## VOLUME IX.

### P A R

**PARAGUAY**, a South American republic, situated in the basin of the Parana-Paraguay system. It is conterminous with Brazil, Bolivia, and the Argentine Republic, and its boundaries were long under dispute. The whole area of the country is estimated at 91,890 square miles, of which 35,280 are in the Gran Chaco portion.

The year in Paraguay is divided into two seasons—"summer," lasting from October to March, and "winter," from April to September. December, January, and February are generally the hottest months, and May, June, July, and August coldest. The most temperate month is April. The mean temperature for the year seems to be about 75° or 76°; for summer 81°, for winter 71°. The rainfall amounting to fifty-eight inches at Asuncion, is distributed over eighty-four days—seventy-five days being cloudy, and 206 bright and clear. Goitre and leprosy are the only endemic diseases; but the natives, being underfed, are prone to diarrhoea and dyspepsia.

As to the mineral resources of Paraguay but little is known—possibly because there is little to know. The gold mines said to have been concealed by the Jesuits may have had no existence; and, though iron was worked by Lopez II. at Ibicuy (seventy miles southeast of Asuncion), and native copper, black oxide of manganese, marbles, lime, and salt have been found in greater or less abundance, the real wealth of the country consists rather in the variety and value of its vegetable productions. Its forests yield at least seventy kinds of timber fit for industrial purposes—some, such as the lapacho and quebrache, of rare excellence and durability, as is shown by the wonderful state of preservation in which the woodwork of early Jesuit churches still remains. Fifteen plants are known to furnish dyes, and eight are sources of fiber. Fruit-trees of many kinds flourish luxuriantly; the cocoa palm often forms regular groves and the orange-tree (reaching a height of fifty feet) is so common and bears so profusely that oranges, like bananas, have a mere nominal value. In the **MATÉ** (*q.v.*), or Paraguayan tea, Paraguay has a commercial plant of great importance, which may be

said to be peculiarly its own; and most of the primary crops of the tropics could be cultivated with ease if there were only men and means. Cattle-breeding was formerly a very important interest in several of the departments, but the stock was nearly all destroyed during the war, and is only being slowly recruited from the Argentine Republic. The total number of horned cattle is estimated at 500,000.

The inhabitants of Paraguay are mainly Guaranis or half-breeds with a strong proportion of Guarani blood. A peaceful, simple people, fond of flowers and fêtes, they displayed during the desolating war of 1865-70 (as so often before in the time of the Jesuits) indomitable courage in the face of overwhelming odds. Formerly, about 1857, divided into twenty-five departments, the country was in 1876 distributed into twenty-three electoral districts, each with a *gefefe politico*, a *juez de pas*, and a municipality. **ASUNCION** (*q.v.*), the capital, is also the largest city (25,000). Other places of present or historical importance are Villa Rica (11,000), often called Villa Pobre, the chief seat of the tobacco trade, and the easternmost of the larger towns; Villa Pilar or El Pilar (3,621), formerly Neembucu, opposite the mouth of the Bermejo, and the "strangers' farthest" under Doctor Francia's despotism; San Estanisló (7,000); San Pedro (9,706), near the Tejui, about three leagues from its junction with the Paraguay; Concepcion (10,697), the northernmost of the towns or villages, 200 miles above Asuncion, and the trading center for the northern maté plantations; Humaitá (4,205), 198 miles below the capital, the site of the great earthworks by which Lopez stopped the advance of the allies for more than a year; Paraguari (5,315), the present terminus of the railway; Jaguaron (3,413), two and one-half leagues from Paraguari, founded in 1536, and the seat of a manufacture of orange-flower essence; Ita (6,332), known for its earthenware; Itangua (6,948), with brick and tile work; Luque (8,878), the provisional capital in 1868; Villa Hayes (Villa Occidental, Nouvelle Bourdeaux), ten miles above Asuncion, founded in 1854 by Lopez with French settlers.

Paraguay is a constitutional republic. The presi-

dent and vice-president hold office for four years, and are again eligible after eight years. The legislative bodies are a chamber of deputies (one deputy for each 6,000 inhabitants) and a senate (one senator from each territorial division with 8,000 inhabitants, and beyond that from every 12,000 inhabitants). There are five government departments, and a supreme court of three salaried judges. The people are nominally Roman Catholics, but full religious liberty prevails. Crime is comparatively rare, and is rapidly diminishing. Marriage has fallen so completely out of fashion that only 3 per cent. of the births are legitimate.

The population consists of about 300,000 whites and 130,000 Indians, with foreigners to the number of about 9,000, who have settled in the country, principally Argentines, Italians, Brazilians, and Germans, and a sprinkling of English and French. In November, 1886, Gen. P. Escobar was elected to the presidency for four years, and on January 1st following the home debt had been reduced about \$179,435, that amount having been derived from the sales of public lands and the levying of an additional tax of 10 per cent. customs duties. The reports for 1886 indicate that the customs receipts during that year amounted to \$844,218, the same being \$75,218 greater than in 1885, the total income to have been \$1,531,892, and the expenditures \$1,378,756. During the summer of the same year the silver dollars of Chili, Bolivia, Peru, Mexico, and the Argentine Republic were admitted for circulation at a par value with the Paraguayan silver dollar, also the five-franc pieces of France, Belgium, and Italy.

There was an increase of imports and exports, and telegraph and postal facilities available were shown to be constantly extending and improving. In November of the same year, the Asuncion Villa Rica Railway was purchased from the government by William Stewart. The consideration was \$2,100,000 in gold, and the sale was conditioned upon the extension of the road by Stewart to Villa Encarnacion, the government engaging to guarantee 6 per cent. interest on the cost of construction, at the rate of \$30,000 per kilometer. The government was also empowered to build a line of railroad and telegraph from the right bank of the Paraguay river to a point of junction on the northwestern frontier of Bolivia and Paraguay. The bill as passed authorized the expropriation of all necessary land on the route, and extended the time for the submission of the plans two years from the date of its passage. In 1887 a commercial treaty was concluded between Germany and Paraguay, and immigration is now invited from all portions of Europe, Germany and France in particular, the government binding itself to furnish a house, seeds, tools and provisions for eight months. No interest will run on the money thus advanced, the colonists to be exempt from taxation, and only in the event of their property being assailed will they be called upon to aid in its defense.

In 1528 Sebastian Cabot, following in the footsteps of De Solis, reached Paraguay and built a fort called Santo Espiritu. Asuncion was founded on August 15, 1537, by Juan de Ayolas, and his successor, Martinez de Irala, determined to make it the capital of the Spanish possessions east of the Andes. From this center Spanish adventurers pushed east to La Guayra beyond the Parana, and west into the Gran Chaco; and before long vast numbers of the less warlike natives were reduced to serfdom. The name Paraguay was applied not only to the country between Rio Paraguay and Rio Parana, but to the whole Spanish territory, which now comprises parts of Brazil, the republic of Uruguay, and the Argentine provinces of Buenos Ayres, Entre Rios, Corrientes, Misiones, and part of Santa

Fé. It was not till 1620 that Paraguay proper and Rio de la Plata or Buenos Ayres were separated from each other as distinct governments, and they were both dependent on the vice-royalty of Peru till 1776, when Buenos Ayres was erected into a vice-royalty, and Paraguay placed under its jurisdiction. Though they succeeded in establishing a kind of *imperium in imperio*, and were allowed to drill the natives to the use of arms, the Jesuits never held rule in the government of Paraguay; indeed they had nearly as often to defend themselves from the hostility of the governor and bishop at Asuncion as from the actual invasions of the Paulistas or Portuguese settlers of São Paulo. It was only by the powerful assistance of Zabala, governor of Buenos Ayres, that the Anti-Jesuit and quasi-national party which had been formed under Antequera was crushed in 1735. In 1750 Ferdinand VI. of Spain ceded to the Portuguese, in exchange for the fortified village of Colonia del Sacramento (Uruguay), both the district of La Guayra and a territory of some 20,000 square miles to the east of the Uruguay. Seven of their reductions being included in this area, the Jesuits determined to resist the transference, and it was only after several engagements that they were defeated by the combined forces of Spain and Portugal. The treaty which they thus opposed was revoked by Spain in 1761, but the missions never recovered their prosperity, and the Jesuits were finally expelled the country in 1767. In 1811 Paraguay declared itself independent of Spain; by 1814 it was a despotism in the hands of DOCTOR FRANCIA, (*q.v.*) On Francia's death in 1840, the chief power passed to his nephew, Carlos Antonio LOPEZ (*q.v.*), and he was in 1862 succeeded by his son Francisco Solano Lopez, whose ambitious schemes of conquest resulted in the almost total extinction of Paraguayan nationality. The three allies, Uruguay, Brazil, and the Argentine Republic, which united against him, bound themselves by the treaty of 1865 to respect and guarantee for five years the independence, sovereignty, and territorial integrity of Paraguay, and at the close of the war in 1870 a new constitution was established, and a president, Jovellanos, appointed under their protection. Reduced to utter helplessness, the country owes its continued existence to the jealousy and balance of power existing between its neighbors. By a separate treaty with Brazil in 1872 it undertook to pay the cost of the war—\$200,000,000 to Brazil, \$35,000,000 to the Argentine Republic, and \$1,000,000 to Uruguay, or more than \$700 per head of the population. An attempt made in 1873 by Messrs. Robinson and Fleming to establish an English colony of so-called Lincolnshire farmers ended in disaster. Somewhat better success has as yet attended the German colony of San Bernardino, on Lake Ipacanay. The Brazilian army of occupation was withdrawn only in 1876.

PARAGUAY RIVER. See PLATE RIVER.

PARAHYBA, or PARAIBA, distinguished as Parahyba do Norte from Parahyba do Sul or S. João de Parahyba to the south of Rio de Janeiro, is a city of Brazil, on the right bank of the river of the same name, twelve miles from the sea, at the terminus of a railway running eighty-seven miles into the interior. The population, which was 40,000 about 1845, has decreased to between 12,000 and 14,000, and direct trade with Europe has been given up since 1840. Sugar, cotton, and india-rubber are still exported.

PARALLAX may be defined, generally, as the change produced in the apparent place of an object when it is viewed from a point other than that of reference. In astronomy, the places of the moon and planets are referred to the center of the earth, those of the fixed stars to the center of the sun. It is shown in

ASTRONOMY (*q. v.*) that the maximum of horizontal parallax of a celestial object being known, its parallax from any point of observation can be calculated. The sun's mean equatorial horizontal parallax (termed briefly the "solar parallax") is the angle which the equatorial radius of the earth would subtend to an observer at the sun when the earth is at mean distance from the sun. For its determination it would appear only necessary to observe the sun's apparent position simultaneously from two widely different points on the earth's surface; the difference of the apparent positions will be due to displacement by parallax, from which displacement the mean equatorial horizontal parallax can be readily obtained.

The requirements of modern astronomy demand that the solar parallax shall be determined with an accuracy of  $\frac{1}{1000}$  part of its amount—that is, within less than  $\frac{1}{100}$  part of a second of arc. But measures in the neighborhood of the sun cannot be made with any approach to this accuracy, not only on account of the effect of the sun's heat on the various parts of the instruments employed, but also of the atmospheric currents created by heat, which tend to destroy steady atmospheric definition and to render the solar image incapable of exact observation. It is thus hopeless to look for any solution of the problem by the most direct method. Two courses remain—either to seek some method which affords a larger angle to measure, or one which permits a mode of observation affording a higher precision. There are many relations to the solar parallax which are well established.

The parallax of the moon is known with very considerable precision by direct determination. The proportion of this parallax to that of the sun is an important term in the lunar theory, and the constant of this term (the *parallactic inequality*) is a known function of the solar parallax. Hence, if the constant of the parallactic inequality is independently determined, the solar parallax becomes known. The elements of the orbits of Venus and Mars undergo secular variations which increase from year to year, from century to century, and at last acquire very large values. These secular variations (on the assumption that all the terms of the theories of the planets are mathematically accurate) have also a well-determined relation to the solar parallax, and therefore afford a means of determining that parallax with an accuracy which increases by the continuation of observation.

It has been shown (see ASTRONOMY and MECHANICS), that the proportions of the interplanetary distances can be very accurately determined and tables be computed from observations of the apparent places of the planets, without any knowledge or assumption as to absolute distances (although an accurate knowledge of the solar parallax is required for giving final perfection to the lunar and planetary tables). In astronomical ephemerides, therefore, the distances of planets from the earth are accurately expressed in terms of the earth's mean distance from the sun, the latter being reckoned unity. Hence, to determine the solar parallax, it is only necessary to measure, at some favorable opportunity, the parallax of any planet, and to multiply the parallax so found by the number which expresses the relation of the distance of the planet from the earth to the earth's mean distance from the sun.

When Jupiter is in opposition he is nearer the earth by the diameter of the earth's orbit than when in conjunction; hence, since light occupies a very sensible time to travel, eclipses of Jupiter's satellites will seem to occur too soon in the first case and too late in the latter, the difference between the extremes of acceleration and retardation being the time occupied by light in

crossing the earth's orbit. This time is about sixteen and one-third minutes for the mean diameter of the earth's orbit; hence, if the velocity of light can be independently determined, the diameter of the earth's orbit becomes known. The determination, by employing the velocity of light, is also arrived at in another way. The constant of aberration (see ASTRONOMY), or the maximum apparent change of a star's true place due to the motion of the observer, depends on the relative velocity of the motion of the observer in space compared with the velocity of light. The angular velocity of the observer is perfectly known; hence if his linear velocity is known his radius of motion is known. Thus, if the constant of aberration and the velocity of light are independently determined, the radius of motion (that is, the sun's parallax) will be found.

There are thus three distinctive typical methods: (1) the gravitational method, depending on terms in the lunar and planetary theories, the constants of which are determined by observation; (2) the geometrical or direct observational method; and (3) the physical method.

The constant of the lunar parallax may be determined by a method precisely similar to that followed in the meridian declination observations of Mars. Our knowledge of the parallax of the moon depends at present entirely on such observations made nearly simultaneously at the Royal Observatories of Greenwich and the Cape of Good Hope. The resulting values of the parallax, found directly from these observations, are then multiplied by a factor which expresses the relation between the constant of the lunar parallax (see ASTRONOMY), and the moon's tabular parallax at the time; thus each nearly simultaneous observation at the two observatories gives an independent determination of the constant of the lunar parallax.

A better method, however, will be found when the results of numerous occultations of stars have been employed to determine the constants of a new and more accurate lunar theory.

The best determination of the constant of the lunar parallax is that of Mr. Stone, viz.,  $3,422.71''$  (*Mem. R.A.S.*, vol. xxxiv. pp. 11–16), derived from meridian observations at Greenwich and the Cape of Good Hope.

The constant of parallax of a fixed star is the maximum angle which a line equal to the earth's mean distance from the sun would subtend if viewed at the star. The distances of the fixed stars are so remote that till very recent times their parallaxes have been found to be insensible; that is to say, the earth's orbit viewed from the nearest fixed star presents a disk (or ellipse) too small for measurement.

The limits of this article do not permit a detailed history of the early attempts of astronomers to determine the parallaxes of the fixed stars. The reader is referred on this point to Peters' *Précis historique des travaux sur la parallaxe des étoiles fixes*, forming the first section of his celebrated work *Recherches sur la Parallaxe des étoiles fixes*, (*Mém. de l'Acad. Imp. de St. Petersbourg*, see *Math. et Physiques*, vol. v.) The most notable incident in that history was the discovery of aberration by Bradley, in 1728, when engaged in an unsuccessful attempt to determine the parallax of the star  $\gamma$  Draconis.

The first determination of the parallax of a fixed star is due to Henderson, His Majesty's astronomer at the Cape of Good Hope, in 1832 and 1833. It was followed by the nearly simultaneous discoveries of the parallax of  $\beta$  Cygni by Bessel and that of  $\alpha$  Lyræ by Struve from observations made in the years preceding 1840. Since that time similar researches have been prosecuted with gradually increasing success.

PARALLELS, THEORY OF. The fundamental principles of mathematics have not in general received from mathematicians the attention which they deserve. Mathematical science might in fact be compared to a building far advanced in construction. As to the firmness of its foundations there can be no doubt, to judge by the weighty superstructure which they carry; but the aspect of the building is not a little marred by the quantity of irrelevant rubbish which lies around those foundations, concealing their real strength and security.

The question of the parallel axiom in Euclid's geometry is to some extent an exception. There have been endless discussions concerning it. The difficulty is well known, and will be found succinctly stated in the article GEOMETRY, (*q.v.*) Those who have treated the subject have devoted themselves either to criticising the form of Euclid's axiom, suggesting modifications or substitutes (sometimes with undoubted advantage, *e.g.*, Playfair), or to questioning its necessity, offering either to demonstrate the axiom or to dispense with it altogether. It would serve no useful purpose to attempt a complete account of the literature of the subject; we may refer the reader who is curious in such matters to the various editions of Perronet Thomson's *Geometry without Axioms*. It will be sufficient to mention Legendre's views, which, although by no means reaching to the root of the matter, may be held as indicating the dawn of the true theory. The delicacy of the question may be illustrated by the story which is told of Lagrange. It is said that toward the end of his life he wrote and actually took to the Institute a paper dealing with the theory of parallels. He had begun to read it; but, before he had proceeded very far, something struck him. He stopped reading, muttered, "Il faut que j'y songe encore," "It is proper that I should dream again," and put the paper in his pocket. There appears to be no doubt that the true theory first presented itself to the mind of Gauss. The history of the matter is interesting, and deserves to be more generally known than it appears to be. In his earlier days, before his career in life was determined, when he had to consider the possibility of his becoming a teacher of mathematics, he drew up a paper in which he gave a philosophical development of the elements of mathematics. It was probably in the course of this discussion (about 1792) that he first came across the difficulty of the parallel axiom. He arrived at the conclusion that geometry became a logically consistent structure only after the parallel axiom was given as part of its foundation; and he convinced himself that this axiom could not be proved, although from experience (for example, from the sum of the angles of the geodesic triangle Brocken, Hohenhagen, Inselberg) we know that it is at least very approximately true. If, on the other hand, this axiom be not granted, there follows another kind of geometry, which he developed to a considerable extent and called the antieucledian geometry.

PARALYSIS, or PALSY, the loss of the power of muscular action due to some interruption of the nervous mechanism by means of which such action is excited (see "Nervous System" in PHYSIOLOGY). In its strict sense the term might include the loss of the influence of the nervous system or any of the bodily functions, the loss of common sensation or of any of the special senses; but other terms have come to be associated with these latter conditions, and the word "paralysis" in medical nomenclature is usually restricted to the loss or impairment of voluntary muscular power. Paralysis is to be regarded rather as a symptom than as a disease *per se*, and is generally connected with some well-marked lesion of some portion of the nervous system. According to the locality and extent of the nervous sys-

tem affected, so will be the form and character of the paralysis. It is usual to regard paralysis as depending on disease either of the brain, of the spinal cord, or of the nerves distributed to parts and organs; and hence the terms cerebral, spinal, and peripheral paralysis respectively. The distribution of the paralytic condition may be very extensive, tending to involve in a greater or less measure all the functions of the body, as in the general paralysis of the insane (see INSANITY); or again, one half of the body may be affected, or one or more extremities, or it may be only a certain group of muscles in a part supplied by a particular nerve.

1. *Paralysis due to Brain Disease*.—Of this by far the most common form is palsy affecting one side of the body, or *Hemiplegia*. It usually arises from disease of the hemisphere of the brain opposite to the side of the body affected, such disease being in the form of hemorrhage into the brain substance, or the occlusion of blood-vessels, and consequent arrest of the blood supply to an area of the brain; or again it may be due to the effect of an injury, or to a tumor or morbid growth in the tissues of the brain. The character of the seizure and the amount of paralysis vary according to the situation of the disease or injury, its extent, and its sudden or gradual occurrence. The attack may come on as a fit of apoplexy, in which the patient becomes suddenly unconscious, and loses completely the power of motion of one side of the body; or a like result may arise more gradually and without loss of consciousness. In either case of "complete" hemiplegia the paralysis affects more or less the muscles of the tongue, face, trunk, and extremities. Speech is thick and indistinct, and the tongue, when protruded, points toward the paralyzed side owing to the unopposed action of its muscles on the unaffected side. The muscles of the face implicated are chiefly those of mastication. The paralyzed side hangs loose, and the corner of the mouth is depressed, but the muscles closing the eye are as a rule unimpaired, so that the eye can be shut, unlike what occurs in another form of facial paralysis (Bell's palsy). The muscles of respiration on the affected side, although weakened, are seldom wholly paralyzed, but those of the arm and leg are completely powerless. Sensation may at the first be impaired, but as a rule returns soon, unless the portion of the brain affected be that which is connected with this function. Rigidity of the paralyzed members is occasionally present as an early or a late symptom. In many cases of even complete hemiplegia improvement takes place after the lapse of weeks or months, and is in general first indicated by a return of motor power in the leg, that of the arm following at a longer or shorter interval. Such recovery of movement is, however, in a large proportion of cases only partial, and the side remains weakened. In such instances the gait of the patient is characteristic. In walking he leans to the sound side and swings around the affected limb from the hip, the foot scraping the ground as it is raised and advanced. Besides this the evidence of the "shock" is felt more or less upon the system generally, the patient rarely (though occasionally) recovering his nervous stability. The paralyzed parts retain as a rule their electric contractility, but they are apt to suffer in their nutrition both from disuse and also from certain degenerative changes which the interruption of nervous influence is apt to exercise upon them.

It is to be observed that in many instances the hemiplegia is only partial, and instead of the symptoms of complete paralysis above described there exist in varied combination only certain of them, their association depending on the extent and locality of the lesion in the brain. Thus there may be impairment of speech and some amount of facial paralysis, while the arm and leg

may be unaffected, or the paralysis may be present in one or both extremities of one side while the other symptoms are absent. Further, the paralysis may be incomplete throughout, and the whole of the side be weak, but not entirely deprived of motor power. To partial paralysis of this latter description the term "paresis" is applied. (See PARESIS.)

Besides hemiplegia, various other forms of paralysis may arise from cerebral disease. Thus occasionally the paralysis is crossed, one side of the face and the opposite side of the body being affected simultaneously. Or again, as is frequently observed in the case of tumors of the brain, the paralysis may be limited to the distribution of one of the cranial nerves, and may produce an association of phenomena (such as squinting, drooping of the eyelid, and impairment or loss of vision) which may enable the seat of the disease to be accurately localized.

2. *Paralysis due to Disease of the Spinal Cord.*—Of paralysis from this cause there are numerous varieties depending on the nature, the site, and the extent of the disease. Some of the more important only can be noticed.

*Paraplegia*, paralysis of both lower extremities, including usually the lower portion of the trunk, and occasionally also the upper portion—indeed the whole parts below the seat of the disease in the spinal cord—is a form of paralysis which is a not infrequent result of injuries or disease of the vertebral column, also of inflammation affecting the spinal cord (MYELITIS, *q. v.*), as well as of hemorrhage or morbid growths involving its substance. When due to disease, the lesion is generally situated in the lower portion of the cord. The phenomena necessarily vary in relation to the locality and the extent of the disease in the cord. Thus, if in the affected area the posterior part of the cord, including the posterior nerve roots, suffer, the function of sensation in the parts below is impaired because the cord is unable to transmit the sensory impressions from the surface of the body to the brain. If on the other hand the anterior portion of the cord and anterior nerves be affected, the motor impulses from the brain cannot be conveyed to the muscles below the seat of the injury or disease, and consequently their power of movement is abolished. In many forms of this complaint, particularly in the case of injuries, the whole thickness of the cord is involved, and both sensory and motor functions are arrested. Further, the functions of the bladder and bowels are apt to suffer, and either spasm or paralysis of these organs is the result. The nutrition of the paralyzed parts tends to become affected, and bedsores and wasting of the muscles are common. Occasionally, more especially in cases of injury, recovery takes place, but in general this is incomplete, the power of walking being more or less impaired. On the other hand the patient may linger on for years bedridden, and at last succumb to exhaustion or to some intercurrent disease.

A form of spinal paralysis, often showing itself as paraplegia, occasionally occurs in children, and is termed—

*Infantile or Essential Paralysis.*—It is caused by an inflammatory affection limited to the anterior portion of the gray matter of the spinal cord throughout a greater or less extent, and affects, therefore, the function of motion, leaving that of sensation unimpaired. This disease is most common during the period of first dentition (although a similar affection is sometimes observed in adults). The commencement may be insidious, or there may be an acute febrile attack lasting for several days. In either case paralysis comes on, at first very extensive, involving both upper and lower extremities, but tending soon to become more limited and

confined to one or other limb or even to a group of muscles. The affected muscles lose their electric contractility and are apt to waste. Hence limbs become shortened, shriveled and useless, and deformities such as club-foot may thus be readily produced. In many instances recovery is complete, and the prospect of amendment is all the greater if the muscles show any reaction to electricity. There is throughout an absence of some of the more distressing of the phenomena of paraplegia, such as disturbances of the bladder and bowels or extensive bedsores, and in general the health of the child does not materially suffer.

*Progressive Muscular Atrophy or Wasting Palsy* is a disease usually occurring in early or middle life. It is characterized by the wasting of certain muscles or groups of muscles accompanied with a corresponding weakness or paralysis of the affected parts, and is believed to depend on a slow inflammatory change in the anterior cornua of the gray matter of the spinal cord. It is insidious in its onset, and usually first shows itself in the prominent muscular masses in the palm of the hand, especially the ball of the thumb, which becomes wasted and deficient in power. The other palmar muscles suffer in like manner, and as the disease advances the muscles of the arm, shoulders and trunk become implicated if they have not themselves been the first to be attacked. The malady tends to spread symmetrically, involving the corresponding parts of the opposite sides of the body in succession. It is slow in its progress, but, notwithstanding it may occasionally undergo arrest, it tends to advance and involve more and more of the muscles of the body until the sufferer is reduced to a condition of extreme helplessness. Should some other ailment not be the cause of death, the fatal result may be due to the disease extending so as to involve the muscles of respiration.

Another form of paralysis in certain respects resembling the last, and supposed by some to be due to a similar cause, is *Pseudo-hypertrophic Paralysis*, a condition occurring most frequently in male children, in whom in such cases there exists at first a remarkable enlargement of certain muscles or groups of muscles, followed sooner or later by wasting and paralysis. The enlarged muscles are chiefly those of the calf and hips, and their abnormal size is caused by an over-development of their connective tissue, and is therefore not a true hypertrophy. The child acquires a peculiar attitude and gait. He stands with his legs widely separated, his body arched forward, and in walking assumes a rocking or waddling movement. Later on the enlarged muscles lose their bulk, and at the same time become weakened in power, so that walking becomes impossible, and the child is completely paralyzed in the limbs and all other affected parts. In most instances death takes place from some intercurrent disease before maturity.

*Paralysis Agitans or Trembling Palsy* is a peculiar form of paralysis characterized chiefly by trembling movements in certain parts, tending to become more widely diffused throughout the body. It is a disease of advanced life. The symptoms come on somewhat insidiously, and first show themselves chiefly by involuntary tremblings of the muscles of the fingers, hand, arm, or leg, which are aggravated on making efforts or under excitement. These trembling movements become more marked and more extensive with the advance of the disease, and along with the tremors there generally occurs increasing weakness of the affected muscles. This is very manifest in walking, the act being performed in a peculiar tottering manner with the body bent forward. The trembling movements cease during sleep. This disease is a chronic one, and is intractable to treatment, but life may be prolonged for many years.

*Glosso-labio-laryngeal Paralysis* is a form of paralysis affecting, as its name indicates, the functions of the tongue, lips, and larynx (besides others), and depending upon disease of certain localities in the medulla oblongata from which the nerves presiding over these functions arise. The symptoms come on slowly, and are generally first manifested in some difficulty of speech owing to impaired movements of the tongue. Associated with this there is more or less difficulty in swallowing, owing to paralysis of the muscles of the pharynx and soft palate, by which also the voice is rendered nasal. With the advance of the disease the paralysis of the tongue becomes more marked. It cannot be protruded, and frequently undergoes atrophy. Certain of the facial muscles become implicated, especially those in the neighborhood of the mouth. The features become expressionless, the lips cannot be moved in speaking, the mouth remains open, and the saliva flows abundantly. The muscles of the larynx may also be involved in the paralysis. In the later stages of the malady the power of speech is completely lost, the difficulty in swallowing increases to a degree that threatens suffocation, the patient's condition altogether is one of great misery, which is in no way mitigated by the fact of his mental power remaining unaffected. Complications connected with the respiratory or circulatory functions, or disease affecting other parts of the nervous system with which this complaint may be associated, often terminate the patient's sufferings, and in any case life is seldom prolonged beyond two or three years.

3. *Peripheral Paralysis*, or local paralysis of individual nerves, is of not infrequent occurrence. The most common and important examples of this condition can only be briefly referred to.

*Facial paralysis*, *Bell's Palsy*, are the terms applied to paralysis involving the muscles of expression supplied to the seventh nerve. It is unilateral, and generally occurs as the result of exposure of one side of the head to a draught of cold air which sets up inflammation of the nerve as it passes through the aqueductus Fallopii, but it may also be due to injury, or disease either affecting the nerve near the surface or deeper in the bony canals through which it passes, or in the brain itself, involving the nerve at its origin. Here the paralysis is manifested by a marked change in the expression of the face, the patient being unable to move the muscles of one side in such acts as laughing, whistling, etc., or to close the eye on that side. The mouth is drawn to the sound side, while, although the muscles of mastication are not involved, the food in eating tends to lodge between the jaw and cheek on the palsied side. Occasionally the sense of taste is impaired. In the ordinary cases of this disease, such as are due to exposure, recovery usually takes place in from two to six weeks, the improvement being first shown in the power of closing the eye, which is soon followed by the disappearance of the other morbid phenomena. When the paralysis proceeds from disease of the temporal bone, or from tumors or growths in the brain, it is more apt to be permanent, and is in many cases of serious import. Throughout there is no diminution of sensibility in the paralyzed muscles; but they early lose their reaction to faradization, retaining that to galvanism.

