teaching, for if man is, as defined by the philosophers, *animal rationale*, he is also by his very nature prone to be the victim of suggestion. As Montaigne puts it, *l'homme se pipe*—man gulls himself, and doubtless will continue to do so to the end of the chapter. To too many mystery is more attractive than common sense.

THE OXFORD OPHTHALMOLOGICAL CONGRESS.

The annual Ophthalmological Congress was held at Oxford on July 9th and 10th, under the mastership of Mr. R. W. Doyne. It was attended by rather more than the average number of members, and proved to be one of the most successful yet held. The addresses given in the mornings were extremely interesting and led to some spirited discussions. On the first afternoon operations were described by several surgeons and some cases of interest were shown. On the afternoon of July 10th an important discussion on the question of compensation in injuries to the eye was opened by Dr. William Robinson of Sunderland, who was followed by Dr. Frank Shufflebotham of Newcastle-under-Lyme. Messrs. Angus MacNab, Jameson Evans, Gray Clegg, G. H. Pooley, and R. P. Coulter also spoke. The annual dinner of the congress was held in the Hall of Keble College on the evening of July 9th, Professor Arthur Thomson being in the chair. After the dinner a discussion on the future of the congress was held, and it was decided, owing to the great success of this and former meetings, that they should continue to be carried on as before. This year the addresses were given and the scientific and commercial museums displayed in the Department of Human Anatomy in the University Museum, kindly lent by Professor Arthur Thomson; that all were under the same roof was a great improvement on the previous arrangement. Amongst the distinguished visitors to the congress from abroad were Dr. Carey Wood, Dr. Rendell Reber, Dr. Brown, and Dr. Gifford from the United States, and Dr. Darien from Paris. The meeting, which ended on July 10th with the usual smoking concert in the evening, reflects great credit on the master and on the energetic secretary, Mr. Sydney Stephenson.

CHAIR OF PHYSIOLOGY AT LIVERPOOL.

Dr. J. S. Macdonald has been appointed to succeed Professor Sherrington as Holt Professor of Physiology in the University of Liverpool. Dr. Macdonald, who is now Professor of Physiology in the University of Sheffield, was at Emmanuel College, Cambridge, and graduated in the mathematical tripos in 1889. In the following year he was elected to a Holt fellowship in physiology in the University of Liverpool. He took the triple qualification of Scotland in 1897, and after holding the post of house-surgeon to the Liverpool Royal Infirmary was appointed demonstrator of physiology in Dundee University College. He was afterwards assistant lecturer in physiology in the University College, Liverpool, until his appointment in 1903 to the chair of physiology in Sheffield. During his residence in Liverpool he at one time held a research scholarship of the British Medical Association; he was president of the Section of Physiology at the annual meeting of the Association in Liverpool in 1912. His contributions to physiology have been concerned chiefly with nerve and muscle.

The Library of the British Medical Association has received, through the kindness of Professor Saundby of Birmingham, Section VI—Medicine I and II—of the *Transactions* of the International Congress of Medicine in London. The volumes so far received include Section XXIII, the general volume, Part II of the Section of Orthopaedics and the Section of Dermatology. The Librarian will be glad to receive any of the other volumes of the series.

The luncheon at which Sir Alexander Ogston is to be entertained by his former dressers and house-surgeons will take place at the Grand Hotel, Aberdeen, at 1.30 p.m. on Thursday, July 30th, when the chair will be taken by Sir James Porter, K.C.B., late Medical Director, R.N. Any former dresser or house-surgeon who wishes to attend to show his esteem and affection for Sir Alexander Ogston, and has not yet informed one of the honorary secretaries, is asked to communicate at once with Dr. J. W. Cook, 26, Manchester Road, Bury, Lancs.; or Dr. W. Sinclair, Royal Infirmary, Aberdeen.

Medical Notes in Parliament.

[From our Lobby Correspondent.]

Prospects of the Session.

As has already been announced the present session is to be wound up after the passage of the Finance and various more or less non-contentious measures after dealing with the Home Rule Amending Bill. The Revenue Bill will be taken in a new session which begins in the winter. It is expected that this session will begin towards the end of November and will be devoted to the Revenue and Housing Bills. There will be, of course, the usual massacre of the innocents, but it is generally anticipated that the Milk and Dairies Bills (England and Scotland) will be passed, as little or no opposition is anticipated on the Report stage.

The Criminal Justice Amendment Bill, which is in charge of Mr. McKenna and which has passed through Committee, is in a much more precarious position. At this stage in the Session the fate of a bill on Report depends largely upon the number of amendments which appear on the Order Paper. In the case of this bill there are several pages of them and, although the Home Secretary will doubtless make every effort to get them cleared off, success is very doubtful. It would be unfortunate if the bill were lost, for it embodies several useful reforms in respect to prisoners, especially juvenile prisoners, which are generally accepted; there is, however, a small, but powerful party in the House which is much opposed to legislation of this character.

Milk and Dairies Bill (England).

The Milk and Dairies Bill was considered in Committee on July 9th, and completed on July 14th. On the first of these days the remainder of Clause 2 was disposed of, and was added to the bill without amendment. Clauses 3 and 4 also were added with no material alteration, except that sundry verbal amendments were introduced to make it clear that the invasion of the area of one authority by the officers of another was not intended as a part of the machinery of the bill.

On July 14th amendments to Clause 8 were introduced to secure that the regulations dealing with the importation of milk from abroad should also apply to milk products and to those which were to be sold for the manufacture of products for human consumption.

Considerable discussion took place on Clause 9, under which local authorities are empowered to maintain dépôts for the sale of milk specially prepared for consumption by infants. A good deal of opposition was manifested by some members to this clause, but it was finally adopted by a majority of 22 votes to 7. It is not likely that opposition will be met with on the Report stage, as there is evidently a very general desire among all parties to see the bill passed during the present session. No material alterations were made on Clauses 10 to 14, except that an important alteration was made in subsection 5 of Clause 14, with a view to defining the local authority which is required to enforce the provisions of Clause 1 with respect to the sale of tuberculous milk. As amended the subsection reads as follows:

> The duty of taking proceedings for enforcing the provisions of Section 1 of this Act shall rest on the county council or county borough council, without prejudice, however, to the power of a a sanitary authority in a county to take such proceedings, and the duty of taking proceedings for enforcing the provisions of any Milk and Dairies Order shall rest on the local authority prescribed in the order, and the clerk of the local authority or other officer whom the local authority may appoint shall have power, if so authorized by the local authority, to institute and carry on such proceedings.

Some important additions and alterations were made in the definitions in Clause 15. A discussion took place on

the qualifications of veterinary inspectors, and the feeling was expressed that the qualification of membership of the Royal College of Veterinary Surgeons as required, with the addition of the words, "or having such other qualifications as may be approved by the Board of Agriculture and Fisheries," might possibly be too wide and allow of the employment of persons not properly qualified. Mr. Herbert Samuel contended that the supply of properly qualified veterinary surgeons was inadequate, and that the words were necessary in the interests of some inspectors who are now employed but who had not the statutory qualification, whilst they might fairly, on their own account, be considered as competent to discharge the duties during their tenure of the office. On the motion of Mr. Bathurst, however, supported by Dr. Addison and others, the word "veterinary" was inserted before the word "qualifications," so as to make clear what was intended and to leave the way open for those who might perhaps hereafter become possessed of a degree in veterinary science.

Subsection 4 of Clause 15 was very materially amended. Notice of amendments had been given by Mr. Dawes, Mr. Astor, Dr. Addison, Mr. Hills, Mr. Courthope and others, with a view to providing that the local authority should be the council of the county or county borough, with power to delegate its duties with the consent of the Local Government Board and the sanitary authorities within their area. The section was subsequently submitted in an amended form by Mr. Herbert Samuel, and was approved of. It now reads as follows:

(4) The expression "local authority" in Section 9 of the Contagious Diseases (Animals) Act, 1886, and in this Act shall include sanitary authorities and county councils, but with respect to the provisions of any Milk and Dairies Order, the order may prescribe by what local authority or authorities the several provisions thereof are to be enforced and executed, and any such order may provide for the giving of assistance and information by county councils to sanitary authorities and by sanitary authorities to county councils for the purpose of their respective duties under this Act or under any Milk and Dairies Order.

In Clause 16, which relates to the application of the Act to London, a new subsection was moved by Mr. Herbert Samuel, which reads as follows:

(4) A Milk and Dairies Order affecting London shall provide for the exercise and performance by sanitary authorities in London of all powers and duties under the order which would have been imposed or conferred on sanitary authorities if this Act had not been passed and the order had been made under Section 28 of the Public Health (London) Act, 1891, as amended by Sections 5 and 6 of the London Government Act, 1899, except that the order may provide for the exercise and performance by the London County Council of powers and duties relating to the inspection of cattle in dairies. Nothing in this Act, or in any Milk and Dairies Order, shall affect the powers with respect to the registration of dairymen and purveyors of milk within their own areas conferred on sanitary authorities in London by Section 5 of the London County Council (General Powers) Act, 1908.

Two further subsections were added on the motion of Mr. Dawes:

(6) The borrowing of moneys by any metropolitan borough council for the purposes of this section shall be subject in all respects to the provisions of Sections 183 to 189 of the Metropolis Management Act, 1855, as amended by any subsequent Act.

(7) Where the authority in default is a metropolitan borough council the provisions of the Public Health (London) Act, 1891, shall apply in all respects as if such default had been made under the said Act.

Clause 17 was added without amendment, and a new clause relating to the compensation due to officers was inserted on the motion of Mr. Dawes:

If in consequence of the passing of this Act or of anything done in pursuance or in consequence thereof any officer or servant of any local authority who held office at the passing of this Act suffers any direct pecuniary loss by abolition of office, or by diminution or loss of fees or salary, he shall be entitled to have compensation paid to him for such pecuniary loss by the local authority, and such compensation shall be determined pursuant to the provisions of Section 120 of the Local Government Act, 1888.

Subsection (2) of the third schedule was also materially altered, and now reads as follows:

The local authority in whose district the sample was taken may take or cause to be taken one or more samples of milk in course of transit or delivery from the seller or consignor within forty-eight hours after the sample of milk was procured from the purveyor, who may serve on the local authority a notice requesting them to procure within a period not exceeding forty-eight hours a sample of milk from the seller or consignor in the course of transit or delivery to the purveyor, unless a sample has been so taken since the sample was procured from the purveyor, or within twenty-four hours prior to the sample being procured from the purveyor; and where a purveyor has not served such notice as aforesaid, he shall not be entitled to plead a warranty as a defence in any such proceedings:

Provided that the purveyor shall not have any such right to require that such a sample shall be taken in cases where the milk from which the sample procured from the purveyor was taken was a mixture of milk obtained by the purveyor from more than one seller or consignor.

If a purveyor has served on the local authority such a notice as aforesaid, and the local authority have not procured a sample of milk from the seller or consignor in accordance with the foregoing provisions, no proceedings under the Sale of Food and Drugs, 1875 to 1907, shall be taken against the purveyor in respect of the sample of milk procured from him.

The last subsection of the schedule was also amended so as to read as follows:

(6) If a sample of milk of cows in any dairy is taken in course of transit or delivery from that dairy, the owner of the cows may, within forty-eight hours after the sample of milk was procured, serve on the local authority a notice requesting them to procure within a period not exceeding forty-eight hours a sample of milk from a corresponding milking of the cows, and the foregoing provisions shall apply accordingly.

Provided that the person taking the sample shall be empowered to take any such steps at the dairy as may be necessary to satisfy him that the sample is a fair sample of the milk of the cows when properly and fully milked.

Finally, the first schedule enumerating the diseases of cows for the purposes of Section 1, was added and is as follows:

Acute mastitis.
Actinomycosis of the udder.
Anthrax.
Foot and mouth disease.
Suppuration of the udder.
Any other disease affecting cows which by a Milk and Dairies Order is declared to be a disease for the purposes of Section 1 of this Act.

Milk and Dairies (Scotland) Bill.—Major Hope asked the Lord Advocate whether, under Clause 3 of the Milk and Dairies (Scotland) Bill, as amended in the Standing Committee, it will be competent for a local authority to retain the services of two or more veterinary inspectors, each carrying out their duties in different areas.—The Lord Advocate replied that the effect of the clause in so far as it related to this matter was not entirely free from doubt, but the point could conveniently be dealt with on the Report stage of the bill.

The Mercantile Marine.

In the discussion on the Board of Trade vote on Thursday, July 9th, a considerable part of the time was occupied in a useful debate on the unsatisfactory conditions as regard health which prevail in many vessels in the British mercantile marine, and interesting statements with regard to sight tests were made by Mr. Peto and Mr. Burns.

Health Conditions on Ships.

With regard to the health conditions in the mercantile marine, Mr. Sandys, who raised the question, said:

As our minimum berthing requirements under the Merchant Shipping Act are 72 cubic feet and 12 square feet of floor space, in order to make a proper comparison between the position of the British seamen and the Norwegian seamen we should compare 72 cubic feet and 12 square feet with 140 cubic feet and 18 square feet, which shows, I think, that other nations are going rather ahead of us in the care which they are taking as to the accommodation of the crews on board their merchant vessels. Then, again, the right hon. gentleman's predecessor last year referred to the improvement of the sanitary arrangements of merchant vessels as being urgently required, and in regard to all these matters the legal minimum laid down by Statute becomes, in effect, the practical measure. That shows what an unsatisfactory state of affairs exists in many merchant vessels, and what the results of the conditions are is very clearly shown by the comprehensive and interesting report issued by the medical officer of the Port of London. He dealt with the question of crew space, and he also gave us a table recording the deaths of seamen from various diseases. I do not want to deal with the table, but I will just take from the medical officer's report a summary of the situation. He says:

Excluding diseases of the heart it will be seen that the number of deaths attributed to tuberculosis is larger than that of any other disease, pneumonia coming next with 113, while the total deaths from

diseases of the respiratory system were 265, or 24 per cent. of the total deaths from disease. This proportion of deaths in a class of men who are leading an open-air life is striking, and the prevalence of such diseases among them is no doubt largely encouraged by the want of ventilation in the quarters in which many of them are compelled to sleep and live when actually not on deck.

Those are very weighty words coming from a medical officer who has such experience as the medical officer of the Port of London. The right hon. gentleman's predecessor last year stated in the course of the debate that in his opinion matters were not satisfactory in many vessels with regard to the accommodation provided for the crew. I do urge that something should be done. It is quite obvious that other seafaring nationalities are taking the lead of us in these questions, and I think that this is a matter which might well be discussed at this International Conference. Indeed, in the medical officer's report to which I have referred, that gentleman specially suggests that the whole question of the accommodation for crews on board merchant ships should be regarded from an international point of view, and should be dealt with at the forthcoming International Conference.

Mr. Peto, in support of Mr. Sandys, said the question of ventilation on shipboard has been dealt with in Australia on the basis that for every man there should be 3,000 cubic feet of air passing through in a certain period. If that were done and we had properly ventilated quarters, the great mortality from consumption, pneumonia, and other diseases of that kind would become a thing of the past. It has already been pointed out that we are behind at least two other countries in this matter. That is a very good reason why we should not proceed on the plan hitherto adopted of doing nothing, but that we should seize the present opportunity of discussing this subject with other countries and arranging to proceed on one uniform method.

In replying to this part of the discussion, Mr. Burns said: I had the advantage of being for eight years Minister of Health at the Local Government Board, and by virtue of that experience I was able to take a general view of the conditions of health, not only of the communities in the municipalities, but also in relation to the various aspects of industrial life, and on going to the Board of Trade I was struck by one very remarkable fact. On looking at the figures of our industrial population I found that from 1891 to 1911 the death-rate of men in the Royal Navy between certain ages had diminished from 4.7 per thousand to 2 per thousand, which is a very considerable and creditable decline. The death-rate in the Army had diminished in a more remarkable way. It had gone down from 9 per thousand to 3.6 per thousand in the same period. Among the civil population of similar ages there had been a decline from 8 per thousand to 4.7 per thousand. So, speaking generally, the men and boys in the Royal Navy, the Army, and the civil population, of similar ages, had shown a tremendous and gratifying decline in the death-rate from diseases. Then it struck me that we ought to see how poor "Jack" fared in the same period, and I found, to my disagreeable surprise, that the death-rate from disease in the mercantile marine during the same period was practically stationary, and that there had been a decline only of from 4.9 to 4.7 per 1,000. Knowing the circumstances—for I have been to sea and I know a great deal of the seaport population—the question arises, Are we drawing from a poorer class of population for the mercantile marine as compared to that from which we were drawing many years ago, or are we drawing from classes inferior to those from which we are drawing for the Army, the Royal Navy, and the industrial civil population of the same ages? I thought if that be so, then there is something about the mercantile marine that prevents men of similar ages, of a certain class and type of physique, going into it, as compared with the Army, the Royal Navy, and civil life. If that be so, then short of legislation and pending legislation, it is really up to shipowners and those responsible for conducting the mercantile marine to see that, by every means within their power, it shall be possible no longer to say that the mortality from disease in the mercantile marine does not show the same decline as is shown in the other three grades of the population. I ventured to direct the attention of a great meeting of shipowners in the Hôtel Métropole to this point two years ago and a year ago, and here from my place in the House as President of the Board of Trade I appeal to both owners of ships and holders of shares in ships, and the leaders of all the sections, to do everything in their power, by voluntary, or personal, or business action, to bring the health and the hygienic and sanitary conditions of our sailors on board ship, so far as their accommodation, their food and their treatment are concerned, abreast of all other sections of the population, so that, speaking generally, we should rather have the mercantile marine conditions superior to those of the other three grades, because it is on the sea that Britain has its supremacy; it is on the sea that we depend; and if there is one branch of our social, industrial, and commercial life in which wages ought to be good, food excellent, and sanitary conditions of the highest possible standard, it is for and among those men who go down to the sea in ships. Hon. members may say, "That is very good so far as sentiment is concerned, but what did you do?" I appointed at once a Committee, not of the House of Lords or of the House of Commons, but a small Committee of specialists with medical officers, statistical experts, and others, to find out why it is that during the period which I have mentioned, in three classes of the population the death-rate from disease has declined remarkably, while it has been practically stationary in the mercantile marine. That Committee has been instructed to get to work to examine the whole subject, and I hope soon to have from them a practical and suggestive report. But in the meantime we have no right to wait for that committee's report, if in the interval we can find out anything can be done. I am glad to say that on the subject of hospital accommodation for the crews much has been done, and more than the hon. member for Wiltshire has suggested. For instance, in regard to crew hospital accommodation on cargo steamers, in January, 1912, the Board of Trade issued a notice to shipowners that in cargo vessels suitable hospital accommodation should be provided for sick and disabled seamen. What has been done? Of 150 large vessels built in 1902 there were only ten with crew hospitals, or 7 per cent.; of 160 built in 1912, twenty-eight, or 17 per cent., had crew hospitals provided; of 213 built in 1913, sixty-eight, or 32 per cent., were provided with crew hospitals. We intend by every means within our power to accelerate the provision of hospitals, not only on emigrant ships and large steamers, but on a large number of tramp steamers, where the men, perhaps, require hospital accommodation even more than on the great liners.

Sight Tests.

The position with regard to the Board of Trade sight tests seems to have been cleared up a good deal by the demonstration which was recently arranged by Mr. Burns at Shoeburyness. On this question Mr. Peto said:

Another question which has been raised in this House for the last two or three years—it has been a thorny question in Board of Trade administration—is the question of sight tests for officers of all grades. Since the right hon. gentleman assumed his present office we have had an example of his method of practically dealing with the question. I frankly admit that the practical sight test he was good enough to allow me to inspect, which was held at Shoebury two or three months ago, did more to clear up this question than any amount of speeches from both sides of the House and a great deal of writing by experts of various opinions, because we found that, as usual, the expert opinion was divided on the matter. The merchant service generally has taken the view that before a man lost his certificate it was only reasonable that he should have a practical test under seafaring conditions. That sounded so reasonable and sensible that I frankly admit I was very much taken with it myself, and thought it was a fair proposal. I went to see the test, which was not actually carried out under seafaring conditions, but under practical conditions, when red and green lights were exposed at a distance of a mile, and I saw that, whereas the tests went on for a couple of hours, even in those two hours the conditions were entirely different during the middle period from those that prevailed at the beginning or at the end of the test. Light vapours came over the low-lying land, the moon rose up to a different position, the clouds cleared away, and what was comparatively easy at 9.30 in the evening was almost an impossible task for anybody, no matter how good their sight might be, only an hour later. That, I consider, knocked the bottom out of the practical test, so far as I was concerned. I ask the right hon. gentleman, he having abandoned what is called the single-eye test, and having made the test for form vision much more reasonable than was proposed, to seriously consider whether it is a fair thing to ask men, whose vision is required for the navigation of ships under seafaring conditions, to let the whole question of whether or not they are to have a certificate depend upon whether they can read certain letters at a distance of 16 ft.

I submit to the Committee that this matter cannot be dealt with on purely scientific lines. It is well known that after a man has been at sea all his life he develops what is called "sea vision." He might not be able to pass the oculist's test, with which we are all familiar, but at the same time he might put us, who consider that we have good vision, to shame by picking out objects at sea under seafaring conditions at distances at which we should see nothing at all. There is room in that respect for an improvement in the vision tests, so as to make them more reasonably agree—I am not speaking of colour tests, but of form-vision tests—with what people really have to see. They have not got to read letters on a card; they have to detect all kinds of objects and appearances at sea, under all conditions, both by night and day. With regard to colour vision, if reasonable time were given, if the candidates were in no way hurried, and if the right hon. gentleman could see his way to use his powers to make the actual form of lantern, or rather what is exhibited in the lantern used for the test conform in one particular to seafaring conditions—namely, if he would have the images which are shown representing the port and starboard lights at the distance of a mile, if he would have these miniature images resemble what would be a ship's light on a ship with a 50-ft. beam instead of 25—he would make the test a reasonable one. At present the candidate has to distinguish these red and green lights, or the miniature representations of them, on what is supposed to be a vessel with a 25-ft. beam and a mile away. I submit that vessels with a 25-ft. beam to-day are practically barges, and that 50 ft. would be a great deal under the ordinary average of the beam of vessels which it would be important for them to detect at the distance of a mile.

In reply, Mr. Burns said that a few members seemed to be under the impression that the sight test adopted by the

Board of Trade was unfair to the officers and needlessly stringent, and continued as follows:

I did what I hope Ministers will do increasingly—that is, when confronted with a practical difficulty, and there is a doubt about it in the minds of practical men, subject the question at issue between the two sections to a practical test. I am grateful to the hon. member for admitting so frankly as he did to-day, and as it has been admitted by outside critics during the last three or four years, that the Board of Trade sight test under the material conditions came out of the demonstration with flying colours. The Board of Trade were justified in the present form of test, and to that test we intend to adhere. It is not that we want to be severe on the seaman. On the contrary, the seaman properly evokes the human sympathy of everybody by virtue of the peculiar nature of his calling. We do not want to be unjust to the officers, because it is not the business of any Department to have such an absurdly high standard of examination for anything as to prevent men coming into a particular service such as the mercantile marine. But we have a duty towards the public, and towards the officers and men themselves, and we have a right to say that where a man cannot comply with a reasonable, fair and just sight test such as now operates, his place is not on the deck of the sailing or steam vessel. His place is in an occupation where his defective vision, if put to the test, would not be the danger to the general communities and himself which it would be upon the bridge or upon the deck of either a sailing or a steam vessel. I am satisfied after a practical demonstration, at which our critics had the opportunity of seeing how the Board of Trade test was conducted, that we have done the right thing, not only in the interests of the community, but in the interests of the officers, the owners, and the men themselves. It is very satisfactory to know that that view is endorsed now by men who were critics and opponents of the Board of Trade test.

In reply to Mr. Lynch, who asked how many of those rejected for colour blindness, as indicated in the last report, failed with the lantern but passed the wool test, and *vice versa*, and whether he would consider the advisability of giving this information in the reports in future, Mr. Burns said that he assumed that the question referred to the sight tests used in the mercantile marine; 138 candidates passed the wool test and failed in the lantern test. Of these, 24 subsequently passed on appeal, and thus 114 finally failed; 101 candidates passed the wool test, and in the lantern test were "referred" for further examination. At the latter examination 76 passed and 25 failed. No candidates failed in the wool test and passed in the lantern test; 3 candidates were "referred" in the wool test and passed the lantern test, all 3 subsequently passing a special examination. The number of candidates who passed, failed, or were "referred" in the lantern and wool tests, respectively, would be given in the next return. "Referred" meant that the candidate was not definitely passed or rejected, but was referred to London for a special examination. The old form of wool test had been abandoned. He had had the pleasure of taking the objectors to, and critics of, the wool test, and the critics of the lantern tests, down to Shoeburyness, and after a pleasant night on the marshes, the objectors were silenced and the critics satisfied.

Crew Spaces on Merchant Vessels.—In reply to Mr. Sandys, the President of the Board of Trade said that it had not been necessary to institute any prosecutions during the past five years for non-compliance with the regulations as to crew spaces, as any irregularities could be dealt with by the power of adding the tonnage of the space to the registered tonnage of the vessel; this power had been found to meet the case sufficiently.

Education Grants.—In reply to Mr. Leach, Mr. J. A. Pease supplied the following figures relating to elementary education:

Elementary Schools.

	Expenditure by School Boards out of Rates.	Grants by Board of Education.
1902-3 ...	£6,620,912	£3,938,014
	Expenditure by Local Education Authorities out of Rates.	Grants by Board of Education.
1911-12 ...	£12,596,715	£11,775,017
Increase in rates ...		£5,975,803
Increase in grants ...		£2,837,003

Between the same years the actual average attendance of children of 5 years of age and over in elementary schools increased by 11.52 per cent., while that of children under 5 years of age decreased by 41.61 per cent.

The Government and Rural Housing.

On July 8th Mr. Runciman, under the ten minutes' rule, introduced a short bill to give power to the Board of Agriculture and Fisheries with respect to the provision of houses in rural districts where the deficiency was serious and pressing and at Rosyth. Under the bill the Treasury is empowered to borrow money by means of terminable annuities for a term not exceeding thirty years the sum of £5,000,000 which the Board of Agriculture and Fisheries is empowered to deal with in respect of £3,000,000 for rural housing and in respect of £2,000,000 for Rosyth. It is intended that the cottages to be built shall be let at an economic rent, but it is not the intention of the Government that the economic rent should cover the provision of a sinking fund on the land value, which may be regarded as remaining, and the rents are not intended to cover the repayment of capital over a period of thirty years, but over such a period as might fairly be said to represent the life of the cottage. In introducing the bill, Mr. Runciman said:

I should not have asked leave to introduce this bill at this late date of the session had it been of a highly contentious nature, but there are some directions in which the Departments require power, if they are to carry out the declared intention of the Government to proceed with rural housing, not along the lines already authorized by statute, or by depending on private enterprise to exercise powers which the Government think can properly be exercised by the Board of Agriculture, the Local Government Board, and the Board of Works. This bill is a small measure of some seven clauses. The first clause provides for dealing with rural housing. The Government have felt for some time past that neither private enterprise nor the activities of the local authorities would in any degree meet the pressing case of housing in the country districts. Either private owners were not able, owing to lack of funds, to do their building, or the local authorities had themselves shown no anxiety whatever to embark on schemes in purely rural areas. Those few private landowners who had themselves indulged in cottage building were the exception and not the rule, and the pressing case of the rural labourer, particularly in country districts, has become increasingly grave. As neither the private landowners nor the local authorities can provide the houses, the Government have decided that it must be done by the central authority, and so far as the agricultural districts are concerned, they have decided to ask the House of Commons to give power to the Board of Agriculture and Fisheries to deal with those districts.

The other object of the bill is to provide for the pressing case of Rosyth. (Hon. Members: "Hear, hear.") I am encouraged by that expression of view on the other side of the House to hope that, so far as Rosyth is concerned, they will enable us to carry the bill at the earliest possible date. Rosyth can best be dealt with by the Government by means either of a public utility company—and already negotiations have proceeded some distance with those who would be prepared to undertake this by a public utility company—or, failing that, a company or association who will be prepared to carry out this work through the Board of Works; and already the necessary practical steps have been set afoot, so that without any unnecessary delay the case of Rosyth may be met, and the employees of the Government, who will shortly find themselves there in large numbers, can be properly housed and have abundance of cottages in which to live.

Mr. J. Hogge: Is that the English Board of Works?

Mr. Runciman: The British Board of Works. It is impossible to carry through these large operations without the use of public funds, and the Government is of opinion that inasmuch as £3,000,000 is to be devoted under this measure for the purposes of rural housing, there would be cheap money thereby provided, to be under the control of the Government department itself and not of private individuals. It is proposed to provide at least £3,000,000 for the Board of Agriculture and Fisheries to deal with the rural housing problem; and, so far as Rosyth is concerned, a sum not exceeding £2,000,000. The Treasury has undertaken to borrow money by means of terminable annuities for a term not exceeding thirty years. This does not mean (although the scheme will be conducted on an economic basis) that the rents will provide for the repayment of the capital over a period of thirty years. It is the intention of the Government, while letting the houses on an economic basis, to make the period more nearly approach the actual age of the cottages which the employees will occupy. With regard to a sinking fund on land, the Government

hold the view that this need not be a charge at all on the occupiers of the cottages, and therefore there will be no charge whatever for a sinking fund on land with respect to any of these cottages. This is a very small proposal. I do not think that it will prove to be very highly contentious, and I hope that not only those who sit on this side of the House but on the other will assist to put both operations on foot as quickly as possible.

Medical Inspectors of the Local Government Board.—In reply to Mr. Astor, the President of the Local Government Board said that the number of sanitary authorities in England and Wales was 1,870. The medical inspectors of the Local Government Board were not specially deputed to make routine inspection of the work of each of these authorities, but in the performance of their various duties, such as the holding of local inquiries, investigations into sanitary circumstances and outbreaks of disease, the inspection of vaccination, the visiting of localities, and conferences with local representatives for various other purposes, they were brought into constant touch with the sanitary authorities and their administration.

Local Government Board Housing Department.—In reply to Mr. Lane Fox, the President of the Local Government Board said that the special Department of the Local Government Board which dealt exclusively with housing and town-planning questions consisted of twenty-three officials, in addition to a staff of eight inspectors, whose time was wholly devoted to this work. The services of the Board's technical officers in the medical, engineering, and architectural staffs were also partly given to housing questions.

Elementary Schools.

Physical Instruction and Playgrounds.

In reply to Mr. King, the President of the Board of Education said that physical training was one of the subjects mentioned in Article 2 of the Code. That Article stated, however, that it was not necessary that all the subjects mentioned should be taught in every school or class. The importance which the Board attached to instruction in this subject was shown in the introduction to the Syllabus of Physical Exercises. In view of what was said there it would be very difficult to satisfy the Board that at any particular school physical training was not required by the needs of the scholars. He did not know of any school in which physical training was not now included in the curriculum, though its efficiency and adequacy varied considerably. He did not think there was any necessity to interfere with the discretion of the local education authorities.

Mr. King asked also a number of questions with regard to deficiencies in the playground accommodation and the facilities for giving physical instruction in various London schools, and was informed that there were thirteen voluntary schools under the London Education Authority which had no playground. The circumstances of the cases were dealt with in official correspondence now under the consideration of the London County Council and the managers. Care would be taken to ensure adequate provision for physical exercises and recreation.

Dental Certificates.

In reply to Mr. Raffan, the Parliamentary Secretary of the Board of Education said that a Departmental Committee had recently been appointed to consider the question of dental certificates, and would report very shortly.

Opium, Cocaine, and Alcohol.—In reply to Sir J. D. Rees, Mr. Harcourt said that the consumption of fermented liquors, especially beer and stout, had considerably increased in the Malay States since 1909, and the working of the Excise enactments was being carefully studied, with a view to the proper control of this consumption. It was also the fact that recent seizures pointed to a certain amount of illicit importation of cocaine. The main object of the Opium Convention of 1912 was to provide for the control of the trade in cocaine, morphine, and their derivatives concurrently with the restriction of opium to medicinal uses.

Bequests to Hospitals.—Lord N. Crichton-Stuart asked the Chancellor of the Exchequer whether he was aware that the Treasury was enforcing the payment of £30, being the duty on a donation of £300 given by the late Mr. William Townsend White to the funds of the King Edward VII Hospital in Cardiff; and whether, having in view the financial needs of this hospital, he would allow the duty to be remitted in this case.—Mr. Lloyd George said: Estate duty at 4 per cent.—that is, £12 and not £30—with interest from the date of the donor's death, is chargeable by statute in respect of the gift in question, and there is no provision of the law under which I could accede to the noble lord's request.

Vaccination.

Telephone Service.

Mr. CHARLES DUNCAN asked the Postmaster-General whether the rule of his Department and of the Civil Service Commissioners, that conscientious objection to vaccination should be respected, applied also to the telephone service; and, if so, why it was stated on the Regulations issued to candidates for situations as female telephonists in the London area that no exemption was allowed in respect of primary vaccination.—Mr. Hobhouse said that the rule applied also to the telephone service and was included in the printed Regulations. Owing to a misunderstanding an obsolete copy of the Regulations had been issued in certain cases, but had now been withdrawn.

Appointments of Old Members of Boards.

Mr. Black asked the President of the Local Government Board whether the Worksop Board of Guardians had delayed the appointment of a public vaccinator for the Clowne district of the union for a period of six weeks, in order to enable them to elect a former member of the board who resigned his seat in July last; and whether he would express to the guardians his disapproval of this attempted evasion of the rule of his department making ex-members of boards of guardians ineligible for appointments under their jurisdiction for one year after ceasing to be guardians.—Mr. Herbert Samuel said that the Worksop guardians had made a temporary contract for the performance of public vaccination in the district referred to, but he had no information as to their reasons for delaying to make a permanent appointment. The guardians had been informed of the Local Government Board's views as to the appointment as officers of ex-members of the board, and their attention would again be drawn to the matter.

Glycerinated Calf Lymph.

In reply to Mr. Keir Hardie, who asked a question about a method of killing extraneous microbes in vaccine lymph by ultra-violet rays, reported recently by Dr. Friedberger to the Berlin Medical Society, the President of the Local Government Board said he was advised that the glycerinated calf lymph supplied by the Local Government Board was satisfactory, and, in the circumstances, he saw no reason for suspending its production.

Exemptions.

Mr. Herbert Samuel, in answer to a question by Mr. Norman Craig, supplied the following figures with regard to exemption from vaccination for the years 1906 to 1913, inclusive:

Year.	Number of Births Registered during the Year.	Number of Exemptions Received during the Year.	Percentage of Statutory Exemptions.	Percentage of Children ultimately Unvaccinated.
1906 ...	935,081	52,391	5.6	16.8
1907 ...	918,042	57,675	6.3	20.4
1908 ...	910,383	162,799	17.3	27.9
1909 ...	914,472	190,689	20.9	32.3
1910 ...	896,962	230,947	25.7	36.3
1911 ...	881,138	248,483	28.2	38.9
1912 ...	872,767	275,929	31.6	42.9
1913 ...	881,480	308,235	35.0	Figures not available.

England and Wales.

LONDON.

London County Council.

Voluntary Boarders at the Maudsley Hospital.

The Asylums and Mental Deficiency Committee of the London County Council on July 14th recommended the Council to pass the following resolution:

> That application be made to Parliament in the session of 1915 for authority to make the Maudsley Hospital available for the reception and treatment as voluntary boarders of persons suffering from mental infirmity, upon such terms and conditions as the visiting committee may think fit, and to enable the County Council or any board of guardians in the County of London, if they think fit, to defray the whole or part of the expenses of maintenance in the hospital of such voluntary boarders.

The Committee pointed out that although the Lunacy Act, 1890, provided that a person not certifiably insane might submit himself to treatment for incipient insanity by entering as a voluntary boarder a licensed house or registered hospital, voluntary boarders could not be received in a county asylum, even by payment. It was extremely desirable that there should be power to permit voluntary in-patients to be received for treatment in the Maudsley Hospital, and the Board of Control, which had been informally approached, concurred in this view. As the Maudsley Hospital would be a county asylum for the purposes of the Lunacy Acts special powers would be required. The method proposed would be more simple and satisfactory in regard to cost of maintenance than the alternative of treating the patient after admission as a pauper, and calling upon the board of guardians to pay for him. The Committee could not say at this stage what the cost of provision for voluntary boarders was likely to be, but if a poor patient by early treatment could be saved from the necessity of certification as insane and from compulsory detention in a county asylum, some saving in the total cost of lunacy administration should result.

The Council passed the resolution.

The Medical Superintendent's House at the Maudsley Hospital.

The Committee had decided that it would be best for the medical superintendent of the Maudsley Hospital not to be resident on the hospital premises, but to find his own residence in the vicinity of the hospital. The Board of Control, however, held that the provisions of Section 276 of the Lunacy Act, 1890, that a medical superintendent must reside in the asylum, could not be varied without parliamentary authority. As there would be two resident assistant medical officers and there was not room on the estate for the erection of a house for the medical superintendent, nor could a house adjoining be obtained at a reasonable price, the Asylums Committee advised the Council to insert a clause in its next General Powers Bill exempting the Maudsley Hospital from the provisions of the section referred to. This was approved.

School Medical Treatment.

In order to comply with a requirement of the Board of Education that agreements for the medical treatment of school children shall be made for the year ending March 31st, the Council considered the arrangements to be made for the period from August 1st to March 31st, 1915. The Education Committee stated that for the year ending July 31st provision had been made for the treatment of a minimum of 98,606 cases at forty-two institutions. During the period ending March 31st next it was proposed to make provision for 72,215 cases, being at the rate of 108,216 cases a year, a net increase of 9,610 cases. During the past year the attendance of the children at hospitals and treatment centres had been satisfactory, but variations in the number of cases at different times of the year had caused difficulty. A minimum number of cases should therefore be provided for in the agreements, and additional sessions allowed in times of pressure. Experience had proved that the number of cases of ear, nose, and throat defects was steadily decreasing, and the number to be provided for had accordingly been reduced. The Board of Education having criticized the arrangements for nursing, the Committee proposed to establish four additional nursing centres, affording an increase in the number of children provided for of 3,960 a year, making the total for this branch of the scheme 19,190. During the year ended December 31st, 1913, 31,858 children were examined for dental defects, and 80 per cent. were found to require treatment. The present number of dental centres was twenty-five, providing for 42,020 cases. Four additional centres should be established and the provision at the London Hospital extended; the number treated would then be 49,720. The expenditure to be incurred under the new arrangements, excluding administrative charges, would be £31,700.

The Council decided to renew its agreements with the various institutions and centres, with modifications as indicated above.

MANCHESTER AND DISTRICT.

The Radium Fund.

The energetic campaign on behalf of the Manchester District Radium Fund which is being carried on by the *Daily Dispatch* is now succeeding in a remarkable way. Each day there is published a long list of subscribers, the amounts varying from 6d. upwards; last week-end brought in over £1,000. Collections are being made at garden parties, dinner and supper parties, golf matches, and at schools, theatres, and all sorts of entertainments. Employees at numerous works have made collections, and the nursing staff of the St. Mary's Hospital have evidently been spending most of their spare time in collecting for the fund. The total sum collected up to July 12th was £17,770 and as donations are coming in at the rate of several hundred pounds a day, and have rather increased than decreased daily, there can be little doubt that the required sum of £25,000, about which there was such anxiety at first, will soon be raised.

Ancoats Hospital.

The enormous amount of work now being done at the Ancoats Hospital has made it necessary to resort to special methods of obtaining financial aid, and arrangements are now completed for a carnival and daisy collections on Friday and Saturday, July 17th and 18th. At a meeting of the general committee the chairman made an appeal for the services of ladies to help in selling the daisies, which have been made by crippled children. A section of the fire brigade, and no fewer than forty-five bands, will take part in the carnival, and from the proceeds it is hoped to endow a bed and cot at the hospital, and to form the nucleus of a fund for providing a new ward.

The British Red Cross in East Lancashire.

A useful *Handbook and Rules* of the East Lancashire Branch of the British Red Cross Society has been prepared by Colonel Wm. Coates, C.B., who is chairman of the Executive Committee of the Branch and Honorary County Director. The East Lancashire Branch was constituted in April, 1910, and now comprises twenty-eight Divisions, covering the whole of East Lancashire as far north as Clitheroe and Colne. The handbook contains a sketch map showing the positions and a large diagram illustrating the use of voluntary aid detachments of the branch in time of war. In addition to the rules of the branch, full information is given for both men's and women's voluntary aid detachments as to organization, duties, training, equipment, examinations, etc. It will be almost indispensable to all members of the branch, and even to non-members is interesting, as showing the high degree of organization which the enthusiasm of the branch has reached.

The Royal Schools for the Deaf, Manchester.

These schools during the last fifteen years have risen into great prominence, and are now the largest schools for the education of the deaf in Great Britain. They were founded in 1823 in Salford, but their real home in the present fine building in Old Trafford was not opened until 1837. The schools have been fortunate in their presidents; the late Lord Egerton of Tatton devoted a great deal of his time to their welfare, and the present President, Lord Sheffield, better known, perhaps, as Lord Stanley of Alderley, is one

of the most prominent educationalists in the country. It is greatly due to his guidance of affairs, together with that of the Chairman, Sir James E. Jones, who received the honour of knighthood on the King's birthday, that so many remarkable developments of more than local importance have of late years come about.

Starting with about 50 children, the institution has grown until now it provides places for 367. During the first fifty-five years of the history of the school all the children were taught by signs and finger spelling, but about the year 1880 a gradual change in methods was brought about by the introduction of the "oral" or speech and lip-reading system. The passing of the Act of 1893, which made the education of the deaf compulsory, gave a great impetus to the new system. The Royal Commission presided over by Lord Egerton visited the chief schools in Europe and America, and reported strongly in favour of speech teaching. The school now grew rapidly, two or three new wings being added in quick succession. The Board of Education, too, came in in a supervisory way, and the standard of the teaching rose accordingly. Higher salaries were paid, and attracted better educated men and women to the work. The capacity of the original buildings and grounds, however, in spite of the extensions mentioned, would not carry more than about 240 children, and about ten years ago it was decided to separate the sign-taught children from the orally taught, and the Clyne House Branch School was built to accommodate 65 backward children. This represents a fairly regular ratio between normal and backward deaf—that is, 80 to 85 per cent. normal, 15 to 20 per cent. backward. The complete separation of these two classes of the deaf had a good effect on both. It raised the average of attainment in the oral school and also the self-respect of the children in the backward school, and allowed of concentrated effort on each distinct method of instruction.

The next advance was made in the direction of industrial training. The extreme importance of hand and eye training had always been very fully realized by the committee, and manual instruction and drawing had been a regular and important part of the curriculum long before these subjects were taught in hearing schools. But however well the deaf boys' hands were trained, a large number of them failed on reaching the age of 16 years to secure apprenticeship to handicraft trades—the ideal thing for the deaf. Through the generosity of the chairman, Sir James E. Jones, an industrial training school, in separate grounds, providing both workshops and a hostel of residence, was established, and has been remarkably successful. Some of the apprentice students are taught trades on the spot, and others go out to such trades as mechanical dentistry, lithography, cabinet making, and stained glass window making in town. The apprenticeship lasts from four to five years, and many of the lads hold technical scholarships from the various school authorities. This branch of the school work is so successful and important that the hostel is being enlarged by the chairman to accommodate sixteen more students. It should be remembered in connexion with the training of the deaf that 98 per cent. of them have to earn their living with their hands.

The last move towards efficient and complete classification was the establishment of the Henry Worrall School for Infant Deaf Children. Here children are admitted at 5 years of age. They are entirely in the charge of selected women teachers, and the nurses are specially chosen for their sympathy with the idea of making the education as much like that of normal children as is possible. Every one about the place always speaks to them, so that the tendency to use any kind of signs is very materially minimized. The bungalow school stands in a large walled garden. The results attained have been most surprising and gratifying to the committee, and lead them to believe that if all deaf children could be sent to school not later than 5 years of age the present 20 per cent. of backward deaf would be considerably lessened.

The 98 per cent. of what may be called working-class children leaves 2 per cent. of children from the richer classes. These are provided for. They have all the advantages of a highly classified and well equipped school, but except in regard to dining and sleeping have no special privileges. It is greatly to their advantage and that of the other scholars that they should all mix together for work and play. The corporate life of a big school may be said to be one of its most important features.

Deaf children on admission to school are very generally underweight and undersized. Their feeding and sleeping has been poor and irregular. If they are to survive industrially they must be pulled up to standard. The Committee therefore attaches great importance to good and proper feeding, and regular sleeping in well-ventilated rooms is equally important. A careful and well-organized system of medical supervision is in operation, and covers aural surgery, dentistry, dermatology, and care of the eyesight. The children are examined regularly by the medical officer and specialists, and a card index is used to tabulate weights, heights, and the various medical sides of the work. The result is that the children generally are turned out into the world physically fit as well as mentally and manually capable.

Ireland.

[*FROM OUR SPECIAL CORRESPONDENTS.*]

THE APPOINTMENT OF LOCUMTENENTS.

THE Local Government Board has written to the Enniskillen Board of Guardians asking it to reconsider its decision in the case in which Dr. Hackett, of Tempo, nominated as his temporary substitute Dr. Charles, of Lisbellaw dispensary district, and in which the relieving officer passed over Dr. Charles and appointed Dr. Betty, of Enniskillen. The Board further desired the guardians to give instructions to the relieving officers whether or not they should accept the nominations of medical officers. The following observations on this subject, which is considered important by all dispensary doctors, are taken from a leader in the *Fermanagh Times*, and are very appropriate:

> Common sense sees in it the only natural and logical positions of medical man and relieving officer, and cannot explain why the latter should be under any circumstances permitted to flout or ignore the suggestion, the recommendation, or the nomination of one who is in every relation, professional and official, his superior.
>
> The law either requires or permits a dispensary medical officer to nominate his substitute when going on leave—either sick leave or vacation. This should be the first and last word with the relieving officer. When the Board next meets, the relieving officer reports that he has appointed the nominee of the absent doctor, and it is then for the Board to sanction that appointment or to appoint another medical substitute. But for a relieving officer to take upon himself to override a nomination, even for a day, is quite preposterous. It is turning the Poor Law itself into an abnormality, and it is humiliating to the whole faculty of medicine.

PAYMENT OF DOCTORS' SUBSTITUTES.

Dr. L. T. Moore (Kilgarvan) wrote recently to the Kenmore Board of Guardians, applying for the usual leave of absence, and stated that Dr. O'Connor (Cork) would do duty for him. One of the guardians spoke strongly against granting leave to doctors unless they paid their substitutes and also appointed as their substitutes doctors other than those elected to their respective dispensaries in this district. It was proposed and seconded that each doctor applying for leave should pay his own substitute. An amendment in the nature of a direct negative was proposed and declared lost. The resolution was then carried.

KINGSTOWN HEALTH OFFICER.

At a recent meeting of the Kingstown (co. Dublin) Urban Council, a councillor, in moving a resolution that the appointment of a superintendent medical officer of health for Kingstown was necessary, that advertisements be inserted, at a salary of £75 a year, and that the resolution of February 13th, 1911, be rescinded, said that when this appointment became vacant in 1910 through the death of Dr. O'Donovan the council then considered that it should be filled, and inserted advertisements inviting applications for the position. The Local Government Board and the Sanitary Association of Dublin stated that it was the duty of the council to make the appointment; but in spite of this the council did not proceed with the election. As chairman of the Public Health Committee he saw that it was absolutely necessary to make this appointment. The

two dispensary medical officers were not always at the council's disposal, because they were not under the management of the board of guardians. Half of the salary of the new officer would be borne by the Local Government Board. Another councillor said that whether the council made the appointment or not it had to pay Dr. Corbet £40 a year and Dr. O'Connor £27 10s. a year as medical officers of health, and it was a very serious thing to contemplate this further appointment. The rescinding portion of the resolution was carried by 13 votes to 5, and the motion to make the appointment by 13 votes to 3.

MENDICITY INSTITUTION, DUBLIN.

The ninty-ninth annual report of the Mendicity Institution, published last week, states that during last year there was a falling off in the number of the artisan class relieved. The number who applied to be sent to other parts of the country was much in excess of that of the previous year. As many as 40,609 persons were supplied with two hot meals a day during the year, so that 81,218 meals were prepared and partaken of in the institution. Thus many a hungry family was saved from entering the workhouse, and the citizens were thereby relieved from increased taxation; 1,060 persons—comprising 518 men, 328 women and 214 children—were the recipients of the Christmas dinner provided by the Committee. During the year 381 persons were sent to their homes, or places of employment. Of these 118 went to different places in England, 125 to Scotland and Wales and 138 to various parts of Ireland.

Scotland.

[FROM OUR SPECIAL CORRESPONDENTS.]

THE ROYAL VISIT TO GLASGOW.

ON July 7th the King and Queen with Princess Mary paid a State visit to Glasgow, during which the King opened the new buildings of the Royal Infirmary, the memorial stone of which he laid as Prince of Wales seven years ago. In reply to an address of welcome from the managers, His Majesty expressed his pleasure at being able to continue the association which has connected the Royal family with this noble institution. It was an additional satisfaction that the buildings had been erected as a memorial of the Diamond Jubilee of the beloved Queen Victoria, who during her long reign was ever mindful of the voice of suffering. "I trust," the King concluded, "that the Royal Infirmary will long flourish as a testimony of Glasgow's care for its sick." A tour of several wards was made by their Majesties, the Queen entering into conversation with two of the patients. Among the presentations made was Nurse Kate Bell, who is a veteran member of the staff, having served under the late Lord Lister so long ago as 1866.

In the afternoon the Royal party drove in state to the new Royal Hospital for Sick Children at Yorkhill, and formally declared it open. Here they were greeted by a gathering of over 3,000 children. The King, in reply to a loyal address from the directors, recalled Queen Alexandra's warm interest in the institution. The directors and a number of the medical and surgical staff were presented. A pleasant ceremony was the unveiling of the nameplate of the "King George V and Queen Mary Ward" by Her Majesty. Passing through the hospital, the King was specially interested in the excellently equipped theatre, and listened with close attention to a description of it by Dr. T. K. Dalziel, the senior surgeon.

Leaving Yorkhill their Majesties drove to the Western Infirmary, where an address was presented, but the crowded nature of the day's programme caused their stay to be very brief. The Royal party afterwards drove through the grounds to the university, where they were received by Lord Rosebery, the Chancellor, and Principal Sir Donald MacAlister.

THE Lord Chancellor has approved the names of Dr. Maxwell Dawson (Buckhaven) and Dr. William Barrie Dow (Dunfermline) as justices of the peace for the County of Fife; of Dr. Robert Clark (Lossiemouth) and Dr. James Alexander Stephen (Elgin) for the County of Elgin; and of Dr. James Davidson Wyness for Aberdeen.

Correspondence.

SPECIAL FUND: TRADE UNION OR TRUST?

SIR,—I would appeal to those Divisions that have already instructed their Representatives to vote at the Aberdeen Representative Meeting in favour of a trade union to meet again before Representatives leave home and reconsider their decision. I have not the slightest doubt that the majority of those Divisions, when voting as they did, did so not because they have any regard for a trade union, but simply and solely because they were under the impression that the only way to safeguard their proposed fund was under a trade union. The most excellent and timely leading article in last week's JOURNAL must, once for all, dispel that "bogey."

It cannot be too clearly pointed out to the members of the Association that, should a trade union be formed, that trade union will be not in association with our Association, but antagonistic to it. One of two things must follow: Either the union will in the course of a short time die a natural death and with it our fund, or, if it is the success that its ardent admirers hope for, it will swamp the Association, which will once again revert to the management of a few scientific meetings. Our constitution, our machinery—everything, in fact, that we have been working for for the last ten years or more—will go. I am sure that point could not have been laid before members voting in favour of a trade union when the vote was taken at their Division meetings.—I am, etc.,

Orpington, Kent, July 13th. A. TENNYSON SMITH.

SIR,—In your issue for June 13th I placed before the advocates of trade unionism for the medical profession certain questions. All tended really to one, namely, *what power of control* did the advocates consider that a *medical* trade union would have which the British Medical Association had not? Those interested have awaited a reply in vain.

It is well known that, when driven to give a reply, these advocates acknowledge that there is no special power of control, and that none can be expected so far as the medical profession is concerned. The only advantage that they urge now is the security of any funds. Let me take that point.

One of the advocates, whilst avoiding answering the set of questions, boldly states in your issue for June 27th that these questions were an attempt to divert the attention of the Divisions from the question which they have to decide, and which appears as the heading to this letter. To one not conversant with the Trade Union Act, 1913, such a statement might appear to be true. But that Act clearly shows that the questions are germane and apposite. With your permission I will quote certain sections in the following order: Section 2 (1), Section 1 (2), Section 2 (2), Section 1 (1). (The italics are mine.)

Trade Union Act, 1913.

Section 2 (1).—The expression "Trade Union," for the purpose of the Trade Union Acts, 1871 to 1906, and this Act, means any combination, whether temporary or permanent, *the principal objects of which are under its constitution statutory objects.* Provided that any combination which is for the time being registered as a trade union shall be deemed to be a trade union as defined by this Act so long as it continues to be so registered.

Section 1 (2).—For the purposes of this Act the expression "*statutory objects*" *means the objects mentioned* in Section 16 of the Trade Union Amendment Act, 1876, namely, the regulation of the relations between workmen and masters, or between workmen and workmen, or between masters and masters, or the imposing of restrictive conditions on the conduct of any trade or business, and also the provision of benefits to members.

Section 2 (2).—The Registrar of Friendly Societies shall not register any combination as a trade union unless in his opinion, having regard to the constitution of the combination, the principal objects of the combination are statutory objects, and *may withdraw the certificate* of registration of any such registered trade union if the constitution of the union has been altered in such a manner that, in his opinion, the principal objects of the union are no longer statutory objects, or

if in his opinion the principal objects for which the union is actually carried on are not statutory objects.

Section 1 (1).—The fact that a combination has under its constitution objects or powers other than statutory objects within the meaning of this Act shall not prevent the combination being a trade union for the purposes of the Trade Union Acts, 1871 to 1906, *so long as the combination is a trade union as defined by this Act*, etc.

From these sections it seems clear that a trade union, to be such, must include certain objects in its constitution; that these objects are those at present carried out by the Association under its memorandum; that if a trade union were formed without these objects and solely for the purpose of protecting a fund, then the courts would not recognize it as such (whether registered or not registered); and if registered with these objects, and these objects were allowed to be idle, the certificate would be withdrawn. This being so, the advocates must undoubtedly urge a trade union that included the statutory objects; in other words, must advocate the formation of a body in active hostility to the British Medical Association, and required by the law, in order to retain its certificate, to continue to be so. Therefore, again, what special power of control do they hope for through such a body?

As I stated in an earlier communication, the only advantages of a trade union that can be advocated are the security for the funds and the liberty to libel your colleagues to your heart's content. Even these advantages the courts are fast whittling away.

The former advantage the National Union of Teachers has secured, whilst its funds are in England; and the militant suffragists (in spite of all the law officers of the Crown) by the simple device of placing theirs in France. Neither body has thought well to adopt a trade union constitution. They see the folly of deliberately asking others to step on their coat-tails.

Which, then, is it that the advocates of trade unionism desire? A trade union in reality, under which the funds would be legally safe and its members compelled by law to endeavour to wipe out the Association from the medico-political field; or a trade union in name only, with no security for the funds, and leaving the Association to continue its work?

Possibly the advocates of trade unionism present at the Representative Meeting will tell us. And, having heard their explanation, it is to be hoped that that body will keep its head, prove loyal to itself, and once more decide to have nothing to do with aiding and abetting the proposal.

Meanwhile, we have the extraordinary situation of the Council of the British Medical Association openly advocating the formation of a new medico-political body that they must know would be legally obliged to compete with the former in the medico-political world. It is time that the loyal members woke up.—I am, etc.,

Hove, July 11th. E. ROWLAND FOTHERGILL.

SIR,—Your leader in the JOURNAL of July 4th seems to me to put the matter very fairly. There is one aspect of the subject which advocates of "trade unionism" entirely ignore, and that is, if the profession goes in for it, it will go in for the whole thing, the good and the bad, the bitter and the sweet, and the bad and bitter include the objectionable fourth clause of the Trade Disputes Act, 1906. This clause renders "trade unionists" immune regarding such acts as the following: "Libels and slanders, negligence or carelessness resulting in injury to another in person or property, nuisance, fraudulent representation in business dealing, omissions of legal duty, etc." I take it the profession does not wish such immunity, and if unwittingly it did any of these things it would want to make the *amende honorable*. It follows that the only real reason in wishing to adopt "trade unionism" is for the supposed better security of the funds, because these would be in danger of attachment in "pursuance of a policy in restraint of trade." But is there not already sufficient security of funds without resorting to "trade unionism"? By the formation of Panel Committees, and in virtue of their legal status, the principle of "restraint of trade" is conceded! And in my opinion all that is needed is fully to develop this, taking care to secure unity of purpose and legislation between the Panel Committees and the British Medical Association (*vide* SUPPLEMENT, May 2nd, 1914, Appendix I, par. 9, 18 (*d*)), at the same time organizing the profession from the centre to the periphery.—I am, etc.,

Swadlincote, July 11th. DAVID ROBERTS.

HOW TO INCREASE THE MEMBERSHIP.

SIR,—If medical students were admitted to the British Medical Association as associates at a nominal subscription there would be a great probability of them becoming full members when qualified.

I would suggest a subscription of 10s. 6d. per annum, as this would allow the JOURNAL to be sent to them without loss to the Association. I would further allow them to attend all meetings if so inclined, but not, of course, to vote.—I am, etc.,

Bury, July 14th. JAMES HOLMES, M.D.

DIATHESIS IN INFANCY.

SIR,—I hope that the valuable article by Dr. H. C. Cameron on diathesis in infancy and the leading article on a branch of the same subject in your issue of July 11th will receive very full attention.

The doctrine that nearly all infants are born with equal chances of good health, and only require cleanliness and a standard diet in order to thrive, has been assiduously promulgated in some quarters, with the effect of starting many on the search for the "philosopher's stone" of an ideal diet. How widespread is this doctrine is evidenced by the impatience of parents whose infants do not make the average progress under good care and attention, and also by the naïve inquiry often made by medical as well as lay persons, "Is there anything organically wrong?"

In no branch of medicine do we more require to install "morbid physiology" on the throne lately occupied by "morbid anatomy," and here is an unrivalled field for the chemical pathologist.

Dr. Cameron has ably touched on two types of morbid progress, but he rightly says that "many other examples of congenital inborn abnormality of constitution might be quoted." One very striking feature of such abnormalities is their familial tendency.—I am, etc.,

Sheffield, July 13th. A. E. NAISH.

HAEMOSTASIS BY APPLICATION OF LIVING TISSUE.

SIR.—Sir Victor Horsley's article in the BRITISH MEDICAL JOURNAL, July 4th, 1914, upon the employment of the cut surface of fresh muscle tissue as a haemostatic is of interest from the fact that he invariably found blood platelets in the adhesive layer formed between the bleeding surface and the muscle.

That the blood platelets in this method are one of the factors in promoting haemostasis seems likely from the fact that for some years past I have found that blood platelets, when isolated in a manner the technique of which I hope to publish shortly, and applied to the bleeding point or surface after being spread over sterile gutta percha tissue and retained in position by slight pressure, invariably brings about satisfactory haemostasis.

In the many cases in which I have used blood platelets in this manner the resulting haemostasis has been permanent after a few minutes, when the gutta percha tissue can be removed without further onset of haemorrhage. In several cases of haemophilia in which teeth had inadvertently been extracted, the lining of the alveolus with platelet covered gutta percha tissue, the tissue being kept in contact with the alveolar walls by means of a loosely applied plug of sterile absorbent wool, led to rapid cessation of haemorrhage.

In addition to this power which blood platelets possess of promoting local haemostasis, when platelets isolated from 30 to 40 c.cm. of blood are administered hypodermically in cases of severe deep-seated haemorrhage, such as haematemesis, haemoptysis, haematuria, etc., the resulting cessation of haemorrhage is remarkable.

Though the results seem to be better when freshly isolated blood platelets are used, I have found little impairment of their haemostatic power when kept for several months in suspension in a minimal amount of

equal parts of blood plasma and 1 per cent. sodium citrate in normal saline solution and stored at a low temperature in paraffin-lined amber-coloured ampoules.

Nottingham, July 13th. LYN DIMOND.

ROYAL MEDICAL BENEVOLENT FUND.

SIR,—Behind all facts and all arguments about whether the Royal Medical Benevolent Fund or Epsom College should have a particular legacy there is a broader question—Does the profession do its duty, or a tithe of its duty, in the matter of supporting these two medical charities? We all know that most medicos are poor, and are generous in attending poor patients for little or for nothing. Still, have not the charities of a man's own calling the first claim on his philanthropy? Poverty is relative, and surely most members of our profession could, if they chose, give half a guinea, or even a guinea, a year to medical charities which are so necessary, for many reasons, as these.—I am, etc.,

Brent Knoll, July 13th. J. W. PAPILLON, M.R.C.S.

POISONING BY BEETROOT.

SIR,—Dr. J. Johnstone Jervis's memorandum in the JOURNAL of June 27th (p. 1408) on acidosis and hepatic disorder is of special interest to me while studying the physiological action of foods. I find it necessary to cease for a time using any article of food whose action I wish to test. By taking a big dose when I resume taking it, its physiological action on me is easily ascertained, and by repeated experiments in that way alone is it possible to learn what should have been known long ago. Dr. Jervis had no doubt the beetroot was the cause of the alarming symptoms which he describes, and he is not afraid to confess his ignorance when he says: "But what particular element in the composition of that vegetable, and the nature of the changes brought about by it in the tissues, I cannot tell." We know the physiological action of tobacco pretty well from our first attempts to smoke, but the system gets used to it if its use is persevered in, unnatural as it may be to use it. But for that power of the system to accommodate itself to almost anything put into the stomach, many of our articles of diet would not be used. The Yorkshire farmer on return after his first visit to London, being asked how he had got on, said: "The first night we had lobster to supper, and my stomach refused to keep it, but determined to show who would be master, I gave it lobster every night, and it never refused it again." It is probable that if the child had been fed on beetroot, when it recovered, it might, like the lobster, have been retained and its ill effects never suspected. I remember asking an old shepherd among the hills as to his experience of tea. He said, "I never tasted it till I was 20 years of age, when it made me ill, and I never took it again." He was wiser than the Yorkshire farmer, for when the action of tea is studied and known, it will be found to be the unsuspected cause of mental, as well as physical symptoms. We are being told about vitamines and deficiency diseases, which shows that we are beginning to know our ignorance as to the action of food (which is the first step towards knowledge), but there is danger, that a little knowledge of the action of some foods, may induce some to use them as drugs are now used, merely to relieve symptoms, instead of trying to find out the natural food of man, by living on which he will never ail, and die of old age alone. We know something of the grape cure, a careful study of which might be helpful in our search for our natural food. In California some families are known to live on fruit and nuts alone, and though very different in appearance from other people, are said to enjoy exceptionally good health and to be much more active than mixed feeders.—I am, etc.,

Denholm, Hawick, June 29th. JOHN HADDON, M.D.

THE D.P.H. AS AN ESSENTIAL FOR MEDICAL REGISTRATION.

SIR,—The time has come when no medical man should be placed on the *Register* unless in possession of a Public Health diploma. I am of opinion that the General Medical Council should lay down that after the year 1919 they would not register any person without such diploma.

It seems wiser for our own controlling Council to do this voluntarily than to be compelled to do so by some outside agency, as will surely be the case. I cannot myself imagine a man practising medicine without such knowledge, whether without or with a diploma. No doubt many men do understand health matters, but we have now to render it compulsory by legal enactment. The moment this is done the teaching of physiology would be brought closer to hygiene. Pathology would also be more clearly understood. Chemistry would be expanded in its outlook, and even the practice of medicine itself would widen its scope.

The study of health laws and regulations would give to the medical student a deeper interest in State regulations, and a fuller conception of their civic duties would come to all medical men. So educated we could meet the modern State in a better position for defence against it or co-operation with it. Closely allied with such civic teaching would come those ethical lectures so needful in the training of the medical man, fitting us better for those weighty responsibilities which, avoid how we may, are certain to fall to our lot. No ethical teaching whatever is given to us to-day.

What the Army Medical Service began half a century ago may now surely be followed up by the medical profession as a whole.

When well-nigh fifty years ago I heard Edmund Parkes, beautiful as a Greek god, give his hygiene lectures, although I held a medical and surgical qualification, the matter was a complete revelation to me. Never once had I heard health lauded in all my student days till he spoke. Let us all follow in his train.

During the student's holidays yearly he could put in practical work at health studies in our municipalities, and so avoid the delay of special post-graduate study, as is now the case. The change of scene and work would be as good as a holiday. It would be necessary to bring all public health training of medical men under the inspection of the General Medical Council, and the State would nominate to membership of that Council certain public health specialists.—I am, etc.,

G. J. H. EVATT, M.D.,
London, S.W., June 25th. Surgeon-General.

Public Health
AND
POOR LAW MEDICAL SERVICES.

POOR LAW MEDICAL OFFICERS' ASSOCIATION OF ENGLAND AND WALES.

(Concluded from page 103.)

The Future of the Poor Law and the Poor Law Medical Service.

AT the annual meeting of this association in Burnley, Dr. Major Greenwood said that there had never been a period in the world's history in which civilized communities had not been confronted with a Poor Law problem. In England the first attempt by the State to grapple with the problem was by the statute of Elizabeth, which laid down the first principles of the present system. By early Poor Law legislation the destitute were regarded more as criminal than unfortunate, and the evil reputation that was still attached to Poor Law administration was an inheritance from those days. The keystone to the present system was put by the Poor Law Amendment Act of 1834, based on the findings of an important Royal Commission that reported in that year. Although there had been no direct legislation since then, there had been certain enactments connected with social reform that had touched on the ground heretofore reserved for the Poor Law—namely, the Old Age Pension Acts, the various Elementary Education Acts, and the Insurance Act. Discontent with the Poor Law system resulted in the appointment in 1906 of another Royal Commission on the Poor Laws, which reported in 1909. Unfortunately, the Commissioners were not unanimous, and two reports were issued. The Local Government Board had, by special orders, carried out some of the recommendations, which were endorsed by the whole Commission. In considering the present Poor Law medical service of the country, the subject naturally divided itself into two parts—the present and the future of the outdoor, and the present and the future of the indoor medical service. The latter would develop more and more on institutional lines, and all indoor Poor Law

medical officers would tend to become whole-time officers. To meet the exigencies of the sick poor the centre for institutional treatment must not be too far away, but wherever possible a central institution, staffed by whole-time medical officers for the service of all the sick poor of the union, would be established. Unions might combine to create a common infirmary, and, as Dr. Thackray Parsons suggested in a valuable paper read at the last annual meeting, the Poor Law infirmary might become a State institution, and be utilized in connexion with State schemes for changes in the general medical practice of the country. As to the outdoor service the district medical officer must remain an important factor in Poor Law medical administration, for a Poor Law administration on anything like the present lines could not exist without him. If in the future the medical wants of the necessitous sick were catered for by a practitioner who, in addition to being district medical officer was also public vaccinator, police surgeon, factory surgeon, medical officer of health, and held any other office that necessitated medical supervision, the poor would not be better off than under the present arrangement. The medley of offices that he held would militate against efficiency in his Poor Law office. In populous areas the whole-time system was more practical, and had been utilized with more success. Sufficient Poor Law work could be found to employ the whole time of a Poor Law medical officer. It was in this way, in his opinion, that in the future part-time district medical officers would tend to be superseded by whole-timers, and if work and salary were equitably settled, it was difficult to see how they could offer opposition, if they wished, to another system which was in practice, or shortly would be, in two of the metropolitan boroughs. The Association of Metropolitan Infirmary Superintendents had recommended that the union infirmary should be made the base of all Poor Law medical relief and the office of district medical officer abolished. The infirmary superintendent was made chief medical authority and supervised all outdoor and indoor medical relief, and assistant infirmary medical officers were put in the place of district medical officers, some residing at the infirmary and others at a convenient site within the district. None of these assistant medical officers had any security; indoor medical officers, except the medical superintendent, enjoyed that right. The scheme, he admitted, on paper looked most tempting, but under the present system of Poor Law administration it meant that all the outdoor poor were in the hands of junior practitioners, for it would not be possible for a medical superintendent of a large infirmary to supervise properly both the indoor and the outdoor work. If he made the attempt he was not unlikely to fail in both. Naturally he would regard the indoor work as his proper function and would relegate the outdoor to his assistants, and the only responsibility he would take would be nominal. Summed up briefly, the changes that were taking place in the Poor Law medical service, both in its indoor and outdoor branch, tended to substitute whole-time for part-time officers.

The Annual Dinner.

In the evening the annual dinner was held at the Bull Hotel, and the members and their guests dined together under the presidency of Surgeon-General Evatt, C.B. Among the guests were: Alderman J. Sellers-Kay, Esq., the Mayor of Burnley and the Mayoress, P. Thomas, Esq., Town Clerk; C. E. Bygrave, Esq., Clerk to the Blackburn Guardians; Dr. Sinclair, Surgeon to the Victoria Hospital, and the following members of the Council of the Poor Law Medical Officers' Association were also present: Dr. Drury (Halifax), Dr. Holder (Hull), Dr. Major Greenwood (London), Dr. Thackray Parsons (London), and Dr. Agnew (Burnley). There was an excellent musical entertainment arranged by Dr. Pullon. After the toast of "The Mayor and Corporation" had been proposed by the President and acknowledged by the Mayor, Mr. C. E. Bygrave proposed "The Poor Law Medical Officers' Association of England and Wales," which was acknowledged by Dr. Major Greenwood.

Mr. Thomas, the Town Clerk of Burnley, proposed "The British Medical Association," and the toast was acknowledged by Dr. Bird, for the last six years Honorary Secretary of the Burnley Division, and now its President. He thought every medical man ought to be a member of the Association, and every student, as soon as qualified, ought to join it. Some such association was absolutely essential from the standpoint of medical science, of medical ethics, and of medical politics. What better organization was there at present than the British Medical Association? Certain people might disparage its efforts during recent legislation, but if they did not get all the points they wanted, they got a good many. The Association was like Hercules, it helped those who helped themselves, and if any Division desired to act it had the Association to back it.

Dr. Holder proposed the toast of "The Guests," to which Dr. Scott (Burnley) responded.

Dr. Pullon proposed "The Health of the President," and Surgeon-General Evatt made an appropriate response.

Dr. Drury (Halifax) proposed "The Health of Dr. Agnew," and "The Health of the Ladies" was also proposed, and responded to by a lady guardian.

Medico-Legal.

"HIGHER THOUGHT HEALING."

AN inquest on the body of Miss Kate Addison Scott, aged 37, who died while undergoing what was described as "higher thought healing," was concluded at Hounslow on July 11th. For some time before her death Miss Scott had been under the care of Mr. Orlando Edgar Miller at Spring Grove House, Isleworth, where she died on June 7th. Mr. Miller told the coroner, Mr. Reginald Kemp, he was a "teacher, lecturer, and healer." At a previous hearing he said he was a Ph.D., a lecturer on higher thought and a practitioner of faith-healing. He was not a Christian Scientist. He had studied medicine in America, but had no medical degree. He described his methods of healing as "mental, and to some extent medical and mechanical." He had opened Spring Grove House as a sanatorium for consumptives where he demonstrated a special method of treatment of his own which he hoped would some day be adopted by the medical profession. According to a report which appeared in the *Daily Telegraph* of July 13th, he went on to say that the house was now used as a kind of nursing home, and people frequently came to stay there to study psychology and the higher thought. He had from thirty-five to forty patients in the home, with a nursing staff of six. There was no medical practitioner in residence, but he called in a physician in certain cases. The local medical men refused to attend. He first met Miss Scott at one of his lectures, and at her request he took her in and treated her for paralysis, from which she had been suffering for fifteen years. She was admitted on June 2nd and her treatment began the next day. She was required to fast for thirty-six hours and he prayed over her. His method was "eliminating treatment," which consisted of exercises, breathing, and injections of distilled water, alcohol, and scopolamine. While he believed in the "laying on of hands and giving the right heart," he administered salts and gave cascara and scopolamine. As the patient got worse he called in a doctor, who diagnosed an internal complaint. Dr. H. L. Wilson, of Gordon Square, said he first attended Miss Scott for dyspepsia early in 1912. She had suffered from a nervous disorder for about thirteen years. She tolerated drugs very badly. He was sent for on the day she died and found her moribund, with practically no pulse. Probably her life would have been saved if she had had medical attendance earlier. For some time past she had been interested in Christian Science. He had treated Miss Scott for paralysis but had simply ordered exercises. Dr. L. B. Christian said that scopolamine would not be a suitable drug to inject in a patient in Miss Scott's physical condition. It was possible that it might have exaggerated her symptoms and hastened death by acting on the heart. Dr. W. H. Willcox, Senior Scientific Analyst, Home Office, said that an analysis showed that in the stomach there was a minute quantity of an alkaloid which would act upon the pupil of the eye in the same way as scopolamine or hyoscine. He found no other poison. The injection of scopolamine was most unsuitable. Death was due to dilatation of the stomach following disseminated sclerosis. The jury returned a verdict of natural death, adding a rider in which they asked that the coroner should severely censure Mr. Miller and report the nurse to the hospital where she had got her certificate. The coroner, addressing Mr. Miller, said, as reported in the *Morning Post*: "You are deserving of the gravest censure for treating this woman in a very improper way. Fortunately the medical evidence is in your favour, or you might have found yourself in difficulties. It was clearly your duty to send for a doctor much sooner than you did. The only extraordinary part of this case is the evidence which it affords of the easy way in which the public are taken in by these quasi-religious faith healers."

Accounts of various enterprises undertaken by Mr. Orlando E. Miller may be found in *Truth* of April 24th, 1912, and April 8th, 1914. From these accounts it would seem that he had a variegated career in America, including a period of imprisonment for a financial operation, of which he informed our contemporary a prejudiced judge and a packed jury took an unfavourable view. From the same source it is to be gathered that in a medical sense he seems to have progressed from grocery through cures for rupture, inebriety, and consumption, up to the "Higher Thought."

BENDLE *v.* UNITED KINGDOM ALLIANCE.

THIS was an action, before Mr. Justice Bray, by Messrs. Sutton Bendle and Co., proprietors of a wine known as Bendle's Meat

and Port Nutrient, against the United Kingdom Alliance (for the legislative suppression of the liquor traffic).

In opening the case on June 15th, counsel for the plaintiffs, as reported in the *Times*, said that in 1908 the British Medical Association, the proprietors of the BRITISH MEDICAL JOURNAL, published a series of analyses of various medicated wines which were being sold and advertised, including a wine which was sold by the plaintiffs' predecessors in title, Messrs. Bendle and Co. That company went into voluntary liquidation in 1912, and the plaintiffs, one of whom had been a director of the company and the other the manager of a wine business, acquired the medicated wine which had been sold by Bendle and Co., and entered into a partnership to deal in it. In June, 1913, the United Kingdom Alliance published in a pamphlet the analysis and statement which had appeared in the BRITISH MEDICAL JOURNAL in 1908, with one important omission. In 1908 the BRITISH MEDICAL JOURNAL was communicated with, and the position of the wine was explained, with the result that in issues of the two weeks following the publication of the analyses the BRITISH MEDICAL JOURNAL published the statements made by the proprietors of the wine in regard to it. The defendants did not publish the two subsequent statements which qualified what had originally been written. For a person to publish that the substance which he sold contained nutritive matter when it only contained meat extract would be a gross imposition. The complaint against the defendants was that in their pamphlet they suggested that the plaintiffs' wine was nothing else than a mixture of wine and meat extract, and therefore did not contain pure meat nourishment, and was stimulative and not nutritious. It did not contain a scrap of meat extract, but contained "Somatose" in sufficient quantities to justify the statement that it was a nutritive wine.

After the first adjournment, the services of the jury were dispensed with. Expert evidence was called on behalf of both parties.