*Lead Palsy* is a not uncommon form of local paralysis. It is due to the poisonous action of lead upon the system, and, like the other phenomena of lead poisoning, affects chiefly workers in that metal (see *LEAD*). The pathology of this disease is still unsettled, but it is believed to depend upon the local effect of the lead upon the nerves of the part rather than to any disease, at least in the first instance, of the nerve centers. The paralysis in this case is as a rule confined to the mus-

cles of the forearm which extend to the hand, and as they lose entirely their power the hand cannot be raised when the arm is held out, which gives rise to the condition termed "wrist drop." The paralysis may come to affect other muscles of the arms as well as certain of those of the legs and trunk, and along with the paralysis there occurs wasting of the affected muscles and loss of their electrical reactions. Occasionally in severe cases other nervous phenomena, such as convulsions, delirium, etc., may become superadded. The symptoms usually disappear on the removal of the patient from the source of lead contamination, along with the application of the treatment appropriate to poisoning with this metal—and all the more speedily if the case has not been of long duration and the affected muscles have not undergone atrophic change.

A form of peripheral paralysis not unlike the last occasionally results from chronic alcoholism. The paralysis occurring after diphtheria, another example of the peripheral variety, has been already referred to (see *DIPHTHERIA*).

It is impossible in a general notice like the present to refer at any length to the treatment of paralysis. The conditions of the disease in any particular case and its associations are so manifold that they can only be fully understood and appreciated by the medical expert under whose direction alone treatment can be advantageously carried out. It may be stated generally, however, that, since paralyzed muscles tend to undergo certain degenerative changes (see *PATHOLOGY*), it becomes an object in treatment to endeavor to maintain as long as possible their molecular integrity. With this view, when pain and other acute symptoms which may be present have ceased, the use of nervine tonics such as iron, quinine, and strychnine, and the suitable dieting of the patient, are the best constitutional remedies; while of local applications, frictions, or massage, but more particularly the employment of electricity, will be found of service, the latter agent often yielding markedly beneficial results.

*PARAMARIBO*, the administrative and commercial capital of Dutch Guiana or Surinam, is situated on the right bank of the Surinam, which, though at that point twenty miles from the sea, is a tidal river nearly a mile broad and eighteen feet deep. Built on a plateau about sixteen feet above low-water level, Paramaribo is well drained, clean, and in general healthy; the straight canals running at right angles to the river, the broad, straight, tree-planted streets, the spacious squares, and the solid if plain-looking public buildings, would not be unworthy of a town in the Netherlands. Among the more conspicuous edifices are—Fort Zeelandia (used as a civil and military prison), at the north corner, between the town proper and the Combé suburb; the Government-house, surrounded by a magnificent garden and park; the town-house, with a tower one hundred feet high; the law courts, the public hospital, where there is a remarkable betel-nut avenue fifty feet in height; the Reformed Dutch, Lutheran, Moravian, and Roman Catholic churches; and the Portuguese and Dutch synagogues. The population, barely 16,000 in 1854, was 20,373 in 1869, and is now (1890) 24,600.

*PARANA*. See *PLATE RIVER*.

*PARANAHYBA* (*PARNAHYBA*, or *PERNAHYBA*), *SÃO LUIZ DE*, a city of Brazil, the chief port of the province of Piahy, is situated on the right bank of the important Rio de Paranyha, near the beginning of its delta. It has a population of about 15,000, and trades in cotton, leather, etc., but its port is little visited by foreign steamers.

*PARASITISM*. The problem suggested by the occurrence of parasites not only in the intestines or the

kidneys but even in flesh and blood, in eye or brain, has occupied alike physician and naturalist from the earliest times. From ancient Egyptian and Jewish sanitary and religious codes we may perhaps infer considerable knowledge of the distribution and danger of parasites—unclean animals, like the pig, rabbit, and dog, being peculiarly infested with them. The schoolmen, too, perplexed themselves with quaint hypotheses as to the time and place and mode of the introduction of the parasites of man, while the long persistence of mediæval myths is evidenced by the “*Furia infernalis*” of the *Systema Naturæ*. The spontaneous generation of parasites seems never to have been doubted until the commencement of the eighteenth century, when Redi proved the origin of maggots from eggs of the blow-fly, and Swammerdam announced the similar origin of lice and other insect parasites. Both naturalists, however, opposed the extension of their results to the *Entozoa*, but the discovery of microscopic animalcules, and the reflection that these must readily be introduced into the body, induced Boerhaave to suggest the origin of parasites from free-living worms and infusorians. The sexuality and characteristics of a few *Entozoa* gradually became better known, while Linnæus, though little dreaming of their complex form-history, expelled the spontaneous generation theory by the fortunate mistake of identifying the free *Bothriocephalus* of the stickleback as the young stage of *B. latus* of man, and certain free Planarians and Nematoids as the young of liver flukes and thread worms. His school vastly increased the hitherto scanty catalogue of known forms, while their exacter knowledge rendered his hypothesis improbable. The origin of *Entozoa* from eggs which leave the body of their host, enter new hosts in food or drink, and when developing in other organs than the alimentary are carried thither by the circulation, was clearly put forward by Pallas, who also revived the early view of inheritance, which had been propounded before by the contemporaries of Leeuwenhoek. With the labors of Rudolphi and Bremser helminthology rose to the rank of an important special study, yet the degeneration of the Linnæan school had nowhere fuller course: observation of faunistic and systematic detail excluded all physiological or morphological research, and the knotty problem of origin was simply cut by a return to the hypothesis of spontaneous generation. This view seemed supported by the absence of reproductive organs in cystic parasites, and reigned almost undisputed until the accumulation of a new chain of evidence. Of this the main links were the discovery of the ciliated larva of a Trematode (*Monostomum*) by Mehlis, in 1831, of the *Redia* or *Cercaria* stages of the same genus, and of the six-hooked embryo of *Tænia* by Siebold in 1835, and the renewed study of *Bothriocephalus latus* by Eschricht, who maintained that the encysted forms were persistently larval, and that the life-history of the *Entozoa* should be viewed as broadly parallel to that of parasitic insects. Yet in spite of all this, and of the corroborative researches of Valentin, many helminthologists remained obstinate, until these incredible life-histories had been confirmed and treated as so many other cases of the “*Alternations of Generations*” in the epoch-making work of Steenstrup (1842). Dujardin next observed the wanderings of *Mermis*, and Siebold those of *Gordius*; the latter, however, advanced the doctrine that cysts were not larval stages, but mere pathological modifications of those worms which had chanced to “wander” into situations unfitted for their normal life. Meanwhile the important labors of Van Beneden traced the actual development of the cystic parasites of the bony fishes into the tapeworms of the rays and dogfishes which had devoured them, so proving that the

transmission of the parasites depended upon the mode of feeding. These results were soon confirmed by Küchenmeister, who not only transmuted cyst into tapeworm by transmission in food, but redeveloped the cystic form by feeding with eggs from the adult tapeworm, thus (1852-53) commencing the modern era of experimental helminthology. Häubner and Leuckart eagerly followed for the same group; Filippi, Valette, Pagenstecher, and Cobbold made similar investigations on Trematodes; while Leuckart transferred *Pentastomum* from rabbit to dog, and traced the formidable *Trichina* from pig to man. From this time (1860) the advances of our knowledge have been no longer in principle, though numerous and important, but in detail. To Küchenmeister, Cobbold, Davaine, and others, but more especially to Leuckart, we owe valuable general works.

It is among vertebrates that parasitism is most frequent and most fatal. Fishes swarm externally with Trematodes, leeches, and parasitic crustaceans, internally with cysts and intestinal worms all too numerous for enumeration. Nothing gives a more vivid idea of the extent to which parasitism has reached than an examination of a ray, or, even better, the common sunfish (*Orthogoriscus*). Amphibians are inhabited by many parasites—the common frog having almost constantly *Ascaris nigrovenosa* in its lungs, and infusorial parasites in its rectum, and may also yield *Distomum*, *Echinorhynchus*, etc., twenty species in all. Lizards harbor tapeworms, Nematoids, including species of *Trichina*, more rarely Trematodes. Ophidians have all kinds of parasitic worms, Chelonians chiefly Nematoids and Trematodes. The parasites of birds are of extraordinary number and variety; preying, fishing, and omnivorous birds serve, of course, very constantly as intermediate hosts; but graminivorous birds are hardly more exempt. The number of parasites is often so vast as to occasion the most serious disease; thus the “gapes” of poultry is due to the choking of the bronchial passages by multitudes of Nematoids (*Sclerostoma syngamus*), and the grouse disease to a similar cause (*Strongylus pergracilis*). Yet a great number of parasites may be borne without apparent injury: thus the post-mortem examination of a single stork has yielded twenty-four *Filaria* and sixteen *Strongylus* from the lungs and air passages, one hundred *Spiroptera* from the coats of the stomach, more than a hundred of various species of *Distomum*, and many hundreds of *Holostomium* from the gullet and intestine. Ticks and insect parasites are also common; of these the most remarkable are the feather-eating *Mallophaga*. The majority of the *Mammalia* have as internal parasites many different species of worms either in adult or cystic form, which are fully described in veterinary works. The special parasites of man are estimated by Cobbold at as many as 121 species (13 Trematodes, 16 Cestodes, 21 Nematoids, 10 Leeches, 17 Arachnids, 44 Insects); many of these, especially among insects, have occurred only very rarely, and should not be reckoned, e.g., *Musca vomitoria* and *Blaps mortisaga*, while a considerable number of the truly parasitic forms have only been once or twice described—the above estimate thus becoming reduced well-nigh to half.

The various modes of transmission of parasites, though of great practical importance, do not call for much discussion here. They may be summarized as follows:—(1) The majority of parasites reach their hosts through the medium of food or drink; (2) eggs are in some cases transferred from one animal to another by actual bodily contact, e.g., the eggs of *Pentastomum* by the licking of dogs; (3) sometimes the eggs are deposited in or on the host by the mother, for example, by insect parasites, such as *Ichneumons*, *Æstridæ*, etc.

(4) in some rare cases parasites are transmitted by self-infection—for example, young *Trichinæ*, born free in the alimentary canal of their host, bore their way thence directly into the muscles, there to grow into the well-known encapsuled worms. Eggs or proglottides of tapeworm may, on gaining the exterior, be transmitted inadvertently to the mouth, and so recommence their life-cycle within the same host.

The mode of diffusion of the ova of parasites presents many analogies to that of seeds in the vegetable kingdom; thus wind and water are alike utilized, passing animals may serve as unconscious bearers, and the like. Though well protected by a usually thickened egg-shell and an often remarkable degree of vitality, so as to resist prolonged drought, burial, and other vicissitudes, the parasite has an exceedingly small chance of success in finding a host; to preserve the species from extinction an enormous number of eggs must be produced, far exceeding that of free-living organisms. Thus Leuckart points out that as a tapeworm has an average lifetime of two years, and produces in that time about 1,500 proglottides, each containing say 57,000 ova, and since the species is not increasing in numbers, an ovum has thus only one chance in 85,000,000 of reaching maturity. The difficulties are of course increasingly greater as the life-history becomes more complicated, demanding an increasing number of hosts. Given a sufficient number of eggs, however, no difficulty is insuperable, and few parasitic forms accordingly seem in any risk of disappearance, except, it is to be hoped, in the case of civilized man and the domestic animals, where the large consumption of cooked food, aided by conscious hygienic precautions and medical aid, tends to exclude or remove them.

As the result of the association of two organisms with more or less constancy, various mutual modifications of form and function must obviously occur. The more important effects of parasite on host may be briefly outlined. Semper cites numerous cases where the commensal or parasite has a mechanically transforming effect on the host. Thus a horny coral with which an annelid is constantly associated has become permanently modified to form an encasing tube. Worms inside corals have enlarged the base of the cavity by stimulating growth, and may also produce permanent pores. Pycnogonids on *Campanularia* produce galls, which acquire specific characters, and various species of crab parasitic on corals form galls, two of which, coalescing, form a sort of "cave dwelling" with two fissures which are kept open by the respiratory currents of the crab, which thus both stimulates and checks the growth of the polyps. In higher animals, and with more intimate parasitism, the mechanical influences of the parasite on the host are more serious and more markedly pathological. Thus parasitic worms, by their size and number, frequently close up passages such as arteries, windpipe, etc., causing often fatal results. But many parasites are also actively destructive to certain tissues of their host—thus, as Semper points out, *Peltogaster* destroys the female reproductive organs of *Pagurus*, a Trematode those of *Limnæa stagnalis*, the larva of a fly (*Cuterebra emasculator*) the testes of various species of American squirrel. In none of the cases, however, is the general vitality of the host affected. The results of active motion within the host are productive of still more serious mischief; thus the internal migration and burrowing of such parasites as *Trichina* and *Bilharzia* is well known to produce violent inflammation. The perforation of vessels, the consequent extravasation of blood, and the destruction of tissue often end fatally for the host. Leuckart distinguishes pathological effects as due either to growth and increase of parasites, or to their wander-

ings within the host, or thirdly to the very considerable loss of nourishment which a number of parasites of appreciable size necessarily entails. Some blood-sucking parasites are specially dangerous, and many less ferocious forms doubtless poison their host to some extent by their waste products. Roux also notes how parasites—an *Echinococcus*, for example—by inducing a flow of nutritive material, may develop a network of capillaries and produce other histological changes.

The history of the medical aspects of parasitism can only be very briefly alluded to. From the time of the ancient Arabian physicians some diseases, such as itch, have been referred to parasites. With the increasing knowledge as to the prevalence and importance of parasitism there arose a distinct parasitic theory of disease. In spite of the gradual unraveling of the mysteries of origin and life-history, physicians long clung conservatively to the old hypothesis of spontaneous generation, even Bremser regarding the pathological states of the host not as caused by the parasites, but as causing and in fact creating them. It was not till within the last forty years that, with the rise of experimental helminthology, medical science shook itself free from superstition and ignorance, and devoted close attention to ætiology and treatment, culminating in that systematic warfare against all forms of parasitism which now occupies so important a place in medicine and the veterinary art.

*Vegetable Parasitism.*—The name of parasites has been given to those plants which are nourished wholly or partially at the expense of other living organisms. The degree and nature of the benefit thus obtained varies greatly with different plants, and the effect produced upon the host ranges from an almost imperceptible one to complete destruction. At one extreme are certain forms which, while drawing the nourishment necessary for life from their hosts, yet do so in such fashion that both organisms continue to live in intimate association, and, it may be, rendering mutual help. From these by a series of gradations we come to parasites of such a destructive influence as to cause widespread death to certain animal and vegetable forms of life. This physiological group is closely related to another, the saprophytes, which obtain their nourishment from the dead remains of organisms. True parasites belong exclusively to the dicotyledonous flowering plants and the fungi. A few algæ are partial parasites.

The remarkable appearance presented by most parasitic flowering plants undoubtedly attracted notice in remote times. They are frequently mentioned by early writers, but there is no evidence sufficient to enable us to determine whether they were regarded as independent plants or merely as pathological excrescences—unless in the one case of the mistletoe, which was recognized as the former by Pliny, who gives an account of its reproduction by seed. The effects of the attack of parasitic fungi were also observed in very early times, as there is abundant evidence to show, but the plants themselves which caused the damage were necessarily not detected as such from their minute size and obscure nature. We must come to the middle of the eighteenth century for the first attempt to establish a botanical group of flowering parasites. The knowledge of parasitic fungi has advanced gradually with the improvement of the microscope, and the accumulation of the life-histories of forms has grown up under the hands of numerous observers, among the earliest of whom Knight performed admirable service. With increasing knowledge of native and exotic forms, and the advance made in the fields of vegetable anatomy and physiology, the whole group of vegetable parasites has become more strictly defined,—the last noteworthy service being the establishment by De Bary (*Morph. u. Physiol. der*

*Pilze, Flechten u. Myxomyceten*) of the physiological group of "saprophytes" to receive those plants which differ from the parasites in obtaining their nourishment from the dead bodies of organisms and from soil rich in humus.

PARCÆ. See FATES.

PARCHMENT consists of skins of various animals, unhaired, cleaned, and dried so as to form sheets of uniform thickness suitable for writing upon and for the numerous other purposes to which such preparations are devoted (see PALEOGRAPHY). The skins employed for parchment are principally those of sheep, lambs, and calves; but goat and ass skins are similarly dressed for special purposes. The preliminary unhairing and cleaning of the skins is effected as in the leather manufacture (see LEATHER). In their moist flexible condition the unhaired skins are tightly and uniformly stretched over a wooden frame termed a herse, and on the flesh side they are carefully gone over with a semi-circular fleshing knife which removes all adherent flesh. The grain side is also gone over to clean the surface and squeeze out a proportion of the absorbed moisture. Ordinary binder's parchment and drumhead parchment need no further preparation, but are simply allowed to dry gradually on the frames on which the skins are stretched. But fine parchment for writing and vellum are powdered with chalk on the flesh side and carefully rubbed with fine pumice stone till a delicate uniform velvety surface is raised. All inequalities on the grain side are also removed by paring and rubbing with fine pumice. Stout vellum is made from calfskins, and ordinary qualities from split sheepskins; for drumheads, tambourines, and like applications goat and calfskins are used, and it is said that wolfskins yield the best drumheads.

*Vegetable Parchment*, or parchment paper, is a modified form of paper produced by chemical treatment, having considerable similarity to ordinary animal parchment. It is prepared by acting on ordinary unsized paper with dilute sulphuric acid, and immediately washing away all trace of acid. Paper so treated will be found to have undergone a remarkable change: the porous intertexture of cellulose composing unsized paper will have expanded and agglutinated, forming a homogeneous surface, translucent, horny, and parchment-like; it will have acquired about five times the strength of ordinary paper; it will become soft and flaccid when steeped in water, to which, however, it is impervious; and it is unaffected by boiling in water. It is most largely used as covers for preserve jars, bottles, etc., and to some extent for tracings of plans, charts, etc.

PARDON is the remission, by the power intrusted with the execution of the laws, of the penalty attached to a crime. The right of pardoning is coëxtensive with the right of punishing. In practice the prerogative is extremely valuable, when used with discretion, as a means of adjusting the different degrees of moral guilt in crimes or of rectifying a miscarriage of justice. By the law of England pardon is the sole prerogative of the king. This follows from the theory of English law that all offenses are breaches of the king's peace.

In the United States the power of pardon vested in the president is without any limitation in cases of offenses against the Federal laws, except in the case of impeachments (U. S. Constitution, art. ii., § 2). The power of pardon is also vested in the executive authority of the different States, with or without the concurrence of the legislative authority. Thus by the New York Code of Criminal Procedure, 1881, §§ 692, 693, the governor of the State of New York has power to grant reprieves, commutations, and pardons, except in

the case of treason, where he can only suspend the execution of the sentence until the case can be reported to the legislature, with whom the power of pardon in this case rests. The usual form of pardon in the United States is by deed under seal of the executive.

PARDUBITZ, a town of Bohemia, situated at the confluence of the Elbe and the Chrudimka, fifty-five miles to the east of Prague. The inhabitants, amounting to 10,000 in 1889, are engaged in the manufacture of sugar, agricultural implements, sweetmeats, spirits, beer, and iron.

PARÉ, AMBROISE, the father of French surgery, was born at Laval, in the province of Maine, in 1517, and died in 1590. A collection of his works was published at Paris in 1561, and was afterward frequently reprinted. Several editions have also appeared in German and Dutch. Among the English translations was that of Thomas Johnson, London, 1634. For Paré's professional career and services, see SURGERY.

PAREJA, JUAN DE, Spanish painter, was a mestizo, born in the West Indies about 1606, and in early life passed into the service of Velazquez, who employed him in color-grinding and other menial work of the studio. His extant works are not very numerous; the best known, *The Calling of St. Matthew*, now in the Royal Picture Gallery, Madrid, has considerable merit as regards technique, but does not reveal much originality, insight, or devotional feeling. He died in 1670.

PARENT AND CHILD. See BASTARD, INFANT, and MARRIAGE.

PARENZO, a city on the west coast of Istria (Austria-Hungary), thirty miles south of Trieste, with about 3,000 inhabitants, has considerable historic and architectural interest. It is built on a peninsula nowhere more than five feet above the sea-level; and from the fact that the pavements of the Roman period are three feet below the present surface it is inferred that this part of the coast is slowly subsiding. The well-preserved cathedral of St. Maurus was erected by Euphrasius, first bishop of Parenzo, probably between 535 and 543.

PAREISIS, a form of partial paralysis, affecting principally and primarily the cerebral region, and indirectly the nervous system of other parts of the body. It is a term of comparatively recent introduction, and is principally used of those cases in which motor ataxy is a prominent symptom. Its treatment, in the nature of things, must coincide with that for paralysis.

PARGA, a town on the Albanian coast, in the Turkish vilayet of Janina, built by the Venetians in 1572. Its population does not now exceed 1,500.

PARHELIA. See HALO.

PARIAN CHRONICLE. This famous Chronicle is contained in the ARUNDELIAN MARBLES (*q.v.*), now at Oxford. It originally embraced an outline of Greek history from the reign of Cecrops, king of Athens (1582 B.C.), down to the archonship of Diognetus at Athens (264 B.C.), but the remaining portion extends no farther than 355 B.C.

PARINI, GIUSEPPE, Italian poet, was born in the district of Bosisio, in the Milanese, on May 22, 1729. In 1752 he published at Lugano, under the pseudonym of Ripano Eupilino, a small volume of *sciolto* verse which secured his election to the Accademia dei Transformati at Milan and to that of the Arcadi at Rome. In 1769 he was given the chair of *belles lettres* in the Palatine School. His subsequent lectures as professor of rhetoric in the Gymnasium di Brera are still of value, and as occupant of the chair of fine arts he was frequently consulted by the artists of the day in matters of taste and design. He died on August 15, 1799.

PARIS, the capital of France, and the second largest city in the world, is situated on the Seine river, which has a course of some seven miles through the city. Its total area is about thirty square miles, and its population (2,344,450 in 1886), is now (1890), not less than 2,600,000. The city occupies the center of what is known as the Paris basin, through which the Seine runs from southeast to northwest. The granitic substratum is covered by Jurassic, Cretaceous and Tertiary forms, and in many places building materials—freestone, limestone and gypsum—are laid bare by erosion. To this plenitude of building-stone Paris is largely indebted for its development. Back from the river on the north rise the heights of Charonne, La Villette, Montmartre, and the Buttes-Chaumont, and on the left bank are the Butte-aux-Cailles, the hill of St. Geneviève, and Montrouge. The ascent is gradual, the highest point being not more than 400 feet above sea-level, while the mean elevation is from 100 to 130 feet. Consequently the site is one of the finest possible for a large city, and art and nature have combined to render this one of the most beautiful on earth. There are three islands in the Seine within the bounds of Paris:—the island of St. Louis, the Ile de la Cité, and the Ile aux Cygnes. The river is crossed by numerous bridges, of which the chief architecturally and historically are the Pont Neuf, Pont d'Iena, Pont des Artes, Pont de la Concorde, and Pont des Invalides. The width of the Seine varies from 440 to 530 feet; it is embanked and quayed on both sides, and these embankments form fine, wide boulevards. The city is inclosed by a line of fortifications measuring over twenty-two miles in circumference. On the right side of the river it presents sixty-eight fronts, and on the left twenty-six, each consisting of a curtain connecting two demi-bastions. It is pierced by fifty-six gates, nine openings for railways, and two openings for the Ourcq and the St. Denis canals. Outside of this enceinte are a number of detached forts arranged in two main lines. First come the forts erected previous to 1870 at St. Denis, Aubervilliers, Romainville, Noisy, Rosny, Nogent, Vincennes, Ivry, Bicêtre, Montrouge, Vanves, Issy, and Mont Valérien; and next the new forts of Palaiseau, Villeras, Buc, and St. Cyr, which protect Versailles, and Marly, St. Jamme, and Aigremont, which surround St. Germain. On the right side of the Seine are Forts Corneilles, Domont, Montlignon, Montmorency, Écouen, Stains, Vaujours, Villiers, and Villeneuve St. Georges. Between the two lines the Chatillon fort occupies the site of the German batteries which bombarded Paris in 1871.

The old part of Paris, which is of great antiquity, is grouped chiefly about the Ile de la Cité, on which is the Cathedral of Notre Dame. In this division the streets are somewhat irregular, but elsewhere they are wide, and the elaborate system of boulevards perfected under the Second Empire affords ready access to all parts of the city.

The line of the boulevards, from the Madeleine to the Bastille, nearly three miles, is one of the busiest and most fashionable in the world; here are the Porte St. Denis, the Porte St. Martin, most of the large cafés, the Opera-House, and the various theaters distinguished as Le Vaudeville, Les Nouveautés, L'Opéra Comique, Les Variétés, Le Gymnase, La Porte St. Martin, La Renaissance, L'Ambigu, Les Folies Dramatiques, Dejazet, Beaumarchais, and Le Cirque. Traffic passes east and west from the Bastille to the Place de la Concorde by Rue St. Antoine and Rue de Rivoli. North and south the line of the Boulevard de Strasbourg and the Boulevard de Sébastopol stretches from the station of the Eastern Railway (Gare de l'Est) to the Seine,

and is continued by the Boulevard du Palais in the Cité and the Boulevard St. Michel, on the left side of the river, as far as the observatory. The total length is not less than two and one-half miles. On the right side of the river may also be mentioned the Rue Royale; the Malesherbes and Haussmann boulevards, which cross the most elegant quarters of the town; the Avenue de l'Opéra, which unites the Place du Palais Royal with the Place de l'Opéra, and terminates at the main entrance of the Opéra; the Rue de la Paix, Rue Auber, and Rue 4 Septembre, which also terminate in the Place de l'Opéra, and are remarkable for their magnificent shops; Rue LaFayette, one of the longest thoroughfares of Paris, traversing the town from the Opera to the end of La Villette; the Boulevard Magenta, from Montmartre to the Place de la République; Rue de Turbigo, from this Place to the Halles Centrales. The older streets, known as Richelieu, Vivienne, De la Chaussée d'Antin, St. Honoré, Montmartre, St. Denis, St. Martin, are full of shops and offices. The Place de l'Arc de Triomphe de l'Étoile is the center of twelve avenues stretching out from it like the spokes of a wheel, but not all as yet lined with buildings. On the left side of the river the main thoroughfare is the Boulevard St. Germain, from Pont Sully to the Pont de la Concorde, which passes in front of the school of medicine, the Place St. Germain des Prés, and the war office. The boulevards are paved with asphalt, and the arrangements for watering and cleaning are perfect.

No city in the world has such an abundance of public squares or "Places" as Paris. Chief among these are the Place de la Concorde, Place de l'Étoile, Place Vendôme, with the column and statue of Napoleon I.; Place du Carrousel, with a small triumphal arch commemorative of the campaign of 1806, which formed the entrance to the palace of the Tuileries, now demolished; Place des Victoires, with the equestrian statue of Louis XIV.; Place des Vosges, formerly Place Royale, with that of Louis XIII.; Place de la Bastille, with the column commemorative of the Revolution of July, 1830; Place de la République, with the Republic statue; Place de l'Hôtel de Ville; Place du Châtelet, with a column commemorative of the Italian campaign of 1796; those which take their names from the Bourse, the Palais Royal, and the Opera; Place de Rivoli, with the equestrian statue of Joan of Arc; Place Moncey, adorned with a monument in memory of the defense of Paris in 1814, as Place Denfert, at the opposite extremity of the town, is adorned with a colossal lion symbolizing the defense of 1871. South of the Seine are the Place St. Michel, adorned with a monumental fountain, and one of the great centers of traffic in Paris; Place du Panthéon; Place St. Sulpice; Place Vauban, behind the dome of the Invalides, and Place du Palais Bourbon, in front of the chamber of deputies.

The public gardens of Paris within the enceinte, although not numerous or large, are laid out with great taste. The gardens of the Tuileries suffered severely under the Commune (1871), when the palace was destroyed, but have been restored. The gardens of the Luxembourg, in front of the palace occupied by the senate, are rather larger than those of the Tuileries; with less regularity of form they present greater variety of appearance. In the line of the main entrance extends the beautiful Observatory Walk, terminating in a monumental fountain, which is in great part the work of Carpeaux. The Luxembourg conservatories are rich in rare plants. The Jardin des Plantes will be mentioned below in the list of scientific establishments. Beside these three great gardens laid out in the French taste, with straight walks and regular beds, there are several in what the French designate the English style. The

finest and most extensive of these, the Buttes-Chaumont Gardens, in the northeast of the city, occupy sixty-two acres of very irregular ground, which up to 1866 was occupied by plaster-quarries, limekilns, and brick-works. The "buttes" or knolls are now covered with turf, flowers and shrubbery. The Montsouris Park, in the south of the city, forty acres in extent, also consists of broken ground; in the middle stands the meteorological observatory. Monceau Park, surrounded by the most aristocratic quarters of modern Paris, is a portion of the old park belonging to King Louis Philippe, and is now the property of the town. The gardens of the Palais Royal are surrounded by arcades and fine shops. There is hardly, it may be further remarked, a district in Paris which has not of recent years its well-planned square kept up at municipal expense on some plot of ground cleared during the improvements. Such are those named after Tour St. Jacques (one of the most graceful monuments of old Paris), the Conservatoire des Arts et Métiers, the Temple, Montholon, Cluny, etc. There have recently been added the park of the Champs de Mars, and that of the Trocadéro with its fountains and aquarium.

But the real parks of Paris are the Bois de Boulogne and Bois de Vincennes, which belong to the city, though situated outside of the fortifications. The former is reached by the wide avenue of the Champs Élysées as far as the Arc de Triomphe, and thence by the avenue of the Bois de Boulogne or that of the Grande Armée. The first of these, with its sidewalks for foot passengers and equestrians, grass-plots, flower-beds, and elegant buildings with gardens and railings in front, affords a wide and magnificent prospect over the Bois and the hills of St. Cloud and Mont Valérien. The Bois de Boulogne covers an area of 2,158 acres, one-fourth of which is occupied by turf, one-eighth by roads, and the rest by clumps of trees, sheets of water, or running streams. Here are the two racecourses of Longchamps (flat races) and Auteuil (steeple-chases), and the gardens of the Acclimatization Society. The Bois de Vincennes, a little larger than the Bois de Boulogne, is similarly adorned with streams, lakes, cascades, and fountains.