Mr. Justice Bray, in the course of his judgement on July 14th, said that the plaintiffs' advertisement said that the wine was "a really genuine nutritive meat wine," and it was contended for the defence that a substance to be called nutritive must be capable of being used as an exclusive food. The plaintiffs, on the other hand, contended that a substance was nutritive if with or without other foods it helped to build up the human frame, and he agreed with that definition rather than the other. He could not find that the word had any technical meaning. Then it was said that the nutritive power of the meat was diminished or destroyed by its being dissolved in port wine, but the evidence had failed to convince him of that. It was said that in any event the proportion in which the meat was used was so small that the nutritive value must be practically inappreciable. But the plaintiffs advertised their wine as "a really genuine nutritive meat wine," not as a "highly nutritive" meat wine, and in his opinion they had proved the statements in their advertisements to be true. The wine, therefore, had the percentage of nutritive value which was claimed for it, though that was not a large amount. Reading the label fairly as a whole, he held it to be substantially true; and the defendants had failed to support their statement that the plaintiffs' claim with reference to their wine was, in the words of the pamphlet, positively absurd. He found also that the statement in the pamphlet that to obtain the 5 oz. of tissue-forming food required each day by an average adult would require a consumption of 1.925 glasses of the wines at a cost of over £30, was grossly exaggerated. The question remained, then, what should be the damages. The libel was serious, and the defendants had continued to distribute the pamphlet after the plaintiffs had complained to them about it. They had persisted up to trial in maintaining its truth; but it must be remembered in their favour that they had not published it for gain, but with a good object—to promote temperance. Unfortunately, their agents had been too zealous and too careless; and on the whole the damages should, he thought, be fixed at £250. There would therefore be judgement for that amount, with costs.

Counsel for the defendants asked for a stay of execution, undertaking not to continue the publication of the pamphlet. The judge replied that, while not wishing to encourage an appeal, he could not refuse the application on the money being brought into court in fourteen days, and the usual undertaking being given as to costs.

Universities and Colleges.

UNIVERSITY OF CAMBRIDGE.

Degrees.

THE following degrees have been conferred:

M.D.—F. R. Martin.
M.B., B.C.—A. G. Evans, F. J. Thorne.

VICTORIA UNIVERSITY OF MANCHESTER.

THE following candidates have been approved at the examinations indicated:

D.P.H. (*Both Parts*).—R. B. Berry, G. D. Dawson, J. Ferguson, H. M. Fleming, W. M. MacIlraith, J. Ramsbottom, E. A. Ramsden, G. K. Thompson, J. A. Tomb, A. E. Townley.
D. PSYCH. MED.—R. M. Stewart.

QUEEN'S UNIVERSITY OF BELFAST.

THE following candidates have been approved at the examinations indicated:

FIRST M.B. (*Chemistry and Physics*).—H. Abernethy, F. C. S. Bradbury, F. Campbell, A. E. Gallagher, J. Grimson, W. Hoey, G. D. F. M'Fadden, F. S. Mayne, T. Montgomery, A. V. Morrison. (*Chemistry alone*).—D. Cromie, P. J. Doherty. (*Physics alone*).—S. E. Clarke, J. W. C. Colquhoun, A. J. May, J. D. Pinkerton. (*Zoology and Botany*).—H. Abernethy, S. Acheson, J. Black, Winnifred W. Boland, F. C. S. Bradbury, S. F. Breakey, J. H. Calvert, Helen M. Calwell, F. Campbell, T. G. Campbell, T. I. Candy, J. Caruth, Gladys E. Chambers, B. R. Clarke, J. M. Clearkin, T. Dickey, P. J. Doherty, S. E. Duff, S. Fullerton, A. E. Gallaher, S. Hall, A. Henry, W. Hoey, Mary E. Irwin, M. G. Kierans, A. E. Keown, Elizabeth A. K. Law, D. Loughridge, G. L. Love, W. J. Lytle, G. D. F. M'Fadden, J. M'Garvey, D. J. M'Gurk, D. M'Lister, R. J. M'Neill, H. F. Macauley, E. A. Maguire, J. A. Martin, F. S. Mayne, Mary M. Merrick, W. Michael, T. Montgomery, A. V. Morrison, S. Owens, H. Paul, H. Poston, R. B. Quinn, W. W. Rentoul, D. A. E. Scott, L. P. St. J. Storey, P. S. Walker, A. Watson. (*Zoology alone*).—J. Craig, D. Cromie. (*Botany alone*).—J. C. Carson.

SECOND M.B. (*Anatomy and Physiology*).—J. Adams, S. T. Alexander, D. D. Anderson, Olive M. Anderson, C. Barton, Annie E. E. Beattie, J. Boyd, G. J. Crawford, Marion Crawford, W. Cupples, J. H. Davison, Dorothy I. Dobbin, F. Hopkins, J. Lascelles, D. J. Laughran, J. C. Loughridge, R. N. B. McCord, J. McCormick, W. C. McKee, J. O'Kane, C. A. W. Ramsay, J. E. Rea, M. H. Turnbull, N. C. L. B. Tweedie, T. Wallace, C. J. A. Woodside. (*Physiology alone*).—Olga R. I. Love, P. Macarthur.

THIRD M.B. (*Pathology and Materia Medica*).—W. L. Agnew, Eileen M. Bell, W. Bryars, G. Chesney, A. C. Dickey, Grace M. English, Mary E. Henry, Mary M. Keirns, Arabella C. Kirker, A. L. M'Creary, N. M'Cullough, J. P. M'Ginley, B. W. M'Kinney, M. M'Menamin, J. C. M'Millan, H. F. M'Nally, F. M'Sorley, P. J. M'Sorley, J. J. Marner, D. Mitchell, F. P. Montgomery, Elizabeth M. Moore, Margaret S. Purce, W. Saunderson, R. L. Sinclair, D. K. Watterson, D. R. Wheeler, C. A. Whitfield, F. H. Whyte. (*Medical Jurisprudence and Hygiene*).—W. L. Agnew, G. V. Allen, W. Bryars, A. G. Campbell, G. Chesney, A. C. Dickey, S. J. W. Donald, Grace M. English, F. Ewart, Mary E. Henry, L. Jefferson, Mary M. Keirns, Arabella C. Kirker, J. M. M'Cormack, N. M'Cullough, J. P. M'Ginley, B. W. M'Kinney, M. M'Menamin, J. C. M'Millan, D. Mitchell, Elizabeth M. Moore, W. Napier, Margaret S. Purce, R. J. Rea, J. Scott, R. J. Sinclair, T. R. S. Thompson, D. R. Wheeler, C. A. Whitfield, F. H. Whyte, J. Wilson, J. J. Thompson.

FINAL M.B., B.CH., B.A.O.—‡R. M. Beath, H. T. Chatfield, W. M'M. Chesney, J. Duffin, *E. C. T. Emerson, ‡A. Fullerton, D. Gaston, Margaret Gorman, T. Grimson, ‡W. S. B. Hay, J. F. D. Hunter, D. Jamison, W. J. Lascelles, B. Lyons, C. M'M. M'Cormack, R. N. M'Kinstry, E. U. MacWilliam, E. A. Mallon, *E. B. C. Mayrs, ‡S. Miller, J. J. Murray, S. E. Picken, ‡G. R. B. Purce, G. W. Rea, Elizabeth M. Robb, J. S. Savage, A. F. L. Shields, J. Tate, J. Warwick, O. Wilson, W. R. E. Wilson, P. P. Wright.

M.D. (*By Thesis*).—D. Finnegan, P. J. Gaffikin, §D. M'Cay, S. M'Clure, W. S. J. Shaw, J. M'G. Williams. (*By Examination*).—*B. A. West.

M.CH. (*By Examination*).—§T. S. S. Holmes. (*By Thesis*).—†. Crooks.

D.P.H.—Marion B. Andrews, N. C. Graham, W. S. Haydock, W. J. T. Mayne, S. P. Rea.

* Pathology only. † First-class honours. ‡ Second-class honours.
§ Awarded a gold medal. ¶ Passed with commendation.

UNIVERSITY OF ABERDEEN.

THE following were among the degrees and diplomas conferred at a meeting of the Senate on July 8th:

M.D.—*A. G. Anderson, *W. J. Reid, ‡J. R. Murray, ‡A. Wilson, D. Craig, W. B. Keith, A. M. Sinclair, F. W. Stuart.
M.B., CH.B. § N. Cantlie, § G. Lipp, A. G. Craib, F. M. Davidson, J. Dow, D. Fettes, J. Foubister, R. W. Galloway, A. M. Gray, W. F. Hawkins, A. J. Ireland, E. A. Mackenzie, D. M. Marr, J. Morrison, J. F. W. Sandison, E. Tawse, W. B. Thomson, W. Walker, W. R. Watt, J. M. Whyte.
D.P.H.—Winnifred M. Gray, J. H. Yule.

† Highest honours for thesis. ‡ Honours for thesis.
‡ Commendation for thesis. § Second-class honours.
¶ Passed with distinction.

The Straits Settlements Gold Medal for the best thesis during the three years 1912–14 on a subject of tropical medicine was awarded to Dr. A. F. Wallace, and the John Murray Medal and Scholarship to Dr. A. E. Campbell.

UNIVERSITY OF GLASGOW

New Fellowships.

THE late Mr. W. B. Faulds, of Glasgow, who died in 1897, bequeathed his estate to the University of Glasgow, subject to his wife's life interest. The widow is now dead, and a sum of over £20,000 will shortly be available to found four Fellowships—one in arts, one in medicine, one in divinity, and one in law. The conditions of the will leave full discretionary power in the hands of the university authorities, and Principal Sir Donald MacAlister, in asking the University Court to accord thanks to the trustees, said that the bequest would enable the university to do something towards providing that kind of tutorial instruction which was so much desired in all departments.

The Fellowships are to be known as the "W. B. Faulds Fellowships." They are to be tenable for three years, and to be awarded after such competition as the Senate may prescribe. The Fellowship in Medicine is to be conferred on students who have just completed their medical curriculum and have taken their degree.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

A QUARTERLY Council was held on July 9th, Sir Rickman J. Godlee, Bart., President, in the chair.

Election to the Council.

The President reported the election of members of the Council as recorded last week, p. 102.

The Retirement of Mr. William Pearson.

The following resolution was passed by the Council:

That the Council desire to express to Mr. William Pearson, upon his retirement from the post of Prosector, their high appreciation of his services to the College during a period of fifty-eight years.

The Council believe that the many preparations added to the museum as the result of his work are justly counted amongst the most treasured possessions of the College, and that they will stand as a lasting record of his exceptional skill and industry.

Mr. H. C. Wilson was appointed Prosector, to succeed Mr. Pearson.

Clinical Congress of Surgeons of North America.

The following demonstrations will be given at the College in connexion with the above Congress:

Monday, July 27th, 11.30 a.m.—Dr. Keith: The nature of peritoneal adhesions.
Tuesday, July 28th, 11.30 a.m.—Mr. Shattock: Specimens illustrating the growth of tumours.
Wednesday, July 29th, 11.30 a.m.—Sir R. J. Godlee: Hunterian and Listerian specimens.
Thursday, July 30th, 11.30 a.m.—Dr. Keith: Hunter's specimens illustrating growth of bone.
Friday, July 31st, 11.30 a.m.—Mr. Colyer: Specimens from the Odontological Collection illustrating general surgery.
Friday, July 31st, 5 p.m.—Mr. A. H. Cheatle: The surgical anatomy of the temporal bone.

The President stated that a reception would be held in the College from 4 to 6 in the afternoon of Wednesday, July 29th.

Appointment of Lecturers.

The following appointments were made:

Hunterian Professors.—Arthur Keith (6 lectures), Rupert Farrant (2 lectures), William Sampson Handley (1 lecture), John Howell Evans (1 lecture), Frederick Charles Pybus (1 lecture), Harry Blakeway (1 lecture).
Arris and Gale Lecturers.—Frederic Wood Jones (1 lecture), David Waterston (2 lectures).
Erasmus Wilson Lecturer.—Samuel George Shattock.
Arnott Demonstrator.—Arthur Keith.
Odontological Demonstrator.—James Frank Colyer.

Election of President and Vice-Presidents.

Sir W. Watson Cheyne, C.B., F.R.S., was elected President, and Sir Frederic Eve and Sir Anthony A. Bowlby were elected Vice-Presidents.

Imperial Cancer Research Fund.

Sir Rickman J. Godlee was elected to serve as a member of the Committee of the Cancer Research Fund, in the vacancy occasioned by the resignation of Mr. R. Clement Lucas.

KING'S COLLEGE HOSPITAL.

THE following scholarships and other prizes have been awarded as the result of recent examinations: The senior scholarship, the *Tanner* prize in diseases of women and the class prize in diseases of children, Mr. D. J. Platts; the *Jelf* medal, the *Todd* prize in clinical medicine, and the class prizes in medicine, obstetrics, pathology, hygiene, and psychological medicine to Mr. E. Watson-Williams; the class prize in forensic medicine to Mr. H. Rivers Pollock.

LONDON HOSPITAL.

THE winners of the principal prizes for the past session are as follows: The *Hutchinson* prize (value £40), Mr. W. S. Perrin; the *Andrew Clark* prize (value £26), Mr. A. C. Perry; the prizes in clinical medicine, surgery, and obstetrics (each of the value of £20), Messrs. A. C. Perry, S. Batchelor, L. M. Ingle; the *Sutton* prize in pathology (value £20), Mr. F. H. Bray; the *Letheby* prizes in organic and inorganic chemistry (value £10 and £15), Messrs. G. Adler and M. Aronsohn. The prize in anatomy and physiology (value £25) was divided between Messrs. G. P. B. Huddy and A. G. Harsant. Some sixteen other students won prizes ranging in value from £2 to 5 guineas.

Obituary.

WILLIAM HARDMAN, M.B., C.M.EDIN.,

BISPHAM, BLACKPOOL.

THE death of Dr. Hardman on July 7th, in his sixty-ninth or seventieth year, will be a source of much regret to his medical friends and fellow students. He was a man of considerable ability, character, and professional skill; he had also a wide knowledge of music, especially of the history and construction of the violin, and was a master of that instrument.

He was born at Blackpool and educated at Rossall, where he became an athlete in boys' sports and a very strong swimmer in the sea, in which he could continue for hours, unfatigued even in rough weather.

The writer of this notice became acquainted with him in 1865 on entering at University College Medical School, where Hardman had already been a year or two, and first attracted his attention by his habit of tuning his violin on one of his gas globes, which sounded G when struck. Another bond of attachment was his evident sincerity and integrity; and the friendship then formed continued unalloyed ever after. He had then a slight but distinct Lancashire accent, which never left him. He had a very acute ear for music and auscultation, as well as appreciation of many vocal sounds and imitations, but was himself no linguist. About 1866 he was present at the great ice-disaster in Regent's Park, and related how he and another were adrift on the same floe, while scores were drowning around them. He calmly told his terrified companion to lie down; but when the latter hesitated, Hardman said: "If you don't lie down, I'll knock you down"! He himself was a very short man, but his fierce determination on that occasion led to his being obeyed, and both floated safely ashore.

After working at anatomy and physiology he went to Edinburgh for a year or two, during Lister's professorship, taking useful illustrated notes, which he later imparted to the writer of this sketch, who made use of them in his own operations. He took the diploma of M.R.C.S. in 1870, and after taking his Edinburgh degrees in 1871, he became house-physician to Middlesex Hospital. At that time he suffered from typhoid of a dangerous and unusual type, but made a good, though tardy, recovery under the care of the Middlesex physicians, residents, and nurses.

He established himself about 1871 in Blackpool, at the house of his mother, and steadily worked up a good practice in a population to whom he and his family were well known and among the numerous visitors of each season. He was always a master of the physician's art, besides being a successful general practitioner, and laid special stress on the value of prognosis. Many wise and some original suggestions were communicated by him from time to time to this JOURNAL.

In surgical matters he held a most modest opinion of his own powers, and was often shy in discussing details; but his integrity and care in reality made him an excellent surgeon, and in his treatment of fractures, dislocations, and all sorts of minor surgery there was not only nothing to be desired, but much to be learnt by men of wider opportunities and experience than himself. Even in operations of major surgery, which he occasionally undertook, everything was done neatly, skilfully, and, above all, rationally, and with advanced method.

After retiring from practice some years ago he married a widow, Mrs. Coop, with several children, by all of whom he was highly respected and deeply beloved. His wife was unremitting in devotion and affectionate care throughout their married life.

For several years he had had heart trouble, and from being a quick and active walker was latterly prevented by dyspnœa from any but slight exercise.

R. P.

DR. J. B. NICOLAS DUGUET, Vice-President of the Académie de Médecine, and Physician to the Paris Hospitals, died recently at the age of 77. Born in 1837 he first studied medicine in the Rheims School. Proceeding to Paris at the age of 23 he became *interne* in the following year and took his doctor's degree in 1866. His progress in his profession was interrupted by an attack

of typhoid fever which threatened his life, and later by the Franco-Prussian war, in which he served as a medical officer. He was taken prisoner, escaped, rejoined the army of the Loire, and when the armistice was signed returned to Paris. In 1872 he won the title of *professeur agrégé*, and in the following year was appointed physician to the hospitals. After serving some time at the Tenon and St. Antoine hospitals he became attached to the Lariboisière, where he remained for twenty years. He was most punctual in his attendance, and the soundness of his teaching attracted large numbers of students and practitioners. Not a few of the leaders of the profession in Paris to-day owe their training to him. He was a member of the Council of Hygiene and Public Health, of the Health Committee of the Seine, of the General Commission on Railways, and many other committees; in the work of all these bodies he was a force that made itself felt. Somewhat brusque in manner, he was a kind-hearted man, ever careful of the welfare of his patients. The straightforwardness of his character made him respected by every one who knew him. He wrote on early ulceration of the pharynx in typhoid fever, on the pathogeny of the blue spots in the same disease, on the treatment of goitre, and other subjects. But he was too busy with practice and with teaching to have much time for leaving records of his large experience.

CAPTAIN JOHN HAY BURGESS, I.M.S., Surgeon to the Governor of Bengal, died on June 10th, of heart failure after an operation, following a few days' illness, in the Eden Sanitarium, Darjiling. He was born on January 10th, 1880, educated at St. Mary's Hospital, and took the diplomas of M.R.C.S., the L.R.C.P.Lond., and the degree of M.B.Lond. in 1902. He became F.R.C.S.Eng. in 1905, and M.R.C.P.Lond. in 1911. He entered the Indian Medical Service as Lieutenant on August 31st, 1903, and became Captain on August 31st, 1906. The *Army List* awards him no war service. He was appointed medical officer of the 88th Carnatic Infantry on March 11th, 1908, and, when the Province of Bengal became a Governorship on April 2nd, 1912, he was selected as personal surgeon to His Excellency Lord Carmichael, the first Governor.

DEATHS IN THE PROFESSION ABROAD.—Among the members of the medical profession in foreign countries who have recently died are Dr. Karl Breus, Extraordinary Professor of Obstetrics and Gynaecology in the University of Vienna, author of a number of contributions to the literature of his speciality, the most important of which is a monograph on malformations of the pelvis in women, written in collaboration with Alexander Kolisko, aged 64; Dr. Eijkman, of Amsterdam, well known by his researches on tropical pathology, aged 51; Dr. Emil Gruening, Emeritus Professor of Ophthalmology in the New York Polyclinic Medical School, aged 71; Dr. Kehrer, Emeritus Professor of Obstetrics and Director of the University Gynaecological Clinic, aged 75; Dr. E. J. Raymondaud, Professor of Surgery and Principal of the Medical School of Limoges, aged 92; and Professor Edmund Rose, Professor of Surgery at Zurich from 1867 to 1881, when he succeeded Professor Wilms as Surgical Director of the Bethanien Hospital at Berlin, aged 78.

Medical News.

WE propose to publish next week an article by Mr. Massac Buist on the lessons, for medical men, of the Grand Prix race of the Automobile Club de France. The article will deal especially with the fuel problem and with the questions of the overhead valve, and the front wheel and four wheel brakes.

THE summer general meeting and luncheon of the Irish Medical Schools' and Graduates' Association will be held at the Grand Hotel, Aberdeen, on Wednesday, July 29th, at 1.15 for 1.30 p.m., and not as previously announced.

A SERIES of post-graduate lectures will be given at the School of Dental Surgery of the Royal Dental Hospital of London in October and November. The course is free to past and present students of the hospital and internal students of the University of London; the fee to others is £2 2s.

THE following members of the medical profession have been appointed to the commission of the peace for the county of Glamorgan: Dr. Peter O'Donnell (Barry), Dr. Sylvanus G. Morris (Mardy), Dr. Thomas H. Morris (Tylorstown), Dr. David N. Morgan (Gilfach Goch), Dr. William E. Thomas (Ystrad Rhondda), Dr. Robert D. Prichard (Resolven).

THE International Society of Surgery will hold its fifth Congress in Paris in 1917. The questions proposed for discussion are the surgery of the heart and vessels, including thrombosis and embolism; transfusion of blood; the treatment of tumours by means of *x* rays and radium; examination of the blood and biological reactions in surgical diseases; fractures of the leg and the ankle-joint; the diagnosis and treatment of tetanus.

A COMMISSION for the study of pellagra—consisting of officers of the medical corps of the United States Navy and Army, the Public Health Service, and the New York Post-graduate Medical School—is now at work at Spartanburg, South Carolina. It was joined on June 20th by Dr. Simon Flexner and Dr. Peyton Rous, of the Rockefeller Institute, New York, and Dr. Linsly R. Williams, Deputy Commissioner of Health of New York State. It has been estimated that there are between 50,000 and 75,000 cases of pellagra in the Southern States.

AT a meeting in Cardiff, on July 15th, Colonel Bruce Vaughan, chairman of the King Edward VII Hospital, Cardiff, announced that Mr. Lynn Thomas intended to present his private nursing home known as Bedford House to the King Edward VII Hospital as an annexe for paying patients. Colonel Vaughan said that it was a splendid gift as the house had only recently been brought up to date for hospital purposes, and was estimated to be worth £4,000. Mr. Lynn Thomas is, we understand, retiring from private practice, but will retain his connexion with the King Edward VII Hospital and with the Glan Ely Surgical Tuberculosis Hospital of the Welsh National Memorial.

AT Gloucester County Court on July 14th, His Honour Judge Ellicott gave judgement in the case (BRITISH MEDICAL JOURNAL, June 20th, p. 1387) in which a school girl, through her father, claimed £6 15s. from Dr. J. Middleton Martin, Medical Officer of Health for Gloucestershire, in his capacity as school medical officer, as general damages in respect of defendant having cut plaintiff's hair without permission. The jury awarded the plaintiff one farthing damages, but, as defendant had paid into court 10s. and costs up to the time the claim was issued, with a denial of liability, his honour gave judgement for defendant with costs subsequent to the payment into court, and ordered the payment out to the defendant of the money paid into court.

MR. JOHN D. ROCKEFELLER has recently given £510,000 to the Rockefeller Institute for Medical Research, New York, for the provision of opportunities for the more complete investigation of the nature and causes of human disease, and methods of prevention and treatment. Part of the sum will be applied to the purchase of additional land, which will give the institute a site covering an area of about four acres. The remainder will be used to erect and equip additional laboratories, buildings, and plant, and to ensure the maintenance and conduct of the extended work for which provision will thus be made. This gift is in addition to the sum of £200,000 given recently by Mr. Rockefeller for the establishment of a department of animal pathology. His previous donations to the institution amount to about £1,800,000; the total endowment is therefore about £2,500,000. The work of the institute includes pathology, bacteriology, protozoology, biological chemistry, physiology and pharmacology, experimental biology, and animal pathology, besides a special hospital for the study of any diseases under investigation at a particular time.

THE Third International Congress on Radioactivity and Electronomics will be held in 1915 (June 27th to July 2nd) at Vienna under the presidency of Professor Sir Ernest Rutherford of Manchester. Among the questions on the programme of the Medico-biological Section are the general biological effects of radium and Roentgen rays on plant life (by Professor Koernike of Bonn), on animal cells and tissues (by Dr. Dominici of Paris), and on the whole organism (by Professor Wiechowski of Prague). The influence of radium and *x* rays on tumours will be dealt with in an introductory address by Professor Aschoff of Freiburg; Professor Kroenig of Freiburg will discuss the principles of the *x*-ray and radium treatment of malignant

growths; Professor Albers-Schoenberg of Hamburg will treat of the *x*-ray treatment of uterine myoma and climacteric haemorrhages. Professor Howard Kelly of Baltimore will discuss the radium and mesothorium treatment of benign tumours. The effect of radio-active substances on the blood, the glands, and the circulation will be dealt with by Docent H. Hansen of Copenhagen, and their influence on gout, rheumatism, and nerves will be discussed by Professor Falta of Vienna. There will be demonstrations of cases and visits to the radium station of the General Hospital. Injuries caused by *x* rays and radium will be discussed by Professor Holzknecht of Vienna.

HEISER reports that over 60,000 fewer deaths occur annually in the Philippine Islands than was the case in 1905. As this reduction has occurred almost entirely among the preventable diseases, it may be regarded as an index of the effect of health work in the Philippine Islands. If the knowledge which is now available could be applied, at least another 100,000 deaths per annum might, it is thought, be avoided by reducing the ravages of tuberculosis, malaria, beri-beri and its indirect effects, and the intestinal diseases. During the year 1913 a general hospital with 60 beds was opened at Cebu, and arrangements have been completed for providing for the sale of quinine at a nominal rate by each of the 789 municipal and township treasurers throughout the Philippines. Four persons were discharged from the San Lazaro Hospital after having been apparently cured of leprosy for a period of over two years. Measures against plague were very successful, and demonstrated in a conclusive manner the control which modern sanitation has over this disease. During the fourth quarter of the year 147 cases of cholera with 104 deaths occurred in Manila, making a total of 161 cases and 110 deaths in the city since it first appeared on August 24th, 1913. There were also suspicious cases for two months before a definite diagnosis of cholera was made. Cholera vibrio carriers were found in practically every community in which cholera had made its appearance. So far it has been possible to eradicate the disease within a comparatively few days in each instance in which prompt measures were taken with the first cases that were discovered. In only a few instances could any connexion between cases occurring even in the same town be traced. The experience in this outbreak is held to emphasize the urgent necessity of making a thorough laboratory study of the disease. The present knowledge with regard to its etiology is not sufficiently satisfactory to explain the spread of the disease during this outbreak.

THE annual meeting of the Association for the Oral Instruction of the Deaf and Dumb was held at the Portman Rooms, W., on July 8th, under the presidency of Sir Gerald H. Ryan. The director, Mr. G. Sibley Haycock, gave some interesting particulars of the Training College for Teachers and School for Deaf Children in Fitzroy Square, where between thirty and forty children are under instruction. Experience of results attained by the pure oral method tended, it was stated, to confirm belief in its efficacy, and the demand for teachers trained on this system continued to be in excess of the supply. The course of training for student teachers extends over two years, and their technical proficiency is tested by the Joint Examination Board for Teachers of the Deaf, which grants a diploma recognized by the Board of Education. At the last examination all the students of the college with a full course secured the Board's diploma with honours, and one was first on the general list of passes. Increased accommodation both for students and pupils was, it was stated, an urgent need. Mr. C. P. Trevelyan, M.P. (Parliamentary Secretary to the Board of Education), spoke of the claims of the association to support, stating that there were known to be some 5,000 absolutely deaf children under 15 in England and Wales, of whom 3,500 received special education, and that the scope of the skilled teacher's work was likely to be considerably extended owing to medical inspection having discovered a large number of partially deaf children in the elementary schools who needed oral instruction. Increased grants were being made by the Board of Education to the deaf and dumb, as well as to the blind and the mentally defective. Grants of something like £33 to £38 a year were paid also on account of each student in the Training College. But the association still stood in need of private subscriptions as well as State grants to enable it fully to accomplish its excellent objects. A demonstration of the methods of instruction used was subsequently given, and prizes were distributed by Mrs. Trevelyan.

Letters, Notes, and Answers.

☞ *Queries, answers, and communications relating to subjects to which special departments of the* BRITISH MEDICAL JOURNAL *are devoted will be found under their respective headings.*

QUERIES.

RETIRED G.P. asks for advice in the disposal of a library of medical works.

B. asks for outline of treatment for chronic painless chordee, causing a large upward curve.

TREATMENT OF SYPHILIS.

J. L. asks for suggestions as to a safe and sure treatment of syphilis for the ordinary patient under the care of his own doctor. From six to eight Wassermann tests and an equal number of salvarsan injections are out of the question. When one injection of salvarsan was supposed to cure, one had no hesitation in encouraging the patient to undergo the treatment. I have used intramuscular injections of grey oil and found them very efficacious. But is the cure permanent? Any one with much experience of Lambkin's calomel cream, or whatever its up-to-date equivalent is, would be doing us all a good turn by telling us how best to use it and for how long.

ANSWERS.

ULCERATIVE STOMATITIS.

DR. DRURY (Birmingham) writes to advise the use of thyroid extract for the relief of ulcerative stomatitis. I took this hint, he writes, from a suggestion in the BRITISH MEDICAL JOURNAL some years ago for a similar case, and found it quite successful.

HERYNG'S INHALER.—Several correspondents have written to inquire as to Heryng's inhaler referred to in the Epitome of Current Medical Literature of April 25th, paragraph 243. A description with illustrations may be found in Dr. Heryng's treatise on laryngoscopy, a French translation of which (*Traité de laryngoscopie et de laryngologie opératoire et clinique*), by Dr. Charles Siems, revised and enlarged by the author, was published in 1912 by Masson et Cie, 120, Boulevard Saint Germain, Paris, VI^e^. The apparatus is there described (p. 155) under the name of thermo-regulator for spray inhalations.

LETTERS, NOTES, ETC.

A DISCLAIMER.

DR. R. FORTESCUE FOX (London) writes: May I ask the courtesy of your columns to state that an article purporting to express my opinions and quoting from my medical writings, which appeared in a daily journal on July 14th, has been issued entirely without my consent or authority, and to my great annoyance?

THE HIGHEST VILLAGE IN SCOTLAND.

A CORRESPONDENT in the south of Scotland claims for Wanlockhead in the north-west of Dumfriesshire, that it is the highest village in Scotland, and that the claim for Tomintoul in Banffshire made in the SUPPLEMENT of July 4th, p. 11, cannot be sustained. The mistake, he says, is a very common one. We find on reference to gazetteers that the height of Wanlockhead is given as 1,350 ft., whereas Tomintoul is at the more moderate elevation of 1,160 ft.

THE INTENSIVE METALLIC IODINE TREATMENT FOR RHEUMATIC ARTHRITIC AFFECTIONS.

DR. THOMAS DUTTON (London, W.) writes: Dr. William Ewart states in the JOURNAL of May 16th, p. 1068, in reference to the above subject, that "hitherto iodine had practically not been tried internally." I may say I have been using iodine internally for more than twenty years, from the tincture to the syrup of iodine, both in rheumatic and tuberculous affections of joints (vide some unique cases of positive cures in the *Medical Press and Circular*, September 25th, 1913). The cases are all private patients who pay fees, who, I consider, are much more valuable in a clinical point of view than hospital patients. The cure was, I think, greatly helped by heliotherapy, another form of treatment I have practised for about the same period, although some of our Continental colleagues would lead the world to suppose they introduced this treatment to us because we have not their climatic advantages.

THE SERUM DIAGNOSIS OF PREGNANCY AND OF CANCER:

A CRITICAL STUDY OF ABDERHALDEN'S METHOD.

BY

ARCHIBALD LEITCH, M.B.,

PATHOLOGIST TO THE CANCER HOSPITAL, LONDON.

I. THE THEORY OF PROTECTIVE FERMENTS AND ITS PRACTICAL APPLICATION TO THE SERUM DIAGNOSIS OF PREGNANCY.

AN amazingly fruitful period in the progress of our knowledge of pathological processes was ushered in with the discovery that the blood serum in certain germ-caused diseases possessed the property of destroying these organisms or of neutralizing their toxic powers. There resulted from this, inspired, helped, or hindered by the theories of conflicting schools, countless experiments that taught us to recognize the fact that the blood serum gives evidence of reaction bodies (immune bodies) to very diverse substances (antigens) that have gained access to the system. Diverse though these substances be at first sight, they can all be classified as complicated proteins. They may be bacteria, toxins, products of vegetable origin, tissues or tissue constituents of other animal species, but they are all foreign to the economy of the particular animal into which they have been introduced by the breaking down of some natural barrier of defence. It is almost certain that the activities of all the reaction bodies towards such foreign substances are differently manifested in test-tube experiments and within the body, but by means of these test-tube experiments we can form some idea of the defensive mechanisms.

When we come to deal with substances less foreign to the body, such as the cells or cellular proteins of other animals belonging to the same species, the biological methods hitherto employed are generally useless to detect the presence of any reaction substances in the serum. That the system elaborates means of defence against them is evident, but we almost always fail to find evidences of that defence in the serum. It is true that occasionally such evidence may be forthcoming, but it is haphazard at the best. For example, Ehrlich, on one occasion, by injecting into a goat overwhelming amounts of the lysed corpuscles of other goats, produced in the serum a reaction body capable of setting free the haemoglobin of certain goats' corpuscles, but the experiment has never been successfully repeated, and had it not been that the name of this great authority was attached to the observation the possibility of its occurrence would have been disputed. At the most it is a rare experimental phenomenon, and no general conclusion can be drawn from it—a point that must be borne in mind when considering the details of Abderhalden's theory. Sometimes human serum exhibits a certain amount of haemolytic power towards the corpuscles of other individuals, and attempts have been made to connect this phenomenon with certain diseased states, but it is very inconstant, and is without any diagnostic value. Experiments in tissue transplantation, and especially the numerous experiments in mouse cancer inoculation, have shown us that the resistance to such grafts is very feeble, and, though an artificial resistance may be induced, it, too, is feeble and transitory, and no evidence of it is traceable in the blood serum by any present methods.

Few and fortuitous as these results are with substances so closely allied as the tissues of other animals of the same species, they are absolutely negative when we attempt to trace reactions to injections of an animal's own tissues. A resistance of a kind to mouse cancer inoculation may be induced by the previous injection of mouse spleen, but the injection of the animal's own splenic tissue is followed by no resistance whatever. This experiment, which we owe to Woglom, is one of the most important in recent cancer research, and quite crushed the expectations entertained by enthusiasts of being able to induce a specific resistance to cancer along the lines of previous research. Four years ago I endeavoured by injections of their own corpuscles into rabbits, subcutaneously or intramuscularly, every other day for a period of six weeks, to produce a haemolytic reaction body in the serum, but the experiments were quite negative. We have, in short, no experimental evidence along the lines on which we have gone that the blood serum shows any power of dealing with the cells of the body by producing reaction substances to them. We cannot, however, deny the possibility of the metabolic products of injected cells being dealt with by some bodies that may be present in the serum. Let me take an example that will focus the problems. In cancer we have a progressive growth, beyond their natural confines, of cells that have sprung from the normal body cells and still retain many of the parent properties. Apart from the extremely rare instances of spontaneous cure, the body shows no resistance against these cells; no state of immunity is induced. They go on growing, and they finally produce death. Omitting those cases in which the cancer prevents the discharge of some vital function, why should the disease be fatal? It can only be that these cells set free metabolic products which, either by their nature or by their amount, upset the regulating mechanisms of the body. It may quite well be that though there is no lethal reaction-body elaborated against them yet an attempt is made to cope with their products. And the question is, how is this attempt made? Are these products dealt with by the normal body cells, or does the blood serum acquire the power of breaking them up into less harmful constituents? If the latter could be shown to be the case we might hope to trace the changes. Here the genius of Abderhalden illumined the beginnings of a road into the fruitful unknown.

Abderhalden imagines that just as the cells of the intestinal tract have at their disposal ferments which split up the complicated food constituents into simple products suitable for absorption, so the cells of the body, having taken what they require from the blood, build it up and break it down into suitable combinations by the help of ferments. Thus in normal circumstances. But if anything foreign gains access to the blood stream, without having undergone preliminary degradation in the alimentary canal, then new and specific ferments are elaborated capable of breaking it down into simple constituents. These new ferments, originating without doubt in the body cells, will be set free in the blood plasma, and as we can only detect a ferment by means of its specific activity, so their presence will be demonstrated if we trace what occurs when the ferment-containing serum is brought into contact with the foreign substance on which it acts, or to use the appropriate nomenclature, when the specific *substrate* is provided. If we add gastric juice to such a protein as egg-albumen we find that the latter is digested into peptones in virtue of the presence of the ferment pepsin. Similarly we test for the presence of proteolytic, peptolytic, or inverting ferments in the blood by adding the plasma or serum to proteins, peptones, or sugar and observing the changes produced in these substrates. We cannot recognize a ferment apart from its action. This being so, it is obvious that we are faced with the question, Given the changes we should expect from the action of a ferment, are these changes due to the ferment or are they due to other causes? We shall only be entitled to assume ferment action when we can rule out of account the operation of all other factors producing the same result. This is the crux of Abderhalden's theory, and, as I shall show later on, he has not taken into account the extent of the other factors that contribute to the results on which he depends.

Abderhalden depends on two chief experiments for the basis of his theory. In the first place, he claimed to have observed in the blood plasma or serum of animals which had been injected with foreign peptone (that is, a peptone not derived from their own tissues) a ferment action on these peptones. This experiment was made by taking a mixture of the serum of the treated animals and a solution of the peptone, observing the polarimetric reading at once and noting the change produced after the lapse of varying periods of time. With the fresh serum of untreated animals or with the heated serum of treated animals (the heating would of course destroy the fermentative power) the initial rotation did not alter, whereas with the unheated serum of treated animals it increased. This observation he verified by repeated experiments. The second set of experiments dealt with the changes produced in mixtures of sugar solutions and the serum of animals which had previously had parenteral injections of sugar. In both cases the polarimetric readings were taken

to demonstrate the presence of peptolytic or inverting ferments respectively. In neither case, if one may take as typical the graphic representations which he gives, was the rotation considerable. The extreme rotation is to be reckoned not in degrees, not even as a rule in tenths of a degree, but in hundredths of a degree; and even supposing we were to admit that such small rotations were conclusive evidence of cleavage of the substrate by a ferment, yet even with the most delicate polarimeters and with the most experienced eyes it is gravely to be doubted if any one working with such a complicated substance as serum can be certain of reading with such meticulous exactitude. We know serum to be very unstable, and very slight departures from the strict isotonicity of added fluids are capable of producing evident changes in it. Generally speaking, it is questionable if polarimetric readings are more delicate than titration methods, and in such an important fundamental experiment it is unfortunate that Abderhalden neglected to bring forward the confirmatory evidence that could be supplied by such methods. He states, however, that the polarimetric readings in the experiments with protein are confirmed by the dialysation method, which will be considered in detail afterwards, and he admits that in the sugar injection experiments the desired results could only sometimes be obtained. If the serum of rabbits which have received injections of egg-albumen be added to this egg-albumen and the mixture dialysed, it will be found that the amount of ninhydrin-reacting substances in the dialysate is not appreciably, if at all, increased beyond the amount obtained when normal rabbit serum is used. I have repeated in rabbits his sugar experiments, but have failed to convince myself that any increase of the initial polarimetric rotation was produced or that the amounts of glucose found by titration differed when the mixtures of sugar and unheated serum were compared with those of sugar and heated serum. Complement deviation experiments were quite negative. In view of the experiments of Weinland previous to those of Abderhalden, and of those of Röhman and Kumagai subsequently, there is some independent support for this part of his claim, but there is considerable divergence as to how the result may be produced and as to what actually occurs.

But however favourably we view these fundamental experiments, we cannot fail to notice that the reactions claimed are against substances, quite foreign to the animal, which have gained access to the circulation in an abnormal way. And just as we have seen in discussing the reactions of immunity that there were reaction-bodies elaborated against proteins quite foreign to the animal body, scarcely any at all when the proteins were foreign to the animal but proper to the species, and none whatever when the proteins were derived from the animal itself, so it behoves us to be cautious before accepting a sweeping theory in which similar experimental links are wanting, all the more so because Abderhalden recently has brought his protective ferments into line with the immune bodies. That this is no captious criticism is evident from some experimental work published by Pincussohn and Petow.[1] These observers found that the *normal* serum of an animal has the power of splitting up the muscle peptone of its own species or that of allied species, but manifests no such action against the muscle peptone of foreign species. Indeed, the average polarimetric rotation in these experiments was greater than the small rotation depended on by Abderhalden for the diagnosis of pregnancy. If this observation be correct, then the polarimetric readings which have been relied on in the diagnosis of pregnancy and diseased conditions must be received with great suspicion. Human serum will break down placental peptone, not because the serum is that of a pregnant woman and the peptone is derived from a placenta but just because the serum *and* the peptone are from human beings.

In pregnancy there is a new organ interposed in the economy, existing only for a time. It will take up from the blood certain constituents for its requirements and it will return to the circulation certain products of metabolism, and it is assumed that these are dealt with, not so much by endocellular ferments as by special specific ferments in the plasma elaborated *ad hoc*. It seems rational, but it may or may not be true. Whether the placenta sets free into the blood characteristic proteins which are broken up by the supposed proteolytic ferments is a question vaguely discussed, but it seems to be assumed that the ultimate cleavage products of a protein are capable of calling forth a whole order of ferments acting specifically on all the higher combinations of these constituents. Thus, for example, the introduction of a peptone into the blood may call forth in response a ferment for the protein from which the original peptone was derived as well as a ferment for the peptone itself.

Two separate methods are employed for the detection of the presence of ferments, the polarimetric method by which the degradation of peptones may be observed, and the dialysation method by which the degradation products of proteins may be separated. The latter is the method on which most of the work has been done. According to Abderhalden, the results of the two methods always agree. I have used the dialysation method solely in the following experiments. If we take the procedure adopted in the diagnosis of pregnancy as an example, the technique is briefly as follows:

Fresh healthy placental tissue from which the blood clot has been removed is cut up into pieces and washed until it is colourless. It is boiled several times in five times its volume of distilled water, until the water when filtered fails to give a colour when boiled with 1 c.cm. of a 10 per cent. solution of ninhydrin. The pieces of placental tissue may then be stored in sterile distilled water under a thick covering of toluol. These pieces contain the coagulated placental protein, in addition, of course, to other substances which are not of immediate importance, and they serve as *substrate* for the demonstration of the ferment action. The serum under examination for the presence or absence of specific ferments is obtained by removing a quantity of blood from the patient by venipuncture, and allowing this to clot spontaneously. Special dialysation tubes are used, which are supposed to retain proteins and to allow peptones and amino-acids to diffuse through. These tubes are placed in 20 c.cm. of sterile distilled water in small Erlenmeyer flasks. Into one tube we put a teased-out portion of the placental tissue (roughly about ½ to 1 gram) and add to this a certain fixed quantity of the serum (either 1 c.cm. or 1.5 c.cm.), taking care to avoid any of the serum getting into the water outside the tube. Into another tube, which is to serve as a control to this test, we put 1.5 c.cm. of the serum only. In both cases we cover the contents of the tube and the surrounding water in the container with a thick layer of toluol in order to prevent evaporation and bacterial contamination. The tubes are incubated at 37° C. for sixteen hours. At the end of that time 10 c.cm. of each dialysate is removed and tested with 0.2 c.cm. of ninhydrin solution, the test tubes being boiled uniformly for exactly one minute. A violet colour denotes the presence of peptones or amino-acids.

Supposing a specific proteolytic ferment is present in the serum, then the dialysate of the first tube will contain peptones and amino-acids, and these will be demonstrated by the violet colour with ninhydrin. If the ferment is absent, then there will be no production of peptones and no reacting substance will be found in the dialysate. On the other hand, the dialysate of the second tube, containing serum alone, will show no ninhydrin-reacting substance, because there is no *substrate* on which the ferment can act; the water will remain colourless. However, some serums contain diffusible substances in sufficient amounts to be detected in the dialysates by ninhydrin, and in such cases we shall have to judge of the presence or absence of specific ferments by the comparative depths of colour in the two tubes. If, therefore, we obtain a violet colour when we add ninhydrin to the dialysate of a tube containing serum *plus* placenta, and no colour (or one much less marked) with the dialysate from the tube containing serum alone, then the conclusion is that the individual from whom the serum was taken is pregnant. If no colour is found in the case of either tube, or no comparative difference of colour, then the individual is not pregnant. Similarly for the diagnosis of certain diseased conditions: in cancer we employ cancerous tissue as substrate; in exophthalmic goitre, thyroid tissue; and so on.

The method has a wide application in the serum diagnosis of disease. Hundreds of papers have been published giving uniformly good results. The conception has deeply stirred the minds of investigators in all parts of the world. It is true that there have been a few doubters, but these sceptics are met with the constant assertion that their methods are faulty, and that they have not taken into account certain possible fallacies.

These fallacies can be invoked to explain away almost every conceivable mistake in diagnosis.

We must seriously ask ourselves if the method is to be relied on for information in clinically doubtful cases. According to Abderhalden, the proper reading of the result is never wrong—a claim that reminds one of the Delphic oracle.

The method of performing the reaction, which has been sketched roughly above, is given in very voluminous detail in Abderhalden's *Abwehrfermente des tierischen Organismus* and in numerous publications in various journals. The method is by no means difficult, and the technique is easy to follow. A method that cannot be carried out by the average laboratory worker who exhibits ordinary care is not of much utility. Though I have worked with this reaction for more than eighteen months, I have rejected the results obtained during the first half of that period, so as to avoid the criticism of being unfamiliar with the technique. During that first period, however, the results were much more favourable to Abderhalden's claims than afterwards. The reason is not far to seek. Captivated by the theory which opened up for us great possibilities in cancer investigation, carried along by the host of communications that hailed the method as well-nigh infallible, perhaps intimidated by the scorn poured on the few that doubted, I accepted uncritically the good results, shut my eyes to those that were doubtful, and found excuses to reject those that were adverse—for a time. In the later period, when I was untrammelled by authority, it was found that the results were far from supporting the claims put forward. The technique given by Abderhalden was slavishly followed. His retort to that is: "I treat such assertions with the scepticism born of a rich experience." Such a reply might be overwhelming if his own published technique were above reproach. I can only say that I have done my best to follow his directions without actually having made the customary pilgrimage to Halle to receive the direct apostolic revelations from the master.

In the following examples of the practical application of the method I first investigated the reaction in pregnancy because the true diagnosis of the condition cannot long remain in doubt and we are soon enabled to verify our results. It is seldom that the condition is doubtful, and the serum diagnosis of pregnancy would only have a limited value. In cancer, on the other hand, a method of serum diagnosis would be of the utmost practical importance. I have tried all the methods hitherto advocated; they are all worthless in practice. But if the procedure of Abderhalden was capable of giving good results in pregnancy it might reasonably be expected to give good results in cancer, though the relation of the placenta to the maternal organism is not strictly comparable to the relations existing between malignant tumour cells and the rest of the body. In every case here recorded the true diagnosis is known. To prevent the knowledge of the condition of the patient furnishing the serum having any effect on our reading of the reactions—a vital point—the tubes were numbered, the numbers written down for later identification, and the tests conducted and the final readings made without being aware of the clinical diagnosis of the conditions. It is impossible to avoid bias otherwise. Again, the tests were manifolded. It sometimes happened that very strange results were recorded. For example, the controls might give deeper colours than the actual tests themselves, or the readings might be equivocal throughout any set. In such cases I rejected the result altogether as well as the dialysation tubes in these cases. The colours obtained with ninhydrin varied from light lilac to deep violet. In making a comparison between the tubes I have neglected weak tints, representing these as negative, except where there was a difference between the test and its control, and in this way I have been generous towards the method. The deepest colours are represented throughout by +++.

The figures in Table I show that 34 cases gave more or less clear positive results, but two cases were absolutely negative; in these two cases the serum was quite fresh. In one of these cases the clinical diagnosis was doubtful; the reaction was negative; the further history of the case showed that the patient was three months pregnant at the time. Positive reactions are therefore the rule in cases of pregnancy, and have been found much more frequently in this than in any other condition I have examined. Unless I have been unconsciously generous in my readings to the theory, or unless the serum of pregnancy is more unstable than is the rule in other conditions, then a certain amount of support might be accorded to Abderhalden's idea of specific guardian-ferments.

TABLE I.—*Tests with the Serum of Pregnant Cases.*

Thirty-six cases were investigated. For most of the material I am indebted to my friend Dr. S. J. Cameron, of Glasgow (26 cases). These serums were sent to me by post and were two to four days old when used. In the other 10 cases I withdrew the blood myself, six of these patients having been sent to me by my colleague Mr. Dinnick.

	Age of Pregnancy, etc.	Serum alone 1 c.cm.	Serum alone 1.5 c.cm.	Placenta + 1 c.cm. Serum.	Placenta + 1.5 c.cm. Serum.

The serum in Nos. 4, 10, 12, 15, 17, 27, 28, 32, 34, was haemoglobin tinted; in the other cases it was free. In Nos. 1, 34, 35, 36, more than four hours elapsed between the taking of a meal and the withdrawal of the blood; in the other cases I am unaware of the times elapsing.

Control Tests with the Serum of Other Gynaecological Conditions.

Particulars of the eleven cases tested are given in Table II. The first case of chorion-epithelioma was only detected after hysterectomy had been performed. There was no suspicion of its presence, but the reaction, as we might have expected, was positive. The serum was again examined after an interval of twenty days, and again one month later, no symptoms or signs of metastases having manifested themselves, but the reaction in both cases was still positive. The case of endometritis (No. 4) might possibly have been one of retained products of conception, as the curettings were not microscopically examined. The other three cases that gave clear positive results

were not pregnant (two of them being re-examined with the same result), and are practical demonstrations of the unreliability of the reaction. No. 6 was considered clinically to be a pregnancy of the third month; the reaction was positive; the case was followed up; she was not pregnant, and had not aborted. The last case of uterine fibroid (No. 11) is of interest because there was a conflict of opinion as to its nature, and the Abderhalden reaction was twice invoked to assist in the diagnosis. Twice it pointed to pregnancy; the surgeon removed the uterus; it was a soft fibro-myoma, and there was no pregnancy. The times that elapsed between meals and the withdrawal of the serum in this case are unknown to me.

TABLE II.—*Control Tests: Gynaecological Patients.*

All the serums were fresh. Only the serum of No. 5 was haemoglobin-stained. The blood in all cases, with the exception of No. 11, was withdrawn at time of operation.

Control Tests with the Serum of Cancer Patients.

The following cases were all operable, and the blood was withdrawn from them at the time of operation when they were in a fasting condition.

TABLE III.—*Control Tests: Cancer Patients.*

The first 10 cases are females, the other 12 males. In Nos. 7 and 17 only had the serum a haemoglobin tint. Throughout the tests were duplicated, with the same results as given below.

	Disease.	Serum alone, 1 c.cm.	Serum alone, 1.5 c.cm.	Placenta, + 1 c.cm. Serum.	Placenta, +1.5 c.cm. Serum.

In No. 6 dialysation of the serum against running water for a few hours failed to remove from the serum all its dialysable ninhydrin-reacting constituents. I have frequently noticed this, and it is probably due to the progressive spontaneous cleavage of the serum proteins. I cannot vouch for the sterility of a serum after it has undergone dialysis against running water, but I do not think that bacterial contamination has much to do with the result.

Several authors have said that cancer serum may break down placental protein, whilst others deny this. If both in pregnancy and in cancer there exist ferments in the serum capable of degrading placental and cancer-cell protein respectively, we should expect *a priori* that these ferments would operate on allied substrates, though perhaps to a lesser extent, because none of the immune reaction bodies that we know is strictly specific. Abderhalden recommends that only placentas should be used in the pregnancy reaction which fail to give reactions with cancer serums. Personally I have never encountered such a placenta, and I doubt if it exists.

Control Tests with Serums from Normal and other Conditions.

With the exception of Nos. 1, 2, 9, 18, 21, 24, 25, 26, in which the length of time that elapsed between the last meal and the withdrawal of the blood is unknown to me, all the others were operation cases, and the blood was removed at the time of operation.

TABLE IV.—*Control Tests: Normal and other Conditions.*

Cases 1 to 20 are females; 21 to 31 males.

	Condition.	Serum alone, 1 c.cm.	Serum alone, 1.5 c.cm.	Placenta, + 1 c.cm. Serum.	Placenta, +1.5 c.cm. Serum.

29	Tuberculous peritonitis ...	0	+	+	+
30	Haemorrhoids	0	0	+	++
31	Chronic appendicitis ...	0	0	+	++

The serum of Nos. 13, 19, 23, 24, 25 was haemoglobin-stained; in No. 25 the serum was more deeply stained than in any other case examined. All the serums were fresh.

This table shows, better perhaps than any of the others, that different readings can be obtained as we compare the tubes containing 1 c.cm. of serum, or those containing 1.5 c.cm. of serum; but taking the readings of the two sets together and leaving out of account the indications

given by a single set, we find that the best we can say for the reaction is that it makes mistakes in 5 cases out of 31. If we believe firmly in the reaction, we may make excuses for two of these five cases (1 and 21) by saying that the blood was withdrawn too soon after a meal, and we may excuse the other three palpable lapses by saying that we must have committed some error of technique, for no man is infallible, and we can the more readily accord the view of fallibility to others than to ourselves. Judging from the large amount of other work that Abderhalden turns out of his laboratory, it is scarcely possible that he can have personally attended to the examination of the very large number of cases on which he or his assistants have reported.

Summary.

To sum up the results of the above 100 cases tested to prove the diagnostic worth of the dialysation reaction in pregnancy, we find that by the most generous reading possible, judging by two sets of experiments and not by the usual one, making allowances for all the hypothetical fallacies, we have still 17 most glaring mistakes in diagnosis, which of itself is a large percentage, sufficient to destroy the diagnostic worth of the reaction. But if we apply to the good results the same code of ethics by which we reject the undesired, then the whole theory becomes worthless.

In a second article the question of protective ferments in cancer will be considered, and the inherent fallacies of the method will be examined in detail.

Presidential Addresses

TO THE

BRANCHES OF THE BRITISH MEDICAL ASSOCIATION.

BORDER COUNTIES BRANCH.

NATIONAL HEALTH INSURANCE.

BY

JOHN BELL FISHER, M.D., D.P.H.,

WHITEHAVEN.

In the first place permit me to express to you my best thanks for the honour you have done me in electing me President of the Border Counties Branch. It is a position I appreciate very highly. Our Association has been and is passing through troublous times. We have had dissensions within and attacks from without; a rush to join our ranks when danger threatened; withdrawals and resignations when these same persons failed to get all their own way. Grumblings we have had in plenty, because the Association failed to secure all the advantages for the profession that these most exacting critics demanded—the critics being for the most part those who did nothing themselves either for the Association or the profession, but thought apparently that membership of the Association entitled them to be spoon-fed with benefits without any effort on their own part.

These tribulations, however, we have survived, and will survive; they should only serve to bind more closely together those who have the best interests of the profession and the Association at heart. For the interests of the profession and the interests of the Association are one, and the Association is doing its best work when it is safeguarding the interests of the profession at large and not of any particular section.

The National Health Insurance Act directly affects the great majority of the profession, and profoundly alters their relation to their patients, to the general public, and to the State. Even those who are not on the panel are bound to be affected sooner or later, for it is quite certain that this Act is only the beginning of still greater changes. Dependants will be brought within its scope; institutional treatment cannot for long be confined to tuberculosis; our general hospitals cannot be expected to undertake the wholesale treatment of insured persons and continue to be supported by voluntary contributions. State aid or municipal aid will have to be accorded them, and this inevitably involves more or less State or municipal supervision. The Act has already checked the flow of voluntary contributions. It will doubtless continue to do so in an ever-increasing degree. Where the end will be no one can tell.

Certain it is, however, that greater changes than we have yet seen will be brought about, and it behoves us to consider and anticipate these changes, so that, as far as possible, they may be so controlled and directed as to secure the best possible results for the profession and the public weal.

I believe most strongly that there is no subject of such vital importance to the profession at the present time, and none so essential to the welfare of our patients, as the establishment on a sound and just basis of the relation that is to exist in future between doctor and patient. That the old relation is to be changed fundamentally none can doubt. It has been altered already for some fifteen million persons, and a vast majority of the profession. The full extent of the change is not yet appreciated, but it is not the less on that account a change of the most radical kind, and whether it is to be for better or worse depends very largely on the wisdom of the course taken by the profession as a whole, and the unity and singleness of purpose with which they persist in carrying out what they conceive to be the best policy alike for themselves and for their patients.

We have to recognize the fact that insurance is the law of the land, and that the vast majority of the medical profession have accepted service under the National Insurance Act as it is. What I want to insist upon to-day, with all the force of which I am capable, is that we are not on that account to consider that there is nothing more for the profession to do than merely go on quietly and submissively attending to the bodily ailments of our patients, leaving the arrangements for organization and control of the relations between the doctors and their patients to committees and Commissioners. It is now for the first time that the necessity has arisen for doctors to attend to their own business. Under the conditions of State insurance unless the doctors look after their own interests they will certainly suffer. The State undertakes that the insured person shall have proper medical attention, and the insured person himself expects it, and the approved societies complain that the demands on their funds are excessive. Amongst so many contending forces the doctor will fare badly unless he can protect his own interests, and this he is absolutely unable to do individually against such powerful influences. Let no one suppose that finality has been reached in the arrangements made for providing and paying for medical attendance, or in the conditions imposed upon doctors.

The National Insurance Act, 1911, only came into operation, so far as medical service is concerned, in January, 1913, yet an amending Act was passed during 1913, and only pressure of other business in Parliament has prevented the introduction of another amending Act in 1914.

We know that the approved societies are exerting their influence to secure that the next amending Act shall restore to the societies the "control of their own doctor," as they term it. We know one great reason for this to be that many of the societies have been very hard hit. The amount of sickness benefit they have been called upon to pay has greatly exceeded their estimate, and they desire the control of the doctor because they think it will enable them to influence him in the direction of giving fewer certificates of incapacity for work, and such as he does give for shorter periods.

I think myself that both the societies and the doctors made a mistake in the first instance in attaching too much importance to this matter of control of the doctor, to the neglect of other and more important issues. When the Insurance Bill was first under discussion it was generally anticipated that the "approved societies" contemplated in the bill were the old-established friendly societies, such as the Oddfellows, Foresters, and the like, together with clubs providing medical attendance as one of their benefits in connexion with certain localities or industries. The inclusion of trade unions, and more especially of the large industrial insurance associations, amongst the approved societies has entirely altered the outlook. I think the objection on the part of doctors to

"society control" as it previously existed was much exaggerated. Each lodge, or court, consisted of local men, who had no antipathy to doctors in general, and certainly none to the doctor of their choice—"our own doctor," as they called him. Little differences necessarily arose, but the objection to "society control" was not found to exist chiefly amongst the supposed victims of a pernicious and tyrannical system, the club doctors. Rather was it a bogie raised to frighten the uninitiated by those who had no connexion with, and knew very little about, club practice. Our own JOURNAL at one time said some very unkind things about the demoralizing effect of "contract practice" alike on patient and doctor, but these persons themselves did not seem to be aware that they stood in need of sympathy or commiseration. The advent of the large industrial insurance companies has entirely altered the conditions. Instead of having to deal with a committee of local men, mostly kindly disposed towards the doctor, we have a huge association of members whose very number prevents them having that personal knowledge of one another from which sympathy and co-ordination spring—an association governed and controlled by a bureau, the constitution of which is absolutely unknown to most of the members, acting through agents who are the mere tools of the managing committee. The members know nothing of their society except as represented by the agent, the agent can only give unquestioning obedience to the instructions of the managing committee, and the managing committee is a body of business men who are guided solely by financial and statistical considerations, to whom insured persons and doctors alike are mere factors in their calculations. The element of personal knowledge and individual sympathy is entirely wanting.

That is what I mean by saying that the friendly societies and doctors alike made a mistake in making this question of control of the doctor a leading plank in their platform at a time when more important matters should have engaged their attention. For, as the matter stands at present, neither has successfully attained what was aimed at. The societies have lost their power of selecting their doctor who shall be entirely responsible to the society, and no one can pretend that "free choice of doctor" is anything more than a pious opinion in the vast majority of cases.

In the case of trade unions or similar bodies, and in pre-existing clubs, free choice of doctor is out of the question for the vast majority of the members, accustomed as they are to acquiesce in the views and obey the orders of their leaders.

In the future, however, this question of control, of which free choice is only one feature, is destined to be the most important that the profession will have to deal with. It may at first sight seem like putting the cart before the horse to attempt to speak about control before settling the question of free choice, for it is obvious that if there is not at least a nominally free choice of doctor—that is, if the doctor is not chosen by the individual patient, but by his society—that doctor will be under the control of the society or the society's managers. He will have to carry out their wishes in all essential particulars, or they will change their doctor if there is another available. It is for this reason that societies so much object to free choice of doctor by the patient. They think, no doubt rightly, that if they have the legal right to engage or dismiss their doctor, the difficulty of control will be reduced to a minimum.

But first of all let us consider what is meant by "control of the doctor," as it is not very euphemistically called. It does not, or should not, mean interference in detail with the medical treatment of a patient by his doctor. But it is essential that either the societies or the State which provides the money, or administers the funds, should have some power to prevent wasteful and extravagant expenditure either in the drugs they have to pay for, or in the cash benefit they have to provide when a patient is certified unfit to follow his occupation.

How can this control be exercised in the most efficient manner and with the least possible interference with the doctor's right to do what he thinks best for his patient?

Compulsory sickness insurance is a new thing in this country. We have had no experience of it. Our views are therefore apt to be distorted or one-sided, according to our preconceived notions. Can we learn anything from the experience of other countries in which insurance laws have been in operation long enough to show the good and bad effects of different methods, the dangers to be feared, and how these may best be avoided?

Germany has had compulsory insurance since 1884. Generally speaking, insurance against sickness has been compulsory for all manual workers except agricultural workers and domestic servants, and for some other classes of workers, such as foremen and commercial employees, if their income did not exceed £100 a year. Under the new law agricultural workers and domestic servants are included, and the income limit for other classes is raised to £125 a year.

In 1909 over 13,000,000, or 21 per cent. of the total population, were insured against sickness. In 1885 it was 10 per cent., in 1890 it was 14 per cent., in 1895 it was 15 per cent., in 1900 it was 18 per cent., in 1905 it was 20 per cent., and in 1910 it was 22 per cent.

Sickness insurance is effected through local societies of insured persons. These societies are of several kinds, and the insured person has no choice of society; it is automatically determined for him by the locality in which he lives or works and the nature of his employment. The only exception is that a person who is adequately insured in a registered society—corresponding to an English friendly society—is released from other insurance, but in this case he has to pay the whole cost himself, his employer has not to contribute to the credit of such an employee.

In ordinary cases (that is, apart from these registered societies) the contributions are a percentage of the wages. The workman pays two-thirds, the employer one-third. The public authorities do not directly grant any subsidy towards sickness insurance, but they supervise the administration, and the cost of this is considerable.

The societies are self-governing. The governing bodies are directly elected by the insured persons and the employers, the number of representatives being proportionate to the contributions—that is, two-thirds are elected by the insured, one-third by the employers.

From what I have said it will be evident that the circumstances in Germany differ from those in England to a considerable extent, and these differences have to be taken into account in applying the lessons of German experience to our own requirements. In the first place, free choice of doctor is not a statutory right of the patient in Germany as it is with us. The societies are left to make arrangements with the doctors as best they can; the State lays down the benefits which the societies must provide, and only interferes when it appears that a society or all the societies in a district have failed to carry out their legal obligations.

In 1903 a new or amending law was passed in Germany which failed to satisfy the doctors because it did not concede the demands which they considered reasonable. Accordingly, they resolved to adopt an independent course of action. At Cologne, in particular, the doctors, who were strongly organized, gave notice to terminate their agreements with the sickness societies at the end of the year. They demanded organized free choice of doctor, higher remuneration, and better conditions of service. The "Federation of Sickness Societies" in Cologne, to which were affiliated all the sickness insurance societies, proceeded to secure the services of doctors from outside Cologne, though continuing negotiations with the Cologne doctors in the hope of a peaceful settlement.

Some of these doctors from outside, on whom the societies had relied, realizing, I suppose, the actual position of affairs, refused to continue their services, despite their contracts. This led to a shortage of doctors, and complaints were made to the local supervising authority that the sickness societies were not providing a sufficient number of doctors to ensure proper and adequate treatment, as they are required by law to do. The local authority called upon the societies to provide more doctors within a very short time. The societies were unable to do so. The local authority accordingly made agreements with the organized doctors over the heads of the sickness societies for the treatment of insured persons. These agreements were made for five years, terminating at the end of January, 1909, and provided for free choice of doctor and increased remuneration. During this period the bitter feeling between the doctors and the

sickness societies was intensified by the fact that the societies had taken action for breach of contract against the doctors who had refused to continue their services in 1904. Before the end of January, 1909, the societies had been busy, through their federation, obtaining doctors in different parts of Germany who were willing to serve them on the terms offered, and were able to enlist a sufficient number to prevent the local authority renewing the arrangements with the organized doctors. The societies had seventy to eighty doctors, mostly imported, whilst over three hundred organized doctors refused to have anything to do with the sickness societies. With the aid of these doctors, gathered from all parts of Germany, the societies are able to carry on their operations, but it is certain that these imported doctors do not represent a high standard of professional efficiency, and the medical treatment provided for insured persons is far from satisfactory.

Such was the position at the end of last year, after thirty years of compulsory sickness insurance law. Surely it behoves us to think seriously and act discreetly, so as to secure that, profiting by their experience, we shall not repeat their mistakes, but from the first combine in an effective organization to safeguard the interests of the profession.

During last year (1913) matters had reached such a pass that throughout Germany doctors had posted up in their surgeries notices to the effect that after the end of the year they would cease to give service under the insurance law, and that all persons requiring medical attendance would be required to pay as private patients. This course was taken partly on account of the inadequacy of the existing rates of remuneration, but chiefly, I believe, to obtain recognition of their organizations, both in the settlement of terms of service and in the exercise of control over medical service, including disciplinary measures. The doctors in Germany are now well organized. Owing to the fact that the societies are self-governing—there is no administrative authority corresponding to our County Insurance Committee—the conditions differ in different localities, and the organizations of the doctors are consequently somewhat of a local character. This has made it more difficult to secure uniformity. With us the existence of Insurance Committees and of Insurance Commissioners tends to secure uniformity, and should render easier an effective organization of the profession.

In Cologne both sides have made great sacrifices for what they consider their rights, and neither has succeeded in obtaining what they desire. It is impossible to believe that either side is absolutely blameless and the other entirely in the wrong.

The doctors, as I have said, failed to secure the insertion in the law of 1903 of the amendments which they desired, and gave notice to terminate their engagements. The societies set to work to secure doctors from outside.

The doctors wanted increased remuneration, free choice of doctor, and "better conditions of service," the last mentioned term meaning, I take it, freedom from lay control.

The societies complained that the cost of medical service was very high, that with free choice of doctor the societies could exercise practically no control over the doctors, who ordered drugs and appliances extravagantly, and gave certificates of inability to work much too freely, with the result that the expenses of the societies were unduly increased.

During the period that the arrangements made by the local authority over the heads of the societies were in force in Cologne and the neighbourhood it was asserted that the expenses of the societies in medical and money benefit had increased 49 per cent. whilst the membership had only increased a little over 21 per cent. Since the societies have resumed the appointment of doctors, and brought in those from outside, it is a remarkable and significant fact that the high level of expenditure for medical benefit attained during the compulsory period has been maintained. The service is admittedly less efficient, its cost to the societies is not diminished. The one fact that stands out prominently is that the result of combination by the doctors is the increased rate of remuneration.

But there is another side to the question. If the societies have not gained anything in the cost of medical benefit, they have certainly effected a saving in respect of other benefits. One of the largest of the Cologne societies found its reserve fund gradually diminishing under the compulsory system (that is, when the arrangement between doctors and the local authority were in force), and in spite of increased subscriptions was getting into financial difficulties. Since the society has appointed the imported doctors, it has been able to commence the rebuilding of its reserves, whilst at the same time increasing its benefits.

These are facts which cannot lightly be set aside. The doctor, like every other expert, is impatient of lay control. Yet it is absolutely essential that some effective control should be exercised over the prescribing of expensive drugs in inordinate quantity, the giving of certificates of unfitness for work on the most trivial pretence, the continuance of certificates of inability after the necessity for them has ceased. Under the old friendly societies there was much less tendency on the part of the patient to get all he could out of the society. On the whole, the members of these societies were the more provident and thrifty men, of independent spirit, who took a pride in never having made a demand on the funds after a long membership. They realized, too, that after all it was their own money that they received in benefits, and that excessive and unnecessary demands on the society's funds weakened their society, the welfare of which they had deeply at heart. The doctor was therefore not so often asked to certify as unfit for work a person whom he thought fit, and on the comparatively infrequent occasions when he refused to certify a patient on the club he was sure of the support of the other members, who realized that he did so in the interests of the society.

Under the new conditions of National Insurance the case is different. We may not have secured free choice of doctor to the extent that is desirable, but the very persons who are most troublesome in this respect are those who know best what freedom they have under the Act. They know they can change their doctor at the end of each year without having to give any reason for doing so, and the doctor knows, too, that if he is too strict in the matter of certificates of unfitness for work he will lose his popularity, and his patients will seek other more obliging practitioners. Without intending to be unduly lenient, even when he thinks that he is acting with all due stringency, the doctor may err from want of consideration of other factors than the purely medical aspects of the case. The doctor must, if he is to do justice to the society to which the patient belongs, endeavour to look at the matter from their point of view. Approved societies consist of persons whose narrow means habituate them to a much sterner standard of life than obtains amongst many of his private patients, and than he is himself accustomed to. And unless this fact is recognized; that is, if the doctor applies to these cases of insured persons the easy standards of persons in more comfortable circumstances, it is quite impossible for the societies to meet their liabilities. In the case of the old friendly societies especially (and these are deserving of the greatest consideration at the hands of the doctor), it is by the contributions of workmen who are living close to the hard realities of a strenuous life that the society is maintained. If every applicant for medical treatment is to be given a few weeks' relief from work at the expense of his club, if we are to ignore the financial side of the question altogether and give to every such applicant the consideration that is given to the opulent valetudinarian, the bankruptcy of the societies is imminent. It may seem that I am pointing out self-evident facts, and making merely general and indefinite statements that have no practical bearing. I am speaking from experience of actual cases when I say that certificates are given too often without due consideration; they are given, no doubt, with a kindly intention, with a sympathetic regard for the comfort or convenience of the particular patient, but at the same time without regard to the interests of those other persons, scarcely less requiring rest and medical treatment in the meantime and whose prospective relief when their turn comes is being frittered away in undeserved charity.

In the matter of prescribing, too, during the short experience we have had of National Insurance, it has been made abundantly evident that a very rigid system of control is necessary.

In Germany, it will have been noticed that whenever the local supervising authority has been appealed to it is with the "organized doctors" that a contract has been made. More and more the doctors throughout Germany have found, as time went on, the absolute necessity of organization. These organizations, at first local and tentative, have so far justified their existence and proved their value that at the end of last year (1913) it was found to be possible to secure practical unanimity throughout Germany, notwithstanding the difficulties inherent in the German system of individual control of its own affairs by every little local society.

The conflict between the organized doctors and the Sickness Society of Leipsig is equally instructive as to the value of organization, and has brought about a generally satisfactory state of things in this society, which is recognized as the most important in Germany. The members have free choice of doctor, and what is of the very greatest importance, the doctors are represented by a committee, which is mainly responsible for control over the doctors. Any complaint against a doctor is made to this committee, which is empowered to take such disciplinary action as may be necessary if the complaint is found to be well founded. The remuneration of the doctors is distributed through this committee, which examines the accounts and prescriptions and checks the extent to which doctors have certified persons as incapacitated for work, with power to fine the doctor and require him to refund any money paid to an insured person on an improper certificate. This, I think, is the best possible kind of control of medical service. The doctors as an organized body agree as to the terms on which services shall be rendered, receive and distribute the remuneration, and themselves exercise disciplinary powers independently of any lay interference.

In addition to this the Leipsig society (not the doctors' committee) employs "confidential medical advisers," as they call them, or, as we should say, "medical referees."

A consideration of the actual experience of Germany seems to me to be useful at the present time, in so far as it shows us what has actually occurred there. The facts revealed and difficulties encountered, it is true, are only such as might almost have been anticipated, still we are on surer ground when we can refer to actual experiences. It is an unfortunate fact that at present the vast majority of the profession in this country take very little interest in the subject of National Insurance, except in so far as it affects their own individual practice. Very few, indeed, consider its bearing on the future, or take any trouble to understand the importance of the change which is taking place.

I attended the conference at Westminster in June of the chairmen and secretaries of the various Panel Committees with the Insurance Commissioners for England, at whose invitation the conference was held, to consider "medical certification for sickness benefit under the Insurance Act and proposals for the improvement of procedure in reference thereto."

What surprised me most of all was the lack of appreciation by many of the speakers of the altered position of the doctor towards insured persons and approved societies that has been brought about by the Act, and the relation of both to Insurance Committees and the Insurance Commissioners.

Various suggestions and arguments were advanced which would have been good in themselves as regards friendly societies before we had any Insurance Act, but which a moment's consideration showed to be absolutely inconsistent with the actual provisions of the Act. The consequence was that very little was done beyond an explanation by the Commissioners of what was expected of the doctors. A circular (marked "Confidential") had been issued to those present on behalf of the Panel Committees, and the different paragraphs of this circular were taken one by one, and after some discussion by the doctors and explanation by the Commissioners, mostly agreed to as they stood. The proposals in the circular were for the most part fair and reasonable, and the attitude of the Commissioners conciliatory and explanatory. What was disappointing was that, owing to the lack of appreciation of the altered conditions created by the Insurance Act to which I have referred, some of the doctors took up so much time in futile advocacy of methods impossible under the Act that suggestions of real value were crowded out and could not be considered.

I refer to this matter here simply as illustrating the impotence of the profession for want of co-ordination or organization. Had the doctors present prepared their case with the same care as the Commissioners there can be no doubt that it might have been presented in a much more effectual form.

It is for organization I am pleading to-day. We have seen that one amending Act has already been required. Others are to follow. In these, and in the amended Regulations which will be made by the Commissioners many matters of vital importance to the profession will be dealt with.

At present certification is engaging the attention of the Commissioners, who purpose to hold conferences with Panel Committees on the subject.

The following and many other subjects will have to engage the attention of the profession if it is not to be hopelessly reduced to a position of abject servility:

The payment for mileage is on a very unsatisfactory footing.
The fact that there is no provision for the payment of an anaesthetist or for assistance in emergency operations;
That abortions and premature confinements are included in the capitation fee;
That persons whose illness is due to their own misconduct are deprived of other benefits, but are still entitled to medical attendance for their capitation fee;
That whilst we engage to attend insured persons for a capitation fee of 7s., deductions are made without our consent, or even in spite of our protests, for the payment of "case values" to other districts.

Then it is to be remembered that 2s. 6d. of the 7s. a head depends, not on the Act itself, but on a Treasury grant. Already there is an outcry in certain quarters that the doctors are overpaid. Unless the doctors can put forward their own claims with some authority, what assurance have we that that grant will not be reduced, or withdrawn altogether, at the end of the three years for which it was made?

One matter of real importance that has not obtained the consideration it deserves in connexion with control of the medical service is the constitution and working of the Medical Service Subcommittee under the Act—the "Complaints Committee," as it was called in the bill as originally drafted. This committee consists of three doctors, three representatives of insured persons, and an independent chairman; many matters have to be referred to it which ought to be dealt with by doctors alone. This view was strongly urged on the promoters of the bill, but was rejected. In Germany it was not provided for at first, but has been obtained by organization amongst the doctors, and doubtless if the doctors here will combine effectually they will be able in future legislation to secure that strictly medical matters shall be left to medical committees, as in the case of the Sickness Society of Leipsig to which I have referred. It is true we have the Panel Committees, and it is perhaps too soon to pronounce definitely on their actual powers and utility, but, judging from appearances at present, I am of opinion that Panel Committees are likely to be bound up in so much red tape and so much under the thumb of the Insurance Commissioners that they will have no real power to protect the interests of the profession, and will be employed simply to assist in the administration of the Act in an advisory capacity. A strong, independent, unofficial body is required to look after the real interests of the profession.