One of the most notable of the public places of Paris is the Champ de Mars, a large sandy space in front of the École Militaire 1,100 yards in length, and 550 yards in breadth. On this the great Exposition of 1889 was located. The Field of Mars has had much to do with history. In 1790 60,000 Parisians participated in the voluntary labor of preparing it for the Fête de la Fédération, and on July 14th of that year (the anniversary of the taking of the Bastille) Louis XVI. swore fidelity to the new constitution there. Napoleon I. celebrated the *Champ de Mai* there on June 1, 1815, and the field was the site of the great Expositions of 1867 and 1878.

Paris is rich in public buildings, many of great architectural merit and others interesting by reason of their historical associations. The Palace of the Louvre, which lies on the right side of the Seine, in the heart of the city, consists of a quadrangle with an inner court 394 feet square, two galleries extending westward from two sides of the quadrangle, and two galleries external and parallel to these, and continued till they meet the side wings of the Tuileries. The east front of the Louvre is 548 feet long and 90 feet high, and the first story is occupied by Perrault's famous colonnade. Toward the west are those portions of the Tuileries which escaped the fire of 1871—the connecting galleries and (on the south) the Flora pavilion and (on the north) the Marsan pavilion, which was entirely rebuilt between 1872 and 1877. From Perrault's colonnade to the Flora pavilion the side facing the quay is

2,250 feet long. In the middle of each façade there is a pavilion rising above an archway. The western archway, which is surmounted by the clock, leads into Place Napoléon III., which has its center occupied by a square, and its north and south sides bordered with porticoes surmounted by statues of eminent Frenchmen. To the west is the Place du Carrousel. On the south side, at the junction of the Louvre and the Tuileries, is a gateway with three arches, of which the middle one is crowned with the bronze group by Mercier, *The Genius of the Arts*, erected in 1875. The river-front of the Louvre is in an older and more elegant style than the side facing Rue de Rivoli. It is connected with the buildings of the quadrangle by Henry IV.'s pavilion, which contains in its first story the elegant Apollo gallery.

The Palais de Justice in La Cité presents on the west side, toward Place Dauphine, a Greek façade by Duc (1865-70), one of the finest productions of modern art. From the Boulevard du Palais on the east it is separated by a magnificent eighteenth-century railing in wrought-iron and gilt. On this side lie the Salle des Pas Perdus and the Sainte-Chapelle. The fine square tower known as the Clock Tower stands at the corner formed by the Quai du Nord and the Boulevard du Palais; and on the north side lies the Conciergerie prison with the dungeon once occupied by Marie Antoinette. Opposite the Palais de Justice, on the other side of the boulevard, is the Tribunal de Commerce with a remarkable staircase under the cupola.

On the left bank of the Seine are the Luxembourg palace, the seat of the senate, and formerly the residence of Mary de' Medici; the Bourbon palace, the seat of the chamber of deputies, fronting the river and Pont de la Concorde, with a fine columned portico and pediment; the palace of the Legion of Honor, an exquisite building of Louis XIV.'s time; and the palace of the Institute, with a handsome dome. On the right side of the river lie the Élysée palace (in the Champs-Élysées), a vast building in a modern style, the residence of the president of the republic, and the palace of the Trocadéro, built for the Exhibition of 1878, the central rotunda of which contains the largest music-hall in Paris (for 15,000 auditors) and a colossal organ.

Among the government and administrative buildings may be mentioned the Hôtel de Ville, burnt in 1871, but rebuilt finer than before on the old site; the ministry of foreign affairs, where the congress of Paris was held in 1856; the ministry of marine, which occupies on Place de la Concorde one of the two pavilions erected by Gabriel on each side of Rue Royale; the ministry of war in the Boulevard St. Germain; the Bank, formerly the De la Vrillière "hôtel," built by Mansard; the Mint, with a fine façade stretching 394 feet along Quai Conti not far from Pont Neuf; the national printing establishment, formerly Cardinal Rohan's mansion; and the national record office, close at hand, formerly the Soubise mansion. These last two buildings are in the Quartier du Marais, where a great many ancient mansions are now used as warehouses and workshops.

The administrative buildings occupied by the various departments of state are principally situated on the left bank of the Seine. The Palais du Quai d'Orsay, formerly used by the Conseil d'Etat (Council of State), and the Cour de Comptes (treasury), was burned by the Communists and is still a ruin, although its walls are so strong that it can probably be restored. The palace of the Legion of Honor, near the Bridge of Solferino, was the residence of Mme. de Staël under the Directory.

The Chamber of Deputies, otherwise known as the Palais du Corps Legislatif or Palais Bourbon, was

built 1722 *et seq.* by the Prince de Condé, at a cost of 20,000,000 francs. It became national property in 1790, and was used for the sittings of the Council of Five Hundred. It is now occupied by the Chamber of Deputies. The residence of the president of the Chamber is to its right, and close by is the Ministry of Foreign Affairs, all these being opposite the Pont de la Concorde, and on the left bank of the Seine. The Ministry of Justice is on the west side of the Place Vendome.

The hotels of Paris are plentiful, and some of them, especially those on the right bank of the Seine, very large and magnificently furnished. The best are located in the Rue de Rivoli, Rue de Castiglione, Rue St. Honoré, Rue de la Paix, Place Vendome, and on the Boulevards des Capucines, and des Italiens, on the Avenue de l'Opéra, and in and near the Champs Elysée. The restaurants of the best class are found on the Boulevards des Capucines, des Italiens, and Poissonnière. The finest shops and retail stores are in the Boulevards, the Rue de la Paix, Avenue de l'Opéra, Rue Vivienne, and Rue de Rivoli, and there are very large stores near the Louvre, and in the Rue de Bac.

The largest and finest of the religious buildings of Paris is the cathedral of Notre Dame (426 feet long by 164 wide), restored between 1846 and 1879 by Viollet-le-Duc. As it now exists this church has five naves running the whole length of the building, and square chapels; the central *flèche*, recently restored, is 312 feet high, and two massive square towers worthily crown the principal façade, which is one of the most beautiful that have come down to us from the Middle Ages. The transept has also two façades, which, while less imposing, are more richly decorated with chiseled work, dating from about the middle of the thirteenth century. Of the elaborate decoration of the interior all that is old is a part of the screen of the choir, from the fourteenth century.

St. Geneviève or the Panthéon, consecrated by the Convention to illustrious men, but since restored to Christian worship, has the form of a Greek cross with a dome in the center and a columned portico in front, the pediment of which contains an immense bas-relief by David of Angers representing great men crowned by their country. Fénelon, Rousseau, Voltaire, Mirabeau, Laplace, Cuvier, etc., may be distinguished. The crypt contains the tombs of Soufflot (the architect of the church), Rousseau, Voltaire, and Victor Hugo. Near St. Geneviève stand St. Étienne du Mont with a magnificent roodloft, and the chapel of St. Geneviève with the tomb of this patroness of Paris. The Madeleine, intended by Napoleon I. for a temple of victory, has the form of a Greek temple. At St. Germain des Près, St. Severin, and St. Vincent de Paul are beautiful frescoes by Hippolyte Flandrin, to whom a monument has been erected in St. Germain.

Of other religious edifices may be mentioned the new church of the Sacred Heart on the heights of Montmartre; St. Sulpice (almost as large as Notre Dame); St. Germain l'Auxerrois; St. Roch, from the steps of which Napoleon Bonaparte directed his cannon on the 13th Vendemiaire against the royalists who were about to attack the Convention.

There are many buildings in Paris devoted to entertainment and amusement, and of these the Grand Opera and L'Opéra Comique may be particularly mentioned. The first is the National Academy of Music and Dancing. It was begun by Napoleon III. in 1861 and completed under the republic in 1875. It covers two and three-fourths acres and cost \$7,220,000. The Opéra Comique is the home of light opera; the Théâtre Français and the Odéon of the classic drama.

Beside these there are the Gymnase and the Vaudeville, Les Folies Dramatiques, Les Bouffes, and nearly a hundred others.

Among the artistic adornments of Paris must be noted the Arc de Triomphe de l'Etoile (the Arch of the Star), the largest triumphal arch in existence. It was begun by Napoleon I. in 1806 to commemorate the glories of France, and was completed in 1836. It consists of a vast arch 67 feet high and 146 feet wide, intersected by a lower transversal arch. The whole structure is 160 feet high, 146 feet wide and 72 feet deep, and it is elaborately ornamented with statuary, groups in bronze and bas-reliefs. There is a smaller arch, a replica of that of Severus, in the Place du Carrousel. The Column Vendome in the Place of the same name, is constructed of masonry cased with bronze plates inscribed with battle scenes. The metal used was obtained by melting down 1,200 Austrian and Russian cannon. It is 142 feet in height and is surmounted by a statue of Napoleon I. In May, 1871, it was overthrown by the Communists, but has since been restored. The Column of July, built in honor of the civic heroes of the 1830 Revolution, stands on the Place de la Bastille. In the vaults under it are buried many hundreds of the victims of the Revolutions of 1830 and 1848. The Obelisk of Luxor, brought from Egypt in 1833, adorns the magnificent Place de la Concorde, the finest in the world, and the scene of the execution of Louis XVI. and Marie Antoinette, of Charlotte Corday, Danton, Robespierre, Camille Desmoulins, Hebert, St. Just, and nearly 3,000 others, who perished by the guillotine between January 21, 1793, and May 3, 1795. The Place de la Concorde also contains eight stone figures emblematic of the chief towns of France.

In the center of the court of the New Louvre is a gigantic monument to Leon Gambetta. Other noticeable statues are those of Joan of Arc, Moliere, and Henry IV., the latter on the Pont Neuf.

The Hôtel des Invalides, with its conspicuous gilded dome, occupies an area of about thirty acres and was founded in 1670 by Louis XIV. Soldiers disabled by wounds and those who have served for thirty years are entitled to admission, and there is room for 5,000. The chief attraction of the Invalides is the tomb of Napoleon I., where the great conqueror rests in a magnificent sarcophagus of granite.

Of educational institutions of the higher order the greatest is the Sorbonne, founded in 1629, and recently removed into more capacious quarters in the street named after it. It comprises the three faculties of theology, letters, and science, and has over 10,500 students. The Collège de France, with thirty-nine professors, is under the direct control of the minister of public instruction.

The so-called *salles d'asile* are infant schools for children from three to six years of age, *i.e.*, from the time when their mothers place them in the *crèches* or day-nurseries, to the time when they may be admitted to the primary schools. The municipality maintains 126 secular *salles d'asile* receiving 15,939 children, and one *salle congréganiste*, (*i.e.*, under the management of a religious society) with 279 children. The private establishments comprise 23 secular "salles" with 1,243 children, and 39 congreganist "salles" with 4,231.

There are 173 primary secular schools (56,369 pupils) for boys, 161 secular schools (46,579 pupils) and 2 congreganist schools (765 pupils) for girls. The private primary schools are 183 secular schools and 70 congreganist for boys, 577 secular schools and 136 congreganist for girls—number of pupils unknown. At certain hours the primary schools are transformed into classes for adults—116, with 14,288 pupils. The

"higher schools" (*écoles supérieures*) supply education for industrial or commercial careers. They have 677 pupils between six and thirteen years of age and 2,956 above thirteen, who are distributed among the Collège Chaptal and the Turgot, Lavoisier, Colbert, J. B. Say, and Arago schools. The apprentice school (*école d'apprentis*) with 228 pupils, the normal schools (for males, 205 pupils; for females, 68 pupils), and the Pape-Carpentier school, which trains matrons for *salles d'asile* complete the list of the municipal establishments for primary education. Besides there are private normal schools for Protestant teachers (male and female), a private normal school for girls, normal classes for ladies under the auspices of the Society for Elementary Instruction, and professional schools for both girls and boys. Commercial instruction is given in two schools placed under the patronage of the chamber of commerce, and a special commercial high school established about 1880. Municipal libraries, subsidized by the city, have been established in all the arrondissements; they lent 401,415 works, the number of books contained in the libraries being 89,355.

Secondary education is provided by the municipal Collège Rollin; in the national lycées (Louis le Grand, Henry IV., St. Louis, and Vanves), which have both boarders and day pupils; the Charlemagne and Condorcet lycées, for day pupils only; and the Collège Stanislas, more especially for boarders. It is between these establishments, subjected to the same university programme, and the Versailles lycée that the great competition of the Sorbonne takes place at the close of each school year. The number of their pupils (Stanislas excepted) is over 10,000. There are also private secular and ecclesiastical schools with nearly 30,000 pupils.

The *Bibliothèque Nationale*, the most extensive library in the world, stands in the block formed by the Rues de Richelieu, des Petit-Champs, Vivienne and Colbert, on the site of the palace of Cardinal Mazarin. It contains over 2,500,000 volumes, beside most elaborate collections of books and maps, engravings, medals and antiques, and has a public reading-room and halls for study.

Among the learned societies of Paris the first in importance is the Institut de France, which has already been described (see INSTITUTE OF FRANCE). The committee of learned societies at the ministry of public instruction forms, as it were, the center of the various societies not maintained by the government; and the French Association for the Advancement of the Sciences, founded in 1872, is based on the model of the older British society, and like it meets every year in a different town. The other societies may be classified as follows:—1. *Historical or Geographical*—History of France, Antiquaries of France (till 1814 known as Celtic Academy), Historic Studies, Numismatics and Archæology, Bibliophiles, School of Charters, Ethnography, Geography (1821, and thus the oldest of its class), Asiatic (1822), French Alpine Club (Club Alpin); 2. *Natural and Medical Sciences*—Anthropology, Zoölogical Acclimatization (which has the direction of the zoölogical gardens in the Bois de Boulogne), Entomological, Geological, Surgery, Anatomy, Biology, Medical of the Hospitals, Legal Medicine or Medical Jurisprudence, Practical Medicine, Pharmacy, Agriculture, Horticulture; 3. *Industrial and Moral Sciences*—Encouragement of National Industry, Statistics, Elementary Instruction, Franklin (for the foundation of popular libraries); 4. *Positive Sciences and Fine Arts*—Philomathic, Physical, Philotechnic, Athenæum of the Arts, Sciences, and Literature (1792), Concerts of the Conservatoire de Musique (1759).

Paris is largely supplied with newspapers, many of

which have a great circulation. Of these the chief are the *Republique Française* (founded by Gambetta and now conducted by M. Clemenceau), the *Moniteur*, official organ, the *Gazette de France*, *Le Monde*, *Le Constitutionnel*, *L'Univers*, *Le Soliel*, *Le Pays* (Bonapartist), *La Justice*, *Le Paix*, *Figaro*, and *Le Petit Journal*. There are also many illustrated papers.

The Jardin des Plantes (1626), about seventy-five acres in extent, forms one of the most interesting promenades in Paris; its museum of natural history (1793), with its zoölogical gardens, its hothouses and greenhouses, its nursery and naturalization gardens, its museums of zoölogy, anatomy, anthropology, botany, mineralogy, and geology, its laboratories, and its courses of lectures by the most distinguished professors in all branches of natural science, make it an institution of universally acknowledged eminence.

The richest museum in Paris occupies the Louvre, the finest of its palaces. On the ground floor are museums (1) of ancient sculpture, containing such treasures as the *Venus of Milo*, the *Pallas of Velletri* (the most beautiful of all statues of Minerva), the colossal group of the Tiber, discovered at Rome in the fourteenth century, etc.; (2) of mediæval and renaissance sculpture, comprising works by Michelangelo, Jean Goujon, Germain Pilon, John of Bologna, etc., and special rooms devoted to early Christian monuments and to Jewish antiquities (this last a feature peculiar to the Louvre); (3) of modern French sculpture, with works by Puget, Coustou, Coysevox, Chaudet, Houdon, Rude, David of Angers, etc.; (4) of Egyptian sculpture and inscriptions; (5) of Assyrian antiquities; (6) of Greek and Phœnician antiquities; (7) of engraving. On the first floor are (1) the Lacaze museum, a magnificent collection of pictures presented to the state by M. Lacaze in 1869; (2) the splendid musée de peinture; (3) the Campana museum; (4) a museum of Greek antiquities; (5) a museum of Egyptian antiquities; (6) an Oriental museum (Persian pottery, Chinese vases, lacquered work, etc.); (7) the Lenoir museum (snuff-boxes, jewels, miniatures, lacquered wares, bequeathed to the Louvre by M. and Madame Lenoir in 1874); (8) the Duchatel room, bequeathed by the widow of the minister of that name (*La Source*, a masterpiece by Ingres); (9) the Timbal, His de la Salle, and Davilliers collections, consisting respectively of furniture and curiosities, drawings, pottery, and tapestry; (10) a mediæval and renaissance museum, comprising French, Italian, or Hispano-Moorish pottery and terra-cotta ware, as well as objects in bronze, glass, and ivory—the Sauvageot collection being of note; (11) the museum of drawings and chalks, of which the more valuable are preserved in drawers; (12) a museum of ancient bronzes; (13) the Apollo gallery, adorned by the leading artists who have been employed on the palace, and containing the royal gems and jewels, articles of goldsmith's work, and enamels. The second floor accommodates the naval museum, the ethnographic museum (African, Chinese, Mexican), part of the French school of painting, and rooms for the study of Egyptian papyrus-rolls.

The museum of the Luxembourg, installed in a portion of the palace occupied by the senate, is devoted to works of living painters and sculptors acquired by the state. They remain there for ten years after the death of the respective artists, when the finest are selected for the Louvre.

The Cluny museum occupies the old mansion of the abbots of that order, built in the fifteenth century by Jacques d'Amboise. It was founded by M. du Sommerard, whose collections were acquired by the state in 1843. Increased from year to year since that date, it

now contains about 10,000 articles—pieces of sculpture in marble and stone, carvings in wood, ivories, enamels, terra-cottas, bronzes, furniture, pictures, stained glass, pottery, tapestry, glassware, locksmith-work, and jewelry of mediæval and Renaissance times. In the neighborhood are the remains of the ancient palace of the emperor Julian; in the midst of the ruins, and in the garden which surrounds them, has been collected a Gallo-Roman museum, to which have been added many fragments of mediæval sculpture or masonry, found in the city or its vicinity. The Carnavalet museum occupies the mansion in which Madame de Sévigné resided; it is a municipal museum, in which are brought together all objects of interest for the history of Paris. The artillery museum, in the Hôtel des Invalides, comprises ancient armor, military weapons, flags, and an ethnographic collection reproducing the principal types of Oceania, America, and the coasts of Africa and Asia. The permanent exhibition of the products of Algeria and the colonies is in the Palais de l'Industrie; and finally the Trocadéro palace contains a museum of comparative sculpture and ethnographic galleries for exhibiting curiosities brought home from distant countries by the principal French official travelers.

Paris is divided for municipal purposes into twenty arrondissements. Each arrondissement is divided into four quarters, each of which nominates a member of the municipal council. The functionaries of the arrondissement are—a mayor (*maire*) and three deputies (*adjoints*) nominated by the prefect of Seine, who act as registrars, and preside over the poor-relief (*bureau de bienfaisance*) of their arrondissement, and a justice of the peace (*judge de paix*) nominated by the government. There is no elective mayor of Paris; the president of the municipal council, who is nominated by his colleagues, merely acts as chairman of their meetings. When occasion requires, the function of mayor of Paris is discharged by the prefect of Seine. The municipal council discusses and votes the budget of the city. The prefect of Seine and the prefect of police (both magistrates named by the government, but each with a quite distinct sphere of action) represent the executive authority as opposed to the municipal council, which latter has no power by refusing a vote of credit to stop any public service the maintenance of which legally devolves on the city; in case of such refusal the minister of the interior may officially insert the credit in the budget; and in like manner he may appeal to the head of the state to cancel any decision by which the council has exceeded its legal functions. The prefecture of Seine comprises a departmental service, differing in no essential particular from that of other prefectures, and a municipal service for the city of much more importance. Elections, rates, municipal debt, city schools, public lands, municipal buildings, markets and market-places (in respect to the collection of dues), cemeteries, roads and streets, public edifices, water-works and sewers, promenades and plantations, river navigation and river ports, public pawnbroking establishments, and the relief of the poor, are all under the control of the prefecture of Seine.

The prefecture of police includes the whole department of Seine and the neighboring communes of the department of Seine-et-Oise—Meudon, St. Cloud, Sèvres, and Enghien. It consists of three sections—political police, police of public safety, and administrative police, the former two being rather national than municipal. The state consequently repays two-fifths of the annual budget of about \$4,000,000 which this prefecture receives from the city.

The municipal police deals with public health, civil

order, and repression of crimes and misdemeanors, whether against person, property, or morals. It exercises surveillance over lodging-houses, the insane, and prostitutes, tests weights and measures, and has charge of the markets, the public vehicles, the fire department, sanitary arrangements, and exhumations and reinterments in the cemeteries.

The prefect of police has a staff of about 9,000 officials—*commissaires de police*, *officiers de paix*, *gardiens de la paix* (a kind of police-magistrate), and inspectors. He has also under his orders the *sapeurs pompiers* or fire-brigade (1,742 men), and the republican guard, long called the municipal guard, which numbers 3,295 men, besides a mounted force of 726. He has full control over the budget of his department, which is voted *en bloc* by the municipal council.

The climate of Paris is fairly uniform, the mean temperature, calculated for seventy-five years, being 51° Fahr. The highest known registration was 101°, the lowest —14° Fahr. The Seine freezes in whole or in part about once in ten winters. Rain falls on the average on 143 days per annum, and snow on 12 days. The numerous railways radiating from Paris start from nine different stations. In addition to the great trunk lines to the north, to Lyons and the Mediterranean, to Orleans, to Strasburg and Germany, and to the west of France there is a central railroad connecting the suburbs and a new metropolitan junction line nearly completed. Intramural communication is afforded by cabs, omnibuses, tramways, steamboats, and a railway (the Chemin de Fer de Ceinture). The steamboats ply up the river to Charenton, down the river to Suresnes. Within the city they plied on 329 days, made an aggregate of 8,162 days of service, traversed 497,997 miles, and conveyed 11,170,980 passengers. The omnibus company employs both ordinary omnibuses and tramway cars. It has 610 omnibuses and 255 tram-cars, conveying 200,187,455 passengers. The two tramway companies, distinguished as Northern and Southern, have conveyed respectively 26,076,761 and 27,067,951 passengers. The Chemin de Fer de Ceinture, which runs around the city just within the fortifications, conveyed 21,617,909. Paris has about 15,000 cabs (*voitures* and *fiacres*). The omnibuses and street-cars stop only at the stations, about two blocks apart, where waiting-rooms are provided for intending passengers. Numbered tickets are issued at these stations, and passengers take their turns. Overcrowding is impossible, and every person gets a seat. The fare is 6 cents inside and 3 cents outside for any distance within the fortifications, and by the system of *correspondances* or transfers one can ride practically all over Paris for one fare.

Paris derives its water-supply (1) from the Seine and the Marne, (2) from the Ourcq Canal, (3) from artesian wells, and (4) from springs. (1) The two steam-pumps at Chaillot on the Seine raise each at their ordinary rate 635,688 cubic feet and at their maximum 1,518,588 in the twenty-four hours. The ten pumps at Port à l'Anglais and Maisons-Alfort above Paris, at St. Ouen below Paris, and at the Quai d'Austerlitz and Auteuil (within the city), can supply about 600,372,000 cubic feet per annum. In 1880 about 2,119,000 cubic feet on an average were taken daily from the Seine. The water is stored in reservoirs at the highest points in Passy, Montmartre, Charonne, and Gentilly. The establishment at St. Maur, situated on the canal which closes the loop of the Marne, and partly moved by the head of water and partly by steam, supplies the Bois de Vincennes and the elevated districts of Belleville and Ménilmontant. It can furnish 2,896,000 cubic feet in the twenty-four hours. (2) The Ourcq Canal, which is also used as a waterway, comes from the department

of Aisne, and terminates at the La Villette basin, which also receives the St. Denis and St. Martin Canals. It brings a volume of 4,414,500 cubic feet per day, to which are added in summer from 2,000,000 to 2,500,000 cubic feet procured from the Marne near the confluence of the Ourcq, and discharged into the canal. The water is hardly suitable for domestic use, owing to the quantity of foreign matter which it contains. (3) The water of the artesian wells is much purer. The Grenelle well is 1,797 feet deep, and reaches the greensand; its daily yield is 12,360 cubic feet of water at a temperature of 80° Fahr., which rises to a height of 238 or 239 feet, and can thus be carried to the summit of Mont St. Geneviève. The Passy well is 1,922 feet deep, and yields an average of 233,000 cubic feet in the twenty-four hours. The total daily water-supply is over 20,000,000 cubic feet. There is an abundant supply of public fountains, public baths, and wash-houses. Peculiar features of Paris are the floating baths and wash-houses in the Seine.

The drainage system has been greatly extended of late years. The drainage of both sides of the river is collected in a great sewer ending in the Seine at Clichy, opposite Asnières; the main sewer of the left side of the river is connected with that of the right side by a siphon which passes under the Seine by a tunnel near the Pont de l'Alma. A departmental sewer, receiving the waters of the elevated districts of Charonne, Ménilmontant, Belleville, and Montmartre, terminates at St. Denis. These sewers are much more than great drains: they are used as passages for water-pipes, gas-pipes, telegraph-wires, and pneumatic tubes. The two largest classes of them have a height respectively of fourteen and a half feet and seventeen feet six inches at the key-stone, and a width respectively of eighteen feet five inches and seventeen feet at the spring of the arch. The smallest class is only six feet high and three feet wide. The most usual class, of which there are 171 miles, has a height of seven and a half feet, and a width of four and a half feet.

The sewage from these mains is partly employed in irrigation in the plain of Gennevilliers, on the left bank of the Seine, opposite St. Denis and Clichy. At the close of 1881 1,216 acres were under treatment, though the system was only commenced in 1872 on a tenth of that area; and the drains employed, varying from one to four feet in diameter, had an extent of twenty-one miles, and discharged the sewage by 571 outlets. The quantity of sewage discharged daily by the sewers varies from 10,171,000 cubic feet to 13,112,266 cubic feet.

The cemeteries of Paris are widely-known. Chief of these is Pere-la-Chaise, situated on a hill at the north-east end of the city, one and one-half miles from the Place de la République. It was laid out as a cemetery in 1804. In 1814 it was the scene of an engagement between French and Russian troops, and in May, 1871, the Communists made their last stand here against the government troops. The sarcophagus of Abelard and Heloise, reconstructed from an old monument, is one of the features of Pere-la-Chaise. Space would fail to tell of the monuments to the distinguished dead to be found here. Among them are those of "the lost La Bédouère;" Casimir Perier; Raspail and Blanqui, revolutionists; Adolphe Thiers, Bellini and Cherubini, the composers; Marshal Kellermann; the Abbé Sieyès; Marshal Macdonald; Talma, the tragedian; Admiral Sir Sidney Smith; Marshal Masséna; Beaumarchais; Béranger; Cambacérès; Geoffroy Saint-Hilaire; Lafontaine; Laplace; Gay-Lussac; Balzac; the Duc de Morny, Delacroix, the painter; Charles and Louis Blanc, Rossini, Alfred de Musset, Ledru Rollin,

Auber, Arago, Mlle. Rachel, and hundreds of others. The other cemeteries of Paris are Montmartre, Montparnasse, St. Ouen (2), and Ivry (2). The Catacombs in the ancient quarries under the southern part of the city contain the remains of hundreds of thousands.

The courts are housed in the Palais de Justice on the Island of the City. It occupies the site of the ancient palace of the kings of France, but very little of the original remains. The Palais was almost completely restored between 1859 and 1870, but a greater part of it was burned under the Commune.

Paris is the seat of four courts having jurisdiction over all France: (1) the Tribunal des Conflits, for settling disputes between the judicial and administrative authorities on questions as to their respective jurisdiction; (2) the Council of State, for litigations between private persons and public departments; (3) the Cour des Comptes; and (4) the Cour de Cassation. The first three sit in the Palais Royal, the fourth in the Palais de Justice, which is also the seat of (1) a cour d'appel for seven departments (five civil chambers, one chamber of appeal for the correctional police, one chamber for preliminary proceedings), (2) a cour d'assises (members nominated for a term of three months; two sessions per month), (3) a tribunal of first instance for the department of Seine (seven civil chambers for civil affairs, sequestration of real estate, and sale of personal property; four chambers of correctional police), (4) a police court where each *juge de paix* presides in his turn assisted by a *commissaire de police*. Litigations between the departmental or municipal administrations and private persons are decided by the *conseil de préfecture*.

The prefect of police, charged with the maintenance of public safety, has the prison department under his supervision. There are eight prisons in Paris—Mazas, La Santé, Ste. Pélagie, St. Lazare (for females), the dépôt (police station) of the prefecture of police, the Conciergerie or lock-up at the Palais de Justice, the Grande Roquette (for condemned criminals), and the Petite Roquette reformatory. The Tribunal de Commerce, opposite the Palais de Justice, is a magnificent structure.

The most recent vital statistics obtainable show that the number of females in Paris exceeds the males by about 13,000. The twenty arrondissements, with an area of 19,177 acres, contained a population of 2,239,928, dwelling in 77,014 houses; giving 117 persons to the acre. The births numbered in one year 59,874, and the deaths 57,066.

The lighting of Paris is practically in the hands of the gas company, electric lighting being still in the experimental stage, and oil being used only in a small and ever-diminishing number of out-of-the-way streets. The daily consumption reaches a maximum (36,005,949 cubic feet) in December and a minimum (14,073,112 cubic feet) in July.

The manufacturing industries of Paris are many and varied. The larger manufacturing establishments comprise engineering and repairing works connected with the railways, similar private works, foundries, and sugar refineries. Government works are the tobacco factories of Gros Caillou (2,000 workmen) and Reuilly (1,000), the national printing establishment (1,000), the mint (where money and medals are coined by a contractor under state control), and the famous tapestry factory and dyeworks of the Gobelins. The list of minor establishments is a very varied one; most of them devoted to the production of the so-called *articles de Paris*, and carrying the principle of the division of labor to an extreme. The establishments which rank next to those above mentioned in the number of workmen are the chemical factories, the gasworks, the printing-offices,

cabinet-makers' workshops, boot factories, tailoring establishments, hat factories, and works for the production of paper-hangings.