In Germany it was by organization amongst themselves that improvements in the conditions of service were at last obtained by the doctors. They first tried to regulate their conditions of service and protect their interests through the official channels. Medical councils sought to lay down the terms on which service should be rendered, and threatened penalties if compliance was not given to their directions. But this was forbidden by the Government authorities as beyond the province of the medical councils.

A society, roughly corresponding with the British Medical Association, had existed in Germany since 1873, but in 1900 another society was formed to protect the economic interests of doctors, especially against sickness societies. This is really a trade union of medical practitioners, and is described as an "aggressive fighting

machine." It has a membership of nearly 24,000, which is said to be over 95 per cent. of the medical practitioners in Germany who have anything to do with insurance practice.

This society tried at first to secure its ends by legislation, but after three years of failure in this direction, by a resolution passed at its annual meeting in 1903 definitely took up the methods of independent action on trade union lines. Since then the doctors' campaign is reported to be on the whole very successful. They have not got all they wanted, but have gained a great deal, both as to conditions of service and remuneration. In many cases there has been a sort of strike or boycott, such as that at Cologne, to which I have referred, and at Leipsig. As I have mentioned also a general strike was threatened last year, but this was averted, the doctors securing much of what they asked for. The method, which is only adopted in extreme cases, takes the form of refusing to treat members of insurance societies on the terms offered. Provision is made by the society for assisting doctors who suffer pecuniary loss through the strike, and in Germany, as here, appeals have been made for contributions to their war chest or guarantee fund. The society of organized doctors reports:

Total number of conflicts	1,022
Decided in favour of doctors	921
In favour of sickness societies ("for the time being")	11
Still pending (May, 1911)	90

This report, dated May 1911, gives the result after twenty-seven years' experience of insurance law, during the first sixteen of which there was nothing in the nature of a trade union. Since then, of course, there has been, amongst others, the threatened general strike of last year, when the doctors won considerable advantages.

With these facts before us, surely we are not going to take sixteen years to make up our minds about the necessity of a trade union. The idea of trade unionism is not attractive to the professional mind; to many it is specially repugnant. But the whole scheme of National Insurance was distasteful to many, and the Act as passed was approved by very few of us. Yet we have accepted it and have entered into agreements to give service under it. It matters not now one iota whether that acceptance was voluntary and cordial or obtained by duress. The profession has accepted the Act and can never repudiate it. What does remain to us is to see that the conditions it imposes on us are not made too irksome or degrading, and that we are properly remunerated for our services. Extension of the Act is certain. Dependants will come to be included and other great additions will doubtless be made.

Let us, then, once for all, make up our minds that organization is as necessary for us as it has been found, after so many wasted years, in Germany. And, whatever organization is adopted, let it be one that can be described, like the German one, as "an aggressive fighting machine."

I am not going to attempt to enter at length into the arguments as between a trust fund and a trade union. That would require a lengthy address to itself, even if I were competent to explain the legal technicalities of each. But I would ask each and every one of you to think seriously over the matter. For my own part, I have no hesitation in saying that I am altogether in favour of a trade union, entirely independent and apart from the British Medical Association.

I rely on the legal opinion, which does not seem to be disputed, that only by forming a trade union can the fighting fund be protected. The funds of a trade union are free from any action for damages for any wrongful actions committed by the members in the prosecution of a trade dispute. A fighting fund which, amongst other uses, would indemnify members who suffered loss through carrying out the policy of the union, is the first necessity of any organization, and it is obviously essential to secure for such a fund the greatest possible measure of protection. This can be done, as I understand the matter, by forming a trade union, and in no other way.

A trust fund which was not a trade union, it appears to me, could have no protection, and would therefore be useless.

The suggestion that the British Medical Association should itself become a trade union is one that I think will obtain little support. The process would be beset by many difficulties, would require considerable time, and would destroy the character of the Association. The British Medical Association is a great power for good; it has a splendid record and a promising future in its own sphere, but trade unionism is not its sphere. Originally an association for the consideration of medical and scientific questions, it has considerably widened the circle of its activities, but to adopt trade unionism as its constitution would be to cripple it in all its most useful functions.

The proposal to form a trade union as a sort of branch or offset of the British Medical Association, with the Council of the Association as the governing body of the union, is even less attractive. The members of the Council are elected to their honourable position for far other qualifications than those required of the managers of a trade union. And beyond this it seems to me that there would be great difficulty in steering clear of the danger, on the one hand, of rendering the whole of the funds and property of the Association liable, in certain eventualities, for the action of the Council in restraint of trade outside the functions of the union; and, on the other hand, of their pursuing a too timorous and ineffective course of action through fear of this very catastrophe.

I sincerely hope, therefore, that the British Medical Association will itself have nothing to do with trade unionism. Let it pursue its own proper course, advocating trade unionism in its JOURNAL, advising its members for their own protection and the good of the profession to join the union, and in any other way furthering the objects of the union, but not itself having anything whatever to do with its management.

There are at present, I believe, in this country only two trade unions, registered as such—the National Medical Guild and the Leicester and Rutland Society.

There is on the agenda of the forthcoming Representative Meeting a resolution, from the Altrincham Division, to instruct the Council of the British Medical Association to advise their members to join the National Medical Guild. I hold no brief for the Guild, and if a better organization can be devised, or one that would obtain more general acceptance, I should gladly support it. Meanwhile it holds the field. Its promoters deserve great credit for their prompt action in forming the Guild as an avowed trade union, at a time when trade unionism was looked upon with contempt or abhorrence by so many of the profession. Now opinion is divided between trade unionism and a trust fund; it is generally admitted that one or other is a necessity. I sincerely hope trade unionism will prevail, and if it does and becomes the accepted policy of the profession, I think the National Medical Guild deserves to be the accepted body to carry on the work which it was the first to undertake, unless, or until, a better scheme is produced. Let us remember, too, that much time would be lost in bringing any new scheme into operation. The National Medical Guild is already constituted and doing good work with the comparatively limited means at its disposal. Much harm has already been done because the profession was not organized or prepared for the fight. The battle was lost while we were floundering about in disorder trying vainly to get into line. Let us not repeat that mistake, but make use of the organization that is ready to our hand, and not waste time and lose opportunity by accepting any new scheme of trade unionism, unless it can be shown clearly to possess very great and obvious advantages which cannot be obtained by the National Medical Guild.

NOTE.—Those interested in the subject will find much useful information in *Medical Benefit in Germany and Denmark*, by I. G. Gibbon, B.A., D.Sc., published by P. S. King and Son, Westminster, to which I am indebted for many of the facts concerning events in Germany.

THE tenth International Congress of Esperantists will be held in Paris in August (2nd to 10th). The Committee of Patronage includes the names of ninety-three of the leading men of France. Among the representatives of medicine are Professors d'Arsonval, Daniel Berthelot, Charles Bouchard, André Broca, Gariel, Landouzy, Charles Moureu, and Roux. During the congress the association of esperantist doctors of all nations (Tulmonda Kuracista Asocio Esperantista) will be held.

An Address
ON THE
POSITION OF THE COUNTRY DOCTOR IN 1879 AND TO-MORROW.

Delivered to the Medical Society of the Vale of Teifi, Llandyssul, Cardiganshire.

By J. LYNN THOMAS, C.B., F.R.C.S.,
CARDIFF.

When I received an invitation to deliver an address before your newly-formed society I readily obeyed the command of your first President for two reasons: the first was that I have not yet been able to shake off the authority and control he exercised over me when I had the privilege of serving my apprenticeship under him in 1879 after I left the Grammar School which then flourished in this town of Llandyssul; the other was that I am much impressed with the idea and the possibilities for good of the new organization of medical practitioners practising in the Vale of the river Teifi (called on the maps Tivy). I feel certain it will be the means of adding new interests and pleasures to your life, which in the pre-motor days would not have been possible of fulfilment. May I venture to hope that in addition to your immediate object of improving, advancing, and co-ordinating the medical service of the district, you will also at least once a year get outside your profession and have a field day under the guidance of an archaeologist, antiquarian, geologist, or philologist, etc., amongst the very interesting relics and the traditions of the past which Nature and man have left in this beautiful area?

Speaking from personal experience, I would venture to suggest to you, as you will be a small manageable band of workers, to pay an occasional visit to a medical and surgical centre, and invite the staff to give you a field day in clinical and operative work. Nothing within the profession can, in my opinion, be more helpful, instructive, and pleasant than such periodical visits to big teaching centres which are now within easy reach.

Since the days of my apprenticeship changes of a radical nature have continuously taken place in matters medical, social, and scientific. As a topical illustration of things as they were then existing, let me recall that it was necessary to take a whole day journey to London, a distance of over 260 miles, to sit for the preliminary examinations. There is now a new and quicker route to London, but it is no longer necessary to travel so far to sit for examinations in order to enter the portals of the medical profession. Devolution in medical education and training has become a note of the day. The University of Wales with its constituent colleges, and county councils with their education authorities have been created, and have revolutionized the conditions of our national life.

When reviewing the changes which have taken place since the beginning of my medical career, I was tempted for a moment to address you upon "things medical which a man of 50 has seen," but that subject proved startling in its magnitude and so bewildering in its diversities, that I decided to drop it in favour of some reflections upon the past, the present, and the future position of the country doctor.

Personally, I am always glad that I went through the days of my apprenticeship, for it instilled into my mind in the impressionable teens the spirit of independence and the ambition to attain, if possible, all those qualities and powers which were necessary to meet the great and variable responsibilities and the inordinate demands made upon my chief, who was sole and absolute monarch of an immense district. The head quarters of my apprenticeship were in a country house, which formed the eccentric pivot of his field of practice, which was done on horseback or in a gig; the area was limited on one side by a ten-mile coast line, the nearest point being six miles off, on the other by the nearest railway station, which was eight miles distant. I had the opportunity of witnessing operations which varied from arm-to-arm vaccination to amputation of the breast and the restoration of sight to the blind by removal of cataract. To me these performances were miraculous. Sometimes on wet days I was left at home to make pills and study pharmacy and pull out teeth on a few occasions to the accompaniment of the click-clack of flails threshing corn.

One of the treasures which I carried away with me at the end of my apprenticeship was my admiration for the mutual relation that existed between the doctor and his patients; at that time they were my public. To-day is the attitude of the general public towards the general body of the profession what it used to be? I think not. I am of opinion that one of the factors which has largely contributed towards this unfortunate condition is of our own making—too much dogma. Dogma in a progressive profession in which empiricism still prevails is unwarranted.

It was not long after I entered hospital that one of the leaders in our profession proclaimed that surgery had practically reached finality; it was difficult for a medical student not to be influenced by the traditional force of authority, but the difficulty soon vanished when successful surgical raids were made into abdominal territories hitherto sacred to pill, physic, blister, and the leech. The old order was passing away, younger members of the profession characterized the methods of the old schools as unscientific, useless, and effete. This outspokenness within our ranks did not pass unnoticed by the public. Orthodoxy in treatment of abdominal organs in the pre-antiseptic days was swept away by the surgical inventions of the Eighties and Nineties. There is nothing sacred to the surgeon; successful anastomosis of the common bile duct to the common hepatic duct (hepatico-choledochotomy) and of severed vasa deferentia have been done with resulting functional efficiency. Twenty-year-old operations become antiquated as records of surgical progress. There is yet no room for dogma and orthodoxy.

I think we must take the public much more into our confidence if we are to put an end to its peculiar attitude towards us. We are accused of all sorts of wickednesses in our endeavour to benefit the human race from the health point of view. I will give you an example from the expressed views of a distinguished adult member of the public. Mr. Bernard Shaw, in a note on "Modern Prize-fighting," writes:

> The legalization of cruelty to domestic animals under cover of the anaesthetic is only the extreme instance of the same social phenomenon as the legalization of prize-fighting under cover of the boxing glove. The same passion explains the fascination of both practices, and in both the professors—pugilists and physiologists alike—have to persuade the Home Office that their pursuits are painless and beneficial. But there is also between them the remarkable difference that the pugilist, who has to suffer as much as he inflicts, wants his work to be as painless and harmless as possible whilst persuading the public that it is thrillingly dangerous and destructive, whilst the vivisector wants to enjoy a total exemption from humane restrictions in his laboratory whilst persuading the public that pain is unknown there. Consequently, the vivisector is not only crueller than the prize-fighter, but, through the pressure of public opinion, a much more resolute and uncompromising liar. For this no one but a Pharisee will single him out for special blame. The labouring masses do not believe the false excuses of the vivisector, because they know that the vivisector experiments on hospital patients; and the masses belong to the hospital-patient class. The well-to-do people who do not go to hospitals, and who think they benefit by the experiments made there, believe the vivisector's excuses, and angrily abuse and denounce the antivivisectors.

Mr. Bernard Shaw is a man who, while acting in his own sphere, is doing what a medical man is doing in his: he is endeavouring to benefit the human race by experiment on social sufferers. The meaning of the word experiment is quite clear, but it is used by the public in an offensive sense when applied to us. Experiment in any sphere or phase is a departure from orthodoxy and may be attended by success or failure. If the medical orthodoxy of 1879 were governing the surgical practice of to-day we should be letting tens of thousands die from diseases of the digestive organs alone. Thanks to successful experiments they are now cured.

Progress in medical matters is likewise suffering from the state of the law of our land. Judges suffer from "precedent" just as the public suffer from "experiment." From the medical point of view both require radical cure. If we suffered from "precedent" there would be an end to progress. The inherent human force which impels medical men to forget precedents when seeking to benefit humanity by introducing new and better methods cannot be stifled in its quest of ease instead of suffering for children, women,

and men. In medical phraseology we would designate men like Mr. Bernard Shaw not only experimenters but vivisectors in the cause of social reform. He inflicts pain, I am sure quite unconsciously, on account of his enthusiasm, very real pain, upon the sensorium of those he criticizes adversely or dissects in the open theatre of the public press. Has he been called names by the medical profession for performing a vivisector's experiment without an anaesthetic upon the Chancellor of the Exchequer? There exists no more justification for hurling back at Mr. Shaw's head offensive but painful criticism than there is for him to fling poisoned darts at the honour of the profession.

We want to restore the profession to the proud position it was in years ago, and it will be done if it is left in the hands of family doctors who understand the inward history of progress of our science and art.

The State and the Need for Further Organization to Meet the Requirements of the Country Doctor.

This society will be able to do much good by helping to place the medical service in country districts in a better position than it is at present with regard to the treatment of medical and surgical emergencies.

When I was apprenticed the medical profession had not discovered the methods which should be adopted in acute abdominal emergencies. The public to-day require to be informed that it is not possible for any doctor to treat certain medical and surgical cases under conditions now existing in such districts as this. Many cases in their early stages require frequent visits from the doctor and constant observation by a trained nurse before a decision to take action can be reached; hospitals are too far away to take patients to for prompt surgical action, the homes are hopelessly unfit and unsuitable; operating in them is unthinkable, and patients naturally do not like to be turned out of their own homes when suddenly taken seriously ill, and placed under strange doctors far away. They will not hear of it, notwithstanding that prompt action may be the only means of saving life. What, then, can be done in your district to meet the demand and to improve existing conditions?

Patients' homes are often far away from you, almost inaccessible, telephonic communication does not exist, suitable ambulances are not to be had, nurses for the homes are not available, women or the folks at home have not yet been taught how to assist by taking the pulse and temperature and to report. Rapid and decisive action cannot be undertaken. Patients are every moment in the firing line, but the country is not yet properly organized to meet these casualties, and loss of life is inevitable. You have the knowledge but not the means to meet the situation.

The public through the State has since my days of apprenticeship thrown new responsibilities upon you: county and district councils have been instituted, and probably it will be indirectly through these bodies that you will be able to get some of the essentials necessary for raising the standard of treating people living in the country to that level which now exists in big cities.

You have gone a long way towards the solution of the difficult problem of how to render the best medical service in country districts by adopting a river valley as the unit of co-operation. With the aid of motor cars, motor ambulances, "a nursing home" for medical and surgical emergencies, and an efficient telephone system, I see no very great difficulty before your society in making the vale of the river Teifi your future unit of administration. The State has quite recently shown its great concern in the medical service by voting funds for the provision of nurses.

I propounded last year a scheme for the organization of voluntary aid in connexion with nursing in Wales, at the annual meeting of the South Wales Nursing Association, taking as my subject "the trained nurse, the village nurse, and nursing in the home." Your President is taking a very active part in the organization of Red Cross voluntary aid detachments, and I feel certain that, with your hearty co-operation, it will be possible to train the men and the women of the voluntary aid detachments to be of great value to your medical service in rendering aid in stretcher and other methods of transport work, and in carrying out intelligently your orders in the homes.

In conclusion, I thank you sincerely for giving me an opportunity to express views which were in the realms of imagination in the days of my apprenticeship, but are to-day realizable, thanks to experiment, which, unfortunately, has not been unassociated with loss of human lives.

[The meeting passed resolutions that steps be immediately taken to approach the proper authorities to provide a nursing home and a suitable motor ambulance for medical service in the Vale of Teifi.]

SPRUE.

BY

P. H. BAHR, M.A., M.D., D.T.M. AND H.CANTAB.

(From the London School of Tropical Medicine.)

THE researches upon which this paper is founded were conducted in Ceylon, where sprue has been especially prevalent in the European planting community during recent years, and has occasioned considerable inconvenience and loss of valuable lives.

The expenses of this work on which I have been engaged for the last two years were met by a combined grant from the Ceylon Government and from the Ceylon Planters' Association.

Since the classical clinical studies of Van der Burg and Manson in 1881 it may be said that no serious or systematic attempt has been made to make a thorough study of the etiology of this disease; I need, therefore, offer no apology for presenting the following communication, which may be regarded as a preliminary to a more detailed study which will be published shortly.

Physical Features of Ceylon.

It is necessary that I should briefly describe the physical features of Ceylon in so far as they have a bearing on the epidemiology of sprue. It has been rightly said that no tropical island possesses such a variety of climatic conditions in so confined an area; four-fifths of it consist of an undulating plain surrounding a mountainous zone, in which the temperature and rainfall are subject to considerable fluctuations, the former ranging from an average of under 60° F. in Nuwara Eliya (6,200 ft.), the sanatorium of the colony, to an average of over 80° F. in Colombo and the low country. The rainfall also varies considerably, from an average of under 75 inches in the north and east—the dry zone—to over 200 inches in the elevated tea-bearing provinces.

Definition of Sprue.

Sprue is a chronic and particularly fatal tropical disease characterized by diarrhoea, progressive emaciation and anaemia, by a specific denudation of the buccal mucosa, and by symptoms suggesting atrophy of the organs subserving digestion. The diarrhoea is of a peculiar kind: the stools, which are large, pale, and frothy, are generally passed in the early morning, and are accompanied by much flatulence. At the same time there is a grave flatulent dyspepsia which becomes particularly severe towards the later hours of the day, and which is only relieved by the passage of stool. In the early stages there is a specific inflammation of the tongue, involving especially the fungiform papillae on the anterior portion and on the edges. At times small, painful, and evanescent aphthous ulcers make their appearance on the tongue itself, the fraenum, and especially on the buccal mucosa in the vicinity of the opening of Stenson's duct. After repeated attacks of the specific inflammation the tongue becomes glazed and superficially fissured, and the papillae are entirely destroyed. Dysphagia, suggesting an involvement of the oesophagus, is often a terminal symptom. Persistence of these symptoms leads to an atrophy of all the organs of the body, and eventually to a fatal termination.

General Geographical Distribution of Sprue.

Recent evidence suggests that sprue has probably a world-wide tropical and subtropical distribution. It is encountered, in this country, in its most virulent form in Europeans hailing from Eastern seaports. It has been

reported from the following countries: India, Burma, Siam, Malaya, Cochin China, China, Japan, Java, Sumatra, Celebes, Macassar, Borneo, Ceylon, the Philippines, Fiji, Porto Rico, Haiti, West Indies, Mexico, South America, Gold Coast, Upper Congo, and Morocco. The scanty records from tropical Africa are of doubtful value.

I made extensive inquiries amongst the European community in Ceylon with the object of ascertaining whether the incidence of sprue were greater in any particular region or district, but I was unable to ascertain any strictly topographical limitation. Cases were found in which the first symptoms occurred in Nuwara Eliya, as also in Colombo, where the mean average temperature is 22° F. higher.

Sprue in Native Races.

All authors who have so far written on the subject are agreed that sprue is pre-eminently a disease of the European in the tropics, and that the native is only occasionally, if ever, attacked. I do not consider this statement to represent the true facts of the case. It is more than probable that it is extremely common amongst the indigenous natives, and that in this respect it conforms to other tropical diseases of known specific origin. I need hardly say that there are certain real difficulties in diagnosing a disease of such an ill-defined nature as sprue in natives, who are so liable to ankylostomiasis and malaria. I managed, however, to obtain notes of eleven cases in natives, members of all the principal races—Moors, Cingalese, and Tamils—inhabiting Ceylon, in whom there could be no reasonable doubt about a correct diagnosis. Five were seen shortly before death; in only one instance was a complete *post-mortem* examination obtained.

Amongst the Europeans, the majority (19) of my 36 cases occurred in females, a figure which, taking into account the disproportion (two to one) of the European males to females in Ceylon, denotes a special liability of the female sex to the disease. Though sprue generally occurs in adults, age is apparently no bar to infection. The youngest case I saw was in a Eurasian boy of 13, the oldest in a Ceylon burgher of over 70 years of age.

Predisposing Causes.

Features in the immediate environment of each case—such as housing, water supply, and food—were each made the subject of a separate investigation. The question of food and water supply being in any way concerned in the production of sprue could easily be ruled out. There is, however, a popular idea in Ceylon that the "dry rot" which infests nearly every wooden tea estate bungalow is in some manner directly connected with the occurrence of sprue cases in "dry rot" bungalows which are considered to be unhealthy. This is not invariably the case, for I found a number of planters in whom symptoms had first commenced in bungalows built entirely of stone or of brick.

A previous attack of some intestinal disease, as dysentery, may be regarded as a most important but not as an essential etiological factor; in one half of my cases no history of such an illness was obtainable. There are ample grounds for regarding sprue as a primary disease, but any depressing influence, such as debilitating disease or unhealthy surroundings, may lower the vital resistance, and thus render the alimentary canal more liable to attack by the specific sprue germ.

Is Sprue Communicable from Man to Man?

The occurrence of sprue in all classes of the community in Ceylon, irrespective of age, race, sex, or environment, suggests that either it is caused by exposure to similar surroundings, or that it is a directly communicable disease. The latter suggestion received support from my discovery of six instances in which one or more members of the same family were simultaneously affected. In one case more or less reliable evidence of direct infection was forthcoming. This was a boy of 13, in whom symptoms commenced while he was living in close association with his mother, who eventually died of the disease.

The Symptoms of Sprue regarded from an Etiological Standpoint.

The symptoms of sprue and the manifestations of the specific desquamation of the epithelium of different portions of the alimentary tract vary so considerably that I concluded that the only possible clinical classification was one which had as its basis a hypothesis that the disease affects the various regions of the alimentary tract to a varying degree, thus giving rise to symptoms according as one or other portion is specially affected.

As *typical or complete sprue* I have included all the cases in my series exhibiting the two cardinal symptoms—the characteristic tongue and stools—but even in this type I have notes of cases in my series which I feel I am justified in regarding as acute, mild, and chronic manifestations of the same disease.

As *incomplete sprue* I classified a number of cases which exhibited the typical intestinal symptoms and the pale and frothy stools, but in which there was—for a period of some years in some instances—no involvement of the tongue and mouth whatever, and also a series of diarrhoea cases with massive bilious and frothy stools accompanied by emaciation, flatulence, and dyspepsia, without any involvement of the mouth, and which I regarded as early cases of sprue, involving especially the intestinal tract.

Finally, I found a number of cases, both in Europeans and in natives, in whom the disease had apparently attacked the buccal cavity alone. The tongue showed the lesions—destruction of the filiform papillae and superficial fissures—which are typical of the sprue tongue. As further evidence in favour of this assumption I may mention that I found four cases in which these tongue symptoms developed during the time the patients were living in close association with typical cases of the disease. These tongues, which appear to be etiologically related to sprue, and cannot be regarded in any way as a local manifestation of syphilis, I have termed for convenience and for the purposes of description "tongue sprue." Although I am inclined to regard tongue sprue as being a distinct affection produced by the same agency as complete sprue, yet it must be borne in mind that an atrophy of the lingual papillae is found in other diseases characterized by general nutritional changes and anaemia, such as chlorosis, pernicious anaemia, ankylostomiasis, and chronic malaria. The clinical evidence I have collected on this point seems to suggest that the loss of the filiform papillae in sprue is the result of some active destructive process, while that in the other diseases I have enumerated is the result of some passive process dependent possibly on a lack of nutrition.

Pathology of Sprue.

(*a*) *Stools.*—The pale colour of the sprue stools is probably due to several causes—first, to the farinaceous or milk diet with which the patients are generally dieted; secondly, to the presence of a colourless reduction product of hydrobilirubin, the normal faecal pigment, which is known as leucourobilin; and, thirdly, to the abnormal proportion of undigested fat they contain. The reduction of hydrobilirubin to leucourobilin is said to take place in the absence of the normal pancreatic juice, and may occur, according to Mayo Robson, in malignant disease or in chronic inflammation of the pancreas in which the glandular secretion is deficient in amount or is prevented from entering the duodenum. The reoxidation of this colourless compound—leucourobilin—to hydrobilirubin takes place with great ease outside the body, an alcoholic extract of a sprue stool, which is at first colourless, soon becomes converted to a brown colour when exposed to direct sunlight. There can be little doubt that normal bile is secreted in sprue, and as such enters the intestinal canal. In six autopsies which I performed I found in all unaltered biliverdin and bilirubin in the gall bladder, so that any change in the chemical composition of the biliary pigments must take place during the passage of faecal matter through the intestinal canal. The fat absorption was found to be reduced in my cases, and was from 70 to 90 per cent., whereas in milk-fed normal subjects it is said to be over 95 per cent. I regret that I was unable, owing to the lack of suitable apparatus, to perform more elaborate analyses on the process of fat splitting in these cases. The reaction of sprue stools was found to be—almost invariably—acid, and was due to the presence of lactic and of butyric acids.

The complete absence of trypsin, which is said to be present in the majority of normal stools, appears to be a further peculiarity of the sprue stool.

(*b*) *Urine.*—The quantity of urine passed by sprue patients appears to be normal, and the urea excretion, on the whole, to be purely of exogenous origin—that is to say, proportionate in amount to the proteins ingested in the food. Indicanuria and urobilinuria were observed during the acute as well as the terminal stages of the disease; the excretion of the former substance is dependent probably on the amount of intestinal putrefaction, the latter on the degree of blood destruction at the time. I found that the excretion of these substances ceased immediately the stools became normal, and the patient reacted to the appropriate treatment. Cammidge's reaction, though performed in twenty-seven cases, was invariably negative.

(*c*) *Saliva.*—The saliva was found invariably acid to litmus paper; this was especially the case in cases with acute tongue lesions and those in the terminal stages of the disease and those whose mouths were overgrown with the thrush fungus.

(*d*) *Blood.*—In the early stages of the disease no alteration in the structure or number of the red cells, the leucocytes, or in their relative numbers was noted, but in two fatal cases a poikilocytosis, polychromatophilia, and normoblasts were present. In fact, the blood picture in these cases resembled, save for the absence of megaloblasts, that of pernicious anaemia. It is probable that the exact degree of anaemia is dependent, as in other anaemias, on certain factors, such as the duration and severity of the intestinal symptoms, the amount of toxin absorbed, and the individual susceptibility of the patient.

Morbid Anatomy and Pathology of Sprue.

Conclusions from *post-mortem* examinations in the tropics are open to the obvious objection. Tissue destruction takes place with great rapidity; this is especially the case in such a delicate structure as the intestinal mucosa. It is possible that the gross tissue changes which have been described as being pathognomonic of sprue are really in great measure the result of *post-mortem* decomposition.

The following account is based upon two autopsies I was able to perform—both in Europeans—within two hours of death. The tissues were immediately fixed in 4 per cent. formalin.

The bodies presented all the external appearances of a chronic starvation: there was a complete absence of fat; all the muscles were dark in colour; the heart small, dark, and atrophied; all the organs exhibited a proportional degree of wasting, and weighed less than half the normal. The liver was yellow and fatty—bile-stained in one case, the gall bladder was full of bile. The most noticeable feature was the transparent and distended ileum. The whole of the intestinal mucosa was covered with ropy mucus. The tongue and oesophagus were overgrown by a white film composed principally of the thrush fungus. The bone-marrow was dark in colour, and exhibited no peculiar macroscopical or microscopical features.

In microscopic sections desquamation of the epithelial coats of the tongue and of the oesophagus and a superficial infiltration with yeast cells and mycelial threads penetrating into the deeper tissues were the most noticeable features. The mucus lining the intestinal canal was overgrown by these organisms in a similar manner, though I could obtain no evidence that any actual invasion of the intestinal mucosa had taken place. In smears from the liver in one *post-mortem* examination these organisms were also sparsely noted. They were cultivated in glucose broth from every part of the intestinal canal, from the liver and spleen in one case, and from the kidneys in the other, but not from heart blood.

Sections made of various portions of the intestinal canal from stomach to rectum exhibit chronic inflammatory changes; the columnar surface epithelium is mostly preserved. It is possible that a certain amount of epithelial destruction took place previous to death. In sections of the liver the hepatic cells have undergone fatty changes, and contain a few granules of free iron, though this reaction is by no means so positive as in pernicious anaemia. In sections of every organ such as the tongue, the stomach, duodenum, ileum, caecum, sigmoid and rectum, the heart, suprarenals, mesenteric lymphatic glands, bone marrow, and spleen, numbers of Gram-positive, acid-fast, hyaline and spherical bodies, which I consider identical with Russell's "fuchsine bodies," were found in abundance.

The endothelial cells of the smaller veins in the trabecular tissue of the spleen were filled with minute hyaline bodies of a similar nature—that is to say, they are Gram-positive, though they differ in not being acid-fast. These bodies are a striking feature in all the six sprue spleens I have examined, and I have failed to find them in forty-three spleens from tropical cases which I examined as controls. (In twenty-two of these cases the immediate cause of death was diarrhoea; amongst them were 4 cases of amoebic dysentery, 10 cases of ankylostomiasis; in the remaining 8 the exciting cause of the diarrhoea could not be ascertained. The controls also included 3 cases of malaria, 2 of kala-azar, 2 of pernicious anaemia, 2 of ankylostomiasis without diarrhoea, 3 cases of tuberculosis without diarrhoea, 1 case each of lymphatic and spleno-medullary leucocythaemia, trypanosomiasis, pellagra, pneumonia, uraemia, lymphosarcoma, filariasis, bacillary dysentery, etc.) I am inclined to regard these bodies as being of a degenerative nature, and as possibly characteristic of sprue. Their homogeneous structure and the lack of surrounding tissue reaction negatives their parasitic origin.

Microscopical sections from a case of "tongue sprue"—that is, from a native who exhibited tongue symptoms only during life—show the same desquamation of the surface epithelium and infiltration with yeast cells as the true sprue tongue. The microscopical structure of these tongues does not differ in any important particular from those of two infants which were overgrown with thrush during life, and with which they have been compared.

Etiology of Sprue.

Several investigators during recent years have favoured the fungoid origin of sprue. Kohlbrugge[1] in 1901 found in the intestinal mucus, in the lymphoid patches of the intestinal canal, and in the epithelial covering of the tongue and of the oesophagus great numbers of yeast cells, which he regarded as being the causative organism, and resembling *Monilia* (*oïdium*) *albicans*. His results have been partially confirmed by Le Dantec.[2] In favour of this theory I can only bring forward as a result of my work the following evidence:

1. Yeast cells and mycelial elements are found *intracellularly* in scrapings of the tongue lesions at an early stage of the disease, and cannot be found in scrapings made from the former site of the lesion at a later stage when symptoms have subsided.

2. Yeasts are the only organisms found in the deeper layers of the tongue in microscopical sections. The evidence that the infection is not one of recent date receives support from the chronic inflammatory changes in the epidermis and corium of the papillae.

3. The desquamation of the epithelial cells accompanied by a subacute inflammation of the tongue and of the oesophagus are changes such as would be expected from a study of the mode of growth of the fungus and of its low order of virulence.

4. A general infection of the intestinal mucus with yeasts was found in sprue autopsies, but no such general infection was found in other chronic wasting diarrhoeas. Yeasts were also the most abundant organisms in the stools and saliva of victims of the disease, especially during the acute and during the terminal stages.

5. The stools of sprue, their frothy and gaseous character, are such as one would expect in a blastomycotic infection of the intestinal canal.

6. The relapsing nature, the chronicity and latency of the disease, are symptoms such as one would expect from a knowledge of the life-history of the blastomyces, their periods of attenuated growth and of sudden recrudescence.

7. There is no evidence in favour of the sprue yeast fungus being otherwise than identical with the thrush fungus *Monilia albicans*—an organism possessing a very low pathogenic power; but it is possible that under certain unknown conditions, more or less peculiar to the tropics, this power may become greatly augmented. In support of this view I may add that it is a well-recognized fact that there are endless varieties of yeasts employed in the brewing of beer and the making of wine, and the predominance of a variety in certain districts imparts, presumably, to the local wine much of its characteristic flavour. These yeasts, though differing widely from each other in their powers of growth and fermentation, yet

resemble each other minutely in their morphological and cultural characters. May it not be that the pathogenic yeasts can be altered similarly by local conditions? It is possible that these fungi, though normally non-pathogenic, can, as in the case of the pneumococcus and diphtheria bacillus, assume at times a pathogenic rôle.

A minute study of the microscopical sections of the tongue and œsophagus in sprue shows that there is a considerable reaction on the part of the host to the invasion of the superficial tissues by this fungus, and there can be little doubt that these fungi in their downward growth are capable of exposing the taste buds and nerve terminals and of causing the very lesions which the lingual and œsophageal symptoms of sprue suggest.

8. Wasting and anæmia—both symptoms of sprue—can be produced in rabbits by continuous intravenous injections of small doses of a broth culture of a pathogenic yeast.

9. Diarrhœa, atrophy of the lingual papillæ as in sprue, digestive disturbances, and aphthous ulceration of the mouth are commonly found in children the subjects of a thrush infection in temperate zones.

10. It is possible that obscure alimentary diseases of children in temperate zones—such as Gee's coeliac diarrhœa—are of the same nature as sprue in the tropics. A hypothesis of this sort would explain the occurrence of sporadic cases of sprue in temperate zones.

11. The local affection of different portions of the digestive tract with this fungus would best explain the varying clinical manifestations of sprue.

12. To maintain such a hypothesis it is necessary to stipulate for a third factor, a predisposing cause which may exist in local tropical conditions—conditions which favour a more precocious and luxuriant growth of all fungi, a matter of common observation to laboratory workers in the tropics.

General Conclusions.

Finally, as a result of my investigations I am able to put forward the following conclusions:

1. Sprue is a specific disease of tropical and subtropical countries, though it is possible that cases occasionally originate in temperate zones.

2. It is a prevalent disease in Ceylon, especially amongst the Europeans. Contrary to the opinion hitherto held, it occurs amongst the natives irrespective of race or mode of life.

3. This fact, together with the occurrence of the disease in people closely associated with one another, suggests some local influence or some communication of the specific cause from man to man.

4. Sprue is a variable disease. It may occur in a mild or in a particularly virulent form, and, in common with many other serious diseases, is prone to sudden exacerbations, remissions, and periods of latency.

5. There is evidence that the disease may occur as distinct clinical forms, according to the portion of the alimentary canal attacked.

6. Researches in the composition of the stools point either to a complete absence or inadequacy of the intestinal digestive ferments.

7. Researches on the blood and on the urine suggest that certain of the more important clinical features of sprue are dependent on an alimentary toxæmia.

8. The pathological findings are also in favour of such a conclusion, and, if anything, point to an invasion with the thrush fungus (*Monilia albicans*) as being concerned in their production.

THE report presented to the annual meeting of the Automobile Association and Motor Union shows that it has 86,402 members. In addition to ordinary members, there are light car members who pay an annual subscription of 1 guinea and 32,000 motor cyclist members paying half a guinea. Mr. Joynson-Hicks, in moving the adoption of the report, said that proposals for the further taxation of motorists should be resisted. He believed that a properly made road was not damaged by motor traffic, and that, as ratepayers and taxpayers, motor users were entitled to demand that roads should be up to sufficient strength to carry the heaviest form of traffic.

THE "CONTROLLED" USE OF NEW TUBERCULIN IN THE TREATMENT OF PULMONARY TUBERCULOSIS.

BY

G. V. STOCKDALE, M.B., Ch.B.Leeds,

AND

RONALD HODSON, M.B., B.C.Cantab., M.R.C.S., L.R.C.P.,

LATE HOUSE-PHYSICIANS AT THE HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, BROMPTON.

It is obviously absurd to say that tuberculin is of value because two or three patients have improved under it, just as the converse is equally absurd. What we have done here is to attempt to work on some fair system by which to prove the efficacy or otherwise of tuberculin, and the system we adopted was one of controls. As many cases as possible of pulmonary tuberculosis (the criterion for which was the presence of tubercle bacilli in the sputum) were collected and paired off in such a way that a febrile patient was paired with another febrile, whilst an afebrile was paired with an afebrile. Then by lot it was decided which should be given tuberculin, so that there should be no suggestion as to picking cases, for if tuberculin is to be given with any idea of proving its value, it is, of course, useless to administer it only in cases in which the prognosis is distinctly favourable. Further, as fresh patients were admitted into the hospital, it was decided by lot which should be given tuberculin and which should act as controls.

Although we admit that it is practically impossible to select two cases precisely similar in degree and extent, yet we think that if a sufficiently large number of cases is observed on this plan this difficulty is to a great extent abolished.

The period over which the treatment should extend was decided as three months. This, unfortunately, is too short, yet we find that it is a period commonly chosen for tuberculin treatment in private practice, and the difficulty of keeping several patients in hospital for a longer period was very great.

The cases were classified into three groups:

1. *Afebrile cases.*
2. *Intermittently febrile cases*—that is, using the term "intermittent" in the sense that after a day or two rise the temperature would fall to normal, and then a further rise would be recorded.
3. *Febrile cases.*

A temperature of 99° F. was our standard; anything over that was considered to be febrile, and the patients were consequently kept in bed. If, however, at the end of the second day following this the temperature was below 99° F. they were allowed up for two hours, this period being gradually increased day by day as long as there was absence of fever. Many of the patients remained febrile as long as a month, and then would pass into an intermittently febrile or afebrile condition, but to overcome this difficulty the original classification was adhered to. Such cases as were severely ill, and those complicated with pleural effusion which masked the signs, by severe recent haemoptysis so that they could not be examined fairly, and extensive laryngitis which obscured the pulmonary sounds, were not included in our series.

Method of Administration.

The tuberculin selected to be used was the new tuberculin T.R., and it was decided to give minute doses, increasing the doses gradually every second or third day at first and later at longer intervals in the case of the afebrile patients, while the febrile patients received a dose every fifth or seventh day. The initial dose in the former case was 1 one hundred thousandth milligram, and was increased to 2, 3, 5, 8 and 12 one hundred thousandths milligram, and then again about three-fourths as much again every dose. In the febrile cases the original dose was 1 two hundred thousandths milligram T.R. The object was to work up to the strength of T.R. the patient would take without producing a reaction. When a reaction did occur the patient was kept quiet, and after a few days the same dose was repeated, and if no reaction followed the treatment was continued as before. If, however, a reaction occurred a second time, then a further

period of rest from tuberculin was given and was followed by a smaller dose than those which produced reactions. The maximum dose reached was one-tenth milligram, and this in the case of one patient only.

Method of Investigation.

We decided that the factors on which improvement or otherwise should be based must be two—namely:

1. The pulmonary condition as determined by the physical signs.
2. The general condition as determined by the weight, temperature, pulse-rate, cough, and amounts of sputum brought up daily by the patient.

These facts were all recorded daily about every patient in our series of cases, except the weight, which was taken fortnightly.

Special attention was paid to the physical signs. A systematic physical examination of every new patient was made and recorded without any information as to his history and without any reference to out-patient notes. A separate examination was made by the physician in charge of the case (Dr. Batty Shaw) in the same unbiassed way, and the two results were then compared. If any discrepancy appeared, an agreement was arrived at and the combined result recorded. Fortnightly examinations of the chest were made by one of us to note any gradual increase or decrease of signs, and prevent the fallacy of attributing a slight superimposed attack of bronchitis, etc., to the original condition. As it was noticed that after a day or two of rest in bed the physical signs tended to subside, the first examination for the comparison was not made on the day of admission. This may not seem fair, as at the end of the three months the patient in many cases was doing exercise, but it must be remembered that he had gradually worked up to this exercise and that he was doing no more than his condition was capable of; whereas several of the patients who had been working up to the time of admission had been doing more than their condition allowed and the lung was consequently very irritable. After rest of a day or two the lung in these cases had returned to what we might call its normal condition, and then a fair comparison could be made. A comparison of the relative increase or decrease of physical signs has been accepted as the only reliable clinical method of estimating the lung condition, but no one imagines the markings of physical signs to indicate the exact extent of the lesion, for *post-mortem* examination almost invariably proved the contrary.

At the end of three months each patient was examined separately by Dr. Batty Shaw and by one of us, and after a comparison of results an agreement was arrived at. The position of the apex beat and the mapping out of the cardiac dullness were found to be very important signs in the diagnosis of fibrosis, and in more than one case a distinct alteration in the position of the heart, due to fibrosis of the affected lung, was noted.

We must state further that when we report that a case showed an increase or decrease of signs at our final examination, it must be understood that the final estimate represents the end of a crescendo or decrescendo movement.

Results.

	Improved.	In statu quo.	Worse.
PHYSICAL SIGNS.			
Afebrile cases (18)—			
Under tuberculin	5	3	1
Without tuberculin	2	5	2
Intermittently febrile cases (40)—			
Under tuberculin	3	6	11
Without tuberculin	7	8	5
Febrile cases (4)—			
Under tuberculin	0	2	0
Without tuberculin	0	1	1
GENERAL CONDITION.			
Tuberculin-treated patients ...	13	10	8
Controls ... ... —	16	9	6
WEIGHT.	Gained Weight.	Lost Weight.	In statu quo.
Tuberculin-treated patients (31) ...	20*	7	4
Controls	22†	7	2

* Average gain = 7¾ lb. † Average gain = 8¾ lb.

It will be noticed that in the table of results the weight statistics are recorded separately, though we have declared above our intention to include them under "General Condition." Further, it will be seen that the two records do not correspond, though we admit that the weight factor is an important one in estimating the general condition of a patient. The extreme difficulty of adding together all these varying factors—physical signs, weight, temperature, etc.—has deterred us from publishing a summary of our results under one heading. The above statistics were compared in three sections quite independently of one another, and we conclude by drawing our inferences in the same independent manner.

CONCLUSIONS.

1. With regard to the local lesion, tuberculin seems to have done good in the afebrile cases, and though it will be pointed out, perhaps, that these are the only cases suitable for tuberculin, it must be remembered that such cases formed less than 30 per cent. of our total. Tuberculin was apparently harmful to the intermittently febrile patients who formed the bulk of our series.

2. Tuberculin had no apparent effect in increasing the weight or in improving the general condition, and in both these cases the balance of improvement is on the side of the controls.

In conclusion we should like to take this opportunity of thanking Dr. Batty Shaw for his kindness in allowing us to pursue these investigations among patients under his care.

A NOTE ON SIXTY-THREE SUCCESSIVE CASES OF ENTERIC FEVER TREATED WITH VACCINES.

BY W. P. MACARTHUR, M.D., F.R.C.P.IREL.,
CAPTAIN, R.A.M.C.

DURING the past year and a half I have been responsible for the vaccine-therapy of 63 cases of typhoid fever. Although so small a series is of little statistical value its publication may interest those at least who wish to collect lists of such cases from as wide a field as possible, since this is the first series published from Mauritius.

From 61 of the 63 the causative organism was isolated, either from the blood (58) or from the faeces (3). All the cultures made from the two remaining cases were negative, but there is little doubt as to the diagnosis.

I have been accustomed to classify the cases as "favourable" and "unfavourable." The former class being those coming under vaccine treatment not later than the tenth day of the disease; and the latter those in which treatment was delayed until the fourteenth day of the disease, or later. No doubt this division is somewhat arbitrary, but some such classification is necessary. It may be mentioned that the date of onset of any febrile infection can usually be determined much more readily here than at home, owing to a pronounced Mauritian weakness for taking temperatures on every possible occasion.

Of the 63 cases under review, 45 belong to the "favourable" class, and 11 to the "unfavourable." They were average examples of the variety of enteric fever endemic in the colony, which resembles that found elsewhere. Some, however, believe that in Mauritius the disease tends to run a longer course than at home—possibly the septicaemic stage lasts longer—certainly, in my experience, the causative organism can readily be isolated from the blood at a period of the disease when, according to home teaching, cultures are likely to be negative. Thus I was successful in isolating the bacillus from the blood in 12 out of 14 cases between the fourteenth and twenty-fourth days of the disease.

The age of the patients in this series varied from 18 months to 70 years, and they usually came under observation as undiagnosed cases with febrile symptoms. The routine procedure was then an immediate blood culture. If the symptoms suggested possible enteric fever, an injection of a stock typhoid vaccine was given at the same time.

If the cultures showed *B. typhosus*, an autogenous vaccine was prepared without delay, with which the patient was treated subsequently. It appeared advisable

to treat a few cases which presented symptoms of profound toxic poisoning with a stock vaccine prepared from an old and very avirulent strain, but the great majority of the cases received autogenous vaccines. The disparity in numbers between the two groups is too great to allow of any comparison of results.

Mortality.

There were two deaths in this series—a percentage mortality of 3.1. The "favourable" and "unfavourable" groups supplied one death each.

The patient belonging to the former class came under treatment on the third day of the disease; he appeared to be progressing most satisfactorily, when he suddenly developed acute bronchopneumonia, and died of this complication two days later.

The other fatal case had already had several haemorrhages before coming under treatment—about the fifteenth day of the disease. She appeared to react neither to her own infection nor to the vaccine, which was administered most cautiously. She had several other haemorrhages, one of which terminated fatally.

Complications.

With the exception of the fatal attack of bronchopneumonia mentioned above, all the complications and relapses were confined to the 11 late cases. Three of this group suffered from haemorrhage subsequent to coming under treatment; of these, one—the second fatal case—had had haemorrhages previously, as already noted. In another the single haemorrhage occurred only the day after treatment was begun.

Two cases suffered during convalescence from localized staphylococcus infections; these can hardly be considered typhoid complications, since they might occur with equal readiness in any other debilitating condition. These complicating infections yielded to autogenous staphylococcus vaccines. There were no other complications.

The "unfavourable" group supplied the only two relapses that occurred. Two of the cases were pregnant, but both passed through the attack without mishap.

Results.

The results in the cases under treatment early were most striking. There is no doubt that the disease was rendered definitely milder, and most of the patients progressively improved from their first or second injection. Three showed a constant and progressive fall of temperature after each injection, but this marked sequence was not a usual feature. The most striking point was the absence of symptoms other than the pyrexia; the headache, lumbar pains, abdominal distress, etc., disappeared, and the patients felt well and slept well; they did not look ill. In the words of one Mauritius practitioner, "My vaccinated enterics give me no anxiety."

From such small numbers it cannot be said that the disease was distinctly cut short, although there seemed to be clinical evidence of this in several instances; certainly the period of convalescence was markedly shortened owing to the mildness of the course and the freedom from distressing symptoms and complications.

These remarks apply especially to the "favourable" group; the advantages of vaccine treatment in the late cases were much less marked, and sometimes there was no appreciable benefit whatever. In spite of the small actual numbers, the distribution of deaths, complications, and relapses in the 11 late cases and the 52 others respectively, is significant. In no case did the treatment cause any appreciable ill effects.

Dosage.

The dosage varied with the age and condition of the patient, but for well-built adults the initial dose was usually from 150 million to 300 million. Increasing doses were given at two or three days' interval. In two cases only was the dosage controlled by opsonic observations. The largest dose given to any patient in this series was 1,500 million.

Of the 63 cases of enteric fever, 7 were treated in the military hospitals, and I am indebted to superior authority for permission to include these; my thanks are due to several Mauritius practitioners for permission to include the remaining 56. These latter were regarded largely in the nature of test cases, and were discussed from time to time at the meetings of the medical society. The results obtained were considered so satisfactory that vaccine therapy is being adopted in the civil hospitals, and generally throughout Mauritius, as routine treatment for enteric fever.

Paratyphoid and Other Infections.

A smaller series of paratyphoid fevers was treated during the same period on similar lines; with one exception all these cases ran a mild course, and there were no deaths.

Amongst the cases regarded as possibly enteric fever until the result of the blood culture became evident may be mentioned — streptococcal endocarditis (one case); septicaemia due to *B. coli communis* (two cases), to *B. lactis aërogenes* (one case), to a bacillus of Group "G," subgroup "*m*," variety 14* (one case), and to a bacillus of Group "H," subgroup "*d*," variety 14* (one case). In the limited literature available I can find no record of the two last-named organisms having been isolated from the blood before. However this may be, their occurrence is probably sufficiently rare to deserve mention.

HERNIA OF THE UTERUS, VAGINA, AND FALLOPIAN TUBES IN A BOY.

BY

L. R. BRAITHWAITE, M.B., Ch.B.VICT., F.R.C.S.ENG.,
LEEDS;
AND
WILLIAM CRAIG, M.B., CH.B.EDIN.,
BINGLEY.

THE following case is recorded, first because it is a very good example of "hermaphroditism" in a boy of 14, and secondly because it illustrates what must be excessively rare contents in the hernial sac of a male.

Virchow in 1872, Boddaert in 1875, Marchand in 1883, and others at a later date have reported cases of reduplication of the genitalia.

There is a specimen in St. Bartholomew's Hospital of a man aged 44. He had the normal conformation of a man with a beard and a full sized penis. He was married, and is said to have had two children. The bladder and external organs of generation were those of a man in whom neither testis had descended into the scrotum. Internally the uterus masculinus and vagina were unusually developed. The uterus, which was nearly the size of that of an adult female, lay between the bladder and rectum, and was enclosed between two layers of peritoneum to which on either side of the uterus were attached the testes.

At a meeting of the British Medical Association in London in 1895 the internal organs of a child who died after operation for inguinal hernia were shown. There was a normal bladder with prostate gland. Projecting backwards were a vagina, uterus, and broad ligaments, round ligaments and Fallopian tubes, with testes in the position of the ovaries.

On May 16th we operated at the Bingley Cottage Hospital on a boy aged 14 years, Dr. Dixon giving the anaesthetic.

The boy was the youngest of a family of eight children. The oldest child is a male; the others are all girls. None of them exhibit any unusual anatomical condition. In addition to the living family the mother had four stillbirths, the first at full time, when both the child's feet were deformed, and three at three months.

The mother said that the boy had always been "boyish" in his ways and habits, fond of boxing and other athletic pursuits. About his sixth year he developed enuresis, which had continued to the present time, but was always most marked when he had discomfort in the region of the hernia. His voice began to break about a year ago, and at the same time he complained of pain in the nipples; the mother found a swelling, which she described as hard and lumpy and the size of a pigeon's egg, round each nipple. As this was only noticed for two or three days, she did not take him to see a doctor. A few months later there was a recurrence of the condition, which lasted less than twenty-four hours; it had not recurred since. Until the hernia began to trouble him he never had occasion to see a doctor.

* Classification of "bacilli which neither ferment lactose, nor liquefy gelatine," as in Local Government Board Report, 1911-12, etc.

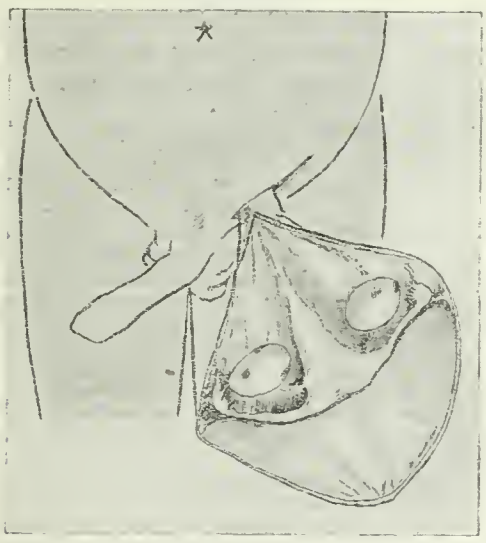
The external conformation of the boy was perfectly normal. There was some growth of pubic hair; the penis was unusually large and perfectly formed. There was no alteration in the formation of the scrotum, and the perineum was not dimpled. The right testis had not descended; on the left side there was a normal-sized testis lying horizontally at the bottom of a hernial sac which reached to the lowest limit of the scrotum. The sac contained what was thought to be omentum, which could be traced up to the internal ring as a thickened cord.

The usual oblique incision was made in the left inguinal region and the hernial sac exposed. Slight traction resulted in delivery of the whole sac on to the surface of the left thigh, bringing with it the left testis.

An incision was made into the sac, and the testis, lying horizontally, was drawn upwards; with it there appeared a perfectly formed Fallopian tube, having no apparent direct connexion with the testis.

Pulling the testis downwards brought into view the whole of the internal organs of generation of a female (as shown in the drawing), with the exception that the positions usually occupied by the ovaries were filled by testes

The uterus was deep red in colour and the normal size for a female of this age; it lay between two layers of peritoneum, was slightly bicornuate, and traces of round



ligaments passed away from its two cornua forwards. The lower part of the uterus ended in a thickened cone at the cervix, and from this there passed off a wide band of fibrous tissue in the position of the vagina; this band of tissue ran up into the abdomen behind the bladder and became lost on the pelvic floor. The vaginal tract did not appear to be hollow at any part.

Behind and below the uterus on either side lay a perfectly formed Fallopian tube; attached to each at its free end was a hydatid of Morgagni. There was a fine fibrous band passing from the uterus below the attachment of the Fallopian tubes to the region usually occupied by the ovaries. These bodies (proved to be testes) lay horizontally, and were attached to the broad ligament by a mesentery. They were of the normal size for a boy of 14, but devoid of epididymis or of vas deferens; in shape they were ovoid, the surfaces being shiny, smooth, and clear white, except for a few areas of a light brown tint apparently due to fat. From the lower part of each testis a sheaf of large veins ran up into the abdomen.

The mobility of the whole sheet of tissue containing the organs was remarkable, and the organs could be drawn out exactly as we have shown it in the sketch, made immediately after the operation.

The question of treatment presented considerable difficulty. Excision of the whole area would have been easy, but removal of the uterus and tubes alone would have been difficult. Reposition of the testis on the left side might have been the correct thing to do, but separation of its blood supply could not be ensured.

Eventually it was decided to close the opening in the sac and return the whole to the abdomen; this was very easily done, and the usual radical cure for hernia performed.

The boy made an uninterrupted recovery.

A portion of each testis was excised and sent for microscopical examination; the report states that both are testes with some excess of fibrous tissue.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

ACUTE VARICOCELE DUE TO THE PRESSURE OF A GREATLY DISTENDED LEFT KIDNEY (NON-MALIGNANT).

C. J., aged 38 years, came to my out-patient department complaining of a large varicocele on the left side, which had developed during the preceding six weeks. Inquiry elicited a history of intermittent haematuria and left renal pain extending over several years, and on examination a large fluctuating tumour could be made out in the left lumbar region, while the cystoscope showed a "pus shoot" from the left ureter.

The kidney was removed intact after resecting the twelfth rib. It contained several branched calculi and a large amount of pus, and weighed 5¼ lb. There was no evidence of a neoplasm. The patient made an uneventful recovery and his varicocele rapidly subsided.

The appearance for the first time of a left-sided varicocele in an adult suggests carcinoma of the corresponding kidney, and clinical teachers love to dwell on the point as being a good example of "diagnosis by induction" based on an accurate knowledge of the destinations and modes of termination of the spermatic veins.

This case is recorded to demonstrate that non-cancerous lesions of the left kidney may also give rise to an acute varicocele.

Sheffield SINCLAIR WHITE.

MEMBRANOUS NON-DIPHTHERIAL LARYNGITIS.

THE rarity of this condition and the fact that primary membranous laryngitis is almost universally attributed to diphtheria are sufficient to justify a review of the following case. It may also, as far as it goes, afford slight proof that our predecessors in medicine were not altogether wrong in differentiating between diphtheritic and non-diphtheritic croup, especially in adults. It is also noteworthy because, although it is common knowledge that there have recently been many cases of membranous pharyngitis characterized by high fever, great pain in swallowing, the presence of a membrane clinically indistinguishable from diphtheria and limited to the tonsils, with absence of the Klebs-Loeffler bacillus and of paralytic sequelae, this is the only case I have heard of in which the membrane has appeared in the larynx.

On May 24th, 1914, I was consulted by a married woman, aged 32, on account of pain in swallowing. The only explanation she could give of her illness was that she had been dusting a very dusty room two days previously. Beyond slight congestion the pharynx was normal, and there was no loss of voice; the case was regarded as one of mild pharyngitis. The next day the pain was much worse, there was tenderness over the larynx, and the patient could only swallow liquids and even those with the greatest difficulty, so that she practically starved herself for several days. She only spoke in a whisper. On laryngoscopic examination congestion of the whole larynx was seen with marked oedema of the arytenoids and aryteno-epiglottidean folds. Respiration was forced, and the patient was afraid that she might choke. Inhalations of compound tincture of benzoin were ordered, the room kept steamed, and antiphlogistine applied externally. Cocaine lozenges failed to relieve the pain of swallowing. There was frequent dry, painful cough. The following day (May 26th) a pearly-white membrane, apparently diphtherial, was seen on both arytenoids, in the inter-arytenoid region, and on the epiglottic folds, but the swelling was less and the temperature, which the day before was 103°, had come down to 101°. Antitoxin was injected and a swab taken, but the report

from the medical officer of health was that diphtheria bacilli were absent. A throat spray containing sanitas was ordered. The next day the oedema had further subsided, but as the membrane was as clearly defined as before, I saw the patient in conjunction with the medical officer of health (Dr. Linton), and we agreed that the case was probably not diphtheria. A further swab was taken and examined by Dr. Linton, who reported the presence of a few diplococci resembling pneumococci, abundant streptococci, and Hoffman's bacilli in fair numbers.

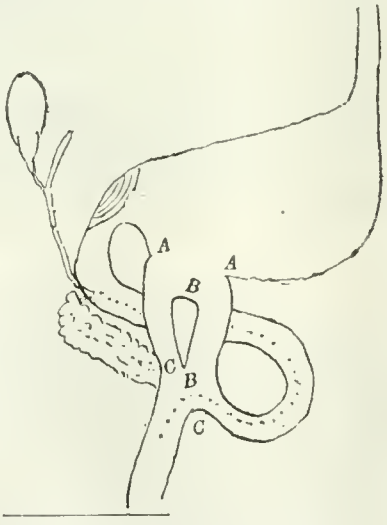
Further progress was uneventful—the temperature rapidly came to normal, the pain subsided, but the membrane persisted for several days, gradually diminishing in size and not separating *en masse*, as in diphtheria. There was never any haemorrhage.

The points that were relied upon as distinguishing from diphtheria were: (1) The absence of toxaemia (the general condition, apart from exhaustion from lack of nourishment and pain, remaining good); (2) the marked pain on swallowing; (3) the high initial temperature; (4) absence of involvement of vocal cords; (5) separation of membrane by dissolution, and not *en masse;* (6) absence of Klebs-Loeffler bacilli.

Tunbridge Wells. FRANCIS RILEY, M.D., B.S., F.R.C.S.

POSTERIOR GASTRO-JEJUNOSTOMY WITH ENTERO-ANASTOMOSIS.

As I have been written to by several surgeons asking me to describe my method of doing the double operation for gastric or duodenal ulcer (April 25th, p. 914), and as some confuse my procedure with that of M. Roux, which is a much more complicated and prolonged affair, I append a diagram showing the completed operation. From A to A = 3 in., B to B = 2 in., C to C = 1½ in.



G. GORE GILLON, F.R.C.S.Ed., Surgeon, Auckland Hospital, N.Z.

A CASE OF GANGRENOUS LITTRE'S HERNIA.

THE occurrence of gangrene of Meckel's diverticulum in a hernial sac appears to be of sufficient rarity to make it worth while to put the following case on record. Apart from the rarity of the condition found, the case presented a great deal of interest from a diagnostical point of view, though it need scarcely be said that a correct diagnosis was not made before operation.

On June 5th, 1914, I was asked by Dr. Johnson, of Callington, to see in consultation a farmer, aged 27; the only noteworthy feature in his previous history was that when he was 4 years old he had a sudden right-sided scrotal swelling. This disappeared within an hour or two and never returned until his present illness. No truss had been worn and he felt no weakness. One week before examination, while he was dancing, he felt an acute pain in the right inguinal region and had been unable to pass urine for several hours. Next day he noticed an inguinal-scrotal swelling; the pain and swelling gradually increased. There was no vomiting, and the bowels had acted well as the result of purgatives. The patient looked ill, the temperature was 100.8° F., the pulse 104, the tongue dry and coated, and there was an extremely painful inguinal-scrotal swelling. The overlying skin was red and oedematous. The swelling was irreducible, there was no impulse on coughing, and the fingers could not be got above the mass. The testicle could not be differentiated, owing to the pain, the scrotum was not translucent, and there was no urethral discharge. We considered that possibly the condition might be one of four things: (1) Torsion of the testicle; (2) rupture of spermatic vein; (3) strangulation of an omental hernia; (4) appendix abscess pointing in a hernial sac.

On the next day I explored the swelling and opened into the sac of a congenital hernia; this contained a quantity of thick pus, the testicle being literally in a bath of pus. Protruding through the external ring was a dirty grey substance which readily broke when fingered; with very gentle traction I pulled upon this, and a piece of gut appeared which ended blindly in the grey substance. On further traction a loop of small intestine presented, and the first piece of gut was then seen to be a blind diverticulum of the same diameter as the small intestine, about 4½ in. long, and strangulated about 2 in. from its proximal end. The loop of small intestine was clamped and the diverticulum removed, the stump invaginated and carefully washed with lysol and returned to the abdomen. Owing to the condition of the patient and the suppuration present, I made no attempt to deal with the hernia beyond placing a few catgut sutures in the inguinal canal. Probably the sac will become obliterated as the result of the inflammatory conditions present. The patient has made a good recovery, and no peritoneal inflammation occurred, in spite of the purulent surroundings from which the diverticulum was removed.

BRIAN METCALFE, M.R.C.S., L.R.C.P., Cornwall. Honorary Surgeon, Liskeard Cottage Hospital.

MANCHESTER CHILDREN'S HOSPITAL, PENDLEBURY.

TUBERCULOUS PERITONITIS IN AN INFANT FED ON UNBOILED COW'S MILK.

(By HUGH T. ASHBY, B.A., M.D.Cantab., M.R.C.P.Lond., Physician to the Hospital.)

THE following case is interesting in that tuberculous peritonitis is very rare in a child so young, and also because it had been entirely brought up on unboiled cow's milk.

Up to 9 weeks of age the infant, a male, had thriven well, but it then had an attack of gastro-enteritis, which lasted four to five days. Directly afterwards it began to waste steadily, and the abdomen gradually enlarged. When seen, three weeks after the onset of the illness, it looked ill; it had evidently wasted, and the abdomen was very distended and tense all over; it was refusing food; the motions were slimy and undigested, and there was slight vomiting. The abdomen was uniformly distended, but was not tender to palpation, and the infant never appeared to have any pain. Rectal examination revealed nothing abnormal, except the distension of the abdomen. The temperature had been raised to 100° to 101° F. each evening, and it was obvious that the baby was steadily going downhill.

It was decided to ask Mr. C. Roberts to explore the abdomen and, if possible, relieve the distension, which was beginning to embarrass the breathing. At the operation about a pint of clear fluid was removed; in the upper part of the abdomen were some miliary tubercles on the peritoneum which gave rise to some opaque cheesy thickening, and the intestines were matted together. The adhesions were separated as far as possible and the abdomen closed. The baby rallied from the operation, but afterwards became worse, and died ten days later.

Tuberculosis of the peritoneum is far more common in children than in infants, especially so young as this (three months). On the other hand, it is more common in infants to have a miliary tuberculosis of the peritoneum in the course of general tuberculosis, which does not, as a rule, show abdominal symptoms. In this case the tuberculosis was limited to the abdomen.

The infant had been brought up entirely on unboiled cow's milk. The family live in the country. No member had had any tuberculosis, all being perfectly healthy. I think it is safe to conclude that the milk was the infecting agent in this infant. The diagnosis was at first not straightforward, but as the abdomen became steadily larger, remained painless, and as there was no serious diarrhoea or vomiting, it was evident that there was a more serious condition present than gastro-intestinal

catarrh. The question of a growth, such as a renal sarcoma, came up for consideration, but the abdomen was always uniformly distended, and no tumour could be felt at any time.

Pituitary extract mj subcutaneously seemed to brighten the infant up each time it was injected, and a few minutes after each injection a motion was passed, showing the very marked effect on the unstriped muscle of the intestines.

British Medical Association.

CLINICAL AND SCIENTIFIC PROCEEDINGS.

DORSET AND WEST HANTS BRANCH.

THE summer meeting of the Dorset and West Hants Branch was held at the Town Hall, Bridport, on July 8th, when the President, Mr. H. H. DU BOULAY, was in the chair, and thirty-one members signed the attendance register.

Autumn Meeting.—It was decided that the autumn meeting should be held at Bournemouth.

A Bridport Worthy.—Mr. C. EDWARDS, Vice-President, gave an interesting account of the life of Dr. Roberts, a Bridport worthy. The PRESIDENT thanked Mr. Edwards for the care he had given to the historical research, and congratulated him on the interest his paper possessed.

The Theory and Practice of Tuberculin Treatment.—Dr. H. C. MANNING (Dorchester), in opening a discussion on this subject, said that tuberculin caused tubercle, and was the weapon with which the bacilli first entrenched themselves and then made further inroads. Efforts towards inflammatory protection after the first few days were cut short, owing to the toxins hindering the nutrition of the newly-formed epithelioid cells. It was the central zone of the tuberculous nodule that tended to break down. Here the toxins were most concentrated, and there was an absence of capillaries, which were unable to grow into the dense nodule. Capillaries already formed became thrombosed and then disappeared. Tuberculosis was indeed a bloodless scourge. Immunization aimed at habituating the body tissues to tolerate contact with tuberculin without affecting their vitality. The healthy man had a natural immunity up to 0.01 c.cm. of old tuberculin, but this, by carefully increasing the doses, could be raised until 1 c.cm. or even 2 c.cm. could be borne. This acquired tolerance was due to the production of an antisubstance capable of neutralizing the toxins and thus protecting the tissues. Ehrlich's hypothesis explained the formation of antitoxin as being due to an over-production of receptors by the central atom of the protoplasmic molecule. In the case of tuberculosis, in such tissues as the lungs and serous membranes, this defensive process was slow and weakly performed. The receptors were not cast off or reproduced quickly enough, and the attached toxins were able to act destructively upon the whole molecule. By concentrating in one spot the bacilli were able to prevent defensive co-operation on the part of the other cells. But tuberculin given subcutaneously was carried by the blood stream into contact with every tissue, and sensitive cells were stimulated to develop defensive powers. The treatment, as it were, inflicted a scratch upon the cell and hurt it so as to harden it; whereas the bacilli, with their concentrated toxins, stabbed it to the heart. Absorption of autogenous tuberculin from the lesion into the general system, with consequent formation of anti-tuberculin, was to be regarded as the natural cure. The strict localization of the bacilli and the non-vascularity of the part, would seem, *a priori*, to impede the absorption of autogenous toxin in sufficient quantity. Possibly, also, the tuberculin lost much of its toxicity in being fixed by the cells, as happened to tetanus toxin with emulsions of nervous tissue. Introduced tuberculin caused, or accentuated, a zone of inflammation round the tuberculous focus where the autogenous toxins had begun to act. Large overdoses might cause necrosis in this situation. The aim was by carefully regulating this inflammation finally to produce cicatrization. Tuberculin stood foremost as a remedy in tuberculosis, but its value would be found to be priceless when used as a prophylactic in the predisposed. The discussion was continued by the PRESIDENT, Mr. C. EDWARDS, Dr. MACPHERSON LAWRIE, and Mr. C. HINE. Dr. MANNING replied to various questions, and at the close of the meeting he showed members the Tuberculin Dispensary at Bridport.

Abdominal Cases.—Dr. NORMAN FLOWER (Yeovil) read notes on the following abdominal cases:

CASE I. *Long-standing Duodenal Ulcer.*—A man, aegd 59, gave a history of duodenal ulcer for thirty years, with frequent attacks of melaena—the last, a very severe one, occurring after he came under observation. Posterior gastro-enterostomy ("no-loop" anastomosis with vertical opening) was done, there being evidence of previous subacute perforation in the shape of numerous adhesions throughout the abdomen. The after-history of the case was complicated by obstruction of the afferent limb of the anastomosis on the fifth day, necessitating a reopening of the abdomen on the left side; later by a giving way of the first wound on the eleventh day during coughing, with prolapse of several coils of small intestine into the bed; and lastly, by an attack of right-sided lobar pneumonia with empyema. The patient recovered, and the ultimate result left nothing to be desired.

CASE II. *Rupture of Bladder.*—A man, aged 70, height 5 ft. 8 in., weight 19 st., an alcoholic, returning home one night, semi-intoxicated, tripped over a stone and fell on his face. Early next morning he was seized with severe abdominal pain, with ineffectual desire to micturate. A catheter drew off 4 oz. of blood-stained urine. The abdomen was opened twenty-four hours after the accident and drained as a preliminary measure, a catheter being tied in. Four days later, his general condition being more satisfactory, the abdomen was reopened and the wound in the bladder sutured, with considerable difficulty, owing to the extreme obesity of the patient. Recovery was uneventful, with the exception of the formation of a left-sided scrotal abscess, the result of percolation of urine through the excessive pre-vesical areolar tissue. This case, Dr. Flower observed, showed how slight an accident might be responsible for rupture of the bladder, and also that signs of rupture might be delayed some hours; in this case, the delay was probably due to his intoxicated condition.

CASE III. *Impacted Gall Stone Simulating Obstruction.*—Mr. H., aged 63, gave a history of intestinal obstruction for three days. There was general abdominal tenderness, but pain was referred to the lower abdomen. A median subumbilical opening revealed no obstruction, but a large gall stone was found impacted in the cystic duct. Cholecystostomy was performed, with relief of all symptoms. The case was of interest as one of absolute reflex inhibitory constipation simulating obstruction, and on account of the misleading distribution of the pain.

CASE IV. *Ruptured Tubal Gestation.*—Mrs. M., aged 39, married, with one child aged 7, had two attacks of sharp epigastric pain radiating through to the right shoulder at intervals of two days, with obstinate constipation. Menstruation was affirmed to be regular. There was slight abdominal distension, but no free fluid. The following day she became suddenly collapsed, with symptoms of internal haemorrhage. Vaginal examination was painful, and there was tenderness in the right fornix. The patient was *in extremis*, and was transfused intravenously during the operation, which revealed a four months ruptured tubal gestation. Recovery was uneventful. The patient subsequently admitted that she had been losing on and off for the previous five weeks.

CASE V. *Carcinoma of Ovary.*—R. W., aged 46, was seized with acute pain in the right iliac region while turning a mangle. She was transferred nine miles to hospital in a cab. The abdomen was acutely tender, especially over the lower part of the right rectus, but rigidity and distension were slight. There was a small area of dullness just above the symphysis, which did not wholly disappear after micturition. The abdomen was explored through Battle's incision; fresh blood escaped, and in the pelvis a thin-walled unilocular ovarian cyst was found, with a rupture at its fundus large enough to admit two fingers. It was removed, and recovery was uneventful. Examination showed it to be a spheroidal-celled carcinoma.

CASE VI. *Pregnancy and Retrocaecal Abscess.*—A woman, aged 30, seven months pregnant, with one child, aged 2 years, became ill with acute abdominal pain, tenderness in the right iliac fossa, vomiting, and absolute constipation. Acute appendicitis with intestinal obstruction was diagnosed, and the question arose as to the best plan of treatment. The uterus was emptied and all the symptoms were relieved. Two weeks later the pulse and temperature rose again, and on opening the abdomen a retrocaecal appendix abscess was found. The appendix was not removed, and the patient is now in robust health and refuses to entertain the idea of appendicectomy.

CASE VII. *Pregnancy and Strangulated Ovarian Cyst.*—A woman, aged 25, four months pregnant, a primipara, on April 30th had an attack of abdominal pain and vomiting lasting two hours. She was seen first on May 3rd. She had then pain and tenderness in the right iliac fossa and a soft swelling. The temperature was 100.8°, the pulse 120, and there was obstinate constipation. On May 4th I found a large tender and painful, but not tense, tumour on the left side of the abdomen, extending from pelvis to costal margin. On May 5th she was removed to hospital, and on May 8th the temperature was normal and the pulse was 110. The periodic vomiting and constipation still persisting, the abdomen was opened on May 9th, and a strangulated cyst of the right ovary was found, which in course of strangulation had rotated to the left side.

There were patches of gangrene in its walls and some peritonitis. It was removed; recovery was uneventful. The interest of the case lay in the fall of temperature and pulse after removal to hospital, while the local lesion within the abdomen was going from bad to worse.

The PRESIDENT and Dr. MACPHERSON LAWRIE discussed the cases; the latter emphasized the marked improvement in surgery in Dorset in the last thirty years.

Luncheon.—The members were most kindly entertained to luncheon at the Greyhound Hotel by the Bridport practitioners before the meeting, and by Mr. and Mrs. Edwards to tea. On the motion of the PRESIDENT, a very hearty vote of thanks was accorded to Mr. and Mrs. Edwards and the Bridport practitioners for their hospitality.

Proposed Hospital for Bridport.—Plans of the proposed hospital for Bridport were shown and explained to members.

Municipal Hospitality.—The Mayor of Bridport kindly allowed a number of papers of historical and antiquarian interest to be shown. Mr. Edwards was asked to convey the thanks of the Branch for the privilege, and also for the use of the Town Hall for the meeting.

Reviews.

APPENDICITIS: THE EARLY OPERATION.

MR. EDMUND OWEN defines the purpose of his short and pithy book on *Appendicitis*[1] in the sub-title, "A Plea for Immediate Operation." In the preface he states that by "immediate operation" he means "that operation ought to be urged as soon as it is well-nigh certain that the appendix is inflamed—that there should be no speaking with the enemy in the gate." We find the doctrine expressed more at length towards the end of the book, when he makes this answer to the question why early operation in appendicitis is not the rule:

> The reply may be that it is all very well to talk about *series of cases*, but when the family doctor is in attendance on any particular case, and is surrounded by anxious parents and apprehensive and criticizing friends, he has to disregard the average and think only of the *individual*. That, in other words, circumstances alter cases. Still, if circumstances do alter cases, they ought not to disturb the principles on which surgical cases should be treated.
>
> But hitherto there has been no principle laid down by general professional consent and teaching in England, as to what should be the rule and guide in the treatment of appendicitis. It must come ere long; and when it comes it will be, I think, in some such form as this: "As soon as it appears fairly certain that the appendix is inflamed it should be removed by operation." The rule of treatment should be made as definite and rigid as is that for the treatment of a strangulated hernia or a cancer of the breast.

More than two years ago Mr. Edmund Owen contributed to this JOURNAL a short paper on "Appendicitis—and quickness"—the quickness with which the process may run its course, and the quickness, therefore, with which the surgeon should make up his mind to operate "when once the presence of the disease is recognized—or, on good grounds, suspected." This article led to much correspondence and discussion, and in particular to a debate at the Medical Society of London introduced by Mr. Owen on February 10th, 1913, in a paper which was published in this JOURNAL (vol. i, 1913, p. 321). The general discussion in the medical press has gone on intermittently ever since, and Mr. Owen has done well to sum up the case and to set out fully the facts and arguments upon which he relies.