Official returns state the number of workpeople at over 600,000, whose annual wages equal \$200,000,000. The largest financial institution in Paris, and in fact in the world, is the Bank of France, which has the exclusive privilege of issuing bank notes. It has ninety branches in the provinces. Other important financial establishments are the Caisse des Dépôts et des Consignations, the Crédit Foncier, and the Comptoir National d'Escompte. The postoffice controls the telegraph and money-order business, and pneumatic tubes are used for the dispatch of messages. The telephonic system is being rapidly extended.

The administration of public charity is in the hands of the government, and the hospitals are supported by subsidies and certain taxes, as those on theaters and the Mont de Piété, the government pawnshop. The Hôtel-Dieu, rebuilt in La Cité recently at a cost of \$9,000,000, has a world-wide reputation. La Salpêtrière, the oldest of all, occupies seventy-four acres. More than 100,000 patients are relieved every year at the fifty-eight houses of relief. The Bicêtre contains 700 male, and the Salpêtrière 720 female insane patients. Foundlings and orphans are supported at the Hospice des Enfants Assistés.

Paris is the seat of a military government, whose commandant has under him all the troops stationed in the departments of Seine and Seine-et-Oise. The soldiers recruited in the two departments are distributed among the second, third, fourth, and fifth *corps d'armée*, whose headquarters are at Amiens, Rouen, Le Mans, and Orleans. The principal barracks belonging to the state in Paris are those of the military school of Prince Eugene and Napoleon; the town possesses the barracks of the republican guard, the gendarmes, and the firemen in different quarters. The most important are those of La Cité, to which the prefecture of police was transferred after the destruction of its former buildings by fire in 1871. Besides the war office and the hospitals named above the main establishments comprise the dépôt of the fortifications, the central artillery dépôt with the workshops of St. Thomas d'Aquin, and the dépôt of the commissariat department.

#### HISTORY.

An island in the Seine, now almost lost in the modern city, and then much smaller than at present, was for centuries the entire site of Paris. The sole importance of the town lay in its being the capital of a similarly insignificant Gallic people, who navigated the lower course of the Seine, and doubtless from time to time visited the coasts of Britain. So few were its inhabitants that they early put themselves under the protection of their powerful neighbors the Senones, and this vassalship was the source of the political dependence of Paris on Sens throughout the Roman period, and of a religious subordination which lasted till the seventeenth century. The capital did not at once take the name of the Parisii, whose center it was, but long kept that of Lucetia, Lucotetia, or Lutetia, of which Lutèce is the generally recognized French form.

Lutetia was somewhat neglected under the Roman emperors of the first centuries. Its inhabitants continued quietly carrying on their river traffic, and devoted part of their wealth to the maintenance of a great temple to Jupiter built on the site of the present cathedral of Notre Dame. It is not known at what date Christianity was introduced into the future capital of France; but it is probable, judging by the use of the title "city," that Lutetia was the see of one of the earliest of the bishoprics of Gallia Celtica.

Lutetia was in some sort the cradle of Christian liberty, having been the capital, from 292 to 306, of the mild Constantius Chlorus, who put an end to persecution in Brittany, Gaul, and Spain, over which he ruled. This emperor fixed his residence on the banks of the Seine. There was the imperial palace, the remains of which, a magnificent vaulted chamber, beside the Hôtel de Cluny, are now known, probably correctly, as Julian's Baths. At some distance up the river, in the quarter of St. Victor, excavations in 1870 and in 1883 laid bare the foundations of the amphitheater, which was capable of holding about 10,000 spectators, and this suggests the existence of a population of 20,000 to 25,000 souls.

Numerous calamities befell Paris from 586, when a terrible conflagration took place, to the close of the Merovingian dynasty. The kings in the long run almost abandoned the town, especially when the Austrasian influence under the mayors of the palace tended to shift the center of the Frankish power toward the Rhine.

Though the Merovingian period was for art a time of the deepest decadence, Paris was nevertheless adorned and enriched by pious foundations.

The first Carolingian, Pippin the Short, occasionally lived at Paris, sometimes in the palace of Julian, sometimes in the old palace of the Roman governors of the town, at the lower end of the island; the latter ultimately became the usual residence. Under Charlemagne Paris ceased to be the capital; and when feudal France was constituted under Charles the Bald it was liberally bestowed, like any ordinary place, on mere counts or dukes.

With Hugh Capet, in 987, the capital of the duchy of France definitely became the capital of the kingdom, and in spite of the frequent absence of the kings, several of whom preferred to reside at Orleans, the town continued to increase in size and population, and saw the development of those institutions which were destined to secure its greatness.

Philip Augustus may be considered the second founder of Paris, and he there built for himself, near St. Germain l'Auxerrois, the Louvre, the royal dwelling *par excellence*, whose keep was the official center of feudalism. He created or organized a regular system of administration with its headquarters at Paris; and under his patronage the public lectures delivered at Pré-aux-Clercs were regulated and grouped under the title of a university in 1200.

This university, the most famous and flourishing in Christendom, considerably augmented the local population, and formed, as it were, a new town on the left side of the river, where the important abbeys of St. Geneviève, St. Germain-des-Prés, and St. Victor, and a vast Carthusian monastery already stood. Colleges were erected to receive the students of the different countries, and became the great meeting-place of the studious youth of all Europe. Under St. Louis, Robert de Sorbon, a common priest, founded, in 1253, an unpretending theological college which afterward became the celebrated faculty of the Sorbonne, whose decisions were well-nigh as authoritative as those of Rome.

Philip the Fair increased the political importance of the capital by making it the seat of the highest court in the kingdom, the *parlement*, which he organized between 1302 and 1304, and to which he surrendered a part of his Cité palace. In 1420 a treaty, from the ignominy of which Paris happily escaped, gave a daughter of Charles VI. to Henry V. of England, and along with her, in spite of the Salic law, the crown of France. The king of England made his entry into Paris in December, 1420. Charles VI. remained almost

abandoned at the Hôtel St. Paul, where he died in 1422, while his son-in-law went to hold a brilliant court at the Louvre and Vincennes. Henry V. of England also died in 1422. His son Henry VI., then one year old, came to Paris nine years later to be crowned at Notre Dame, and the city continued under the government of the duke of Bedford till his death, in 1435.

Without assuming the mission of delivering Paris, Joan of Arc, remaining with Charles VII. after his coronation at Rheims, led him toward the capital; but the badly conducted and abortive enterprise almost proved fatal to the Maid of Orleans, who was severely wounded at the assault of the gate of St. Honoré on September 8, 1429. The siege having been raised, Charles awaited the invitation of the Parisians themselves upon the defection of the Burgundians and the surrender of St. Denis. The St. Jacques gate was opened by the citizens of the guard to the constable Arthur of Richemont on April 13, 1436.

Previous to 1533, the date of the commencement of the Hôtel de Ville and the church of St. Eustache, Paris did not possess, apart from the "Court of Accounts," any important building in the new style. Between 1527 and 1540 Francis I. demolished the old Louvre, and in 1541 Pierre Lescot began a new palace four times as large, which was not finished till the reign of Louis XIV.

When, after the murder of the duke of Guise at Blois at the close of 1588, Henry III. desired to return to Paris, he was not yet master of the city, and was obliged to besiege it in concert with his presumptive heir, the king of Navarre. The operations were suddenly interrupted on August 1, 1589, by the assassination of the king, and Henry IV. carried his arms elsewhere. He returned with his victorious forces in 1590. This second siege lasted more than four years.

Henry IV., who carried on the building of the Louvre, was the last monarch who occupied it as a regular residence. Attempts on his life were made from time to time, and at last on May 14, 1610, he fell under Ravallac's knife near the market-house in Rue de la Ferronnerie. Whether royalty gave it the benefit of its presence or not, Paris continued all the same to increase in political importance and in population. If the city on the left side of the river neither extended its circuit nor increased its population, it began in the sixteenth century to be filled with large mansions (hôtels), and its communications with the right bank were rendered easier and more direct when Henry IV. constructed across the lower end of the island of La Cité the Pont Neuf, which is now the oldest bridge in Paris. Mary de Medici built the palace of the Luxembourg, which, after being extended under Louis Philippe, became the seat of the senate.

Louis XIII. finished, with the exception of the eastern front, the buildings inclosing the square court of the Louvre, and carried on the wing which was to join the palace to the Tuileries. Richelieu built for himself the Palais Royal, since restored, and rebuilt the Sorbonne, where now stands his magnificent tomb by Girardon. The island of St. Louis above La Cité, till then occupied by gardens and meadows, became a populous parish, whose streets were laid out in straight lines, and whose finest houses still date from the seventeenth century. Though Louis XIV. ceased to stay in Paris after he grew up, he did not neglect the work of embellishment. On the site of the fortifications of Étienne Marcel, which during the previous hundred years had been gradually disappearing, he laid out the line of boulevards connecting the quarter of the Bastille with that of the Madeleine. Though he no longer inhabited the Louvre (and it never was again the seat

of royalty), he caused the great colonnade to be constructed after the plans of Claude Perrault. The Place Vendôme, the Place des Victoires, the triumphal gates of St. Denis and St. Martin, and several fountains, are also productions of the reign of Louis XIV. The hospital of La Salpêtrière, with its majestically simple dome, was finished by Libéral Bruant. The Hôtel des Invalides, one of the finest institutions of the Grand Monarque, was also erected, with its chapel, between 1671 and 1675, by Bruant; but it was reserved for the architect Hardouin Mansart to give to this imposing edifice a complement worthy of itself; it was he who raised the dome, which rises 344 feet above the ground.

In 1789 Paris doubled its extent by the accession of the great monasteries, the faubourgs of St. Germain and St. Marceau, the Jardin des Plantes, and the whole of Mont Ste. Geneviève. The line of the new enceinte is still marked by a circuit of boulevards passing from the Champs de Mars at Pont d'Austerlitz by Place de l'Enfer and Place d'Italie. Similar enlargements, also marked out by a series of boulevards, incorporated with the town on the right side the faubourgs of St. Antoine and Poissonnière and the quarters of La Chaussée d'Antin and Chaillot. During the consulate hardly anything of note took place at Paris except the explosion of the infernal machine directed against Bonaparte on December 24, 1800. The coronation of Napoleon by Pope Pius VII. was celebrated in Notre Dame on December 2, 1804. After the return of the Bourbons, Paris had to submit to a treaty more humiliating than the capitulation. Already in 1763 Louis XV. had signed in his capital the treaty with England known as the shameful (*Honteuse*), by which he surrendered a great part of the American and Indian colonies, and notably Canada. That of May 30, 1814, was more truly disastrous, since it dismembered the mother-country, canceled almost all the conquests of the republic and the empire, and lessened the military strength of France by robbing it of half its fleet. And worse even than this was the treaty of November 28, 1815, which not only suppressed the slight accession of territory recognized by the treaty of 1814, and doomed to demolition the fortifications of Huningue, but exacted a war indemnity of 700,000,000 francs (\$140,000,000), and demanded the maintenance in seven departments of 150,000 soldiers of the allied army until the payment of the entire sum.

Under Louis XVIII. the only event of note that occurred in Paris was the assassination of the duke of Berri by Louvel, February 13, 1820. Ten years later the revolution of 1830, splendidly commemorated by the Column of July in Place de la Bastille, put Charles X. to flight and inaugurated the reign of Louis Philippe, a troublous period which was closed by the revolution of 1848 and a new republic. It was this reign, however, that surrounded Paris with bastioned fortifications, with ditches and detached forts. The republic of 1848 brought no greater quiet to the city than did the reign of Louis Philippe. The most terrible insurrection was that of June 23 to 26, 1848, distinguished by the devotion and heroic death of the Archbishop Affre. It was quelled by General Cavaignac, who then for some months held the executive power. Prince Louis Napoleon next became president of the republic, and after dissolving the chamber of deputies on December 2, 1851, caused himself to be proclaimed emperor just a year later. The second empire completed that material transformation of Paris which had already begun at the fall of the ancient monarchy. It was under the first empire that the new series of improvements were inaugurated which have made Paris a modern city. Napoleon I. began the Rue de Rivoli,

built along this street the wing intended to connect the Tuileries with the Louvre, and erected in front of the court of the Tuileries the triumphal arch of the Carrousel, in imitation of that of Septimius Severus at Rome. In the middle of the Place Vendôme was reared, on the model of Trajan's column, the column of the grand army, surmounted by the statue of the emperor. To immortalize this same grand army he ordered from the architect Pierre Vignon a Temple of Victory, which, without changing the form of its Corinthian peristyle, has become the church of the Madeleine; the entrance to the avenue of the Champs Élysées was spanned by the vast triumphal arch De l'Étoile (of the star), which owes its celebrity not only to its colossal dimensions and its magnificent situation, but also to one of the four subjects sculptured upon its faces—the *Chant du Départ* or *Marseillaise*, one of the masterpieces of modern sculpture. Another masterpiece was executed by David of Angers, the pediment of the Panthéon, not less famous than Soufflot's dome. The museum of the Louvre, founded by decree of the Convention on July 27, 1793, was organized and considerably enlarged; that of the Luxembourg was created in 1805, but was not appropriated exclusively to modern artists till under the Restoration. The Conservatoire des Arts et Métiers, due to the Convention, received also considerable additions in the old priory or abbey of St. Martin des Champs, where the Council of Five Hundred had installed it in 1798.

Under the Restoration and under the government of July many new buildings were erected; but, with the exception of the Bourse, constructed by the architects Brongniart and Labarre, and the colonnade of the chamber of deputies, these are of interest not so much for their size as for the new artistic tendencies affected in their architecture.

Under Louis Philippe the Place de la Concorde was altered in various ways, and adorned with eight statues of towns and with two fountains; on October 25, 1836, the Egyptian obelisk, brought at great expense from Luxor, was erected in the center. The general restoration of the cathedral of Notre Dame was voted by the Chamber in 1845, and intrusted to Viollet-le-Duc; and the palace of the Luxembourg and the Hôtel de Ville were considerably enlarged at the same time, in the style of the existing edifices.

But the great transformer of Paris in modern times was Napoleon III. To him or to his reign we owe the Grand Opéra, the finest theater in the world; the new Hôtel-Dieu; the finishing of the galleries which complete the Louvre and connect it with the Tuileries; the extension of the Palais de Justice and its new front on the old Place Dauphine; the tribunal of commerce; the central markets; several of the finest railway stations; the viaduct at Auteuil; the churches of La Trinité, St. Augustin, St. Ambroise, St. François Xavier, Belleville, Ménilmontant, etc. For the first international Paris exhibition (that of 1855) was constructed the "palace of industry;" the enlargement of the national library was commenced; the museum of French antiquities was created by the savant Du Sommerard, and installed in the old "hôtel" built at the end of the fifteenth century for the abbots of Cluny.

All this is but the smallest part of the memorials which Napoleon III. left of his presence. Not only was the city traversed in all directions by new thoroughfares, and sumptuous houses raised or restored in every quarter, but the line of the fortifications was made, in 1859, the limit of the city. The area was thus doubled, extending to 7,450 hectares or 18,410 acres, instead of 3,402 hectares or 8,407 acres. It was otherwise with the population; to the 1,200,000 inhabitants which Paris

possessed in 1858 the incorporation of the suburban zone only added 600,000.

Paris had to pay dearly for its growth and prosperity under the second empire. This government, which, by straightening and widening the streets, thought it had effectually guarded against the attempts of its internal enemies, had not sufficiently defended itself from external attack, and at the first reverses of 1870 Paris found itself prepared to overthrow the empire, but by no means able to hold out against the approaching Prussians. The two sieges of Paris in 1870-71 are among the most dramatic episodes of its history. The first siege began on September 19, 1870, with the occupation by the Germans of the heights on the left side of the river and the capture of the unfinished redoubt of Châtillon. Two days later the investment was complete. General Trochu, head of the French Government and governor of the city, had under his command 400,000 men. The guards displayed a certain warlike spirit, but it was for the sole purpose of exciting disorder. Open revolt broke out on October 31st; it was suppressed, but increased the demoralization of the besieged and the demands of the Prussians. The partial successes which the French obtained in engagements on both sides of the river were rendered useless by the Germans recapturing all the best positions. In obedience to public opinion a great sortie was undertaken; this, in fact, was the only alternative to a surrender; for, the empire having organized everything in expectation of victory and not of disaster, Paris, insufficiently provisioned for the increase of population caused by the influx of refugees, was already suffering the horrors of famine. The bombardment began on December 27th, and great damage was done to the forts on the left of the Seine, especially those of Vanves and Issy, directly commanded by the Châtillon battery. A third and last sortie (which proved fatal to Regnault the painter) was attempted in January, 1871, but resulted in hopeless retreat. An armistice was signed on January 27th, the capitulation on the 28th. The revictualing of the city was not accomplished without much difficulty, in spite of the generous rivalry of foreign nations.

On March 1st the Germans entered Paris. This event, which marked the close of the siege, was at the same time the first preparation for the "commune;" for the national guard, taking advantage of the general confusion and the powerlessness of the regular army, carried a number of cannon to the heights of Montmartre and Belleville under pretext of saving them. President Thiers, appreciating the danger, attempted on March 18th to remove the ordnance; his action was the signal for an insurrection which, successful from the first, initiated a series of terrible outrages by the murder of the two generals, Lecomte and Thomas. The government, afraid of the defection of the troops, who were demoralized by failure and suffering, had evacuated the forts on the left side of the river and concentrated the army at Versailles (the forts on the right side were still to be held for some time by the Germans). Mont Valérien remained in the hands of the government, and became the pivot of the attack during the second siege. All the sorties made by the insurgents in the direction of Versailles (where the National Assembly was in session from March 20th) proved unsuccessful, and cost them two of their improvised leaders—Generals Flourens and Duval. The incapacity and mutual hatred of their chiefs rendered all organization and durable resistance impossible. On Sunday, May 21st, the government forces, commanded by Marshal MacMahon, having already captured the forts on the right side of the river, made their way within the walls; but they had still to fight hard from barricade to barri-

cade before they were masters of the city; Belleville, the special Red Republican quarter, was not assaulted and taken till Friday. Meanwhile the communists were committing the most horrible excesses; the archbishop of Paris (GEORGES DARBOY, *q.v.*), President Bonjean, priests, magistrates, journalists, and private individuals, whom they had seized as hostages, were shot in batches in the prisons; and a scheme of destruction was carried into effect by men and women with cases of petroleum (*pétroleurs* and *pétroleuses*). The Hôtel de Ville, the Palais de Justice, the Tuileries, the Ministry of Finance, the palace of the Legion of Honour, that of the Council of State, part of the Rue de Rivoli, etc., were ravaged by the flames; barrels of gunpowder were placed in Notre Dame and the Panthéon, ready to blow up the buildings; and the whole city would have been involved in ruin if the national troops had not gained a last and crowning victory in the neighborhood of La Roquette and Père-la-Chaise on May 28th. Besides the large number of insurgents who, taken in arms, were pitilessly shot, others were afterward condemned to death, to penal servitude, to transportation; and the survivors only obtained their liberty by the decree of 1879.

From this double trial Paris emerged diminished and almost robbed of its dignity as the capital; for the parliamentary assemblies and the government went to sit at Versailles. For a time it was thought that the city would not recover from the blow which had fallen on it. All came back, however—confidence, prosperity, and, along with that, increasing growth of population and the execution of great public works. The Hôtel de Ville has been rebuilt, the school of medicine adorned with an imposing façade, a vast school of pharmacy established in the old gardens of the Luxembourg, and boulevards completed. The exhibition of 1878 was more marvelous than those of 1855 and 1867, and unlike that of the latter year has left a lasting memorial—the palace of the Trocadéro. Still more wonderful and far-reaching in its results was the Paris exhibition of 1889, which attracted visitors from all parts of the world, and it, too, has left behind it a memorial of mechanical skill in the Eiffel tower.

PARIS, the son of Priam, king of Troy. Before he was born his mother Hecuba dreamed that she was delivered of a firebrand. The dream was interpreted that her child would ruin his country, and when Paris was born he was exposed on Mount Ida. His life was saved by the herdsmen, and he grew up among them, distinguished for beauty and strength, till he was recognized and received by his parents. When the strife arose at the marriage of Peleus and Thetis between Hera, Athena, and Aphrodite, each claiming the apple that should belong to the most beautiful, Paris was selected as the judge. The three rivals unveiled their divine charms before a mortal judge on Mount Ida. The scene afterward became a favorite subject in Greek art, and it is usual to represent Hermes escorting the goddesses. Each tried to bribe the judge, Hera by promising power, Athena wisdom, Aphrodite the most beautiful woman in the world. Paris decided in favor of Aphrodite, and thus made Hera and Athena the bitter enemies of his country. To gain the woman whom Aphrodite had promised, Paris set sail for Lacedæmon, deserting his old love CEnone, daughter of the river-god Cebren, who in vain tried to induce him to give up his purpose. He was hospitably received by Menelaus, whose kindness he repaid by seducing his wife Helena to flee with him to Troy.

PARIS, the capital of Bourbon county, Ky., is situated nineteen miles northeast of Lexington, at the junction of several railroads. It contains a court-house,

several colleges for females, a military institute, three newspaper offices, and banks, and is lighted by gas. Its manufactures include flour, hemp, and whisky, and its population is 6,200.

PARIS, a post-town, capital of Edgar county, Ill., in Paris township, on several railroads, nineteen miles west-northwest of Terre Haute, thirty-six miles south of Danville, and 170 miles east-northeast of St. Louis, Mo. It contains a court-house, seven churches, a normal academy, two national banks, and three newspaper offices. Population, 5,049.

PARIS, an active town, capital of Lamar county, Tex., is on the Texas and Pacific railroad (Transcontinental Division), sixty-four miles east of Sherman. It has a female seminary, a high school, two newspaper offices, and manufactories of brooms, furniture, plows, wagons, sash, blinds, etc. The population at the last census was 8,258.

PARIS, MATTHEW OF. See MATTHEW OF PARIS, *ante*.

PARISH. In England the parish may be regarded as essentially an ecclesiastical institution, being defined as the township or cluster of townships which was assigned to the ministrations of a single priest, to whom its tithes and other ecclesiastical dues were paid; and it has been decided that if a place has not a church, churchwardens and sacramentalia, it is not a parish in this original sense of the term.

The term "parish" is not in use as a territorial designation in the United States except in Louisiana, the fifty-eight parishes of which correspond to the counties of the other States of the Union.

PARK, MUNGO, a celebrated African traveler, was born in Selkirkshire, Scotland, on September 20, 1771, at Fowlshiels, on the Yarrow. Having received a good education, he was apprenticed to a surgeon named Anderson, in Selkirk, and then attended the university of Edinburgh for three sessions. He afterward obtained the post of assistant-surgeon on board the *Worcester* East Indiaman, and made the voyage, in 1792, to Bencoolen, in Sumatra, and on his return, in 1793, he contributed a description of eight new Sumatran fishes to the *Transactions* of the Linnæan Society. Park next offered his services to the African Association, and was successful in his application. On June 21, 1795, he reached the Gambia, but it was not till December 2d that he started for Pisania with only two negro servants into the interior, from which he was to return with the proud distinction of being the first of modern Europeans to reach the well-nigh fabulous waters of the Niger. He reached England December 22, 1796.

Again, on January 30, 1805, he sailed from Portsmouth for Africa, and the expedition started from Pisania on May 4th. On November 19th he sailed down the river from Sansanding with the "fixed resolution to discover the termination of the Niger or perish in the attempt." They managed to make their way to Bussa (Boussa), and they were there attacked by the natives, and were drowned in endeavoring to escape.

PARKER, JOHN HENRY, architectural archæologist, was born in London in 1806. He died January 31, 1884.

PARKER, MATTHEW, archbishop of Canterbury, was born at Norwich, August 6, 1504. He was educated partly in St. Mary's Hostel and partly in Corpus Christi College.

On Cranmer's election to the archbishopric of Canterbury, Parker received a license to preach, and soon became known in Cambridge and neighborhood as a divine of considerable oratorical power. He was summoned to preach at court; and in 1535 the queen, Anne Boleyn, appointed him her chaplain. He was

shortly afterward made dean of the college of St. John the Baptist, at Stoke, near Clare, Suffolk.

He was selected by Thomas Cromwell to preach at Paul's Cross, on account of "his learning in holy letters and uncorrupt judgment in the same." He was appointed one of the king's chaplains, and in the year 1541 was made a canon of Ely.

In December, 1558, he was summoned by royal command to London, where it was intimated to him that he was to be appointed to the primacy. His election to the office took place on the first of the following August, and his consecration on December 17th, in the chapel of Lambeth Palace.

During the fifteenth year of his primacy, Parker's best energies were devoted to defining more accurately the discipline and belief of the newly constituted Church of England, and to bringing about a general conformity. The Thirty-Nine Articles were passed by convocation, under his presidency, in 1562. In the year 1566 he issued his celebrated "Advertisements," "for the due order in the public administration of common prayers and using the holy sacraments, and for the apparel of all persons ecclesiastical." He died on May 17, 1575.

PARKER, THEODORE, a distinguished American rationalistic preacher and social reformer, born at Lexington, Mass., August 24, 1810. His father, John Parker, a small farmer and skillful mechanic, was a typical New England yeoman, and a Unitarian in his theology before Unitarianism was known in New England as a system, and a Federalist in his politics when there were but four Federalists in Lexington. Theodore's paternal grandfather, Captain John Parker, fired the first shot upon the British at the battle of Lexington, commanding on that occasion a troop of seventy men. The historic musket from which that shot was fired became one of the most valued ornaments of the grandson's study. He obtained the elements of knowledge in the schools of the district, which were open during the winter months only. During the rest of the year he worked on his father's farm. At the age of seventeen he became himself a winter schoolmaster, and in his twentieth year he entered himself at Harvard, working on the farm as usual while he followed his studies, and going over to Cambridge for examination only. At the close of his college career he began his translation of De Wette's *Introduction to the Old Testament*. His journal and letters show that he had made acquaintance with a large number of languages, including Hebrew, Chaldee, Syriac, Arabic, Coptic, Ethiopic, as well as the classical and the principal modern European languages. When he entered the divinity school he was an orthodox Unitarian; when he left it, he entertained strong doubts about the infallibility of the Bible, the possibility of miracles, and the exclusive claims of Christianity and the church. Emerson's transcendentalism greatly influenced him, and Strauss' *Leben Jesu* left its mark upon his thought. His first ministerial charge was over a small village parish, Roxbury, a few miles from Boston. He was ordained June, 1837, and held his pastorate there until the autumn of 1843.

In 1841 he preached at Boston a sermon on "the transient and permanent in Christianity," which presented in embryo the main principles and ideas of his final theological position, and the preaching of which determined his subsequent relations to the churches with which he was connected and to the whole ecclesiastical world. The only permanent element he discovered in the Bible, in Christianity, in Christ, was "absolute, pure morality, absolute, pure religion, the love of man, the love of God acting without let or hindrance." He denied all special authority to the Bible,

to Christ, to Christianity. He maintained that "Jesus had not exhausted the fullness of God." The Boston Unitarian clergy denounced the preacher, and declared that the "young man must be silenced." No Unitarian publisher could be found for his sermon, and nearly all the pulpits of the city were closed against him. To exchange with him was fatal to a minister's reputation for Unitarian orthodoxy. But when the Unitarian clergy cast Parker off the laity took him up. A number of gentlemen in Boston invited him to give a series of lectures there. The result was that he delivered, in the Masonic Hall, in the winter of 1841-42, as lectures, substantially the volume afterward published as the *Discourse of Matters Pertaining to Religion*. The lectures in their published form made his name famous throughout America and Europe, and confirmed the stricter sect of the American Unitarians in their attitude toward him and his supporters. In 1844 he resigned his charge at Roxbury and devoted himself exclusively to his work in Boston. In addition to his Sunday labors, he lectured throughout the States, and prosecuted his wide studies, collecting particularly the materials for an *opus magnum* on the development of religion in mankind. Above all, he took up the question of the emancipation of the slaves, and, at the imminent risk of his life, nobly and powerfully advocated in Boston and throughout the States, from the platform and through the press, the cause of the negroes. He assisted actively in the escape of fugitive slaves, and helped to furnish John Brown with means for carrying out his schemes of liberation. His Sunday sermons were themselves often elaborate essays, almost treatises, on great questions of social and political reform, and he was all along contributing articles and papers on literary, political, social, and theological subjects to the periodical press. By his voice, his pen, and his utterly fearless action in social and political matters, he became a great power in Boston and America generally. In January, 1859, he had an attack of bleeding of the lungs, and sought relief by retreating first to Santa Cruz, and afterward to Europe. He died at Rome, May 10, 1860.

PARKERSBURG, a city, next to Wheeling the largest city in West Virginia, is the capital of Wood County, is beautifully situated on the left bank of the Ohio river, at the mouth of the Little Kanawha river, about 95 miles below Wheeling, and 12 miles below Marietta. By railroad it is 384 miles west of Baltimore, and 195 miles east-by-north of Cincinnati. It is a western terminus of the Baltimore and Ohio Railroad, which here connects with the Marietta and Cincinnati Railroad. The railroad train here crosses a fine railway bridge which was erected in 1869-71, and cost more than \$1,000,000. It is one and one-third miles long, has six spans over the river and numerous approaching spans. Steamers ply both on the Ohio and the Little Kanawha, which is rendered navigable for thirty-eight miles. Parkersburg contains a courthouse, twelve churches, several high schools, three national banks, gasworks, a fine new building erected by the United States for a postoffice and courthouse, five oil refineries, two large lumber-mills, three iron-foundries, five machine-shops, chemical works, two boiler-shops, and two barrel factories. Three weekly newspapers and two monthly papers are published here. The city has an extensive trade in oil (petroleum), which is procured in this and adjoining counties. Population, 9,750.

PARLIAMENT. The British Parliament is the supreme legislature of the United Kingdom of Great Britain and Ireland, consisting of the King, or Queen, and the three estates of the realm, viz., the Lords Spiritual, the Lords Temporal, and the Commons.