The book is addressed especially to the physician and general practitioner. Other books on the subject which we have seen have not been of the type a busy and overburdened practitioner could read with advantage. They have been books essentially written for the pathologist and operating surgeon, but this book should find its way into the hands of every man whose daily avocation brings him to the bedside of the victim of appendicitis in the earliest phases of the lesion. Mr. Owen has dealt with every phase in his own inimitable language, and the book will become a classic, for few writers in our profession possess the ease and grace of style by which this valuable monograph is distinguished. The author marshals his facts in logical order, examines the subject from all points of view, argues whole-heartedly and fairly with his opponents, and finally states in clear, concise and masterly language the way in which experience teaches that this many-sided, treacherous, and too often fatal disease can be met. The many deaths from appendicitis which occur every year are to a great extent preventable, and Mr. Owen's book should lessen this appalling death-rate; it ought to be read by every practitioner, and its publication should result in a great and lasting good.

[1] *Appendicitis: A Plea for Immediate Operation.* By E. Owen, F.R.C.S., D.Sc. (Hon.) Bristol: J. Wright and Sons, Ltd.; London: Simpkin, Marshall, Hamilton, Kent, and Co., Ltd; Toronto: The Macmillan Co. of Canada. (Cr. 8vo, pp. 226; 4 figures. 3s. 6d. net.)

DERMATOLOGY.

A PRACTICAL test of Dr. STELWAGON'S very complete treatise on *Diseases of the Skin*,[2] on all subjects—diagnostic, controversial, and therapeutic—connected with the speciality, justifies the statement that it is one of the most useful textbooks on the subject in the English language. A very convenient feature, and one that should appeal particularly to the busy man, is the printing of references to literature in journals and other textbooks in the form of footnotes on the same page as the subject discussed in the letterpress. Of undoubted value, moreover, is the simultaneous projection in brackets of the Continental value of every prescription cited in English terms. The illustrations, of which there are a very generous number, are particularly good, and the majority will stand magnification with a small lens, which is good evidence of the excellence of the photographic technique employed. The histological reproductions are simple, and should impart a concise and easily remembered knowledge of all the most salient pathological features of the conditions illustrated. The chapters on blastomycosis, sporotrichosis, and pellagra are thoroughly up to date, and contain references down to April, 1913. The treatment of syphilis is fully discussed under such headings as duration of treatment, and duration of treatment based upon the serum test. This chapter is particularly vivid and carefully considered, and agrees closely in the record of its experiences with those published by authorities in Europe. The writer shows no bias in favour of any special form of treatment, and he is particularly careful in the wording of his eulogies of some of the newer remedies, which, to take radium as an example, "in the hands of those skilled in its use produces brilliant results in some conditions." Of the *x*-ray treatment of acne he says, "The Roentgen rays have been used in this, and sometimes with brilliant results. I can add my endorsement of its value. Many cases can be managed just as well without it." That is the attitude of the cautious and experienced practitioner, who has seen too many changes to be easily carried away by the swing of the therapeutic pendulum. From cover to cover the book is full of sound sense and originality, and the careful reader will extract many a valuable hint in the course of his leisured study of its pages.

In his *Einführung in die Dermatologie*,[3] Professor S. BETTMANN has not adhered to the conception suggested by the title. The book is not in any sense an "introduction," but an advanced histo-physiological study of dermatological principles, and certainly presupposes a textbook knowledge of dermatology. The style is discursive and vigorous, but would hardly meet with the appreciation it deserves in any but the specialist's hands. There are no illustrations, and only one really practical chapter, that on the common localization of the various types of skin disease, in the arrangement of which the author follows the original lead of Sabouraud's *Dermatologie Topographique*. The histology and physiology of the skin are discussed on general lines in the opening chapters, but the absence of photomicrographs and diagrams in illustration of the text renders the meaning somewhat obscure at times, and demands a very close application and concentration on the reader's part. Eruptions are divided into ephemeral and stable varieties,

[2] *Treatise on Diseases of the Skin: For the Use of Advanced Students and Practitioners.* By H. W. Stelwagon, M.D., Ph.D. Seventh edition, thoroughly revised. Philadelphia and London: W. B. Saunders and Co. 1914. (Roy. 8vo, pp. 1250; 334 figures; 33 plates.)

[3] *Einführung in die Dermatologie.* Von Professor Dr. S. Bettmann. Wiesbaden: J. F. Bergmann. Glasgow: F. Bauermeister. 1914. (Sup. roy. 8vo, pp. 194. 6s.)

and the specific types are then dealt with in detail. The nomenclature devised by Hebra and the Viennese school—macule, papule, vesicle, wheal, etc.—is closely followed, and the various diseases enumerated and discussed under one or other of these types. Where they do not conform to them, or are of a mixed or polymorphous character (for example, dermatitis herpetiformis, erythema exsudativum multiforme, etc.) they are treated in a separate chapter, headed "aberrant types." Particular interest attaches to a series of paragraphs on diseases of the nails, which are here more concisely tabulated than in most textbooks, and a new departure—the chapter on the involvement of mucous membranes in skin diseases—is a really valuable contribution to a somewhat neglected subject. There are several other original paragraphs, which include such subheadings as "diagnostic difficulties," "atypical dermatoses," "localizations, courses, and complications of skin diseases," and there is a complete chapter on clinical microscopic methods, and animal experiments. The etiology of skin disease, both exogenous or parasitic, and endogenous or toxic, finds separate treatment in a chapter towards the end of the book, and the relation of the nervous system to skin eruptions is also a new and interesting feature in a work of this kind. As a dermatological treatise and as an aid to the lecturer no more suitable or up-to-date volume exists, but an alteration in the title would prevent much misconception of the contents, and would assuredly be more in keeping with the author's acknowledged reputation.

PHARMACOLOGY.

PERHAPS no branch of biology has made greater progress during the last twenty years than has that of pharmacology. But it is only quite recently that its direct relationship with pathology has been appreciated fully, and the future is full of hope that a symbiosis of these two sciences may explain how pathologically disturbed functions of tissues or organs may be influenced by drugs. MEYER and GOTTLIEB'S *Pharmacology*[4] has as its aim and object this ideal. A translation of this work has now been made by Dr. J. T. HALSEY, which brings before the English reader German conceptions of the science. The arrangement of the book is essentially different from the textbooks of pharmacology with which we are familiar in this country. The drugs are divided into two classes—those which influence organs or functions and those which act on causative agents of disease. Thus chapters are devoted to drugs influencing motor nerve-endings, drugs influencing the eye, the blood, metabolism, and so on. This treatment of the subject certainly commends itself when it is required to be used as a work of reference or by the advanced students, but for the ordinary student of medicine it presents great difficulties. Should he require, for example, to assimilate the general action of caffeine, it becomes necessary to consult the chapters dealing with the central nervous system, voluntary muscle, heart and respiration. So that by this means of developing the subject the attention is directed rather to the tissue which is affected by the drug than to the drug which affects it. Organic chemistry was at one time taught on this same broad principle; the alcohols, ketones, and aldehydes were treated generally, and in groups, but this broad method of teaching, excellent as it may be for the advanced student, is unsuitable for the beginner; experience has shown that it is much more important that the characteristic properties of ethyl alcohol should be fixed on the mind of the beginner than that he should attempt generalization on alcohols as a whole.

We think, then, that this textbook is not for the elementary student of pharmacology. The chapters are for the most part clearly written and intelligently translated, though occasionally words are used which sound strange to English ears, such, for example, as "obstipants" (p. 211), a word used to indicate a drug which stops peristaltic movements. The subject is treated almost entirely from the experimental point of view, and the text contains abundant references to which the reader can refer for additional information. Many drugs of little or no practical importance receive an amount of attention quite out of proportion to their significance; curare is a notable example. Considerable space is also allotted to the vegetative nervous system. It is, we think, a matter of doubt whether any real advantage is derived by using the term "autonomic nervous system," instead of speaking of the nerves to glands or involuntary muscle.

The subject matter of the book is for the most part correct and in conformity with modern ideas, but several remarkable views are set forth in different places which have long since been disproved. Two or three examples of these may be mentioned; on page 247 pilocarpine is stated to act on the vagus in the same position as nicotine. It has, however, been clearly shown that it acts more peripherally than nicotine and that its action is associated with "nerve-endings." Again, nothing can be more certain than that the nitrites act peripherally, directly on plain muscle, yet here we find the old experiments of Filehne (1874 and 1879) recorded as if they were the last word on the subject, and the nitrites are stated to act centrally.

The chapter on the circulation, and especially the references to the mode of action of digitalis, leaves much to be desired. Cardiac slowing is regarded as entirely vagal in origin; the effect of drugs on conductivity and irritability is hardly mentioned, and the translator has commented on this and inserted a paragraph; no intelligible reasons are suggested for the cardiac acceleration under caffeine, whilst the action of camphor and some other drugs on the heart receives an amount of attention which its importance does not warrant.

This is not in any sense a textbook of materia medica and the preparations of the various drugs are not even mentioned. Besides the pharmacological action the indications for the use of the drugs are given or suggested. One distinct feature of considerable value is the discussion of new remedies which have come into use, and in this respect the book is surprisingly complete. It is clearly written, the illustrations are excellent and for a translation the subject matter is particularly easy to follow. As a work of reference it should find a place in the library of all those interested in the progress of pharmacology.

INDUSTRIES FOR THE FEEBLE-MINDED.

Industries for the Feeble-minded and Imbecile[5] is written by Mr. BICKMORE, who has had the advantage of being craftsmaster in charge of the industries for the feeble-minded and imbecile at Darenth during the ten years which saw its transformation into the leading industrial colony for defectives in this country. This position has given him an experience which has fallen to the lot of few others in any part of the world, as Dr. Rotherham, in his introduction, points out. The book is written in a direct, practical manner, and is marked by shrewd observation and common sense.

The last forty pages are devoted to a description of the trades taught at Darenth, which number some seventeen in all. The special merits and difficulties of each trade are discussed, and a brief account given of the apparatus required and most convenient order in which to build up the industry, together with the general principles to be observed by the trainers.

In the opening pages more general questions are dealt with, such as the economic aspect of the matter, the general benefit conferred on the patients, the grading of the patients for work, the training staff, etc. Mr. Bickmore holds the view that it is useless to continue kindergarten methods after the patients have reached 12 years of age; these methods should then be superseded by practical teaching and by the making of articles which the patients see in everyday use. A boy or girl learns more from 12 to 16 than after that age.

The author is fortunate in having had an enlightened board of management who were prepared to spend £9,000 on the erection of workshops and workrooms; this expenditure was more than justified by the results. In considering these, it seems clear that the success achieved was due not a little to certain special factors. In the first place, Darenth contains 2,000 patients, a large number

Authorized translation into English by J. T. Halsey, M.D. Philadelphia and London: J. B. Lippincott Co. 1914. (Med. 8vo, pp. 616; 65 figures. 25s. net.)

[5] *Industries for the Feeble-minded and Imbecile: A Handbook for Teachers.* By A. Bickmore. London: Adlard and Son. 1913. (Fcap. 8vo, pp. 72; 11 illustrations. 2s. net.)

of them defectives of very high grade, from whom to draw; of these, 830 are employed in the adult shops; this enables a large number to be employed in the various stages of each industry, and also allows of the provision of a wide choice of industries to suit different capacities. Moreover, the Metropolitan Asylums Board has nearly sixty institutions of its own in which to dispose of the goods made without competing with the market in regard to quality—a most important point on the economic side.

The author calls his work a handbook for teachers, and no doubt it will be serviceable in this way, though it is possible that rather more detailed information in regard to some of the trades, and particularly as to where some of the material and apparatus may be procured, would be helpful to them. It is even more likely to appeal to the managers of institutions now in contemplation, in guiding them in the organization and planning of buildings and the general scope of their work.

A HANDY ENCYCLOPAEDIA.

THE *New Encyclopaedia*[6] has the great advantage that it is in one volume, and therefore is more convenient for reference than works of larger scope, in which one may have to hunt for the information wanted through a number of different volumes. The articles, many of which are written by specialists, are in general short but fairly adequate for the purpose intended, and the information as a rule is brought up to date. The needs of the average man have been kept in view, and in the best sense this new encyclopaedia is a popular work of reference.

The medical articles, as far as we have tested them, are, on the whole, accurate, though they are necessarily so short that we venture to doubt whether they are of any more practical use than the definitions of words given in a big dictionary. To this statement, however, there is at least one notable exception. Gynaecology is treated in an article which seems to us quite out of place in such a publication; no good purpose can be served by describing diseases of the ovary, vagina, and vulva in sufficient detail to make women imagine that they are the subjects of these conditions. On the other hand, the article on surgery is just what it should be: it is written on general lines, states principles briefly and clearly, and is largely historical. In the article on medicine, too, an excellent account of the development of the healing art is given. We think, however, that the names of Manson, Ross, and Bruce, who have done so much to advance tropical medicine, should have been mentioned. The articles on parasitic disease, bacteriology, and pathology give just the kind and amount of information that all educated people should possess. Under the heading "Larynx" the only disease mentioned is laryngitis, of which an account is given that is too detailed for a popular work and too scanty for any scientific purpose. The laryngoscope is not mentioned, and the name of its discoverer appears in two lines under that of his father. In the article on cancer it is said that cancer is increasing, for reasons which are not fully understood, although the eating of meat, and particularly tinned meats, is suggested as a cause. We are glad that our old friend the tomato finds no place in the etiology, as it did in an encyclopaedia of much more ambitious pretensions. In the note on Oliver Wendell Holmes no mention is made of his medical writings, even of the essay in which he showed the contagiousness of puerperal fever. The article on Lister is very poor and sketchy. That on vaccination, though short, is satisfactory enough; but nothing is said of vaccine-therapy, which might well have found a place. The work of Pasteur is dismissed in sixteen lines, which give no real notion of the scope and results of his work. Servetus did not, as is said, foreshadow the discovery of the circulation of the blood, though he actually described the pulmonary circulation. The article on vivisection is written in a reasonable and enlightened spirit, and it is rightly stated that the cause of antivivisection has been greatly harmed by ignorant advocates. The article on homoeopathy is likely, we think, to convey a wrong impression. So far from advancing, it is admitted by its own adherents to be receding, even in America. According to Abraham Flexner, in his report on medical education in the United States and Canada (Carnegie Foundation for the Advancement of Teaching, *Bulletin* No. 4, 1910), in the year 1900 there were twenty-two homoeopathic colleges in the United States. In the succeeding ten years the number had fallen to fifteen; during the same period the number of students enrolled dwindled from 1,909 to 1,009, and the graduating classes from 413 to 246.

On the whole, however, the *New Encyclopaedia* fully justifies its claim to existence. Within the compass of its sixteen hundred pages it contains an amount of information sufficient for the requirements of the ordinary reader.

NOTES ON BOOKS.

X-RAY literature commonly is so very practical and pedestrian that it is something of a refreshment to come upon a book which has *X Rays* on its title-page and professes no immediately utilitarian purpose.[7] Dr. KAYE is one of that small band of young physicists who have been attracted by the problems opening up fascinating vistas ever since Roentgen's discovery. He is not so much immersed in physical theorizing, however, as to fail to give a brief but able account of *x*-ray practice and application. The work is not a popular treatise, for the author, while he is painstaking and even elementary in his description of *x*-ray technique, assumes that his reader has a good mathematical grounding and that he is familiar also with recent developments in physics. It is useful to have within the covers of a moderately priced book an account of those investigations which have not hitherto reached beyond the scattered and somewhat inaccessible pages of society transactions. The most recent research, and in some respects the most influential in its results, concerns the reflections and diffractions of *x* rays by crystals, and the collected account of these investigations makes, perhaps, the most valuable section of the book. There are several appendices, in one of which Sir James Mackenzie Davidson gives his recollections of an interview with Professor Roentgen; and that the subject is capable of lighter treatment than the mathematical formulae would suggest is shown in some verses by a Cambridge friend of the author, who describes first the freeing of the corpuscle from the atom, and then the birth of the *x* ray:

> The corpuscle won the day,
> And in freedom went away,
> And became a cathode ray.
> But his life was rather gay,
> And he went at such a rate,
> That he ran against a plate;
> When the aether saw his fate,
> Its pulse did palpitate.

The marked improvement in the anatomical textbooks of the present day over those of twenty years ago, particularly in respect to illustrations, has made it possible for the medical student to acquire a knowledge of anatomy sufficient for the purpose of passing the ordinary examinations while evading to a greater or less extent the one and only true way of obtaining a sound and permanent knowledge of the subject—namely, dissection. Teachers have become more and more alive to the dangerous and disastrous effect of such a short cut, rendered as it is all the more seductive by the steady increase of the subjects in the medical curriculum with no corresponding increase in its length. Professor A. M. PATERSON'S volume, *The Anatomist's Notebook*,[8] is written for those students, wise in their generation, who wish to follow the old accredited path. In it are given plans of dissections, the order in which structures should be found, and outline drawings to be filled in during the actual dissection. It is a book for notes rather than a book of notes, notes made by the student himself from his own observation. It is in the truest sense educational, both in object and plan, and can be warmly recommended to all those who are willing and wise enough to spend a little extra time in laying a secure foundation for their future studies. The figures, which are purposely diagrammatic, are helpful and on the whole accurate. The drawing of the feet of the subject in Fig. I is, however, quite unnecessarily bad, while the course given to the deep epigastric artery in Fig. 17 is definitely wrong. These are, however, small blemishes, and in no serious way detract from the value of the book.

MOTOR NOTES FOR MEDICAL MEN.

By H. MASSAC BUIST.

THE OVERHEAD VALVE ENGINE AND THE PRIVATE MOTORIST.

DESPITE the fact that the Grand Prix race of the Automobile Club de France was for machines with engines of moderate size, coming within the six-guinea tax, otherwise 274½ cubic inches cylinder volume, and that the winning speed over perfect roads, with a minimum of hill-climbing, was only 65½ miles an hour, there was little enough in the event at Lyons to interest the medical motorist. It was again a race between multi-valve motors of very high compression, wherein the overhead setting was used, with its present disadvantages of noise and inaccessibility. If the side-set touring form of mushroom valve ordinarily used goes wrong, it is generally possible to attend to it on the high road. In any case, it is not necessary to break up the engine. But the Grand Prix, like the Tourist Trophy race, showed that when anything goes wrong with the overhead form of mushroom valve, there is no option but to consider the car quite out of the running and to stay by the roadside until somebody comes to tow it home, for it is not possible to get at the valve without dismantling the engine.

If we are looking to the future of motor design, we may of course assume that presently we shall find out enough from racing to be able to construct overhead valves so that they will be at least as reliable as the sort set at the side of the engine. But design will have to be improved besides if overhead valves are ever to come into general use, because there are occasions when side valves go wrong, even to-day, after the many years of experience of them. Therefore it will be necessary to find out how to employ overhead valves so set that in the event of their failure, however rare, it will not do considerable damage to the engine, as we have seen happen so very often in connexion with this year's racing. Further, apart from the matter of damage done in the event of failure, we must consider the question of accessibility. There is no more reason why either of these points should prove insurmountable difficulties when enough experience of the business has been gained than there is that we should not find out how adequately to silence engines with overhead valves.

ECONOMY OF FUEL.

To the question Why should we trouble to develop a new system of valve operation at present attended with such obvious disadvantage? the answer is—Chiefly because it was demonstrated in the Grand Prix race of 1913, run on a fuel consumption limit, that the overhead valve engine gives better results for the amount of petrol used, and last year's Coupe de L'Auto race for 3 litre cars, this year's Tourist Trophy race for 3.31 litre cars, and this year's Grand Prix race for 4½ litre cars, have all shown that the highest efficiency so far obtainable is got with overhead valve engines.

Thus we have the almost picturesque situation that the overhead valve engine, which perhaps comes into most prominence through this business of racing would be obviously the most suitable type for the commercial motor vehicle, for example, which is nevertheless in other respects the antithesis of the racing proposition. Maybe for touring purposes we shall first come to the use of the overhead valve engine, in a general sense, through its gradual exploitation for commercial motor vehicles, where the question of quiet running is not of so much importance as it is to the private motorist. Roughly, by the use of the overhead valve motor, it should be possible to save anything up to 20 per cent. on the fuel consumption, so that under this heading alone there is something worth striving for in pursuing the problem of the overhead valve motor to a stage further.

Of course, the overhead valve has not been unknown to touring car practice in standardized form for a long period, as instance notably the Bedford-Buick car. But in it there is no attempt to exploit the business in its most complicated form, as in racing cars, where the majority are using two inlet and two exhaust valves per cylinder.

PHASES OF THE PETROL PROBLEM.

Though there are only enough supplies of crude oil above ground at the moment to run the world for six months, it is quite possible the price of fuel may be further reduced at no distant date. This is not, according to popular error, because the profit on selling petrol is much higher than the profit on selling crude oil. On the contrary, the chief reason that petrol costs as much as it does is that the demand for it is out of proportion to the demand for the residuary product after the process of distillation. Therefore, when a gallon of petrol is bought in the circumstances which are and have been obtaining, the purchaser has also to pay for a considerable amount of crude material which is simply wasted. Create a demand for those residuary products, and the petrol purchasers would no longer have to pay for them; hence the price of fuel could be lowered. It is largely through the rapidly increasing use of liquid fuel for ships that a demand is arising for residuary products, apart from which it is fortunate that the world supplies of the raw material are being opened up at an enormous rate. Had they not been developed thus rapidly, the expansion of the motor movement would have received a sudden check. As it is, we have merely seen high prices ruling for fuel.

There is some talk that the co-operative and other organizations to which the public has been invited to subscribe in face of the high price of motor fuel are the causes of the price being brought down. This, however, is wildly inaccurate. Of the many proposals that have been put forward under this head, the majority have not been practical propositions. Only a handful have materialized into producers; some of those that are giving delivery buy their supplies in the open market, so that the business is not on a sound basis. There is, nevertheless, a residue of genuine enterprise to relieve the situation. But it is proportionately so small in regard to the total requirements of the country that it figures only as a drop in the ocean, and has no effect whatever on controlling the market. For example, what could any enterprise producing five million gallons of fuel in a year do in the way of causing a lowering of price in a country that requires over a hundred million gallons of petrol per annum?

The chief factors that control the present and future price of the motorist's fuel are the ratio of expansion of the world's supplies to that of the motoring movement. If we are arrived at the point when the former is about to outgo the latter, then the price of fuel must become cheaper. An investigation of the world's motor trade at the moment suggests that, as regards private vehicles of the middle and the large sort, the possible rate of expansion has reached something like a fixed quantity. Therefore, as far as these are concerned, fuel production is either going ahead or is about to go ahead of demand.

On the other hand, we are only beginning to develop the light car and the commercial motor vehicle. The latter would upset all calculations were it not certain that it will soon either be run on other fuel than petrol or on much cruder spirit than is used for the pleasure car, therefore creating a demand for the residuary product and so making for cheapness all round. But the light car, which is perhaps the vastest field we are about to enter, will call for the use of the highest grade spirit. The situation of supply and demand would look grave were it not for the fact that the average light car is extremely economical of fuel; a vast number of these machines can be brought into use without making any heavy additional demand by comparison with the increased consumption of fuel when big batches of large cars are brought into use. Add, therefore, to these facts the all-important one that the requirements of shipping service are all the time creating a demand for residuary products, and it is seen plainly that the price of fuel will probably not rise, but on the contrary come down somewhat in the near future, particularly in face of the fact that the next year or two will see some ambitious projects materializing for producing fuels alternatively to petrol. These, however, are scarcely likely to be used in any appreciable quantities by the private motorist for years to come. They are more suitable for agricultural motor work and for service where unpleasant odours, and so forth, are matters of indifference.

FRONT WHEEL BRAKES AND THE GRAND PRIX.

Anybody who watched the Grand Prix race being run on the Lyons circuit could not have failed to be struck by two things. A few years ago, when British inventors introduced the detachable wheel, the Automobile Club of France forbade the use of it in racing, on the ground that it was dangerous. A fortnight ago in the biggest international road race yet organized, not a single competitor started without detachable wire wheels either of the Rudge-Whitworth sort or those of its licensees in the various countries.

The other point was that front wheel brakes—which were first brought into use in this country, standardized in many cases too hastily by those who had not mastered the principles, and therefore withdrawn after much trouble had been experienced, save in such a singular case as that of Argylls, who have mastered the underlying principles—were adapted from touring-car practice to racing practice by the French champions, Peugeot and Delage; were used by the Swiss Piccard-Pictet, and by sundry Italians, including Fiat; but not by the Germans, in whose country the invention has not been developed yet; nor by the British, in whose country there has been accumulated more experience concerning front wheel brakes than anywhere else in the world.

The race was over roads of the billiard-table variety as regards surface, compared with what one meets with when motoring out in the world, say in the colonies, where there are tracks instead of roads, or in Russia or Sweden. It was possible to race two cars abreast all round the course. Only a couple of miles of it presented the semblance of hill-climbing work. On the outward legs of the course, however, the route abounded in turns. This fact made the motor engineers who designed the competing machines pay more attention to qualities of acceleration than ever. Those who put on their thinking-caps also realized that it is no less important to economize time in reducing speed than it is to save it when gaining speed. Hence they harked back to touring-car practice by distributing the braking effort over four instead of two wheels.

We were told before the race that disaster could only attend such a policy, that the tyres would be destroyed in a hair-raising manner, and so forth. None of these things occurred. On the contrary, front wheel brakes, of course, proved a saving of tyres in relation to the actual amount of braking work done. To judge this it should be known that those who had front wheel brakes would rush up to the corners with the accelerator pedal full down for anything from fifty to seventy yards after those with brakes working on the back wheels only had applied them to those wheels. Therefore the total amount of braking effort on the cars with four wheel brakes was of course vastly in excess of those with two, because the machines were slowed in about half the distance. In the words of one mechanic on board one of the racers: "When they put the brakes on all four wheels, it is like going into butter."

WHERE THE SAVING OCCURS.

This was certainly worth a minimum of a minute a lap in time saving, therefore the total amount of tyre wear per car must have been greater in the machines with four wheel brakes than on those with two. Nevertheless the result was no more extravagant because, to do the best with brakes on two wheels only represents, let us say, straining the two tyres 100 per cent., whereas to do 50 per cent. better by using brakes on four wheels represents straining each of those tyres only 75 per cent. Of course, it is the last 25 per cent. that spells the ruin. Stress anything well below its limit, and you can go on wearing it for a great length of time without any appreciable deterioration. Let it be had in mind, moreover, that the front wheel brake men did not all quite understand their business, as is proved by the fact that some of them used smaller tyres on the front wheels than on the back ones.

Moreover, this must not be considered a full test of the possibilities of front wheel braking, because the majority of the competitors so designed their brakes that they could not be used on the front wheels while steering round corners; whereas it is a point of the principle behind the Argyll system that when going round the corner the steering is rather assisted than impeded by the braking action.

Nevertheless, such as it was, the demonstration of the use of front wheel brakes was remarkable. The Peugeot cars were not as fast as the Mercédès, but by reason of the French vehicles having front wheel brakes they could take shelter from pursuit, and delay the inevitable overhauling whenever they came to a series of corners or bends. This difference in the powers of decreasing speed, contrasting as it did with the different powers to increase it, made the race as a spectacle fresh and unprecedented.

It should be appreciated that the moment braking is applied to the front wheels the result is to throw weight forward on to those wheels, thereby increasing their power of adhesion to the road surface, and accordingly preventing the wheels locking and skidding. It is skidding that destroys tyres and that reduces braking effort to its least possible value. We see, therefore, that a natural physical law assists those who desire to employ the principle of brakes on all four wheels. One result of the race will be to give a big impetus to the employment of front wheel brakes for touring cars. But the medical man must be warned that it is one thing to want to have brakes on the front wheels and quite another so to scheme them that they shall prove a blessing instead of a bane. In this country we have already seen very numerous examples of how not to employ front wheel brakes. We may be sure that if there is any sudden demand for the motor manufacturers to employ the system, a number of them will rush into the business without realizing the difficulties ahead. Argylls and some Italians are, so far, about the only folk who have mastered even the rudiments of the matter.

LARGE-SIZED TYRES.

Another feature of the race was that the winning Mercédès cars used proportionately larger Continental tyres than their rivals; also they employed plain treaded ones from the start to the finish of the race. What the larger-sized tyres took off in speed was more than saved by what was gained in their extra wearing qualities; there was in those tyres more material to be worn away before the time came to change. Translated into terms of the private motorist's position, this means also that, within reason, it is more gainful to use large than small tyres. On the other hand, when employing large section tyres on small rims, the motorist must be careful to keep an eye on his pneumatics. Thus if he allows them to get slack he has that amount more twisting action of the walls when taking corners, and that extra liability temporarily to displace the bead, which in flying back may perchance nip the tube. On the other hand, he must not go to the other extreme of keeping tyres too hard in summer weather. Many motorists remember to their cost the hot summer of two or three seasons ago when tyres burst wholesale about the country through being kept at too high pressure in hot weather. We are still at the period when the individual motorist has as much to gain from carefully studying his own case as regards tyres as he has as regards carburation, electric lighting, or engine starting gear. Pneumatics have been so vastly improved of recent years that it is easy to fall into the habit of comparatively neglecting them; but it pays to take the opposite course. No general rule applies equally to all sorts of vehicles, from heavy, high-powered ones to the lighter sort, unless it be such an obvious thing as that it is foolish to run on slack tyres, to neglect ugly cuts, to leave nails or horse shoes stuck in treads, and so forth. Provided corners are not taken too fast, large section tyres which are now made by Dunlops, as well as by the Continental Company, have many advantages.

THE *American Medicine* gold medal for 1914 has been awarded to Dr. George W. Crile, of Cleveland, Ohio, as the American physician who, in the judgement of the trustees, has performed the most conspicuous and noteworthy service in the domain of medicine and surgery during the past year.

THE Royal Academy of Medicine of Turin announces that the thirteenth competition for the Riberi Prize, of the value of £800, is open. The prize will be awarded for scientific researches in medical science. Competitors may enter their names up to December 31st, 1916. Forms to be filled up may be obtained from Dr. V. Oliva, the secretary of the Royal Academy of Medicine, 18, Via Po, Turin.

SOME FIGURES IN MEDICAL HISTORY.

SIR JAMES McGRIGOR, BART.

SOMETIME DIRECTOR-GENERAL OF THE ARMY.

In the list of men who have been at the head of the medical service of the army there is none whose name shines with a brighter lustre than that of James McGrigor. He served his country for more than half a century with rare distinction and efficiency. The early years of his service were passed in a period of almost unceasing war; he had to wage battle against death in every form in the most various climes, to suffer the attacks of dangerous disease in his own person and to face danger on the sea and in the field. Tried by every kind of difficulty and emergency, he was never found wanting, and he won the esteem and warm personal regard of Wellington, Marshal Beresford, Sir David Baird, and the other generals under whom he served, the respect and devotion of the officers of his own department, and the affection of the fighting men among whom his lot was cast. He did much to increase the efficiency of the medical service of the army and to improve the position of medical officers. He died in the fullness of years, with the record before his mind of a life spent in the unfailing fulfilment of duty, and having about him—

> That which should accompany old age . . honour, love, obedience, troops of friends.

SIR JAMES McGRIGOR.
(Reproduced, by permission, from a print in the Royal College of Physicians of London.)

James McGrigor was born in 1771 at Lethendrey in Strathspey, Inverness-shire, and was educated at the Grammar School of Aberdeen. Entering at Marischal College, he in due course took the degree of M.A. "which was then," he says, "obtained after an examination not the most severe and searching."

Having no inclination to follow the occupation of his father, who was a merchant, he hesitated for some time as to the choice of a profession. Of his early associates and friends a large proportion had entered on the study of medicine. With these young men he spent much of his time. He accompanied them to the Royal Infirmary and read their books; this aroused in him a strong interest in medicine, and he determined to take it up as a profession. He admits that he was also attracted by the cockade and cocked hat of a senior student who got an appointment as assistant surgeon to a regiment in Jamaica, and the impression was not entirely effaced from his mind after he joined the army. He attended the few lectures then given on the different branches at Aberdeen, and after three years' attendance at the infirmary and dispensary he proceeded to Edinburgh, where he attended Munro's class of anatomy, Gregory's course of practice of physic, and some other classes. He studied so hard that his constitution gave way and several months elapsed before he recovered his health. On his return from Edinburgh he took a leading part in founding the Medical Society of Aberdeen. This society was formed in 1789, and McGrigor continued throughout his life to take a keen interest in it, watching its advancement and success, as he says, with the anxiety of a parent. Becoming united with Marischal College, though never forfeiting its independence, the Medical Society of Aberdeen attracted, in addition to the youths who were its first members, an increasing number of doctors, and became a potent educational influence in the profession.

In 1793 McGrigor purchased a surgeoncy in the 88th Regiment, or Connaught Rangers, then just formed, and joined the corps at Chatham. In 1794 the regiment was sent to Jersey, which was then full of French exiles. Typhus was raging in the regiment and in the army. He himself was attacked by the disease in its severest form. His popularity with the men is shown by the fact that when it was considered necessary to move him from St. Helier's into the country soldiers volunteered to carry him in a framework made to hold his bedding, as they thought this would be easier for him than being drawn in a wagon. Before his convalescence was complete the regiment was ordered to Flanders where there was much fighting. He shared the hardship of the winter retreat in 1794-95. The hospitals were filled to overflowing and the mortality among medical officers in particular was very heavy. At Norwich, where the regiment was stationed after its return to England, fever again made terrible havoc, and the situation was made worse by the prevalence of a strong republican feeling among the inhabitants, who insulted the officers and encouraged the soldiers to desert. The regiment, which was to form part of an expedition for the capture of the French West India Islands, was sent to Southampton to join the force which was to embark there. The hospital was full and there were many sick in barracks. The commanding officer, Colonel (afterwards Field Marshal) Beresford, was very angry and told McGrigor that he was being deceived by malingerers. McGrigor on his part attributed the sickness to the filthy state of the barracks in which they were quartered. After the colonel had visited the barracks, abusing most of the officers, McGrigor begged that he would accompany him to the hospital. With this he could find no fault, but relations continued strained, and McGrigor negotiated for an exchange. Beresford.

however, apologized, and explained that he had been dissatisfied with the state in which he found the corps, and that the only department of it of which he could say anything favourable was the hospital, and that he had so reported to the Horse Guards. They became warm friends, and continued so throughout life. Owing to a mistake in signals McGrigor sailed for the West Indies in a ship to which he had been sent to select some recruits for his regiment; he had only the clothes he stood up in, but the officers of the 48th on the *Betsey* between them made up a kit for him. The *Betsey* reached the West Indies a fortnight before the rest of the fleet. When the fleet did arrive McGrigor learnt that one of the transports with his regiment on board had been obliged to put in at Gibraltar, and that the *Jamaica*, in which he was to have sailed and in which he had left all his baggage and clothes, had been captured a few days after putting to sea by a French frigate and carried into Brest. He was thought to be dead, as on the day when the fleet was getting under way at Portsmouth an officer in attempting to pass from one transport to another, had been crushed to death. From the description the officer was supposed to be McGrigor and another surgeon was appointed in his place. This chapter of accidents was really a blessing in disguise, for it caused him to escape a French prison. The island of Grenada had been seized by the blacks some time before, and the governor and twenty of the principal inhabitants had been shot in cold blood. The whole island except Georgetown and Richmond Hill was in their possession. A transport with a number of men of his own regiment arrived and McGrigor was hailed with cheers by the soldiers and carried forward in triumph. He was placed at the head of the medical staff. There was some heavy fighting. When the island was recaptured and quiet was restored yellow fever appeared and caused frightful mortality. The deaths from disease were four times as many as those due to bullet and bayonet. McGrigor was severely attacked by dysentery, and in the autumn of 1796 was sent home with dispatches for England. The voyage was marked by adventures which make this part of the *Autobiography* read like one of Marryat's novels.

On Christmas Day, 1798, McGrigor went with his regiment to Bombay. The Connaught Rangers were soon ordered to Ceylon, the objective of the expedition being Batavia and ultimately the Isle of France. But its destination was changed to the Red Sea, and great was the joy of the soldiers at the prospect of helping to drive the French out of Egypt. McGrigor was appointed head of the medical staff by the Medical Board of Bombay, being the first King's Medical Officer employed by the Company, and was presented to Colonel Wellesley, who was to command the expedition. McGrigor was to see much of that officer later, but the future Lord Wellington was prevented by illness from going to Egypt, and the expedition was commanded by Sir David Baird. It landed at Cosseir in the early summer of 1801 and, crossing the desert, went down the Nile to Rosetta. McGrigor, who had been attacked by fever, which was at first thought to be plague, was carried on board by the soldiers, and he bears testimony to the kindness always shown to the doctor by men who were among the wildest of a wild regiment. To mend his diet they stole sheep and fowls for him, and when he insisted on paying the owners, the Rangers thought this a very unnecessary proceeding. The Indian Army was encamped at El Hamed, about two miles from Rosetta; the King's troops whom they found there gibed at the luxury with which they had crossed the desert, likening them to the army of Darius. And, indeed, the Indian contingent made itself very comfortable, if we may judge from McGrigor's account of his own quarters:

> I had upwards of a dozen Indian servants, with their wives, besides my English soldier servant, and for my stock three camels, two horses, twenty-four sheep, three goats, several dozen of fowls, with a good many pigeons, rabbits, etc. My own large Indian marquee was in the centre, and around were the small Arab tents which my Indian servants had raised for themselves. In another quarter were found all my animals and a store tent, in which some of the servants nightly kept watch, and made rounds to see that no marauders made incursions upon us; which, however, they did occasionally, carrying off fowls, sheep, etc. Outside the whole I had a high mound thrown up, made from the vegetation on the bank of the river, having only one large gate to my premises. El Hamed was on the border of the desert and a sandy plain, but my animals were fed with the grasses from the bank of the river and the grain which my blacks, with two Arab servants, could collect. I can never forget the astonishment of some officers of the English army, old friends who had visited me, on my showing them the extent of my premises. They told me that I brought to their mind the age of the patriarchs of old, with their herds and their flocks, their man-servants and their maid-servants.

Soon McGrigor was called upon to move into Rosetta to assume the medical superintendence of the army from India. He was then stationed at head quarters in Alexandria. There plague broke out but was quickly subdued.

On the cessation of hostilities McGrigor returned with Sir David Baird to Bombay, where he was appointed superintendent of quarantine. On the return journey to England he and his companions learnt from an American privateer that England and France were again at war. They were dogged for a time by a suspicious looking vessel, but frightened her off by "bluff"; the captain had wooden guns made, and these, with the outside of the ship, were painted so as to make her look like a frigate. Every one on board paraded in uniform, and the sailors, some of them invalided men, ran up and down the rigging so as to create the appearance of a strong crew.

In February, 1804, McGrigor left the Connaught Rangers, in which he had served eleven years, and became surgeon of the Horse Guards Blue, then stationed at Canterbury. A few months after he joined, gangrene ran rapidly through the hospital. In every case, even the slightest, of wound or contusion, where venesection had been performed or a blister applied, hospital gangrene appeared. When the regiment moved to Windsor, where the hospital was large and roomy, the disease was checked.

At Windsor McGrigor came under the notice of George III, whom he found fully acquainted with his services. The Queen did him the honour of prescribing for him when he was afflicted with whooping-cough; she advised him to have oil of amber rubbed on his spine. McGrigor, like other patients prescribed for by less august physicians, did not follow the royal counsel.

McGrigor, who in 1804 had proceeded M.D. at Marischal College, was in 1805 gazetted deputy inspector, an advance of three steps, which was first announced to him in a curious manner. The adjutant of the regiment came to his room one morning and said the King while being shaved said to the non-commissioned officer in attendance: "You are about to lose your surgeon in the Blues; I have this morning signed a new commission for him on his promotion." McGrigor's new sphere of duty was very congenial to him, for from his first entrance into the service he had a turn for the collection of statistics. The Medical Board had, he says, till then, in the reports and returns required from the medical officers, looked solely to fiscal concerns, to the neglect of professional matters.

> The most minute and scrupulous attention was not only exacted in the number of ounces of soap, salt, oatmeal, etc., given to each patient, but an error even in the fractional parts brought down the animadversion of the board, and was frequently the subject of protracted correspondence; while no notice was taken of any new or extraordinary feature of prevailing diseases, no proposition for the trial of new remedies and for the return of reports thereon, nor any injunctions issued to notice *post-mortem* appearances. In short, nothing with regard to professional duty in the interests of science was noticed, unless there happened to be an extraordinary mortality in a corps. About this time, and for some time afterwards, the duties of regimental surgeon and assistant-surgeon were chiefly those of clerks, as accounts to the public for their expenditure on each sick man.

McGrigor was appointed to the Northern District, the head quarters of which were at Beverley. He cautiously introduced his new system, first impressing on the medical officers what a fine field for experience and observation lay before them. He showed that a military hospital was the best for trying the effects of all new remedies or methods of treatment, because there the patient was more under the control and observation than anywhere else. His plan in the inspection of hospitals was to examine each patient's history, the medical officer reading the particulars of the case at the bedside and the treatment adopted. McGrigor then questioned the patient, generally approving of what had been done, but suggesting anything that occurred to him in the way of further treatment. In the evening he had the hospital books sent to him, and made notes on the reports. These remarks he embodied in a letter to the surgeon, referring to the different authors on the diseases

which were prevalent or on those in which the surgeon appeared not to have been successful. These letters, which were always expressed in a friendly manner, had, he says, with only few exceptions, the best effect, and he seldom had occasion to report any of his officers to the general in command of the district. The reports of his inspections were communicated confidentially to the inspector-general, who generally approved of what he did. Nevertheless, he slyly remarks, he found that he had not satisfactorily accomplished all that was expected of him, for he had not scrutinized so minutely as was desired the expenditure on each article of hospital consumption!

Soon afterwards McGrigor was transferred to the larger sphere of the South-west District, which included Hampshire, Dorset, Wilts, Somersetshire, and South Wales. To this area Portsmouth and the Isle of Wight, which had previously formed a separate district, were soon added. This added largely to the work of the deputy-inspector, for all the great embarkations took place at Portsmouth; almost all the great expeditions were equipped at that port; there was a very large dépôt of prisoners of war afloat as well as ashore, while in the town and its neighbourhood there was a garrison of nine or ten regiments. In the Isle of Wight was the dépôt of the recruiting for all the regiments of the service; there was also a large general hospital. At Portsmouth McGrigor received the sick and wounded after the battle of Corunna. After occupying all the ordinary hospital accommodation in and about Portsmouth, and converting some barracks into hospitals, and getting leave from the Admiralty to use the unoccupied part of Haslar, the number of typhus cases continued to increase, and McGrigor was compelled to have recourse to floating hospitals, such as transports, prison ships, and so forth.

It was the Peninsular war which gave McGrigor the great opportunity of his life. At first his old friend, Marshal Beresford, asked that he should be sent to Portugal as chief of the Portuguese medical staff with the rank of inspector of hospitals. Before he could start for Lisbon, however, he was ordered to Walcheren to take the place of Sir John Webb as head of the medical department. The ship in which he sailed was wrecked, and the people she carried had to be taken off in boats from Flushing. McGrigor says the amount of sickness at Walcheren was beyond all comparison greater than anything he had seen elsewhere. The troops were surrounded by the French force, and orders came that they were to return to England. It was acknowledged on all hands that he had done his work well, and the parliamentary inquiry which followed did him no harm. He returned to his old duties at Portsmouth.

In June, 1810, McGrigor married Miss Grant, a sister of Wellington's famous scout, Colonel (afterwards General) Colquhoun Grant. In due course his wife presented him with a son, but he was not allowed long to enjoy family life, for in 1811 he was ordered to the Peninsula to be chief of the medical staff under Wellington. On January 10th, 1812, he reached Lisbon where he found a great accumulation of sick. To relieve the congestion he proposed that each corps should have a temporary hospital of its own where all slight cases should be dealt with, only serious cases being sent to the rear. When he joined Wellington at head quarters, he found the general much pleased with what had been done.

McGrigor remained throughout the campaign in close touch with Wellington, who evidently recognized the value of the man. Though it was inevitable that differences of opinion should arise between two men of such strong character, there seems to have been only one serious quarrel, and that was soon over. This occurred at Madrid soon after the battle of Salamanca. McGrigor when he called found Wellington sitting for his portrait to a Spanish artist. This was probably Goya, to whom we owe the most living, if not the most attractive, likeness of the great commander. Asked to give an account of the wounded at Salamanca, McGrigor told him of the number of sick he had found at so many places, and described their miserable state. But when he reported that for their relief he had ordered up purveying and commissariat officers, Wellington started up, and in a violent manner reprobated what he had done, exclaiming:

> I shall be glad to know who is to command the army? I or you? I establish one route, one line of communication for the army; you establish another, and order the commissariat and the supplies by that line. As long as you live, sir, never do so again; never do anything without my orders.

It was in vain that McGrigor pleaded that there was no time to consult the general to save life; he was told peremptorily never again to act without his orders. Wellington's sudden passion soon died out, however, for he asked McGrigor to dine with him that day, and at dinner he showed him marked attention, making him sit next to him on his left, the Prince of Orange always sitting on his right hand.

The influence McGrigor had with Wellington is shown by the fact that after the siege of Badajoz he induced the general to mention the services of the medical officers in dispatches. This was the first time their merits were thus publicly acknowledged. When, after the passage of the Bridge of Salamanca, McGrigor was severely kicked by a horse, Wellington, as soon as he heard of the accident, sent his own carriage, the only one in the army, for him. The most masterful of men, Wellington, on one occasion when he dissented from an opinion expressed by McGrigor, took the trouble afterwards to set forth his reasons in a letter written with his own hand on two sheets of foolscap paper. This is all the more remarkable, as at the time Wellington's mind must have been fully occupied with the manifold and complicated preparations for moving his whole army against the enemy.

McGrigor was present at every battle from the time he joined up to the last engagement at Toulouse. Striking witness to the efficiency of his medical administration is given by Napier in his *Peninsular War*:

> During the ten months from the siege of Burgos to the battle of Vittoria the total number of sick and wounded which passed through the hospitals was 95,348. By the unremitting attention of Sir James McGrigor and the medical staff under his orders, the army took the field preparatory to the battle with a sick list under five thousand. For twenty successive days it marched towards the enemy, and, in less than one month after it had defeated him, mustered, within thirty men, as strong as before; and this, too, without reinforcements from England, the ranks having been recruited by convalescents.

In London McGrigor continued to pay his usual visit to Wellington, who one day, after winding up the usual business, said:

> Mac, we are now winding up all arrears with the Government; I have asked them how you are to be disposed of, and I am told you are to be placed on half-pay; but I consider your peculiar services will entitle you to a specific retirement.

The end of this little negotiation was that near the end of 1814 McGrigor retired with an allowance of £3 a day, and received a knighthood.

It is characteristic of the man that he used his newfound leisure in attending lectures on anatomy and chemistry. But he was not long left unemployed. On June 13th, 1815, he was appointed Director-General of the Medical Department with a salary of £2,000 a year and the relative rank of major-general. That position he continued to hold till 1851. In 1848 he expressed a wish to retire, but Wellington, then Commander-in-Chief, said, "No, no, McGrigor; there is plenty of work in you yet." The financial head of the army, in bringing forward his estimates in the year 1851, said:

> In the army medical department the service has lost by the retirement—not, I am happy to say, by the death—of Sir James McGrigor, an officer to whom the public is much indebted.

Wellington, in his *Dispatches* (vol. xii, p. 79), had written of him:

> I have every reason to be satisfied with the manner in which he conducted the department under his direction, and I consider him one of the most industrious, able, and successful public servants I have ever met with.

How popular McGrigor was with the officers who served under him is shown by the fact that on his return to England after the Peninsular war he was presented by them with a service of plate of the value of one thousand guineas. When he finally retired from the army it was proposed to present him with another costly testimonial, but this he would not accept. An address signed by more than five hundred officers of the medical department was, however, presented to him.

McGrigor's services were rewarded with many honours. In 1831 he was created a baronet, and in 1850 he was made a Knight Commander of the Bath. For his services in the Peninsula he was made a Knight Commander of the

Tower and Sword of Portugal, and for the part he played in the Egyptian campaign the Turkish Order of the Crescent was bestowed upon him. He was a Fellow of the Royal Society and of many other learned bodies, British and foreign. Marischal College, Aberdeen, thrice elected him Lord Rector—in 1826, 1827, and 1841. The students presented him with his portrait, painted by William Dyce, R.A., now in the hall of Marischal College. Another, painted by Sir David Wilkie, is in the officers' mess at the Army Medical College, Millbank, where there is also a statue of him. The portrait here reproduced was painted by J. Jackson, R.A., and presented by his brother officers to Lady McGrigor. After his death an obelisk of polished granite, seventy-two feet high, was placed in the quadrangle of Marischal College. It now stands in the Duthie park, Aberdeen, by the side of the Dee.

McGrigor wrote little. His principal contribution to medical literature is a book entitled, *Medical Sketches of the Expedition from India to Egypt*. He was also the author of a *Memoir on the Health of the 88th and other Regiments, from June, 1800, to May, 1801*, presented to the Bombay Medical Society in 1801; *Medical Sketches of the Expedition to Egypt from India*, London, 1804; *A Letter to the Commissioners of Military Enquiry*, London, 1805—this was a reply to animadversions on the fifth Report of the Commissioners of Military Enquiry, which had been published by Dr. E. N. Bancroft. McGrigor instituted a system of medical reports and returns intended to advance the interests of science and the improvement of medical officers of the army. During his long tenure of office as director-general he collected a vast number of records which he had bound up in folio volumes, each duly lettered with the name of the colony or district to which it related and indexed. This formed the basis of the *Statistical Returns of the Health of the Army* now published yearly as a Blue Book. His *Autobiography*, published in 1861, is a fascinating volume which throws a vivid and often amusing light on the conditions of the service of which he was so conspicuous an ornament.

Among other things which he did for the benefit of the medical officer, McGrigor founded a museum of anatomy and natural history bearing on military surgery. To this he attached a library to which he himself gave a number of books. To him was due the establishment of the Army Medical Friendly Society, in 1816, and of the Army Medical Benevolent Society, in 1820. He also presented some prizes to be competed for by the students of Marischal College.

Sir James McGrigor spent nearly fifty-seven years of his life in the active service of his country. Few men had seen more of disease and suffering; he had passed through many dangers of shipwreck, siege and battle, but the end of his strenuous life was peaceful. He died in London on April 2nd, 1858, within a week of the completion of his eighty-eighth year, "without pain and almost without disease."

In addition to his great ability as an administrator, McGrigor had the qualities of character that command success. Ever straightforward in his dealings, he combined tact and courtesy with firmness in a most unusual degree. From the time of his joining the Connaught Rangers to the very end of his career he was recognized as an officer who could be trusted to do his duty at whatever cost to himself. The confidence of the soldiers in him reminds one of the story of Ambroise Paré's reception by the garrison of Metz, "Our Ambroise is with us; we shall not die." From first to last he was on the best of terms with the officers of his own department, and also with those of the combatant branches. He was always treated by them as one of themselves, dining with generals and royal dukes, being present at Court balls at Windsor and sharing fully in the social life of the army. In the Peninsula he was a frequent guest at Wellington's table. The man, as well as the officer, was evidently held in the highest respect. In his personality he combined the best qualities of the doctor and the soldier.

AN illustrated handbook to medical Bern has been issued by the general inquiry office in that city. It gives particulars about Bern and its medical institutions, and among the pictures is a portrait of Professor Kocher, the grand old man of surgery. Copies can be obtained on application to the Verkehrsverein, Bern.

ROYAL COMMISSION ON VENEREAL DISEASES.

THE following is the official report issued to the press by the Secretary of the Commission:

The Danish System.

At the forty-sixth meeting of the Royal Commission on Venereal Diseases evidence was given by Dr. Svend Lomholt, Surgeon at the Municipal Hospital at Copenhagen, regarding the methods adopted for dealing with venereal diseases in Denmark. The principle has been to provide free treatment and to render it as easily accessible as possible. As early as 1773 a rescript provided for free treatment of all poor persons suffering from venereal diseases in one of the provinces of Denmark, and similar regulations were made from time to time, until by an Act of 1874 it was laid down that every person should be entitled to free treatment for venereal disease without regard to his ability to pay. In reality little was done to make this right to free treatment of practical value until 1906, when an Act was passed which contained a provision compelling the municipalities to arrange easy access for free consultation and treatment for all persons suffering from venereal disease. Since that date, especially in Copenhagen, in which town probably 80 per cent. of the disease occurring in the country was to be found, a great deal had been done. Very complete hospital facilities had been provided, and in addition there were three public consulting-rooms for contagious and venereal diseases, at one of which evening consultations were held.

Twelve municipal doctors (two of whom were women) had been appointed for the purpose of giving free treatment of venereal diseases.

The experience had been that patients had shown themselves very ready to take advantage of these facilities. In some directions compulsory measures had been adopted. A doctor treating a case of venereal disease was required to point out all the consequences of the disease, and there was also provision for securing that persons suffering from venereal disease should continue their treatment. Dr. Lomholt thought that this latter provision had been very useful. A system of confidential notification of venereal diseases was in force. The names and addresses of the patients were not notified and the cases were identified only by numbers; the notification was consequently only of use for statistical purposes. Dr. Lomholt had made a critical examination of the published figures and showed that they could only be accepted with a good deal of reserve.

Facilities for Treatment: Notification.

Mr. Charters Symonds, consulting surgeon to Guy's Hospital, giving evidence, laid stress on the need for largely increasing the means available for treating venereal diseases. He thought that existing institutions should be utilized as far as possible, and that these, together with any additional provision which might be made, should be linked up with Insurance Committee areas and with panel doctors. Evening clinics should be provided at every centre. It would be necessary that a scheme of this kind should receive adequate subsidies from the State. Mr. Symonds advocated the formation of a National Society which should supervise the selection of lecturers, the scope of teaching, and the publication of books and pamphlets, with a view to the education of the public respecting venereal disease. Such a society, he thought, should be voluntary and should be ready to assist the Government in any measure of which the Government approved. He would propose that the Royal Society of Medicine should nominate persons to serve as a committee of this National Society, and that a definite sum of public money should be placed in the hands of that committee.

With regard to the question of notification, Mr. Symonds said that the experience of other countries showed that in the present state of mind of the people notification was ineffective. It led to greater concealment of disease and tended to drive sufferers to quack treatment. He thought there could be little doubt that notification would help towards suppression of disease, but it was necessary to wait until people had become educated in the matter, the demand for notification and international action might then come from the great mass of the population of this and other countries.

Mr. Arthur J. Evans, honorary surgeon to the Stanley Hospital, Liverpool, was of opinion that if better facilities for treating venereal diseases could be provided at the general hospitals the spread of the infection would be reduced. The establishment of such a clinic to a hospital should, he thought, be financed and controlled by the State and not by the committee representative of the charitable public.

Poor Law Patients.

Mr. Evans stated that in his capacity as visiting surgeon to the Brownlow Hill Poor Law Infirmary, a very large number of venereal cases were brought to his notice. He thought that in Poor Law patients the general percentage of the later manifestations was very high. In the male sex this was exceedingly striking, and in a larger number of cases permanent incapability of earning a livelihood was produced; many also were beyond any hope of benefit even by modern treatment. A great difficulty in regard to Poor Law patients arose from the fact that there was no law to compel these patients to remain till properly cured; patients frequently left the hospital while still in an infectious state.

Importation.

As medical adviser to an important shipping company, Mr. Evans said that it was his experience that a great deal of venereal disease was introduced from abroad, and it was his opinion that this continuous introduction of disease into this country should undoubtedly be brought under control. He recommended that the Board of Trade should take steps to warn and explain to seamen and others the dangers of contracting venereal disease and the danger of infecting others of the community. The importation of disease would, he thought, be greatly lessened if sailors were aware of the risks encountered in foreign ports and especially in the tropics.

IMPERIAL CANCER RESEARCH FUND.

THE annual meeting of the General Committee of the Imperial Cancer Research Fund was held at the Examination Hall, Queen Square, Bloomsbury, on July 21st, the DUKE OF BEDFORD, K.G., President, in the chair. Among those present were Sir R. Douglas Powell, Sir Thomas Barlow, Sir Rickman J. Godlee, Sir William Church, Sir W. Watson Cheyne, Sir John Tweedy, and Professor Sims Woodhead.

REPORT OF EXECUTIVE COMMITTEE.

In the report it was stated that the committee had had under consideration a proposal that a notice should be issued to the medical profession and the general public, calling attention to the importance of the early recognition of the symptoms of cancer. In this connexion much information was collected relating to the practice adopted in France, Germany, the United States, and other countries, but after mature deliberation it was decided that it was not desirable at the present time to issue any general pronouncement. The committee had been glad to accept an offer from the Radium Institute, through Sir Frederick Treves, to supply radium emanation for researches. Further investigation would therefore be carried out during the ensuing year.

REPORT OF GENERAL SUPERINTENDENT OF RESEARCH.

Dr. BASHFORD stated that during the past year fewer claims to the possession of a cure for cancer had been brought to the notice of the fund. In no instance was the information of a kind to necessitate further inquiry. None of the alleged remedies were new, all having been brought to notice in one form or another in earlier years.

The Two Categories of Transplanted Tumours.

During the year it had been stated by a distinguished German investigator that transplanted tumours in mice might be made to disappear by an injection of thiosinamin, and it was deemed desirable to repeat the experiments. It was found, however, that thiosinamin had no power of arresting the growth of the mouse tumours on which it was tested in the laboratory. The source of error appeared to be insufficient knowledge of the biology of tumour cells. As the result of the work carried out in the laboratory, it was becoming more and more generally recognized that transplanted tumours fell into two main categories—namely, a very small group which grew progressively because they did not produce resistance to their own growth, and a large group in which the tumours tended to disappear spontaneously in varying proportions because of the resistance to their growth, which was induced in the body as a result of their presence; indeed, in extreme cases every animal, as it were, cured itself. The claims to cure cancer in mice had without exception been made by investigators who had not recognized the latter fact with regard to the propagation of tumours, and who had been dealing with the latter class of tumours not supplied from the laboratory of the fund. The Imperial Cancer Research Laboratories had distributed widely a tumour-strain of the former class which grew progressively in all animals and produced metastases, and these were the tumours which ought to be employed for the purposes of therapeutic experiments; up to date no successful results had been obtained with them. It seemed well to emphasize these facts because most, if not all, the transplantable tumours in the possession of other investigators did not fully reproduce the natural features of cancer, and a large number of proprietary preparations, many of them metallic and possibly dangerous, were now on the market as cures for cancer, on the basis of these unreliable laboratory experiments. It appeared from correspondence that these preparations were being extensively tried on man, and that patients or their friends were urging their medical attendants to employ them, not only in cases which had passed beyond the aid of surgery, but even as an alternative to surgical removal. Up to the present time, even in the laboratory, the only way in which rabbits, guinea-pigs, rats, and mice could be freed with certainty from transplanted and often spontaneous tumours was by early surgical removal.

Abderhalden's Serum Test.

Owing to the urgent necessity for the early diagnosis of cancer, if tumours were to be successfully treated by surgery, many attempts had been made to obtain aids to diagnosis in suspicious cases. None of these had up to the present given constant or entirely specific results, and all were therefore unreliable. The latest method was that announced by Abderhalden. It was claimed that the serum of cancer patients had the power of breaking down or digesting tumour tissue in a test tube in a way that normal serum did not, and by a special technique a colour-reaction might be obtained which, if present, was held to be diagnostic of cancer. This reaction had been studied for many months in the laboratory, in the first place with the object of doing away with the admitted irregularities and imperfections in the method quite apart from any diagnostic value in the reaction. The technique had been improved, and it was now possible to avoid contradictory results. As regards the diagnostic value of the reaction the investigations were not quite complete, but it appeared expedient even now to sound a note of warning that too great reliance ought not to be placed on this reaction either in pregnancy or in the diagnosis of cancer.

Increase of Cancer in Certain Situations.

It was quite justifiable to make such a crude statement as that the number of deaths assigned to cancer had increased in 1911 for females to 1,038 per million living in 1911 as compared with 500 in 1860, and for males to 891 from 200 during the same period. It was also justifiable to express these facts in another way (also crudely), namely, that of women attaining the age of 35, 1 in 12 was recorded as dying of cancer in 1889, but 1 in 7.4 in 1911, and of men 1 in 21 in 1889, but 1 in 9.7 in 1911. The latter statement also brought out more clearly how the male rate had been overtaking and approximating to the female. But these figures ought not to be set out, as they still were, before the public without any qualification and interpreted forthwith as a demonstration of the reality of the increase of cancer. The increase in the number of deaths was not uniform for the different parts of the body, and for some parts, notably the uterus, an actual fall was persistently evident since 1902. For that organ diagnosis was relatively easy. Therefore, the number of cases treated probably approximated more closely than in other sites to the absolute number, and the effects of successful surgery were showing themselves in diminution of the

deaths. For other parts of the body the increase might be apparent, for others real, although it was as yet impossible to decide. All the statements widely circulated in the newspapers as to the increase of cancer as a whole should be ignored and attention only paid to those in which cancer affecting the different parts of the body are considered.

Heredity.

There were still no reliable data available as regards cancer in man. In mice hereditary predisposition had been shown to exist, sufficient to double the incidence of cancer in female mice in the ancestry of which cancer had occurred not further back than the grandmother, as compared with animals in which the cancerous ancestry was more remote.

Cancer Areas and Cancer Houses.

The question of cancer houses had been allowed to stand over till experiment and the improvement in the collection and tabulation of statistics had advanced to a point which made it possible to discuss the subject on the basis of positive knowledge. With the awakening of interest in the study of cancer in animals, the belief in cancer houses was naturally transferred to "cancer cages," largely on the basis of statements made by breeders. The extensive experience of the Royal Prussian Institute for Experimental Therapeutics agreed with the even larger experience of the Imperial Cancer Research Fund under laboratory conditions. Cancer cages, in the sense that animals housed in them became infected, were a myth. Contact with animals with natural or inoculated cancer did not increase the liability to the development of the disease.

A considerable part of the report was devoted to the discussion of the question of "cancer houses." It was stated that the determination whether cancer was more frequent in certain houses was very much more complex than the simple arithmetic of enumeration. All the details of the population, not only of the "cancer houses," but also of the other houses in the same neighbourhood, must be known as regards numbers living in each house, sex, age, nature, and site of the growth, duration of stay, occupation (environment and irritation), habits (alcohol, tobacco). Economic considerations must also be taken into account, since a house might be sought after by old people who had to content themselves with old or insanitary buildings because of the low rental, or a house might be let to couples without children, or be frequented by aged lodgers.

Five of the best known instances of cancer houses had been inquired into and the places visited. Inquiries had also been instituted into a sixth area which had also been visited. Full details as to population and deaths of these alleged cancer areas and houses would be published in due course. It appeared, however, that the facts elicited for these human populations accorded with the more exact data for a laboratory population of mice. There was no positive evidence of infection of any kind whatsoever. Aggregations of cases of cancer to have any significance at all must occur with a frequency which removed them from all possibility of being merely what would be expected owing to the great frequency of the disease. In the course of years it was quite natural that a number of cases should occur in a village, a street, a house, or even a family which had inhabited the same house for generations, without the numbers necessarily meaning anything more than what was to be expected according to the theory of probabilities. This criticism applied without exception to all statements as to cancer houses, cancer streets, and cancer villages, which had been adduced as evidence that cancer was infective, although this statement must not be understood as denying that cancer, or rather certain forms of it occurring on different parts of the body, may, and actually do, vary in different areas. So far as the investigations into "cancer houses" and "cancer areas" had proceeded, they accorded with what had been established by experiments on animals. "Cancer houses" were as much a myth as were "cancer cages."

Sir WILLIAM CHURCH, Chairman of the Executive Committee, moved the adoption of the report, and gave a concise account of its tenor. Professor WOODHEAD seconded the motion, which was carried.

REPORT OF HONORARY TREASURER.

Sir W. WATSON CHEYNE stated that, unlike last year, he was unable to report any increase in the total receipts for the researches. The total number who had subscribed to the fund during the year was 146, as compared with 137 in 1913, but whereas the number of small contributions had increased, those of higher amounts had somewhat declined. The total expenditure had exceeded the fixed income of the fund from investments by £1,444 18s. 9d.

LITERARY NOTES.

THE July number of *Science Progress* contains an editorial article on irrationalism which is said to be generally the enemy of humanity.

> It is a defect of the reason comparable to that defect of the vision which we call colour blindness; but while colour blindness is admitted by those who suffer from it, because it does not affect their reasoning powers (as, for example, in the distinguished case of Dalton), those who suffer from reason-blindness are unable, from the very deformity which afflicts them, to recognize their deficiency. They therefore pursue their fad at all costs, whatever mischief they may inflict by their efforts upon humanity or upon individuals. And we see innumerable examples of this in our present state of civilization—antivaccination, antivivisection, militant suffragism, anarchism, and nihilism are some of them. It is a difficult question to know what to do with these forms of semi-insanity. There is one way in which the press could help towards disarming them—simply by placing their propagandisms on the same level as personalities, indecencies, and libels, and by refusing to publish them. We think, however, that the time has come when a more organized campaign should be conducted against them by bringing certain forms of them within the action of well-considered laws.

Legislation, we fear, would only tend to aggravate the evil. Among the rest of the contents are papers on the terrestrial distribution of radium, by A. Holmes; on the cause of variation, by A. D. Wilde; on the awakening of pond life in the spring, by A. H. Drew; and on coloured thinking and allied conditions, by Professor D. Fraser Harris.

The *Undergraduate* is the title of the University of London magazine published by the Students' Representative Council. It is intended that it should be both a common medium of expression for all members of the university and at the same time the official organ of the council. Among the contents of the first number we would call special attention to a paper by Sir Sidney Lee on the importance of practice in literary composition. He lays down the axiom that no one writes well who has not read well, that no one writes good English who has not read good English with appreciation and intelligence. The magazine, besides reflecting undergraduate life in the results of examinations, in its academic and social aspects, and in its sports, contains articles on general subjects and discusses matters affecting the prosperity and future development of the university. We wish it success.

In a book entitled *Things I Remember*, by Frederick Townsend Martin (Eveleigh Nash, 1913) reference is made to Sir Oscar Clayton. He is described as a quaint-looking little man, a distinguished physician, and a great favourite with the late King, whose recovery from typhoid fever was always attributed to his skill! This is a remarkable specimen of history as it is written. The doctors who snatched the Prince of Wales, as he then was, from death were Jenner and Gull, who had the assistance of the late Dr. John Lowe. Mr. Martin goes on to say that Sir Oscar Clayton dearly loved a lord, a weakness, by the way, which Mr. Martin seems to share with him and with less excuse, for lords and ladies were the doctor's living, while the love of titles, though so common in Americans, is incongruous in a Republican. Mr. Martin once heard Clayton say with tremendous pride, "I've been in luck to-day; I've met no less than seven duchesses." Some curious stories used to be told about Oscar Clayton's reverence for royalty. Mr. Martin, however, bears witness that he was a kindly man, and on one occasion, when he complimented him upon his wonderful success in his profession, he replied with a smile:

> Ah, Mr. Martin, I should have been far more successful if I had been able to write cheques instead of prescriptions for my patients. I have not reached the age of eighty-three without knowing that worry kills most people, and that want of money is often the root of bodily evil.

One thinks of Thackeray's physician who used to leave sovereigns surreptitiously on the mantelpiece with the instruction, "One to be taken p. r. n."

British Medical Journal.

SATURDAY, JULY 25TH, 1914.

THE INSURANCE ACT IN WORKING.

THE Second Report of the National Health Insurance Commissioners, of which an account, containing a reprint of the Commissioners' general review of medical benefit, appeared in the SUPPLEMENT of July 11th, is a document which will well repay detailed study.

It may be noticed in passing as an interesting sociological fact that the number of deposit contributors is surprisingly smaller than was anticipated, and that, although there have been 454,000 at various times, the effective number left paying contributions during the sixth quarter was only 194,994. From the low average age and the surprisingly low sickness rate they present, it would appear that they must consist to a great extent of relatively young workers, a large number of whom only expect to remain in insurance for a short period because they are likely to rise above the income level. It appears, therefore, that practically the whole of the working industrial population has been absorbed into the various approved societies. We are afraid that when the new arrears scheme comes into operation it will be found that the number of those who may have to be penalized will be materially larger than would have been the case had the original anticipation of the number of deposit contributors been realized.

The sickness rate, as we anticipated would be the case, has proved to be generally in excess of the actuarial estimates, particularly amongst women; especially is this the case in sickness associated with pregnancy. Apart from these considerations the sickness rates vary materially in different societies and in different localities. The actuarial anticipations were based mainly upon statistics of the Manchester Unity, and represented its average with an additional 25 per cent. "loaded" on for the extra risks. But the insured persons are not all members of one great society; they are grouped to a great extent locally, and by trades in a large number of different societies, so that the rate of sickness, for example, amongst chemical workers and miners is not averaged down by a low rate of sickness prevailing amongst agricultural labourers. This segregation of workers accounts to some extent for the variations shown by different societies. The character of the work in which the people are engaged accounts in another way for some of the diversities. What would be considered incapacity in a miner or in a railway worker where heavy labour is required would not be considered incapacity in a clerk or in some other kinds of indoor work. There is evidently also a considerable degree of looseness in the administration of some societies as compared with others. Some of the excessive sickness is attributed by the actuaries to laxity in medical certification, it is stated that "there is no doubt that great improvement in certification is both necessary and practicable." We commented on this statement recently and are certainly not disposed to accept findings of this kind without material proof, though some of the evidence before the Schuster Committee is said to indicate that in some districts careful inquiry may be called for. The profession has always recognized it to be both its duty and its interest that scrupulous care should be taken in the granting of certificates, and we have nothing to fear from any proper inquiry that may be undertaken to discover and rectify any irregularities that may have occurred. The experience of Bristol seems to show that the services of referees will go a long way to abate unnecessary and ill-founded claims, but the report confirms the opinion, which the Chancellor of the Exchequer appeared to accept in his Budget speech, that, beyond this, it will be necessary to make separate arrangements for the sickness associated with pregnancy in married women, and possibly generally to alter the apportionment of the contributions of women between the societies and the sinking fund, so as to provide a greater margin for sickness benefit amongst women generally.

The report contains some very important statements with reference to medical benefit, and in some of them the profession may justly take pride. The Commissioners say that the working of medical benefit has already revealed, more clearly than had previously been possible, the loss which the country has suffered through the past inability of large sections of the community to obtain adequate treatment of the diseases from which they suffered. They describe the arrangements as a machine which needs to be "not only far-reaching and comprehensive, but elastic and adaptable; not only complex, by reason of the many intricate personal relations involved, but also swift in action and responsive to the sudden emergencies of disease," and they are of opinion that up to the present the system has provided a scheme for treatment by general practitioners for cases suited to home treatment, as well as a foundation on which extended provision can suitably be based. As regards the standard of the treatment given, they state that an enormous number of men and women are now receiving treatment for their ailments who previously were accustomed to go without, and that insured persons "have been enjoying at the hands of the more conscientious and competent doctors a service of the standard of that accorded to remunerative patients of the well-to-do classes." There is nothing new to us in this, as it has been a tradition and a pride of our profession for generations, but it must be a source of satisfaction to find that the Commissioners report that "definite tendencies are in operation, originating with the medical profession themselves and fostered by the responsible authorities, to raise the standard of the whole of the industrial practice of the country." We have said many times and are fully assured that it would always be found that the medical profession was ready and willing to co-operate in any well-thought-out scheme for raising the standard of professional work, and the Commissioners' statement only emphasizes the importance of the fact that the new services now under consideration should be so modelled and directed as to enlist its hearty support and co-operation.

It would appear that the system of green and yellow vouchers for temporary residents and travellers has gradually become understood by insured persons generally and is being more freely used, although progress is slow. On the whole, it is probably true to say that the return of 800,000 medical cards out of the 10½ million medical cards dispatched was less than might have been expected, considering the enormous number of removals which take place among the industrial classes. London is behind-

hand in regard to medical cards, and in regard to the allotment of medical funds, as well as in regard to the arrangements for sanatorium benefit; the London County Council, too, in the matter of sanatorium benefit, is clearly not worthy of imitation. It is sincerely to be hoped that in the new London Insurance Committee, which meets during the course of the present month, we shall have a body which will be more concerned in the efficient administration of the Act.

The percentage of insured persons who have placed themselves upon the panel lists is surprising. The report states that by the end of 1913, 96 per cent. of the insured persons in England had entered their names on the medical lists. Even in London, where there are greater difficulties to contend with, the percentage is as high as 90. We are all interested to discover the reasons which have operated in the case of the 10 per cent., or so, of the insured who have not placed their names on medical lists, and the investigation into this question, which is recorded in the report provides some very interesting and striking results. It appears from the inquiry made in one of the home counties that nearly 70 per cent. of those returned as not having had their names put on a doctor's list had either actually put their names on some list, though they had not been returned owing to some misapprehension or clerical error, or that they had left the district or the country or had ceased to be insurable. In the case of another 24 per cent. they had either neglected to do anything at all or were ignorant of the procedure. Of the remainder, 0.6 per cent. had paid privately for treatment, and 3.8 per cent. preferred a private medical man who was not on the panel, and it is reported that these two classes together comprised 1.97 per cent. of the total insured population of the area.

Some evidence is given of the migrations of medical practitioners into industrial areas; they relate, however, chiefly to London boroughs, and after all only indicate a very small number of additions to the medical men in those districts.

A tribute is paid to the Insurance Committees, and, in view of the great difficulties which have confronted those Committees and the enormous amount of work they have had to undertake throughout the whole country of an entirely novel character, the tribute is, on the whole, well deserved. The report says that "Insurance Committees have successfully discharged many onerous duties of administration and negotiation, and their enthusiasm and interest in the problems with which they have to deal is uncommon in the history of similar local bodies."

NERVE CELLS IN THE AORTA AND ANGINA PECTORIS.

In a histological study of the innervation of the ascending and transverse parts of the aortic arch in dogs, Manoélian was struck with the existence of numerous nervous centres in the posterior cardiac plexus.[1] This plexus, situated in front of the trachea and behind the aorta, is composed of a rich anastomosis of nerve filaments, and here were found ganglia composed of cells of the sympathetic type. For the most part these were microscopic, but sometimes it was possible to detect them with the naked eye in silver-impregnated sections. Their number was found to vary, and in addition it was not uncommon to find in the interstitial tissue of the plexus solitary nerve cells. Seeing that the posterior cardiac plexus is formed by the majority of the sympathetic cardiac nerves and the cardiac nerves of the vagus, and that the cardiac plexus itself plays such an important part in the innervation of the heart and large vessels, the existence of these nerve cells would appear to be a very important observation. More remarkable still, Manoélian found solitary nerve cells of the sympathetic type in the connective tissue of the middle coat of the aorta. Nerve fibres, of varying thicknesses and more or less wavy, ran from the connective tissue towards the elastic fibres and the smooth muscle cells where they terminated, either in a rounded knob-like swelling or in a finely-drawn-out end. Close to the smooth muscle cells there were arborizations similar to the motor plates of striated muscle. The connective tissue of the middle coat was found to be richly innervated, and apart from the fibres to the elastic tissue and the muscle cells a large number of these nerve fibres were found to end in this situation. The way in which these fibres terminated varied. Some had a club-shaped extremity, and these clubs might be grouped together in numbers; others had a knob-like ending, whilst others again became resolved into fine fibrillae, which formed a delicate skein. Since all these nerve fibres were not in connexion with motor elements but terminated in the connective tissue, Manoélian considered that they were sensory in nature. Sensory terminations have never before been observed in the middle coat, but they must play an important part in the mechanism of dilatation and constriction of the arteries. It would appear that the stimulus is carried by the sensory vascular fibres to their cells, which by their central prolongation send it directly or indirectly to the vasomotor neurones, the peripheral prolongation of which receives the stimulus to the arterial muscle cells, and that, in short, we have to deal with a reflex arc beginning with the sensory arborization and ending with the motor nerve termination.

The idea formerly held that angina pectoris was due to lesions of the coronary vessels has not been supported by pathological observation, for no lesion of the coronaries has been found at autopsy in cases of angina pectoris, whereas stenosis and even obliteration of the cardiac arteries have been observed in cases in which during life there had never been any attacks of angina. Further, it is a matter of experimental observation that ligature of a branch of a coronary artery is followed by cessation of contraction in that part of the heart supplied by it; after ligature of the two coronary arteries the heart ceases to beat. Nothnagel, in studying the relation between angina pectoris and peripheral vascular spasm accompanied by hypertension, distinguished a vasomotor type of angina pectoris. Vaquez and others have shown that the blood pressure, even if it is normal or diminished during the intervals, rises very considerably during an attack. The increase of arterial tension is attended by hypertrophy of the left ventricle and dilatation of the commencement of the aorta, but even before the production of this definite lesion a transitory distension may be inferred from the accentuation during acute rises of tension of the second aortic sound, which becomes normal again as the tension falls.

The point to bear in mind is that it is not only the heart but also the aorta that bears the brunt of increased arterial tension. Vaquez concluded that any accidental increase of pressure, distending an already diseased aorta, would bring about anginal attacks. This theory is strongly supported by Manoélian's discovery of numerous

[1] *Annales de l'Institut Pasteur*, June, 1914.

sensory nerve terminations and nerve cells in the middle coat of the aorta, as well as the large number of nerve centres externally in the posterior cardiac plexus, all the more so as aortitis and periaortitis are almost constant phenomena in cases of angina pectoris.

OPINION OF THE PROFESSION ON THE BUDGET PROPOSALS.

THOSE who have followed the discussion of the Budget proposals, and have read the report (SUPPLEMENT of June 13th), issued on the authority of the Council by the Future Developments of the Insurance Acts Committee, appointed by the Council last October in accordance with the instructions of the Annual Representative Meeting last year, will see with interest the analysis of the replies of the Divisions in the SUPPLEMENT for this week.

The Committee, in its report, expressed the opinion that to place arrangements which are mainly clinical under the care of an authority whose work is mainly concerned with sanitation, and whose medical adviser, the medical officer of health, tends by the steady imposition on him of more and more administrative duties to be forced out of actual personal participation in clinical work, would be a mistake. Such a course, the Committee considered, would tend to overburden an officer already fully occupied, and would not be likely to give the new clinical proposals a proper opportunity of developing on satisfactory lines.

It will be seen that not a single Division is in favour of control by the public health authority, and that many of them state with great emphasis the opinion that it would be unwise to place clinical arrangements in the hands of that authority. With regard to the authority by which the new systems should be administered, a majority of the Divisions which have replied are in favour of establishing a joint committee of the Insurance Committee, the County Council, the local hospitals and Local Medical Committees, as was suggested by the Association's Committee in its report.

With regard to the proposed clinical laboratories, valuable suggestions are made by various Divisions, among others that local practitioners should be encouraged to attend the laboratories, and that great stress should be laid upon the personality of the head of the laboratory, who should be a well-qualified pathologist. Practically all the Divisions approve of the proposal that the laboratories should be linked up with universities and similar institutions, although difficulties in the way of establishing a connexion with a university in some districts are pointed out.

All the Divisions are in favour of the provision of a nursing service to be utilized for the whole working-class population, except two which consider that the work is already adequately done by charitable associations; all agree that such associations should be utilized. Several urge the necessity of State registration of nurses before the new service is instituted in order that a proper standard may be maintained; and others advise that the model rules of the Association as regards nursing associations should be incorporated in any rules for a nursing service. Some of the replies utter a warning note as to the need for safeguards lest nurses be used as independent practitioners, and several Divisions suggest that there should be a wage limit for persons entitled to use the nursing service.

A large majority of the Divisions which have replied to the questions as to referee-consultants express the opinion that they should be appointed by the Commissioners, that they should be whole-time officers, and that they should advise the proposed joint committee, or failing that the Insurance Committee, on medical questions. The majority appear to agree also that in ordinary circumstances a specialist should be called in by the referee after consultation with the practitioner in attendance, but that arrangements should be made entitling the practitioner in an emergency to call in a consultant, and afterwards to report to the referee. There is almost complete unanimity that these consultants should not be whole-time officers; the majority would seem to be in favour of requiring the attending practitioner to furnish a report of the case to the referee, while one Division suggests that a practitioner should be required either to furnish a report or to attend the consultation. There is unanimity in answering in the affirmative the question whether an approved society desiring the services of a referee should be required to make a full report as to its reasons.

With regard to treatment centres or clinics, the majority of Divisions which have expressed an opinion are in favour of the recommendation that such centres should be provided for cases the treatment of which cannot be properly carried out at the surgery of a practitioner, and that they should be used as consultation centres at which the referee could examine cases sent to him, and at which the consultant or specialist could examine and treat suitable cases. On the other hand, a number of Divisions disagree with the plan outlined, and point out various difficulties and make certain suggestions, especially with regard to country districts.

The report and the analysis of the replies of Divisions will come before the Representative Body during its meeting in Aberdeen, and it is hoped that the practical unanimity of the Divisions will enable the meeting to give instructions to the Council at once to press on the Government the opinion of the medical profession, as expressed through the local organization of the Association throughout Great Britain, on these important and urgent matters.

A GUIDE TO ABERDEEN.

WE are indebted to the kindness of Mr. Scott Riddell for the opportunity of studying the *Handbook and Guide to Aberdeen*[1] which he has compiled at the request of the Local Executive Committee for the use of members attending the Annual Meeting. It is a compact and businesslike volume, and the only regret that it rouses is that it should not, equally early, have been in the hands of every member going to Aberdeen, that he might become the better acquainted beforehand with the ancient and modern interests of the granite city, and learn the general disposition of its streets and institutions from the very excellent detailed map the volume contains. Mr. Scott Riddell has done us the compliment to reprint three illustrated articles published in the BRITISH MEDICAL JOURNAL some months ago on the city of Aberdeen, on the history of the city, and on the University. These are followed by chapters on the Royal Infirmary by Mr. J. Wallace Milne, senior assistant surgeon to the infirmary; on the Royal Hospital for Sick Children, opened in 1877 and since greatly enlarged both on the site and by the acquisition of convalescent homes in the country, by Mr. H. M. W. Gray; on the City Hospital for Infectious Diseases, by Professor Matthew Hay; on the Maternity Hospital, established in new buildings in 1900, by Emeritus Professor W. Stephenson;

[1] British Medical Association, Aberdeen, 1914. *Handbook and Guide to Aberdeen.* Compiled for the Local Executive Committee by J. Scott Riddell, M.V.O., M.A., M.B., C.M., Senior Surgeon, Aberdeen Royal Infirmary. Cheltenham: E. J. Burrow and Co. 1914. (Cr. 8vo, pp. 162; 3 plans and numerous illustrations.)

on the Aberdeen Dispensary, by Dr. Middleton Connon; on the Eye Institution, founded by Sir James McGrigor, Director-General of the Army Medical Department, in 1835, where students have ever since been trained in ophthalmology, by Mr. A. Rudolf Galloway; on the Morningfield Hospital for Incurables, by Dr. G. M. Edmond; on the Royal Asylum, Aberdeen, and the Kingseat Mental Hospital, by Drs. William Reid and H. de M. Alexander, their medical superintendents; on the Newhills Convalescent Home, by Mr. Walter A. Reid, Chairman of Directors; on the Nordrach-on-Dee Sanatorium, Banchory, by Dr. Geoffrey Lucas; and on Duff House, Banff, by Dr. E. I. Spriggs. After notes on the nursing homes in Aberdeen there follows an interesting summary of the rise and growth of the educational institutions of Aberdeen by Mr. George Smith, LL.D., Director of Studies; it is concerned chiefly with the Grammar School whose history goes back many centuries; with Robert Gordon's Technical College dating from 1732 and opened in 1750, with the training centre for elementary school teachers and with the work of the School Board. Then come four other special articles: the first on Aberdeen doctors, by which title is to be understood eminent physicians or surgeons educated at Aberdeen, by Professor John Marnoch; the second on the Aberdeen Medico-Chirurgical Society, founded and long maintained by students, by Dr. J. R. Levack, President of the Society; the third on Aberdeen artists, recalling the achievements of Jamesone, who made a portrait of Charles I when he went to Edinburgh to be crowned in 1633, of Dyce the pre-Raphaelite, and of "Philip of Spain," by Dr. W. R. Pirie; and the fourth on Aberdeen and the Medical Services, by Dr. David Rorie. The volume concludes with extracts from the publisher's guide to Aberdeen giving a topographical account of the city, and a list of cycle and motor excursions, illustrated by a bird's-eye view and a map. There are many illustrations from photographs and the frontispiece is a very characteristic portrait of Sir Alexander Ogston.

THE SCHOOL OF TROPICAL MEDICINE, CALCUTTA.

IN February last, as recorded in an illustrated article in the JOURNAL of March 7th, the foundation stone of the new laboratories of the Calcutta School of Tropical Medicine was laid by Lord Carmichael, the Governor of Bengal, and messages of sympathy and approval were read from the Viceroy and high officials of the Government of India. Within a few weeks a sensational article was published in a Calcutta paper to the effect that the Governments concerned were unwilling to provide the whole-time staff asked for by Lieutenant-Colonel (now Sir Leonard) Rogers, who has been so closely identified with the whole scheme, and that the resignation of that officer was feared. The Bengal Government promptly contradicted this report. It issued a statement to the effect that there was no truth in the rumours regarding Colonel Rogers's resignation, nor was there any difference of opinion between him and the Government of Bengal regarding the employment of Indian Medical Service officers in the Tropical School; that the question of the necessary staff was under consideration; that Colonel Rogers was being fully consulted in the matter; and that the probable delay in opening the school was due to considerable difficulties which had to be overcome in obtaining a fair foundation for the new building. We are now glad to learn that the Bengal Government has submitted to the Government of India proposals for supplying a distinguished whole-time staff for the school. When these proposals have been accepted by the Government of India only financial questions will remain, which, it is hoped, will be settled without much difficulty. Moreover, the Government of India has already addressed a letter to all the local Governments, setting out the courses of instruction in the school, and stating that it will be opened very soon after the new buildings are completed. The difficulties with the foundations have been overcome; two out of the three stories have already been constructed, and the arrangements for supplying the fittings and apparatus are far advanced. What really prevented the opening of the school in October next, as originally contemplated, was the necessity of preparing entirely new plans and estimates as late as November last, owing to a portion of the site which the former plans were designed to cover having been required by the Improvement Trust for the new central road of Calcutta. This left only nine months for building and equipping the school, while the foundation difficulties reduced still further even this short period. It is now expected that the school will be ready to be opened for a three months course for assistant surgeons on June 15th, 1915, and be in full working order for the six months' post-graduate course for the diploma in tropical medicine commencing on October 15th, 1915. The Government of Bengal has also acquired a site continuous with that of the new laboratories for the special hospital for tropical diseases, which will enable the research work to be organized on the lines of the very successful Rockefeller Institute of New York, and much of the money for building the hospital has already been obtained in response to the appeal issued by Sir Leonard Rogers last February. Considerable annual contributions for the endowment of research work have also been promised. All that is now required to ensure the success of this great scheme is the sanction of the Government for the staff asked for, and a substantial annual grant from Imperial revenues towards the cost of upkeep. Such a grant is fully justified by the fact that the whole of India, far beyond Bengal, will be benefited both by the teaching and researches of the new institution. In view of the encouraging messages of the Viceroy, and Sir Harcourt Butler, the Member for Education on the Governor-General's council, and the sympathetic speech of Sir Pardey Lukis at the foundation stone ceremony, this essential and crowning help may reasonably be expected from the Government of India. It was indeed with that Government that the proposal "to establish a fully equipped school of tropical medicine in Calcutta, with a special staff of its own," originated in 1910.

THE TOMB OF AVICENNA.

SIR WILLIAM OSLER has recently suggested that the tomb of Avicenna should be restored. An account of a pilgrimage to the last resting place of that famous philosopher and physician at Hamadan is therefore especially opportune. It is contained in the July number of the *St. Bartholomew's Hospital Journal*. The pilgrim was Dr. A. R. Neligan, physician to H.B.M.'s Legation, Teheran. Abu Ali al Hussein ibn Abdullah abu Sina, to give the old Arab physician his full name, was born near Bokhara in 980 A.D. At 16, after studying mathematics, philosophy, metaphysics, and medicine, he was already practising as a doctor. At 17 he was appointed physician to the Amir of Bokhara. This post gave him access to the celebrated library of Bokhara, and thus enabled him to pursue his studies. After travelling in north-eastern Persia he settled at Hamadan, where he spent the rest of his life. He became physician to the ruling prince, Shams-ed-Dowleh. But, says Dr. Neligan, like many a Persian doctor of the present day, Avicenna took to politics and became a Minister. The sea of Persian politics has always been particularly stormy, and therefore it is not surprising that Avicenna was often in peril of his life, and was at one time thrown into prison. After a time he made his escape from Hamadan and took refuge in Isfahan, where the governor welcomed him and made him his physician. In that capacity he made several campaigns, and in the course of one of these, which was directed against Hamadan, he was attacked by colic, and thus it came to pass that he died in the town from which

he had fled, and was buried there. Wherever Avicenna was and in whatever circumstances he found himself he was an indefatigable writer. His varied adventures did not prevent his going on with his great treatise, the *Kanun*, or Canon of Medicine. In that work, which was divided into five books, Avicenna collected all that was best in the medical knowledge of his time. It was the textbook at the universities of Louvain and Montpellier up to the middle of the seventeenth century, and it is read in Persia, Arabia, and India at the present day. It was taught in the royal university at Teheran as recently as twenty years ago. It was translated into Hebrew and Latin, and the Latin version went through thirty editions. Avicenna is said to have written in all more than 100 books, most of them dealing with medicine, but others with logic, philosophy, music, natural history, astronomy, and physics. His grave, says Dr. Neligan, is in a simple brick building near the steep banks of the river which flows through Hamadan. A little mausoleum of fire-burnt bricks with a mud dome stands at one end of a small compound, surrounded by a low stone and mud wall. The building is square, but inside there are small arches at each corner, which give it the appearance of being eight-sided. The internal measurements are as follows: Floor, 15 ft. by 15 ft.; apex of dome from floor, 16 ft. The floor is paved with large square bricks. Immediately opposite the doorway is the tombstone, 49 in. long, 21 in. wide, and 24 in. high. The inscription is carved in large bold characters. It begins with the usual invocation "To Him who is and does not die"; this is followed by a verse from the Koran reciting the virtues of the Almighty. Then come lines of verse, in the translation of which, as well as of the verses that follow, Dr. Neligan acknowledges the help of his friend Moin-ul-Vazareh: "Worthy testimony upon earth of the omnipotence and wisdom of God, Abu Ali Sina sprang from non-existence into being in the year 373. He had mastered the sum total of knowledge in 391; in 427 he bade farewell to this transitory world." Then comes the usual conclusion to epitaphs on the graves of Mohammedan sages or celebrated men: "The death of Sheikh Abu Ali Sina, may his tomb be surrounded by light! 427."

SCIENCE AND THE STATE.

SIR RONALD ROSS has in a very spirited manner taken up the cudgels on behalf of men of science who, by their discoveries, have conferred great benefits on the State, but receive from it no reward for their life's work and the pecuniary sacrifices entailed upon them. Taking his own case as an example, he has presented a petition asking for compensation for loss in his profession incurred through his long-continued investigations on malaria. His object clearly is to revive a precedent which has fallen into desuetude, under which early in the last century Parliament voted grants of money to men of science. Last week Mr. Cowan addressed a question on the subject to the Chancellor of the Exchequer, who replied that the the petition was not in accordance with modern usage. On the following day the same member asked the Prime Minister whether there was any fund in existence out of which men of science might be compensated for losses incurred by them in doing unremunerative scientific work, but which proved of advantage to the Government and the community, and if not, whether he would consider the advisability of providing funds for meeting such cases in the future. The answer the Prime Minister returned was, in fact, in the negative, although the point was somewhat confused by his reference to civil list pensions. Nine such pensions, he said, were awarded last year for scientific work, two to scientists themselves, and seven to their widows or daughters. In reply to a further question, he denied that such civil list pensions were of the nature of charity, and asserted that they were rewards for services rendered by deceased persons who left their families in necessitous circumstances. The reply has drawn a strong protest from Sir Ronald Ross, who, in a letter to the *Morning Post*, says that "the wretched Civil List pensions are frequently allotted to those who have conferred great benefits on the nation, or to their widows who have been left nearly destitute by the self-sacrificing labours of their husbands. How should we describe these pensions, then? They place the British Empire in the position of a manufacturer who has attained enormous wealth by the inventions of some of his workmen, but who is not noble enough to give them or their widows more than the most wretched subsistence money in return. I venture to maintain that all these pensions are a disgrace both to the intelligence and the morality of the country." The matter, we understand, is not to be allowed to rest where it is, but will be again brought to the notice of Parliament. Meanwhile the British Science Guild has appointed a Special Committee, consisting of the President, the Right Hon. Sir William Mather, Sir Norman Lockyer (Chairman), Lieutenant-Colonel Sir Charles Bedford, Hon. Sir John Cockburn, Professor Meldola, Major O'Meara, Sir Boverton Redwood, Major Sir Ronald Ross, and Professor Silvanus P. Thompson, to consider and report upon various matters arising in connexion with science and the State and the encouragement of discovery referred to in an address delivered by Sir Ronald Ross at the annual meeting of the Guild, at the Mansion House, on May 22nd last.

MR. H. P. SYMONDS AND THE RADCLIFFE INFIRMARY.

ON the evening of July 16th a dinner was given at Christ Church by the committee and medical staff of the Radcliffe Infirmary, Oxford, to the senior surgeon, Mr. H. P Symonds, on the occasion of the presentation to the Infirmary of a portrait sketch by Mr. John Sargent, R.A. Among those present in addition to the medical staff were the Mayor of the city, the President of Magdalen, Mr. Gamlin, the treasurer of the Infirmary, the secretary (Captain Rynd), and in addition a number of old house-physicians and house-surgeons, of whom the senior was Mr. Wingfield, to whom Mr. Symonds was originally apprenticed. Sir William Osler, in presenting the portrait, remarked that Mr. Horatio Symonds was the seventh surgeon in direct succession from Richard Symonds, who practised at Atherstone in Warwick in the early part of the seventeenth century. His son Joshua was a surgeon at Shrewsbury, the third, John, practised at the same place, the fourth, also a John, at Kidderminster. His son John practised at Oxford and was the father of Frederic, for many years surgeon to the Radcliffe Infirmary, whose son Horatio succeeded him. For three centuries members of the Symonds family had served the public of that part of England in the capacity of surgeons. A son of the first John who settled in Oxford, John Addington, who practised at Bristol for many years in the middle of the last century, became one of the most distinguished physicians of his generation. His son, of the same name, became the interpreter of the Italian Renaissance to the last generation, and his daughter, Mrs. Green, a member of the committee, was one of the warmest friends the Infirmary had ever had. Horatio Symonds studied at University College, London, and, after qualifying in 1874, settled in practice with his father, and soon became a leading surgeon in the Oxford district. He was elected on the staff of the Infirmary in 1878, and was largely instrumental in introducing the new methods of Listerian practice. It is well known that it was through his influence that the late Mr. Briscoe left the Infirmary the large sum of nearly £65,000, which has made possible the recent additions. Sir William Osler then read an exceedingly gracious letter from Mr. Sargent, to whom the company voted their hearty thanks for the splendid representation of the well known features of their old and valued friend.

THE FALLOPIAN TUBES AND STERILIZATION.

In order to prevent the recurrence of gestation in a subject whose life has already been imperilled by pregnancy or parturition, the most logical procedure would seem to be ligature of both Fallopian tubes; but now that Caesarean section is frequently performed and operations for ectopic gestation are yet more often undertaken, experience has proved that whatever may be the best way to ensure sterility, ligature, section, and even cauterization of the Fallopian tubes, are all untrustworthy. Pregnancy after double ovariotomy has been recorded by Meredith, Doran, and others within the present century, and several authentic records have been published of women becoming pregnant after the old—that is, Lawson Tait's—operation for the removal of diseased appendages. These cases prove that the stumps of the Fallopian tubes and the relics of ovarian tissue on the ovarian ligaments may function perfectly, allowing of impregnation and transference of the ovum to the uterus. In the case of the old, very incomplete "salpingo-oöphorectomy," a considerable piece of the ovary itself was often left behind. An ovum has been known to become implanted on a tubal stump, and in one such case reported by Vineberg the condition was betrayed by intestinal haemorrhages. Recurrence is so frequent in the opposite tube that when a tubal gestation sac is removed some surgeons consider that it is safer to amputate that tube, while in Caesarean sections on rachitic dwarfs and other subjects to whom pregnancy must involve permanent danger, sterilizing procedures have been repeatedly applied to both tubes. The results have not been satisfactory, and an instructive summary of the subject[1] has recently been published by Dr. V. N. Leonard, of the gynaecological clinic of the Johns Hopkins Hospital, Baltimore. Kossmann, in 1875, showed by experiments on hens that ligature of the oviduct did not prevent gestation. Zweifel and Thomas tied both tubes with stout silk ligatures during a Caesarean section, and Pissemsky, Stansbury-Sutton, and Fritsch adopted the practice, using silk, yet the patients all became pregnant again; and Kossmann himself, as well as Arendt, experienced similar failures after the use of catgut ligatures. Taylor performed Caesarean section on a rachitic dwarf and ligatured both tubes. The patient became pregnant and he repeated the operation, not omitting the securing of the tubes. Gestation occurred once more, and Martin of Birmingham did Caesarean section. He removed both tubes with a small portion of each corresponding cornu of the uterus. Dr. Leonard has traced 14 out of the 23 instances in the Johns Hopkins Hospital in which it was deemed advisable to attempt sterilization by ligature of the tubes; 5 out of the 14 were over 40 years of age at the time of operation. Out of the remaining 9, no less than 2 became pregnant after the operation. These cases are described by the author, but both were suspensory operations, not Caesarean sections. Kehrer introduced division of the tubes between two catgut ligatures placed about the isthmus. Abel adopted this practice in a second Caesarean section on the same patient, but three years later the patient again became pregnant, and at the operation both tubes were found to have become reunited and one was patent throughout its entire length. Braun-Fernwald and Bühl introduced resection of the tubes with burial of the uterine end in the broad ligament, the peritoneum over it being closed. On the occasion of a second laparotomy, Bühl found the uterine end of the tube opening freely into the abdominal cavity. Reifferscheid operated on a lady with markedly contracted pelvis; she had already undergone one Caesarean section, and consented to a second operation only on the condition that sterilization was ensured. Two centimetres of each Fallopian tube were resected between two non-absorbable ligatures, and the uterine stumps were buried and closed over carefully with peritoneum. Yet one year later the patient became pregnant once more. Bilateral salpingectomy, as above stated, is no guarantee against impregnation, nor is section by the cautery reliable. Kossmann and others have practised it, but Fränkel has shown that it cannot ensure complete atresia. Lastly, even resection of the interstitial portion of the Fallopian tube by removal of a wedge shaped piece of the uterine cornu has been known to fail. Küstner recently reported two instances of pregnancy after this method had been adopted; the operation was in each case not Caesarean section but ventrifixation. Polk removed a dermoid cyst of the right ovary, excising a wedge-shaped piece of the adjacent uterine cornu. Two months later the patient had characteristic symptoms of ruptured ectopic pregnancy; the ruptured sac, it was found, had developed not in the left tube but in the right cornu, of which so much had been excised only four months previously. The obliteration of the mucous channel is always hard, but there is an additional feature of interest in Polak's case, as there must have been transmigration of the ovum. Dr. Leonard considers that this last mentioned method seems, after all, that which affords the most reasonable assurance of preventing subsequent conception, but the evidence he brings forward shows that it is far from sure, and it would seem better surgery, in many cases, to amputate the uterus.

[1] The Difficulty of Producing Sterility by Operations on the Fallopian Tubes, *Amer. Journ. Obstet.*, March, 1913, p. 443.

THE NATURAL LIGHTING OF SCHOOLS.

Daylight seems to be the illuminant about which mankind knows least, at all events in terms of scientific precision. This fact is brought home again in connexion with the lighting of schoolrooms, where, as the school day usually ends at about 4 p.m., the proper admission of daylight is obviously far more important than the installation of artificial light. Yet what experts have to say on the subject of the natural lighting of schools is vague and inconclusive when compared with their recommendations on the subject of artificial lighting. When, last year, a report on the artificial lighting of schoolrooms was presented by a joint committee, representing the Illuminating Engineering Society, some educational bodies, and the Medical Officers of Schools Association, it was possible to set up an absolute standard or minimum of illumination. The same committee has since been grappling with the problem of natural lighting, and has found it extremely difficult to fix an equivalent standard, or at least to express it in simple terms. One of the troubles is due to the fact that accommodation plays a great part in daylight phenomena, whereas in artificial lighting, in which the factors are approximately constant, it is comparatively unimportant. At the annual meeting of the British Medical Association in 1911,[1] Mr. Bishop Harman suggested a standard of 9 foot-candles for daylight illumination in schools, but a whole set of physiological and even psychical factors have to be taken into account before any figure is accepted. On a dull day, for example, it has been found possible to work comfortably with 5 foot-candles, whereas on a bright day, in a shaded corner, 8 and even 15 foot-candles have seemed insufficient. At the same time, there is some ground for suggesting, tentatively, that the minimum daylight illumination for reading should be the same as in artificial lighting—namely, 2 foot-candles on the printed surface. This is one of several useful suggestions to be gathered from the interim report of the committee.[2] Perhaps the most simple and practical recommendation is that no place is fit for use in a schoolroom where diamond type cannot be read by a normal observer at a distance of 20 inches. More difficult to grasp, save by the experienced photometrist, is the requirement that the darkest desk should receive an illumination equivalent to that derived directly from

[1] British Medical Journal, November 4th, 1911, p. 1177.
[2] *Illuminating Engineer*, July, 1914.

50 reduced square degrees of visible sky; but the thing that seems most desirable to the layman in these matters is that some constant and, if possible, automatic means of registering the failing illumination on the darkest desk should be provided, so that when a minimum is reached—2-foot candles or otherwise—artificial light may be brought into use. The windows in the ideal schoolroom will be placed in the wall to the children's left, as right-hand lighting causes confusing shadows; in the absence of any structural reason to the contrary, the glass will be carried up to the ceiling, and no desk will be further from the window wall than twice the height of the top of the glass above the desk surface. The lighting expert is equally concerned for the blank wall as for the window spaces, and it is urged that the wall opposite the windows and the wall behind the children should be lightly coloured from 30 in. above the desk level, while the wall around the blackboards should be somewhat darker than the rest of the room. The ceiling, of course, should be white. The report urges, finally, several lines of investigation which require to be carried out on a scale beyond the resources at the command of the committee. The principal labour to which it points the way is the making of some tests to show the average daily variation of daylight. Data on a subject so important to the eyesight and the energies of the community seem to be curiously scanty.

ANOMALIES OF PIGMENTATION AMONGST NEGROES.

STANNUS[1] has recently described some very interesting anomalies of pigmentation amongst natives in Nyasaland, and has presented an interesting study of albinism in general. From the numerous photographs which are given, absence of pigmentation seems to be fairly common amongst natives in Nyasaland. The condition generally seen is local and limited, but may, however, take on a general characteristic, resulting in a pure white negro. Such cases are seen in other parts of the world; for example, they are not uncommon in the West Indies, all varieties of piebalds and spotted cases existing. It is not, of course, easy to determine whether a case is one of albinism or of leucoderma. Dr. Stannus believes that melanin, to which skin pigmentation is due, is not a direct (and probably not an indirect) product of haemoglobin but of the splitting of a complex lipoid substance, possibly as the result of a ferment action, akin to the formation of pigment from tyrosin by tyrosinase. The complex granules containing the lipoid substance are, he believes, produced as the result of the metabolic activity of the individual cells of the epiderm. Melanin in the cutis is probably derived from the epidermis; the explanation of its more or less complete absence in albinism is by no means easy. He considers Pearson's hypothesis a masterly summing up of the position, and that it is certainly warranted in the light of his own series of cases.

THE FUTURE OF THE LISTER INSTITUTE.

EARLY in the present year, at a meeting of the governing body of the Lister Institute, it was proposed by Lord Iveagh that the institute and all its resources should be offered to the nation as the head quarters of national medical research. The conditions to be attached to the offer were that the name of the institute should be retained, that the governing body should have the privilege of nominating representatives to serve on the National Medical Research Committee, and that suitable employment, or compensation, should be offered to the existing staff. Before this proposal was made it was ascertained that it had the unofficial but cordial support of Lord Moulton, Chairman of the Medical Research Committee, and of Dr. C. J. Martin, Director of the Lister Institute, to whom, we are informed, the inception of the proposal was largely due. About this time the Research Committee had purchased the Mount Vernon Hospital for purposes of clinical and pathological research, and this fact made it at first a little difficult to see how the proposed gift could be best utilized. The difficulty was, however, overcome by an offer from Lord Iveagh to build a hospital in place of the Mount Vernon, adjacent to the Lister Institute, in order that the institute should then become the national head quarters of both clinical and pathological research. We are informed that the Medical Research Committee at once intimated to the responsible Ministers that it approved of the proposed offer, and was informed in return that the Ministers were prepared to approve and endorse the arrangement, including the conditions attached to the offer to which the Committee had already given its cordial assent. On July 17th the governing body of the Lister Institute received the report of a subcommittee appointed to conduct negotiations on its behalf, and decided to recommend to the members that the proposed offer should be made. It will be remembered that, in response to a public appeal made by Lord Lister, a quarter of a million was given by Lord Iveagh to the institute. The amount expended on the buildings at Chelsea was £71,000. We are given to understand that the chief object of Lord Iveagh and his advisers in offering the Lister Institute to the Medical Research Committee as a central institute of research was to enable that committee to utilize the funds available under the Insurance Act for purposes of research throughout the kingdom under conditions which would not require too large a capital expenditure in London. The proposed gift was also intended by Lord Iveagh as a deliberate endorsement of the principle of assumption by the State of the burden of medical research, and as a mark of his confidence that the Research Committee appointed by the Government was fully competent to discharge its difficult functions. At the same time it was recognized that the suggestion of entrusting to Government control the destinies of an institute of research that had hitherto enjoyed, under wise governorship, a position of freedom and independence involved a grave responsibility, the assumption of which was certain to invite criticism. It was foreseen that the proposal would meet with well-grounded opposition if it were thought that the establishment of a central institute necessarily implied adherence to the obsession of centralization to the exclusion of the universities and other centres of learning in London and outside it. Those who are primarily responsible for the idea of offering the Lister Institute to the Medical Research Committee desire to avoid these dangers, and entertain the hope that all existing agencies for the prosecution of medical research can be utilized to the full if immediate provision were made of such ways and means as the State might not at once be able to provide. The originators of the idea, we are informed, are opposed to lending support to the domination of research by State officials merely because the cost of that research is to be borne by the State. They believe that a central station with radiating lines for reciprocal interchange of supplies and workers should be established and that in this way the activities of outlying centres will be given full scope. They believe that the Government authorities will be wise enough to bestow full independence of action on their delegates; they believe also that this object has been attained, and that a scheme may be evolved under which the universities and other centres of research will retain their independence, and that the Research Committee may be trusted not to sterilize research by discouraging voluntary enterprise, or by interfering with the teaching responsibilities of research workers.

THE Edinburgh University Court, at its meeting on July 20th, received and approved a proposal from the honorary secretaries of the Royal Victoria Hospital for Consumption for the foundation of a chair of tuberculosis.

Medical Notes in Parliament.

[FROM OUR LOBBY CORRESPONDENT.]

Prospects of the Session.

In the review of the prospects of the session which the Prime Minister gave on July 17th, in what is commonly known as the "Annual Massacre of the Innocents," it was gratifying to notice that few of the bills relating to national health are likely to be interfered with by the curtailment of the session.

The Elementary Education (Defective and Epileptic Children) Bill was read a third time at the conclusion of that day's sitting. The Criminal Justice Administration Bill passed through Report on Monday, July 20th. The Prime Minister anticipated that both the English and the Scottish Milk and Dairies Bills would be passed, and, as there are very few notices of motions for the Report stage, they are likely to be disposed of at an early date. Mr. Asquith expressed the hope that Mr. Runciman's Housing Bill, which we noticed in our issue of last week, would be passed before the end of the sssion. Some parts of this bill, however, are very controversial, and the prospects of the measure are not bright. The Prime Minister recognized this by placing it in a doubtful class of its own.

The Direct Representatives of the General Medical Council Bill is to be dropped. It is unfortunate that this simple measure, removing a standing difficulty in connexion with the election of members to serve on the Council, should have to be dropped. It was, however, likely to meet with considerable opposition, and there are some members who appear to entertain a strong antipathy for medical tribunals of all sorts, and without any particular reason other than this—they have expressed their intention of obstructing medical bills.

The Insurance Act (Amendment) Bill, Part 1, will be introduced in the next session, so as to enable any amended proposals relating to deposit contributors and other matters to be passed in time to give effect to them before the end of 1915. The nursing grants, it was announced, in answer to questions, would be dealt with on a supplementary estimate. We may take this to mean probably that it has been decided—for the present, at all events—that they should be administered through Insurance Committees. The county and county borough councils would need legislation to enable them to make use of the grants, except as agents, whilst Insurance Committees already have statutory power to provide nursing. No definite announcement was made, but a strong hope was expressed that if the nursing grants are to be administered through Insurance Committees some arrangement will be made to give dependants of insured persons the benefit of the service as far as possible.

Science and the State.—Mr. W. H. Cowan (East Aberdeen) asked the Chancellor of the Exchequer, on July 14th, whether he had received a petition from Sir Ronald Ross, K.C.B., F.R.S., asking for compensation for loss in his profession incurred through his long-continued investigations on malaria; whether the petition was based upon the precedents of similar petitions successfully submitted to the House by Dr. Edward Jenner in 1802 and again in 1807, and by George William Manby in 1823; and whether he would recommend Sir Ronald Ross's petition, as required by Standing Order 66, in order to enable it to be laid before the House. Mr. Lloyd George replied: I have seen the petition referred to, but have not felt justified in taking the course suggested, which is not in accordance with modern usage. On the following day Mr. Cowan asked the Prime Minister whether any existing fund was available out of which men of science might be compensated for losses incurred by them in doing unremunerative scientific work when such work had proved to be of advantage to His Majesty's Government and subjects: and whether, if no such fund were available, he would consider the advisability of providing funds for meeting such cases in the future. The Prime Minister said: I am not aware of any fund other than the Civil List. The conditions for the granting of Civil List pensions are laid down by Sections 5 and 6 of the Act 1 and 11 Vict., c. 2. I am not satisfied that further provision is necessary. I may add that nine pensions were awarded last year for scientific purposes—two to scientists themselves, seven to their widows or daughters. Mr. Cowan: May I ask whether it is not the case that Civil List pensions are in the nature of charity and not a reward for services? The Prime Minister: No, sir, I never regarded them as in the nature of charity. They are a reward for services rendered by deceased persons who have left their families in necessitous circumstances. Mr. J. Hogge: Can the right hon. gentleman state on what basis the Government gives grants for these scientific purposes, and will he explain, for example, why £10,000 is given to the Sir Edward Shackleton expedition before he makes any investigation, and will not give anything to Dr. (Sir David) Bruce? The Prime Minister: That does not arise out of the question. I personally investigate every one of these cases.

Housing Acts.—Sir Arthur Griffith-Boscawen asked the President of the Board of Agriculture on what principle it was decided to borrow £3,000,000 for building houses in agricultural districts; and whether he expected to build with this sum sufficient cottages to make good the shortage, which both he and the Chancellor of the Exchequer estimated at 125,000 last year.—Mr. Runciman replied that the estimate of £3,000,000 was necessarily conjectural, for it was impossible to foresee to what extent the building of cottages would be undertaken by authorized societies under the bill, and to what extent the Board itself would have to build. The answer to the last part of the question was in the negative: he had never estimated the shortage of cottages at 125,000, but hoped that the sum named in the bill would be sufficient to enable at any rate a substantial beginning to be made. In reply to Colonel Yate, Mr. Runciman said that a cottage let by the State at an economic rent would be let at such a rent as would be sufficient to pay interest on the capital expended and provide for other regular charges on the cottage. In those districts in which the wages of labourers were insufficient to enable them to pay an economic rent, the Government's land proposals would provide means for raising their remuneration to the level of a fair living wage.—Sir A. Griffith-Boscawen asked whether it was intended by Clause 2 of the Housing Bill to give the Government power to house permanent employees of Government departments or only men employed temporarily on contract work for the Government; and, if the former, whether the Government proposed to build houses for postmen in places where a scarcity now existed.—Mr. Runciman said that the object of Clause 2 of the bill was to provide dwelling accommodation for permanent employees of Government departments, including postmen, where sufficient accommodation was not already available. In reply to Mr. Lane-Fox, he said that the number of local authorities carrying out building schemes in agricultural districts was extremely small. In selecting the agricultural districts in which cottages were to be built under the provisions of the Housing Bill, the Board would have regard to the urgency of the demand and to the practicability of obtaining land at a reasonable price. Any representations which might be made on behalf of local authorities would be considered, but the Board could not bind itself to refrain from exercising its powers in any particular district merely on the ground that the local authority had or had not taken action under the Housing and Town Planning Act.

Public Health Lectures.—Mr. Astor asked the President of the Local Government Board whether either county councils or local sanitary authorities had any power to provide for lectures on matters relating to public health, and, if so, under what statute or statutes.—Mr. Herbert Samuel replied that Section 60 (1) (*b*) of the National Insurance Act, 1911, provided that the Insurance Committee of a county or county borough might make provision for the giving of lectures and the publication of information on questions relating to health, and Section 61 (3) of that Act empowered any local authority to subscribe such sums as it thought fit towards the general purposes of the Insurance Committee. Subject to this he was not aware of any general statutory authority for county councils or sanitary authorities in England and Wales to provide lectures of the kind. He assumed that the inquiry was not intended to relate to the powers of the local authorities

as education authorities. The President of the Board of Education, to whom Mr. Astor addressed a similar question, said that the Board did not itself in the usual course arrange for the provision of lectures. The duty of the Board under the Board of Education Act, 1899, was to superintend matters relating to education in England and Wales, and lectures on public health came within its cognizance only in so far as they were related to education. Grants were payable by the Board under the "Regulations for Technical Schools, Schools of Art, and other Forms of Provision of Further Education in England and Wales," in aid of suitably organized courses of instruction provided by local education authorities in accordance with their powers under the Education Act, 1902. Grants were made also in aid of medical schools, which in some cases provided lectures of the kind mentioned.

Inspectors under the Mental Deficiency Act.—Mr. Snowden asked the Home Secretary what appointments had been made to the posts of medical inspectors under the Mental Deficiency Act; if all the persons appointed were men; at what salaries they had been appointed; if the posts were advertised; if it was intended to appoint a woman or women medical inspectors; and, if so, at what salaries.—Mr. McKenna replied that three such appointments had been made, all of men, at the following salaries: Chief inspector, £200, in addition to his salary as inspector under the Inebriates Act; one inspector, £500, rising to £800; one inspector, £400, rising to £600. The last two posts were advertised. It was intended to appoint a woman medical inspector, and provision was made in the estimates for a salary of £350, rising to £550; the Board of Control had not yet secured the services of a suitable person. In reply to Lord Ninian Crichton-Stuart the Home Secretary said that the names of the medical inspectors lately appointed under the Mental Deficiency Act were, in order of seniority, Dr. R. W. Branthwaite, Dr. A. E. Evans, Dr. S. E. Gill.

Education of Crippled Children.—Mr. Goldsmith asked the President of the Board of Education whether he was considering the advisability of giving Education Committees power to board out crippled children not needing special treatment in suitable homes near ordinary elementary schools, and if he would say under what Act and clause Education Committees were at present denied that power.—Mr. Pease promised to consider the matter, but added that, as a rule, an ordinary public elementary school was not a suitable place for crippled children. Such children should usually attend a special school. He was not aware of any statutory provision conferring the power on Education Committees, and thought statutory authority would be required for the purpose.

Notification of Births Act.—Mr. Alden asked the President of the Local Government Board whether, in order to assist the working of the Notification of Births Act, he had any objection to the superintendent registrars handing to the parents who attended to register a birth a notice containing a short reference to the provisions of the Act; and, if he had no such objection, whether he could see his way to issue a circular to the various superintendent registrars calling their attention to the matter.—Mr. Herbert Samuel replied that, in view of the fact that notification under the Notification of Births Act had to be given within thirty-six hours of the birth of the child, while a period of six weeks was allowed for registration, he feared that the advantage of adopting the suggestion would not compensate for the additional trouble caused.

Medical Inspection of Secondary Schools.—In reply to Mr. Astor, the President of the Board of Education said that medical inspection was provided in some secondary schools, and was paid for out of the funds available for the maintenance of the school. Where medical treatment was provided, it was generally, he thought, provided at the cost of, and by arrangement with, the parents. Some information on the subject would be found in the annual report for 1912 of the chief medical officer of the Board.

A Suffragist Prisoner in Perth.—Lord Hugh Cecil (Oxford University, Opp.) asked the Secretary for Scotland whether his attention had been called to the forcible feeding and medical treatment of a female prisoner recently confined in Perth prison, and Mr. Pratt (Linlithgow, Min.) asked whether his attention had been called to the condition of Miss Frances Gordon on her release from Perth prison on July 3rd. Mr. T. M. Healy (Cork, N.E., Nat.) also asked a question on the medical treatment of Miss Gordon. Mr. McKinnon Wood said: Miss Frances Gordon was sentenced to one year's imprisonment for breaking into the mansion house of Springhall, near Rutherglen, with intent to set fire to it. Among the articles found on the premises were three flasks of paraffin and other combustibles, and a revolver. The prisoner fully admitted her intention to set fire to the house. I asked for and received a report from the prison doctor which contradicts a number of allegations contained in Mr. Healy's question, of which the most important are the statement as to her treatment when asleep and the statement that the quantity of food was diminished day by day and never retained. The doctor states that he is convinced that she had undergone a course of systematic drugging before entering the prison. She was found to be suffering from sickness and vomiting shortly after admission and before she had been fed or received any medical treatment in the prison. She was not fed till June 25th. On admission she was at once put to bed and treated as a sick prisoner. Her condition required the administration of enemata, and I have no reason to doubt that in the circumstances the doctor treated her case properly and humanely. The doctor states that there was very little difference in her appearance when she was discharged. She was carefully examined before leaving the prison, and the doctor states that there was no swelling of the wrists, that she made no complaint of pain, that she was able to converse, and did converse, freely with the doctor's assistant who accompanied her on the journey to Glasgow; that it is true that the breath was offensive, but that it had been offensive from the date of admission, and that generally the statement as to her condition is exaggerated.—Lord Hugh Cecil asked Mr. McKinnon Wood to lay on the table the report he had received from the medical officer, and to say whether he was guided wholly by the opinion of the medical officer whose action was called in question, or had he had any independent opinion?—Mr. McKinnon Wood replied: I must be guided by the report of the medical officer who is responsible for this woman. I will consider the question of laying the report. I wish to do so.—Sir W. Byles (Salford, N., Min.) asked whether Dr. Jones had reported that the statements contained in the report of the medical officer were in the main inaccurate?—Mr. McKinnon Wood said that the report of Dr. Mabel Jones was largely founded on the statements made by the prisoner herself and not on the observations of Dr. Jones. The answer he had given dealt with the allegations in that report.—Mr. Healy asked whether it would not be possible to establish the facts by an independent inquiry.—Mr. McKinnon Wood said that the prisoner had been released, and he did not see how an independent investigation could bring out any fresh facts, but if it could he would be perfectly willing to grant it. In reply to Mr. F. Whyte (Perth, Min.), Mr. McKinnon Wood said that women prisoners in recent cases had been sent to Perth prison because the doctors there were thoroughly skilled in the matter of forcible feeding. In answer to Lord R. Cecil, Mr. McKinnon Wood said that Miss Gordon was able to walk to a cab and to walk from the cab to the station, and in the railway train to Glasgow was able to sit up and, as the doctor said, to admire the scenery and to chat to the assistant doctor who was with her.

Small-pox Outbreak, Rochdale.—In reply to Mr. Albert Smith, the President of the Local Government Board said that thirteen cases were notified as small-pox at Milnrow. Two of these, however, proved to be measles. The eleven cases of small-pox all occurred among adults. One patient was unvaccinated; ten had been vaccinated in infancy; none revaccinated. The medical inspector had investigated the source of the small-pox infection, and the evidence clearly pointed to the conclusion that infection originated within the mill where the patients were employed. The sanitary condition of the stream running near this mill did not come within the scope of his inquiry; but there were no epidemiological facts supporting the notion that small-pox could originate from such a source.

Scotland.

(FROM OUR SPECIAL CORRESPONDENTS.)

PRESENTATION TO PROFESSOR WILLIAM STEPHENSON OF ABERDEEN.

AT a meeting of representatives of the University and of the medical profession in Aberdeen and district, held some months ago, it was resolved to commemorate the retirement of Professor Stephenson from the Chair of Midwifery, which he had so long and honourably held. A large general committee with a small executive subcommittee was formed and it was arranged that the presentation should take the form of a portrait.

The response to a circular issued to former students and colleagues requesting subscriptions has been most cordial and satisfactory. Mr. C. Lindsay Smith was entrusted with the commission, and he has now completed two portraits, the larger of which is to be accepted by the University Court, while the smaller is to be presented to Professor Stephenson.

Arrangements for the presentation have had to be somewhat hurriedly completed in order that it might synchronize with the meeting of the British Medical Association and it is unfortunately impossible to notify subscribers individually. This opportunity is taken to announce that the presentation has been fixed for Tuesday, July 28th, at 3 p.m., in the Midwifery Class Room, Marischal College. Professor Matthew Hay will hand over the portraits and it is hoped that the Principal, George Adam Smith, will be present to accept it on behalf of the University. The committee hope that a large number of subscribers and their friends will find it convenient to be present. A photogravure, a copy of which will be forwarded to each subscriber in due course, has been prepared by Messrs. Annan, Glasgow.

CONGRESS OF THE ROYAL INSTITUTE OF PUBLIC HEALTH AT EDINBURGH.

The annual congress of the Royal Institute of Public Health was opened in Edinburgh on the evening of July 15th by an address by its President, the Marquis of Linlithgow, and it was closed on the evening of July 20th by a public lecture on the history of hygiene by Dr. Otto Neustätter of Dresden. The President touched upon many important matters in his address, including the education of public opinion, towards which the Child Welfare Exhibition in connexion with the congress would lend efficient aid, the fight with tuberculosis, the problem of the milk supply, and the care of the child. Two sentences from the address may be specially referred to. There was that one in which he said, "A young girl of 15 or 16 will own hardly a sound tooth in her head; yet in a few years she may be the mother of a child, and every ounce of food that goes to support life in both her and her child must pass through a mouth so violently septic as to make it only a matter of surprise that either can survive the ordeal"; and there was the other, "I wonder if the general public realizes that ours is the only country in which the leading surgeons, physicians, and specialists do not as a general rule control laboratories and so research work."

On July 16th the sectional meetings began at 10 a.m. in weather which was a dreary contrast to the magnificent sunshine which had marked the King's visit in the preceding week, and the photographing of the members of the congress had to be abandoned. There were six sections—namely, State medicine (with subsections of epidemiology and urban, rural, and port sanitary administration), bacteriology and comparative pathology; child welfare; industrial hygiene; naval, military, and colonial hygiene, and tuberculosis. The respective presidents were Dr. Leslie Mackenzie, Professor Hunter Stewart, Dr. Maxwell Williamson, Professor James Ritchie, Dr. John Thomson, Professor Sir Thomas Oliver, Fleet Surgeon Bassett-Smith, and Sir Robert W. Philip. These meetings were continued on July 17th and July 20th, whilst Saturday, July 18th was given up to excursions and to the dinner by the Royal College of Physicians; on Sunday there was a special service in St. Giles's Cathedral, when the Rev. Professor W. P. Paterson, D.D., preached, and the military stationed in Edinburgh were in attendance. Among the subjects of interest discussed in the various sectional meetings special reference may be made to cancer, to sexual disease and the education of the individual, to housing and tuberculosis, to the care of children under school age, to the incidence of tuberculosis in childhood, to isolation and quarantine periods, to the problem of the declining birth-rate, to the milk supply, and to national insurance and public health administration. There were dozens of separate papers dealing with subjects so diverse as toilet soaps and the control of rat plague, tubercle bacilli in Edinburgh milk and prematernity nurses at the Royal Maternity Hospital, the campaign against mosquitos and the early diagnosis of syphilis. Alcoholism, a hindrance to national health, was discussed at a breakfast given to the delegates by the president and committee of the National Temperance League; whilst at the congress dinner reference was made to the institute's history, and Sir Thomas Oliver drew attention to the fact that last year in Scotland there were only eight deaths from typhoid fever, whereas not so many years ago they constituted a considerable part of the mortality. It was generally felt that, with the exception of the miserable weather prevailing on the first two days, the congress had been very successful.

The Glasgow water supply, which was the subject of much controversy recently in Parliament, was referred to by Professor Glaister when dealing with the subject of "The conservation of Scottish watershed areas." Within the Glasgow water supply area the number of persons to whom water had to be purveyed amounted in 1913 to 1,151,240 persons, or practically a fourth of the entire population of Scotland. When the bill for an extension of the supply was recently before a committee of the House of Lords opponents contended that Glasgow should not be allowed to encroach further on the watershed of the Forth, as sources of supply of that commodity were still available in the head waters of the Clyde on their own watershed, as well as from sources in the vicinity of Loch Lomond. Professor Glaister said that the principal gathering grounds at the head waters of the Clyde had already been taken up as sources of supply by other communities within the same watershed, and there were few available gathering grounds left for appropriation. Another problem was that of the prevalence of rickets, referred to in Dr. Scott's paper on "Deformity as a cause of industrial disablement and inefficiency." Fifty per cent. of the Glasgow deformity was due to rickets, which, however, was decreasing.

GLASGOW BACTERIOLOGIST'S REPORT.

The report for the year 1913 by Dr. R. M. Buchanan, Bacteriologist to the Corporation of Glasgow, affords evidence of the useful work undertaken in this branch of the Glasgow Public Health Department. No fewer than 7,234 specimens were submitted during the year to the bacteriological laboratory by medical practitioners in the city from suspected cases of diphtheria, enteric fever, and tuberculosis; positive results were obtained in 28 per cent. of the cases. This is an increase of nearly 2,000 specimens as compared with 1912, and brings the total number, since the establishment of the department in 1900, to 51,791. The work is performed without any charge to practitioners. Last year the cases were: Diphtheria, 3,078 specimens, positive 27 per cent.; enteric fever, 595 specimens, positive 19 per cent.; tuberculosis, 3,561 specimens, positive 31 per cent. In addition to this routine work from practitioners there were received from diphtheria contacts 1,364 specimens; from patients attending the tuberculosis dispensaries, 1,419; and for the diagnosis of ophthalmia neonatorum, 664. The Wassermann test has also been carried out since September 24th for practitioners free of charge, and 159 specimens were submitted. Miscellaneous investigations undertaken by the laboratory for the medical officer of health, the sanitary inspector, the veterinary surgeons, and other departments totalled 1,415, and included examinations of milk and foodstuffs, water from the public baths, tissues for glanders, etc. In addition 1,236 rats taken from the city, from ships, and from the docks were examined for plague. The volume of work was much increased last year owing to the increased area of the city, the total examinations amounting to 13,940, as compared with 9,912 in 1912.

GLASGOW POST-GRADUATE COURSES.

A course of post-graduate classes will be held at the Glasgow Royal Infirmary during the autumn, commencing on September 4th. Particulars of the course will be found in the advertisement pages. They include classes in clinical medicine, surgery and gynaecology, in surgical diagnosis, in diseases of the ear, the skin, the throat and nose, and the eye, in urology, and diseases of the bladder and urethra, in the clinical examination of urine and digestive products, and in haematology, electro-therapeutics, and anaesthetics. Special classes will be given also in clinical gynaecology and operative surgery.

Ireland.

[FROM OUR SPECIAL CORRESPONDENTS.]

THE DROUGHT AND THE WATER SUPPLY.

THERE have been various warnings in the press recently advising the inhabitants of Dublin to spare the use of water, as owing to the dry season there is a danger of the Vartry supply running short. The chairman of the Waterworks Committee stated last week that the total storage capacity of the Roundwood reservoir might be taken at 2,500,000,000 gallons. Since April 25th last only 5 in. of rainfall have been recorded. The daily consumption in the city and townships averaged about 15,000,000 gallons. He continues: "Even with the decreased quantity of water available, if the citizens confined themselves to the economic use of the water, namely, 25 to 30 gallons per day per head of the population, instead of using, as at present, 40 gallons per head, there would be little cause for alarm." He states that "the frequent use of baths should be discontinued for the present, and drain-flushing likewise should not be indulged in." This statement and advice has called forth some strong protests; it has been asked whether Dublin is to run the risk of a typhoid epidemic because the Roundwood reservoir is at a low level. The droughts of of 1893 and of 1911 ought to have warned the corporation that Roundwood is insufficient for all the calls that may be made upon it. An additional reservoir at Roundwood was begun over three years ago, and was due to be completed this year. It is stated that work on this has been practically at a standstill for months, but no mention is made of this additional reservoir by the chairman of the Waterworks Committee, and it does not appear to the ordinary observer as if it could be of any practical value in guarding against a water famine within any reasonable time. There may possibly have been exceptional causes which have brought about this delay, but it is a very serious state of affairs when the chairman of the Corporation Waterworks Committee advises the citizens against the frequent use of baths and flushing of drains, in order to avoid a water famine.

The long spell of dry weather has resulted in the drying up of the source of supply of the Cashel reservoir. Only on a few days in the week are the public given any water from the mains, and, if there is not a change in the weather, even this meagre supply will have to be discontinued.

SUPERANNUATION OF ASYLUM ATTENDANTS.

Dr. Kirwan, Resident Medical Superintendent, recommended to the governors of the Ballinaslee Asylum that future appointments to the asylum staffs should be subject to three years' probation. The employees could be insured under the National Insurance Act, and if they broke down in that time, physically or mentally, the governors would not be responsible. Under the existing arrangement, if they were only two days in the asylum service, they would be entitled, through the Asylum Officers Superannuation Act, to compensation. The suggestion was adopted.

DEATH OF AN ASYLUM PATIENT.

Last week an inquest was held with regard to the death of an inmate of Londonderry Asylum, aged 51, who escaped from the asylum after stabbing a warder. He was painting buckets and suggested that if he had a knife he could cut out a stencil containing the word "Fire" for the buckets. A warder refused the knife, but proceeded to cut out the stencil himself. Shortly afterwards Dr. Watson, assistant medical officer, found the warder with seven serious gashes in his face, shoulders, and arms, and another patient injured in the neck. The deceased had fled and was pursued by warders, while other warders from Strand Road Asylum were directed by telephone to intercept the runaway. When he reached the centre of Carlisle Bridge in Derry, three miles from the asylum, finding the warders closing in on him, he jumped into the Foyle and, making no effort to save himself, was drowned.

SALARIES OF MEDICAL OFFICERS.

At the last meeting of the Birr Board of Guardians Drs. Dalton, Fitzgerald, O'Sullivan, Meagher, and Houlihan made applications for an increase of £10, and a further increase of £10 every three years until a maximum of £180 was reached. On the suggestion of the chairman, who said the insurance business was not settled and it was not known how the doctors would benefit, the matter was adjourned for three months.

England and Wales.

WALES.

KING EDWARD HOSPITAL, CARDIFF.

Two important gifts to the King Edward Hospital, formerly called the Cardiff Infirmary, were announced at a meeting held at the hospital on July 13th. The anonymous donor, who had already promised the sum of £50,000 conditionally that an additional £10,000 was subscribed, has now consented to make himself responsible for the £60,000. This, with the £30,000 given by Sir William James Thomas, makes possible the extension and completion of the medical school, which will be immediately started. Discussion is still proceeding in the Interdepartmental Committee appointed by the Treasury to determine the amount of grant from the Government.

The other important announcement was to the effect that Mr. Lynn Thomas, C.B., surgeon to the hospital, intended, as mentioned last week, to present to the institution his private nursing home, known as Bedford House. This is a fine building, which immediately adjoins the existing main buildings of the hospital, and has only recently, at considerable cost, been fully equipped as a private hospital.

This gift constitutes a most valuable extension of the hospital, and probably the new wing will be reserved for private or paying patients belonging to the middle classes, many of whom find it difficult to defray the cost of treatment in the ordinary nursing homes. Thus the great work of the hospital will be brought to the notice and consideration of this important section of the community, and this can but redound to the advantage of all concerned. Moreover, these gifts will serve to stimulate public spirit and generosity to further the beneficent work of the premier hospital in the principality, and also to advance the project of the completion of the Welsh medical school. Mr. Lynn Thomas is relinquishing private practice, and intends to devote his time to the hospital and medical school of the Welsh University, of which he is Junior Deputy Chancellor, and the Welsh National Memorial Association, to whose surgical tuberculosis hospital he is consulting surgeon.

Mr. Lynn Thomas has been connected with the hospital for twenty-six years, and for twenty years has been on the honorary surgical staff. In 1900, when on active service in South Africa, Mr. Lynn Thomas was appointed full surgeon to the hospital, and great satisfaction is expressed that his valued services will still be given to it. He was the first medical man to practise as a consulting surgeon in the Welsh metropolis, and he has always been regarded as the apostle of asepsis at the King Edward Hospital. He has built up a great reputation, not only in this country, but also on the Continent, which he frequently visits for the purpose of studying foreign methods. His work and efforts have been of national importance, and the Welsh

University in particular is to be congratulated upon his decision to devote still more time to its interests and aspirations.

BIRMINGHAM.

CHILD WELFARE.

A REPORT on child welfare in the city of Birmingham for the year 1913 has been published by the medical officer of health. It shows that in districts where careful artisans live under fair conditions the infant mortality-rate is half that in districts where there is poverty and accompanying carelessness and inefficiency. The infant mortality-rate for the whole city was 129 per 1,000 births, but in St. Mary's and St. Bartholomew's wards it was 229 and 205 respectively, while in Balsall Heath, Saltley, and Sparkbrook wards (all more or less inhabited by artisans) it was 99, 94, and 98. Taking the mean mortality in the last two years, the wards might be divided into a central group, with rates varying from 130 to 210; a middle ring, in which they ranged from 90 to 130; and an outer ring, in which they were below 90 per 1,000. While it is true that the present mortality-rate is still heavy, although much of it is preventable, it is equally true that the prospects of substantial reduction are most hopeful. The following table shows the mortality among infants during 1913 from the main groups of diseases:

	Deaths.
Diarrhoeal diseases	746
Prematurity and malformation	599
Debility, marasmus, etc.	506
Bronchitis and pneumonia	480
Convulsions and meningitis	202
Measles and whooping-cough	147
Suffocation	91
Tuberculous diseases	85
Syphilis	37
Scarlet fever and diphtheria	16
Other causes	161

The experience in the third quarter of 1913 shows that breast feeding, because it ensures cleaner conditions than can bottle milk, is a great safeguard from diarrhoea and enteritis. Up to the age of 3 months the deaths of bottle-fed babies were twenty times more frequent than those among an equal number of breast-fed babies. Summer diarrhoea is limited to the small house property, and is practically non-existent among that half of the population which lives in five-roomed houses or houses of larger size. In 54,000 houses with four rooms or less there were 756 deaths, and in 55,000 houses with five rooms or over there were only 33 deaths from diarrhoea. There is no doubt that alcoholism plays an important part in increasing infant mortality. It produces carelessness, dirtiness, and poverty, and if the evidence recently obtained in the Ladywood area by the licensing justices of Birmingham be correct, it indicates that a large proportion of the family income is often misspent. The conditions surrounding infants born in the central areas of a large city make it very difficult for even a reasonably careful mother to rear her child without exposing it to the infections of epidemic summer diarrhoea.

Prematurity and malformation accounted for 599 deaths, while debility and marasmus caused 506. It may be said that nearly all these deaths (1,105 less 160 malformations) were preventable and largely due to some defect on the part of the mother before the birth of the child.

The lines along which further work must go in order to prevent this great waste of infant life are those of better education of the parents, and particularly of the mothers of the children, as to what constitutes healthy conditions of feeding and rearing of young children. Of less importance and of a more temporary character will be the advice and treatment given to mothers, infants, and children who are actually ill in the areas where ignorance exists, and where immediate advice and perhaps temporary removal may save life or prevent serious illness. The two main lines to be followed by further educational work are: (1) A more extended and detailed training of children in public elementary schools, and (2) further means to impart information to adults as to the rearing of young children, and to deal with the health of parents, so that a healthy stock may be produced. At present this work is performed by voluntary associations and by the municipality. There are numerous voluntary associations doing excellent work by visiting the mothers, giving them advice, food, clothing, etc., and also by the holding of infant consultations. Municipal consultations are held, and health visitors attend within ten days or a fortnight of the birth if it is thought that such a visit will be useful. During 1913, 16,219 primary visits were made by the special baby visitors or the ordinary health visitors. These visits are of immense value, and one important result is the supervision of the midwives. Frequently it is found that there has been neglect on the part of the midwife, and such instances are reported to the inspector of midwives. Other agencies indirectly bring influence to bear on the health of mothers and infants. Some of these are the tuberculosis visitors, a large number of organizations engaged in social work, which report to the Public Health Department cases requiring attention, and the Poor Law officers when dealing with boarded-out children. It is suggested that special buildings should be erected, or old buildings converted so as to form institutions which might properly be called welfare stations for mothers and children, and that these institutions should cover the whole area of the city. The following, it is said, would be the minimal requirements at these child welfare stations:

(*a*) A medical consultation for mothers to enable ante-natal conditions to be thoroughly dealt with.
(*b*) A consultation for infants.
(*c*) A consultation for older children up to school age.
(*d*) Various classes for mothers for the teaching of elementary cookery and the type of needlework required in the designing and making of infants' clothing. Incidentally, a good many other matters might be introduced, such as saving clubs, the question of food values, etc.

Another very important means to prevent infant deaths would be the provision of a very much larger hospital accommodation for sick babies during certain periods of the year.

MANCHESTER AND DISTRICT.

A HOSPITAL FOR BABIES.

THE medical women of Manchester have just resolved to open a hospital for babies, especially for those suffering from gastro-intestinal disorders and defects of nutrition, and as it is felt to be important that it should be ready for the season when diarrhoea prevails, a house has been taken at Chorlton-on-Medlock, where it is hoped to begin work early in August. It has been urged that infants suffering from diarrhoea and other disorders are taken to the existing hospital out-patient departments by their mothers in such numbers that it is impossible to devote more than a few seconds to each case and to give a prescription and advice to the mothers, whereas what is wanted is more continuous treatment, which the proposed hospital will attempt to provide. Only about twelve beds will be provided immediately, but the promoters hope that the public will soon appreciate the work done and will be willing to support a larger scheme. The committee feels confident that there is ample room for such a hospital without overlapping any existing institution. By a combination of trained nurses with young women who desire training in the nursing of children, and who would give their time in return for such training, it is hoped that the experiment of running a hospital completely staffed by women, which is already being done in London, may succeed in Manchester. It is estimated that the expenses during the first year will amount to about £800, and a lady has offered £300 if the expenses of the opening in August are secured.

Sydney.

[FROM OUR SPECIAL CORRESPONDENT.]

A TRAVELLING HOSPITAL.

A SCHEME of medical and dental treatment of State school children, whose parents are unable to procure it in the ordinary way, has been outlined by the New South Wales Minister for Education. Dr. Willis, Principal Medical Officer of the Department of Public Instruction, who has

been engaged on the details of the scheme, reports that 54 per cent. of the children found to be physically defective in the metropolis and 73 per cent. or more of those found to be physically defective in the country remain untreated. He ascribes this to three causes:—First, to some extent indifference on the part of the parents; secondly, the inability of parents to afford treatment; thirdly, the want of facilities for obtaining treatment. Dr. Willis regards the latter as perhaps the most serious of all, especially in the country. In the metropolitan area the greatest difficulty among the poorer people appeared to be in obtaining dental treatment. In the larger country centres the greatest difficulty experienced by patients was in regard to obtaining treatment for bad teeth. The following recommendations have been made by Dr. Willis: (1) The establishment of travelling hospitals (clinics) in the country districts to treat practically all the conditions found in school children; (2) the establishment of a dental clinic in Sydney; (3) the establishment of a travelling dental clinic for the larger country towns; (4) the appointment of an ophthalmic surgeon to follow the school medical officers round the larger country towns, prescribe glasses when needed, and treat eye defects generally. The dental clinic in Sydney is intended for the children attending the metropolitan schools. The total cost per annum, starting with one travelling hospital for the country, a dental clinic in Sydney, a dental clinic for large country towns, and a travelling ophthalmic surgeon is estimated at £3,445. Steps have been taken to initiate the scheme, which will involve an outlay of £522 for the remaining months of the financial year 1913-14.

The Treatment of Mental Diseases.

The Inspector-General of the Insane in New South Wales has issued a statement containing recommendations for improvement in the care and treatment of mental diseases and allied conditions. Dr. Sinclair says: "What is specially needed is a more vigorous treatment of early cases with a view to preventing them becoming less curable." It is pointed out that the lunacy laws in the past have taken more care of the legal requirements than of the medical. The report then goes on to state: "The best prospects of successful treatment in mental, as in other diseases, lie in its treatment in the early stages." He emphasizes the point that the patient's disease should not remain undealt with owing to legal formalities until it had advanced to a stage in which it was certifiable. His recommendation is that provision should be made for mental cases in the general hospitals, which should be open to patients without legal formalities on the simple recommendation of their medical attendants, certificates for those whose illness required legal restraint to be provided at a later stage.

Since cases of mental disease occur generally throughout the community, the treatment of the early stages cannot be reserved for mental specialists. Facilities must be offered to the general practitioner for this purpose in the shape of suitable hospital accommodation and of education during his career as a student. Accommodation requires to be available even in remote country towns. In the metropolis, however, the numbers are large enough to warrant a ward in each of the large general hospitals. As these hospitals are used for clinical teaching, the student would become familiar with the early symptoms of the disease, the cases being more like those they meet in practice than those in the later stages usually observed in the ordinary mental hospital. Greater attention to the teaching of mental diseases at the university is also necessary, and the subject should no longer be regarded as one of minor or optional ones. The lunacy department need not be associated with the work, except so far as it may be desired to have inspection. For more advanced cases the Inspector-General recommends: (1) The enlargement of the mental hospital; (2) remodelling of the reception house; (3) further classification of existing hospitals; (4) classification of all mental cases into (*a*) those to be treated medically without certification, (*b*) those to be treated needing moderate certification, (*c*) those to be treated needing full certification. He also considers the cases of the feeble-minded, imbeciles, inebriates, epileptics, and the criminal insane, in each of which he makes certain recommendations necessary to the bringing of lunacy administration in New South Wales abreast of the most modern practice.

The Medical Journal of Australia.

Dr. Armit, who was selected to be the editor of the new *Medical Journal of Australia*, was warmly welcomed by the profession when he arrived in Adelaide. He was also welcomed at Melbourne, and arrived in Sydney on June 4th. Last week he was entertained at dinner by Dr. David Thomas, the President of the New South Wales Branch of the British Medical Association. The *Medical Journal of Australia*, the first number of which is to appear on July 4th, is a new journal, in which are incorporated the *Australasian Medical Gazette*, which has been the organ of all the Branches of the British Medical Association in Australia except Victoria, and the *Australian Medical Journal*, which has been the organ of the Victorian Branch.

Canada.

[FROM OUR SPECIAL CORRESPONDENTS.]

Co-operation among Medical Officers of Health.

An effort is being made in Ontario to bring the medical officers of health into closer touch with each other, and societies are being formed with that object in view. Such meetings will give opportunity for the discussion of questions concerning public health. On May 21st eighteen medical officers of health, representing the counties of Wentworth, Norfolk, Haldimand, and Brant, in the province of Ontario, met at Hamilton at the invitation of Dr. McClenahan, the district medical officer of health, to form an association which will meet in May and October of each year. The appointment of county officers to co-operate with local officers and the establishment of rural laboratories from which practitioners could secure emergency supplies were discussed. These matters will be given further consideration in October, when the association meets at Hamilton. On June 9th the medical officers of health of the counties of Lincoln and Welland met at St. Catharines, Ontario. On this occasion the Association of the Medical Officers of Health of the Niagara District was formed, with Dr. King, of St. Catharines, as president.

The Nova Scotia Sanatorium.

The provincial sanatorium at Kentville, Nova Scotia, was established in 1904 by the Government for the treatment of persons suffering from pulmonary tuberculosis. A weekly fee of 5 dols. is charged, which must be paid in advance, and only those who are in the early stage of the disease and have no serious complications are admitted. The ninth annual report states that during the year 1913 64 patients received treatment in the sanatorium and 38 were discharged; of the latter only 2, or 5 per cent., failed to respond to treatment. Two pavilions, each with accommodation for 16 patients, were added to the sanatorium last year. Since January, 1910, 94 patients have received treatment and 59 of them are well and working, 19 are well but are not working, 15 are dead, and the fate of one is not known. The report states that tuberculin appears to be of benefit to patients while in the sanatorium but that it has little ultimate effect. The Kentville sanatorium is the only institution of its kind in the province of Nova Scotia, the population of which is 492,338. The sanatorium contains 40 beds, and there are 23 antituberculosis leagues in the province. There is great need for free hospitals to which needy patients may go, especially those in the later stages of the disease. Throughout the Dominion, with its population of something over 7 millions, there are 31 sanatoriums, providing altogether 1,423 beds for patients suffering from tuberculosis.

Tuberculosis and the Milk Supply.

For the past two years the question of bovine tuberculosis and its relation to human tuberculosis has been under consideration by the Federal Department of Agriculture. The problem in Canada presents much the same difficulty as in other parts of the world and an Order in Council has now been passed to authorize the Department of Agriculture to enter into an agreement with cities whereby some arrangement may be made to lessen the possibility of infection through the milk supply. In the province of British

Columbia provision is made to pay compensation for dairy cattle infected with tuberculosis and, so far, the results of this regulation have been most satisfactory. A good deal has been accomplished in certain cities in Canada to prevent infection through the milk supply, but it is hoped that the Minister of Agriculture will now be able to make arrangements to ensure an improvement in dairy conditions throughout the Dominion.

Scarlet Fever and Measles.

Both scarlet fever and measles have been very prevalent of late throughout the country. Many of the cases are slight and it frequently happens that a physician is not called in. In Hamilton, Ontario, 267 cases of measles were reported during the month of May, and in June as many as 108 cases are said to have been reported in a single week. In Moose Jaw, Alberta, 101 cases were reported during the first three weeks of June.

The Montreal Association for the Blind.

In addition to the Mackay Institute, which for many years has done much good work, a second school for the blind was opened in Montreal about eighteen months ago. It stands on eight acres of land, and has accommodation for forty pupils. The course of instruction includes an elementary commercial course, technical training in piano tuning, typewriting, machine knitting and sewing, and instruction in the piano, organ, and violin. An industrial home for the adult blind is now in course of erection on the school grounds. A social club, also, has been organized in connexion with the Association and has proved most helpful, especially to those who recently have lost their sight.

The St. Justine Hospital.

The new building of the St. Justine Hospital for Children at Montreal was opened on June 22nd. It contains eighty beds, and has one private and three public wards. It is the intention to give a course of lectures, which will be free to the public, on the care of infants and the treatment of minor ailments; these lectures will be given in connexion with the outdoor department of the hospital.

Special Correspondence.

PARIS.

Parameningococcus Serum.—Diabetes Insipidus.

M. Pasteur Vallery-Radot reported to a recent meeting of the Société Médicale a case of cerebro-spinal meningitis in which, after three injections of antimeningococcus serum amounting together to 120 c.cm., the symptoms of the disease became more accentuated, and the cerebro-spinal fluid remained turbid. The patient became comatose, and it was then decided to try the antiparameningococcus serum of Dopter, although the parameningococcus had not then been identified in the case; 40 c.cm. were injected into the spinal canal, and on the following day there was a great improvement both in the patient and in the appearance of the cerebro-spinal fluid. Three more injections of Dopter's serum were given; altogether 145 c.cm. After each injection the turbidity of the cerebro-spinal fluid lessened and the general condition of the patient improved. Eventually the cure was complete and the fluid normal. M. Dopter himself identified the organism in this case as a parameningococcus. M. Hallé observed that if before the complete bacteriological examination antimeningococcal serum did not improve the condition, antiparameningococcal serum should be tried. Dopter, in discussing the bacteriological diagnosis of cerebro-spinal meningitis, pointed out that formerly the differentiation of the meningococcus and the parameningococcus was considered relatively simple by the agglutination test. But coagglutinations were frequently observed, and the problem could not be solved quite satisfactorily by the relative amounts of agglutinations. He preferred the test of the situation of the agglutinins, and with it his results had been very accurate. To the tubes necessary for this test he added another containing saturated antimeningococcal serum, which he kept prepared for this purpose. If coagglutination occurred in the two serums and no agglutination in the saturated serum the organism was the meningococcus. If agglutination occurred in the saturated serum also the organism was the parameningococcus. The method, he said, was both quick and accurate.

Experiments by Professors Camus and Roussy have thrown some new light upon the etiology of diabetes insipidus, and upon the function, or rather lack of function, of the pituitary gland. Numerous researches, both experimental and clinical, during the last few years are held to suggest that hydruria depend either upon a lesion of the nervous centres in the base of the brain, or in the medulla, or upon a perversion of the function of the pituitary gland. The researches of MM. Camus and Roussy point very strongly towards the former. In the first series the relation of removal of the pituitary gland to polyuria was studied. The glands were removed in a number of dogs by the buccal and trans-sphenoidal route. In the majority of cases an abundant polyuria occurred, but in a few there was no diuresis. The autopsies showed that in the former cases the base of the brain had been slightly injured in the course of the operation, and that in the latter the brain was quite intact.

The second series of experiments was concerned with the relation of polyuria to lesions of the base of the brain. The base in the neighbourhood of the pituitary gland was injured in five dogs, and all showed an abundant polyuria, notwithstanding the integrity of the pituitary glands, as shown later by the autopsies. In two other dogs the pituitary gland was removed without producing polyuria; after a few weeks the base was injured in these two dogs, and intense polyuria followed immediately. The duration of polyuria produced by lesions of the base was found to be variable. In some cases it was transient, but in the majority it lasted from two to six months. Occasionally a transient glycosuria appeared immediately after the puncture. Injection of many different preparations of pituitary extract did not in any way modify the experimental polyuria. The region, lesions of which were followed by polyuria, appeared to be limited to the opto-peduncular space, especially in the neighbourhood of the infundibulum. Lesions in front of the optic chiasma did not produce polyuria. The hydruria in the animals was accompanied, as a rule, by a corresponding polydipsia. In one case in which the amount of water allowed after the operation was restricted, the polyuria was quite as intense, the excess of water being abstracted from the tissues. When the dog was allowed to drink water freely it soon repaired the loss. Some animals after the experiments drank very much more water than was necessary for them, and others seemed inclined to take very little extra. In the latter cases MM. Camus and Roussy hold that the centres for water metabolism had either been injured or were defective developmentally.

Correspondence.

THE UNIVERSITY OF LONDON.

Sir,—In an annotation under this heading in your issue of July 11th, to which my attention has just been directed, you comment on the question of providing a new site for the University, and you refer to a resolution passed by the Senate at its meeting on June 17th, from which you draw the conclusion that "the Senate therefore would seem to have stepped aside, at any rate for the present, and the next move lies with the Departmental Committee, but there is no indication of when this move will be made." The assumption, inherently improbable, that the Senate had "stepped aside" in a matter so vitally important to the University which it controls is immediately disproved by a reference to the preamble to the resolution as it appears in the minutes of the June meeting confirmed at the meeting of July 15th.

The occasion of the resolution was the report to the Senate of its Sites Committee, and in its preamble to the resolution, which was ultimately endorsed by the Senate, the Sites Committee state that they "have had before them particulars of a large number of sites, eight of which they have investigated in detail." (Your annotation refers to only three sites as having been "spoken of.") The preamble then goes on to say:

Your Committee are of opinion *that some steps should be taken to counteract the effect of ill-informed criticism in regard to the action or inaction of the University with reference to a site for its head quarters.* The position of the University is set forth in Senate Minute 2,992 of May 30th, 1912, and your Committee think it would be wise for the Senate to make clear to His Majesty's Government the attitude of the Senate towards the site question at the present time.