## HISTORY.

The origin of parliament is to be traced to Anglo-Saxon times. And we find in the Anglo-Saxon polity, as developed during their rule in England, all the constituent parts of parliament. In their own lands they had chiefs and leaders, but no kings. But conquest and territorial settlement were followed by the assumption of royal dignities; and the victorious chiefs were accepted by their followers as kings. They were quick to assume the traditional attributes of royalty. But the Saxon monarch was a patriarchal king of limited authority, who acted in concert with his people; and, though his succession was hereditary, in his own family, his direct descendant was liable to be passed over in favor of a worthier heir. Such a ruler was a fitting precursor of a line of constitutional kings, who in later times were to govern with the advice and consent of a free parliament.

Meanwhile, any council approaching the constitution of a House of Lords was of slow growth. Centuries were to pass before the English nobility was to assume its modern character and denominations. At the head of each village was an eorl, the chief of the freemen, or ceorls—their leader in war and patron in peace. The king's gesiths and thegns formed another privileged class.

The revival of the Christian church, under the Anglo-Saxon rule, created another order of rulers and councilors, destined to take a leading part in the government of the state. The archbishops and bishops, having spiritual authority in their own dioceses, and exercising much local influence in temporal affairs, were also members of the national council, or witenagemôte, and by their greater learning and capacity were not long in acquiring a leading part in the councils of the realm. By these several orders, summoned to advise the king in affairs of state, was formed a council of magnates—to be developed, in course of time, into an Upper Chamber, or House of Lords.

The rise of the commons, as a political power in the national councils, was of yet slower development; but in the Anglo-Saxon moots may be discerned the first germs of popular government in England. In the town-moot the assembled freemen and cultivators of the "folk-lands" regulated the civil affairs of their own township, tithing, village, or parish. In the burgh-moot the inhabitants administered their municipal business, under the presidency of a reeve. The hundred-moot assumed a more representative character, comprising the reeve and a selected number of freemen from the several townships and burghs within the hundred. The shire-moot, or shire-gemôte, was an assembly yet more important. An ealdorman was its president, and exercised a jurisdiction over a shire, or district comprising several hundreds. Attended by a reeve and four freemen from every hundred, it assumed a distinctly representative character. Its members, if not elected by the popular voice, were, in some fashion, deputed to act on behalf of those whose interests they had come to guard. The shire-moot was also the general folk-moot of the tribe, assembled in arms, to whom their leaders referred the decision of questions of peace and war.

Superior to these local institutions was the witenagemôte, or assembly of wise men, with whom the king took counsel in legislation and the government of the state. This national council was the true beginning of the parliament of England.

The witenagemôte made laws, imposed taxes, concluded treaties, advised the king as to the disposal of public lands and the appointment and removal of offi-

cers of state, and even assumed to elect and depose the king himself. The king had now attained to greater power, and more royal dignities and prerogatives. He was unquestionably the chief power in the witenagemôte; but the laws were already promulgated, as in later times, as having been agreed to with the advice and consent of the witan. The witan also exercised jurisdiction as a supreme court. These ancient customs present further examples of the continuity of English constitutional forms.

The Anglo-Saxon polity was suddenly overthrown by the Norman Conquest. A stern foreign king had seized the crown, and was prepared to rule his conquered realm by the sword. He brought with him the absolutist principles of Continental rulers, and the advanced feudal system of France and Normandy. Feudalism had been slowly gaining ground under the Saxon kings, and now it was firmly established as a military organization.

Such a revolution seemed fatal to the liberties and ancient customs of Saxon England. What power could withstand the harsh conqueror? But the indestructible elements of English society prevailed over the sword. The king grasped, in his own hands, the higher administration and judicature of the realm; but he continued the old local courts of the hundred and the shire, which had been the basis of Saxon freedom. The Norman polity was otherwise destined to favor the liberties of the people, through agencies which had been designed to crush them. The powerful nobles, whom William and his successors exalted, became formidable rivals of the crown itself; while ambitious barons were in their turn held in check by a jealous and exacting church. The ruling powers, if combined, would have reduced the people to slavery; but their divisions proved a continual source of weakness. In the meantime the strong rule of the Normans, bitter as it was to Englishmen, repressed intestine wars and the disorders of a divided realm. Civil justice was fairly administered.

While these social changes were steadily advancing, the barons were already preparing the way for the assertion of popular rights. Ambitious, turbulent, and grasping, they were constantly at issue with the crown. The power of the people was ever increasing, while their oppressors were being struck down.

The crown was weakened by disputed successions and foreign wars, and the baronage by the blood-stained fields of civil warfare; while both in turn looked to the people in their troubles. Meanwhile the church was struggling, alike against the crown and the barons, in defense of its ecclesiastical privileges and temporal possessions. When William Rufus was threatened by his armed barons, he took counsel with Archbishop Lanfranc, and promised good laws and justice to the people. His promises were broken; but, like later charters, as lightly set aside, they were a recognition of the political rights of the people. By the charter of Henry I. restoring to the people the laws of Edward the Confessor, the continuity of English institutions was acknowledged: Henry II. commenced his reign with another charter. Under Richard I. the principle of representation was somewhat advanced, but it was confined to the assessment and collection of taxes in the different shires. It was under King John that the greatest progress was made in national liberties. The loss of Normandy served to draw the baronage closer to the English people; and the king soon united all the forces of the realm against him. He outraged the church, the barons, and the people. He could no longer play one class against another; and they combined to extort the great charter of their liberties at Runnymede. It was there ordained that no scutage or aid, except the three regular feudal aids, should be imposed, save by the

common council of the realm. To this council the archbishops, bishops, abbots, earls, and greater barons were to be summoned personally by the king's letters, and tenants in chief by a general writ through the sheriff. The summons was required to appoint a certain place, to give forty days' notice at least, and to state the cause of meeting. At length we seem to reach some approach to modern usage.

The charter of King John was again promulgated under Henry III., for the sake of a subsidy; and henceforth the commons learned to insist upon the redress of grievances in return for a grant of money. This reign was memorable in the history of parliament.

In the reign of Edward I. parliament assumed substantially its present form of king, lords, and commons. It formed part of Edward's policy to embrace the clergy in his scheme for the representation of all orders and classes of his subjects. They were summoned to attend the parliament of 1295, and succeeding parliaments of his reign, and their form of summons has been continued until the present time; but the clergy resolutely held aloof from the national council, and insisted upon voting their subsidies in their own convocations of Canterbury and York. Meanwhile the commons, unconscious of their future power, took their humble place in the great council of the realm. They knew that they were summoned for no other purpose than the taxing of themselves and their fellow townsmen; their attendance was irksome; it interrupted their own business; and their journeys exposed them to many hardships and dangers. It is not surprising that they should have shrunk from the exercise of so doubtful a privilege. But the principle of representation, once established, was to be developed with the expansion of society; and the despised burgesses of Edward I., not having seceded, like the clergy, were destined to become a potential class in the parliaments of England. Another constitutional change during this reign was the summoning of parliament to Westminster instead of to various towns in different parts of the country. This custom invested parliament with the character of a settled institution, and constituted it a high court for the hearing of petitions and the redress of grievances. The growth of its judicature, as a court of appeal, was also favored by the fixity of its place of meeting.

Henceforth the financial necessities of a succession of kings insured the frequent assembling of parliaments. Nor were they long contented with the humble function of voting subsidies, but boldly insisted on the redress of grievances and further securities for national liberties.

At this period the constitution of parliament was also settling down to its later and permanent shape. Hitherto the different orders or estates had deliberated separately, and agreed upon their several grants to the crown. The knights of the shire were naturally drawn, by social ties and class-interests, into alliance with the barons; but at length they joined the citizens and burgesses, and in the first parliament of Edward III. they are found sitting together as "the Commons."

This may be taken as the turning point in the political history of England.

The reign of Edward III. witnessed further advances in the authority of parliament, and changes in its constitution. The king, being in continual need of subsidies, was forced to summon parliament every year, and in order to encourage its liberality he frequently sought its advice upon the most important issues of peace or war, and readily entertained the petitions of the commons, praying for the redress of grievances. During this reign, also, the advice and consent of the commons, as well as of the lords spiritual and temporal,

was regularly recorded in the enacting part of every statute. But a more important event is to be assigned to this reign—the formal separation of parliament into the two Houses of Lords and Commons. The date of this event is not clearly established, but is generally assigned to the 17th Edward III.

Parliament had now assumed its present outward form. But it was far from enjoying the authority which it acquired in later times. Instead of enjoying an equal share in the framing of laws, the commons appeared before the king in the humble guise of petitioners. Their petitions, together with the king's answers, were recorded in the Rolls of Parliament; but it was not until the parliament had been discharged from attendance that statutes were framed by the judges, and entered on the statute rolls. Under such conditions legislation was, in truth, the prerogative of the crown rather than of parliament. Henry V., in the second year of his reign, promised "that nothing should be enacted to the petitions of the commons, contrary to their asking, whereby they should be bound without their assent;" but, so long as the old method of framing laws was adhered to, there could be no security against abuse; and it was not until the reign of Henry VI. that the introduction of the more regular system of legislating by bill and statute insured the thorough agreement of all the estates in the several provisions of every statute. The commons, however, notwithstanding these and other discouragements, were constantly growing bolder in the assertion of their rights. The foreign wars of Henry IV. and Henry V., by continuing the financial necessities of the crown, maintained for awhile the powers which parliament had acquired by the struggles of centuries. But a period of civil wars and disputed successions was now at hand, which checked the further development of parliamentary liberties. With the close of the Wars of the Roses the life of parliament seems to have well-nigh expired.

This check in the fortunes of parliament affords a fitting occasion for examining the composition of each of the three estates of the realm.

The archbishops and bishops had held an eminent position in the councils of Saxon and Norman kings, and many priors and abbots were from time to time associated with them as lords spiritual, until the suppression of the monasteries by Henry VIII. They generally outnumbered their brethren, the temporal peers, who sat with them in the same assembly.

The lords temporal comprised several dignities. Of these the baron, though now the lowest in rank, was the most ancient. Next in antiquity was the earl, whose official title was known to Danes and Saxons, and who after the Conquest obtained a dignity equivalent to that of count in foreign states. The highest dignity, that of duke, was not created until Edward III. conferred it upon his son, Edward the Black Prince. The rank of marquis was first created by Richard II., with precedence after a duke. It was in the reign of Henry VI. that the rank of viscount was created, to be placed between the earl and the baron. Since that time no new dignity has been invented, and the peerage consists of the five dignities of duke, marquis, earl, viscount, and baron. During the fifteenth century the number of temporal peers summoned to parliament rarely exceeded fifty, and no more than twenty-nine received writs of summons to the first parliament of Henry VII. There were only fifty-nine at the death of Queen Elizabeth. At the accession of William III. this number had been increased to about one hundred and fifty.

The commons formed a more numerous body. In the reign of Edward I. there were about 275 members, in that of Edward III. 250, and in that of

Henry VI. 300. In the reign of Henry VIII. parliament added twenty-seven members for Wales and four for the county and city of Chester, and in the reign of Charles II. four for the county and city of Durham. Between the reigns of Henry VIII. and Charles II. 130 members were also added by royal charter.

To resume the history of parliament at a later period, let us glance at the reign of Henry VIII. Never had the power of the crown been greater than when this king succeeded to the throne, and never had a more imperious will been displayed by any king of England. Parliament was at his feet to do his bidding, and the Reformation enormously increased his power. He had become a pope to the bishops; the old nobles who had resisted his will had perished in the field or on the scaffold; the new nobles were his creatures; and he had the vast wealth of the church in his hands as largesses to his adherents. Such was the dependence of parliament upon the crown and its advisers during the Reformation period that in less than thirty years four vital changes were decreed in the national faith. Each of the successive reigns inaugurated a new religion.

With the reign of Elizabeth commenced a new era in the life of parliament. She had received the royal prerogatives unimpaired, and her hand was strong enough to wield them. But in the long interval since Edward IV. the entire framework of English society had been changed; it was a new England that the queen was called upon to govern. The parliaments of Elizabeth, though rarely summoned, displayed an unaccustomed spirit. The conflicts between Elizabeth and the commons marked the revival of the independence of parliament, and foreshadowed graver troubles at no distant period.

James I., with short-sighted pedantry, provoked a succession of conflicts with the commons, in which abuses of prerogative were stoutly resisted and the rights and privileges of parliament resolutely asserted. The "remonstrance" of 1610 and the "protestation" of 1621 would have taught a politic ruler that the commons could no longer be trifled with; but those lessons were lost upon James and upon his ill-fated son.

The momentous struggles between Charles I. and his parliaments cannot be followed in this place. The earlier parliaments of his reign fairly represented the earnest and temperate judgment of the country. They were determined to obtain the redress of grievances, and to restrain undue prerogatives; but there was no taint of disloyalty to the crown; there were no dreams of revolution. But the contest at length became embittered, until there was no issue but the arbitrament of the sword. This period proved the supreme power of the commons, when supported by popular forces. Everything gave way before them. They raised victorious armies in the field, they overthrew the church and the House of Lords, and they brought the king himself to the scaffold.

On the restoration of Charles II. parliament was at once restored to its old constitution, and its sittings were revived as if they had suffered no interruption. No outward change had been effected by the late revolution; but that a stronger spirit of resistance to abuses of prerogative had been aroused was soon to be disclosed in the deposition of James II. and the "glorious revolution" of 1688.

On the union of Scotland in 1707, important changes were made in the constitution of parliament. The House of Lords was reinforced by the addition of sixteen peers, representing the peerage of Scotland, and elected every parliament; and the Scottish peers, as a body, were admitted to all the privileges of peerage,

except the right of sitting in parliament, or upon the trial of peers. No prerogative, however, was given to the crown to create new peerages after the Union; and, while they are distinguished by their antiquity, their number is consequently decreasing. To the House of Commons were assigned forty-five members, representing the shires and burghs of Scotland.

With the reign of George III. there opened a new period in the history of parliament. Agitation in its various forms, an active and aggressive press, public meetings and political associations, the free use of the right of petition, and a turbulent spirit among the people seriously changed the relations of parliament to the country. And the publication of debates, which was fully established in 1771, at once increased the direct responsibility of parliament to the people, and ultimately brought about other results.

In this reign another important change was effected in the constitution of parliament. Upon the union with Ireland, in 1801, four Irish bishops were added to the lords spiritual, who sat by rotation of sessions, and represented the episcopal body of the Church of Ireland. But those bishops were deprived of their seats in parliament in 1869, on the disestablishment of the Church of Ireland. Twenty-eight representative peers, elected for life by the peerage of Ireland, were admitted to the House of Lords. All the Irish peers were also entitled to the privilege of peerage. In two particulars the Irish peerage was treated in a different manner from the peerage of Scotland. The crown was empowered to create a new Irish peerage whenever three Irish peerages in existence at the time of the Union have become extinct, or when the number of Irish peers, exclusive of those holding peerages of the United Kingdom, has been reduced to one hundred. And, further, Irish peers were permitted to sit in the House of Commons for any place in Great Britain, forfeiting, however, the privilege of peerage while sitting in the Lower House. The expediency of both these provisions has often been called in question.

At the same time 100 representatives of Ireland were added to the House of Commons. This addition raised the number of members to 658. Parliament now became the parliament of the United Kingdom, and high hopes were entertained of a salutary fusion of diverse nationalities into a single assembly; but these hopes have scarcely been realized, and the relations of the Irish people to Great Britain and the imperial government continue to be a source of the gravest embarrassment and danger.

By the union of Scotland and Ireland, the electoral abuses of those countries were combined with those of England. The grave defects of the representation were notorious, and some minor electoral abuses had been from time to time corrected. But the fundamental evils—nomination boroughs, limited rights of election, the sale of seats in parliament, the prevalence of bribery, and the enormous expense of elections—though constantly exposed, long held their ground against all assailants.

The result of the memorable struggle which ensued may be briefly told. By the Reform Acts of 1832 the representation of the United Kingdom was reconstructed. In 1852, and again in 1854, Lord John Russell introduced further measures of reform; but constitutional changes were discouraged by the Russian war. In 1859 Lord Derby's Conservative government proposed another scheme of reform, which was defeated; and in 1860 Lord John Russell brought in another bill, which was not proceeded with; and the question of reform continued in abeyance until after the death of Lord Palmerston. Earl Russell, who succeeded him as

premier, was prompt to redeem former pledges, and hastened to submit to a new parliament, in 1866, another scheme of reform.

Still further reform bills were presented and enacted in 1867-68. In 1872 the subject was again taken up, but nothing was accomplished. In 1880 additional legislation ensued; and in 1884-85 sweeping changes were made with the result of placing representation in Great Britain and Ireland on a uniform basis, and the addition of nearly 2,000,000 voters to the election rolls. The redistribution of the kingdom resulted in an increase of representation for England and Scotland and a diminution for Ireland.

#### POWERS AND PRIVILEGES OF PARLIAMENT.

Such being the history and constitutional character of parliament, this survey would be incomplete without a more detailed view of the powers and privileges of each of its constituent parts, and of its ordinary proceedings.

*Prerogatives of the Crown.*—The crown, preëminent in rank and dignity, is also the legal source of parliamentary authority. The Queen virtually appoints the Lords Spiritual, and all the peerages of the Lords Temporal have been created by herself or her predecessors. Thus the entire House of Lords is the creation of the crown. The Queen summons parliament to meet, and prescribes the time and place of its meeting, prorogues and dissolves it, and commands the issue of writs for the election of members of the House of Commons.

*Powers of the House of Lords.*—The House of Lords, which at present consists of about 520 members, is distinguished by peculiar dignities, privileges, and jurisdictions. Peers individually enjoy the rank and precedence of their several dignities, and are hereditary councilors of the crown. Collectively with the Lords Spiritual they form a permanent council of the crown; and, when assembled in parliament, they form the highest court of judicature in the realm, and are a coëqual branch of the legislature, without whose consent no laws can be made. Their judicature is of various kinds, viz., for the trial of peers; for determining claims of peerage and offices of honor, under references from the crown; for the trial of controverted elections of Scotch and Irish peers; for the final determination of appeals from courts in England, Scotland, and Ireland; and, lastly, for the trial of impeachments.

*Powers of the House of Commons.*—The House of Commons also has its own peculiar privileges and jurisdictions. Above all, it has the paramount right of originating the imposition of all taxes, and the granting of supplies for the service of the state. It has also enjoyed, from early times, the right of determining all matters concerning the election of its own members, and their right to sit and vote in parliament. This right, however, has been greatly abridged, as, in 1868, the trial of controverted elections was transferred to the courts of law; but its jurisdiction in matters of election not otherwise provided for by statute is still retained intact. As part of this jurisdiction, the House directs the Speaker to issue warrants to the clerk of the crown to make out new writs for the election of members to fill up such vacancies as occur during the sitting of parliament.

*Privileges of Parliament.*—Both Houses are in the enjoyment of certain privileges, designed to maintain their authority, independence, and dignity. Each House has its separate rights and jurisdictions; but privileges properly so-called, being founded upon the law custom of parliament, are common to both Houses. Each House adjudges whether any breach of privilege

has been committed, and punishes offenders by censure or commitment. The Lords may imprison for a fixed period, and impose fines; the Commons can only imprison generally, the commitment being concluded by the prorogation, and have long discontinued the imposition of fines.

*Freedom of Speech.*—Freedom of speech has been one of the most cherished privileges of parliament from early times. Constantly asserted, and often violated, it was finally declared by the Bill of Rights "that the freedom of speech, and debates and proceedings in parliament, ought not to be impeached or questioned in any court or place out of parliament."

*Freedom from Arrest.*—Freedom from arrest is a privilege of the highest antiquity. At present members are themselves free from arrest within forty days after prorogation, but otherwise they are liable to all the processes of the courts. If arrested, they will be immediately discharged, upon motion in court whence the process issued. Peers and peeresses are, by the privilege of peerage, free from arrest at all times. The privilege of freedom from arrest is limited to civil causes, and has not been suffered to exempt members from the operation of the criminal law, nor even from commitments for contempt by other courts. But, whenever the freedom of a member is so interfered with, the courts are required immediately to inform the House of the causes of his commitment. Witnesses, suitors, counsel, and agents in attendance upon parliament are protected from arrest and molestation, and from the consequences of statements made by them, or other proceedings in the conduct of their cases.

PARMA, one of the finest cities of northern Italy, is situated at thirty-five and one-half miles by rail south-east of Piacenza and thirty-two and one-quarter north-west of Modena, in a fertile tract of the Lombard plain within view of the Alps, and sheltered by the Apennines. The population in 1861 was 47,067 for the city and 47,428 for the commune; the removal of the military and civil functionaries of the old duchy caused a considerable decrease, and the figures for 1881 were only 44,492 and 45,217.

PARMENIDES OF ELEA, the most notable of the philosophers of the Eleatic succession, is said by Diogenes Laertius (presumably on the authority of Apollodorus) to have been "in his prime" in Olymp. 69 (=504-500 B.C.); whence it would appear that he was born about 539.

Parmenides embodied his tenets in a short poem called *Nature*, of which fragments, amounting in all to about a hundred and sixty lines, have been preserved in the writings of Sextus Empiricus, Simplicius, and others. *Nature* is traditionally divided into three parts—the "Proem," "Truth" (*τὰ πρὸς ἀλήθειαν*), and "Opinion" (*τὰ πρὸς δόξαν*). In "Truth," starting from the formula "the Ent (or existent) is, the Nonent (or non-existent) is not." Parmenides attempted to distinguish between unity or universal element of nature and its variety or particularity, insisting upon the reality of its unity, which is therefore the object of knowledge, and upon the unreality of its variety, which is therefore the object, not of knowledge, but of opinion. In "Opinion" he propounded a theory of the world of seeming and its development, pointing out, however, that, in accordance with the principles already laid down, these cosmological speculations do not pretend to anything more than probability.

PARMENIO, a distinguished Macedonian general, born about 400 B.C., was the son of Philotas, and first appears in history as a favorite counselor of Philip. He was stabbed by Cleander, at the instance of the king, in 330,

**PARMIGIANO.** The name of this celebrated painter of the Lombard school was, in full, Girolamo Francesco Maria Mazzuoli, or Mazzola. Francesco, born on January 11, 1504, was the son of a painter. A fever carried him off on August 24, 1540, before he had completed his thirty-seventh year. By his own desire, he was buried naked in the church of the Servites called La Fontana, near Casal Maggiore.

**PARNASSUS**, a mountain of Greece, in the south of Phocis, rising over the town of Delphi. It had two prominent peaks, Tithorea and Lycoreia, besides smaller ones, Hyampeia, Nauplia, etc. Parnassus was one of the most holy mountains in Greece, hallowed by the worship of Apollo, of the Muses, and of the Corycian nymphs, and by the orgies of the Bacchantes. The Delphic oracle, the Castalian fountain, and the Corycian cave were all situated among the clefts in its densely wooded sides.

**PARNELL, THOMAS**, has a place in literature among the minor Queen Anne poets. He was born in Dublin in 1679, and died in 1718.

**PARNY, ÉVARISTE DÉSIRE DE FORGES, VICOMTE DE**, minor French poet, was born in the Isle of Bourbon on February 6, 1753. He died in 1814.

**PARODY** (*παρωδία*, literally a song sung beside a comic parallel) may be defined as an imitation of the form or style of a serious writing in matter of a meaner kind so as to produce a ludicrous effect. By common consent, the most subtle and dexterous of metrical parodists is the late Mr. C. S. Calverley, who succeeded in reproducing not merely tricks of phrase and meter, but even manneristic turns of thought. Johnson's dictum about pastoral poetry, that most of it is "easy, vulgar, and therefore disgusting," might be applied to parody; but Calverley would escape the censure.

**PAROS**, or **PARO**, an island in the Ægean Sea, one of the largest of the group of the Cyclades, with a population of 8,000. It lies to the west of Naxos, from which it is separated by a channel about six miles broad, and with which it is now grouped together, in popular language, under the common name of Paronaxia. Its greatest length from northeast to southwest is thirteen miles, and its greatest breadth ten miles. It is formed of a single mountain about 2,400 feet high, sloping evenly down on all sides to a maritime plain, which is broadest on the northeast and northwest sides.

**PARQUETRY** is a kind of mosaic of wood used for ornamental flooring. Materials contrasting in color and grain, such as oak, walnut, cherry, lime, pine, etc., are employed; and in the more expensive kinds the richly-colored tropical woods are also used. The patterns of parquet flooring are entirely geometrical and angular (squares, triangles, lozenges, etc.), curved and irregular forms being avoided on account of the expense and difficulty of fitting. There are two classes of parquetry in use—veneers and solid parquet. The veneers are usually about a quarter of an inch in thickness, and are laid over already existing floors.

**PARR.** This name was originally applied to small Salmonoids which are abundant in British rivers, and were for a long time considered to constitute a distinct species (*Salmo salmulus*). They possess the broad head, short snout, and large eye characteristic of young Salmonoids, and are ornamented on the sides of the body and tail with about eleven or more broad dark cross-bars, the so-called parr-marks. However, these fishes represent merely the first stage of growth of the salmon, before it assumes, at an age of two years, and when about six inches long, the silvery smolt-dress preparatory to its first migration to the sea.

**PARR, SAMUEL**, English schoolman, and the most able educator of his day, the son of Samuel Parr,

surgeon at Harrow-on-the-Hill, was born there January 15, 1747. After a long term of service as the educator of youth, among his pupils being some of the most notable names of modern English history, Parr died at Hatton vicarage March 6, 1825, and was buried in the chancel of its church.

**PARRAMATTA**, a town of New South Wales, at the head of the navigation of the Parramatta river, and fourteen miles to the west of Sydney, with which it is connected by railway, was one of the earliest inland settlements, and the seat of many of the public establishments connected with the working of the convict system.

**PARRHASIUS**, of Ephesus, was one of the greatest painters of Greece. Seneca relates a tale that Parrhasius bought one of the Olynthians whom Philip sold into slavery, 346 B.C. (see **OLYNTHUS**), and tortured him in order to have a model for his picture of Prometheus; but the story, which is similar to one told of Michelangelo, is chronologically impossible. Another tale recorded of him describes his contest with Zeuxis. The latter painted some grapes so perfectly that birds came to peck at them. He then called on Parrhasius to draw aside the curtain and show his picture, but, finding that his rival's picture was the curtain itself, he acknowledged himself to be surpassed, for Zeuxis had deceived birds, but Parrhasius had deceived Zeuxis.

**PARROT**, according to Professor Skeat, from the French *Perrot* or *Pierrot*, a proper name and the diminutive of *Pierre*, the name given generally to a large and very natural group of birds, which for more than a score of centuries have attracted attention, not only from their gaudy plumage, but, at first and chiefly, it would seem, from the readiness with which many of them learn to imitate the sounds they hear, repeating the words and even phrases of human speech with a fidelity that is often astonishing.

The home of the vast majority of Parrot-forms is unquestionably within the tropics, but the popular belief that Parrots are tropical birds only is a great mistake. In North America the Carolina Parakeet, *Conurus carolinensis*, at the beginning of the present century used to range in summer as high as the shores of Lakes Erie and Ontario—a latitude equal to that of the south of France; and even within the last forty years it reached, according to trustworthy information, the junction of the Ohio and the Mississippi, though now its limits have been so much curtailed that its occurrence in any but the Gulf States is doubtful. In South America, at least four species of Parrots are found in Chili or La Plata, and one, *Conurus patagonus*, is pretty common on the bleak coast of the Strait of Magellan. In Africa, it is true that no species is known to extend to within some ten degrees of the Tropic of Cancer, but *Pionias robustus* inhabits territories lying quite as far to the southward of the Tropic of Capricorn. In India the northern range of the group is only bounded by the slopes of the Himalayas, and further to the eastward Parrots are not only abundant over the whole of the Malay Archipelago, as well as Australia and Tasmania, but two very well defined families are peculiar to New Zealand and its adjacent islands (see **KAKAPO** and **NESTOR**). No Parrot has recently inhabited the Palæarctic region, and but one (the *Conurus carolinensis*, just mentioned) probably belongs to the Nearctic; nor are Parrots represented by many different forms in either the Ethiopian or the Indian regions.

**PARROT-FISHES**, more correctly called **PARROT-WRASSES**, are marine fishes, belonging to the Wrasse family, and referred to four closely-allied genera, viz., *Scarus*, *Scarichthys*, *Callyodon* and *Pseudoscarus*. They are easily recognized by their large scales, of which there are from twenty-one to twenty-five in the lateral line, by

having invariably nine spines and ten rays in the dorsal fin and two spines with eight rays in the anal, and especially by their singular dentition, of jaws as well as pharynx. The teeth of the jaws are soldered together, and form a sharp-edged beak similar to that of a parrot, but without a middle projecting point, and the upper and lower beak are divided into two lateral halves by a median suture. Nearly one hundred species of Parrot-Fishes are known from the tropical and subtropical parts of the Indo-Pacific and Atlantic Oceans; like other coral-feeding fishes, they are absent on the Pacific coasts of tropical America and on the coasts of tropical West Africa.

PARRY, SIR WILLIAM EDWARD, arctic navigator, was the fourth son of Dr. Caleb Hillier Parry, a physician of some celebrity in Bath, and was born there December 19, 1790.