Then follows the resolution, which in effect advises the University to hold on to what it has, unless very definitely assured of something better. If the words which I have italicized constitute a rap upon your editorial knuckles, I am not responsible for the punishment, and it is not undeserved: your criticism cannot escape the reproach that it is ill-informed.

The interpretation of the resolution presented by the Sites Committee—which includes, in Lord Moulton, Lord Cozens-Hardy, Sir Edward Busk, and Mr. Budd, a sufficiently remarkable combination of legal authorities—is to be found in the events, some of which have been made public, which followed in the train of the very interesting, but wholly unsuccessful, attempt of the Royal Commissioners to commit the university to the Bedford site before the Commission's final report was published. The Senate very properly refused to be hustled. They could not imitate the rapidity of decision of the Commissioners who accepted, *on the same day on which it was made to them*, the proposition for the removal of the University laid before them by Sir Francis Trippel. The Senate with a higher sense of its responsibilities than was exercised by the Commissioners adopted the wiser course of entrusting to a very authoritative committee the duty of investigating patiently and fully all the possibilities open to them. The present report conveys their considered judgement to the effect that the Senate ought not to exchange the undeniable substance of their present advantages in the engagements of His Majesty's Treasury towards the University, which are recorded in the Minute 2,992, for the shadow of nebulous offers, chief among which I would instance Sir Francis Trippel's "million pound fund," which was launched with such a flourish of trumpets by the Commissioners, and which was so speedily discredited.

The degree to which His Majesty's Treasury is committed to the University by the minute quoted seems a little uncertain; but in the opinion of the present Master of the Rolls, who is a member of the Sites Committee, there is, at the lowest estimate, "a very good parliamentary case" for the undisturbed possession by the University of all its present privileges of tenure and maintenance; and there seems, moreover, a reasonable prospect of the reversion to the University of the remainder of the buildings of the Imperial Institute. This happens to be one of the finest of modern examples of the architectural art, and its near proximity to the Imperial College and other great educational institutions and museums, makes it peculiarly well adapted for the purposes of a university.

Equally infelicitous with your reflection on the Senate is your statement that the next move in direction of the choice of a sito "lies with the Departmental Committee." Now inasmuch as that committee was appointed solely "to give effect to the recommendations of the Royal Commission," and further comprises a large proportion of past members of that Commission, it must find itself in a peculiarly unenviable position as regards the selection of a site. It cannot ignore the Commissioners' recommendation of the Bedford property, so flamboyantly eulogized by Lord Haldane; and it is even more impossible to resurrect a scheme which, shorn as it now is of all those early anonymous and, as many of us think, largely mythical promises of support, is surely as dead as mutton. The committee may indeed sorrowfully address to Sir Francis Trippel a query similar to that of his illustrious compatriot, Hans Breitmann, and ask him, "Vhere ish dat million now?" Your annotation closes with the prudent reflection that there is no indication of when the Departmental Committee will take action in this matter; and it may confidently be predicted that that is one of the very last questions on which it will be anxious to make a pronouncement.—I am, etc.,

E. GRAHAM LITTLE, M.D., F.R.C.P.,
Member of the Senate; Vice-President of the University of London Graduates' Association.

July 21st.

*** Our knuckles are not very badly bruised. Shorn of rhetoric, the main facts are that on May 30th, 1912, the Senate of the University appointed a committee "to consider and report on the question of an adequate site for the head quarters of the University and generally on the question of accommodation from the point of view of the development of the University as a whole." On June 17th, 1914, the Senate resolved to inform His Majesty's Government that, having considered various sites, it was of opinion that it was "undesirable to proceed further with such consideration," and so on as printed in the JOURNAL of July 11th, pp. 86 and 100. This action of the Senate is, we think, quite fairly described as stepping aside. In assuming that the next move lay with the Departmental Committee we may have erred, though but for our correspondent's authority we might have supposed that the President of the Board of Education meant what he said in his letter of November 12th, 1913, to the Vice-Chancellor of the University. In that letter Mr. Pease stated that the Government had decided that the scheme of the Report of the Royal Commission was "calculated to produce a University of London worthy of the name," and that "the business of the Departmental Committee" would be "to discover how far the numerous bodies and persons concerned are prepared to co-operate on the basis of the principles underlying the scheme" which Mr. Pease considered to be "in themselves simple." The fourth of these simple principles was:

> That as much of the University work as possible, together with the University administration, should be concentrated in a central University quarter. (The question of the particular site to be selected is one on which the Departmental Committee will be able to advise the Government after they have considered the various alternatives that have been proposed.)

The Senate is quite right not to be hustled, and there seems to be no real risk of any such untoward result, but it may be recalled that on May 30th, 1912, the Senate adopted a resolution welcoming "the efforts of Lord Haldane and of other friends of university education in London to raise funds towards the present and future needs of the University." We do not altogether sympathize with our correspondent in his joy that these efforts have so far failed of success.

CARDIAC THROMBI.

SIR,—In a recent annotation on free thrombi and ball thrombi in the heart (p. 33) no reference is made to one form of cardiac thrombosis of great importance and by no means uncommon. It is met with in patients who have been "long-a-dying," as in phthisis or cancer. These thrombi are flat, and moulded to the shape of the ventricle and auricle, and represent the cavities in the condition of extreme contraction. They have the ordinary character of *ante-mortem* clots, being firm, pale, and fibrinous. They measure from an eighth to a quarter of an inch in thickness, but this varies in different parts, and they may be several inches in length. They form in the ventricle or auricle, commencing probably behind the columnae corneae, or in the irregular meshwork of the auricular appendix. In extreme cases they may occupy both auricle and ventricle, with a narrow band connecting the two parts, and with extensions into the great vessels—the pulmonary artery on the right and the aorta on the left. Generally they are kept *in situ* by bands which are felted in with the chordae tendinae and columnae corneae. They may be detached, and then cause sudden death. On the right side this would lead to pulmonary embolism. But detachment may occur on the left side also, though much more rarely. An instance of this I described some years ago under the title of "Embolism of the aorta." The arch of the aorta was found plugged with a large mass of decolorized clot. On unravelling this in water it displayed a large, flat clot such as I have described, which could be replaced without difficulty *in situ* and shown to correspond exactly with the cavities of the left ventricle and auricle.

This form of cardiac thrombosis is by no means rare. It has escaped description, I suppose, because these thrombi have not been distinguished from the soft, gelatinous, *post-mortem* clots which are so much more common.—I am, etc.,

SAMUEL WEST.

London, W., July 20th.

MITRAL OBSTRUCTION AND PULMONARY PHTHISIS.

SIR,—In Dr. Price's article on cardiac disease, in the JOURNAL for June 20th, there occurs a statement which appears to require modification. On p. 1342 he states that "the most common cause of haemoptysis in pulmonary phthisis is mitral stenosis."

Rokitansky taught that all conditions which induce a state of venosity of the blood impart an immunity from tuberculosis. Whether this is strictly correct or no may be open to argument, but it has certainly represented general medical opinion for many years.

It is currently believed that while congenital heart disease, especially pulmonary stenosis, predisposes to phthisis, acquired forms of heart disease, particularly mitral stenosis, are antagonistic to its development. Dr. Percy Kidd states[1] that most writers agree in saying that mitral stenosis is scarcely ever met with in association with phthisis, but that he has met with at least a dozen clinical examples. In the same work[2] is found the statement "only two (*post mortem*) cases of tuberculosis in association with mitral stenosis came under the notice of Sansom, but according to Potain the coexistence is frequent." In face of this conflict of opinion among authorities it seems premature to assert that the most common cause of haemoptysis in pulmonary phthisis is mitral stenosis.

In my limited experience as physician to a sanatorium and large general hospital for thirteen years, I cannot recall a single case of phthisical haemoptysis which presented the physical signs of mitral stenosis. Some years ago I attended a girl who had repeated haemoptysis, crepitations at one apex and a mitral systolic cardiac bruit. I recently saw this patient again after an interval of seven years. I could find no sign of phthisis except that the heart was somewhat exposed from retraction of the left lung, suggesting a healed lesion. My inference from this is either that my original diagnosis of phthisis along with heart disease was mistaken, or that the heart disease increased the patient's resistance (Rokitansky's immunity) to the tuberculous process. The cardiac bruit remained, and there were signs of heart failure.

There is certainly a source of "error in the diagnosis of cardiac disease" which it seems desirable to mention in connexion with those alluded to by Dr. Price. I do this not in a spirit of criticism but from a desire to supplement what he has said. I allude to difficulties in the diagnosis of mitral stenosis, particularly where, as Dr. Price says, murmur and thrill are absent. A patient comes with a history of cough and haemoptysis, and crepitations are heard at the apex of one or both lungs. I have myself diagnosed such a case as phthisis when after-events proved the incorrectness of the opinion, and that the mistake is a common one I feel quite sure from the numbers of cases of haemoptysis sent to me as due to phthisis where the real disease is mitral stenosis. The wasted appearance of many of these patients increases the suspicion that they are phthisical. The crepitations at the apices generally clear up with rest, and seldom develop into the signs of definite and advancing phthisis. No doubt phthisis and heart disease are occasionally found associated, but my experience tends to confirm Dr. Kidd's statement, "All diseases of the heart which bring about passive congestion of the lungs confer a certain degree of protection against pulmonary tuberculosis" (Allbutt).—I am, etc.,

Nottingham, June 23rd. C. H. CATTLE, M.D., F.R.C.P.

THE BRITISH MEDICAL ASSOCIATION AND THE MEDICAL PROFESSION.

SIR,—When expenditure exceeds income, it is time to seek out the cause and remove it. When the *Lancet* is a commercial success at a subscription of £1 1s. per annum, reduced from £1 11s. 6d., it is surely a huge mistake to increase the British Medical Association subscription to £2 2s.

The fight for the partial recognition of the rights of the profession cost the Association a large amount, to which many subscribed, and, with the increased subscription, caused a loss of about 2,000 members. Would it not be the best thing to set one's house in order—to abolish the Representative Meeting, which, in my opinion, is simply a waste not only of time, but also of money (speaking roughly, £2,000 a year)—to restrain and prevent further officialism? The Association was much better and more economically managed by the Council elected by the Branches, before the formation into Divisions, etc., and laid a good foundation. Why not revert to the former method?

Why should the ordinary member of the British Medical Association have to pay for working up the panel system, with which, perhaps, he has no sympathy? and why should he be compelled to become a trade unionist, which possibly he regards as a degradation to the profession?

Would it not be wiser and more just to have a Panel Committee, or guild, or branch of the Association, with its own secretary, for which it paid, and, if it were considered desirable, for it to become allied under the Trade Union Act? Also to lower the general subscription to £1 1s., or, say, 10s. 6d. for membership and 10s. 6d. or £1 1s. for the JOURNAL, and so on, so as to embrace all who have an interest in their profession, as only by union and organization can influence be obtained. Now is the time; delays are dangerous.—I am, etc.,

Harrogate, July 14th. CHAS. GIBSON.

SIR,—There seems a tendency on the part of the profession to split up into various political societies and trade unions; this will be absolutely fatal to it. Could not the British Medical Association try and get the whole profession into its ranks? This can only be done by dividing definitely into two sections—(1) scientific, (2) political—and having a separate subscription for each, the subscription to the scientific section to include the JOURNAL, and the subscription to the political side the SUPPLEMENT. I believe there would be a very great increase in the number of members. A slightly reduced subscription might be made to members of both sections.

Depend upon it that if a crisis occurred the scientific members would back up the political ones, whereas if we are split into numerous societies each will claim prior right to represent the profession, and the various societies will quarrel with each other, and meanwhile the Government of that day will just do as it likes with the profession. A number of men say the profession will never be united, but I still believe it is possible, but only if the Association takes immediate and prompt action.—I am, etc.,

Leytonstone, July 17th. ARTHUR TODD-WHITE.

THE METHODS OF THE CHILDREN'S COUNTRY HOLIDAYS FUND.

SIR,—May I ask you to find space for a few comments on the circular on "Children's Country Holidays" issued by the Local Government Board? The Board draws attention to the allegation that from time to time infectious disease has been introduced or spread in country areas, and that overcrowding in country cottages has also been caused by the boarding out of town children during holiday time.

The Children's Country Holidays Fund, which sent over 45,000 London children into the country for a fortnight last summer, and since its establishment by Canon Barnett thirty years ago has provided holidays for more than a million children, has for many years given close attention to the points mentioned in the circular. As the fund draws support from such a wide circle of sympathizers, I am sure your readers will be interested to know what regulations are laid down to avoid the dangers suggested.

1. To prevent any risk of sending children to cottages where infection or overcrowding might be possible, the fund allows no centre to be used unless a lady or gentleman resident in the place has undertaken supervision, and children are only sent to cottages which have been inspected by these honorary "visitors." The latter also see that the definite restrictions as to numbers accommodated in each cottage are observed, and visit the children during their stay so that no breach of the regulations may pass unnoticed.
2. The fund enjoys the co-operation of the L.C.C., whose nurses inspect all the children on the score of health and cleanliness before they go away, and report three times on each child before the holiday is given.
3. Honorary assistants of the fund visit the home of every child at least once before the holidays, and in case of any suspicion of illness in the house or immediate neighbourhood,

[1] Allbutt's *System*, vol. v, p. 290.
[2] Ibid., vol. vi, p. 345.

a doctor's opinion is obtained. Before the children leave London their parents are required to see that they take with them a supply of clean clothes.

4. A special fund is set apart for medical assistance when required at the country centres, and this fund is drawn upon up to a specified amount in case of need for medical advice, special food or hospital charges.

Seeing that the Children's Country Holidays Fund has been at great pains to minimize any risks attendant on its work, I should be glad if you would put this brief statement before your readers.—I am, etc.,

F. MORRIS,
Chairman of Executive Committee.

Children's Country Holidays Fund,
18, Buckingham Street, Strand, W.C.,
July 9th.

A PROBLEM OF DENTAL LEGISLATION.

SIR,—As the progress of dentistry is closely associated with that of medicine, it is gratifying to find, as is shown by the recent judicious leader, that you are disposed to take an interest in "a problem of dental legislation," which, as you say, the British Dental Association has been for some time aware is "serious and difficult." The unregistered men are also aware of this, and are busily studying the situation from their own point of view. They are scarcely, as you say, "an unorganized mass," and as a body they have naturally sympathies and interests in common. It will be very awkward if registered dentists in alliance with medicine are not the first to understand the true nature of the conditions that have led to the present unfortunate state of dental affairs, and the first also to propose and institute the necessary reforms to rectify it. It would be humiliating, although not from the numerical point of view, for the registered dentists to be outwitted by the unregistered, which will inevitably happen if the former do not immediately proceed with the necessary reforms.

It may be readily shown that neither the registered nor the unregistered practitioners have yet grasped the true nature of the problem with which they are confronted; at least, if they have, they have not yet honestly stated it. Those who had interpreted the meaning of the Dental Act properly and calculated that it would be carried out were confident that the recent decision given by the Lords would turn out as it did, and it was those few who knew this who prevented the matter being tested by the House of Lords sooner. So that apart from the delay occasioned by this false waiting policy and making the situation clear to a greater number, the state of matters in dentistry was not affected by the decision.

The practice of dentistry in a professional sense as well as of medicine must be based on other considerations than mere law, although regular dental practice may be fortified and protected by law. Victory lies with that dental party or body which first recognizes the true nature of dental reform and initiates and promotes it. So much the better would it be if registered and unregistered by conciliation and compromise acted conjointly, but that is unlikely. The necessary reforms indicated below are sure to come sooner or later.

Instead of saying as you do that the "object of the Dentists Act is to a large extent defeated," perhaps it would have been nearer the mark, as I am inclined to think, to say that the Act aggravated the very evils it was intended to reduce. Your opinion also that "it is clear that nothing short of a prohibition of unqualified practice, such as exists in other countries and many of our colonies, would have the desired effect," is open to grave doubt, although that opinion is widely shared, not only by the members of the British Dental Association and other qualified practitioners, but also by unregistered and unqualified men. There is a suspicion of some fallacy lurking in their arguments when opposed parties are in complete agreement as to the main aim and issue. The unregistered are satisfied that their claims for some kind of recognition cannot in the end be withstood, so they at least may be excused for adopting the creed that prohibition of practice is good law.

The policy of direct prohibition either of the use of the title of dentist or of practice in dentistry is obnoxious to the widespread British sentiment of the freedom of the individual, both as to speech and action, so that prohibition of practice in this country would be difficult to secure, and if secured, proportionately less effective and more harmful in its results. There is, however, a perverted taste for legislation in this country at present, and the medical Insurance Act has whetted the dental palate. Surely Parliament will not pander to it, but let it cure itself by wholesome reflection. Even although there were only 8,000 unregistered dentists in established practice, as I am inclined to estimate, and 4,000 registered dentists—that is, about one-third of the number of men in active medical practice—would Parliament be inclined immediately to increase the machinery of the medical Insurance Act so that it could produce an additional one fourth revenue to pay the dentists? The medical Insurance Act requires simplification first rather than to be complicated by a large addition, and for this among several other less obvious reasons dental insurance benefits of a comprehensive and substantial kind are probably somewhat far off.

It is chiefly by the improvement of dental education and the curriculum that progress in dentistry and especially the increase of the number of men that will become dentists, will be attained. The curriculum is ill conceived, it is unattractive, and having been gone through, the graduate is ill equipped and consequently vulnerable by the "dental artificer" or dental mechanic.

The medical and dental curriculums resolve themselves into two chief parts—a general, and a special or technical part. The general part in both should be the same, namely, physics, chemistry, and biology. Biology, including protozoology, has been, by some grave error, omitted from the dental curriculum, whereas aspects of human anatomy and physiology, medicine, and surgery that are irrelevant to dentistry, are included. Instead of having full courses of, and his attention concentrated on, dental anatomy and physiology, dental surgery and pathology, and mechanical or prosthetic dentistry, the dental student's mind is distracted by a multiplicity of cognate subjects. Dentistry being to all intents and purposes an operative and mechanical art, the pupilage or apprenticeship should run throughout the whole course, which undoubtedly should have a minimum duration of five years.

Dentistry, besides, as a profession, suffers badly because knowledge of dental diseases or dental pathology is merely empirical and not rational. Dentists neither know the etiology of nor how to prevent dental caries, dental pyorrhœa, the deposition of tartar on the teeth or dental erosion; at least no textbook gives a rational account of these diseases. Is there any virtual argument concerning their cause or etiology and of their prevention in current dental literature? There was never greater general discord on these aspects of dental and peridental diseases than at present. This constitutes a grave drawback to the professional aspect of dental surgery.

But as dentistry is an art so nearly associated with medicine and surgery, it might nevertheless be a more honourable institution in civilized life were not presumption and quackery such prevalent failings as is alleged, probably with truth. These failings, if they really exist, should have the serious consideration of those who would reform dentistry: for if they exist among registered men to any considerable extent, no law can effectively defend such an institution from presumption and quackery from without. In order to counteract this tendency the public also require education in certain essential dental matters. The Dentists Act was in a sense the product and expression of the dental snobbery and ignorance of the third quarter of last century. These lower sentiments, the lack of a rational knowledge of dental pathology and a lax and scrambling dental curriculum, lie at the root of present dental troubles rather than defective legislation. Dental regeneration will certainly come when these defects are rectified, but not till then.

Instead of 5,000 names being on the *Dentists' Register* there should be 15,000 if the work confronting us is to be successfully coped with. Ostensibly the General Medical Council is to blame for the present scarcity of qualified dentists and this it ought to have observed long ago. But the Representative Board of the British Dental Association, having voluntarily taken upon itself the burden of the conduct of the Dentists Act, is the real culprit. An analysis of its proceedings will show that it has never revealed that it was conscious at any time of the real cause of dental troubles. Its policy and actions have for the most part, both on broad issues and in detail, been

detrimental to dentistry, and its present attempt to institute an anticipatory public service is doomed, like its past successive attempts at reform, to abject failure. In a word, there is something rotten in the state of dentistry in this country.

In order to have raised the number of names on the *Register* since the passing of the Act to 15,000 an average annual increment of 285 would have been necessary. The average annual increment is *nil*. To make up the deficiency in ten years it would require an annual addition of more than 1,500. The problem now presents itself, How within a reasonably short period can this deficiency be supplied? Obviously special means must be adopted, both to attract more recruits and by some means to reduce the numbers of the unregistered and make unregistered practice less attractive.

Under the present régime the mechanism for this purpose should emanate from the Medical Council. The Dental Act does not confer on the Medical Council the power of forming a supplementary list. The licensing bodies should be vested with powers to modify their curriculums as above suggested, and, if they see fit, to admit unregistered practitioners to examinations *sine curriculo* or after a modified course of classes. It is an obvious logical deduction that, if existing examining bodies examine the hitherto unqualified practitioners, existing teachers should be allowed to afford instruction.—I am, etc.,

WILLIAM WALLACE, M.D., L.D.S., R.F.P.S.Glasg.,
Glasgow, June 15th. Lecturer, Glasgow Dental School.

PRACTICE IN BRAZIL.

SIR,—By the courtesy of the Privy Council I have received a dispatch from His Majesty's Consul-General at Rio de Janeiro, stating the conditions under which persons holding foreign diplomas are permitted to practise medicine, surgery, and dentistry within the Federal district. This I shall be happy to show to any one who cares to call at this office; it will be incorporated in the next edition of the pamphlet published by the Council giving the conditions under which persons qualified in their own country may practise abroad.—I am, etc.,

NORMAN C. KING,
General Medical Council Office, 299, Oxford Street, W. Registrar.

Universities and Colleges.

UNIVERSITY OF OXFORD.

Degree.

THE following degree has been conferred:

D.M.—G. H. Hunt, Christ Church.

Awards.

The Theodore Williams Scholarship in Anatomy has been awarded to K. F. D. Waters, Keble College, and the corresponding scholarship in pathology to H. St. H. Vertue, University College.

UNIVERSITY OF LEEDS.

Degrees.

THE following degrees have been conferred:

M.B., CH.B.—J. C. Gillies, H. R. Knowles, *W. H. Lonen, *H. Shochet, *C. Wilson.

Examinations.

The following candidates have been approved at the examinations indicated:

SECOND M.B., CH.B. (*Part I, Anatomy and Physiology*).—E. W. Drury, E. E. V. Glover, K. Jaidka, I. Silverstein. (*Part II, Pharmacy*).—Z. P. Fernandez, F. H. Goss, H. V. Horsfall, C. R. Knowles, A. L. Telling.

FINAL (*Part I, Pathology and Bacteriology*).—J. J. D. La Touche, H. Hyman, W. L. Ingham, C. E. Leake, J. Rosenewige, R. S. Topham, A. Umanski. (*Part II, Forensic Medicine and Public Health*).—W. D. Anderton, S. N. Cohen, C. M. Gozney, A. S. Hebblethwaite, H. R. Knowles, H. S. Lockwood, H. W. Whitteron, H. Shochet, J. Wilkinson, C. Wilson.

* With second-class honours.

UNIVERSITY OF LIVERPOOL.

FACULTY OF MEDICINE.

AT the end of a meeting of the Faculty of Medicine the Dean reported a considerable increase in the number of students taking courses of instruction in the medical school. The number of new undergraduate students preparing for medical degrees and diplomas who registered during the session was 49. The number of new dental students registered for dental degrees and diplomas was 31. He further reported that the total number of undergraduate students taking complete courses of instruction in the school was 166, which was 23 in excess of the previous maximum. In addition to the increased number of undergraduate students, there are also considerable increases in the numbers taking public health courses, and in those registered as research students.

VICTORIA UNIVERSITY OF MANCHESTER.

CERTIFICATES in School Hygiene and in Factory Hygiene have been awarded to Drs. G. D. Dawson and W. M. MacIlraith.

UNIVERSITY OF BRISTOL.

THE following candidates have been approved at the examinations indicated:

SECOND M.B.—E. J. Ball, R. B. Britton, N. Durant, F. V. Jacques, R. H. Tasker.
FINAL (*Part I*).—O. C. M. Davis.
D.P.H (*Part I*).—W. T. Torrance. (*Part II*).—J. R. Kay-Mouat.

UNIVERSITY OF EDINBURGH.

UNIVERSITY COURT.

A MEETING of the University Court was held on July 20th, when Principal Sir William Turner was in the chair.

Medical Education of Women.—An application on behalf of the teachers for the medical education of women in Edinburgh for renewal of recognition for next academical year was granted.

Additional Vans Dunlop Scholarships.—The Senatus reported that the funds for the endowment of the Vans Dunlop Scholarships would now admit of the foundation of two additional scholarships of £100 each, and that they had resolved to institute a new scholarship in pathological bacteriology and another in modern languages.

Extensions at the Royal Infirmary.—Payment was authorized of the cost of the work carried out at the Royal Infirmary under an agreement between the Court and the Infirmary in connexion with the fitting up of rooms for "side-room" teaching and the extension and equipment of the pathological department.

Degrees.

The following were among the degrees and other awards distributed at a graduation ceremony on July 10th:

M.D.—T. M. Anderson, ‡J. W. Cairns, E. F. Coghlan, J. Crocket, ‡J. A. Cruickshank, ‡J. M. Dewar, ‡T. R. Evans, ‡K. Fraser, *J. D. Gunn, ‡W. R. C. Heslop, J. Hume, E. C. C. Maunsell, R. C. J. Meyer, R. Park, ‡A. H. Porter, J. N. M. Ross, S. I. Silberbauer, W. D. D. Small, M. W. Smart, *S. A. Smith, K. R. Tampi, J. Tennant, A. B. M. Thomson, M. A. Wajid, A. S. Walker, ‡A. Watson, W. H. Williams, *L. S. Willox.

M.B., CH.B.—R. C. Aitchison, H. S. A. Alexander, R. H. Alexander, B. C. Ashton, C. Atkinson, Mary A. H. Baird, §R. G. Bannerman, Rachael M. Barclay, §R. C. Batchelor, H. W. Bell, J. G. Bell, J. W. Benuett, S. E. Bethell, J. Biggam, H. B. Binks, W. Bird, E. J. Blair, A. B. Brook, H. P. Caithness, A. Cameron, R. E. Cameron, H. E. Collier, A. N. Craig, J. W. Darling, T. M. Davie, W. M. Dickson, C. L. Dold, C. E. Dukes, G. K. Edwards, ‖J. D. Evans, F. B Eykyn, G. D Fairley, S. S. Fenwick, T. C. Findlater, E. S. Fowler, H. R. Friedrichs, T. A. Fuller, H. J. C. Gibson, R. E. Gibson, D. J. Glen, A. S. Glynn, H. P. T. Haddow, A. R. Hamilton, N. E. M. H. Hay, J. J. Healy, G. F. P. Heathcote, F. Henderson, Gertrude M. A. Herzfeld, J. B. Hogarth, K. Husain, Florence E. Inglis, B. O. Jarrette, C. P. M Joubert, P. W. J. Keet, C. G. Lambie, S. J. A. Laubscher, L. Levy, §P. MacCullum, T. M Fetridge, R. M. Mackay, E. F. W. Mackenzie, E. L. Mackenzie, J. J. M. Mackenzie, Jessie A. MacLaren, I. K. F. MacLeod, Jean M. M'Minn, F. G. Maenaughton, E. Mansfield, V. H. Mason D. J. Max, B. Mendelssohn, G. Millar, R. W. Miller, E. M. Molesworth, G. T. Mowat, R. McI. Muir, W. Murdoch, J. C. Neil, H. S. Palmer, C. C. Philip, G. S. Pirie, R. Power, §J. M. Pringle, M. Razakhan, H. A. Rippiner, R. L. Ritchie, H. C. Robins, C. Sand, A. C. Shaw, H. K. Shaw, B. Shires, H. J. Simson, H. C. Sinderson, T. W. Smart, ‖A. H. D. Smith, D. M. Smith, A. S. Taylor, J. S. Taylor, A. B. Theron, A. R. Thomson, §R. O. C. Thomson, R. Thorp, F. E. Tillyard, P. du Toit, Janet P. Walton, C. H. Wan, H. D. Welply, H. P. W. White, G. S. Williamson, ‖D. G. Wishart, E. W. N. Wooler, P. C. V. Woudberg, B. E Wright, G. D. Yates, J. B. Young.

D.P.H.—J. W. Gray, V. M. Lambah, N. S. Williams.

DIP. TROP. MED. AND HYG.—G. A. Borthwick, L. G. Fink, W. Mackenzie, D. Martin, S. L. Mitra, S. R. Rao.

* Awarded a gold medal for thesis. † Highly commended for thesis.
‡ Commended for thesis § First-class honours.
‖ Second-class honours.

Prizes.

The Cameron Prize in Practical Therapeutics was awarded to Professor Paul Ehrlich; the Gunning Prize in Forensic Medicine to S. A. Smith; the Ettles Scholarship to R. C. L. Batchelor; the Allan Fellowship to D. J. Glen; the M'Cosh Graduate's and Medical Bursaries to R. G. Bannerman; the Beaney Prize to P. MacCallum; the Monat Scholarship to R. C. L. Batchelor; the Conan Doyle Prize to C. P. M. Joubert; the Annandale Gold Medal to I. Keith-Falconer MacLeod; the Buchan Scholarship to P. MacCullum; the James Scott Scholarship to A. B. Theron; the Dorothy Gilfillan Memorial Prize to Gertrude M. A. Herzfeld; the Wellcome Medals in the History of Medicine to J. Schneider and W. Everett; the Pattison Prize to A. J. Caird

and W. Goldie; the Wightman Prize to R. G. Bannerman; the Cunningham Memorial Medal to R. Walker; and the Whiteside Bruce Bursary to H. J. Parish.

Examinations.

The following candidates have been approved at the examinations indicated:

FIRST M.B. (*Zoology*).—M. S. Abasa, A. F. Abbassi, A. Ainslie, Catherine J. Anderson, W. Anderson, T. F. Andrew, G. S. Bainbridge, R. F. Balmaio, I. C. C. Barclay, R. B. Barnfather, J. J. R. Biunie, C. Blake, S. Boodoosingh, H. Booth, K. S. Brown, C. Browulee, R. M. Burnio, R. M. Cairns, A. Campbell, E. Chonglop, A. C. Y. Chow, E. H. Counell, J. A. L. Cook, J. H. Crawford, Mary E. Cripps, A. W. G. Cumming, D. A. Cunningham, J. Davidson, W. H. Davies, F. J. Dean, A. A. Denbani K. S. Dick, Isabel M. Don, Jean D. Don, A. E. Dowden, W. J. Dunn, D. N. Dutt, C. G. L. van Dyk, C. G. N. Edwards, D. Fergusson, J. E. Fletcher, Millicent Fox, E. M. Fraser, G. S. Freeman, R. L. Galloway, R. M. Gardner, M. J. Gibson, G. S. Gill, J. Glover, E. H. Goodfellow, E. F. Gordon, G. H. Gunn, S. D. Gupta, H. Hastings, A. H. M. Henderson, W. H. Herberg, G. C. I. Hervey, C. Edith L. Hole, H. M. Horrox, L. J. Howie, G. J. Hughes, G. M. W. Johnson, Hana D. Knott, J. Laltoo, D. C. Lamont, R. L. Langley, J. Learmoot, J. E. C. Liddell, R. K. S. Lim, M. Lipschitz, T. W. Louden, G. A. Macadie, W. M. M'Alister, J. I. M'Caa, J. F. M'Conchie, Anne L. MacDonald, M. Macdonald, J. C. Macgown, R. B. MacGregor, D. P. M'Iver, D. Mackay, G. S. Mackay, Ella G. F. Mackenzie, J. F. Mackie, A. R. M'Lean, J. M'Nabb, Jane S. M'Phail, W. M. MacPhail, A. MacPherson, R. C. B. Macrae, Elizabeth M'Vicker, W. D. Walker, P. F. V. Walsh, R. B. Watson, K. B. Williamson, D. C. Wilson, J. T. Wilson, D. F. Yuille, M. R. Zada.

SECOND M.B. (*Physiology*).—J. J. Ackerman, J. Aitken, J. G. Allan, L. G. Allan, A. Badenoch, R. E. Batson, C. G. Booker, J. S. Bow, G. B. Brewster, J. C. Burns, W. E. Canekeratne, Gladys Carleton, Y. Y. Chan, F. Chilton, A. C. C. Craig, W. C. Craig, P. C. Datta, G. W. Dunlop, H. C. Elder, W. Everett, J. W. C. Fairweather, A. S. Garewal, B. R. Handoo, J. W. A. Hunter, R. H. R. Innes, A. Joe, D. A. Knight, J. L. Laidlaw, J. L. Lamont, J. P. Leckie, H. S. Lucraft, R. MacGarrol, A. G. Mackay, R. D. Mackenzie, W. D. Mackinnon, P. D. M'Lareu, G. J. M'Lean, H. H. Macrosty, R. Maller, F. A. Meine, D. A. Miller, R. N. Okholm, R. D. Osler, H. Patlausky, A. S. Paranjpe, J. E. Purvds, A. Robertson, Susan A. Robertson, S. S. Rosenthal, A. O. Ross, F. B. Sanderson, J. Schneider, S. Schwars, J. O. P. Smith, J. H. R. Smith, R. S. Smith, S. L. Smith, J. A. Stirling, V. A. Stookes, D. G. Stoute, J. H. Sypkens, H. W. Taylor, J. M. Tyrrell, L. Walker, R. Walker, W. A. Weatherhead, E. W. Wilbourne, B. O. Wilkin, J. Wolfson.

THIRD M.B. (*Materia Medica*).—A. G. Anderson, C. B. C. Anderson, H. F. Armour, A. Aziz, D. L. Baxter, K. P. Brown, R. R. Buchanan, H. W. Burne, A. J. Caird, R. D. Cameron, A. F. Campbell, J. E. Chow, F. W. Clark, A. Cleland, R. P. Cormack, J. A. Crawford, H. J. Davidson, D. G. Duff, J. J. B. Edmond, E. C. Fahmy, H. F. Ferguson, A. K. Gibson, W. N. Greer, Jane E. Hay, C. E. Hill, L. W. Innes, T. Janakiramiah, J. M. Johnstone, Muriel H. Kerr, J. B. Kirk, A. C. Kirton, A. R. Laurie, P. M. Little, T. J. Lloyd, A. L. M'Ilwaine, W. K. M'Intyre, I. Mackenzie, J. A. Mackenzie, R. M'Kinlay, R. M'Laren, Isobel M. MacLullich, J. de V. Meiring, J. Milne, H. S. Moore, G. Morris, W. G. F. O. Morris, G. Nicholson, P. H. Nixey, J. M. Norman, J. L. Owen, G. Paris, A. M. Paterson, J. R. Payn, J. E. Phillips, A. Prentice, E. G. Pyott, P. V. Ramanamurty, C. B. B. Reid, A. Robertson, P. A. Rostant, A. J. D. Rowan, B. J. Ryrie, G. C. Sahgal, J. G. R. Scarff, E. S. Seah, J. J. Shannon, B. H. Simon, C. I. Stockley, T. J. Sumner, A. J. Taylor, D. R. Thomas, W. E. Thompson, W. G. Thomson, R. A. Warters, R. R. S. Weatherson, M. E. Willcock.

THIRD M.B. (*Pathology*).—A. G. Anderson, C. B. C. Anderson, R. Andrew, Dorothea I. Baird, D. L. Baxter, J. Bennet, K. P. Brown, R. B. Buchanan, A. J. Caird, R. D. Cameron, A. H. Chu, T. F. Corkill, W. F. Craig, D. G. Duff, H. B. Dykes, J. J. B. Edmond, E. G. Fahmy, W. H. Ferguson, A. M. Ferrie, M. Foster, G. H. Fraser, A. M. Ghosh, N. Gilbio, A. K. Gibson, W. N. Greer, C. Harris, Jane E. Hay, C. S. van Heerden, Wilhelmina W. Hendry, C. E. Hill, F. Holmes, W. L. Hunter, R. L. Impey, E. Jamieson, H. B. Kirk, J. B. Kirk, A. C. Kirton, A. R. Laurie, Marjorie I. S. M'Gregor, J. R. S. Mackay, J. A. Mackenzie, N. Macleod, Isobel M. MacLullich, P. T. Majmundar, J. O. Marais, J. de V. Meiring, F. H. van der Merwe, G. H. Middleton, C. Milne, H. S. Moore, Isabella Morison, W. G. F. Owen Morris, D. J. Morrison, G. Nicholson, J. L. Owen, G. Paris, A. M. Paterson, D. H. Paterson, J. R. Payn, J. E. Phillips, A. Prentice, J. Ratcliffe, K. S. Ray, J. O. Reid, C. D. Ritchie, A. Robertson, B. J. Ryrie, J. G. R. Scarff, B. H. Simon, E. O. A. Singer, J. M. Smellie, E. D. Söderström, E. T. N. Taylor, G. R. Waller, Gladys Ward, R. A. Warters, A. A. Watson, T. P. Woo, P. H. Young, C. W. Ng-a-Yow.

FINAL (*Forensic Medicine*).—M. H. Alikhan, F. A. Anderson, J. M. Anderson, J. S. Armstrong, F. W. W. Baillie, T. Y. Barkley, I. J. Block, R. B. Boston, T. C. Bowie, J. Brown, H. J. Bruwer, W. K. Chalmers, W. M. Christie, A. G. Clark, T. L. Clark, A. Clarke, I. A. Clarke, W. A. Cochrane, C. H. H. Coetzee, M. K. Cooper, J. R. Crolius, M. W. Danzig, J. C. Dobson, D. Dunlop, R. B. Eadie, Dallas S. Falconer, A. J. Ferguson, Mary O. Fergusson, G. W. M. Findlay, F. J. Ng-a-Fook, A. W. Forrest, E. Fullerton, E. L. Galgut, W. Goldie, A. W. Gunn, F. M. Halley, J. A. Henderson, J. Hepburn, H. A. Hewat, R. M. Hume, J. E. Hurworth, E. B. Isreal, O. D. Jarvis, G. G. S. Johnston, F. J. C. Johnstone, C. W. S. D. Jones, S. A. Kuny, A. C. Laing, P. W. Lam, J. L. Lamond, E. Law, J. Lawson, R. Lawson, H. Lewis, A. J. E. G. Lim, H. H. Lim, J. G. Louden, J. E. M'Cartney, Helen M'Dougall, I. M'Dowall, R. J. S. M'Dowall, G. C. M'Ewan, M. M'Kerrow, Marjory Macnaughton, P. C. MacRae, J. W. Malcolm, D. Malloch, Mary Martiu, A. P. Meiring, M. F. Meiring, R. W. H. Miller, S. N. Mitra, J. J. Molyneux, T. C. StC. Morton, R. F. T. Newbery, C. H. Newton, R. N. Phease, W. B. Postlethwaite, J. W. Potter, W. J. Purdy, N. L. Reis, C. Resnekov, J. W. G. H. Riddel, J. W. Riddoch, J. Rodger, G. M. Scott, A. H. Shenuan, J. M. Smith, R. B. Stewart, S. H. Stewart, T. M. J. Stewart, B. P. Varma, J. Walker, J. W. Watthews, L. H. Werden, J. M. Wishart, A. Wotherspoon, F. G. Wright, Margaret K. J. Wright, C. J. Young.

FINAL (*Public Health*).—F. A. Anderson, J. M. Anderson, J. S. Armstrong, F. W. W. Baillie, T. Y. Barkley, I. Block, R. B. Boston, T. C. Bowie, J. Browne, B.A., W. K. Chalmers, W. M. Christie, A. G. Clark, T. L. Clark, I. A. Clarke, W. A. Cochrane, C. H. H. Coetzee, M. K. Cooper, J. R. Crolius, M. W. Danzig, J. G. Dobson, D. Dunlop, R. B. Eadie, D. S. Falconer, Mary O. Fergusson, G. W. M. Findlay, F. J. Ng-a-Fook, A. W. Forrest, E. Fullerton, E. L. Galgutt, Helen M. Gall, W. Goldie, A. W. Gunn, F. M. Halley, J. A. Henderson, J. Hepburn, H. A. Hewat, Helen G. Hewat, Y. H. Hoashoo, R. M. Hume, J. E. Hurworth, M. P. Inglis, O. D. Jarvis, L. F. E. Jeffcoat, G. G. S. Johnston, C. W. S. D. Jones, S. A. Kuny, A. C. Laing, P. W. Lam, N. B. Laughton, E. Law, J. Lawson, R. Lawson, H. Lewis, A. J. E. G. Lim, H. H. Lim, J. G. Louden, J. E. M'Cartney, Helen M'Dougall, I. M'Dowall, R. J. S. M'Dowall, G. C. M'Ewan, Marjory Macnaughton, J. W. Malcolm, D. Malloch, A. P. Meiring, M. F. Meiring, E. S. Mellor, R. W. H. Miller, S. N. Mitra, J. J. Molyneux, T. C. St. C. Morton, R. F. T. Newbery, C. H. Newton, R. N. Phease, J. W. Potter, O. D. Price, W. J. Purdy, A. Ravunni, N. L. Reis, C. Resnekov, J. W. G. H. Riddel, J. W. Riddoch, J. Rodger, C. Russell, G. M. Scott, W. Shanks, A. H. Shennan, J. M. Smith, L. J. Spence, R. B. Stewart, S. H. Stewart, T. M. J. Stewart, H. Tren, B. P. Varma, J. Walker, J. W. Wathews, L. H. Werden, J. M. Wishart, A. Wotherspoon, F. G. Wright, Margaret K. J. Wright, C. J. Young.

UNIVERSITY OF DUBLIN.

Degrees.

THE following degrees have been conferred:

M.D.—H. R. M. Ferguson, E. S. Johnson, C. O'Brien, R. O. Smyth, R. E. Tottenham, H. L. W. Woodroffe.

M.B., B.CH., B.A.O.—T. W. Allen, J. N. Armstrong, C. D. M. Buckley, J. G. Butt, J. C. A. Dowse, J. S. English, H. R. Ford, N. H. H. Haskins, Rev. E. E. Lavy, T. A. Lawder, H. C. D. Miller, J. D. Oliver, T. D. Power, F. A. Roddy, W. A. Ryan, W. O. Tobias, W. R. L. Waters, G. H. Wood.

Examinations.

The following candidates have been approved at the examinations indicated:

PRELIMINARY SCIENTIFIC (*Chemistry and Physics*).—A. G. Bewley, R. P. Hemphill, T. M. Bentley, F. Gill, R. M. D. Devereux, P. C. Parr, L. Albertyn, J. F. Stewart, E. E. Rollins, J. W. Scharff, J. Posner, E. B. Edge, W. F. McConnell, J. M. Semple, E. F. Wilson, T. H. R. McKiernan, J. M. Hill, J. H. B. Levis, J. A. Acheson, T. S. McDouald, D. McElwee, J. C. Fouché, J. N. H. Murphy, T. B. H. Tabuteau, J. C. Campbell-Henry, P. C. Cowan, N. Grey, S. W. Russell. (*Botany and Zoology*).—R. P. Hemphill, L. Albertyn, J. A. Acheson, R. G. Lewis, E. F. Wilson, Gertrude Rice, W. B. Briggs, S. A. Clark, W. L. Lloyd, W. L. Young, G. H. Davis, J. W. Scharff, S. W. Russell, E. B. Edge, A. H. Thompson, C. W. Parr, H. A. Lavelle, R. M. D. Devereux, W. F. McConnell, J. E. McCormick, J. H. Coolican, T. Madill, J. F. Stewart, E. F. W. Smith, H. Birney, E. S. E. Mack, E. E. Rollins, I. W. Beatty, A. Blagoff, T. R. Warren, R. N. Nunn, H. J. Wright, G. C. Robb, W. Sweetnam, C. D. Shortt, P. Casey, F. W. Godbey, W. A. Shannon, S. J. Laverty, G. R. G. Smyth, J. D. Watson. (*Botany*).—J. M. Hill.

INTERMEDIATE M.B., B.CH., B.A.O. (*Part I.*).—E. D. McCrea, W. R. Fearon, B. A. McSwiney, A. R. Barlas, A. L. Gregg, R. N. Murray, J. R. Duggan, W. P. Elford, W. H. Flinn, S. C. Mitchell, J. J. Beasley, W. P. Lubbe, F. J. Smith, C. P. Chambers, G. W. B. Shaw, P. S. Snell, W. J. M'Clintock, R. W. Neabitt, C. L.

McDonogh, A. H Davidson, F. C. Tucker, M. C. Dippenaar, H. H. Molloy, F. G. Henston, J. McClelland. (*Part II*).—T. J. Lane, S. V. Furlong, S. R. Hill, J. P. Macnamara, E. Parker, F. J. Murphy, J. T. Westby, F. M. Ferguson, F. A. McHugh, B. A. Merrin, J. J. Keatley, R. Gordon, G. L. Murphy.

FINAL, (*Part I*).—H. Daniel, E. D. T. Hayes, J. W. Bigger, R. W. Shegog, G. Jonghin, Violet M. Deale, G. O. F. Alley, D. S. Martin, H. Mitchell, W. F. Wilson, A. F. Grimbly, T. Stanton, A. J. Horne, E. J. Hamilton, R. W. Acheson, D. H. Hall, A. L. Wilson, W. J. Dowling. (*Materia Medica and Medical Jurisprudence*).—F. W. O'Connor, T. G. Roche. (*Pathology*).—W. B. Walker. (*Part II, Medicine*).—J. N. Armstrong, P. W. McKeag, G. H. Wood, F. J. O. King, T. D. Power, H. C. D. Miller, J. C. A. Dowse, C. D. M. Buckley, W. A. Ryan, Dorothy E. Webb, F. A. Roddy, H. R. Ford, T. A. Lawder, W. H. Elliott, W. O. Tobias, Amy F. Nash, J. S. Dockrill, J. H. Fletcher. (*Surgery*).—J. C. A. Dowse, E. E. Lavy, J. C. Ogilvie, J. P. Quinn, T. W. Allen, E. Evans, F. S. Mitchell, C. D. M. Buckley, R. I. Sullivan, A. G. Varian, W. R. L. Waters, J. H. Fletcher, G. H. Wood, F. R. Dougan, N. H. H. Haskins, B. C. O. Sheridan, W. O. Tobias, F. J. O. King, J. N. Armstrong, H. R. Ford, R. A. Anderson, W. M. Snodgrass. (*Midwifery*).—N. M. Boyce, W. E. Tyndall, R. R. G. Atkins, J. S. Robinson, E. Robinson, F. Harris, J. V. Cope, H. S. Collins, Clara B. M. Adderley, W. B. Cathcart, W. M. Snodgrass.

D.P.H. (*Part I*).—J. R. D. Holtby, E. O'Connor, A. V. J. Richardson, H. T. S. McClintock, K. L. Kapur. (*Part II*).—A. V. J. Richardson, G. H. Culverwell, K. L. Kapur, R. H. C. Lyons, E. O'Connor, H. T. S. McClintock.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH.

THE following candidates have been admitted to the Fellowship:

R. B. Blair, J. J. Brown, A. B. Cardew, H. A. Gibson, D. P. Goil, W. W. Greer, A. G. Hamilton, L. Hirsch, J. Honeyford, E. H. Howard, G. L. Little, J. McClellan, J. D. MacEwen, E. Muir, J. B. Wilkie.

The following have been granted the single Licence of the College:

T. J. Williams, Vinayak L. Sathe.

UNIVERSITY COLLEGE, LONDON.

Appointment.

THE newly-created office of Lecturer and Demonstrator of Anatomy in the Faculty of Medical Sciences has been filled by the appointment of Dr. T. B. Johnston, a graduate of Edinburgh and Lecturer on Anatomy in its University.

Awards.

The following silver class medals have been awarded: Senior Anatomy, E. Sakoschansky; Junior Anatomy, G. V. Anderson; Senior Physiology, M. Schwartz; Organic and Applied Chemistry, J. de S. Wijeyeratne; Hygiene, C. I. de Silva. The winner of the gold medal in the Junior Pharmacology Class is Mr. B. Maclean.

CONJOINT BOARD IN ENGLAND.

THE following candidates have been approved at the examinations indicated:

FIRST COLLEGE (*Part IV, Practical Pharmacy*).—E. B. Alabaster, H. Amin, G. K. Arthur, E. Atkinson, E. R. Batho, J. H. Bayley, A. G. Bodman, M. V. Boucaud, C. R. Cade, P. Cheal, G. E. Chissell, P. C. Collyns, A. R. Crane, T. H. R. Davies, L. B. A. de Kretser, E. R. Dermer, M. A. El Dardiri, A. M. El Mishad, A. H. El Rakshi, T. G. Evans, M. Fahmy, A. Foster, A. A. E. R. Galal, E. F. Gillett, F. E. Harger, A. G. Hewer, C. E. Hopwood, E. L. Ivens, W. A. Jolliffe, F. C. Lapage, G. N. Lomax, A. V. Lopes, J. McDonnell, B. H. Mellon, T. S. Nelson, T. Owen, C. S. Parker, F. Y. Pearson, D. J. Platts, J. W. Rammell, C. R. Reckitt, J. H. E. Sandford, J. M. Smith, J. M. Stack, F. R. Sturridge, C. P. Thomas, H. M. Wharry, R. H. Williams, S. Yahilevitz.

SECOND COLLEGE (*Anatomy and Physiology*).—E. Ahmed, D. H. Anthony, P. A. Ashcroft, R. Aspinal-Stivala, Y. Aziz, P. Banbury, N. A. H. Barlow, M. C. Breese, J. L. D. Buxton, H. H. Castle, E. A. Clegg, A. M. Clément, C. F. Cobb, C. J. C. Cooke, Jean Crétin, C. L. Curle, A. Y. S. Davies, A. B. Dunmere, S. G. Dunn, F. O. Fehrsen, P. E. F. Frossard, A. Girgis, Constance Hart, J. A. Hill, G. Hoffmeister, F. H. Hyland, L. G. C. Iniago, M. Kamil, G. S. L. Kemp, G. E. Kidman, K. F. McAlpin, M. W. H. Miles, J. O. R. Montocchio, R. Moser, W. W. Newton, A. L. Packham, J. A. P. Pereira, A. Rose-Innes, A. H. Sany, J. A. A. P. Scott, N. M. Sen-Gupta, J. P. R. Tennekoon, I. Tewfik, K. R. Traill, W. A. Turner, P. Ward, W. H. White, J. H. Wiseman, A. F. Wyatt.

CONJOINT BOARD IN SCOTLAND.

THE following candidates have been approved at the examinations indicated:

FIRST COLLEGE.—A. J. Meek, L. Macduff, J. Chambers, P. C. H. Homer, W. V. Jackson, H. G. Smith, D. C. Thiems, S. D. Vania, E. L. Adendorff.

SECOND COLLEGE.—J. C. Bedwell, W. A. Mein, F. C. J. Mitchell, J. H. Brown, D. M'G. Stewart, J. Byrne, Martha H. Hoahing.

THIRD COLLEGE.—E. A. Neilson, B. C. Haller, T. D. Renwick, J. Bannerman, W. J. F. Craig, A. Evans, J. V. R. Rohan, A. W. M'Gregor, J. E. Ainsley, W. H. A. D. Sutton, R. V. Clarke, J. P. Fairley, L. Fraser, J. H. Blackburn, A. Parker.

FINAL.—J. K. Venables, K. G. Fraser, T. E. Lawson, D. C. Graham, R. M'C. Paterson, R. E. Illingworth, J. M. Chrystie, E. C. Brooks, N. R. Whitaker, W. Millerick, J. M. Beyers, W. Chapman, T. B. Truter, J. V. Duffy.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Promotion to Staff Surgeon.

AT the recent examinations held at Greenwich and London the following officers qualified for promotion to the rank of Staff Surgeon, R.N.:

George M. Levick, Arthur T. Rivers, Thomas R. L. Jones, Kenneth H. Hole, M.B., Gilbert F. Syms, Hugh F. Briggs, M.B., Michael P. Fitzgerald, M.B., James Barrett, M.B., Gordon A. Jackson, M.B., B.A., Alfred G. Malcolm, M.B., Horace C. Devas, Harry W. Nichols.

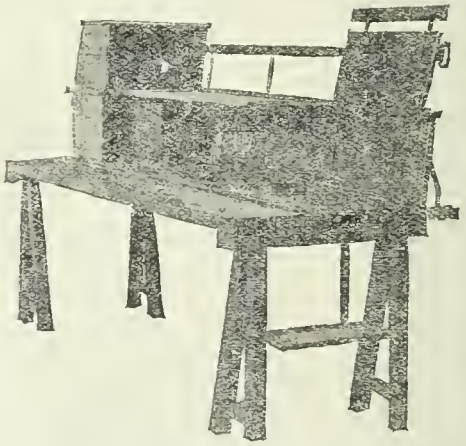
Two of these officers—Surgeons Hole and Syms—obtained first class certificates, thus becoming eligible for accelerated promotion to the extent of twelve months' seniority.

THE TERRITORIAL FIELD AMBULANCES.

A Model for Teaching Wagon Drill.

CAPTAIN JOHN MILLER (R.A.M.C.T.), 3rd North Midland Field Ambulance, writes: One of the greatest difficulties of a Territorial field ambulance is the proper teaching of the wagon drill to both officers and men. In many cases the drill halls are too small to admit an ambulance wagon, or where the ambulance wagon is housed away, it cannot be brought to the drill hall on account of the want of horses. Wagon drill is therefore limited to two or three afternoon field days before camp, when the time is too short to teach the details of wagon drill in a proper manner.

It occurred to me to construct a dummy ambulance wagon which can be put up in any drill hall or lecture room. It consists of a half long section of the body of an ambulance wagon Mark 5 star, the off side, full size, with the upper and lower compartments, the locker under the upper compartment, and



the whole width of the gangway. The front is boarded up to the level of the driver's seat, having the two holes in it for the passage of the handles of the upper stretcher. The sides and seats are a facsimile of ambulance wagon Mark 5 star. The back is open, having no tailboard, only a fixed step as is shown in the photograph. The body of the dummy wagon is bolted on to two four-legged trestles, so that the dummy stands at the same height as an ambulance wagon on wheels; two of the legs of each trestle are screwed to the floor by iron brackets, so that the dummy stands quite steady, the whole being painted the regulation colour.

The dummy was made under my directions by two members of the unit, the wood part being done by Quartermaster-Sergeant Tonks and the iron work by Staff-Sergeant Richards; the whole cost was £9. It is quite easy to take the dummy off its trestles for removal.

In this unit we have found the dummy to be of great value in teaching the whole of the wagon drill to all ranks. The above dummy wagon would be of great service not only to the Territorial field ambulances, but also to ambulance brigades anxious to learn the wagon drill.

FIELD-MARSHAL EARL ROBERTS announces that the committee of the Capetown Cathedral Memorial Fund, which was formed in 1901 for the purpose of building the east end of the cathedral at Capetown as a memorial to those who died and a thank-offering for those who were spared in the war in South Africa, has almost finished the work entrusted to it. The Roll of the Dead, written on vellum and beautifully illustrated, will be open to the inspection of the subscribers to the fund, and to the general public, at the Royal United Services Institution, Whitehall, until the end of the present month. The manuscript will eventually be deposited in the Shrine in Capetown Cathedral.

Medico-Legal.

STEVENS v. BRITISH MEDICAL ASSOCIATION.

THE second hearing of this case was commenced before Mr. Justice Shearman and a special jury on July 15th. On the former occasion (October, 1912) the jury failed to agree. The action was brought by Mr. Charles Stevens, managing director of Stevens and Co., Ltd., a company formed for the sale of a specific for the cure of consumption, to recover damages for a libel alleged to have been published in *Secret Remedies*. The defendants denied that the words published were capable of the meaning alleged, and said that so far as the allegations consisted of fact they were true, and so far as they were expressions of opinion they were fair comment on a matter of public interest.

The plaintiff appeared in person; Mr. Colam, K.C., and Mr. Dickens (instructed by Messrs. Hempsons) were for the defendants.

The plaintiff, in opening his case, said that he claimed to have discovered a positive cure for consumption which had made a new man of him some seventeen years ago. He had been sent out to South Africa with two months to live. The book, *Secret Remedies*, in effect charged him with being a swindler. If the Association's analysis was correct it was true that he had been foisting a worthless remedy upon the public; but if the analysis was incorrect they (the Association) were getting money by false pretences, besides committing a gross libel upon him. A number of doctors had been called at the last trial and had said——

Mr. Justice Shearman: We cannot have what was said at the last trial.

Mr. Stevens then proceeded to read passages from *Secret Remedies*, p. 29 et seq. He had complained in his statement of claim of the following: "... But with other proprietary medicines it is quite clear that the makers cannot in the slightest degree believe in the claims they make; the 'remedy' in these cases is some substance or mixture devoid of medicinal activity, or possessing some slight therapeutic property having no relation to the disease for which the nostrum is put forward as a cure. It is often, indeed, for inert preparations that the most extravagant and emphatic claims are made; the makers and the advertisement writers whom they employ are untrammelled by any necessity of squaring their statements with the real properties of the thing to be recommended, and having set out consciously and deliberately to deceive, they are able to give their whole attention to telling the most effective stories in the most plausible manner and reaping the maximum of payment for the minimum of expenditure. ..."

"It is the victim's money that is wanted; therefore let the price be fixed high, and the advertisements be written up to it. ..."

"The sale of another preparation advertised as a cure for consumption, Stevens's Consumption Cure, is conducted in a very similar way, but this time the herbs are said to be African, and the odd names they bear certainly have a Kaffir flavour. ..."

"Although Stevens is so engagingly candid about his rivals, he follows the plan of sending one letter after another to any sufferer whose name he may have obtained, a system which seems to have been invented in America; it is certainly cheaper than bold advertisement in newspapers, and is apparently found even more satisfactory, as it enables the vendor to give individual attention to the depth of his correspondent's pocket, if not the severity of his disease. ..."

"The farce of revealing a formula by the employment of such fancy names as these is one of the oldest dodges of the quack medicine man, and no such names as 'umckaloabo' and 'chijitse' appear in any available work of reference on pharmacy."

The analysis was as follows: "The medicine was a clear red liquid, and analysis showed it to contain in 100 fluid parts 21.3 fluid parts of alcohol, 1.8 parts of glycerine, and 4 parts of solid substance; this solid substance contained about 1 part of a tannin and 0.2 part of ash, the remainder being extractive. No alkaloid was present, and no other active substance could be detected. The solid substance agreed in all respects with the solids of decoction of krameria, or a mixture of this decoction with a little tincture of kino. The formula thus appears to be approximately: Rectified spirit of wine 23.7 parts by measure, glycerine 1.8 parts, decoction of krameria (1 in 5) to 100 parts by measure."

What he (the plaintiff) objected to was the suggestion that his remedy contained krameria or kino, which it did not do. He pointed out that he first put his remedy on the market as sacco, but was swindled out of it.

Mr. Colam: If the plaintiff is going to merely read the libel and then put us to proof, he cannot make statements or comments.

Mr. Justice Shearman: That is so.

Having read the libel, the plaintiff said that was his case. He was now entitled to call upon the defendants to justify.

Mr. Justice Shearman: The plaintiff may by leave call rebutting evidence.

Mr. Colam, in opening the defendants' case, said that the object of the book referred to was to protect the public either against remedies which do actual harm or which are not apt to perform the cures they are said to perform. If a man appealed to the public as the plaintiff had done, persons were entitled to fairly comment upon his statements.

Mr. Justice Shearman: That is for me.

The comment would, of course, have to be fair and accurate. The defence was that the facts were true and the comments were fair. There was no doubt that the substance which the plaintiff sold was a good cough mixture. It relieved the cough, and a consumptive patient, being of a sanguine temperament, was inclined to imagine that it was a cure; but to say that it was a cure for the "Great White Plague" was a total misrepresentation.

Mr. Justice Shearman: You are relying on fair comment. The case has been opened by your opponent as a libel which is justified. If you mean to justify, ought not the pleadings to be amended so as to let the plaintiff treat the case in that way?

Mr. Colam: I do not desire to amend.

Mr. Justice Shearman: I do not desire to rule whether it is justification or fair comment, but the bent of my view at present is that you are only entitled to treat it as fair comment. The stronger the comment is the more facts you must prove.

Continuing, Mr. Colam said that this mixture could not from any point of view be said to be a cure for consumption in any sense of the word, much less a cure for consumption in its last stages. In an advertisement in the *News of the World* this gentleman said that persons should consult him when doctors and specialists could do no more for them. His cry was, "No cure, no pay," and that he could give an absolute cure when every one else had given up the case. Was not that trying to frighten people? It was against advertisements of this kind that the defendants protested. He had published advertisements galore—"No cure, no pay," and "Absolute cure." He had written: "It has been admitted the world over that there is no remedy known to the medical fraternity to really cure consumption, so it is preposterous to claim the ordinary drugs that are known to every chemist to cure this disease, just because they are given a fancy name, and are advertised by a Polish or German Jew; it is not only preposterous but a wicked swindle." He also said: "I do not say in my advertisements 'Consumption can be cured,' 'Consumption is curable,' or any such evasive remarks, but I say *I will guarantee to cure you* if you are consumptive, or *return your money* in full, and that my terms are 'No cure, no pay.'" Moreover, as to the analysis, the defendants did not say the medicine appeared to be made of krameria; they merely said it might have been so made. The plaintiff wanted to create an appearance of being perfectly fair by desiring to have a doctor in attendance; but in one of the cases he would show that the plaintiff had told the patient not to pay any attention to the doctor. He (counsel) would prove by many eminent medical witnesses that there was no drug which could cure consumption, and that for an all-sufficient reason. When the bacillus once got hold in the lungs it became entrenched behind a wall of tissue, and the blood could not get at it. He would be able to prove that, so far from being a germ killer, the bacillus would grow in the plaintiff's mixture. The plaintiff offered his remedy free to the doctors. That was a very safe offer to make, as no doctor would venture to give to his patient a drug the properties of which he did not understand. Although the public advertisements spoke of absolute cure, when it came to the actual guarantee it was that no trace of tubercle would be found after three months' treatment. It would be found that in a number of cases which could be proved the plaintiff did not repay the fees when his treatment failed. The statements that the cure was "a vegetable germicide, a blood purifier, stomach cleanser, and a nerve stimulator" were entirely false. The plaintiff had issued a circular to the medical profession saying that the formula for his remedy was "80 grains of umckaloabo root and 13 and one-third grains of chijitse to every ounce prepared according to British Pharmacopoeia methods." But this was vain and illusory, because neither of the two substances mentioned could be found in any pharmacopoeia in the world. As to the analysis, he (counsel) would call the gentleman who made the analysis, and he would prove that it could be made from krameria. In *Truth* of September 14th, 1905, at p. 631, an article had appeared with reference to the plaintiff.

Mr. Colam read this article, and said that the plaintiff had subsequently published extracts from it which were calculated to mislead, inasmuch as certain expressions of opinion were wholly omitted. For instance, *Truth* had condemned the plaintiff's statement that he had found a cure for consumption. He would now draw attention to some of the "cases" with which the plaintiff had dealt. On July 15th, 1908, a man wrote from Spain saying that he had spent several years working in the mines in the Transvaal, and that he was suffering from a bad cough. On July 22nd the plaintiff wrote saying that his correspondent probably had a "touch" of miner's phthisis, and that some years before he (the plaintiff) had discovered a cure for this complaint. After undergoing the treatment for three months the patient lost weight to the extent of 20 lb. He went on procuring further supplies of medicine for many months. In a letter written in March, 1909, the plaintiff said, in effect, "This is a complicated case, which I ought to have seen." That was his method of hedging! Later on the patient wrote to point out that he had been taking the medicine for six months, when the plaintiff said, "It all depends upon the state of the lungs and the grip which the disease has of one." He did not say that in his advertisements. He had said in the first instance, "You seem to have a touch of the

disease!" A month later the patient's wife wrote to ask for something to relieve her husband, and eventually, when the patient died, the plaintiff refused to pay back anything which had been paid. The plaintiff wrote in one of his pamphlets: "If it fails, no matter through whose fault, I will return the money!"

In another case, that of a man named Bramley, after treating him for some time, he wrote to his patient, "Think yourself lucky if you get cured within a year." Counsel proceeded to read a number of letters passing between the plaintiff and various persons whom he had treated. He also mentioned a case in which the widow of a man who died of consumption had to bring suit in the county court to recover money paid for medicine. It was noteworthy that although the plaintiff said in his advertisements the cough would be the first thing to disappear, he pointed out in a letter to Bramley that the cough might be one of the last symptoms to disappear. Mr. Colam said that the cases to which he referred showed that the plaintiff professed to effect cures which he could not do. Consumption was one of those peculiar diseases where patients suddenly recovered without treatment of any kind. A change of scene, climate, and occupation, might also assist nature to throw it off. Although there were some cases in which the plaintiff may have thought that his remedy had effected a cure the fact probably was that the cure was due to a change of surroundings.

Mr. E. F. Harrison, B.Sc., analyst and consulting chemist, of Chancery Lane, examined by Mr. Dickens, said that in 1908 he made certain analyses for the British Medical Association which were to be published in *Secret Remedies*. He was partly responsible for the articles which had appeared in the JOURNAL and were republished in *Secret Remedies*. He ordered a bottle of Stevens's medicine in April, 1908, and received a letter from the plaintiff offering to guarantee a cure or return the money. On May 3rd he had another letter from the plaintiff again pressing him to take up the treatment. A number of printed documents were sent with the letters.

Mr. Justice Shearman: You will notice, gentlemen, that these letters were written in 1908.

Continuing, witness said he received a bottle containing a red clear fluid. He stood by his analysis. The word "extractive" meant material which could not be identified. In the present case on examining the solid extract he had found a tannin, that is, a substance which belonged to the class of tannins. The ash was a mineral residue which was present in all drugs. He tested specially for alkaloids and found there were none. He also applied as many general tests as were reasonably available for any other active substance but could detect none. The tannin and red colouring matter were rare in medicinal drugs, and he tried to remember one which did contain it. Krameria or ratany (to give it its common English name) was one, and kino was another. He then examined various preparations of krameria.

Mr. Justice Shearman: It was by various experiments that you came to the conclusion that the substance resembled tincture or decoction of krameria?—Yes.

Continuing, witness said that in April, 1912, he made another examination, when the result was different. The medicine then contained less alcohol and more tannin. The extractive was the same as before. He had had other bottles sent him this year, one labelled "Stevens Mixture (1908)," and the other "Umckaloabo tincture." The latter contained 18.9 parts alcohol, 5.9 glycerine and 1.7 of deposit. The liquid after the deposit contained rather less than 1 per cent. of tannin. He had also examined some 1914 medicine, in which case the alcohol was 12.8 and glycerine 6.7. The deposit at the time of analysis was 0.7 and tannin 0.5; extractive including ash 2.3. As regards the qualitative result all the samples had a general resemblance to krameria and kino but they differed quantitatively and in their reactions.

Cross-examined by the plaintiff, witness said he was 45 and had examined drugs for many years. This kind of analysis required a good deal of experience. Some part of what appeared in *Secret Remedies* was not in the JOURNAL, but he wrote the whole of the two articles in the BRITISH MEDICAL JOURNAL. He was not a medical man.

Mr. Stevens: Do you say that that analysis on p. 32 is correct?—I intended to state what appeared to be in the medicine which I analysed.

Continuing, witness said he did not know whether the medicine was made of krameria. Nor did he know whether there was kino in it, and he did not intend to convey that there was.

Mr. Stevens: You say "It appears to be approximately——." If his lordship said to you "You appear to be telling the truth," would you infer that he thought you were telling the truth?—No. I would infer that he thought I appeared to be telling the truth.

Mr. Justice Shearman: The meaning of the words of the libel is for the jury.

Continuing, witness said that krameria was not a cure for consumption.

Mr. Stevens: If a man sold it as a cure for consumption, would he be a swindler?—No, he might be a fool. If he was not a fool, he would be a swindler.

Continuing, witness said that the alcohol was probably used as a means of extracting a medicine. In addition to the alcohol and glycerine, he could swear to the existence of a tannin

Mr. Stevens: Can you tell me the percentage of hydrogen in tannin?—No. I cannot carry such figures in my head.

Continuing, witness said it was true that there was a large difference between different kinds of tannin. There were possibly twenty tannins in that class, and he could not say to which class it belonged. As to "extractive" that was an unidentifiable substance.

Mr. Justice Shearman (at 4.15 p.m.): I shall sit until you finish with this witness.

Continuing, witness said that he had made many analyses in 1908. He evaporated down a 2-oz. bottle.

Mr. Justice Shearman: The only evidence this gentleman has given is contained in his analysis which is here set down in the book.

Mr. Stevens: Upon what grounds do you say I victimized people?

Mr. Justice Shearman: That is for the jury.

Continuing, witness said that tartarated antimony to the best of his recollection precipitates every kind of tannin.

Mr. Stevens: Do you say that I deliberately set out to deceive?

Mr. Justice Shearman: That is for the jury.

Re-examined by Mr. Colam, witness said that having regard to the analysis it was obvious the substance could not be a germicide. There was no active principle in it.

On July 16th, 1914, Mr. Hempson having proved the purchase of certain bottles of the plaintiff's remedy in 1912, Dr. Landon Hill gave evidence.

Charles Edward Sage, F.I.C., M.P.H.C., consulting and analytical chemist, examined by Mr. Dickens, said that he had had many years' experience of analysing drugs. He had a sample of the so-called cure before him on April 24th, 1912. It contained by weight alcohol, 11.23; glycerine, 6.84; tannin, 1.04; organic colour substance, 2.76; mineral matter, 0.2; water, 77.93. He could identify no special drug and no active substances. In most respects the medicine agreed with krameria. He had also tested the cure and a bottle of umckaloabo extract in 1914. He found no active medicinal principle in either sample; the only thing was tannin, which was slightly astringent. These samples varied slightly, both qualitatively and quantitatively, from the 1908 mixture.

Cross-examined by the plaintiff, he said he could not say whether the various samples were or were not made from the same plants. In the umckaloabo extract he found a trace of glucose after several months. He could not find krameria. He could not say whether the residue had any medical activity or not. He did not know what it was or what it came from. He tested the medicine with tartar emetic, but found nothing conclusive.

Mr. William Hardcastle Smith, a clerk in the Great Northern Railway, said he went to see Mr. Stevens in 1911 about two fellow clerks who had been treated. He told Mr. Stevens that he suffered from colds, which had a tendency to go to his chest. Mr. Stevens offered to examine him, and did so with a stethoscope. He led witness to understand that his left lung was in a bad condition, and had been so for several years. Witness was upset, and went to see Dr. Distin on the following day. Mr. Stevens had given him a bottle of medicine. After seeing Dr. Distin he saw Dr. Price. Having seen them, he wrote to Mr. Stevens to say the doctors told him there was nothing wrong with his lungs. In reply Mr. Stevens wrote asking him to see him again, but witness did not do so.

Cross-examined, witness said that he did not visit the plaintiff as a prospective patient. Witness was prepared to pay for what was done, but was not asked to pay. When he went to see the plaintiff witness had a cold in the head. He was still subject to colds, but during the last two years he had had better health than ever before. He did not remember the plaintiff asking him to let him have a sample of his sputum.

Dr. Bulloch, M.D., F.R.S., Professor of Bacteriology in the University of London and Bacteriologist at the London Hospital, examined by Mr. Colam, said that a bottle of umckaloabo extract was handed to him in April, 1914. The bottle of 6 oz. was marked 11s. Certain documents were in the case with the bottle. One of these was a certificate by a consulting bacteriologist. This gentleman had certified that the medicine contained no harmful ingredients; that certain medical men had found it beneficial in consumption cases; that it contained no poison or alkaloid; that it was capable of killing the bacillus of phthisis; and that it contained a new drug of some kind. It was stated in the pamphlet that a 1 in 100 solution was able to kill a bacillus in ten minutes. The witness set about making a test to see the effect of the medicine on bacilli. He took a pure cultivation of the bacillus from a patient at the hospital and also a bovine culture. He tested the effect of the medicine on a culture of bacilli. In one case the medicine was diluted to one in a hundred. He shook them together so as to give the medicine as much chance as possible. At various periods he took a quantity of the bacteria out, and planted them on a good medium to see if they were alive. He found that with the dilution of 1 in 100 there was still an abundant growth of tubercle after ten minutes in the medicine. The pure medicine also failed to kill the bacillus in fifteen minutes, and it was still living after forty-eight hours. The latest period was six days, when there was still an abundant growth, but after twenty-six days he could get no further growth. Apparently the medicine was capable of destroying the growth in time, but growth would be stopped in time by alcohol or tannin. When medicine was taken it was very much diluted in the blood, and if taken through the stomach much of it was digested and very little got into the blood. One must admit that it had a certain amount of retarding action, but in the human body its power was infinitesimal. A large

number of experiments had been made and various substances had been tried as cures for consumption, but none had succeeded. It had been discovered that cyanide of gold to a dilution to one in a million would prevent the growth if injected into the blood, but he knew of no medicine which would do so when taken through the stomach. The tubercle bacillus was notoriously hard to kill. When the lung became consumptive it became infected with other bacteria, with the result that it was coughed away. In the course of his experiments he found that he got other bacilli besides those of tubercle. He found that there were 60,000 bacteria in every cubic centimetre of the umckaloabo mixture itself, which clearly proved to him that it was neither antiseptic nor germicide. He had also injected the medicine in which a culture had grown into a guinea-pig when the guinea-pig weighed 610 grams. Seven weeks later it had lost a third of its weight, and it died in an emaciated condition of extensive tubercle. As to the "amorphous body quite new to science" which the medicine was said to contain, he knew nothing about it.

Cross-examined, he said that tubercle bacilli might sometimes encapsule themselves, but there was some doubt about it. He did not admit that they generally do. It was possible to kill the tubercle bacilli by pressure between glasses. No one had ever seen an encapsuled tubercle. He did not know what chemical action this medicine had when mixed with human blood. A second bottle which he opened contained bacteria in the medicine which might have come from the cork, but he did not say they were harmful bacteria. His point was that they could not have lived if the liquid had been a germicide.

At the conclusion of Dr. Bulloch's evidence one of the jurors inquired whether they were bound to sit and listen to this evidence.

Mr. Justice Shearman: The plaintiff is entitled to be heard. You must trust me, gentlemen, as the plaintiff is not represented.

Mrs. Sarah Archer having given evidence,

Dr. Howard Distin said he had seen and examined Mr. William Smith. There was nothing whatever wrong with his chest.

Dr. Price gave similar evidence. He said that consumptive patients were generally sanguine, and a new medicine tended to make them hopeful. In his opinion it was not possible to cure consumption by means of drugs. The tubercle bacillus was a very virile organism, and it got surrounded by inflammation in the lung. Anything injected which was strong enough to kill the bacillus would at the same time kill the patient.

Cross-examined, witness said that the administration of tuberculin was intended to affect the tissues of the body to which it got through the blood.

Mr. Justice Shearman: When a person is cured of consumption what becomes of the bacillus?—It is destroyed by the natural powers of the body. The development of the general powers of the body has a tendency to enable the body to deal with the tubercle, and extra food is generally necessary.

Dr. Theodore Dyke Acland, M.D., M.A., F.R.C.P., Physician to St. Thomas's Hospital and Consulting Physician to the Brompton Hospital, said he had studied tuberculosis and diseases of the chest throughout his medical life. When the tubercle bacillus effected a lodgement it was either destroyed or created inflammation. The witness explained how the disease of consumption might get hold in the lungs. Anything which tended to weaken the patient enabled the disease to grow. Infection might take place through the blood stream. No two people were alike, and the disease would attack different people in different ways. It was absolutely essential to see each patient before treating him. Recovery might take place owing to expectoration or the formation of fibrous tissue. In his view it was impossible to reach the tubercle bacillus by means of anything circulating in the blood. If one was told that a case was silicosis, it was not safe to treat it as if it was not tuberculous. If he heard that a man was coughing up black stuff from his lungs he would assume that he was a miner, but the matter coughed up might even be blood or a part of the lung itself. The fact that a man was bringing up more secretion might indicate that he was worse instead of better.

Cross-examined by Mr. Stevens: Silicosis might tend to make the chest expansion less, but a definite rule could be applied to varying conditions.

Mr. Stevens: If a man who was bringing up a white sputum took the medicine, and then brought up a black sputum, what would you deduce?—That depends upon a number of considerations.

Continuing, witness said that cavities in the lungs did exist in cases of miner's phthisis. That was to the best of his knowledge.

Mr. Stevens: If fifty British medical men wrote saying they had found a cure for consumption, would you believe them?—I would like to know their names.

If fifty reputed medical men whom you knew, or whose names are in the *Directory*, wrote me telling me of the amount of good it had done to their patients, would not that justify my believing in it?—I do not know what you are, and I would want to know their names.

Sir Douglas Powell, Honorary Physician to the King, etc., examined by Mr. Colam, said he knew of no drug which could cure consumption. He had heard Dr. Acland's evidence, and he agreed with it. It very often happened that a consumptive patient got quite well, but scars would remain, and the disease might light up again. There was no analogy between the treatment by serum and the treatment by drug.

In cross-examination, witness said that in 1912 he saw Mrs. Whiteman, who had recovered from disease of the lungs.

In re-examination, he said he found no cavities in her lungs, but there may have been one. There was nothing on the certificate he gave to indicate that her getting well was due to any particular treatment.

On July 18th Dr. Arthur Latham, examined by Mr. Colam, said it was very unlikely that any drug would ever be discovered which would cure consumption. The plaintiff's specific could not do it.

Cross-examined, he said that there was no drug which could get at the bacillus in the lungs. He did not know what chemical action the plaintiff's medicine had on the gastric juices of the stomach. He had not tested it, but he was confident from his knowledge of chemistry that it could have no useful effect. The analysis conveyed to him that the medicine was practically inert and incapable of doing any good. He had not sufficient experience of krameria to say whether continual doses for a fortnight would be harmful. He knew of no medicine which could be given to a consumptive patient which would always relieve a cough.

Mr. Stevens: Can you give me the names and addresses of patients who have been in an advanced state of consumption and were cured?

Mr. Justice Shearman: He need not state them openly but may write them down.

Witness: They were mostly hospital patients.

Continuing, witness said that he had given a certificate in which he said a Mr. Hodson was not suffering from consumption, but he knew nothing about his having undergone a cure. Had he known what use was going to be made of his certificate he would have required proof that the sputum he examined was the sputum of Hodson.

Re-examined, he said that he had brought an action to restrain the plaintiff from publishing his name in connexion with his cure, and an injunction was granted. He then ascertained that Hodson had been sent to him at the instance of the plaintiff. It was concealed from him that the certificate was wanted as an advertisement.

Mr. Stephen Morrey, employed by the British Medical Association, produced correspondence between the Association and persons in South Africa as to the existence of the drugs. The Chief Government Analyst at Capetown wrote saying that, as to umckaloabo and chijitse, he could get no information about them. Nor was there anything in the South African *Materia Medica* about them.

This concluded the defendant's case, the learned judge intimating that he would allow the defendants to call further evidence in certain eventualities.

Dr. Edwin Grün, L.R.C.P., M.R.C.S., medical officer of the Steyning Union, said he was in general practice, but he had taken a great deal of interest in consumption. In 1890 he went to Berlin to investigate Dr. Koch's treatment with tuberculin, and got out a report on the subject. He had heard of the plaintiff in 1898.

Mr. Colam: I submit that evidence as to cases treated by this witness is not relevant.

Mr. Justice Shearman: You have written a long article attacking the plaintiff, and I think he is entitled to call general evidence in rebuttal. You have tried to prove that cures by the drug were impossible, and he is entitled to call evidence to show that it is possible.

Continuing, witness said he had used Mr. Stevens's preparation on a patient.

Mr. Colam: If the plaintiff is going to deal with particular patients, I shall have to call evidence to deal with those cases. That is a test to show that this is not really rebutting evidence.

Continuing, witness said that he had used the plaintiff's medicine for four or five years. In his opinion, the result was extremely good, and until quite recently he found it more useful than any other remedy. He had found it act favourably even on advanced cases. As soon as it was used the patients immediately and rapidly improved. He would not say on oath that it had a germicidal action. He believed it had. It acted well on a patient with a cavity in the lung. He had treated patients with cavities and the cavities had so disappeared that it was impossible to say that they had been present. He was a member of the British Medical Association, but that made no difference whatever. He considered this was a matter which should be investigated, as the investigation would do harm to no one.

Cross-examined by Mr. Colam: Would you like to say that you would guarantee a cure with this remedy?—I would not guarantee to cure any one of anything.

Would you like to publish to the whole world that this is the only remedy for consumption?—No, I am a doctor.

Assuming you were not a doctor?—If I had the evidence from my own experience, I might delude myself into believing it. I say *caveat emptor*.

Mr. Justice Shearman (interpreting to the jury): That means, "The buyer must look after himself."

If you thought, as a medical man, that it contained tannin, alcohol, and glycerine, would you think it could cure consumption?—I do not believe in any chemical analysis.

Continuing, he said that medical men did rely upon analyses in a rough way. They wanted to know roughly what was in a drug. The condition of the tubercle bacillus in the body was so different from its condition in a test tube that he did not think the tests were final. The medicine affected the tubercle through the blood. It raised the resistance of the body.

Mr. Colam: Is not the tubercle bacillus cut off from the

blood, as Dr. Acland said? There are many things in which I differ from Dr. Acland.

Continuing, witness said that each germ had its own antidote. It would be quite wrong to say that anything was a universal germicide.

Mr. Colam: In how many cases have you given this medicine?—Twenty.

Have any of them died?—Yes.

Did not one die after three weeks' treatment?—Yes.

Continuing, in another case he had examined the sputum, and found that after three weeks' treatment there were still bacilli to be found. In one case a patient had certainly been cured. He had recently begun to use the strong solution of iodine internally. That had not been used internally before, and he had certainly found results better than he had before. There were some cases which were not, in his opinion, apt for Stevens's treatment. He did not think it right to give this medicine to patients without seeing them, but the British law did not prevent that.

Re-examined, witness said that although he would not like to give it himself unless he could see the patient, he might do so if the patient were abroad. Doctors based their treatment on empirical remedies. It was impossible to tell by any analysis what a drug was going to do.

Mr. Parry, B.Sc., F.I.C., said he had analysed several samples of the plaintiff's remedy and had seen it made. There was certainly no krameria in the medicine.

Mr. Justice Shearman: What did you find there?—On February 16th, 1914, I found on analysis that the figures agreed substantially with those on p. 32 of *Secret Remedies*. The only variation was rather less alcohol. Of the solids 75 per cent. were extractive which was certainly not krameria, but the results of his tests were that the extraction agreed in all respects with umckaloabo and chijitse. He produced specimens in bottles.

Continuing, witness said the extractive was vegetable matter from a plant containing neither alkaloid or glucoside, but it did contain a trace of fluorescent body, which he could not identify.

Cross-examined by Mr. Colam, witness said that he had the greatest respect for Mr. Harrison. He thought that the analysis was careless in that there were three or four conclusive tests for krameria. That substance contained an intense red dye and another substance which could be easily identified.

Mr. Justice Shearman: What would you have described this as if you did not know of the two African drugs?—I know of nothing.

Continuing, witness said the only active principle isolated was tannin. He had given evidence on the Select Committee on Patent Medicines.

Mr. Colam: Did you state in 1913 to that Committee that diseases like consumption and cancer were incurable by mere drugs?—I said that and I meant it.

Re-examined, witness said that if consumption was shown to be curable by drugs he might modify his view.

By the Court: There was no reason to say one way or another why this substance was inert. The fact that it could not be identified did not prevent its lung action. A large number of medicines were so.

Mr. A. H. Bennett, examined by the plaintiff, said he was M.B., C.M.Aberd., and surgeon for the Liberian Frontier Force. He had decidedly heard of and used umckaloabo, which means "life everlasting." It was produced from a plant which grows in Liberia. He was employed by the Government. The heathens were more civilized than the Liberians. He had administered this drug to 1,000 cases. In all chest complaints it was used by the negroes. The natives made a decoction of the leaf of the plant with salt. It contained a vegetable substance which was an antitoxin in all chest complaints. He himself treated the drug with sodium salicylate. He brought the plant over to England in order to try and get it included in the *Pharmacopoeia*. He had only seen this case in the paper the previous day, when he communicated with the plaintiff's solicitor.

Cross-examined by Mr. Colam, he said he took his degree in 1891, and he afterwards practised on the "Lord's Pathway," having been medical officer on many ships for ten years. He then went to Japan. He had formerly lived in Australia. Having been ten years at sea, he settled in Liberia. He was a Commissioner there: he added, "I could hang you there if you committed an offence." His duty was to keep the peace.

Mr. Colam: Did you keep the peace?—Yes; I disarmed my own soldiers.

Mr. Justice Shearman: Is there any salary attached to the post?—Yes; it is sometimes paid.

Mr. Colam (producing a piece of umckaloabo root) asked whether this was not like a Spanish onion. Witness said it grew on the St. Paul river, and the Chief Justice of the colony would prove what he said. That was a small specimen of "the life everlasting." It grew to a height of three or four feet in semitropical Africa. He had picked that specimen on June 4th, and brought it home in a Saratoga trunk. The nation did not know it. It was called "the life everlasting" because nothing but fire would kill it. He was going to bring it to Mr. Holmes.

By the Court: You told us that the medicine was made from the leaves. Why did you bring over and produce the root?—The leaves fell off, and are now in my trunk.

It was arranged that the specimen brought home by the witness from South Africa should be examined by a botanist.

Mr. Chamberlain, a commercial traveller, said he suffered from chest trouble in 1911. He saw various doctors, and then went to the Brompton Hospital. He finally went to a place called the Home for the Dying Poor, where he stayed for about two months. Subsequently he tried the plaintiff's treatment, and he was greatly improved in about six months' time. He was up and down. He also saw a Dr. Harvey, of Watford, who told him there was no hope for him. So far as he felt, he was now perfectly well. He had, however, seen a medical man for an attack of pleurisy since he underwent the plaintiff's treatment.

Cross-examined by Mr. Colam, witness said that he was not free from colds. He now got phlegm at times.

Mr. Skipwith and his mother, Mrs. Skipwith, having given evidence,

Mr. Albert George Hodson said he first became ill with consumption in 1894. In 1908 he went to Mr. Stevens who guaranteed to cure him in eight months, the money being lodged in a bank. He was cured and told the bank to pay over the money. He had been attending work since March, 1909. He saw Dr. Latham in 1911 by appointment. He sent him his own sputum.

In cross-examination, witness said it was true that he told Dr. Latham that he was being shunned by his friends as they thought he was infectious.

Mr. Justice Shearman: Who paid the fee to Dr. Latham?—Mr. Stevens.

Mr. Colam: Did he tell you to go to Dr. Latham?—Yes.

Mr. Justice Shearman: Do you consider that an honest way of obtaining a certificate?—Yes.

The Judge: Well, I express no approbation of it.

A bank manager who was called said he had held as much as £6,000 as stakeholder for patients of the plaintiff. He had returned one sum of £2 12s. 6d. to a patient.

Cross-examined by Mr. Colam he said that probably he had some hundreds in the bank at a time. The plaintiff probably had £5,000 or £6,000 a year coming in.

Mr. Pollock, having given evidence, Captain Bailey said he had been in South Africa and had seen the herb used as a styptic and antiseptic applied externally. He also knew that the natives took it for chest trouble.

Captain Bailey, continuing his evidence on July 20th, said that it was exceedingly probable that a plant which grew on swampy ground would develop differently in dry ground. He was not, however, a botanist, but he had been meticulously careful to be exact. It looked like a Spanish onion with rings, or had a long root like a parsnip.

In re-examination, he said that he had seen potatoes growing. He would judge from what he saw that tubers formed on the plant, a specimen of which had been produced.

Mr. Stevens: Did you write about this plant long before you heard of me?—Yes.

What did you write?

Mr. Justice Shearman: You can't have that.

Mr. Howard, the cashier to a firm in Liverpool, who described himself as a prominent church worker, said he had a brother who suffered from consumption. He thought it was rheumatism.

Mr. Justice Shearman: You are only entitled to tell us what you saw yourself.

Mr. Stevens: Is your brother here?—Yes, but he does not know so much about the case as I do.

Continuing, witness said that his brother took the plaintiff's medicine and was cured. The doctor had suggested a sanatorium, but his brother did not go there.

Cross-examined, witness said the doctor who attended him was not present.

Mr. Stevens: He refuses to come.

Mr. Justice Shearman: You have no right to say that here, Mr. Stevens.

Continuing, witness said that his brother lived in an ordinary bedroom in his own house. He suffered from a tuberculous abscess, which burst. He did not know that such an abscess would either cure or kill a patient.

Mr. Joseph Howard, examined by Mr. Stevens, said that he had suffered from tuberculosis, and his weight had gone down to 8 st. 2 lb. He was "aspirated" several times when at the convalescent home. After he had taken the plaintiff's medicine for three months the abscess ceased to discharged. He now weighed over 12 st.

Cross-examined, witness said that he began to get well after the aspiration.

Dr. J. Elliot Jamieson, before being sworn, said he wanted to make a statement that he was a member of the British Medical Association and was not there as a voluntary witness: he had been subpoenaed.

Mr. Justice Shearman: You are not entitled to say that before you are sworn.

Upon being sworn and examined by the plaintiff, witness said that he had used the plaintiff's medicine in six cases. In the first case he thought a child of 6 was suffering from consumption. He attended it for three weeks, and gave it some medicine which seemed to do it good. The second was a genuine case of chronic pulmonary phthisis which had been under his treatment for a year. It was still suffering but had improved considerably, having lost all the bad symptoms. No. 3 was a very bad case with haemorrhage. She died, but she had stopped using the medicine for about a month. No. 4 was the case of a boy who had bad symptoms. He certainly improved, putting on a stone in weight, but he left the district. No. 5 was a bad case, in which the patient refused food and died of starvation. As to No. 6, that was a case of tuberculous peritonitis, which was better one day and worse the next.

Mr. Stevens: Have you used any medicine which has as good

an effect as this?—Well, to tell you the honest truth, I have not formed any opinion about the medicine.

Mr. Colam: I ask no question.

Mrs. Ethel Neville, who did not like to give her address, said she had suffered from consumption. A doctor told her it was tuberculosis. She was twelve weeks at the Brompton Hospital. She took the plaintiff's medicine and felt better. She was able to get married, and could do the housework and the washing.

Cross-examined, she said she felt better after leaving the sanatorium, owing to the exercise.

Mr. Colam: When did you feel able to get married?—About June, 1913.

And then I suppose you got well rapidly?—Yes, but not on account of that. (Laughter.)

Mr. C. E. Cassal, Public Analyst for the City of Westminster, F.I.C., etc., said he had had over thirty-five years' professional experience. He had analysed the plaintiff's medicine on February 26th, 1914. His analysis was as follows: Specific gravity 1075, total solids 2.85 parts, ash 0.26 part, absolute alcohol 13.99 parts by measure, glycerine 11.45, tannin 0.722 parts per 100 fluid drachms. From other experiments he found that a medicine made according to the formula in *Secret Remedies* contained three times as much tannin as the plaintiff's medicine. He found that umckaloabo and krameria roots were quite different.

Cross-examined, witness said he did not know whether his figures varied from those of Dr. Parry. It was not a matter of opinion whether a test was absolute or not. It was, however, true that there might be a difference of opinion as to the cause of a reaction. He did not know which kind of krameria was being used—there were three kinds.

Mr. Justice Shearman: It is fairly clear that umckaloabo root was used to make the plaintiff's medicine.

Mr. Colam: I am on the point that it is said to have been negligent on Mr. Harrison's part not to find it was not krameria.

Continuing, witness said that tannin might get deposited if a mixture were to stand some time.

Mrs. Mary Morrison said she began to suffer from consumption sixteen years ago. She went to Canada, but returned. The plaintiff's medicine had done her good. She had got a doctor's certificate, but the doctor took none of her sputum, as she had none at the time. Her husband was called to prove that his wife had spoken the whole truth and nothing but the truth.

Miss Annie Keene, living at Hove, said she had been to the Brighton Sanatorium. Within a month of taking the plaintiff's medicine the cough was better, and in three months there was a decided improvement.

Miss Lucy Keene, sister of the last witness, corroborated. She had been a mother to her sister since she was ill.

Mr. William Stannard, living at Epsom, said that his sister-in-law had had consumption.

Mr. Dickens: How is this relevant?

Mr. Justice Shearman: I cannot exclude it. He is entitled to say what he knows.

The witness said that she had been cured by the plaintiff's medicine.

George Green, an ex-warrant officer in the navy, said he had suffered from consumpton, and had had to leave the navy. The doctors considered him hopeless, but the plaintiff's medicine caused him to improve month by month. He was now in good health. He was not, however, allowed to go back to the navy, as the certificate merely stated that the disease was quiescent.

Miss Florence Teddington, of King's Lynn, having given evidence,

Mr. George Isaac Cooper said that in 1900 he went to South Africa for consumption. From there he went to Australia, and thence to London. Since 1906 he had been in bed off and on for three years. In October, 1913, he began taking the plaintiff's medicine. Three months later there was some improvement.

In cross-examination, he said that he left the Bournemouth Sanatorium because he was a vegetarian. He took milk from doctors under protest.

Mrs. Wigley said that she had suffered from consumption and that since taking the medicine she had never brought up any blood, except on one occasion after she took dumbbell exercise. She had taken the medicine ever since the last trial—for example, November, 1912. She now felt splendid.

Cross-examined, she said that two doses of the plaintiff's medicine had been sufficient to make a change. She always had her window open at night.

Mr. F. D. Bowden, living at Beaufort Park, said he had had tuberculosis of the glands of the neck for the last sixteen years. His last operation, of which he had had eight, was in February, 1912. When he visited the plaintiff the plaintiff injected his neck, with the result that the gland disappeared. He had five or six injections at the most. Each time the gland discharged it got smaller.

In cross-examination, witness said that his glands had been removed by operation. On the last occasion the place did not heal. The doctor tried to make it discharge and opened it for that purpose. It was in that condition when witness went to Mr. Stevens. He pricked it with a needle and it discharged three weeks later. The doctors told him that patients generally grew out of glands.

In re-examination, witness said he was better in his general health after the glands were removed.

Another witness said that in October, 1904, she had double pneumonia and pleurisy. She lay at home, and then went to St. Mary's Hospital for about seven weeks. Her temperature was up and down. She got a little better in St. Mary's Hospital, but she could not sit up when she went home. They wanted her to go to a convalescent home, but she could not go. In February, 1913, she began to take Mr. Stevens's medicine, at a time when she had given up hope. After taking the second bottle she began to feel better and began to get fatter. The doctor said——

Mr. Justice Shearman (to the plaintiff): You cannot get out of the difficulty of not calling doctors by making statements as to what the doctor said.—I am sorry, my lord.

Mr. Stevens: Were you given to understand that it was a perfectly hopeless case?

Mr. Justice Shearman: You cannot have that.

Continuing, witness said she saw a doctor upon the question whether she should get married, and she was now married.

In cross-examination by Mr. Colam, witness said that a specialist advised her to go to a sanatorium, but she did not do so. She had been lying about out of doors for four weeks before she began to take Mr. Stevens's medicine.

Mrs. Heyman, in giving evidence, said she went to the Mount Vernon Hospital in 1909. Her husband died of consumption. She went to a hospital, where they could do no more for her. She suffered from haemorrhage. She was quite well about four months after she commenced to use the plaintiff's cure.

In cross-examination she said she had a bad attack of blood-spitting after she took the medicine, and she afterwards picked up.

Mr. Frederick Charles Monk, living at Peckham Rye, produced a pair of crutches and a leather support which he used to use. He suffered from a tuberculous knee when he was 15 years of age. He saw Dr. Hill of Peckham, who advised an elastic knee-cap. That made no improvement. He then went to St. Thomas's Hospital, where he was told that the knee was tuberculous. He was attended there for three years, during which his knee got worse. In September, 1910, he first heard of the plaintiff. His knee was then so bad that he could not bear it on the ground. He went to see the plaintiff on crutches, his leg being wasted away below the knee. The plaintiff injected him every week, and he also took the plaintiff's medicine. In two months there was an improvement. The leg began to fill out after he began to put it to the ground. He continued using the plaintiff's remedy for about two years. The knee was now perfectly well itself.

In cross-examination, witness said he had not known any other cases of tuberculous knee. He was not told that he would be able to get rid of the crutches, etc., if the disease ran its normal course.

A juror: Are we compelled to sit here for a year to hear these witnesses?

Mr. Justice Shearman: We cannot refuse to hear any evidence which may be relevant.

The Plaintiff: I could go on calling witnesses for a month, but will try and conclude it to-morrow evening. I shall then have my own evidence to give.

Mr. Harry Earle said that in March, 1912, he was suffering from consumption, and he went to a sanatorium, and was not benefited by that.

Mr. Justice Shearman: We are not here trying the question whether sanatoriums are efficient.

Continuing, witness said that he commenced taking the plaintiff's medicine in September, 1913, and as a result he regained his strength.

In cross-examination, witness said that when he went back to work his duties were lessened.

Mrs. Florence Wood, examined by the plaintiff, said she had heard Mr. Monk give evidence. She had suffered from tuberculosis, and was told so by a doctor. She went to the Chest Hospital in City Road. Having attended hospital for fifteen months, she first heard of his cure in March, 1908, and it did her good.

Mr. Edward Spencer, no occupation, of Cropstone Road, said he had suffered from consumption, and first knew of it in October, 1910, when he had a bad haemorrhage, and they continued on and off until the following July. In 1912, he had the plaintiff's medicine, and he saw two doctors later, in 1913. He was very low when he first took the medicine. He had no great faith in it when he commenced taking it, but after the first bottle he had, and in June, 1912, he started work.

In cross-examination, witness said he thought he could now do a day's work, but did not think of starting.

Mrs. Fell, 77, West End Road, Southall, said she commenced to suffer from consumption in February, 1913. After six weeks she began to take the plaintiff's medicine. One bottle cured paroxysms of coughing. She could now do her work without any difficulty.

At the resumed hearing on July 21st, Mr. George Fell and Mr. W. J. Stephens, M.A., having given evidence, Mr. Archibald Thomas Alexander Stewart said that since 1908 he had been shipping sacks of roots from South Africa to Mr. Stevens. In answer to the learned judge, he said that about sixty-four bags came over each year.

Dr. Buchanan Hamilton, L.R.C.P.Edin. and L.R.C.P.Irel., said he was not in general practice, but he sometimes attended friends and relatives. He had been a medical officer in the navy. He had ordered umckaloabo for a patient at Southsea, but he took it himself, as he suffered from a cough. He began with small doses, and in a fortnight's time all the barking and coughing disappeared as if a wizard had come to the house. He had other remedies which also did well.

Cross-examined, he said that he took the medicine two months ago—that was this summer; but he had not yet tried it in winter.

In re-examination, he said that as a man of honour himself he would prescribe it for a patient.

The plaintiff then gave evidence on his own behalf. In about the month of September, 1897, he became very ill and went to his family doctor in Bermondsey—Dr. Taplin. He had been his doctor when he was brought into the world.

Mr. Justice Shearman: You cannot know that of your own knowledge!

Continuing, witness said that Dr. Taplin told him he was suffering from pulmonary tuberculosis, and in consultation with a specialist advised him to go to South Africa. Having arrived in Capetown he went up country to Bloemfontein. On the morning after his arrival he went into the market square and began talking with a Dutchman named "Pepper" in charge of a wagon. This Dutchman said he knew a native who had cured an Englishman of consumption. In consequence, he went to Maseru, on the outskirts of Basutoland. The Dutchman had supplied him with a little tarpaulin with which he erected a tent. On the following evening an old native arrived dressed in a leopard skin and a blanket. Witness made him understand that it was consumption which had brought him from England, although he found it difficult to make him understand. Two hours later the native came up with an old grain sack, in which he had some crushed roots. Having got a Kaffir pot he boiled some of the roots. When it cooled he gave Mr. Stevens a dose of the infusion, which caused him to vomit. Subsequently he took it many times, and he vomited every time. After taking it for a week he found his energy returning, and in two months, with the exception of a cough and slight expectoration he felt as well as ever he did. Returning to Capetown he brought about 40 lb. of the root with him. He booked a passage home on January 13th, 1898. He thought that all he had to do was to get his stuff analysed and he would have discovered a cure for consumption. His little sister, who was now gone—(here the witness was overcome with emotion). After pulling himself together he said that his sister took him to a doctor in Clerkenwell. He spent quite a long time trying to get at the active principle of the root witness had brought him. Later on he returned to South Africa. He had given the remedy free of charge, and had never asked a single individual even for postage money. The testimonials that he received—

Mr. Justice Shearman: We cannot have that.

Continuing, witness said that after closing the business of C. H. Stevens and Co. he went with his medicine to Dr. Anderson, who was lecturing for the Society for the Prevention of Consumption. He did not take any interest in it. Dr. Gregory, medical officer of health for Capetown, refused to have anything to do with it. A Mr. Harris made a communication to him, after which he decided to offer his remedy to the public generally. He did so, putting it on the market as "Sacco," a proprietary medicine. In the first year he made £6,000 clear profit; £5,000 at least out of the £6,000 went to the poor consumptives of Capetown and district.

Mr. Justice Shearman: Do you mean you made donations?—In a Jewish quarter there was great poverty, and I relieved their suffering by giving them medicine, and what they needed to sustain life.

Continuing, he said that he gave away in actual solid cash £5,000, but it was only given to those poor unfortunate consumptives who appeared to be in such position that they could not pay for medicine. He gave some of it in orders to grocers and butchers. He made a very large income in Capetown—about £1,000 a month. A lady, Miss Lee, came to him—

Mr. Justice Shearman: You cannot say what Miss Lee said.

Continuing, he said that owing to certain litigation he decided to give up all claims upon the company "Sacco Limited." That litigation had damaged the business to such an extent that he decided to leave, and he then started a business at Johannesburg for "the sale of Lungsava." He began to mix chijitse with Lungsava. That substance acted as a styptic.

At this point Dr. Smith Whitaker was interposed.

Examined by the plaintiff, he said that at the present time he was Deputy Chairman of the National Health Insurance Commissioners. He had been Medical Secretary of the Association. He recollected seeing some paper, and he could identify it as a prospectus of Lungsava, Ltd., which he dealt with in his official capacity.

Mr. Stevens: Did you count the testimonials?

Mr. Justice Shearman: You cannot have that.

Mr. Stevens: In 1907 were the British Medical Association aware that I had testimonials from a number of names of medical men?

Mr. Justice Shearman: Do you object, Mr. Colam?—No, my lord, I shall have to bring it out.

Continuing, witness said that he wrote to a number of medical men who were mentioned on the prospectus. He probably wrote to all, and received a number of replies.

Mr. Colam: I do not object to the replies going in. I have no question for Dr. Whitaker.

Continuing his evidence, Mr. Stevens said that the business in Johannesburg was more successful than in Capetown, as there was no haemorrhage, even in advanced cases. In Johannesburg it was illegal to give alcohol in any form to a native. He had been prosecuted for doing such things as belonged to the medical profession. He was fined £10 in the first case and £25 in a second, having cured two miners of phthisis. In 1907 he came to England and settled down at Wimbledon. Shortly after he returned the British Medical Association published a scathing article about him in the JOURNAL on August 22nd, 1908, pp. 505, 518. It was then dealt with as "Stevens's Treatment for Consumption." He wrote to the Association on August 28th, saying that any journal which would publish mutilated extracts must have for its proprietors the most unscrupulous persons existing. Their analyst was either a fool or he was ignorant. In reply he got a letter on September 1st which was not even signed. The witness went through the correspondence which he had with the manager of the JOURNAL. He then went on to say that in treating patients he only took their money if there was an improvement. He also undertook to remove all traces of the disease, and the money was paid over to the manager of a bank. Eighty-five per cent. of the patients who came to him expressed gratitude for the improvement made. When the guarantee was given he received nothing unless a cure was effected. In his practice generally he treated a large number of persons both by correspondence and in person. The patients he treated free of charge did not even pay the postage on their medicine. The number of patients he saw free were two-thirds of the whole number. One day last year he saw nineteen patients, of whom seventeen paid nothing. The greater number of them were Jews employed in sweated labour. In many cases he could give their names and addresses; and he had even supplied them for months at a stretch with the necessaries of life. He ought, perhaps, not to have mentioned that fact. No matter where he came from, the patient was entitled to treatment free of charge. At least 95 per cent. of the patients improved; for him to get a failure where he could *see* a patient was almost unheard of. He did not undertake to cure when there was a complication. Even in cases treated by correspondence 90 per cent. were cured. It had been said that patients were hopeful. The people who came to him said—

Mr. Justice Shearman: You will have a right to reply. If you indulge in this now it may weaken the effect of your address to the jury hereafter.

Continuing, witness said that he had treated thousands of cases of miner's phthisis, and he had never come across one that had produced a cavity. In that respect he disagreed with Dr. Acland. With regard to Smith, the Great Northern Railway clerk who came to see him, he said that he had been suffering from continual colds for the last six years. He told Smith there was nothing to worry about if he only did what he was told for a few months. He had asked Smith for a specimen of sputum, as witness did not like to say anything definite until then.

Mr. Justice Shearman: Did you say to Smith: "Your left lung is in a bad condition, and has been so for three years"?—I may have done.

Continuing, witness said that one case in a hundred needed diagnosis, as his patients had been at hospitals, etc.

Mr. Justice Shearman: Is not that argument and not evidence?—I withdraw it.

In 1908 a gentleman came to see him in Wimbledon. He was local representative of the British Medical Association.

Mr. Justice Shearman: He could not make admissions for the Association.

Continuing, witness said he had treated a Mr. Bowman. He asked for his money back, and witness had sent it back. That was before the libel was published. When he returned to England he saw a number of medical men.

Mr. Justice Shearman: Really, I shall have to stop this! I do not want to shut out anything that is evidence, but I have told you that what passes between you and medical men who are not called cannot be stated.

Continuing, witness said he sent his medicine to many medical men. With regard to the witness Langford, he remembered having correspondence with him. Witness told him that he was not suffering from consumption. He could guarantee no cure in such a case. A judgement was given him for £10 and costs. He went round to every solicitor in Basingstoke. As to Mrs. Archer, she came and said she had a son. He denied that he guaranteed to cure her son. He did tell her that he never guaranteed to cure a patient for £25 or upwards. She first came to see him on June 15th, 1908. He did not say that he would give £10 if he could not cure—that only applied to cases in which he had given an undertaking. Her son collapsed when his mother brought him to the office at Wimbledon. It was untrue that he said that Brompton was no good, nor had he ever said to any patient or in any circular that Brompton or any other hospital was no good. He did consider from the way he saw Archer's mother treating him that he got little help to enable him to get rid of his trouble.

Continuing, witness said that Dr. Latham had applied for an injunction to restrain the use of a certificate. He had not opposed the application and had to pay £100 in costs, as he found, on consideration, that the advertisement was open to misconstruction. Whilst in South Africa he had supplied the medicine to a large number of medical men, who assured him——

Mr. Justice Shearman: Once again, we cannot have that.

Continuing, witness said that Dr. Bulloch had given evidence. In August, 1911, he (witness) had obtained cultures of tubercle bacilli from Baird and Tatlock, 14, Cross Street, Hatton Garden, London, E.C. It was a poor culture. He placed them in his own incubator to develop. On September 20th, 1911, after the cultures had been growing since August 28th, he intended to carry out certain experiments. He took two microscopic slides. The growth which he had received had developed sufficiently to take a specimen. He treated some of the cultures with a filtered decoction of umckaloabo 1 in 16 for five minutes. It

was then put in 10 minims of distilled water. He then took two rabbits and inoculated them.

Mr. Dickens: I do not know whether the witness knew it was a criminal offence.

The Witness: I know it, and I am here to tell the truth. It was done for the benefit of humanity! They would not let me have a licence.

Mr. Justice Shearman: I hope you do not suggest that unlicensed persons should be allowed to carry out such operations.

Continuing, witness said he injected the transparent portion of the eye of one rabbit with some distilled water which contained bacilli. The other rabbit was injected with the washing from a slide which had been in contact with his medicine. The first suffered from a tuberculous discharge from the eye. The other rabbit developed no disease, but remained perfectly well. He carried out the same experiment with bovine tuberculin with the same result.

This concluded the plaintiff's evidence-in-chief.

Mr. Stevens was then cross-examined by Mr. Colam: He did not think that his own cure from consumption was a good advertisement of the medicine. He had exploited no other medicine except those connected with African herbs. He had a large sack of roots at home which could cure rheumatism, but did not advertise it, as his time was taken up with this cure for consumption. He had never been connected with any other cure for consumption. He denied that he procured his present remedy from a Mr. Weimann. He knew that gentleman.

Mr. Colam: Did you get a consumption cure from him?—No, he used to get roots for me.

Was it his or yours?—It was mine when I bought it from him.

The roots or the cure?—The roots.

Did you go into partnership with him?—No; he was a farmer.

Continuing, witness said that the bottles labelled "Umckaloabo" were pure extract. When called "his mixture," it contained chijitse. He meant to tell the jury that before the fire took place he had run the business as a charity. After the fire—some time in May, 1904—he was nearly ruined, and had to carry it on as a business for the first time. That was at 29, Long Street, Capetown.

Mr. Colam read a letter headed from a cycle agency addressed by the plaintiff to Mr. Weimann in which he referred to the money the plaintiff had spent on Weimann's medicine, saying that he would get it back 10,000 times over. The plaintiff said that the herbs referred to in the letter referred to the bubonic plague.

Mr. Colam: Do you say that what you were dealing with with Mr. Weimann was the cure for bubonic plague?—No, he was collecting the roots for rheumatism and umckaloabo.

Continuing, witness said that the business he had was formerly carried on as Leslie and Smuts. He did not at that time know the name umckaloabo.

Mr. Colam: How did you tell him to get the medicine if he did not know the name?—He knew where the herb grew.

Mr. Justice Shearman: Where did it grow?—I saw it growing from Port Elizabeth to Basutoland.

Continuing, witness said that one of his circulars which stated that he had spent thousands of pounds in procuring the medicine had been written by an advertising agent. Although it was true, he withdrew it from circulation as he did not like the wording. He had suggested the name "South African Microbe Killer" to Mr. Weimann in November, 1903, but he thought that might refer to bubonic plague.

Mr. Justice Shearman: You have called your medicine a germicide.

Continuing, witness said that in September, 1904, he was receiving herbs from Mr. Weimann. In a letter written to him he said, "Did you put any of the leaves in this medicine?"

Mr. Colam: Does not this show that you were speaking of a medicine made up by him?—I think that refers to the rheumatism cure.

Listen to the next line, "Send me a few of the leaves, as there are so many people here with colds on the chest."—Oh! that was another medicine used by the natives for colds.

You also say in the letter, "There is £1,000,000 for anyone who can bring a consumption cure to light. I only want half of it and you shall have the other"?—Certainly, if he was true to me.

Let me see the stuff which comes over from South Africa.

At this point two sacks in court were opened and what were stated by the witness to be chijitse and umckaloabo were produced. Witness said that the second was a tuber root. He had never said it was a bulb; it was a bulbous tuber.

Mr. Colam: I am suggesting you have not got the umckaloabo which Captain Bailey produced?—The roots have skins which peel off.

Continuing, witness said he had heard Captain Bailey describe the cure for wounds as something like the rind of a Spanish onion. Although he had had nearly two years since the last trial to produce an original plant, he did not do so because that was what the medical profession were waiting for.

Mr. Colam: It is said in the alleged libel that you kept the real article from the medical profession?—I have told them what the original plant is, but I will not show it to them after the way your Association has treated me.

Continuing, witness said the plant was not cultivated, although attempts had been made to cultivate it. He knew that Mr. Weimann did not know the name.

Mr. Colam: Did you ever tell him the name?—I do not think I knew the name until after the date when Mr. Weimann stopped collecting in 1906 or 1907.

Did you say on the last occasion that you told him the name in 1904?—It would be later than that.

Continuing, witness admitted that he wrote to Mr. Weimann saying he was Stevens and that Weimann would be the Company, and that Stevens and Co. would be successful. In June, 1905, he wrote to Mr. Weimann saying that he might grind the herbs with the skins on as soon as he liked. That was the time when he was making a big income.

Mr. Colam: Did you write to Mr. Weimann saying that things were so tight you could not send him anything?—That must have been after the litigation.

Continuing, witness said that, notwithstanding the correspondence, he adhered to what he said, that he had got the remedy originally from a native. The medicine had been advertised originally as "Sacco." As to some of the advertisements, he did not recognize and was not responsible for them. He did recognize a little grey-covered book which had a picture on the outside of "The Last Victim." It was published in England in 1905.

Mr. Justice Shearman: The outside of the cover suggests Perseus and Andromeda! The pamphlet states that "An Englishman travelling in South Africa was cured by a native." Were you the Englishman?—Yes.—Why did you not say so?—Because I did not wish to brand myself as a consumptive.

Continuing, witness said he had sent the Lungsava prospectus to the British Medical Association. The testimonials went to show that it contained some medicinal activity. He did not rely upon the testimonials sent with them. He relied on his experience.

Mr. Colam: Did the letters fall very far short of any recommendation?—I know that your Association has intimidated a large number of my witnesses.

Continuing, witness admitted that a Dr. Riordan wrote saying that he never had such a patient as was alleged, and it was a most unwarranted use of his name, that he had never been approached by the Lungsava company, and that it was an impudent fraud. His answer was that the testimonials related to Sacco.

Mr. Justice Shearman: The point is that this doctor wrote to say he had no such patient. The witness is entitled to show that he was mistaken.

Mr. Stevens produced a letter from the same doctor written about a fortnight ago, in which he said that in 1905 he was led to express his satisfaction with a case treated with the plaintiff's medicine.

A juror: I should like to hear the letter to which that is an answer.

Mr. Justice Shearman: Mr. Stevens has produced this letter to show that the doctor was mistaken. The defendants, on the other hand, may use this doctor's first letter to justify their comment.

Continuing, witness said he had added the letters "M.D." in one case. The originals of some of the testimonials were not in existence. One doctor was described as Dr. Wilson although not on the *Register*. This gentleman, writing to the Association, said he had tried it and found the drug was worse than useless. He (witness) was responsible for the prospectus which was published in 1907. He had not asked the permission of the doctor or any of the doctors to publish the testimonial.

Mr. Justice Shearman: Did you try to raise money on these certificates?—Yes.

Mr. Stevens (to Mr. Colam): Dr. Wilson was afraid of you. You have power to strike him off the rolls any time.

Mr. Justice Shearman: You should not make statements of that kind. They have no such power. I want to know the connexion between Sacco and Lungsava.

Continuing, witness said Sacco went into liquidation, and he published the testimonials as they were addressed to him. He sold Lungsava at Johannesburg, and he then tried to float a company for Lungsava in England. He did start a branch of "Sacco" in England; it was carried on from Basinghall Street. Sacco was still being sold in England by people calling themselves the Sacco Co., down in New Cross. A man named Pickering bought the right to use Sacco from the liquidator for £126, and witness did not know whether they obtained their stuff from Mr. Weimann in East London.

Mr. Colam next referred to a letter from Mr. A. E. Price, of Cheltenham, who said that he had never heard of Lungsava and had never signed himself "M.D." In the course of his letter he said that it was private and confidential and that it was evident that they (the promoters) had taken pieces of it and strung them together. He had written to Sacco to say that he had no faith in the medicine. The patient subsequently died.

Mr. Colam also referred to an alleged testimonial given by Dr. A. Stoddart Kennedy. Dr. Kennedy received a letter from the Sacco company expressing regret and saying that the letter referred to something different, and had been taken from them by a former employee. Witness said he suggested that these doctors did not desire to fall out with their own trade union.

Mr. Justice Shearman: How were these reports obtained?—The profession were circularized and these are the letters they sent after trial.

Did not the Sacco company write (August 23rd, 1905): "If you give us a report we will undertake not to publish without consent"?—That was after I left the company.—Who was carrying on the business then?—I do not recognize the letter. I never sent it out.

Mr. Colam: The dilemma is that the testimonials were either

obtained by you on a promise not to publish without permission, or that they were published without authority?—Not at all.

Mr. Justice Shearman: How did you get the testimonials?—Mr. Whiteman gave me a bundle of letters.

Continuing, witness said that he prescribed the medicine when the patient stated he had consumption. He did not always prescribe merely on symptoms. He did not know what bronchiectasis was, although he was a lung specialist. He did not know that its symptoms were similar to those of consumption. He knew that empyema was a fluid which collects close to the pleura, and that its symptoms were not similar to those of consumption. He did not know the treatment of that disease.

Mr. Colam: Would you take it from me that it would be dangerous to treat it as for consumption?—I will not take anything from you.

What would happen if it burst into the lung?—It would wash the lung away.

Continuing, he did not know what subphrenic abscess was, and did not know anything about the diseases below the diaphragm. As regards Mrs. Archer's son, it was untrue that he said at the last trial it was a hopeless case to cure. He gave her to understand, after treatment, that it was not a hopeless case. He said he did not undertake to cure for less than £25.

Mr. Colam read from an advertisement issued by the plaintiff which stated that when patients had been given up by the doctors, and disease was "slowly devouring all but your soul and your bones," they should "send a postcard to Stevens."—That was not meant to frighten but to give hope. He suggested that the profession would not even give it a test, let alone recognize it. He never said that sanatoriums would not cure. He had said that "a landslide to the grave" would be a more accurate description. He did not know that the statistics given in one advertisement stating that but 3 per cent. of the cases were cured were founded on one particular sanatorium. He had not published these statements about sanatoriums since the last trial. He had heard Dr. Acland's evidence. The statements he made were true all the same. On December 31st, 1911, he had referred in advertisement to a Miss Olley as having been sent from Brompton incurable, and was now enjoying good health.

Mr. Colam: Do you know that she has since died of consumption?—I thought she died of bronchitis.

Counsel produced a death certificate showing that Miss Olley had died of pulmonary tuberculosis. The witness now was publishing a certificate by Mr. Lord who upon the document stated that he was public analyst to various public bodies.

Mr. Colam: Was not Mr. Lord a man to whom you paid 30s. a week to address envelopes?—Certainly not, he may have addressed a few envelopes. He had a retainer to come in and examine sputums.

Mr. Justice Shearman: Is he alive?—I do not know.

Mr. Colam: Is he not in a Church Army home and a dipsomaniac?—I do not know.

Mr. Colam then referred to the evidence given by Mr. Lord on the former occasion. Mr. Stevens said that it was untrue that he was a mere clerical assistant. Mr. Colam then read the certificate sent in the packet with the bottles of medicine.

Mr. Colam: Was he not employed by you to make this certificate?—No, not at first; but the certificate was obtained by me from him after your analysis had appeared.

Continuing, witness said that there was no word of his in the pamphlet. He wanted to show that it contained no kino or krameria, and he asked Mr. Lord to make the analysis with that object.

Mr. Colam: Do you suggest this was a certificate a bacteriologist would give?—Yes.

Mr. Justice Shearman: Was this a qualified medical man? He recommends the treatment to persons suffering from tubercle.—He is not; he is an analyst.

Continuing, witness said that amongst the documents which he circulated was a photograph of a hand purporting to have been cured by his medicine. It was a photograph of a photograph. The first photograph could not be used, because it was under exposed. The picture was made from a painting of the hand and the man's description.

Mr. Justice Shearman: Is the original here?

Continuing, witness admitted that the same pamphlet contained the following passage: "If I do not completely cure every such case of external tuberculosis within one month and every clear case of pulmonary consumption within a few months from the date the treatment is commenced, no matter how many hospitals have failed to even give relief, then I will consider the name 'quack,' which so many medical men give me, to be a just description of myself, but if I can cure every case submitted to me in the time mentioned above, I must ask to be considered a man who has the ability to save his fellow men from this insidious scourge—consumptive tuberculosis."

Do you really tell the jury that you honestly believe that you can cure every case of pulmonary consumption within six months?—I agree, and so I will, provided there is a possible chance. I will cure them if they are not half in the grave.

Continuing, witness said that he was afraid it was worms killed poor Miss Olley. As to Archer, he was not properly looked after by his mother. As to Bramley, he went back to work. Witness did not remember the name of a man named Brunt.

Do you say that your medicine will build up a broken-down system entirely by itself?—Yes; that is true in the way that any one with common sense would take it.

In further cross-examination, witness said that he brought no action against *Truth* in 1906; he had no money, and could not afford to leave South Africa. Although he disclaimed medical knowledge, he considered himself competent to make the experiments on rabbits.

Mr. Justice Shearman: Did it not occur to you that your experiments on rabbits should have been attended by a man with scientific training?—Yes; but it was a criminal offence and I could not get a licence.

Did it not occur to you that if you wanted to see if the bacilli were killed it would be well to submit them to a trained man?—No.

In re-examination, witness said that when he found out what umckaloabo actually was he was in Masern. With regard to the correspondence with the British Medical Association, witness referred to a letter which one Bell had sent to the Association. Witness said he had received a large number of letters from patients whose money had been returned.

Mr. Charles Coster, a dentist practising at Wimbledon, said he knew Mrs. Archer. She never told him that she had paid twenty guineas.

Professor Henry George Greenish, author of various standard works and one of the editors of the *British Pharmacopoeia*, said that he knew a good deal about the anatomy of plants. Having examined the plant and pieces of root, he came to the conclusion that they were entirely different. The small, slender plant could not have produced the dried root. The structure and type of the two roots was entirely different. In the small root there were small crystals of calcium oxalate. He would not say that the root was bulbous or tuberous. The plant had dried considerably since he first saw it.

In cross-examination, he said he could not tell the court what natural order it belonged to merely by looking at the stem. He had never to his knowledge seen either of these plants before. A juror asked whether the plant was tropical, but witness could not say.

Dr. Theodore Dyke Acland, recalled, said he had been in court while all the plaintiff's witnesses were called, and he said that in every case the evidence was quite inconclusive that the drug had done any good. He could give many instances of pulmonary cases in which patients had been cured without any drug. Were the powers of resistance of the individual sufficient, the glandular disease was overcome. Young people had it and recovered from it. Operation for glands was often performed to prevent scarring. Tuberculous knee was not very rare. That was a complaint which also attacked young people. Rest was part of the treatment. Surgical treatment, with which he was not familiar, was also common. He had heard the description of Mr. Stevens's experiments with tubercle. Those experiments would convince no one with technical knowledge. There was no evidence of sterilization of himself or his instruments. The alleged tuberculous bacilli in the rabbit's eye might have got there when the injection was made. They were extremely delicate experiments, to which no importance would be attached unless they were done by an expert. Of the diseases mentioned, the first—dilatation of the bronchial tubes—was often mistaken for tubercle. It was important to examine a patient personally in order to distinguish the two complaints. To give a medicine which increased expectoration in a case of bronchiectasis was to expose the patient to grave risk of being drowned in his own secretion. If empyema manifested itself at the upper part of the chest it was difficult to distinguish from tubercle. There were also the same physical signs outside. As to subphrenic abscess there were certain abdominal diseases where discharge took place through the lung. That was very fortunate for the patient. Such cases were very difficult to distinguish from pulmonary tuberculosis, but they required absolutely different treatment. As to miner's phthisis cavities were certainly formed as a result of that disease. As to the statement that only 3 per cent. of the persons who went to sanatoriums went back to work, that was quite untrue. Mr. Stevens's statistics must have been derived from a misreading of some German figures.

In cross-examination, Dr. Acland said that he had not said that all the witnesses on the other side were dishonest.

Mr. Justice Shearman: He says that the evidence of the thirty witnesses you have called is consistent with their having got well apart from your medicine.

[After a lengthy summing up, which we hope to publish in full next week, the learned judge invited the jury to answer two questions—namely, (1) Are the words libellous? (2) Were the comments fair? The jury after an absence of ten minutes answered the first question in the negative and the second in the affirmative. Upon the application of Mr. Dickens, the learned judge entered judgement for the defendants, with costs of both trials. He also certified for a special jury. Mr. Stevens applied for a stay of execution pending an appeal. Mr. Justice Shearman said that as it was only as regards costs he could not do it.]

ALLEGED NEGLIGENCE: VERDICT FOR DEFENDER.

IN the Court of Session, on July 14th, Lord Anderson and a jury heard evidence in an action by Mrs. Edgar against Dr. A. Lamont, Chryston, Lanarkshire. The pursuer stated that while pruning in her garden she cut her left little finger very deeply. She washed and dressed the wound, but next day sent for the defender, who diagnosed that the finger was poisoned. The pain and swelling increased, in spite of the defender's treatment, and the pursuer went to Glasgow and consulted another doctor, who amputated the finger. She complained that the loss of the finger was occasioned by the defender's treatment of

it. The defender denied that he was guilty of fault or negligence. He was, he said, most careful in his attention to the pursuer's wound, and there was no negligence or failure in skill as regarded his treatment.

The case occupied the greater part of two days, and the jury, after an absence of an hour and three-quarters, returned a unanimous verdict for the defender.

HIGHER THOUGHT READING.

CHARLES W. J. TENNANT (Christian Science Committees on Publication) writes: In your issue of July 18th a report is given of the inquest held on Miss Scott. A statement is made by one of the witnesses that for some time past she had been interested in Christian Science. The mere fact of her having Higher Thought treatment would disprove this statement, as Christian Science and Higher Thought have nothing whatever in common.

Obituary.

SIR CHRISTOPHER NIXON, BART., M.D.,

SENIOR PHYSICIAN, MATER MISERICORDIAE HOSPITAL, DUBLIN.

WE regret to have to announce the death of Sir Christopher Nixon, Bart., which took place on July 19th at his residence, Roebuck Grove, Milltown, County Dublin. His health had not been satisfactory for some time, but it was only recently that it became a cause of anxiety to his family and friends.

Christopher John Nixon was born in Dublin on June 29th, 1849. He was educated at Trinity College, and at the Catholic University, Dublin. He obtained the licence of the Royal College of Surgeons in 1868, and took the degree of M.B.Dublin in 1878. He became a Fellow of the Royal College of Physicians in 1876, and was afterwards its President. He received the degree M.D. (*honoris causa*) from the Royal University in Ireland in 1885. He was also an LL.D. of Trinity College, Dublin.

He practised as a physician in Dublin, and was appointed physician to the Mater Misericordiae Hospital, which post he held till the time of his death. He was Professor of the Practice of Medicine in the old Catholic University, and was appointed Professor of Medicine in University College, Dublin, when the National University was founded. In these chairs he gained distinction as a teacher, and won the esteem of the students. He was also Visiting Physician to the Criminal Asylum, Dundrum, and St. Patrick's College, Maynooth, and Consulting Physician in Lunacy to the High Court of Chancery, Ireland.

He was a member of the General Medical Council from 1897 until his death—for the first twelve years as representative of the Royal University of Ireland, and afterwards of the National University. He worked actively for the new university, as a member of the Senate, and was also its Vice-Chancellor. He was a Fellow of the Royal Academy of Medicine in Ireland, and had been President of its Pathological Section. He took a leading part in bringing the scheme for a Royal Veterinary College in Ireland to fruition, and was elected its first President.

His publications include *A Handbook of Hospital Practice and Physical Diagnosis*, and several papers on diseases of the heart and nervous system.

In 1895 he was created a Knight, and in 1906 a Baronet of the United Kingdom. In the New Year's Honours list of this year he was nominated a member of the Privy Council in Ireland. He married in 1872, Mary Agnes, daughter of Dominick Edward Blake and grand-daughter of Joseph Blake, of Castlegrove, County Galway, by whom he had issue one son and three daughters.

H. H. B. writes: Dr. HUGH THOMAS SHAW died at his residence in Liverpool on July 16th, at the age of 57, from acute nephritis, which came on a few weeks after a severe attack of streptococcus tonsillitis. He retired some years ago from a very large private practice, transferring it to his partner, Dr. O'Connell. Later he became medical referee to the Royal Liver Assurance Company, and also resumed private practice. He was extremely well informed, and his deep knowledge and his sound judgement made him respected by all those who came into contact with him, while his unassuming kindness of heart, sympathy, and generosity made him loved by them. He cared nothing for social position, and held a too modest opinion of his own powers. Those of us who were proud to believe ourselves his intimate friends found that he endeared himself to us more the longer we knew him. The writer read with him for the diploma in eye surgery of the University of Liverpool, and was especially deeply impressed by his knowledge of bacteriology and the ease with which he overcame problems in physiologic optics. He was M.D., M.Ch., R.U.I., and held also the diplomas of public health, of tropical diseases, and of ophthalmology of the University of Liverpool. He was laid to rest at Yew Tree Cemetery on July 19th in the presence of a large number of his colleagues, friends, and former patients, the funeral affording impressive testimony to the great respect and affection they entertained for him.

MAJOR NICHOLAS MARDER, R.A.M.C. (retired), died at Exeter on July 10th, aged 50. He was educated at St. Bartholomew's Hospital, took the diplomas of M.R.C.S. and the L.R.C.P.Lond. in 1891, and entered the army as Surgeon-Lieutenant on July 27th, 1892, becoming Surgeon-Captain on July 27th, 1895, and Major on July 27th, 1904. He retired on July 27th, 1912, and joined the Reserve of Officers. He served on the North-West Frontier of India in 1897–98, in Tirah, and in the operations on the Samana range, receiving the frontier medal with three clasps; and in South Africa in 1899–1901, when he took part in the operations in Natal in 1899–1900, including the action at Talana and the defence of Ladysmith, and in the Orange River Colony in the second half of 1900, and gained the Queen's Medal with four clasps.

Medical News.

SIR JOHN TWEEDY, formerly President of the Royal College of Surgeons of England, has been elected President of the Medical Defence Union, in the room of Dr. Edgar Barnes, who has retired.

THE medical staff of the Central London Throat and Ear Hospital, Gray's Inn Road, will entertain American members of the Clinical Congress of Surgeons in London at breakfast at the Great Northern Railway Hotel at 9 a.m. on Thursday, July 30th, and afterwards, at 10 a.m., at a demonstration of cases at the hospital.

THE gold medal of the Royal Institute of Public Health, awarded annually to a public health medical official at home or abroad, in recognition of conspicuous services rendered to the cause of preventive medicine in the British Empire, has been conferred for the year 1914 upon Dr. James Niven, M.O.H. Manchester.

THE following Hull medical men have been made justices of the peace for the city: Dr. Frank Nicholson, Senior Physician, Hull Royal Infirmary, late president of the East Yorkshire and North Lincoln Branch of the British Medical Association; Dr. George Gantby, ex-sheriff of Hull, and Dr. C. H. Milburn, of Hull, a member of the Central Council of the British Medical Association.

WE are informed that the Life Assurance Medical Officers' Association intends to extend the scope of its work in order to include all medical questions connected with assurance. The next meeting of the association will be held in November and will be devoted to a discussion on the certification of incapacity under the National Insurance Act. The honorary secretaries are Dr. R. A. Young, 57, Harley Street, W., and Dr. Otto May, 19, Well Walk, Hampstead, N.W.

A COURSE of instruction for qualified practitioners will commence at St. Bartholomew's Hospital on Tuesday, September 8th, and conclude on Tuesday, September 22nd. Those entering for the course will be entitled to attend any part of the practice of the hospital as well as special classes, which will include clinical classes on medicine and surgery, electro-therapeutics and *x*-ray work, and diseases of children, of the eye, and the ear, throat, and nose. There will also be demonstrations of modern methods of examining the blood, the gastric contents, and cases of nerve disease, and others dealing with such subjects as vaccine treatment and modern therapeutic methods. Further information may be obtained on application to the Dean.

THE report of Colonel D. Wardrop, House Governor and Medical Superintendent of the Convalescent Home for Officers of the Navy, Army, and Marines, Osborne, for the

year ending March 31st, 1914, shews that 272 officers and the wives of 60 officers were admitted during the year. Of the 272 officers, 15 belonged to the Royal Navy. Of the officers admitted, 35 per cent. had been invalided home from tropical and subtropical countries. The recoveries among the officers numbered 206; of the remainder, 29 were improved, 13 were transferred to military hospitals, and 23 remained in the home on March 31st. One officer, who had shortly before undergone a very severe operation, died four days after admission. Various methods of physical treatment, including massage and electricity, radiant heat baths, ionic medication, and mechanical appliances, were used in 116 cases.

THE usual monthly meeting of the Executive Committee of the Medical Sickness and Accident Society took place on July 17th at 429, Strand, W.C. Dr. F. J. Allan was in the chair. The half-yearly balance sheet, which was submitted, showed that the society's reserves continue to expand. The funds amount to over £260,000, and the income of the society to over £35,000 per annum. The claim account presented was slightly lower than that of last year, and was under the expectation provided for by the tables. The report on new business showed an increase over that for the same month of the preceding year. For prospectus and all information apply to the Secretary, Medical Sickness and Accident Society, 33, Chancery Lane, London, W.C.

WE had occasion about a year ago to notice the reproductions made by Messrs. W. H. Beynon and Co., St. Alban's Lodge, Cheltenham, of drawings of Guy's Hospital and King's College Hospital by Mr. Hanslip Fletcher, and the same firm has now issued eight corresponding drawings of St. Bartholomew's Hospital. Those we have seen include the entrance in West Smithfield, with the tower of St. Bartholomew-the-Less, the fountain in the quadrangle, the great staircase, and the tomb of Rahere in St. Bartholomew-the-Great. All are excellent in their several ways, but especially attractive perhaps are those of the fountain and of the West Smithfield entrance; the set will certainly appeal to old St. Bartholomew's students as a charming memento of their hospital life. The subscription price for artist's signed proofs, printed on Japanese paper, with plate paper mounts, is 42s. the set.

A QUARTERLY Court of the Directors of the Society for Relief of Widows and Orphans of Medical Men, was held on July 8th, when seventeen members of the court were present. Dr. Rigden, senior vice-president present, took the chair. Nine gentlemen were elected members of the society. The sum of £1,890 was voted for the payment of the half-yearly grants to the widows and orphans. At the present time there are 45 widows and 13 orphans in receipt of grants. The invested funds of the society now amount to £139,500. Membership is open to any registered medical practitioner who at the time of his election is resident within a 20-mile radius of Charing Cross. The annual subscription is 2 guineas; the terms for life-membership vary with the age of the member. Relief is only granted to the widows and orphans of deceased members. Since the last court five letters had been received from widows of medical men asking for relief, but this had to be refused as their husbands had not been members of the society. Further particulars and application forms for membership may be obtained from the Secretary, at the offices, of the Society, 11, Chandos Street Square, W.

THE annual meeting of the Society for the State Registration of Trained Nurses was held at the rooms of the Medical Society of London on July 16th, Mrs. Bedford Fenwick, the President, in the chair. A resolution was passed in support of the memorial recently presented to the Prime Minister by Dr. W. A. Chapple, M.P., on behalf of the Central Committee for the State Registration of Nurses, urging the Government to grant facilities for the Nurses' Registration Bill which passed its first reading by a majority of 228 on March 3rd last. During the meeting a message was received from Dr. Chapple, stating that the Home Secretary had consented to receive a deputation from the society. A resolution was also carried, pointing out that "under the National Insurance Act the qualifications of medical practitioners and midwives attending insured persons are registered under State authority," and urging that nurses subsidized by State funds should be similarly guaranteed. Sir Victor Horsley addressed the meeting on the registration question, and said the movement did not aim at the selfish aggrandizement of nurses, but had in view the benefit of the public. Whilst the very poor obtained the best of nursing in public institutions, those in moderate circumstances had no security that they would receive trained nursing aid.

QUERIES.

ASTHMA desires to hear of a public school within thirty miles of London suitable for a boy of fifteen suffering from asthma.

DOCTOR HURRYING TO AN ACCIDENT.

DR. EDWARD JEPSON (Ruislip) writes: A short time ago I was hastily summoned to a serious accident; I availed myself of the nearest vehicle at hand, and the man drove the horse as fast as he could, but we happened to meet a motor, which must assert a sort of precedence, and did not make way, and so stopped me in my hurried course, thereby causing me to lose some minutes of very valuable time. I ask if we cannot establish some signal whereby a doctor in a vehicle or motor shall secure a free course before him. I would suggest that the waving of a handkerchief should be accepted as a signal on those occasions. The police, on being properly instructed, would, no doubt, gladly accept this as a signal to be regarded, and make a clear course for a doctor hurrying to an accident, or where medical aid is urgently needed. In the case of a wrong use of the signal a penalty should be inflicted.

ANSWERS.

THE FLY NUISANCE.

DR. J. N. TURNBULL (United Free Church Mission, Bhandara, C. P., India) writes: With regard to the fly nuisance (BRITISH MEDICAL JOURNAL, June 13th, p. 1330), received here by last mail, you may have heard of many formulae containing formalin. The following one, which hails from America, was reproduced in the *Indian Medical Gazette* in August, 1912. It is: Formalin, 1 fluid oz.; Milk, water, of each 8 fluid ozs. This mixture is to be placed in five or six shallow plates, with a piece of bread in the centre of each on which the flies can alight and feed. My experience has been that this method is very efficacious, the flies falling dead a few seconds after drinking.

LETTERS, NOTES, ETC.

A DISCLAIMER.

MR. W. THELWALL THOMAS (Liverpool) writes to disclaim any responsibility for an article in a Blackpool newspaper with reference to a case of a bullet wound admitted to the Blackpool Victoria Hospital. The article appeared, he informs us, without his knowledge, and is an exaggerated and highly-coloured account of a consultation he attended at the hospital.

FLIES AND AËRATED WATERS IN STOPPERED BOTTLES.

A MEDICAL OFFICER OF HEALTH writes: The other day I sent for a bottle of lemonade and noticed all around the mouth of the stoppered bottle evidence of filth deposited there by flies. It is clear that the flies had been attracted by the remaining saccharine matter. This would, of course, also apply to the mouths of siphons. I write this letter in order that some inventive genius may bring forward a stopper—a simple matter—which will cover, as a shield, the aperture of the bottle and prevent flies depositing their filth there. A paper cover over the stopper could be used for bottles, as in the case of a well-known brand of bottled beer, and a small metal shield or cap, with chain, for syphons. It must be patent to every one that if some protection is not made, when the fluid is poured out of the bottle or syphon, the filth of the flies must become mixed with it.

President's Address

DELIVERED AT THE

EIGHTY-SECOND ANNUAL MEETING OF THE BRITISH MEDICAL ASSOCIATION

BY

SIR ALEXANDER OGSTON, M.D., K.C.V.O.,

EMERITUS REGIUS PROFESSOR OF SURGERY IN THE UNIVERSITY OF ABERDEEN.

ON THE MAKING OF A SCOTTISH MEDICAL SCHOOL.

My first word to-day from the presidential chair must be to wish the members of the British Medical Association a very cordial welcome to this city, and at the same time to offer them my thanks for electing me to this honourable position.

It is a frequent custom for whoever presides at the Annual Meeting of the Association to open the proceedings by an address dealing with the progress that medical science has made in the year that has just terminated, or on some kindred topic; but I may perhaps be excused for departing from this custom, particularly since those who, like myself, have withdrawn for several years from the ranks of investigators, and fallen out of touch with the medical problems and questions of the day, quickly lose the knowledge requisite for treading in this path.

It may, however, add much to the interest and profit of your stay in Aberdeen if I venture to draw your attention to the city and neighbourhood which you have come to visit, and tell you something of their history in so far as it led to the establishment of what is said to be the oldest Faculty of Medicine in any university in Great Britain or Ireland. For while our town and district may appeal to those who love the beautiful by their physical attractions; and their inhabitants interest anthropologists, philologists, and students of character, as exhibiting a highly successful amalgamation of many races; yet their history is chiefly that which, were it properly told, should touch a responsive chord in Englishman and Scot alike.

A word in the first place as to the inhabitants. The earliest race of whom we possess anything that can be called knowledge was a Celtic stock, as was also the case in England, and down to the time of the Roman conquest of Britain they were the undisturbed possessors of these, the north-eastern counties of Scotland. Though they have left their language in the names of the localities along the sea coasts, they were not a maritime race, but placed their settlements far inland, and evidently neither loved the sea nor made use of it as a regular means of trading or procuring supplies of food. So far as these earlier generations belong to the age of prehistory, they have left behind them, in this part of Scotland, a large number of structures of various kinds, such, for instance, as the so-called "Druidical" circles, and especially, on the higher hills, mountain forts of a magnificent character, exceeding in number, antiquity, and perfection anything that exists in any other country except perhaps Ireland. A full interpretation of the meaning of these constructions has not yet been attained to; and those who have antiquarian interests ought not to miss the present opportunity of inspecting them.

Except for place-names, the Celtic language has died out as a living tongue in this vicinity; but the personal type of the Celt is still strong among us. From personal observation of the students attending our university, I should incline to estimate that 7 per cent. of the population still exhibits a tolerably pure Celtic type.

From days earlier than can well be dated, however, other and non-Celtic immigrants, maritime in their tastes, crept gradually along our coasts, coming mainly from the north and east, and did not so much dispossess the Celts as settle along the less occupied shores, which the latter did not covet; there they practised the art of fishing, finding abundant reward in doing so, and were the main channels through which elementary trade began. They were the introducers of the Lowland Scots tongue, and were partly Scandinavians, partly Teutons and Saxons. Their physical difference from the Celts can still be readily observed among the inhabitants of our coastal villages and hamlets. The newcomers gradually fused with, and no doubt in some cases dispossessed the Celts, who were mostly hunters, and introduced better methods of agriculture into the country. In this manner, by the amalgamation of these stocks, the people and speech of this part of the kingdom of Scotland were formed, and Aberdeen eventually came to be their chief town.

The Times in which the University and Medical School were Established.

If you will now take a long step of a thousand years or so, forwards into historical times, during which interval the autochthones and immigrants had amalgamated into a harmonious whole, and progress in the arts and industries been made, a progress due chiefly to the increasing numbers of the settlers along the sea coasts, it will bring us to the time to which I wish specially to invite your attention, the latter part of the fifteenth century, which was not only one of the most interesting periods in the history of Scotland, but also the epoch in which are found the earliest beginnings of organized medical tuition in Great Britain.

At that date, towards the year 1500, the wars of York and Lancaster, after lasting half a century, were drawing to a close in England, and, surprising as it may seem to us, owing to the very indirect connexion, it was indeed partly due to these Wars of the Roses that the earliest of all the British schools of medicine was established in our city. It came about in this wise.

When there was turmoil in England, Scotland could never be quiet. England's difficulties were the opportunity of France, and France was perpetually requisitioning the help of Scotland. Consequently, in the entire period of 170 years preceding 1500, Scotland, although she may have had an occasional moment of imperfectly-kept truce with England, had virtually been uninterruptedly at open war with the latter kingdom, and therefore never enjoyed the quiet necessary for developing the arts that thrive only in time of peace. But the impulse to do so was felt only the more keenly for its repression, and acted the more powerfully when the restraint was removed. There were many directions, as we shall presently find, in which these wars affected Scotland, and indirectly brought about the foundation of our university and school of medicine; but, before dealing with them in detail, it may be advantageous to pause for a moment and endeavour to trace the condition of Scotland at that time.

The few accounts that have come down to us of the state of our country in the latter half of the fifteenth century vary according to the prepossessions of their authors, but suffice to show that while Scotland was not altogether destitute of products which she could advantageously barter with the rest of the world, she was so exceedingly wealthy in fighting men and a warlike spirit, that ambassadors and diplomatists were continually streaming to her Court from the Continental Powers or across the borders from England, with the mission either to incite the Scots to make war or induce them to make peace. Several of these emissaries, in their written reports to those who sent them, have left interesting narratives of the condition in which they found the country. A Spaniard, for example, called Don Pedro de Ayala, gave a business-like account of the trade and commerce which he found there about the year 1498; while an Englishman, John Harding by name, who was sent to spy out our nakedness (it is said about 1460, but from his mentioning the university here, we think possibly forty years later) has left behind him a minute and detailed statement in rhyme of the different parts of Scotland, how it could best be invaded by the English, and its several provinces be destroyed in succession.

From these and other similar writers it may be discovered that, at the date of which we speak, the greater part of our country was a cold, treeless, barren moorland, where intersecting mountains and arms of the sea impeded development by interposing barriers insuperable except to the few whom necessity compelled to traverse them at much risk and discomfort. Where, however, there was a good harbour, or the mouth of a river, there had sprung up little towns which drove a trade with the Continent and England in fish, furs, hides, wool, and similar produce. All these places were as yet but small; St. Andrews, perhaps, was the largest; but there was no recognized

capital; and possibly the then citizens of Edinburgh would have been astonished had it been foretold them that their town was destined to be the future metropolis of Scotland. Around these towns the land was cultivated, and sheep were generally pastured; while the harbours served as centres for the distribution of Continental produce. Yet, taken as a whole, the commerce was by no means great, for all the customs of the kingdom were not worth more than £3,000 a year. That figure gives us a measure of the poverty of Scotland.

Regarding the roads, one may gather that probably the eastern Roman road of northern England was connected in Scotland with that which led by Berwick and the Lothians to Edinburgh and Stirling, extending to Perth, and even, after a fashion, on to Aberdeen; but as the condition in which they were was of the worst, most of the northern traffic that existed was sea-borne; and even anywhere it was a toilsome enterprise, and one not lightly to be undertaken, for even a wealthy traveller to proceed from one part of Scotland to another by land.

The Condition of Aberdeen in 1490.

Could we cast an eye backwards on our city, and describe what it was like in those days, as we may suppose it would have impressed a stranger who had elected to come to it by land, we should find that he could reach it only by undertaking a weary ride of twenty miles or more, probably from Bervie, where he might have passed the night, and his way would have lain over uninhabited moors by rough hill-tracks, until he reached a ford of the river Dee a couple of miles or so above the town. There he might have forded the river if the water had been low; possibly he might have been ferried across; but not improbably he and his horses might have had to wait for days till the river had subsided. As he neared the town after overcoming this and minor obstacles, his path would have led him to the valley where the railway station at which you arrived now stands, where the ground was then a quagmire, partly covered with mud and seaweed, and partly a reedy expanse where the wild-fowl bred in summer; while where the railway runs northwards under Union Street Bridge he would have had to ford a stream which the salmon ascended in order to reach a loch, now no longer in existence, on the eastern side of the present Infirmary, while a few crofts would have been visible fringing the left bank of the stream.

On the western side of the stream, where the music hall in which we are assembled now stands, there were no houses, but there stretched out for many miles a great moor, nearly devoid of trees, with here and there some of those pillar-like upright stones (erected by a forgotten race of menhir-worshippers), such as the "Lang Stane" and the "Crab Stane"; it was a hunting ground, a camping place for the kilted Highlanders and others when they approached the town for spoil or more peaceful objects, and on it more than one battle was also fought.

Where spacious docks now accommodate our shipping, the river Dee then ran; a tidal stream, with channels winding about among numerous islands which were nearly covered by the sea at high tides; and on the northern bank of the Dee was the small town of Aberdeen, of 1,500 or perhaps 2,000 inhabitants, who carried on their Continental trade in ships of 20 or 40 tons burden, and were many of them occupied in the capture of the large quantities of salmon and herring, which even in those days formed a considerable part of their trade with the rest of the world. This was the infant stage of the huge fishing industry which now adds so much to the prosperity of the town, but it was a sturdy infant, for between 50,000 and 100,000 salmon alone were yearly caught, and mostly cured and exported; though that may seem small in comparison with the 200 to 1,000 tons of fish now daily landed here preparatory to being sent away to many parts of the world.

The population of the town was indeed but small; probably no more than one or two hundred fighting men could have been mustered; it has never been a really fortified city or a place of great strength, and was, therefore, frequently taken and retaken in the wars that preceded and followed the period which we are considering.

Though far from being large, yet Aberdeen was then one of the five chief towns of the kingdom, for Cosmo Innes, in his preface to Parson Gordon's *Description of both Towns of Aberdeen*, tells us that "long before Edinburgh had acquired the precedency of a capital, or even the first place among the four burghs of Southern Scotland—while Glasgow was yet an insignificant dependent on its Bishop—Aberdeen had taken its place as a great and independent royal burgh"; and John Major, who wrote his *Historia Majoris Britanniae* a year or two after 1495, testifies that "ea tempestate Aberdonia Scotorum erat regia"; so that our burgh, had it not been for its remote situation, was in the running for being the metropolis of Scotland. It was not till about 1503 that Edinburgh was recognized as occupying that position.

The town, lying on the slope of the hill, extending from the shore upwards to where Marischal College now is, or a little farther, presented many signs of prosperity in its own way. Small ships were being loaded for Continental ports; fishermen, in small boats came and went with their cargoes of fish; and boats and nets were plying for the capture of salmon both on the river and on the loch which, as we said, lay in what is now the northern centre of the town. It was even then a place which pleased strangers. Kings resided and Parliaments were held in it. Parson Gordon of course praised his own town; "The citie of Aberdeen," he wrote, "exceeds not onlie the rest of the touns of the north of Scotland, bot lykewayes any citie quhatsumever of that same latitude, for greatness, bewtie, and frequencie of trading"; but even a foreign traveller like Jean de Beaugue said in 1548 that "Aberdeen is a rich and handsome town, inhabited by excellent people."

Our independent little burgh had a fair chance of prospering, for it possessed a good many advantages to counterbalance its remote situation. The harbour, though only a second class one, has always been a most valuable asset, and the fishing trade which then flourished there has now so grown as to have become one of the sights of the world. But even four centuries ago the harbour was, in the words of Gordon and de Beaugue, very easy and safe for ships to make, were it not for its entrance, which is narrow. The trade consisted of salmon, herring, woollen goods, linen, stockings, skins, and hides, and all that the country yielded, to quote the Parson once more, and the traffic in his day was, as it still is, with "Norroway, Swethland, Denmark, Pole, Germany, Holland, Flanders, France, Spayne, and England." Moreover, owing to its having been, as early as the ninth century, made a royal burgh by Gregory, King of Scots, all the market towns, villages, and hamlets which were in the neighbouring shires, excepting the other royal burghs, were so far subject to it that they could trade neither by sea nor land without its licence.

Though the picture thus drawn of our city by contemporary writers in and before 1500 shows that it contained many elements of future prosperity, yet it is plain that the tints they used ought not to have been altogether rose-coloured. Though the sides of the roads leading out of the city exhibited fruitful fields and good pastures, yet everywhere beyond a mile from the town the country was barren, with stony hills or extensive plains full of marshes and mosses, interspersed with moors covered with heather or expanses of stony, unprofitable ground; and, moreover, we learn that in 1482, just before the time we are concerned with, "There was great dearth and hunger in Scotland which continued for two years and more, while also there was great war between England and Scotland and great destruction through the wars of corn and cattle. And these two things caused both hunger and dearth, and many poor folk died of hunger." The country, too, was full of a debased currency, which added enormously to the general distress.

The State of Culture and Education in Aberdeen.

Turning from the material to the intellectual aspect of things, there can be no doubt that the oasis of the city was so isolated by the surrounding desolation and its great inaccessibility that it had more than its share of the rudeness and illiteracy of the rest of Scotland; we find that this was recognized by the older historians, while the contemporary sources of information tell the same tale. When writing of this period Cosmo Innes says: "It is not easy to overstate the physical and ethnical impediments to education in the Highlands and Isles of Scotland"; and Pope Alexander VI (otherwise Rodrigo Borgia, father

of Cæsar and Lucretia Borgia), in his Bull regarding the foundation of the university, uses the following terms concerning our district at the very time of which we are treating: "In the Boreal and northerly parts of the kingdom of Scotland there are certain places so distant from other parts and so cut off by arms of the sea and the highest mountains, wherein live rude and illiterate men, almost savages, and who on account of their great distance from spots where there are schools of learning find it dangerous to travel to where letters are studied, who, moreover, are so ignorant of learning that persons cannot even be found capable of reading the word of God, preaching, or administering the sacraments."

While one must fully admit that the state of affairs existing in Aberdeen warranted such statements, yet it should not be overlooked that the character of its inhabitants, who were a mixture of the finest and most energetic races, as we may without boasting claim them to have been, was not one to have passively submitted to such ignorance without efforts to remedy it. Pope Alexander expressly admits this: "Si in inclita civitate veteri Aberdonensi, quæ locis prædictis satis vicina est, vigeret generale Studium literarum, . . . quamplures homines ipsius regni et præcipue partium illarum, tam ecclesiastici quam laici, literarum studio libenter intenderent" (if in the town of Old Aberdeen, which is in the immediate neighbourhood of such places as the aforesaid, a university of letters were carried on . . . many inhabitants of the kingdom of Scotland, and particularly in that neighbourhood, ecclesiastics as well as laymen, would gladly avail themselves of the opportunity of cultivating such literary studies).