After eleven years' service in the British navy he obtained an appointment to the *Alexander* brig in the expedition of Sir John Ross to discover the probabilities of a Northwest Passage to the Pacific. Ross, mistaking clouds for the Croker mountains barring his way westward, returned to England in the belief that further perseverance was hopeless; but Parry, confident, as he expressed it, "that attempts at polar discovery had been hitherto relinquished just at a time when there was the greatest chance of succeeding," obtained the command of a new expedition, consisting of two ships, the *Griper* and *Hecla*, with which he sailed from the Thames in May, 1819. After wintering in Melville Island he made an effort to force a passage to Behring's Straits, but the state of the ice rendering this impossible, he returned to England, reëntering the Thames in November, 1820. A narrative of the expedition appeared in 1821. Shortly after his return he was promoted to the rank of commander, presented with the freedom of Bath and Norwich, and elected a member of the Royal Society. With the *Fury* and the *Hecla* he set sail on a second expedition in May, 1821, and after great hardships returned to England in November, 1823, without achieving his purpose. During his absence he had, in November, 1821, been promoted to post rank, and on December 1, 1823, he was chosen acting hydrographer of the navy. His *Journal of a Second Voyage for the Discovery of the Northwest Passage* appeared in 1824. With the same ships he, in May, 1824, set sail on a third expedition, which, however, was unsuccessful, and after the wreck of the *Fury* he returned home in October, 1825, with a double ship's company. Of this voyage he published an account in 1826. Having obtained the sanction of the Admiralty to journey to the North Pole from the northern shores of Spitzbergen in boats that could be fitted to sledges, he set sail with the *Hecla*, March 27, 1827, and in June set out for the Pole. He, however, failed to find the solid plain of ice he expected; and as, moreover, owing to the ice drift, he found his efforts at progress northward in great degree frustrated, he was compelled, after reaching 82° 45' N. latitude to retrace his steps, and arrived in England in October. Of his journey he published an account under the title of *Narrative of the Attempt to reach the North Pole in Boats*, 1827.

In 1853 he was appointed governor of Greenwich Hospital, which post he retained till his death, July 8, 1855.

PARSÎS, or PARSEES, are the followers of Zarathustra, and the descendants of the ancient Persians who emigrated to India on the conquest of their country by the Arabs, about the year 720 A.D.

The men are well formed, active, handsome, and intelligent. They have light olive complexions, a fine

aquiline nose, bright black eyes, a well-turned chin, heavy arched eyebrows, thick sensual lips, and usually wear a light curling mustache. The women are delicate in frame, with small hands and feet, fair complexion, beautiful black eyes, finely arched eyebrows, and a luxurious profusion of long black hair, which they dress to perfection, and ornament with pearls and gems.

The Parsîs are much more noble in their treatment of females than any other Asiatic race; they allow them to appear freely in public, and leave them the entire management of household affairs. They are proverbial for their benevolence, hospitality, and sociability. They are good scholars, and usually learn several languages—Gujarâtî, Hindûstânî, and English. The Parsîs are notoriously fond of good living, and do not hesitate to spend their money freely for the best the market affords. They indulge in wines, but do not reach the vice of intoxication.

The marriages of children engage the earliest attention of the parents. Though the majority of Parsî marriages are still celebrated while the children are very young, instances frequently occur of marriages of grown-up boys and girls.

The numerical strength of the followers of Zarathustra at the present day does not exceed 82,000 persons, including the Parsîs of Persia at Kermân, Yazd, and Teherân. The greater number is found in Bombay, and in some of the cities of Gujarât, as Nowsarî Surat, Bharoch, Ahmedâbâd, etc. Parsîs have also settled for the purpose of trade in Calcutta, Madras, and in other cities of British India, in Burmah, China, and in other parts of Asia. According to the census of 1881, there are in the Bombay presidency 72,065 Parsîs, and in Persia 8,499, according to Houtum-Schindler (see *Journal of the Oriental German Society*, vol. xxxvi. p. 54).

PARSON is a technical term of English law, and is a corruption of *persona*, the parson being, as it were, the *persona ecclesiæ*, or representative of the church in the parish. Parson imparsonnee (*persona impersonata*) is he that as rector is in possession of a church parochial, and of whom the church is full, whether it be presentative or improper. The word parson is properly used only of a rector, though it is sometimes loosely extended to anyone in holy orders. Though every parson is a rector, every rector is not a parson. A parson must be in holy orders; hence a lay rector could not be called a parson. The parson is tenant for life of the parsonage house, the glebe, the tithes, and other dues, so far as they are not appropriated.

PARSONS, or PERSONS, ROBERT, a celebrated Jesuit, son of a blacksmith, was born at Nether Stowey, near Bridgewater, England, in 1546, and died in 1610.

PARSONS, a post-town in Kansas, is located in Labette county, on the Neosho division of the Missouri, Kansas and Texas Railroad, and on the Memphis, Kansas and Colorado road, thirty-two miles northeast of Independence, fifty miles southwest of Fort Scott, and thirty-four miles southeast of Humboldt. It is a growing and prosperous place, having five churches, two school-buildings, two newspaper offices, two hotels, one bank, and other evidences of Western progress and development, including stores and warehouses, substantially constructed and well adapted to the uses to which they are devoted. The lines of manufacture conducted at Parsons are varied and valuable, embracing a foundry and machine-shop, furniture factory, plow factory, the machine-shops of the railroad, etc., etc., giving employment to a large force of men, and annually turning out productions valued at thousands of dollars. The population in 1890 was 6,736.

PARSONSTOWN, formerly BIRR, a market-town

of King's County, Ireland, is situated on an acclivity rising above the Birr, and on a branch of the Great Southern and Western Railway, twelve and a half miles north of Roscrea and seven and a half south of Banagher. The population was 5,401 in 1861, 4,939 in 1871, and 4,955 in 1881.

PARTÁBGARH, PRATÁBGARH, or PERTABGURH, a district of Oudh, India, is bounded on the north by Rái Bareli and Sultánpur, and on the east, south and west by Jaunpur and Allahábád districts. The Ganges forms the southwestern boundary line, while the Gumti marks the eastern boundary for a few miles. The area (1881) is 1,436 square miles. The population in 1881 was 847,047.

PARTÁBGARH, or PERTABGURH, a native state in Rájputána, India, lying between 23° 14' and 24° 14' N. latitude, and between 74° 27' and 75° E. longitude, and entirely surrounded by native territory, has an estimated area of 1,460 square miles, and an estimated population (1881) of 80,568, mostly Bhíls and other aboriginal tribes.

PARTHENIUS, a Bithynian poet, said to have been captured in the Mithridatic war and carried to Rome. He lived there for many years, as late as the time of Tiberius. His poems were on erotic subjects, and many of them treated of obscure mythological stories. The only work of his which is preserved is a collection of short love-tales in prose, dedicated to the poet Cornelius Gallus, but apparently not intended for publication.

PARTHENON. See ATHENS.

PARTHIA. See PERSIA.

PARTINICO, a town of Sicily, in the province of Palermo, and twenty-eight and a half miles west of Palermo by rail, has a good trade in wine and oil, and in 1881 had 21,000 inhabitants.

PARTITION, in law, is the division between several persons of land or goods belonging to them as co-proprietors. In English law the term partition applies only to the division of lands, tenements, and hereditaments, or of chattels real between coparceners, joint tenants, or tenants in common. It is to be noticed that not all hereditaments are capable of partition. There can be no partition of homage, fealty, or common of turbary, or of an inheritance of dignity, such as a peerage. Partition is either voluntary or compulsory. Voluntary partition is effected by mutual conveyances, and can only be made where all parties are *sui juris*. It must be made by deed, except in the case of copyholds. Compulsory partition is effected by private act of Parliament, by judicial process, or through the inclosure commissioners.

In the United States, in a large majority of the States, partition may be made by a summary method of petition to the courts of common law. In the other States the courts of equity have exclusive jurisdiction. As between heirs and devisees the probate courts may in some States award partition.

PARTNERSHIP, in law, is a voluntary association of two or more persons for the purpose of gain. This is, of course, not an exhaustive definition, but will serve to include most of the definitions of partnership which have been attempted. The word *partner* is a contracted form of *partitioner*.

There is no statutory or judicial definition of partnership in English law. It is defined as "the relation which subsists between persons who have agreed to share the profits of a business carried on by all or any of them on behalf of all of them." Sir N. Lindley declines to pledge himself to any definition, but lays down the following principles:—(1) Partnership is the result of an agreement to share profits and losses; (2) partner-

ship is *prima facie* the result of an agreement to share profits, although nothing may be said about losses, and although there may be no common stock; (3) partnership is *prima facie* the result of an agreement to share profits, although community of loss is stipulated against; (4) partnership is not the result of an agreement to share gross returns; (5) partnership is not the result of an agreement which is not concluded; (6) partnership is not the result of an agreement to share profits so long as anything remains to be done before the right to share them accrues.

In the United States the English common law is the basis of the law. Most States have, however, their own special legislation on the subject. Partnership is defined by Chancellor Kent to be "a contract of two or more competent persons to place their money, effects, labor, and skill, or some or all of them, in lawful commerce or business, and to divide the profit and bear the loss in certain proportions." The definition of the New York Civil Code, art. 1283, runs thus:—"Partnership is the association of two or more persons for the purpose of carrying on business together, and dividing its profits between them." The most striking feature of the law in the United States is the existence of limited partnerships, corresponding to the *sociétés en commandite* established in France by the ordinance of 1673. The State of New York was the first to introduce this kind of partnership by legislative enactment. The provisions of the New York act have been followed by most of the other States. In many States there can be no limited partnership in banking and insurance. In this form of partnership one or more persons responsible *in solido* are associated with one or more dormant partners liable only to the extent of the funds supplied by them. In Louisiana such partnerships are called partnerships *in commendam* (Civil Code, art. 2810). In New York the responsible partners are called *general* partners, the others *special* partners. Such partnerships must, by the law of most States, be registered. In Louisiana universal partnerships must be created in writing and registered (Civil Code, art. 2800). In some States nominal partners are not allowed. Thus in New York, where the words "and Company" or "and Co." are used, they must represent an actual partner or partners. A breach of this rule subjects offenders to penalties. In most States claims against the firm after the death of a partner must, in the first instance, be made to the survivors. The creditors cannot, as in England, proceed directly against the representatives of the deceased. The law as to the conversion of realty into personalty on the administration of the estate of a deceased partner in some States agrees with English law, in others does not.

PARTRIDGE, from the Latin *Perdrix*, which word in sound does not imitate badly the call-note of this bird, so well known throughout the British Islands and the greater part of Europe as to need no description or account of its habits here. The English name properly denotes the only species indigenous to Britain, often nowadays called the Gray Partridge. In Asia the English Partridge seems to be unknown, but in the temperate parts of Eastern Siberia its place is taken by a very nearly allied form, *P. barbata*, and in Tibet there is a bird, *P. hodgsoniæ*, which can hardly with justice be generically separated from it. The common Red-legged Partridge of Europe, generally called the French Partridge, *Caccabis rufa*, seems to be justifiably considered the type of a separate group. The French Partridge has several congeners, all with red legs and plumage of similar character. In Africa north of the Atlas there is the Barbary Partridge, *C. petrosa*; in southern Europe another, *C. saxatilis*, which extends eastward

till it is replaced by *C. chukar*, which reaches India, where it is a well-known bird. Two very interesting desert-forms, supposed to be allied to *Caccabis*, are the *Ammoperdrix heyi* of North Africa and Palestine and the *A. bonhami* of Persia; the groups of birds known as Francolins and Snow-Partridges are generally furnished with strong but blunt spurs, and therefore probably belong to the Caccabine group. Of the former, containing many species, there is only room here to mention the Francolin, which used to be found in many parts of the south of Europe, *Francolinus vulgaris*, which also extends to India, where it is known as the Black Partridge. By English colonists the name Partridge has been very loosely applied, and especially so in North America. Where a qualifying word is prefixed no confusion is caused, but without it there is sometimes a difficulty at first to know whether the Ruffed Grouse *Bonasa umbellus* (see GROUSE) or the Virginian Colin (*Ortyx virginianus*) is intended.

PASADENA, a city of Los Angeles county, Cal., in the San Gabriel valley, is one of the most popular health resorts of the Pacific coast. Within the past ten years its growth has been phenomenal and its population has increased in a greater ratio than that of almost any of its contemporaries, while the improvements made upon its site are of an attractive and substantial character. It contains churches, schools, banking facilities, etc.; an opera-house and two commodious and desirably-appointed public halls, five hotels, and other accommodations, for the convenience of the influx of visitors annually sojourning there to avail themselves of the benefits and health-giving properties of the climate. The raising of oranges and other fruits is the principal business interest of the vicinity, and large shipments of these productions are made yearly from Pasadena to the eastern States and elsewhere. Some manufacturing is carried on in the city, including grist and planing mills, electric-appliance and barbed-wire factories, a fruit-canning establishment and some other enterprises, embracing about 100 stores, shops, etc. The city is lighted with gas and electric lights, and its population, as at present (1890) estimated, is 15,000.

PASCAL, BLAISE, was born at Clermont Ferrand, France, on June 19, 1623. His father was Étienne Pascal, president of the Court of Aids at Clermont; his mother's name was Antoinette Bégon. The Pascal family were Auvergnats by extraction as well as residence, and they had for many generations held posts in the civil service. It does not appear that Blaise, who went to no school, but was taught by his father, was at all forced, but rather the contrary. Nevertheless he has a distinguished place in the story of precocious children, and in the much more limited chapter of children whose precocity has been followed by great performance at maturity, though he never became what is called a learned man, perhaps did not know Greek, and was pretty certainly indebted for most of his miscellaneous reading to Montaigne. How, purposely kept from books, he worked out the more elementary problems of geometry for himself; how at sixteen he wrote a treatise on conic sections which Descartes refused to believe in except as the work of a master and not of a student; how he wrote treatises on acoustics at twelve, and began elaborate calculating machines when he was still a boy, are things dwelt upon in all biographies of him.

His bodily health was in youth far from satisfactory, and he appears to have suffered, not merely from acute dyspepsia, but from a kind of paralysis. He was, however, except when physicians positively forbade study, and probably sometimes when they did so forbid, indefatigable in his mathematical work. In 1647 he pub-

lished his *Nouvelles Expériences sur le Vide*, and in the next year the famous experiment with the barometer on the Puy de Dome was carried out for him by his brother-in-law Perier, and repeated on a smaller scale by himself at Paris. As early as May, 1648, Jacqueline Pascal was strongly drawn to Port Royal, and her brother frequently accompanied her to its church. She desired, indeed, to join the convent, but her father, who at the date above mentioned returned to Paris with the dignity of counselor of state (his functions at Rouen having ceased), disapproved of the plan, and took both brother and sister to Clermont. Pascal staid in Auvergne for the greater part of two years, but next to nothing is known of what he did there. He, his sister, and their father returned to Paris in the late autumn of 1650, and in September of the next year Étienne Pascal died. Almost immediately afterward Jacqueline fulfilled her purpose of joining Port Royal—a proceeding which led to some soreness, finally healed, between herself and her brother and sister as to the disposal of her property. It has been supposed that Pascal, from 1651 or earlier to the famous accident of 1654, lived a dissipated, extravagant, worldly, luxurious (though admittedly not vicious) life with his friend the Duc de Roannez and others. His *Discours sur les Passions de l'Amour*, a striking and characteristic piece, only recently discovered and printed, has also been assigned to this period. As to Pascal's worldly life, it might be thought that only the completest ignorance of the usual dialect of the stricter religious sects and societies (and it may be added of Port Royal in particular) could induce anyone to lay much stress on that. A phrase of Jacqueline's about the "horribles attaches" which bound her brother to the world may pair off with hundreds of similar expressions from Bunyan downward. It is, however, certain that in the autumn of 1654 Pascal's second "conversion" took place, and that it was lasting. He betook himself at first to Port Royal, and began to live a recluse and austere life there. Madame Perier simply says that Jacqueline persuaded him to abandon the world. Jacqueline represents the retirement as the final result of a long course of dissatisfaction with mundane life.

From November 23, 1654, dates the singular document usually known as "Pascal's amulet," a parchment slip which he wore constantly about him, and which bears the date followed by some lines of incoherent and strongly mystical devotion.

But, whatever may have been the immediate cause of Pascal's conversion and (for a time) domestication at Port Royal, it certainly had no evil effect on his intellectual or literary powers. It must be noted that, though he lived much at Port Royal, and partly at least observed its rule, he never actually became one of its famous solitaries. At the end of 1655 Arnauld, the chief light of Port Royal, was condemned by the Sorbonne for a letter which he had published expressing doubt whether the famous five propositions were to be found in Jansen, and, as much was made of this condemnation, it was thought important by the Jansenist and Port Royal party that steps should be taken to disabuse the popular mind on the whole controversy. Arnauld would have undertaken the task himself, but his wiser friends knew that his style was anything but popular, and overruled him. It is said that he personally suggested to Pascal to try his hand, and that the first of the famous *Provincial Letters* (this familiar name, or rather misnomer, is an abbreviation from the proper title of *Lettres Écrites par Louis de Montalte à un Provincial de ses Amis*) was written in a few days, or, less probably, in a day. It was printed on

January 23, 1656, and, being immensely popular and successful, was followed by others to the number of eighteen, in which not merely the special points at issue but the whole ethical and doctrinal system of the Jesuits was pulled to pieces.

Shortly after the appearance of the *Provinciales*, on May 24, 1656, occurred the miracle of the Holy Thorn, a fragment of the crown of Christ preserved at Port Royal, which cured the little Marguerite Perier of a fistula lacrymalis. The Jesuits were much mortified by this Jansenist miracle, which, as it was officially recognized, they could not openly deny. Pascal and his friends rejoiced in proportion. What may be called his last illness began as early as 1658, after which year he never seems to have enjoyed even tolerable health, and as the disease progressed it was attended with more and more pain, chiefly in the head. In June, 1662, having given up his own house to a poor family who were suffering from smallpox, and being unwilling that his sister should expose herself to infection, he went to her house to be nursed, and never afterward left it. His state was, it seems, mistaken by his physicians, who to the last maintained that there was little danger—so much so that the offices of the church were long put off. He was able, however, to receive the eucharist, and soon afterward died in convulsions on August 19th. A *post-mortem* examination was held, which showed not only grave derangement in the stomach and other organs, but a serious lesion of the brain.

Eight years after Pascal's death appeared, in a small volume, the book which has given most trouble to all students of Pascal, and most pleasure to some of them. It purported to be Pascal's *Pensées*, and a preface by his nephew Perier gave the world to understand that these were fragments of a great projected apology for Christianity which the author had in conversation with his friends planned out years before.

PASCHAL I., pope from 817 to 824, a native of Rome, was raised to the pontificate by popular acclamation, shortly after the death of Stephen V, and before the sanction of the emperor (Louis the Pious) had been obtained. His relations with the imperial house never became cordial; and he was also unsuccessful in retaining in Rome itself the popularity to which he had owed his election. He died at Rome while the imperial commissioners were investigating the circumstances under which two important officers of Lothair, the eldest son of Louis, had been seized at the Lateran, blinded, and afterward beheaded; Paschal had shielded the murderers, but denied all personal complicity in their crime. The successor of Paschal I. was Eugenius II.

PASCHAL II., pope from 1099 to 1118, was the successor of Urban II. Of his early history nothing is known except that his proper name was Rainieri, that he was of Tuscan origin, and that in early life he became a monk, probably of Cluny. He was raised to the cardinalate by Gregory VII. about 1076, and was elected to the papal chair on August 13, 1099. In the long struggle with the imperial power about INVESTITURE (*q.v.*) he zealously carried on the Hildebrandine policy, but hardly with Hildebrandine success. The Lateran council, held in March, 1112, repudiated as void, under penalty of excommunication, the concessions that had been extorted by the violence of Henry V., and a council held at Vienne some months afterward actually excommunicated him, the pope himself ratifying the decree. On the death of the Countess Matilda of Tuscany, who had bequeathed her whole possessions to the church (1115), the emperor at once laid claim to them as imperial fiefs, and, descending into Italy, drove the pope first to Monte Casino and then to Benevento.

Paschal returned to Rome, after the emperor's withdrawal, in the beginning of 1118, but died within a few days (January 21, 1118). His successor was Gelasius II.

PASCHAL CONTROVERSY. See EASTER.

PASCO. See CERRO DE PASCO.

PAS DE CALAIS, a maritime department of northern France, formed in 1790 of nearly the whole of Artois and the northern maritime portion of Picardy, including the Boulonnais, Calaisis, Ardrésis, and the districts of Langle and Bredenarde, is bounded north by the Straits of Dover ("Pas de Calais"), east by the department of Nord, south by that of Somme, and west by the English Channel. The distance from England is only twenty-one miles. Nord, which separates Pas de Calais from Belgium, is at one place only three miles wide, and from Arras (the chief town) to Paris in a direct line is about 100 miles. Vast plains, open and monotonous, but extremely fertile and well cultivated, occupy most of the department. The greenest and most picturesque valleys are in the west. To the north of the hills running between St. Omer and Boulogne, to the south of Gravelines and the southeast of Calais, lies the district of the Wattergands, fens now drained by means of canals and dykes, and turned into highly productive land. The climate is free from extremes of heat and cold, but damp and changeable. At Arras the mean annual temperature is 47°; on the coast it is higher. The rainfall in the one case is twenty-two inches, in the other thirty-one.

With a total area of 2,550 square miles, the department has 1,899 square miles (more than two-thirds) of arable land, while woods and pasture-land each occupy only about a twentieth. No department except Somme breeds fowls so extensively. Wheat, beetroot, and oil seeds are the principal crops. Besides there are considerable quantities of poppy-seed, flax, hops, hemp, and tobacco. There are two great coal-fields, that of Pas de Calais proper, a continuation of the coal-field of Valenciennes and Hainault, and that of Boulonnais. The former contains a total area of 134,270 acres; the latter is about a tenth of that size. The national powder-mills of Esquerdes are among the largest in France. The port towns fit out a considerable number of vessels for the mackerel, cod, and herring fishing—a growing industry. Calais is emphatically a transit port. Boulogne has besides an export trade in local products, such as marble, freestone, minerals, and Boulogne horses, remarkable for size and strength. The roads of the department (national, departmental, etc.) make a length of 9,393 miles, the waterways 105½ miles, the railways 546 miles, and the industrial railways 60 miles. In 1881 Pas de Calais had 819,022 inhabitants (311 per square mile), ranking sixth among the departments in density of population. It forms the diocese of Arras, in the archbishopric of Cambrai, belongs to the district of the first (or Lille) *corps d'armée*, and is within the jurisdiction of the Douai court of appeal. There are six arrondissements bearing the names of their chief towns—Arras (27,041 inhabitants), Bethune (10,374), Boulogne (44,842), Montreuil (3,352), St. Omer (20,479), and St. Pol (3,664). Other places of importance are St. Pierre-lès-Calais (30,786 inhabitants), the industrial town of Calais (13,529), Lens (10,515), Lievin (8,281), Carvin (6,430)—the last three with important coal-mines, and Aire (5,000), formerly a fortified place.

PASIPHAE. See MINOS.

PASKEWITCH, IVAN FEDOROWITCH, prince of Warsaw, and general-in-chief of the Russian army, was born at Poltava May 8, 1782. His first active service was in 1805, in the auxiliary army sent to the assistance of Austria against France, when he took part in the battle of Austerlitz. From 1807 to 1812 he was engaged

in the campaigns against Turkey, and distinguished himself by many brilliant and daring exploits. During the French war of 1812-14 he was present, in command of the twenty-sixth division of infantry, at all the most important engagements; at the battle of Leipsic he took 4,000 prisoners. On the outbreak of war with Persia in 1826 he was appointed second in command. In reward of his services he was raised by the emperor to the rank of count of the empire, with the surname of Erivan, and received a million of rubles and a diamond-mounted sword. From Persia he was sent to Turkey in Asia, and, having captured in rapid succession the fortresses of Kars, Erzeroum, and Akalkalaki, he was at the end of the campaign made a field marshal. In 1831 he was intrusted with the command of the army sent to suppress the revolt of Poland, and after the fall of Warsaw, which gave the death-blow to Polish independence, he was raised to the dignity of prince of Warsaw, and created viceroy of the kingdom of Poland. On the outbreak of the insurrection of Hungary in 1848 he was appointed to the command of the Russian troops sent to the aid of Austria, and finally compelled the insurgents to lay down their arms at Vilagos. In April, 1854, he again took the field in command of the army of the Danube, but on June 9, at Silistria, where he suffered defeat, he received a contusion which compelled him to retire from active service. He died January 29, 1856.

PASQUIER, ÉTIENNE, one of the glories of the French bar, and one of not the least remarkable men of letters of the sixteenth century, was born at Paris on June 7, 1529. He studied law early, and in 1547 was a pupil of the famous Cujas at Toulouse. Thence, like many of his contemporaries, he went to finish his studies in Italy. In 1565 his fame was established by a great speech still extant, in which he pleaded the cause of the university of Paris against the Jesuits, and won it. He was thenceforward constantly employed in the most important cases of the day, and his speeches, many of which we possess, displayed a polished eloquence which was new in his time. For some years Pasquier lived at Tours, but he returned to Paris in Henry IV.'s train on March 22, 1594. He continued until 1604 at his work in the *Chambre des Comptes*; then he retired. He survived this retirement more than ten years, producing much literary work, and died after a few hours' illness on September 1, 1615, at the age of eighty-six.

PASQUINADE is a variety of libel or lampoon, of which it is not easy to give an exact definition, separating it from other kinds. It should, perhaps, more especially deal with public men and public things. According to the received tradition, Pasquino was a tailor (others say a cobbler) who had a biting tongue, and lived in the fifteenth century at Rome. His name, at the end of that century or the beginning of the next, was transferred to a statue which had been dug up in a mutilated condition and was set up at the corner of the Pallazzo Orsini. To this statue it became the custom to affix squibs on the papal government and on prominent persons.

PASSAIC, a city in Acquackanock township, Passaic county, N. J., is located on the Boonton Branch of the Delaware, Lackawanna and Western and on the Erie railroad, eleven miles north of Jersey City and five miles south of Paterson. It is also situated on the Passaic river, and contains a city-hall, ten churches, two schoolhouses, two newspaper offices, and a large number of stores. The manufactures carried on are numerous and extensive, being made up of planing and saw mills, worsted and woolen mills, foundries and machine-shops, chemical works, print and blanket manufactories, sash, door, and blind, belting and pack-

ing, hard-rubber, wire, brick, cigar factories, etc., also gas and electric-light works. The banking facilities and hotel accommodations are ample, and the transportation conveniences requisite and adaptive. The population in 1890 was 13,027.

PASSAU, an ancient town and episcopal see of Bavaria, in the district of Lower Bavaria, at the confluence of the Danube, the Inn, and the Ilz, ninety miles to the northeast of Munich, and close to the Austrian frontier. Passau is one of the most beautiful places on the Danube, a fine effect being produced by the way in which the houses are piled one above another on the heights rising from the river. The chief products of the insignificant industry of the town are tobacco, leather, and paper. The well-known Passau crucibles are made at the neighboring village of Oberzell. Trade is carried on in iron and timber, large quantities of the latter being floated down the Ilz. The inhabitants (15,365) are nearly all Roman Catholics.

PASSERAT, JEAN, a poet of merit and a contributor to the *Satire Ménippée*, was born at Paris in 1534. He was a scholar by natural taste, and became a teacher at the Collège de Plessis, and at the death of Ramus was made professor of Latin in the Collège de France. This, however, was not till 1572. In the meanwhile Passaret had studied law, and had composed much agreeable poetry in the Pléiade style, the best piece being his short ode *On the First of May*, and the charming villanelle, *J'ai perdu ma tourterelle*. He died at Paris in 1602, and his poems were not published completely till four years later.

PASSION-FLOWER (*Passiflora*) is the typical genus of the order to which it gives its name. The species are mostly natives of western tropical South America; others are found in various tropical and subtropical districts of both hemispheres. The tacsonias, by some considered to form part of this genus, inhabit the Andes at considerable elevations. They are mostly climbing plants having a woody stock and herbaceous or woody branches, from the sides of which tendrils are produced which enable the branches to support themselves at little expenditure of tissue. Some few form trees of considerable stature destitute of tendrils, and with broad magnolia-like leaves in place of the more or less palmately-lobed leaves which are most generally met with in the order. The flower itself consists of a calyx varying in form from that of a shallow saucer to that of a long cylindrical or trumpet-shaped tube, thin or fleshy in consistence, and giving off from its upper border the five sepals, the five petals (rarely these latter are absent), and the threads or membraneous processes constituting the "corona." This coronet forms the most conspicuous and beautiful part of the flower of many species, and consists of outgrowths from the tube formed subsequently to the other parts, and having little morphological significance, but being physiologically useful in favoring the cross-fertilization of the flower by means of insects. The name passion-flower—*flos passionis*—arose from the supposed resemblance of the corona to the crown of thorns, and of the other parts of the flower to the nails, or wounds, while the five sepals and five petals were taken to symbolize the ten apostles—Peter, who denied, and Judas, who betrayed, being left out of the reckoning. In some of the botanical books of the sixteenth and seventeenth centuries curious illustrations of these flowers are given, in which the artist's faith or imagination have been exercised at the expense of actual fact.

PASSION PLAYS. See DRAMA. On the Oberammergau Passion Play, see OBERAMMERGAU.

PASSION WEEK, the fifth week in Lent, begins with Passion Sunday (*Dominica Passionis* or *de Pas-*

*sione Domini*), so called from very early times because with it begins the more special commemoration of Christ's passion. In non-Catholic circles Passion Week is often identified with HOLY WEEK (*q.v.*), but incorrectly.

**PASSOVER AND FEAST OF UNLEAVENED BREAD.** It is explained in the article **PENTATEUCH** that the ancient Israelites were accustomed to open the harvest season by a religious feast. No one tasted the new grain, not even parched or fresh ears of corn, till the first sheaf had been presented to Jehovah, and then all hastened to enjoy the new blessings of divine goodness by eating unleavened cakes, without waiting for the tedious process of fermenting the dough. This natural usage became fixed in custom, and at a comparatively early date a new significance was added to it by a reference to the exodus from Egypt, when, as tradition ran, the people in their hasty departure had no time to leaven the dough already in their troughs. The two elements of a thankful recognition of God's goodness in the harvest, which everyone was eager to taste the moment that Jehovah had received His tribute at the sanctuary, and of grateful remembrance of the first proof of His kingship over Israel, went very fittingly together.

**PASSPORT.** A passport or safe-conduct in time of war is a document granted by a belligerent power to protect persons and property from the operation of hostilities. In the case of the ship of a neutral power, the passport is a requisition by the Government of the neutral state to suffer the vessel to pass freely with her crew, cargo, passengers, etc., without molestation by the belligerents. The violation of a passport, or safe-conduct, is a grave breach of international law. The offense in the United States is punishable by fine and imprisonment where the passport or safe-conduct is granted under the authority of the United States (act of Congress, April 30, 1790). In a time of peace a passport is still necessary for foreigners traveling in certain countries, and is always useful, even when not necessary, as a ready means of proving identity. It is usually granted by the foreign office of a state, or by its diplomatic agents abroad.

**PASTE, or STRASS.** See **GLASS**.

**PASTON LETTERS.** This collection of documents consists of the correspondence of the principal members of the Paston family in Norfolk between the years 1424 and 1506, including several state papers and other documents accidentally in their possession. The papers appear to have been sold by William Paston, second earl of Yarmouth, the last representative of the family, to the antiquary Le Neve early in the eighteenth century.

**PASTORAL** is the name given to a certain class of modern literature in which the "idyl" of the Greeks and the "eclogue" of the Latins are imitated. It was a growth of humanism at the Renaissance, and its first home was Italy.

**PASTORAL EPISTLES**, the name given to three epistles of the New Testament which bear the name of St. Paul, and of which two are addressed to Timothy and one to Titus. The reason of their being grouped together is that they are marked off from the other Pauline epistles by certain common characteristics of language and subject-matter; and the reason of their special name is that they consist almost exclusively of admonitions for the pastoral administration of Christian communities. None of the Pauline epistles have given greater ground for discussion, partly on account of the nature of their contents, partly on account of their philological peculiarities, and partly on account of their historical difficulties.

**PASTORAL LETTER**, a letter addressed, in his pastoral capacity, by a bishop to his clergy, or the laity of his diocese, or both. In the Church of Rome it is usual for every bishop to issue at least one pastoral annually, the Lenten Mandates or Instructions, containing exhortations relating to that fast, and enumerating the dispensations granted and devotions prescribed. Others are issued in connection with the principal solemnities of the church, or as occasion arises.

**PATAGONIA**, in the widest application of the name, is that portion of South America which, to the east of the Andes, lies south of Rio Negro, and to the west of the Andes, south of the Chilian province of Chiloe, with a total area of 322,550 square miles (306,475 continental, 16,075 insular). By the treaty of October 22, 1881, this vast region was divided between Chili and the Argentine Republic, whereby about 62,930 of the 322,550 square miles fell to Chili and 259,620 to the Argentine Republic.

The southern coast of Patagonia is bounded for 365 miles by Magellan's Strait, which separates the mainland from the countless islands of the Tierra del Fuego archipelago and breaks it up into a number of very irregular peninsulas. Of these the largest are King William IV. Land and Brunswick Peninsula, and between them lies the extensive inlet of Otway Water, which is further connected westward by Fitzroy Channel with Skyring Water. On the east coast of Brunswick Peninsula opposite the Broad Reach of the strait, and in the finest part of the straitward district, lies the Chilian military post and penal settlement of Punta Arenas or Sandy Point.

Patagonia east of the Andes is for the most part a region of vast steppe-like plains. Unlike the pampas of the Argentine Republic, with which it is conterminous on the north, it rises in a succession of abrupt steps or terraces about 300 feet at a time, and is covered, not with soft, stoneless soil, but with an enormous bed of shingle, which, instead of luxuriant grass, supports, where it is not absolutely bare, only a thin clothing of coarse and often thorny brushwood and herbage. So peculiar is this, the largest tract of shingle in the world, that from D'Orbigny downward geologists have generally characterized it simply as the Patagonian formation. The guanaco, the puma, the zorro or *Canis Azarae* (a kind of fox), the zorrino or *Mephitis patagonica* (a kind of skunk), and the tuco-tuco or *Ctenomys magellanicus* (a kind of rodent) are the most characteristic mammals of the Patagonian plains. Vast herds of the guanaco roam over the country, and form with the ostrich (*Rhea americana*, and more rarely *Rhea Darwinii*) the chief means of subsistence for the native tribes, who hunt them on horseback with dogs and bolas.

Eastern Patagonia is traversed from west to east by a considerable number of rivers, but few, if any, can ever be of much use as highways. In their passage seaward they are joined by comparatively few tributaries from the low country; rain falls seldom, and the water sinks away among the shingle and sand. The Rio Negro, which separates the pampas from Patagonia proper, is formed by the junction of the Neuquen and the Limay. For some distance the Rio Negro is navigable for steamers drawing twelve feet, but only vessels with powerful engines can make head against the current. The next great Andean river is the Chubut, which gives its name of Chubut Territory to the northern division of Argentine Patagonia, and is well known from the Welsh colonies established in its valley in 1865 by Mr. Lewis Jones. Patagonia was discovered in 1520 by Magellan, who called the country Tierra de Patagones, from the large footsteps observed near his winter quarters at San Julian. In the latter half of the eight-

eenth century our knowledge about Patagonia was considerably augmented by Byron (1764-65), Wallis (1766), Bougainville (1766); Thomas Falkner, a Jesuit who "resided near forty years in those parts," published his *Description of Patagonia* (Hereford, 1774); Francesco Viedma founded El Carmen, and Antonia advanced inland to the Andes (1782); and Villarino ascended the Rio Negro (1782). The *Beagle* and *Adventure* expeditions under King (1826-30) and Fitzroy (1832-36) were of first-rate importance, the latter especially from the participation of Charles Darwin; but of the interior of the country nothing was observed except 200 miles of the course of the Santa Cruz. Captain Musters wandered in company with a band of natives through the whole length of the country from the strait to the Manzaneros in the northwest, and collected a great deal of information about the people and their mode of life. Since that date explorations of a more scientific character have been carried on by Moreno (1873-80), Rogers (1877), Lista (1878-80), and Moyano (1880, etc.)

PATARENES, a name apparently first used in Milan about the middle of the eleventh century to denote the party most extremely opposed to the marriage of priests; besides Patareni, the forms Paterini, Patarelli, Pataræi occur among others.

PATENTS. By the means of patents inventors obtain a monopoly in their inventions for a certain span of time considered sufficient to remunerate the deviser. This monopoly is founded on exactly the same principle as the copyright enjoyed by authors and artists. There are persons who argue that no such privilege should be permitted; there are others who think that the most trifling exertions of the inventive faculties should be protected. The right course lies between these extremes. All civilized nations have in modern times considered it desirable to give inventors an exclusive right to their inventions for a limited period, not only as a matter of justice to individuals but as a piece of sound policy tending to the advantage of the whole community. The monopoly is granted in the expectation that the inventor will derive some profit from it; and the hope of profit is known to be a great stimulus to invention. When an author writes a book, or an artist designs a picture, the law allows a right of property to those persons in their productions, and accompanies the recognition of this right with the power to repress infringements. If this were not so, probably very few persons would employ their time in writing books or creating works of art; and hardly anyone will be bold enough to assert that the extinction of the race of authors and artists is to be desired. The same principle applies to inventors, who ought to have the works of their brain protected from piracy fully as much as the other classes of mental producers. By holding out to them the prospect of gain they are induced, at a present loss of time and money, to attempt to discover improvements in the useful arts, in machinery, in manufacturing processes, etc.; and thus the interests of the community are advanced more rapidly than if such exertions had not been brought into play. Just as the rule of rewarding inventors is in theory attended with some difficulty, so is the practical application of it. To grant a very long term of exclusive possession would be detrimental to the public, since it would tend to stop the progress of improvement. A limited property must therefore be allowed—large enough to give the inventor an opportunity of reaping a fair reward, but not barring the way for an unreasonable period. And, when this compromise has been decided on, it will be seen how difficult it may be to determine beforehand what is the real merit of an invention, and apportion the time

to that merit. Hence it has been found necessary to allot one fixed period for all kinds of inventions falling within the purview of the patent laws. This regulation appears to be open to the complaint that the least valuable and the most meritorious inventions are placed on the same footing. But it may be replied that in the result this is of little consequence, since meritorious inventions alone obtain the patronage of the public, those which are destitute of value being neglected. Besides, if the complaint were well founded, there is here no sound argument against the policy of privileges of this nature, seeing that it is impossible to weigh beforehand one invention against another in the scale of merit, or to obtain a true standard of comparison.

The inventions for which patents are obtained are chiefly either vendible articles formed by chemical or mechanical operations, such as cloth, alloys, vulcanized india-rubber, etc., or machinery and apparatus, or processes. It may be remarked here that a scientific principle cannot form the subject of a valid patent unless its application to a practical and useful end and object is shown. An abstract notion, a philosophical idea, may be extremely valuable in the realm of science, but before it is allowed to form a sound basis for a patent the world must be shown how to apply it so as to gain therefrom some immediate material advantage.

The principal classes of patentable inventions seem to be these: (1) new contrivances applied to new ends, (2) new contrivances applied to old ends, (3) new combinations of old parts, whether relating to material objects or to processes; (4) new methods of applying a well-known object.

With regard to a patent for the new application of a well-known object it may be remarked that there must be some display of ingenuity in making the application, otherwise the patent will be invalid on the ground that the subject-matter is destitute of novelty.

Whatever be the nature of the invention, it must possess the incidents of utility and novelty, else any patent obtained in respect of it will be invalid. The degree of utility need not, however, be great. As to novelty, this is the rock upon which most patents split, for, if it can be shown that other persons have used or published the invention before the date of the patent, it will fall to the ground, although the patentee was an independent inventor deriving his ideas from no one else.

The attributes of novelty and utility being possessed in due degree by an invention, the chief remaining difficulty with which a patent has to contend resides in the complete specification, the instrument by which the inventor describes the nature of the invention and the means by which it may be carried into effect. An inventor is bound, in return for the monopoly conceded to him, to instruct the public how to work the invention when the monopoly shall have expired, and to inform them in the meantime what it is they are shut out from using; and now the patent is not granted till the complete specification is filed. The patentee is bound to make by this instrument a full disclosure of his secret; he must not keep anything back either willfully or accidentally; he must render everything plain and clear, showing no attempt to mislead, and leaving nothing ambiguous; he must distinguish what is old from what is new; he must point out distinctly what it is that he claims as his own exclusive property, and he must take care that he claims no more than he is entitled to.

Patent privileges, like most other rights, can be made the subject of sale. Partial interests can also be carved out of them by means of licenses, instruments which

empower other persons to exercise the invention, either universally and for the full time of the patent (when they are tantamount to an assignment of the patentee's entire rights), or for a limited time, or within a limited district. By an exclusive license is meant one that restrains the patentee from granting other licenses to anyone else. By means of a license a patentee may derive benefit from his patent without entering into trade and without running the risks of a partnership.

Under an act passed in 1874 a patent must in all cases be applied for in the name of the original inventor, although he may contemporaneously execute an assignment of the invention, and the patent will thereupon be issued to the assignee. Every application is referred to an official examiner. The patent will be refused if any part of the invention is wanting in novelty, or if the application is not in proper form. The applicant may, however, make a re-application, and if the inventor is dissatisfied with the report of the examiner he can appeal. Patents are issued for the term of seventeen years, but expire with any earlier foreign patents for the same invention. A foreign inventor may obtain a patent if his invention has not been in public use or on sale in the United States for more than two years prior to his application.

**PATERCULUS, MARCUS VELLEIUS**, a Roman historian, was probably born about 19 B.C. His father, a cavalry officer, belonged to a good Capuan family, several members of which had risen to some military or magisterial distinction. The historian himself served as military tribune in Thrace, Macedonia, Greece, and the East, and in 2 A.D. was present at the interview on the Euphrates between C. Cæsar (grandson of Augustus) and the Parthian king. Afterward as præfect of cavalry and legatus he served for eight years (from 4 A.D. onward) in Germany and Pannonia under Tiberius, in whose triumph (12 A.D.) he and his brother bore a conspicuous part. For his services he was rewarded with the quæstorship in 7, and, along with his brother, with the prætorship in 15. He was still alive in 30, for his history contains many references to the consulship of M. Vinicius in that year. The date and manner of his death are unknown. It has been conjectured that he was put to death in 31 as a friend of Sejanus, whose praises he celebrates.

He wrote a compendium of Roman history in two books dedicated to M. Vinicius, from the dispersion of the Greeks after the siege of Troy down to the death of Livia in 29 A.D. The first book brings the history down to the destruction of Carthage, 146 B.C.; portions of it are wanting, including the beginning. The latter history, especially the period from the death of Cæsar, 44 B.C., to the death of Augustus, 14 A.D., is treated in much greater detail.

**PATERINES.** See **PATARENES.**

**PATERNÓ**, a town of Sicily, in the province of Catania, stands at the southwest foot of Mount Ætna, ten miles northwest of Catania, near the railway from that city to Leonforte. Population, 15,230.

**PATERSON**, capital of Passaic county, New Jersey, is situated on the Passaic river and the Morris Canal, seventeen miles northwest of New York. As the river which forms the boundary of the city for a distance of nine miles has at one place a sheer fall of fifty feet, it is an unfailing source of abundant water-power; and Paterson ranks second among the manufacturing cities of the State. Silk, iron, and cotton are the great industrial staples; silk-dyeing is also practiced. One of the chief industries is the making of locomotives. Further, fire-engines, "Whitney" sewing-machines, iron bridges, brass wares, flax, hemp, and jute goods, calico-prints, paper, and chemicals are all

manufactured. The population was 11,334 in 1850, 19,586 in 1860, 33,579 in 1870, and 51,031 in 1880, and is now (1890) 78,347. Founded in 1792 by a cotton company under the patronage of Alexander Hamilton and named after Gov. William Paterson, who signed its town charter, Paterson obtained the rank of a city in 1851.

The city contains a public library with 12,000 volumes, has a system of water-works and is lighted by gas and electricity. It has a police force of seventy-five men, costing \$70,000 per annum. The volunteer fire department consists of 636 men, with 9 steam fire-engines, 11 hose-carts etc., maintained at a cost of \$48,200. The annual expenditure for schools is \$144,353, and for public charities \$38,000. In 1889 the city treasury receipts were \$1,507,025, the expenditures \$1,343,100; total debt, \$1,513,490.

**PATERSON, WILLIAM**, founder of the Bank of England, projector of the Darien scheme, and a voluminous writer on subjects connected with finance, was born in April, 1658, in Scotland. About 1690 he was occupied in the formation of the Hampstead Water Company, and in 1694 he founded the Bank of England. The government of the day required money, and the country, rapidly increasing in wealth, required a bank. The subscribers lent their money to the nation, and this debt became the bank stock. The credit of having formulated the scheme and persuaded the government to adopt it is certainly due to Paterson. He was one of the original directors, but in less than a year, in consequence of some dispute with his colleagues, he withdrew from the management. He removed to Edinburgh, unfolded his Darien scheme, and soon had the whole nation in favor of it. He, it is supposed, drew up the act of 1695 which formed the "Company of Scotland trading to Africa and the Indies." This company, he arranged, should establish a settlement on the isthmus of Darien, and "thus hold the key of the commerce of the world." There was to be free trade, the ships of all nations were to find shelter in this harbor not yet erected, differences of race or religion were to be made nothing of; but a small tribute was to be paid to the company, and this and other advantages would so act that, at one supreme stroke, Scotland was to be changed from one of the poorest to one of the richest of nations.

On July 26, 1698, the first ships of the expedition set sail "amidst the tears and prayers and praises of relatives and friends and countrymen." Some financial transactions in which Paterson was concerned, and in which, though he had acted with perfect honesty, the company had lost, prevented his nomination to a post of importance. He accompanied the expedition as a private individual, and was obliged to look idly on while what his enemies called his "golden dream" faded away indeed like the "baseless fabric of a vision" before his eyes. Ill, weak, and helpless, and yet protesting to the last against the abandonment of Darien, he was carried on board ship, and, after a stormy and terrible voyage, he and the remnant of the ill-fated band reached home in December, 1699. In his native air Paterson soon recovered some of his strength, and immediately his fertile and eager mind was at work on new schemes. First he did all he could to prevent the Darien scheme already engaged in from being finally abandoned, then he prepared an elaborate plan for developing Scottish resources by means of a council of trade, and then he tried to induce King William to enter on a new Darien expedition. About the beginning of the century he removed to London, and here by conference with statesmen, by writing, and by personal persuasion helped on the Union. He died January 22, 1719.

**PATHOLOGY**, anatomy and histology investigate the naked-eye and microscopic structure of the healthy body; physiology examines the functions of the parts and elements revealed by them, and studies the chemical processes which constitute healthy life. To obtain a knowledge of disease parallel courses must be adopted. In post-mortem examinations we note all naked-eye departures from normal anatomy; next, the microscope is employed to show the finer changes to which these departures are due; and, lastly, we endeavor to find out the causes of the abnormal structure and function which constitute the disease, their mode of action, and the nature and sequence of the disturbances which they produce. We thus get pathological anatomy and histology, and pathology—the physiology of disease.

The guiding principle of modern pathology being that pathology has to deal with no new tissue-cell or function, but simply with disturbance of normal elements and functions, it is obvious that for the purpose of studying disease our acquaintance with the body in health cannot be too intimate. As causes, not products, of disease, new cells (bacteria) and even entire animals (parasitic worms, etc.) are frequently introduced into the tissues.

The complex human organism can be reduced to very simple elements—cells and the intercellular substances to which they give origin. These elements make up every tissue, the cells being sometimes in excess, as in epidermis, where they seem to be in absolute contact—sometimes the intercellular substance, as in the connective tissues. It is now universally accepted that the cell is the seat of nutrition and function. Health and disease must be considered as terms referring not to the body as a whole, but to the cells of which it consists.

Before treating of disease we will say a few words upon the constitution of cells in health, and upon their functions and the conditions under which they are physiologically discharged.

*Constitution of Cells.*—When Schwann established the analogy between the animal and vegetable cell, the former was held to be constructed, in all cases, upon the same principle as the latter, and to consist of a cell-wall inclosing a cavity in which were contained a nucleus and fluid contents. But the fact that no cell-wall can be demonstrated in embryonic cells, blood corpuscles, and the cells of many rapidly-growing new formations led Leydig and Max Schultze to believe that a little mass of matter, inclosing a nucleus, was all that was necessary to constitute a cell. Max Schultze established the identity of the cell substance with animal sarcode, a contractile substance existing in the lower animals, and showed that it also was capable of spontaneous movement. He called the substance of which all cell-bodies, animal or vegetable, are, at least at one period of their existence, composed, protoplasm, and pointed out that a distinct cell-wall resulted from a retrograde process occurring in its outer layers. Doctor Beale promulgated similar views.

The definition of a cell has been still further modified by the discovery that a nucleus is not essential; for none exists in the cryptogamia and in some of the lowest animal forms. In these exceptional cases the cell consists of a simple mass of protoplasm, but in the higher animals the nucleus is almost constant. The cell-wall is much less so, and must be regarded, in point of vitality, as inferior to the rest of the cell.

Protoplasm is a very complex body, of the molecular constitution of which we are ignorant. It contains a large quantity of water, and its solid residue is largely made up of albuminoid material; but with this there are always associated, apparently in an amalgam-like way, some carbohydrate, fat and inorganic salts; for they

are invisible, yet not in true combination. Some authorities regard the proteid element as alone essential to the manifestation of life. Protoplasm, as seen in the bodies of normal cells, is generally structureless, soft, and viscid, but varying much in fluidity. Granules are frequently present in it, often in one part and not in another, and these probably always differ chemically from true protoplasm. Small cavities, full of fluid, looking like clear spaces, are often seen; they are called vacuoles, and may either riddle the cell or one large one may occupy much of its body. They appear, disappear, and change their position.

In highly specialized cells protoplasm has acquired a distinct structure, *e.g.*, the fibrillation of muscle and nerve-cells and the striation of many ciliated cells and gland-cells. In many cells, after hardening in chromic acid, a fine network of fibers is seen in the cell-substances, a fact which has led Klein and others to believe that the protoplasm of cell-bodies is really arranged like a sponge, the interstices being occupied by fluid containing granules which are moved about by contractions of protoplasm. This view explains many phenomena of cell-life; but up to the present time has not been supported by the observation of living cells.

Under certain circumstances protoplasm undergoes metamorphoses into various substances, *e.g.*, mucin, globulin, keratin, pepsin, and other ferments, glycogen, celloid, and fat, which may form large portions of the bodies of cells. When glycogen and fat arise from a proteid, a nitrogenous molecule must also be formed.

This protoplasm is the essential constituent of the body of every cell. In comparison with the nucleus the body varies much in size, being sometimes large, sometimes quite insignificant. The cell-wall, when present, is of much firmer consistence than the rest of the body, and seems to be due to some metamorphosis of the protoplasm of the latter.

The nucleus is more constant than the body, in both size and form. It is usually spherical or oval, but may be quite rod-shaped; is generally placed near the center of the cell, and may be single or multiple. It resists destructive reagents more strongly than does the body, and in disease often remains after this has been destroyed; it is stained more deeply by carmine and logwood. Its presence may be concealed by fat, pigment or other substances in the cell body. The nucleus does not exist in red blood-corpuscles, and it is doubtful whether the nucleated red blood-corpuscles of the early embryo disappear or are converted into the non-nucleated disks which succeed them. Those formed endogenously in connective tissue-corpuscles in later foetal and extra-uterine life are apparently never nucleated; they have been likened to chlorophyll-granules. The nucleus of epidermic scales may finally be converted into keratin, and disappear.

The nucleus, which was formerly regarded as a spherical vesicle bounded by definite membrane which separated the nuclear fluid from the cell substance, is now known to possess with great constancy the following much more intricate structure:—(1) A membrane bounding it externally; (2) a network of fibers, probably contractile, and certainly capable of great changes in closeness and general form; (3) one or more nucleoli, said by some to be only nodal points in the network; (4) a clear, more or less fluid substance which fills the membrane and lies in the meshes of the network. The more solid portions, membrane, network, and nucleoli are spoken of as nucleoplasm; the less solid as nuclear matrix. Under **GENESIS OF CELLS** (*q. v.*) we shall describe the remarkable changes which occur in nuclei previous to the division of cells.

*Physiology of Cells.*—We will now give a short **sum-**

mary of the normal function of cells, and of the conditions under which they are physiologically discharged.

A unicellular organism, like the amœba, takes in food, grows and excretes, performs certain functions, of which motion is the most obvious, and reproduces its like. The whole of this may be regarded as work done, and implies the expenditure of force; and we may be quite sure, although we know nothing of the chemical processes going on in an amœba, that its excreta are simpler compounds than its ingesta, the difference in heat value between these two sets of compounds representing the force which is available to the organism. The ability to effect these chemical and physical processes, in which the "life" of the animal—as recognizable by us—consists, is inherited, and is spoken of as "vital activity," or "vital energy." The possession of this is naturally the first essential to living. The other requirements of the cell are a sufficient supply of suitable food and appropriate surrounding physical conditions, such as normal temperature and suitable density of the surrounding fluid.

In man, a multicellular being, the cells vary much in form and in the results of the chemical action which they effect. Although retaining more or less independence, varying with the kind of cell, they are bound together for the common good, and each has some special function to perform. Thus there are muscle-cells to produce motion, gland-cells to secrete and excrete, and nerve-cells to control the working of muscle, glands, and perhaps other tissues; certain cells are set apart for reproduction; and, finally, there are the connective tissues to unite and support the other structures, and surface epithelium to protect them. Thus each kind of work done by the one cell of the amœba is in man performed by a group of cells specialized for the purpose. If, then, we recognize the interdependences of the cells in the human organism upon each other, and the differences in their structure and purpose in the economy, all that has been said of the amœba will apply to each cell of the body; all the functions of the amœba are probably present in each cell; but one—*e.g.*, contractility of a muscle-cell—is often so highly developed as to be called the function of the cell.

*Vital Activities.*—The vital energy of each cell manifests itself in three channels; hence Virchow speaks of the nutritive, functional, and reproductive activities. Between the two former there is no line—the existence of the one implies that of the other; both are chemical and may be considered together. Food is taken into the body, digested and absorbed by lacteals and blood-vessels from the intestines; the various excretory organs give off urea, and, in small quantity, other nitrogenous bodies, carbonic acid and water. Supposing the body to be in nutritive equilibrium—neither gaining nor losing weight—the amounts excreted will account for the nitrogen, carbon, and hydrogen taken in as food. Putting aside water, certain salines, and oxygen, which are essential to life, the foodstuffs are albumen, carbohydrates, and fats—the materials of which the body consists. It is evident that a large amount of heat must be set free in the breaking down of these bodies to the excreta above mentioned; and this is the source of the force by which every act is performed. The blood carries the prepared foodstuffs to the capillaries, where they pass out with the lymph to come into actual contact with the cells—some in solution, others only in suspension. Certain or all of these bodies are now taken up (apparently actively, for albumen will not diffuse from a watery fluid), and become part of the substance of a cell, replacing some older material, which has been broken down to supply force for assimilation and all other actions of the cell. This breaking down

of cell substance consists in union of it with oxygen obtained from the blood and stored by the tissues in some unknown way. All such oxidation processes are believed to take place in the cells, not in the blood; and this almost necessitates that all food shall become part of a cell before it is oxidized; it is not oxidized directly. Although the tissues of the body and the foodstuffs have almost the same chemical composition, waste tissue is not repaired by a process of simple replacement from the food, if we except fat; when a fat of the same composition as human fat is contained in the food, it may be stored in the cells without undergoing previous change, but usually some slight addition or subtraction of hydrogen is necessary. It is probable that many changes, both analytical and synthetical, occur in the arrangement of the elements of foodstuffs before they form protoplasm, the real living tissue, and force is thus alternately liberated and rendered potential; but this does not affect the main fact that the body ultimately obtains the force equivalent to the difference in heat value between the ingesta and excreta.

We have enumerated the compounds presented to cells in lymph, and also those which leave the body as the ultimate products of cell-action; but in no instance do we know the connecting links between the end products. While the ingesta of cells must be tolerably uniform in character, their excreta are probably as various as are the uses of the cells in the body—witness the different compositions of the many secretions and the unequal distribution of the extractives such as kreatin, xanthin, etc. The breaking down of tissue, or waste, which is going on constantly on the one hand, and the building up or repair which in health keeps pace with it on the other, constitute the nutritive exchange of the cell or of the whole body. This process is constantly being disturbed from pathological causes; and, physiologically, formation exceeds waste during the period of growth, but the opposite obtains in old age, when the vital energy of all cells is failing and their functions are imperfectly discharged.

The excreta pass in two directions—into lymph and back into blood, or out into a mucous or cutaneous surface, whence part may be absorbed—*e.g.*, saliva, gastric juice, and part of the bile.

*Conditions of Health of a Cell.*—That the nutritive exchange of the cells of the body may be normal the same conditions must be present as those necessary for the healthy life of an amœba. These are—1, the possession of normal vital activity or ability to effect chemical change; 2, a sufficient supply of food of suitable quality, depending in man upon the circulation and blood constitution; and 3, the presence of appropriate surrounding physical conditions. To these must be added, in the case, at least, of nerve, muscle and certain gland-cells, 4, connection with a healthy nervous center.

*Influence of the Nervous System upon Nutrition.*—When motor nerve fibers are cut off from ganglion-cells of the anterior cornu, or when sensory are severed from those of the posterior spinal ganglion, they rapidly atrophy, the axis-cylinders being probably long processes of these cells. Section of a motor nerve causes atrophy of the muscles supplied by it, and section of the chorda tympani is followed by wasting of the submaxillary gland. Each of these tissues has an active function to perform, but physiologically this function is never performed except in response to nervous stimulus. Removal of this consequently checks or annuls their nutritive exchange and deprives them of the afflux of blood which accompanies their action. In the above instances the nervous system undoubtedly exercises a trophic influence, though not by means of any special

trophic nerves. It is said by some to have the same influence over all the cells of the body; but this is denied by others, who fully allow its power over nerves, muscle, and such glands as secrete physiologically only in response to stimulation of special secretory nerves. The question at issue is, whether the nervous system influences those chemical changes in which the life of cells, other than gland, muscle, and nerve, consists. The discussion is carried on mainly with reference to the "non-working cells"—connective tissues and epidermis. Can the nervous system increase the vital energy of a cell and cause it to assimilate more food, to grow and multiply? Can it exhibit the performance of these functions and produce atrophy? Or can it so change the metabolism of cells that their products become irritating and cause inflammation? The question is a very important one, and cannot at present be decided.

In the first place, a general objection has been raised to experiments having for their object to prove the presence of special trophic nerves, viz., that the influence of other kinds of nerves, especially vaso-motor, has not been eliminated. It is necessary to remember always that after section of the nerves of a limb the part beyond is insensitive, its muscles never contract, the afflux of blood which accompanies their action is lost to the part, and the venous circulation no longer receives help from them. Its vessels at first dilate when the central control is removed, and the part reddens and warms from flow of a larger quantity of blood through it; but soon the general increase of tonus compensatory to the local diminution dies away, the vessels of the part remain dilated, and the flow through them becomes slower than natural, consequently the part is cold and pale or bluish. After a time, however, the local vascular nerves gain power, and a certain amount of tonus, which is easily upset, is restored. These disturbances in the nutritive and physical conditions of a part may explain many changes in it without calling into existence a special set of nerves.

The facts which are held to prove the influence of the nervous system on the nutrition of cells in the non-working tissues are the following:—The fall of the carbonic acid discharge which occurs when the body is exposed to a high external temperature and the increase which results from opposite conditions, show that diminished and increased chemical changes share with vaso-motor changes the duty of maintaining an average temperature. It seems most probable that the alterations in metabolic activity are owing to nerve influence, but it has not been proved that this is exercised on non-working tissues. It has been stated above that the chemical decomposition which gives rise to muscular contraction occurs physiologically only in response to nervous stimuli, and part of the force liberated appears as heat. It is possible that the decomposition may be effected slowly under nerve influence without causing contraction, force being manifested as heat only. Perhaps this may be one way in which the rise of temperature in fever is raised.

The diabetes which results from head injuries and from puncture of the floor of the fourth ventricle seems certainly to be due to a too rapid conversion of glycogen into sugar in the liver cells; and Foster inclines to the view that this is due to the direct action of nerves on the cells. But others connect the abnormal metabolism with the dilation of the hepatic arteries and free supply of arterial blood which always results from puncture.

Many inflammations of the skin, mucous membranes, viscera, bones, and joints are described as due to section or irritation of trophic nerves.