There is no lack of corroborative evidence that the Pope had been correctly informed of the Aberdonians' eagerness to learn, and that they had a taste for letters; for without pretending that the pre-university tuition could have amounted to much, we have the notable fact, of which the city is justly proud, that there was a Grammar School in Aberdeen in 1262, and more or less continuously ever since. Even a hundred years before the date of which we speak it was under the management of the magistrates, community of the burgh, and the Chancellor of the diocese; while the interest which our city took in schools at the time we are describing is shown by the King, acting under influences which, as will be mentioned later, emanated from Aberdeen, having in 1496 passed a law for Scotland "That all barons and freeholders were to send their eldest sons to the schools from the time they were eight or nine years old. At the Grammar Schools, says the Act, they were to remain till they had acquired perfect Latin. They were then to proceed to the schools of art and law, where a curriculum of three years would qualify them to administer law and justice to the parts of the country where they belonged, so that the poor 'should have no need to seek our sovereign Lord's principal Auditors for each small injury'" (Hume Brown).

It is rather wonderful to think how much natural appreciation of literature existed in Aberdeen in those days. Long before 1500 there had been in it poets of no small merit, who composed their verses in the Scots tongue, though fragments only of their works have as a rule come down to us, and some 120 years previous to that date John Barbour, Archdeacon of Aberdeen, a contemporary of Chaucer, had written (in 1377) a poetical history of the Bruce, as well as other poems, all in the Scots vernacular. It is not possible to conceive that a cultured cleric like Barbour would have been the author of works in the ancient Scottish language unless he had had a large and appreciative audience to address; and it is evident that such had existed for centuries in Scotland, as well as in Aberdeen, for writers elsewhere used the same speech, and besides many poets who flourished about 1500, Wynton's "Chronicle," or History of Scotland, written in Scottish verse by a monk of St. Andrews, was composed about 1400, a date not very much later than Barbour.

Such, then, was the educational state of this part of the world. Its people had a natural love of letters, cherished their vernacular poetry, did what was in their power to maintain education in their midst, and were ripe for further enlightenment when it could be obtained.

The Advent and Character of Bishop Elphinstone.

Some time about the year 1483 there came to Aberdeen, in all probability by land, one who was destined to be its greatest benefactor, William Elphinstone, who had just been nominated to the bishopric of the diocese. It is difficult to reconcile the dates given by his biographers, but it must have been within a year or two of that time, and Elphinstone was a man approaching 60 years of age, when the churchmen, nobles, and citizens alike went out in procession, with music, to meet him and do honour on the occasion to one whose advent they had greatly desired.

We possess a portrait of him in King's College in Old Aberdeen, which shows, I think, that he was a person of not more than medium height, with a sweet benevolent expression of face; his features indicating that he was a healthy man who had led a temperate life, and being unmarked by any lines that point, as do so many portraits of Scots of that period, to hardness or unscrupulousness, but showing thoughtfulness, earnestness, and goodness; altogether a beautiful character, in every respect coinciding with what we otherwise know of him. If one were to judge from the portrait alone, one would perhaps rather rank him among dreamers and visionaries, than among men of affairs.

Before he came to Aberdeen as its Bishop, Elphinstone had already occupied a post of high preferment in the diocese of Glasgow, and those were days which soon tested the characters of men, particularly of such as held high positions in the Church, both in England and Scotland. The ancient Church was being threatened, and the seeds of heresy were springing up in both countries. The "New Learning," as it was termed, was teaching men everywhere to think for themselves regarding religious matters, and Scotland was notoriously a bad place for churchmen if the laity were to think independently and to criticise them, for "there was no Christian country where ecclesiastical scandals had been more flagrant than in Scotland," and according to all historians that century "was marked by a rapid declension both in the morals of the clergy and the government of the Church. By the sale of benefices and the appointment of unfit persons to important offices even the King and his courtiers were giving abundant proof that the good of religion was not very near their heart" (Hume Brown). Hence the ecclesiastical dignitaries had found it expedient, in the beginning of the century, to burn the free-thinking James Resby at Perth, and only three years before Elphinstone was born the Bohemian envoy Paul Craw was also burnt at the stake for his doctrines. Moreover, at the very date we speak of, the thirty "Lollards of Kyle" were already giving trouble, and a year or two later were to be arraigned before King James and Archbishop Blackadder of Glasgow on the charge of heresy, and probably they would have been burnt too had not the good-natured King turned the whole matter into a jest. It was indeed a thorny problem for the priesthood how to deal with such disturbing opinions, and it is greatly to the honour of Bishop Elphinstone that he sought what he believed to be the more excellent way to encounter heresy than by an *auto da fé*. His very portrait tells that he was not the material of which his contemporary Torquemada was made.

In more than spiritual matters Elphinstone appears to have kept his conscience clear. At that particular time in the history of Scotland (and it was the same, though perhaps to a less degree, in England) the clergy had attained to a power and influence which they did not enjoy to quite the same extent at any subsequent period. This was greatly due to the civil wars in England—the Wars of the Roses—and war in England was a galley in which Scotland must needs always pull an oar. Their exigencies called for the employment of numbers of skilled jurists to act as negotiators, experienced diplomatists, and ambassadors to foreign countries, who must also be linguists, to carry on the negotiations between nations and arrange their treaties. This work fell mainly on the churchmen, who were almost the only persons possessed of real education, skill in documents and legal questions, and the gift of tongues. In such positions their power became very great. Thus, in the Scots Parliament of 1478, out of thirty-nine real members—for the extra commissioners of burghs, fourteen in number, had no influence at all—there were sixteen ecclesiastics, not

much less than one half of its working body. Again, during the first five years of James III's minority, that is from 1460 onwards, the good Bishop Kennedy of St. Andrews was the main administrator, and carried on the government of the country well and successfully; and when the King was being kept in ward in Edinburgh Castle in 1482, his government was carried on by five persons, two of whom were the Archbishop of St. Andrews and the Bishop of Dunkeld. Similarly, previous to the battle of Sauchieburn, wherein he lost his life, the same King James sent six envoys to negotiate with his rebellious son and nobles, and one of them was a cleric, no other than our Bishop Elphinstone; while of the five negotiators on the opposite side the Bishop of Glasgow was one. This was in 1488. Lastly, in Anglo-Scottish affairs, Bishop Fox of Durham was chosen by Henry VII of England to arrange the marriage of his daughter Margaret with James IV of Scotland. A host of such examples might be cited.

The temptation to use such positions for their own temporal interests was too much for the integrity of many of the churchmen, and they acquired riches by means that were highly questionable. The most shameful Scottish cleric was Andrew Forman, Bishop of Moray, whose name is still vile in his countrymen's ears; for when he acted as James IV's ambassador to congratulate Henry VIII of England on his accession to the throne and at the same time negotiate treaties of peace; also when in 1511 he went again to the English Court to make peace; and when for the third time in 1513 he went back there for the same purpose; he accepted rich ecclesiastical preferment from England, and was the cause of that fatal battle of Flodden Field where Scotland's King was slain and Scotland's nobility almost exterminated. He appears to have had his pockets open to every purchaser, for when he was dispatched to France in order to tell how affairs in Scotland stood, he came back Archbishop of Bourges, for which substantial honour he no doubt gave an equivalent. He was a man of whom the historian Hume Brown, in words which are mild enough, says, "A counsellor in James's later years was Forman, Bishop of Moray, whose promptings emphasized the weakest sides of his nature, and involved him in a policy which had such a tragic result for himself and his country." Forman's prosperity in Scotland received no check, for the Pope made him Archbishop of St. Andrews before he died.

Elphinstone's History.

Elphinstone was a man of a very different character from Forman, and it was not from want of opportunities to enrich himself that he came a comparatively poor man to Aberdeen in 1483, since four years previously he had been marked out for preferment in being sent by the King on a mission to Louis XI of France, and in the preceding year had been ambassador to Edward IV of England.

James III appreciated Elphinstone's abilities and honourable nature; created him a Privy Councillor in the same year as he received his bishopric; twice afterwards—in 1484 and 1485–6—sent him on embassies to England; and appointed him Lord High Chancellor of Scotland in 1488. Loyally in return Elphinstone served his master James III, a difficult service in which he yet secured the esteem of all; and it is one of the finest possible testimonies to the respect and trust which he inspired, that although he had at the battle of Sauchieburn been in the camp opposed to the succeeding King, James IV, and also in spite of the fact that it was in the bishop's own diocese that the turbulent Aberdeenshire men had, the next year after Sauchieburn, risen in rebellion, exhibiting as their banner James III's blood-stained shirt, yet the new King almost at once received him into favour, made him ambassador to France in 1493, and gave him the office of Lord Privy Seal, which he held from three years after Sauchieburn until his death. Our local records tell the same tale of how Elphinstone was esteemed by his opponents; for prominent among those who helped him by their donations to found his university were some of those very landholders who had been in the ranks of his enemies at the battle of Sauchieburn.

To the new King also he gave wise and faithful counsel, and there can be little doubt that it was he who inspired that monarch to pass the Act to which reference has already been made for the better education of the eldest sons of barons and freeholders. It will be remembered that the Act included compulsory Latin instruction from nine years onwards, and thereafter a three years' curriculum in a school of art and law, which is in fact the curriculum of a university. The inference is unavoidable that this legal definition of what a lad ought to study, dated in 1496, coupled with Elphinstone's being at work planning the machinery of his university in that same year, and also then holding the office of Lord Privy Seal, almost certainly earmarks the legislative measure as having originated with the bishop. If we are correct in drawing this conclusion, it follows that to Elphinstone belongs the credit of having anticipated, by several hundred years, the introduction by the State of the principle of compulsory education, which first appeared in England in the Education Act of 1870; in Scotland in that of 1872; and in France in 1882. Even before these dates, however, some of the burghs and town councils of Scotland had tried to give effect to the principle which he had been the means of first placing on a British statute book.

Such were the personality and character of the new prelate. He was, it is true, only the illegitimate son of a canon of Glasgow, but he had taken the degree of Master of Arts in its university; had studied in the University of Paris and there taken the degree of Doctor of Decrees; had been lecturer in Orleans and Rector of Glasgow University; and had proved himself a ripe scholar and experienced politician. He was, in fact, one of the foremost statesmen as well as one of the finest characters of his day, and is well summed up in the words of the *Dictionary of National Biography*: "Elphinstone was at once the foremost churchman and statesman of his time in Scotland; his pre-eminence in wisdom, learning, benevolence, and generosity has never been questioned, nor his name mentioned except in terms of high praise."

Elphinstone's Reception in Aberdeen.

Some people are of opinion that the better the Aberdonians are known the more they are found worthy of respect and even liking; although this opinion is not universally held, and "the sainted Samuel Rutherford," who was banished for two years to Aberdeen on account of his treason, while acknowledging that the citizens were kind to him, has put it on record that they were "dry, cold, and general," and that in 1637 there were only two pious persons in the town. However this may be, one good quality at least they may claim, that they know how to esteem men of ability and honour who come amongst them; and though some coolness is said to have existed in those days between the Church and the city, they received the good bishop so warmly that thenceforth he devoted the best part of his time and thoughts to planning and promoting their interests and those of their town.

It is probable that he found the strangeness of the northern city mitigated from the first by ties of relationship; for his family seems to have belonged to those Elphinstones who were lords of Kildrummy in Strathdon. At all events, he was soon at home with the people and their wants. He appreciated with the insight of a great administrator the possibilities of the place, and foresaw future greatness for it, not as a factor in war, which to ordinary minds would have seemed most imperative in those days of trouble, but in the development of commerce and culture. On his decision to promote the latter depended much of the subsequent eminence of Aberdeen, and Elphinstone went to the very root of this matter, as only a man of the most uncommon foresight could have done.

As a question of necessity his first care was to regulate the condition of his diocese. The shocking condition into which the Ancient Scottish Church had fallen in those days has already been intimated; and from various sources it may be discerned that it took the bishop five or ten years to restore it to proper order; while the thoroughness with which the task was accomplished is shown by the absence of scandals which local history reveals for many decades, one may even say for centuries afterwards. One is sometimes inclined to think that Elphinstone's spirit still survives among the various religious bodies here, for any bitterness that a layman observes in their relations seems to be invariably stirred up by some stormy petrel from elsewhere.

While he was engaged upon Church reforms, however, it is clear that Elphinstone was also considering his other benefits to the city, for when his schemes regarding them came to be produced, they all bore the stamp of long and careful consideration and ripe planning.

In all things Elphinstone was a contrast to most of the other Scottish prelates of his time, with the exception of his senior, Bishop Kennedy of St. Andrews, who had now been dead for twenty years, but whom he must have known well, and possibly taken for his model. It is pleasing to think that he was happier in his remote diocese, with no one to envy him, than Kennedy and his successors were in the more central see, for he is known to have refused the offer of the Archbishopric of St. Andrews.

Elphinstone's Schemes.

Elphinstone's principal schemes for the benefit of Aberdeen were three in number, and we shall take them in our own order, not chronologically. They were — the restoration of the cathedral; the provision of a good and practicable access to the city by land; and the foundation of a university. We, who witness the results of his designs, which to him can have been only dimly viewed in the future, can best appreciate the wisdom of the man who, though a churchman, devoted less attention to the first of these than to the latter two, or at least seems to have assigned to it but a secondary importance.

Cathedral.—The financing of his schemes must have caused Elphinstone much consideration; he himself was a poor man, and at this time poverty was sore in Scotland; indeed, the best that could have been said for the prospects of his carrying out his plans was that, provided there were no further famine, although money might locally be scarce, other things would be plentiful enough (Estienne Perlin). A choice of priority had, however, to be made among them, and accordingly he first built the great steeple or tower of the Cathedral of Old Aberdeen (long since fallen), placed in it a large peal of bells, covered the steeple and Cathedral roof with lead, and left the work on the rest of the edifice to be completed by his successor, Bishop Dunbar. All Elphinstone's labours on the Old Town Cathedral have long since disappeared, but his other benefits to Aberdeen still remain.

The Old Bridge of Dee.—Next, as to his second scheme. When Elphinstone arrived in Aberdeen access from the south by land could be obtained only by a difficult and often impassable ford across the river Dee, just above the town, or by other similar fords up the river towards the west. It is said that once previously there had been a sort of bridge over the river, but if this had been the case it had long ago disappeared. It is to Bishop Elphinstone that we owe the beautiful Old Bridge of Dee, two miles up the river, though now reached in a few minutes by the tramway, which long remained the only, and still forms the chief, means of approach to the city for southern road traffic; and, although he did not live to see it finished, he collected the materials and bequeathed a large sum of money for it to his successor and executor, Bishop Dunbar, by whom it was supervised and completed in 1527. It deserves the quaint encomium it received from Parson Gordon 150 years later: "Two mylls from Aberdeene, towards the south-west, standeth the bridge of Dee. It hes 8 pyks and 7 arches, the greatest and brawest bridge now to be seen in Scotland, built at first at the cost of William Elphingstoune, bishope of Aberdeen, about the yeer 1518."

King's College and University of Old Aberdeen.

There are few beyond our walls who realize how magnificent a gift Elphinstone bestowed on Aberdeen and the North of Scotland when he founded our university, and there are still fewer who appreciate the wisdom he displayed in its organization.

The bishop lived in an era of intellectual restlessness. From Italy and Germany, as we know, the "New Learning" was spreading, and altered ideas of morals and religion were being accepted in England and Scotland as the Middle Ages gave place to the Renaissance, but all that must have been familiar to Elphinstone, and caused him and the other prelates of the Ancient Scottish Church much disquietude. The appropriate remedy was to be sought, so he believed, in a wider development of learning and the better instruction of the priesthood of his church, while if these objects were to be carried into effect the only possible means were the establishment of a "Studium Generale," or, in modern phrase, a university. Eighty years previously Bishop Wardlaw had been the means of founding such a place of study in St. Andrews, where it proved successful; while thirty-seven years after that Bishop Turnbull (or, according to Boece, Bishop Dursdeir) had done a similar service for Glasgow, where it had been less satisfactory. In the latter university Elphinstone himself had been a graduate in Arts as well as Rector, and he therefore possessed the knowledge requisite to avoid the errors which had caused it to be a comparative failure. His father, moreover, was in Glasgow University the Dean of the Arts Faculty, so we perceive that, besides being well versed in the methods of working such institutions, and familiar with the benefits to be derived from them, Elphinstone possessed a hereditary attachment to them, a force not to be overlooked in the consideration of his mental operations.

It was fortunate for the bishop's design that he stood high in the confidence and esteem of the King of Scotland. As Lord Privy Seal he participated in his sovereign's most intimate counsels; and to understand the import of this connexion, it is necessary to know something of the monarch, King James IV, who then occupied the throne.

King James IV.

James was one of the ablest, most brilliant, and most picturesque of the Scottish kings, and though his memory is darkened by his faults, and by the calamity which, through the influence of unwise advisers, against Elphinstone's counsels, and at the cost of his own life and that of almost his whole nobility, he brought on his country by the fatal battle of Flodden, yet he is still dear in fact and fiction to the inhabitants of Scotland. James was a most active and energetic administrator, and was the first Scottish King who fairly faced the rebellious and turbulent Highland tribes, penetrated with his forces into the fastnesses of the clans, reduced them to such order that his mandate ran throughout all Scotland, and ruled so effectively and wisely that those Highland warriors were among the bravest troops who followed him to Flodden. During his reign "Scotland increased her resources and her prosperity to a degree greater than at any former period of her history . . . and his nobles, who had caused such trouble to preceding kings, were content to be his servants and counsellors" (Hume Brown). With a wisdom which was much in advance of his contemporaries, he strove to strengthen Scotland, which though very formidable on land was weak at sea, by the creation of a powerful navy. The English fleet regularly harried the commerce and coast of Scotland, and seven years before the commencement of his reign the English, under Lord Howard, had carried off eight large vessels, probably the whole Scottish navy, from the Frith of Forth; and James set himself to repair the loss by bringing trained shipwrights over from France and importing wood for building vessels from that country and Denmark, owing to the wood in Scotland, which was never abundant, being soon exhausted. By the conclusion of his reign he had so far succeeded in his purpose that in 1502 he was able to send two ships and 2,000 men to the aid of his uncle, the King of Denmark, and in 1513 another fleet to the assistance of France.

James's right-hand man in forming his fleet was Sir Andrew Wood of Largo, the Scottish Sir Richard Grenville, who with only two ships made prizes of five English vessels which were working havoc among the shipping in the Frith of Forth, and in the same year (1489) after a sea fight that lasted for two days, and was waged along the coast from St. Abb's Head to opposite Dundee, defeated and captured Stephen Bull and his three English ships, by means of the same two vessels, and brought his captures into that port. Wood was a trader as well as a naval commander, and not above a little piracy at times, but he was a gallant man, and no worse than other sailors of the period. Naval warfare was a rough trade in those days: another commander of James's, Andrew Barton, being commissioned to effect reprisals on the Dutch who had been pillaging the Scottish merchants, sent the King home certain casks with the heads of the Hollanders whom he had slain, after taking many ships. Scotland's naval strength was

eventually so much augmented by James, that a mere letter from him sufficed to bring to reason the magistrates of Dantzig, who had been dealing hardly with Scottish traders to the Baltic.

For peaceful as well as warlike objects James IV fostered the building of ships, and passed a law for the benefit of the fisheries, ordaining that all towns should construct boats of not less than 22 tons burden, and compulsorily man them with all their waifs and idle men, for the prosecution of that industry.

These instances of James's energy and forsight must suffice; but it has also to be borne in mind that he was fully alive to the value of learning. He introduced printing into Scotland; he himself spoke five Continental languages, besides Latin, and in addition "the language of the savages who live in some parts of Scotland and on the islands," as we are told by Ayala. In bringing up his talented natural son Alexander Stewart, he also showed his appreciation of study by having him well taught by his own secretary, Patrick Panter, before sending the lad abroad to finish his education under Erasmus of Rotterdam.

Perhaps the less said about James's morals the better; but he evidenced so much interest in ecclesiastical matters that in 1507 he received from Pope Julius II the title of "Protector of the Christian Religion."

The Charters of the University.—There could hardly have been a ruler to whom the bishop might have applied with more hope of finding sympathy with his plans for the intellectual improvement of Aberdeen, and accordingly we find the King writing, in terms inspired doubtless by Elphinstone, to the Pope for his authority to found the university.

Unfortunately, no traces of King James's letter, or of any correspondence of Elphinstone with the Holy See relating to the proposed creation of the university, now exist in the archives of the Vatican, for they would likely have revealed much that would have been instructive about the condition of Scotland. But what their terms were may be inferred from the wording of Alexander VI's Bull, which bears the date of February 4th, 1494. They are, that Old Aberdeen was a centre of a district inhabited by ignorant and nearly savage men, many of whom were desirous of being taught, but were destitute of instructors, and were separated by dangerous and arduous ways from those who could impart knowledge, while it was nevertheless possessed of a good climate and fertile soil; and finally, that owing to unfavourable local conditions the ministrations of the Church could hardly be carried on.

Almost exactly a year later than this Bull, on February 5th, 1495, the Pope gave the first donation to the university of the revenues of the Hospital of St. Germanus in East Lothian, which had been attached to the diocese of St. Andrews, but had fallen into disuse, and these were to form an endowment for the maintenance of the three faculties most nearly connected with instruction in religion.

Three weeks later still, armed with these documents, Elphinstone published *his* proclamation that the university was now established; and the date of this, February 25th, 1496, is the real date of the birth of the University of Aberdeen. From that time onwards it had an actual existence, and taught, though as yet it possessed no buildings; for however important, these were but the garments, not the body, of the university.

The Medical Faculty.

At this point we pause to hold up to admiration the great wisdom of the bishop in respect to the study of medicine. Not a single university in the British Islands had up to that time, we believe, seriously set itself to establish a teaching Medical Faculty as part of its machinery; and indeed this is not to be marvelled at. The profession, or rather trade, of medicine had sunk very low, particularly in Scotland, and the specimens of the physicians to be met with there would not have encouraged an ordinary mind to provide a faculty for them in a university. The bishop must have been personally acquainted with two of the Court physicians of his former master King James III, namely, William Scheves, who flourished about 1472, and was acceptable to James on account of his knowledge of astrology—a reptile who schemed for the deposition of Bishop Graham of St. Andrews, successor to Kennedy, so effectually that he himself stepped into his shoes in 1478; and also his successor in the King's favour, Dr. Andrews, likewise an astrologer, in 1479, who as it proved lost his master both his life and kingdom by some pretended message from the stars warning him against his brothers, the Earl of Mar, and Albany "the father of chivalry." James III was indeed a facile prey to adventurers of this kind; one may almost read his character in Scott's description of his contemporary, Louis XI, with whom he has more than once been compared. In truth even his successor, James IV, though inheriting a stronger character from his mother, a daughter of the virile King Christian I of Denmark, and though he possessed many fine qualities, and gave enlightened help to the bishop in founding the northern university, was not a great deal wiser than his father in the matter of superstition, though his leaning was to the more excusable belief in alchemy.

Whether or not Elphinstone was one of the small body of scholars who were acquainted with Greek, and knew or had heard of the writings of Hippocrates, Galen, and Aretaeus, which were then beginning to be translated into Latin on the Continent, and to revive the science of medicine, but were unknown in Britain, we cannot pretend to say, though it seems probable enough. But his clear vision saw, what most of his contemporaries did not discern, that medicine, like other branches of knowledge, was likely to share the impetus resulting from the "New Learning," and not only was a proviso introduced into the Bull founding the university that there should be a faculty "tam in Theologia ac iure Canonico et Civili, necnon Medicina et Artibus liberalibus quam quavis alia licita facultate"; but he was so concerned about the interests of medicine that he procured from James, within a year of the inception of the university, a charter which, while repeating the Pope's injunctions about the teaching of theology, civil and canon law, medicine, and arts, gifted to God the Omnipotent, the most glorious Virgin Mary, all the Saints, the university, and to a graduated Doctor in the faculty of medicine, the sum of £12 6s. yearly, thus supplying the deficiency in the Pope's endowment. From this charter, and the King's co-operation in founding the university, it came eventually to be called King's College, as Elphinstone had always wished it to be named.

The Selection of the Principal.

The narrative of Elphinstone's care in the establishment of his university would be incomplete without an account of the foresight he displayed in selecting the first Principal. Knowing well how much depended on the character of that official, and solicitous to avoid the causes which had made the University of Glasgow a partial failure, he cast about to select one who should ensure the full success of that in Aberdeen.

Of all the men available for the post there were two marked out by their promise of eminence in scholarship as by far the most suitable, and these were John Major and Hector Boece, both of them Scots, and both at the moment in France. Each was destined to be a future historian of Scotland.

John Major.

John Major, or Mair, born in Haddington, who had studied first in Christ's College, Cambridge, and then in Ste. Barbe's in Paris, and been for two years a graduate of the University of Paris, had acquired a tremendous reputation for learning, and become Regent, Fellow, and Lecturer in the College of Navarre. There seems reason to believe that he was an unstable and difficult, but at the same time an austere, man; and, though his subsequent career was one of the greatest eminence, it was probably well that Elphinstone's choice did not fall upon him. He was one of those bigots who wrote in defence of the martyrdom of Patrick Hamilton by Beaton, the Archbishop of St. Andrews. When Boece vacated his professorial chair at Montaigu, Major succeeded him in that office, became Doctor of Divinity in 1505, lectured in the Sorbonne, and was the author of many works on Aristotle's Logic and Ethics, Peter the Lombard's "Sentences," and the Four Gospels, as well as of a history of Great Britain. Though he undoubtedly became a marvellously learned man, he could not be contented to

settle anywhere for long. After declining the Treasureship of the Chapel Royal, which was offered to him by Gavin Douglas, he became Principal of the University of Glasgow, was the teacher of George Buchanan and John Knox, went back to Paris in 1521, wrote more books, finally held the appointment of Provost of St. Salvator's College in St. Andrews for seventeen years, and died in 1550. I do not know of the existence of any portrait of John Major.

Hector Boece.

Hector Boece, or Boyce, a native of Dundee, on whom Elphinstone's selection fell, was a very different kind of man from John Major. A portrait, reputed to be his, and full of character, hangs in the staircase of the Senatus Room of King's College, though in a poor light for being seen. Intellect and thoughtfulness are indicated by the beautifully shaped craninm and well-opened eye; blood, breeding, and refinement by the finely formed, delicate features of the face and ears; and in the 400 years old likeness there looks down upon us the presentment of a gentle scholar. Fortunately it has escaped damage from the brush of the restorer. When we study Boece's and Elphinstone's portraits we can understand that the two men must have harmonized with one another.

Boece was a man of about 33 years of age when Elphinstone and he came together at the starting of the university. His early education had been in Dundee, after which he had studied in Paris for ten years, and he then became for five or six years professor of philosophy in the College of Montaigu. Among his contemporaries and acquaintances were Panter, Secretary to the King of Scotland, John Major, and Erasmus of Rotterdam. Boece and Erasmus were intimate friends, and corresponded with one another during their whole lives, even up to the year 1530, when they were both old men. None of Boece's letters have been preserved, but no apology is needed for quoting one delightful letter from Erasmus to him, as it throws into relief his genial side and also that of the Principal of Elphinstone's new university. It was written from Paris in 1497, and Nichol's translation of it runs thus: "What is the meaning of so many scolding letters? What is all this insistence about? You write again and again, you threaten, reproach, and in fact declare open war against me, if I do not send you a copy of some of my poetry. Only look how unfair it is of you to demand from me a copy of that of which I have no copy myself. I solemnly swear that I have not for a long time been versed in such studies; and if I did as a boy amuse myself with them, I left all that behind me at home. For how could I dare to bring my barbarous Muses with their dull and foreign tones to this famous school, in which I knew there were so many persons absolute in every sort of letters? But I see you do not believe this, and suspect my professions to be themselves poetical. Who on earth induced you to believe that Erasmus was a poet? For you repeatedly call me in your letter by that name, once honourable, but now odious, thanks to the stupidity and incompetence of many that are so called. Therefore, if you love me, pray do not address me again by that title.

"However, Hector, my dear friend, that you may not tire yourself and annoy me by writing the same thing over and over again, it is well that we should speak more freely and plainly of the matter. In the first place, I am not such a fool as to wish to be taken by any one at more than my true value. Although, when I was a boy, the Muses were above all things my delight, I have not laboured so carefully in this sort of study as to produce out of my workshop anything worthy of Apollo. . . .

"It is no pleasure to me, when I fail to satisfy my own judgement, to be approved by that of the unskilful; of whom *one* admires nothing but what he does, or could do, himself, another on the contrary nothing but what he does not comprehend. This person is captivated by fine writing and ornament, 'tuneful trifles,' as Flaccus has it. Another reads with respectful emotion, *aurai frugiferai*. A third, delighted with a heap of words, takes garrulity for eloquence. What is solid is admired by few, as indeed there are few that recognize it. The painter Apelles (unless my memory fails me) disliked to have his works criticized by Alexander, a powerful monarch. May not, then, a learned man well dislike to be judged by every cobbler or by every clown? Consider, too, that persistent monster of jealousy, which attacks most eagerly everything that is best. Why should I for no reason at all provoke the hissing of that cobra? No, I leave the contest for those who are charged to utterance by the command of hunger, or who, at any rate, are so charmed by that siren of praise and fame that they had rather be ennobled after the fashion of Herostratus than live inglorious. For my part, I will not buy glory at such a cost.

"But what does all this tend to? you will say. Simply to this, that as I am not learned enough to satisfy the ears of the learned, if there be any such, and am too learned perhaps, or at any rate too proud, to condescend to a contest with these busybodies, I am resolved, if I have written anything, to dedicate it rather to Harpocrates than to Apollo.

"Nevertheless, not to appear too much in the character of Demea towards a friend who is united to me by so much kindness, I have taken Mitio for a pattern, and allowed myself to be overcome; for who can resist Hector? Departing, therefore, a little from my plan, I send you a few verses with which I lately amused my leisure when taking a country walk by the side of a stream, and in which you must not look for the felicity of Maro, the sublimity of Lucan, the copiousness of Naso, or the seductiveness and learning of Baptista Mantuanus. For while I appreciate all excellences, yet in writing I somehow prefer that Horatian dryness and simplicity. If your admiration is given to solid and more ambitious works, I still hope you will not altogether despise what I send.

"I had almost forgotten, by the way, what of all things I most wished to enjoin on you. If you have any love for Erasmus, do not bring his trifles out anywhere. Farewell.

"Written in haste in the country, 8 November."

We should like to know a great deal more than we do of Boece's life in the university, and his doings there, but perhaps the scantiness of such information is the best indication of the quiet prosperity which the institution enjoyed under him, while he was gradually raising it to be the first in popularity and efficiency among the Scottish universities. It was probably characteristic of the man that he came to King's College for the small salary of £2 4s. 6d. per annum; though that sum was soon considerably augmented by other benefices, a plurality necessary in his case. Here he wrote his great *History of Scotland*; became Doctor of Divinity of King's College in 1528; and on that occasion the magistrates of the city "voted him the present of a tun of wine when the new wines should arrive, or, according to his option, the sum of £20 to purchase a new bonnet." He died here in 1536, and his body lies under the stone floor of King's College Chapel on the north side of his patron the bishop, whom he long survived. His only harmless little vanity as a scholar seems to have been that of calling himself Boetius or Boethius, the name of the fifth century author of the *Consolations of Philosophy*, etc., under which appellation he published his historical and other works.

There remains little more to be told here about the founding of the university. The Scottish records of the period are scanty; but there are enough to enable us to discern another trait of Elphinstone's sagacity—namely, that when he had founded the teaching part of the institution, and was devising the ways and means of establishing it in suitable buildings, it was not from the great territorial magnates, whose influence in the university might have overshadowed to its hurt that of any others, but from the burgesses, lesser nobility, and gentry that he sought and obtained endowments for his work. These endowments were given mostly in the shape of revenues of portions of land, for coined money was scarce in the kingdom, and by such donations the bishop was enabled to have his schemes carried out, particularly that of building our beautiful King's College Chapel, with its quaint, and in some respects unique, work in wood and stone.

A terrible epidemic of plague prevailed in Aberdeen in the years 1499 and 1500, but it does not seem to have in any way hampered Elphinstone's good works, nor cooled the helpfulness of his many warm friends.

When the bishop died, in 1514, his body was embalmed

and now rests under a great slab of black marble in the centre of the old chapel in his own university.

Medicine in Aberdeen.

The medical seed which Elphinstone planted in his college did not at once spring up into full vegetation. It could not have been expected to do so under the conditions then prevailing. The English masters of medicine had not yet arisen; the scientific foundations on which modern medicine rests were not even begun to be laid. Linacre had not then introduced the works of the ancient Greek physicians to the profession in this country, and the great Harvey did not appear until a generation later. Physicians were barely more than herbalists and surgeons than barbers. We have mentioned some of the positions attained to by those who added quackery and astrology to their healing functions; but for the honest practitioners knowledge was but obscurity, and their recompense small. I am indebted to our Public Librarian, Mr. G. M. Fraser, for information as to the status of doctors in Aberdeen about the time of Elphinstone. In 1417 there was in the city an English physician of the name of John, but he does not appear to have found his practice very satisfactory, if one may judge from the solitary record of him which remains—that he sold his crofts beside the Stockrud in the Denburn, at the end of the castrum of John de Ressivat, which is called the Kilecroft, for four shillings.

The first "Mediciner," or Professor of Medicine, in the university was James Cuming, who before 1503 had been selected by Elphinstone and appointed to lecture on that subject. Elphinstone built him a house, as he did for the other professors, and it was probably through the bishop's good offices that the city assisted in providing him with a more adequate salary than he received from King James's benefaction, for it is recorded that in the year 1501 the aldermen, baillies, council, and community consented to give him ten marks yearly, "aye and until they promote him to a half of a net's fishing in the Dee, free of entry money, he paying for it the usual rent, and engaging that he, his wife, children, and household, shall personally reside within the burgh, go and visit the sick, and show them his medicines, they paying for them, but the town is to pay nothing till Cuming has actually come to reside in it." From this it may be seen that Cuming was not a priest, but a regular medical graduate and a married man, with his patients to look after as well as his university duties.

It does not detract from Elphinstone's merit in taking specific steps to ensure that medicine should have a due place in his university, that another Scottish "Studium Generale," even earlier than that in Aberdeen, should have had a similar authority to establish regular medical instruction conferred on it at its commencement. As early as 1413 St. Andrews had that right conceded to it in its Bull of Foundation; and possibly the licence for a Faculty of Medicine may have been a not unusual portion of the formula which the Popes employed when bestowing their sanction on universities modelled on those of Paris and Bologna. Glasgow University, however, had no such privilege, only three faculties—Theology, Law, and Arts—having been specified in its Bull. In Aberdeen alone, however, was there found a prelate sufficiently far-sighted to recognize the full value of such a licence, and at once establish practically what in other places was a dead letter for many years after his day.

Though the intentions of Elphinstone regarding the full success of the Faculty of Medicine were a long time in coming to fruition, nevertheless his foresight had prepared the ground, and his endowments planted the seed which was afterwards to spring up into the flourishing school of medicine of which all Aberdonians have good reason to be proud.

James Cuming died in 1521, having held office for about twenty years, and was succeeded in the following year by Robert Gray, of whom almost the only record we have is that he was a Doctor of Medicine, and that he died not earlier than 1549.

Marischal College and University.

It may be interesting, and at any rate it enhances our appreciation of Elphinstone, to remark that when the second University of Aberdeen—that of Marischal College—was founded, in rivalry to the earlier one, a hundred years later, no provision was made in it for a Faculty of Medicine. It was instituted under the sour atmosphere of Calvinistic reform, and concerned itself more with religion and politics than with science.

What we have said above regarding some only of the many claims which Elphinstone has to be honoured is no more than a just tribute to the memory of a truly great man, whose marvellous wisdom and prevision it is a duty to acknowledge; it is a tribute heartily paid by us all, whether we were alumni of King's or Marischal universities, now happily fused into one. But here our brief sketch must stop. Worthily to tell of the after-history of the Aberdeen universities and our medical school would demand greater eloquence than nature has allotted to me, but a visit to the beautiful window in the Mitchell Hall of Marischal College will, I am sure, add an interest to your visit to this city, by calling to your minds a few of the men whom they have sent forth, whose names are known wherever the English tongue is spoken, while there are others, and these not a few, whose memories are cherished by at least every well-informed inhabitant of this district, men whose deeds and works have been such that Scotland, and even England, would be shorn of a portion of their glory, were their names to be deleted from the rolls of fame of our common fatherland.

(In addition to the authorities mentioned in the text, I have to acknowledge the valuable assistance, in my historical researches into the life and times of Bishop Elphinstone, of the Right Reverend Æneas Chisholm, Bishop of Aberdeen; Sir Donald MacAlister, Sir James Donaldson, and Dr. George Adam Smith, Principals respectively of the Universities of Glasgow, St. Andrews, and Aberdeen; and Professor Grierson and Mr. P. J. Anderson, of the University of Aberdeen.)

Address in Medicine

DELIVERED AT THE

EIGHTY-SECOND ANNUAL MEETING OF THE BRITISH MEDICAL ASSOCIATION.

BY

ARCHIBALD E. GARROD, D.M., M.A.,

PHYSICIAN TO ST. BARTHOLOMEW'S HOSPITAL.

MEDICINE FROM THE CHEMICAL STANDPOINT.

MR. PRESIDENT, LADIES, AND GENTLEMEN,—So rapidly is our field being extended that year by year it becomes more difficult to deliver an address in medicine which shall treat of the subject in any of its wider aspects. None the less I would express my sincere gratitude to the Council of the British Medical Association for the honour which it has done me in inviting me to essay the task.

Seeing that we are met together within the precincts of an ancient seat of learning, which was the first of all British universities to establish a Chair of Medicine, it might be fitting that I should take as my subject some phases of the past history of our science and art. However, we see around us so many signs of a spirit of emulation and progress, and of a vitality which has been stimulated rather than inhibited by the lapse of centuries, that I have no fear lest, in selecting as my theme some of the most recently acquired aspects of medicine, I shall be in less complete accord with the *genius loci*.

The curriculum laid down for our students bears witness to the complexity of medical science. No student is held competent to enter upon his clinical studies until he has acquired some grounding in chemistry, physics, and biology, and a more detailed knowledge of human anatomy and physiology. In a word, medicine rests upon a substructure of other sciences, and the entire system of medical education is based upon the fundamental truth that a knowledge of the normal must needs precede any profitable study of the abnormal.

It need hardly be pointed out that such a curriculum in no way reflects the path along which medicine, as we know it, has been evolved. Hippocrates, Galen, and their contemporaries enjoyed no such advantages as do our

students of to-day. They initiated the study of clinical medicine at a time when the very foundations of chemistry and physics were as yet unlaid—when the anatomy of the human body was, to all intents and purposes, a sealed book, and when physiology, pathology, and pharmacology did not yet exist. At a later period, and with the passing of the Dark Ages, science began to awaken from her long sleep, and there came, with the revival of learning, a realization of the need of a new medicine, freed from the trammels of tradition, and based upon observation and experiment. Physicians began to observe for themselves once more, and no longer relied almost wholly upon the teachings of the ancients. Step by step the study of those primary branches of science upon which rational medicine needs must rest was pursued, to a large extent by medical men who recognized, and strove to supply, the growing demands of the healing art. Thus it has come about that, immense as is the debt of medicine to the pure sciences, the reciprocal debt of those sciences to medicine is hardly, if at all, less.

The more ancient sciences were studied, at the outset, merely as stepping-stones to practical ends—ends which were, for the most part, far less worthy than those of medicine, were sometimes grotesque, and usually unattainable. Thus astronomy had its origin in astrology; the earliest chemists were alchemists who were intent upon the discovery of the philosopher's stone and the elixir of life; and physics is beholden, in no small degree, to the futile quest of perpetual motion.

Then came a time when knowledge began to be pursued for its own sake, and the true scientific spirit was born. But progress was for a long time slow, and only now, when chemistry has advanced beyond all recognition, when every detail of structure of the human body has been revealed by anatomy, and when physiology and pathology find many who make them the study of their lives, are the foundations of the clinical edifice being securely laid.

So complex is modern medicine, and so diverse are its aspects, that we cannot hope to attain to any comprehensive notion thereof if we regard it from any single point of view. We need to adopt, on the one hand, the standpoint of the human organism engaged in its unceasing struggle to ward off the assaults of disease, and, on the other hand, that of the agents of disease which are as incessantly striving to gain a foothold. The clinical worker whose task it is to diagnose the nature and seat of the malady, and to intervene in the interests of the patient, has *his* special outlook; and the pathologist, who studies the havoc worked by disease, has *his*.

Again, we may contemplate the human organism as a whole, or as a complex structure built up of diverse organs and tissues, each with its assigned functions, or once again, as a nation of cell units endowed with manifold activities. Lastly, we have to picture each individual cell as a congeries of chemical molecules which are being continually pieced together and broken down by the agency of intracellular enzymes.

Thus physician and physicist, physiologist and pathologist, biologist, bacteriologist, and chemist, each looks out upon the field of medicine from his own standpoint, and to each it wears a different aspect. Only by the combination of the several mental pictures can a stereoscopic presentation be obtained.

Many of the early chemists were practitioners of medicine, and from the days of that eccentric genius who assumed the name of Paracelsus, and of van Helmont, the father of physiological chemistry, down to the earlier years of the nineteenth century, the chemical outlook was that most widely adopted by medical men. But in those earlier days chemistry itself was in far too embryonic a stage to lend much aid to the elucidation of the problems of disease, and, as time went on, the chemical outlook was abandoned to a large extent in favour of that afforded by the rapidly advancing study of morbid anatomy. Throughout the greater part of the last century morbid anatomy and histology held the field unchallenged; and they were justly entitled to do so in view of the progress made in the macroscopic and microscopic study of diseased structures, upon which was reared the imposing edifice of cellular pathology.

If, of recent years, morbid anatomy has yielded the foremost place to other branches of pathology, this should not be interpreted as showing that the subject is exhausted, nor that its value is less than used to be supposed, but rather as evidence of the need to bring forward the less advanced branches to the same level. The advance guard is being strengthened by calling up the supports, in order that the army of progress may present an even front.

Yet, during the period when morbid anatomy and pathology were synonymous terms, the science of chemistry, both in its inorganic and organic branches, was making rapid strides, and when medical investigators turned back once more to pick up the chemical threads, they found, in the chemistry of that later day, a mass of systematized knowledge ready prepared to aid them in their advance. This new science—for such it is—had its birth in the epoch-making discoveries of Priestley and Lavoisier.

Nor had that side of chemistry which bears most directly upon medicine been neglected. The syntheses of urea, by Wöhler in 1823, brought the products of life within the province of the pure chemist, and there had always been investigators who, with Liebig, studied the intake and output of living organisms, and who added to our knowledge of the chemistry of the urine, and of the problems presented by such maladies as diabetes and gout. Amongst these not a few countrymen of our own will always be remembered with honour.

In any modern treatise on chemistry the section which deals with the compounds of carbon far exceeds in bulk that which is devoted to the inorganic branch. Carbon compounds of ever greater complexity have been built up, step by step, from their elements, and even the synthesis of proteins is being brought within our reach, thanks to the labours of Emil Fischer and of a body of workers who have derived their inspiration from him.

Thus have been gained possibilities of fresh and conspicuous advances in the field of physiology. A new era of pathology has dawned. Side by side with the new science of bacteriology, which has already, in but a few years, transformed our conceptions of disease, there is growing up a vigorous science of chemical pathology, and, for the moment, morbid anatomy is resting upon its laurels.

The provinces of bacteriology and pathological chemistry are very different. Whereas the former investigates the actual agents of disease, the latter reveals the disturbances which result from their invasion. If I may venture to employ again an analogy already used elsewhere, the bacteriologist deals with a stone which, falling into the pool, ruffles its surface, whereas the chemist directs his attention to the ripples which spread outwards, in expanding circles, from the point of impact of the stone.

Yet bacteriology is ever setting new tasks for the chemist, who, just as he is coming to grips with the older problems of the structure of proteins, carbohydrates and fats, and of the chemical changes which constitute the life of the tissues, is confronted with a demand for information regarding substances and processes which are still beyond his reach—intangible entities revealed as yet by single properties. As he surmounts the foothills there open upon his view loftier heights beyond.

Biochemistry presents itself under two aspects: a static, which is concerned with the study of chemical structure, and a dynamic, which deals with the chemical changes of which the living tissues are the seats.

Thus we may wander among the streets of some deserted city of the past, may study the fabric of its buildings—the stones, bricks, and mortar employed in their construction, and in this way may gain some knowledge of the uses for which the several buildings were designed. Just so the anatomist investigates the structure of the organs of the dead body, and the chemist, by his analyses, gains a minute insight into the molecular groupings of the materials of which its tissues are composed.

Even in the dead city all is not still and at rest. The ancient walls are subject to weathering and decay, and gradually crumble under the influence of air and rain. Yet other changes are wrought by lowly forms of animal and vegetable life, which undermine the ruins and, in the end, bring about their downfall. So, too, in the dead body, destructive agencies are constantly at work until the dust returns to its dust again.

Once more we may tread the streets of a city of to-day, may watch the movements of the crowds as they pass,

the gathering and dispersal of groups of people. We may study the arrangements for the disposal of waste products, the ways in which food supplies are brought in, dealt with, and distributed. Or we may investigate the police arrangements, the sanitary services, and the various devices resorted to by the community for its protection. The study of the human organism on such lines is the province of physiology, and it is to designate the sum total of the manifold chemical processes in action within the living organism, and which constitute its life, that the term "metabolism" is employed.

But the chemical physiologist is far from sharing the opportunities afforded to our wayfarer. He is hardly permitted to set foot within the walls of the living city, and on that account his investigations are carried on under serious disadvantage. Determination of the balance of intake and output affords clear indication of the grosser chemical interchanges in the body, but the study of the intermediate stages is a far more difficult task, and only now are we beginning to gain an insight into the details of metabolism. Such knowledge of these details as we have acquired is largely based upon circumstantial rather than upon direct evidence. But here, as in so many fields, pathology lends valuable aid to physiology, and Nature's experiments and her mistakes afford, to him who is able to read them aright, insight into the methods of her orderly working.

Among the building materials employed in the construction of living organisms the proteins hold a place apart. They are the actual vehicles of life, and upon their properties the very possibility of life depends. Important, and indeed essential, as are the parts played by compounds of other kinds, carbohydrates, fats, water and inorganic salts, their functions within the organism are secondary. They are employed in the service of the proteins of the tissues. Fats and carbohydrates are in part burned to supply the daily demand for kinetic energy, the energy expended in muscular action, in glandular activities, and in the maintenance of the temperature of the body, and are in part stored for future use. Even much of the protein of the food is, as we now believe, stripped of its nitrogen and utilized as fuel, whereas another portion is employed in the reconstruction of the tissues.

No less essential to the organism are the inorganic salts, in the regulation of the osmotic phenomena, in the maintenance of the alkalinity of the body fluids and the acidity of the gastric juice, in conferring the required rigidity upon the skeleton, and in a hundred other ways.

The more intimate knowledge of the structure of protein molecules which we now possess is an acquisition of the still young twentieth century. The huge molecules have been teased out—to borrow a term from histology—and, as a result, the conception of an unwieldy group of atoms has been replaced by that of an orderly structure composed of comparatively simple building stones, of a neatly constructed block of masonry rather than an amorphous mass of concrete. These building stones are the now familiar protein fractions. Some of them have long been known as rare ingredients of the excreta—such, for instance, as tyrosin, leucin and cystin—but whence they came and how they were formed in the body was, until recently, unknown.

Widely as the protein fractions differ in their structure, they have this in common—that they are amino- or di-amino-acids. Seeing that they share the properties of acids and bases, they are capable of combining with each other to form the complicated chains or networks which constitute the protein molecules; and since they admit of combination into many different groupings, there is a possibility of almost infinite varieties of protein structure. The number of distinct fractions is by no means large, but every change of grouping, however slight, brings into existence a new protein.

The poet Lucretius, whose marvellous insight led him, as by instinct, to views of the constitution of matter which science has only reached after centuries of observation and experiment, was fully alive to these capabilities of atomic rearrangement. Writing before the commencement of the Christian era he tells us how, just as in his verses many different words are formed by the rearrangement of but a small number of letters, with the result that word from word, and verse from verse, differs both in sense and sound; so also, by the various groupings of a few essentials, are built up all the objects of animate and inanimate nature: "Tantum elementa queunt mutato ordine solo."

Abderhalden has estimated that the possible combinations of the twenty known protein fractions, in which each individual fraction is represented once, and only once, need for their expression a number composed of no less than thirteen digits. When we consider that from some proteins one or more of the amino-acid fractions are missing, and that in almost all of them the representation of the several fractions differs widely from that assumed in the calculation, we can realize that the number of possible varieties of grouping can only be expressed by figures which surpass those with which the astronomer is wont to deal. Nor is evidence lacking that the proteins of living organisms do actually differ among themselves in ways not dreamed of until quite recent times.

The dictum, so painfully familiar, that "all flesh is not the same flesh, but there is one kind of flesh of men, another flesh of beasts, another of fishes, and another of birds," has acquired a new reality. We are learning, upon evidence which admits of no question, that the very proteins which perform identical functions in different animals are not themselves identical, but differ from genus to genus, from species to species, and differ the more widely the further the several species are separated from each other in the evolutionary scheme.

Much of this evidence is derived from delicate and subtle reactions, such as the precipitin test, and from the study of the response of the organism to the introduction of foreign proteins, the phenomena of anaphylaxis, and the formation of protective enzymes; but some facts which have been demonstrated to generations of students, such as the differences in the crystalline forms of the haemoglobins of animals of different species, bear witness to specificity of chemical structure. Nor can we suppose that the differentiation stops short at the boundaries of species; chemical individuality follows as a necessary corollary to chemical specificity.

The effect upon physiological thought of this conception of chemical specificity has already been far-reaching. We no longer think of the proteins of food as utilized, after comparatively slight change, and in such complex forms as albumose and peptone. The differences between the food proteins and those of the animal fed necessitates the assumption that their disintegration by the digestive juices is far more thorough than used to be supposed, and that reconstruction of the proteins in the organism fed starts from the primary amino-acid fractions. That the primary fractions are able to be so utilized has been demonstrated by experiment.

During the earliest period of life, when the digestive functions are as yet but imperfectly performed, Nature supplies for the infant organism a natural diet exactly adapted to its requirements, and containing, in due proportions, all the materials necessary for its nutrition. Mother's milk has the additional advantage that its components have the specific stamp, an advantage which is, in all probability, connected with the phenomenon known as anaphylaxis. In later life any such exact adaptation is clearly unnecessary, and vegetivorous animals, whose earliest food was mother's milk, thrive upon a diet of which the protein constituents are not even of animal kinds.

Even this does not exhaust the complexity of protein structure, for each tissue-protein bears not only the impress of the specific stamp, but also of a second stamp derived from the organ of which it forms part. The recent work of Abderhalden and the study of cytolysins afford evidence that the proteins of the liver, spleen, pancreas, or any other organ have their special peculiarities. It seems probable that the liver proteins of the sheep and dog, although they exhibit specific differences, agree in containing in their molecules some particular group of atoms the possession of which confers the hepatic impress. Thus an independent system of cross classification is indicated.

It has long been known that sulphur is a constituent of proteins, and that in some of them phosphorus is also contained. We have now learnt that the small quantity of sulphur met with is contained in one particular amino-acid fraction—namely cystin—and that an unusually large proportion of sulphur indicates a large cystin

content. The phosphorus, on the other hand, is a constituent of the nucleo-proteins, which, as essential constituents of the cell nuclei, may lay claim to an importance second to that of no members of the protein group. In them also is included the purin grouping, the parent complex of most of the uric acid of the urine. As another example of a protein to which a special atomic group is attached haemoglobin calls for mention, seeing that, in virtue of the iron-containing haematin which it includes, it is able to fulfil the all-important function of carrier of oxygen to the tissues.

The highly complicated protein molecules naturally afford the greatest scope for specific differentiation, but differences of a like type are exhibited by the fats of different animals, and are manifested not only in the results of chemical analysis, but also in such naked-eye appearances as depend upon a lower or higher melting point. The far simpler carbohydrates admit of but slight variations, and the inorganic salts of *none at all*. However, in some species of animals, elements which but seldom enter into the composition of organic compounds are embodied in the tissues, as, for example, copper, which is a constituent of the blood pigments of some lowly animal forms, and of the red pigment turacin which colours the feathers of certain birds.

The flight of time forbids me to dwell at greater length upon the diversity of the chemical structure of the animal organism, but enough has been said to show how essential is an acquaintance with the leading facts of the statical side of biochemistry, if we are to gain any adequate conception of metabolism, of that bewildering whirl of chemical activities of which the tissues are the seat.

In every organ and every cell in the body chemical changes are constantly in progress. Processes of synthesis and of analysis, of oxidation and reduction, of anabolism and catabolism, proceed side by side in the same tissue, and even in the same cell, smoothly and without clashing or mutual disturbance.

The foodstuffs which enter the alimentary canal are dealt with by the digestive juices, are broken down into their simple fractions, and are so prepared for absorption. The products thus yielded are employed in part for the maintenance of the optimum body temperature and for the supply of kinetic energy of muscular movements, both voluntary and involuntary. Another portion is stored for future use, either in the fat dépôts, storehouses of potential energy which serve the additional purpose of providing a warm covering for the deeper structures, or as glycogen in the liver and muscles. From the glycogen reservoirs glucose is distributed in a continuous, regulated supply to meet the requirements of the tissues.

Some of the protein fractions are built up anew into specific proteins to replace the loss which results from the wear and tear of metabolism, and may be utilized in other ways. The remainder, and probably the greater part, are stripped of their amino-groups and used as fuel.

What has been learnt of the intermediate steps of metabolism has already served to modify profoundly our conceptions of the metabolic processes. We no longer think of the foodstuffs as so much gross fuel cast into a furnace, but of each kind of foodstuff, and indeed of each individual protein fraction, as following its own special metabolic path. Moreover, there are paths for fats and paths for carbohydrates, and it is evident that even dextrose and laevulose are dealt with in different manners, for a patient whose power of burning dextrose is grossly impaired may deal with laevulose with far better success.

In the same way the power of catabolizing a single protein fraction may be lacking in an individual who is able to dispose of the other protein fractions in a normal manner.

It is believed that these changes are wrought by specialized enzymes, many, if not all, of which are capable of reversed action. We may picture to ourselves the individual protein fraction as handed on from enzyme to enzyme, each responsible for some particular step in the series of changes, until the series is completed and the specific protein has been built up, or the final excretory product has been reached.

Thus are produced numbers of intermediate products which are subjected to further changes as soon as they come into existence, and which call to mind a moving staircase rather than a flight of steps. Most of these intermediate products are never met with in an examination of the excreta, or only when the further transformations which they naturally undergo are in some way arrested.

Regarded from the chemical standpoint, each cell in the body is an individual member of a community, although, in all organisms but the simplest, the various cells are differentiated for the performance of special functions, and to that extent have sacrificed their individuality. Each product of glandular activity bears witness to specialized metabolic processes in the cells by which it is produced.

So far is the differentiation carried out that, as in a highly civilized community, the destruction of a single part may suffice to bring the life of the community to a standstill.

We may ponder over this conception of the elaborate metabolic activities carried on in the living organism until the brain reels, and the imagination is no longer able to cope with their infinite variety.

It is only to be expected that, in the course of evolution, a state will have been brought about in which the end products of metabolism will be harmless to the organism in which they are formed; but so delicately are the relations of tissue change adapted to the requirements of the organism that any deviation from health which disturbs the chemical processes, however slight the disturbance may be, leads to the formation of products which are less well adapted, and tend to do harm. Some are so little noxious that their deleterious action is only manifested after the lapse of many years, whereas others, such as the substances of the acetone group, lose no time in working mischief.

This harmonious working, side by side, of antagonistic processes will continue for many years, unless it be disturbed by influences from without. But such are the conditions of life upon this planet that the vital processes seldom have the chance of working themselves out to their natural termination in death from sheer old age, their natural ending, because the human machine is not perfect, and gradually deteriorates from the cumulative effects of infinitesimal errors of experiment, until it is brought to a standstill at last.

Obviously, it is only by a rigid system of control that the orderly working of the intricate metabolic changes can be maintained, and the working of regulating mechanisms in the animal body is made manifest in a variety of different ways. Only by strict regulation can the breakdown of tissues be kept within bounds, can the uniform composition of the blood be maintained, and the optimum temperature of the body be ensured—to quote only a few examples out of many. Yet the regulator mechanisms are not devoid of flexibility, as witness the phenomena of fever, the growth of the body in early life, the developments which constitute puberty, the coming into play and passing into abeyance of specialized functions, and the adaption of the organism to changes of environment.

In recent years we have gained some insight into the mechanisms by which regulation is affected, and of the importance in this connexion of the internal secretions of glands, ductless and others. We see how disease of a gland which yields such a secretion may disturb the metabolic balance in the direction of excess or defect, and in so doing may influence growth and development. Such studies are profoundly modifying our conceptions of such anomalies as obesity and infantilism, and we are learning that the glands which may be classed together as members of a hormonopoietic system constitute a group of balanced regulators of metabolism, although it may be conceded that, in this connexion, theory tends for the moment to outstrip established fact.

However, the internal secretions are implements, rather than originators of control. The hormones are themselves but chemical products of certain specialized cells, and the activities of the glands which produce them are themselves under the control of the vegetative nervous system, which transmits to them impluses in response to the chemical demands of the tissues. Thus, in a sense, the regulation of metabolism is automatic.

The chemical processes in the tissues are not moulded upon uniform lines throughout the animal kingdom, any more than is chemical structure. Evidence of this is afforded by the formation of special protective secretions,

of specific bile acids, and of peculiar excretory products, such as the kynurenic acid found in the urine of members of the canine tribe.

Moreover, just as certain individuals of a species exhibit conspicuous deviations from the structure of the species, malformations by arrest or of other kinds, so also individuals are met with who exhibit some striking metabolic anomaly, a chemical freak.

These inborn errors of metabolism are individually as rare as structual malformations, and much more liable to be overlooked. Their scientific value far exceeds their clinical importance, for they constitute true natural experiments. Those which are known advertise themselves in conspicuous ways, and appear to have their bases in failures to carry out some special catabolic process, rather than in a deflection of metabolism into unusual paths. Thus, in cystinuria, cystin, and sometimes other protein fractions also, escape their normal fate, and appear unchanged, or only slightly changed in the urine. In alcaptonuria, on the other hand, there is a failure to complete the breakdown of the aromatic protein fractions, and the homogentisic acid which is excreted is thought, with good reason, to be an intermediate product of normal metabolism. From the study of alcaptonuria we have learnt nearly all such details as we know of the fate of tyrosin and phenyl-alanin in the body, and have gained an insight into the differential treatment of the protein fractions in general, and into the intermediate steps of their catabolism.

I set out to draw a sketch of the normal metabolic processes; the outcome of the attempt is but a crude diagram. Time will not permit of any attempt to fill in details, nor to put before you the evidence upon which the outlines of my description are grounded. I am content if I have succeeded in conveying some notion of the ceaseless chemical turmoil in the living human organism.

When into this field of intricate, but orderly, metabolic activities there intrude the agents of disease, a new set of phenomena is brought into action. The entire community bestirs itself to beat off the intruders, and there are called into play protective mechanisms of immense variety and displays of infinite resource; just as a national community, whose members are at ordinary times engaged in the calmer pursuits of commerce and agriculture, may, on the occurrence of a hostile invasion, assume the attitude of a nation in arms. Such a transformation involves profound disturbance of the ordinary life of the people, and so, too, the invasion of morbific agents produces derangements of metabolism which are the more profound and far-reaching the greater the danger to be faced. We must suppose that in many, and indeed in most, instances the forces of defence gain the upper hand, and the invaders are beaten off. When the first line of defence is overcome disease results, but even then the defences of the second line usually suffice to counter the attack, and the patient recovers.

The mechanisms of defence are of various kinds. Some are comparatively simple chemical reactions, as when free acids are neutralized by ammonia diverted from its ordinary path to the formation of urea; or when aromatic poisons are combined up with sulphates, and are excreted in harmless forms. But aromatic poisons are also combined with products of protein or carbohydrate metabolism, with the protein fraction glycin to form the harmless hippuric acid and its allies, or with glycuronic acid to form compound glycuronates.

Other mechanisms are far less simple, and the very nature of the protective agents is beyond the ken of the chemist. These are the agents known as antitoxins, agglutinins, precipitins, opsonins, and the like.

Quite recently the researches of Abderhalden have opened up a new field of such studies by revealing the production of protective ferments, capable of destroying protein substances foreign to the organism. It would seem, indeed, that each constituent cell of the body brings into play its enzyme-forming powers to meet an emergency.

It is a question of much interest whether or no the various protective mechanisms have been evolved to meet the assaults of those toxic agencies to which the organism is specially exposed, or whether an entirely new mechanism can be devised, at any moment, to meet an unforeseen emergency. Evidence may be adduced in support of either hypothesis. The laws of chemistry are so immutable that, given certain conditions, definite reactions may be expected to occur. We are able to predict the formation of compounds which may never have existed previously, and to foretell their properties with some degree of accuracy. So we might expect that a given poison launched into a medium in which a number of metabolic products are present, will combine with one or other of these. But in the human organism the conditions are far less simple than in the laboratory, and we are driven to suppose that enzyme action is concerned in the production of such compounds as hippuric acid or a compound glycuronate; and we may well imagine that, even when the requisite materials are forthcoming, combination may fail for lack of the required enzyme.

As Hopkins has pointed out, it is unlikely that until Baumann administered brombenzine to a dog, that compound had ever found its way into the canine organism. Yet any dog to which that substance is given excretes it in combination with the metabolic product cystein, in the form of a so-called mercapturic acid. The mechanism is ready to hand, although we can hardly suppose that special provision is made for the contingency.

The simpler mechanism for the neutralization of acids by ammonia supplies an argument in support of the alternative theory, for this is not developed in herbivorous animals, which, from the nature of their diet, are far less exposed than the carnivora to poisoning by acids.

There are many other ways in which derangements of metabolism are brought about by disease, apart from the calling into play of protective mechanisms. When an important organ becomes the seat of structural changes its functions become disturbed, and their normal orderly working is put out of gear, either permanently or only for a time.

Thus if the lungs are rendered inefficient the respiratory interchange is interfered with, and deficient supply of oxygen to the tissues, and imperfect removal of carbon dioxide, being in their train obvious and well-recognized results. Diseases of the heart muscle produce similar effects by impairing the circulation in the lungs and elsewhere. When the liver is attacked, either primarily or as the result of circulatory disturbances, the assault falls upon an organ which is the seat of more multifarious chemical activities than any other in the body. When the bile ducts are blocked the absence of bile from the intestine grossly impairs the absorption of fats, and the constituents of the retained bile fluid find their way into the circulation, and are deposited in the tissues. When the parenchyma suffers many metabolic processes which are carried out in the liver are disturbed, yet the effects of these disturbances are less conspicuous than might be expected.

The effects of disease of the pancreas are less obvious, but the absence of pancreatic juice from the intestine causes profound derangement of the digestion of proteins and fats, and the effects of the failure of its internal secretion upon carbohydrate metabolism are familiar to all.

Diseases of the alimentary tract cause impairment of the intake of nutritive materials, and changes wrought, by the bacteria which inhabit the intestines, upon the intestinal contents, may result in the formation of poisonous products which undergo absorption, to the great detriment of the organism. When the kidneys are the seats of disease, the elimination of waste products—the hygiene of the tissues—is impaired, to a greater or less extent, and these products accumulate in the organism where they induce a chain of morbid effects which culminate in the stormy symptoms of uraemia.

It is because diseases of glands of internal secretion produce such profound disturbance in the chemical field that we have learnt to recognize the important part which they play as regulators of metabolism. We see how functional inactivity of the thyroid gland renders sluggish the metabolic processes as a whole, whereas its over-activity—if that be the correct interpretation of the phenomena of exophthalmic goitre—causes the metabolic fires to burn too brightly. We see also how a too active pituitary gland stimulates the organism to abnormal growth, whereas loss of its functional activity brings in its train obesity and recessive infantilism.

Phenomena of a like order result from diseases of the

adrenal and pineal glands, and we are only beginning to learn how great a part variations in the secretion of adrenalin by the chromaffin tissues may play in connexion with a number of maladies in which the adrenals themselves are not primarily implicated.

Indeed, it may be said that all diseases, whether they affect the organism as a whole or whether their brunt be borne by single organs, bring about greater or less disturbance of metabolism. The field of chemical pathology is practically coextensive with the field of medicine.

In the case of many maladies, even of the more acute and graver ones, the chemical disturbances which they bring in their train are far less conspicuous than the structural changes. In others, again, the metabolic disorders occupy the forefront of the clinical picture, as is the case in those maladies which we are accustomed to group together under the collective name of "diabetes."

In not a few cases of diabetes grave, and even fatal, metabolic disturbances are attended by no structural lesions which we can detect.

It is natural that the attention of chemical workers in medicine has always been directed to such "diseases of metabolism," and the problems which they present are still very far from solution.

Hitherto we have been considering what may be described as *positive* diseases, which result from attacks upon the organism by morbific agents introduced from without; but there remains to be considered a group of maladies which may be classed as *negative*, seeing that they have their origin in the withholding of some portion of the supplies which the organism derives from external sources, and upon which its well-being depends. The extreme example of such a disease is starvation—a condition in which the body, being deprived of its food supplies, lives for a time upon its own fats and carbohydrates, and ultimately upon the proteins of its tissues. Minor degrees of the same condition are induced by restriction of the intake below an adequate calorie value, of proteins below the amount compatible with maintenance of nitrogen balance, or by complete deprivation of carbohydrate foods.

The cutting off of carbohydrates, or failure to assimilate them, is promptly responded to by disturbance of fat and protein metabolism, with the result that the substances of the acetone group, aceto-acetic and β-oxybutyric acids are formed and excreted in large quantities. This condition of acetonaemia, which plays so important a part in diabetes, and is met with in children suffering from many diseases, affords the most conspicuous example known of the formation of actively harmful products as a result of the throwing out of gear of the normal metabolic processes.

There is much that is still obscure in the pathology of acetonaemia, and it is probable that future researches will profoundly modify the current views on acidosis. This much is certain—that many facts of clinical observation can with difficulty be reconciled with the prevalent theories.

Of equal interest are certain maladies which result from dietetic shortcomings of far less obvious kinds—defects which cannot be estimated in terms of calorie value or nitrogen balance. It is becoming evident that a normal dietary must contain constituents of which we have hitherto taken no reckoning, just as the air which we breathe contains gases of the existence of which we had no inkling until recent years.

The new study of vitamines and of the effects of a diet consisting of pure proteins, fats, and carbohydrates upon the growth of young animals, is beginning to throw light upon the nature of such factors—exogenous hormones, if I may so style them.

That scurvy results from errors of diet has long been known, but the dietetic factor in the causation of beriberi is of far more recent recognition.

It is not surprising that such diseases of defect, when once recognized as such, are far more readily amenable to treatment than any others. The missing factor supplies the specific remedy. Starvation is readily cured by food, and scurvy by a diet of fresh meat and vegetables, just as myxoedema yields to treatment by thyroid extract; but in all such cases continuous administration of the missing factor is essential for the continuance of well-being.

Thus we see how delicate a matter is the maintenance of the integrity of the metabolic processes in the human body, and how slight disturbing influences may lead to their derangement. Any failure of adaptation to environment, any attack from without, any failure of supply of foodstuffs, water or oxygen, produces effects which are not merely local, but which awaken chemical echoes throughout the entire organism.

To us who are engaged in the practice of medicine the knowledge which has been gained of the chemical structure of the human body, and of the dynamic chemistry of its tissues, has no mere academic interest. It cannot fail to influence profoundly our conceptions of disease, and no less profoundly our therapeutic measures.

At the outset the feeling induced by such studies is one of awe. We are impressed by the infinite complexity of the mechanism with which it is our business to interfere, as would be a man ignorant of horology who undertook to repair a watch.

No less profound is the feeling of admiration aroused by the contemplation of Nature's methods for the combating of disease. We appreciate the force of Paracelsus's rebuke to his professional brethren: "Nature is the physician, not thou. Thou must learn of her, not of thyself."

We realize how inefficient are our therapeutic efforts as compared with the powers of protection with which our patients are themselves endowed. Yet the physician has the satisfaction of knowing that he can often render valuable aid, and that by his care many a life is saved. In some maladies, due to animal parasites, he can even attain to the final aim of therapeutics—namely, to destroy the agents of disease without damage to the tissues of their host. But Nature has means by which to parry each stroke in detail, can produce antidotes to specific toxins, or substances lethal to specific bacteria, and can sometimes protect the patient from a repetition of a particular infection for the remainder of his life.

It is in the field of diagnosis that the practical utility of chemical knowledge is most obvious. The derangements of metabolism caused by disease are reflected in the excreta. In these, and especially in the urine, are found abnormal ingredients indicative of the nature of the disturbance at work. Some are substances which are present in normal urine, but in traces so small as to escape detection by the simpler methods of analysis; others are intermediate products of metabolism which have escaped destruction, and are excreted as such or in slightly altered forms, or in combination with toxic substances, which they render innocuous. In the urine, too, we find evidences of undue waste of tissues, or of failure to eliminate waste products.

Methods of ever greater delicacy and precision are being applied to urinary analysis. Quantitative estimations supplement qualitative findings, and many of the modern methods can only be carried out in a well-equipped laboratory.

By examination of the urine we learn much concerning the condition of the kidneys and urinary tract, and by the application of functional tests we may get to know something of the incidence of disease upon different parts of the renal apparatus. Indications are afforded of the activities of intestinal bacteria and of the absorption of toxic substances from the alimentary canal. We can trace the development of acetonaemia in the maladies in which it occurs, and can obtain evidence of disease of the liver, pancreas, and other glands, and even of the bone marrow, in certain cases.

Analysis of the gastric contents is giving us a new insight into diseases of the stomach, and the chemical examination of the faeces affords indications of hardly less diagnostic value, amongst others, of the presence of occult blood, and of derangements of the splitting and absorption of fats.

But perhaps the greatest recent advance in diagnosis by chemical means is the perfecting of methods which enable accurate and reliable estimations to be carried out, of such substances as glucose and uric acid, in small quantities of blood drawn from a vein, and even in a few drops of blood from a prick in a finger. Now that it has become possible to estimate the glucose content of the blood from day to day, a new chapter in the study of diabetes is being opened.

Again, the diagnostic methods of Abderhalden, which reveal the workings of protective ferments, afford means of

diagnosis of a subtlety hitherto not dreamed of, and give promise of widely extended utility in the near future. However, these methods are complicated in technique, and reliable results can only be got by those who have had experience of their working.

Although there are few diseases in which, as in diabetes, chemical findings supply the diagnosis, shape the prognosis, and guide our treatment from day to day, it may be asserted with confidence that there is no branch of medical practice in which a knowledge of chemistry and of its methods is not of service to the practitioner of medicine.

To turn to the field of therapeutics, there is no branch of treatment in which chemistry should help us more than in dietetics, but there is none in which we rely less upon the guidance of science, and in which the influence of tradition is so powerful.

In so far as tradition embodies the accumulated experience of mankind, and of generations of sufferers from particular maladies, it is entitled to our fullest respect, and is sometimes our safest guide. But too often it rests upon the dicta of some teacher of the past, which have been repeated so frequently that they assume an authority to which they have no real claim. I am far from maintaining that our dietetic prescriptions must always have a scientific basis, for our knowledge does not suffice to render this possible. Indeed, in matters of treatment, there is danger in setting up too rigid a standard. A prescription which aims at the attaining of some particular object, although based upon scientific reasoning, may fail because we are not able to take into account all the conditions of the experiment. Not a few therapeutic measures have been introduced in deference to scientific reasoning which has since been shown to be unsound, and some of these—such is the irony of things—have nevertheless proved of real value.

There are scientific grounds for the belief that mankind habitually takes more protein food than is required for the due nutrition of the tissues, and undoubtedly the amount taken habitually exceeds that required for the maintenance of nitrogen balance. When, however, it is realized that the lower animals and savage races have adopted a standard of diet quite apart from medical advice, and presumably in accord with their needs, it seems more probable that our reasoning fails to take into account some unknown factors than that the instinct of whole races is at fault. But when we find bodies of men living under conditions which are in no sense natural, men leading sedentary city lives, but who habitually consume quantities of protein food suited to the strenuous existence of members of nomad races who seek their meat from day to day, we are certainly called upon to interfere, and can do so with confidence in the strength derived from the teachings of experience and the knowledge which physiology supplies.

As regards details of dietary, I would venture to assert that two-thirds of the restrictions imposed upon sufferers from particular maladies find no real justification in the teachings of science or of experience. How contradictory are the directions given by different advisers to gouty patients as to details of dietary, and how few of them can be justified by argument when called into question!

Certain general principles are clearly defined. We should aim at a diet of adequate calorie value, with due representation of the main classes of foodstuffs. The food should be so prepared as to be easily assimilable, and with due regard to the condition of the patient's alimentary canal. Some at least of it should be in a fresh state, and special restrictions are often desirable in view of defects of excretion, to rest damaged mechanisms, or to limit accumulation in the blood of metabolic products which fail to be dealt with in the normal ways.

Yet it should be realized that, in prescribing a restricted diet, we incur serious responsibility. A diet from which one of the chief food factors is missing can hardly be maintained with impunity over long periods. Thus, although there can be no doubt that restriction of carbohydrates is of great value in the treatment of diabetes, a restricted dietary, if imposed by rule of thumb, and unless carefully watched, may do far more harm than good. In any case of diabetes a careful study of the response of the patient to carbohydrate restriction is desirable; a strict diet should only be reached by degrees, and throughout the course of the case the medical attendant needs to keep his hand on the tiller, ready to turn now in the direction of increased strictness, now to relax.

So, too, as regards treatment by drugs. Throughout the centuries drugs have been employed in the treatment of disease, and we almost forget that the control of disease by such means was a discovery, and not part of instinctive knowledge. Remedies introduced on empirical grounds, or in deference to superstition or fantastic hypothesis, have nevertheless proved valuable weapons in the hands of many generations of medical men.

In default of knowledge of anatomy and physiology, therapeutics could not be other than empirical; but step by step, as we learn more of the ways in which drugs act, and of the morbid processes which we seek to influence by their means, a scientific system of therapeutics is being built up. We are learning of Nature, as Paracelsus bade us do. When we administer a serum or a vaccine, or such a drug as thyroid extract, we are copying Nature's methods, and employing her own weapons; and even when the results do not come up to our hopes, we have the satisfaction of knowing that we are working upon sound lines, and may expect that, as technique improves, many difficulties will disappear.

When, on the other hand, the drugs which we employ are toxic substances, foreign to the organism, we need to realize that, in giving them, we often produce not only the effect aimed at, but by-effects which we cannot fully estimate. Pharmacology is teaching us how such drugs act, the limitations of their utility, the nature of their active principles, and how they may best be employed. In this way the discoveries of empirical therapeutics are being placed upon a scientific footing, and the blunderbuss prescription is giving place to the employment of single drugs of known efficiency.

Not only are the weapons improved but the progress of knowledge is making our aim more sure. We have learnt that, although it often is necessary to treat special symptoms, all morbid symptoms do not call for treatment, since many of them are manifestations of protective mechanisms; and even pain leads to the saving of many lives. But in guarding against a particular danger Nature sometimes imperils the organism as a whole. Thus increased blood pressure is doubtless advantageous to many who possess it, but when it reaches such a degree as to endanger the integrity of the arteries, or to cause symptoms distressing to the patient, we feel justified in attempting to lower it.

Nor must mention be omitted of the triumphs of preventive medicine, which bear eloquent witness to what science can accomplish in the medical field—triumphs exemplified by the guarding of communities from epidemic diseases, and the ridding of huge tracts in tropical lands of insect-borne maladies. Modern hygiene is a vast protective mechanism which aims at doing for the community what Nature does for the individual.