In some cases of hemiplegia (especially from hemor-

rhage), and occasionally from saber-wounds of the brain, extremely acute bedsores form on the opposite buttock; and similar lesions appear over the sacrum in paraplegia from sudden extensive pathological or traumatic lesions of the cord. They are distinguished from ordinary bedsores by the early date (second or third day) and acuteness of their onset, and the uselessness of the usual precautionary measures. Cohnheim objects to these that they are but differences of degree, and that there is no constancy in their occurrence with apparently similar lesions of any particular part of the cerebro-spinal axis. It certainly is strange that trophic influence should be so marked just at pressure spots: doubtless the nerve lesion is merely predisposing. In this class of cases, too, cystitis and pyelitis may appear at about the same time as the bedsores; and Charcot thinks that these inflammations are due to irritation of trophic nerves; but as exceedingly foul urine, which invariably contains organism, is noted before or with the cystitis, others believe that the latter is due to organisms introduced from without (often by a septic catheter), or from within through the kidneys, which render the urine extremely irritant by putrefaction. Similar cases occasionally occur after the passage of a few catheters in cases of enlarged prostate.

*Trigeminal Keratitis, etc.*—Intracranial section of the fifth nerve causes cloudiness of the cornea twenty-four hours, and often destructive panophthalmitis; at the same time ulcers appear on insensitive parts of the mucous membrane of the mouth and nose. The ulcers in the mouth are probably due to unheeded injuries from the teeth, but ulcers from the nose cannot thus be accounted for.

It is said that keratitis can be prevented by most carefully protecting the eye from injury with the still sensitive ear. Ulcers on the foot, often progressive, after section of the sciatic are similarly accounted for.

Pneumonia after section of the vagi is due to entry of food, etc., through the insensitive glottis, but this will not account for pneumonia or pulmonary apoplexy on the side opposite to a cerebral hemorrhage. Acute fatty degeneration of the heart may follow section of the vagi; the *modus operandi* is unknown.

Erythema, Urticaria, Pemphigus, and especially Herpes, may appear in the distribution of nerves which are the seats of some irritant lesion, as after fractured spine, in locomotor ataxy and other scleroses of the cord, compression by an aneurism or tumor, or inflammation of the Glusserian or a posterior spinal ganglion. The nerves supplying the area of the rash have been found in a state of neuritis.

The rapid variations of erythemata and urticaria certainly seem to point to a nervous origin, but do they involve more than an acute vaso-constrictor paralysis?

*Glossy Skin (Paget).*—In some cases of irritative lesion of the sensory nerves of limbs (*e.g.*, from gunshot) the skin becomes smooth, shiny, hairless, sometimes hyperæmic, sometimes œdematous, often superficially inflamed or the seat of sores like chilblains; at the same time the part is often the seat of intense neuralgia. Less severe symptoms, but obviously similar, are seen after simple section, and may be due to disturbances of circulation and temperature and to anæsthesia.

*Pigmentation.*—More or less symmetrical patches of leucoderma and melanderma may occur all over the body with more or less anæsthesia; pallor with anæsthesia and localized grayness of hair may to some extent return between the attacks. Cases have been recorded in which the hair has within a short time of a fright become gray.

Serious synovitis and arthritis, with rapid, painless and great erosion of the articular ends of the bones

may occur in cases of hemiplegia and ataxia, and are supposed to be due to involvement of the cells of the anterior cornu by progressive sclerosis. The casual relationship between the nervous disease and the peripheral lesion cannot be yet said to be proved.

*Atrophy of Parts Cut Off from the Nervous System.*—Muscle and certain glands have been treated of above. In the case of muscle, it is to be noted that if it is regularly exercised by the galvanic current, atrophy may long be postponed. In a paralyzed limb all tissues ultimately waste; so also does the face when paralysis of the facial nerve is not recovered from. This is due to impaired blood-supply, for it occurs in limbs which are simply kept at rest. Atrophy of the cock's comb and turkey wattles results from section of their nerves, and is perhaps to be similarly explained. In cases of progressive atrophy of half the face there may be nothing to guide one to the nervous system as the cause; there may be no subjective symptoms, and sensation and motion remain normal. If due to nervous influence, this atrophy would seem to favor the existence of trophic nerves.

Hypertrophy of bone may follow section of the sciatic in young animals and is inflammatory; for it never occurs unless large ulcers form extending to the bone and even causing necrosis. Hypertrophy of the rabbit's ear after section of its nerves has been said to occur, but many observers have failed to produce it or have at most seen thickening of epidermis and hair upon it.

There is, then, no reliable evidence of the existence of special trophic nerves and no convincing proof of the interference of the nervous system and the chemical processes of cells which perform no special function. That these processes may go on undisturbed in the absence of nervous influence is shown by the perfect development of other parts which is found in anencephalous and amyelous embryos, by the growth of transplanted epithelium and connective tissue and by the union of completely severed parts. At the same time, as we cannot offer a perfect explanation of many of the above-mentioned cases, we cannot say that the nervous system has no direct influence upon connective tissues and epidermic cells: it seems most probable that it has. In the present state of our knowledge, however, it is dangerous to explain anything by such an influence; it is better to leave it doubtful.

*The Reproductive Activity.*—Having now dealt with the nutritive and functional activities, we must consider the reproductive. In early life at least all cells possess the power of reproducing their like and in the majority this power is retained, although it may not be exercised physiologically up to advanced age. Cessation of growth does not imply absence of ability to grow, for growth seems to cease when the supply of nutritive material to a part is only just sufficient to maintain its *status quo*. This is seen in a hair which will not grow beyond a certain length. Cut it short and a growth at once begins again, the supply of food being greater than the now shortened hair requires for simple nutrition. To cause cells which are capable of multiplying to do so the supply of food must be increased. Thus, exercise of a muscle causes increased blood supply and consequent growth, but increased blood supply to a working tissue without exercise will not have this effect. It is different with non-working tissues. The hyperæmia around an ulcer of the skin and even chronic congestion of the œdema of a part causes thickening of epidermis and connective tissues, and nothing is commoner than new formation of bone around a carious focus. For this effect the increased supply must be very frequent or long continued.

A non-working tissue apparently tends to grow also

when the resistance offered to its growth by neighboring tissues is diminished. Of this we shall find many examples in cirrhotic processes and in the etiology of malignancy.

The cells of the body inherit very different amounts of vital energy. The cells of the thymus are soon exhausted, those of the epiphyseal cartilages, later, and of the generative organs later still. In all cases probably the reproductive activity is the first of the vital manifestations to suffer, then the functional and nutritive. Inability to perform such chemical changes as are necessary to remove effete material and to repair waste is natural in old age. Death which may be termed natural then results from senile decay.

#### DISEASE.

Having thus dealt with the structure and functions of cells in health, we may now turn our attention to disease. The functions of an organ are really the functions of the cells of which it consists. If all these act normally we say that the organ is sound, and when all the functions of every organ and tissue of the body are normally performed we say the individual is in perfect health. A very little experience shows that the physiological functions of the body vary within certain, perhaps rather wide, limits, the perfect well-being of the individual being maintained; consequently our standard of health is no rigid one. Its maximum and minimum are widely separated, and the latter shades off imperceptibly into disease.

The tendency to inherit disease either exists in the ovum at the commencement of development or is acquired by the ovum in fertilization. Later than this any tendency appearing is obviously acquired. As in normal development certain organs manifest their inherited tendencies many years after birth—*e. g.*, the development and atrophy of the female generative system at puberty and menopause, the appearance and union epiphyses—so inherited tendencies to disease (although, like normal tendencies, they may appear *in utero*) may not show themselves until late in life, as is the case in cancer of the breast or uterus. It is possible that in many cases the same unrecognized conditions which induced in a parent the morbid tendency handed down continue to act on the offspring, until—with or without some obvious exciting cause—the disease becomes evident.

Starting with an organism or part, the vital energy of which is normal, disease, if it occur, must necessarily be the result of external conditions. The supply of food is faulty in either quantity or quality, or the physical conditions to which the part is or has been exposed are unsuitable. It is difficult to separate the two. If the blood supply to a part is abnormal in quantity the temperature of the part will be changed. If a portion of the body is mechanically injured its blood supply becomes abnormal. If a poison excites fever, the cells are exposed to a higher temperature than normal. A *circulus vitiosus* is established. Disease may be acquired during intra-uterine life, *e. g.*, acute specific syphilis.

Any change in the external conditions acting upon a unicellular organism would probably affect every particle of its substance and modify all its functions. All its disease would therefore be general, but multiplication of cells and specializations of functions enable abnormal conditions to act upon certain groups of cells and to disturb their functions without affecting, primarily, those of other groups. We thus get local disease, and the great majority of diseases belong to this class. Perhaps, indeed, we may say that every disease is primarily localized in a tissue or or-

gan, the blood being counted as a tissue of the connective type, of which the intercellular substance is fluid.

A disease is localized in an organ or tissue during life by its symptoms and by its physical signs, and after death we as a rule find the localization justified by the discovery in the part of some constant structural change. This is structural disease. In a large number of cases, however, there are no physical signs, only symptoms, for the signs are secondary to some primary abnormality of function in one or more organs. There may then be doubt as to the organ or system at fault, and often this doubt can be settled only by the discovery of the constant structural change associated by the symptoms in question. Diseases in which no such change has been found have been classed as functional, the belief being that in them the functions of certain cells are abnormally performed without any structural change. Modern research has greatly diminished the number of functional diseases. Organic disease probably in the first place meant that pathologists had been able to localize a disease in an organ by means of structural change in it. It is now come to be used as synonymous with structural.

The causes of diseases are divided into two—predisposing and exciting.

Any agency which tends to cause departure from the physiological state of the body must be regarded as predisposing to disease—*e. g.*, privation, frequent irritation. Many such agencies when acting more strongly become excitants of disease, that is, cause the step outside the physiological limit to be taken. The power of resisting certain causes of disease does not imply power to resist others of a different nature, nor does it necessarily go with muscular strength. It varies at different times in the same individual. The following predisposing causes are generally considered: Age, sex, heredity, exciting causes, which may be ranged under the headings of abnormal food-supply and abnormal physical conditions. The organs special to the sexes are or may be each liable to special diseases. We cannot explain the special liability of women to endemic and exophthalmic goiter and myxœdema or their comparative immunity from Addison's disease, ataxy and general paralysis. As to heredity, it may be noted that disease in the father is more likely to be transmitted to sons, and in the mother to daughters. The diseases which most obviously run in families are functional nervous disorders, as hysterics, neuralgia, epilepsy, insanity, carcinoma, some simple growths, gout, and tubercular disease.

Some diseases when once acquired tend to recur again and again. Catarrhal inflammations of mucous membranes, rheumatism and erysipelas are familiar examples. On the other hand, there are several diseases which are said to be protective against themselves. An individual who has had smallpox is for a time at least not liable to the disease. This has been explained by the theory that the smallpox produces such an effect upon the cells that they no longer produce the pabulum necessary to support the disease, and if smallpox be caught a second time it is regarded as proof that the organs have returned to their normal condition. It has been suggested on the other hand, that the growth of a specific poison produces some substance which is incompatible with the life of the virus, as carbolic acid and creosol are produced by putrefaction, and alcohol by fermentation. So we have no satisfactory explanation of acquired immunity. In addition to acquired immunity

we may mention the state of inherited immunity. The best examples we have are instances in which individuals resist the virus of the specific disease in spite of frequent and prolonged exposure to it. Example given: a fever nurse may not have had the scarlet fever, and may never catch it, in spite of long exposure to it.

Primary disease of an organ or tissue is frequently followed by secondary disease of other parts. This may happen in several ways—by direct spread of morbid process, as when inflammation extends from skin to subcutaneous tissue, or cancer of the mamma involves skin, by the carriage of causes of disease from a primary focus to parts at a distance by the lymphatics or by the blood-vessels, as in embolism of the most varied substances, mechanically, by so-called "back-telling." Thus stricture of the urethra causes hypertrophy of the bladder to overcome the obstacle to the outflow of urine, or dilation of the bladder if its efforts are futile. In either case the difficulty of entry of urine into the bladder is increased, and the ureters, pelvis, and kidneys dilate. Interstitial nephritis results from the pressure if the renal functions are imperfectly performed, and this is detrimental to the organism at large. The succession of changes which result from mitral incompetence is another familiar example of this mode of extension of disease.

*Failure of Any Part to Do Its Share of Work in the Economy.*—The result will depend upon the completeness with which its defection can be compensated. If the work can be done by other parts, as can that of a sweat or sebaceous gland, nothing is noticed; but after extirpation of a kidney which was doing work, a time of danger from diminished excretion of urinary products has to be gone through, the other kidney being at first unequal to the double duty. Failure of the cardiac or of the respiratory function will cause death, there being no power of compensation.

*Terminations of Disease.*—The possible terminations of disease are recovery, or return of the part to the discharge of its normal functions; partial recovery, and death, or complete cessation of function. Certain diseases can scarcely be said to have a termination; when once established, they remain stationary.

It will be useful here to give a list of the morbid processes to which all organs are more or less liable:—The results of mechanical or physical injury, displacement, hemorrhage, development errors, anæmia, hyperæmia, œdema, inflammation, atrophy, infiltration, metamorphosis, necrosis, regeneration, hypertrophy, tumor-formation, lodgment of parasites; stricture and its consequences may occur in every duct or canal, and calculi may develop in connection with all such.

We close this brief essay with a glance at the bacterial theory.

*The Vegetable Parasites (bacilli)—Parallel Between Fermentation and Infective Disease.*—It has long been thought that the group of acute specific diseases must have a very special cause. The characteristics of this group are, that they occur epidemically; that they are obviously contagious and infectious; that each member is absolutely distinct from its fellows and runs a very typical course, and that the poison which gives rise to each of them multiplies in a marvelous manner. A single case of one of these if introduced into a community may cause the death of even millions. Nothing could be discovered by science to account for the appearance of these diseases, yet they were obviously produced by something which multiplied in the sick, which clung about his clothing, etc., perhaps for long periods, and which could be carried through the air for considerable

distances. This something is called the "contagion" of the disease, and for many years science has been endeavoring to discover its nature. It early became obvious that no gas would meet the requirements of the case, for diffusion would soon put an end to its power for mischief. A fluid was not to be thought of; so "contagion" was necessarily regarded as a solid in a very fine state of division *particulate*. It has been shown to be insoluble in fluids in which it can live, by subsidence and by filtration, the poison not passing through the filter. These facts, taken with its power of multiplication, seem to show that the contagion was some living organism. Hence the origin of the contagium or germ theory of disease, which was promulgated in a very crude form even as far back as the Roman era. It had long been noticed that a close parallel might be drawn between an infective disease and fermentation. It may be presented thus:—Infection corresponds to addition of ferment; incubation, to the period during which nothing is noticed; fever outbreak and course of disease, to rise of temperature and active fermentation; decline of disease, to gradual cessation; period of protection from same disease, to the fact that addition of more ferment has no effect.

It may be further noticed, except in cases in which yeast was added to the saccharine liquid, the source of fermentation in the production of alcohol was as mysterious as was the source of the poison which gave rise to an epidemic of whooping-cough. The germ theory started by Astier, Spalanzani, Schwann, and Cagniard de Latour and perfected by Pasteur explained the matter, and is adopted by the great majority of scientific men at the present day. The physical theory started by Willis in 1659 and perfected by Liebig affirms that fermentation is a "molecular motion" transmitted to organic compounds by albuminoid particles which of themselves are the seat of "motor decay." It is very difficult to absolutely disprove the physical theory. The disputers of this theory take alcoholic fermentation as the type of all specific diseases. The supporters of it, on the other hand, admit the frequent presence of organisms in fermenting fluids, but regard them as accidents or spontaneously generated, and adduce in support of this proposition the fact that the same decompositions can in some instances be effected in their absence, thus dilute alcohol by being run over wood shavings so as to expose a large surface to the air can be changed into vinegar. The germ theorists have rendered it certain that the particles "in a state of motor decay" adhere very closely to the organism, which is constantly present, and are able to impart their molecular motion to such substances only as its organism will grow in, for if the organism dies no fermentation occurs. The particles in a state of motor decay have never been demonstrated apart from organism. Antiseptics, which are selected on account of their ability to destroy the low organisms, invariably check the molecular motions of the physical ferments, so also does heat sufficient to destroy organism. In fact, the properties of the physical ferments are those of organisms. We conclude, therefore, that while the physical theory may be possible, science has shown that its rival, the vital theory, is a true one, and that all the processes generally known as fermentations and putrefactions are due to the presence and action of countless vegetable organisms.

Where are these microscopic vegetable organisms to be found? A putrid wound swarms with them. Whence come they? They may enter from the world external to the body. They may exist in the healthy body existing under special circumstances. They

may be spontaneously generated under special circumstances from the elements of the tissues.

The investigations of Dr. Koch of Berlin, followed by those of the more advanced members of the medical profession all over the world, have produced a profound impression. Their researches prove that all disease is caused by poison. Some of the diseases are known absolutely to be caused by the poison of bacteria, and an unavoidable conclusion is that all, in the course of time and investigation, will be found to be so caused. These poisons are known under the general name of *ptomaines* and the results of investigation so far show that each species of microbe has its especial ptomaine. It is this that acts upon the living tissue, killing the tissue so that it may become food for the microbe. Disease is the occupation by a microbe of the tissues of the body which offer least resistance to it, the killing of its cells by its poison, ptomaines, and then consuming them as food. The ptomaines may be taken up by the general circulation, and more or less the whole body is poisoned. This causes fever by acting on the nerve centers. No other poison than a ptomaine causes a rise in the temperature of the body.

In these conditions moisture is always necessary. Bacteria do not live without water. There are several ways of preventing the action of bacteria, some of them verified by common facts. Heat beyond a certain point kills them. If we boil milk we kill the germs contained in it, and it will remain sweet until other germs come and occupy it. Canned goods, the germs being killed by heat before the can is closed, remain sweet by the germs being kept out mechanically. Antiseptics kill them, and dryness.

The treating of disease under the germ theory presents a difficulty that may be said to be mechanical. For the rule is that any poison, or germitoxic, or disinfectant, which can kill bacteria will also destroy tissue-cells. They can therefore only be used to a limited extent; to such an extent as does not endanger life. But nature provides a cure as the result of the disease. This is why in disease there is always noticeable a tendency to recovery, a prolonged struggle between death and life. If the sick person lives, immunity to the action of the disease-poison is the result of having been poisoned, because the tissue-cells acquire a tolerance to the poison. It is this result of the poisoning which accounts for the recovery of the sick man, and ends epidemics, and this is why persons who have had small-pox, or scarlet fever, or measles, or any one of a large number of diseases that could be named, are thereafter immune. The object of vaccination to prevent small-pox is to cause the tissue-cells to become immune by having been subjected to the action of the poison in a controllable form. The cure of rabies discovered by Dr. Koch is supported by the same law. But also by the action of this law the world may look forward to the time when there will be an end of all disease.

PATMOS (now pronounced by the natives "Patino"), an island in the east of the Ægean Sea, one of the group of the Sporades, about twenty-eight miles south-southwest of Samos. Its greatest length from north to south is about ten miles, its greatest breadth six, its circumference, owing to the winding nature of the coast, about thirty-seven. The island, which is volcanic, is bare and rocky throughout. The woods which once covered the island have disappeared; of the palms, from which it formerly received its Italian name of Palmessa, not more than one is left. Of the numerous bays and harbors the chief is that of La Scala, which, running far into the land on the eastern

side, divides the island into two nearly equal portions, a northern and a southern. A narrow isthmus separates La Scala from the Bay of Merika on the west coast. On the belt of land between the two bays, at the junction between the northern and southern half of the island, stood the ancient town. To judge from its traces, it may have contained 12,000 to 13,000 inhabitants. The town clusters at the foot of the monastery of St. John, which, crowning the hill with its towers and battlements, resembles a fortress rather than a monastery. Of the 600 MSS. once possessed by the library of the monastery only 240 are left, badly preserved, and none of them of value. Scattered over the island are about 300 chapels. Population, about 4,000.

Patmos is mentioned first by Thucydides (iii. 33) and afterward by Strabo and Pliny. From an inscription it has been inferred that the name was originally Patnos. There are some grounds for the conjecture that the island was first colonized by Carians. Another ancient inscription seems to show that the Ionians also settled there at an early date. The chief, indeed the only, title of the island to fame is that it was the place of banishment of St. John, the Evangelist, who, according to Jerome and others, was exiled thither under Domitian in 95 A.D., and released about eighteen months afterward under Nerva. Here he is said to have written the Apocalypse; to the left of the road from La Scala to the town, about half-way up the hill, a grotto is still shown in which the apostle is said to have received the heavenly vision.

PATNA, a district in the lieutenant-governorship of Bengal, and in the division or commissionership of Patna, is bounded on the north by the river Ganges, which separates it from Sáran, Muzaffarpur, and Darbhanga, on the east by Monghyr, on the south by Gayá, and on the west by the Son, which separates it from Sháhábád. Patna district, with an area of 2,079 square miles, is, throughout the greater part of its extent, a level plain; but toward the south the ground rises into hills. The soil is for the most part alluvial, and the country along the bank of the Ganges is peculiarly fertile. The general line of drainage is from west to east; and high ground along the south of the Ganges forces back the rivers flowing from the district of Gayá. The result is that, during the rains, nearly the whole interior of the district south of a line drawn parallel to the Ganges, and four or five miles from its bank, is flooded. There are no forests or jungles of any extent, but fine groups of trees are found in many places. Hot springs are common on the Rájágríhá Hills. The chief rivers are the Ganges and the Son. The only other river of any consequence is the Pún-pún, which is chiefly remarkable for the number of petty irrigation canals which it supplies. So much of the river is thus diverted that only a small portion of its water ever reaches the Ganges at Fatwá.

The census returned the population at 1,756,856 persons (males 858,783, and females 898,073). Hindus numbered 1,541,061, Mohammedans 213,141, Christians 2,588, and "others" 66. The following towns in the district contained a population exceeding 10,000:—Patna city (170,654); Behar (48,968); Dinápur, including the cantonment (37,893); Bárh (14,689); Khagaul (14,075); Mukáma (13,052); Fatwá (10,919).

Rice, which forms the staple of the district, is divided into two great crops—the *kartiká* or early rice, sown in June or July, and reaped in October or November; and the *aghání* or winter rice, sown after the commencement of the rains, and cut in November or December. Patna is one of the two places in British India where opium is manufactured. The climate of Patna is considered remarkably healthy.

PATNA, chief city of the above district, is situated on the right or south bank of the Ganges, and adjoining Bánkipur, the civil station and administrative headquarters of the district. Its central position at the junction of three great rivers, the Son, the Gandak, and the Ganges, where the traffic of the Northwestern Provinces meets that of Bengal, gives it great natural advantages. According to the census of 1881 its population was 170,654—Hindus 127,076, Mohammedans 43,086, "others" 492.

PATNA, a native state in the Central Provinces of India, has an estimated area of 2,399 square miles, of which 550 are under cultivation, and other 950 are returned as cultivable. The estimated population in 1881 was 257,959, nearly all of whom were Hindus.

PATRAS, or PATRÆ, a fortified city of Greece, the principal port of the Morea, and the chief town of the nomos of Achaia and Elis, lies on the north coast of the Morea, on the east side of the Patras, which opens into the Gulf of Corinth by the Little Dardanelles, marked by forts Kastro Moreas and Kastro Rumelias. Since the War of Independence Patras has been one of the most prosperous cities in the kingdom. The population, which had sunk to 8,000 at the time of the war, was 16,641 in 1870, and is now 28,000. Patras is the seat of one of the four courts of appeal in the kingdom, and the residence of the archbishop of Patras and Elis. The custom-house is the most important in all Greece. The commerce of Patras consists mainly in the export of currants, valonia, olive-oil, wine, and sheepskins, and the import of cotton and woolen goods, grain, flour, and colonial wares.

PATRIARCH (lit. the head or ruler of a tribe, family, or clan) occurs four times in the New Testament, being applied to Abraham, the twelve sons of Jacob collectively, and David, and several times in the LXX., where the word is used to denote the officials called by the chronicler "princes of the tribes of Israel," "princes of hundreds," "chiefs of the fathers." Under the late Roman empire the title was officially applied down to the fifth century to the chief rabbi in Palestine; the head of the synagogue at Babylon appears also to have been known as patriarch until 1038. The title at an early date passed over into the Christian church as an honorific though not official designation of all bishops. At the present day the heads of the various extant churches and sects in the East are very commonly called patriarchs, and in the West the Roman Church gives the honorary title to several dignitaries, such as the archbishops of Lisbon and Venice. In a strictly technical sense, however, that church recognizes only five patriarchates, those of Constantinople, Alexandria, Jerusalem, Antioch, and Rome.

PATRICIAN. The history, in the Roman state, of the hereditary patrician order (*patricii*, *patres*, house-fathers, goodmen), who originally constituted the entire *populus Romanus*, has been traced in the article NOBILITY. With the transference of the imperial capital to Byzantium under Constantine, the title *patricius* became a personal and not an hereditary distinction; the name was held to denote a fatherly relation to the emperor, and those who bore it stood first among the *illustres*, receiving such appellations as "magnificentia," "celsitudo," "eminentia," "magnitudo."

PATRICK, ST. In one of the incursions of the Scots and Picts upon the neighboring Roman province south of the wall of Severus, probably that of 411 A.D., the year after Honorius had refused aid to the Britons, a youth of about fifteen was carried off with many others from the district in the neighborhood of the wall at the head of the Solway, and sold as a slave on the opposite coast of Ireland, in the territory of the Irish Picts called

Dal Araide. This youth was the future apostle of the Irish. As his name implies, he was of noble birth, and he tells us so himself. He was the son of the deacon Calpurnius, who was the son of Potitus, a priest. His father was a decurio or magistrate, and, as Patrick, according to tradition, was born at Nemthur, he must have exercised his functions of magistrate at that place, but on the withdrawal of the Roman garrisons from Britain probably retired for safety south of the wall of Severus, where, as Patrick tells us, he had a small country place near the town of Bannavem Taberniæ, whence Patrick was carried off.

The youth Succat or Patrick remained in hard slavery for six years, tending cattle, probably on Slemish Mountain, in the county Antrim. He seems to have been of an enthusiastic temperament, and much given to prayer and meditation. After his escape he appears to have conceived the noble idea of devoting himself to the conversion of the Irish, and to have gone somewhere for a few years to prepare himself for the priesthood. His biographers take him to Tours to St. Martin, who was then dead several years, afterward to the island of Lerins in the Mediterranean, and lastly to Rome, where he received a mission from Pope Celestine. For all this there is no evidence whatever, the whole story being the result of the confusion of Palladius with the real Patrick. The tradition of some connection between the Irish apostle and St. Martin of Tours, the monastic type of the earliest Irish Church, the doubts as to Patrick's fitness for the work which led to his writing his *Confession*, and indeed all the difficulties that beset the question of the origin of the Irish Church, receive a simple and satisfactory explanation upon the hypothesis of Patrick having prepared himself for the priesthood at Candida Casa, the monastic institution founded by ST. NINIAN, (*q.v.*)

Patrick tells us that after a few years (*i.e.*, after his escape) he was among the Britons with his kindred, who received him as a son. He was evidently bent upon his mission, for they besought him after such tribulations not to part from them again. Full of it, he dreams that a man whose name was Victoricus came to him bearing innumerable epistles, one of which he received and read; the beginning of it contained the words, "The voice of the Irish;" while repeating these words he says, "I imagined that I heard in my mind the voice of those who were near the wood of Fochlad, which is near the western sea, and thus they cried: We pray thee, holy youth, to come and henceforward walk among us." This dream was followed by others, which shows how completely his mission occupied his mind. Patrick was about twenty-two years of age when he escaped from slavery, and, if we allow seven or eight years for the "few years'" preparation, he probably was not more than thirty years of age when he entered on his mission, about 425. There is a passage in his *Confession* which shows that he was still a young man when he commenced his work: "You know and God knows how I have lived among you from my youth up." Probus, the author of the fifth life published by Colgan, who has many claims upon our confidence, supports this view that Patrick began his mission while still a priest. We see in Patrick's own authentic acts that he must have sought among his friends in Britain to be made a bishop, for he complains in his *Confession* that a friend to whom he had communicated some fault he had committed when about fifteen years old had urged this thirty years after as a reason against his being consecrated to the higher office. This proves that he was only about forty-five years old when made bishop. If we assume that 411 was the year he was carried off as a slave, his consecration as bishop would fall in

about 441, the fifteenth year of his mission, a date which corresponds with the results of Doctor Todd's speculations based on a close analysis of all available chronological data.

The date of St. Patrick's death is as uncertain as that of every other event connected with him. *The Annals of the Four Masters* give 493, with which Ussher agrees; Tirechan's *Annotations*, on the other hand, state that Loegaire, son of Niall, king of Ireland, lived from two to five years after St. Patrick. According to this account the death of St. Patrick took place in 469, and that of Loegaire in 471 or 474, after a reign of thirty-six years, so that Loegaire's reign began either in 435 or 438. The *Annals of the Four Masters* record the death in 457 of Senn Patraicc, or Old Patrick, and of Loegaire in the following year, 458. The Patrick who died in 493 is a fiction due to the fusion of the acts of the two real Patricks, Palladius Patrick and Senn Patraicc, doubtless so called because he was the Patrick known as a priest before the arrival of the Roman bishop. Assuming Tirechan's statement as correct, and that St. Patrick died in 469, his mission as priest and bishop lasted about forty-four years.

PATRICK, ST., ORDER OF. See KNIGHTHOOD, *ante*.

PATRICK, SIMON, bishop of Chichester, and afterward of Ely, author of a number of works in practical divinity, was born at Gainsborough, Lincolnshire, England, on September 8, 1626, entered Queen's College, Cambridge, in 1644, and, after taking orders in 1651, became successively chaplain to Sir Walter St. John, and vicar of Battersea, Surrey. He was afterward (1662) preferred to the rectory of St. Paul's, Covent Garden, London, where he continued to labor during the year of the plague. Dean of Peterborough from 1678, he became bishop of Chichester in 1689, in which year he was employed, along with others of the new bishops, to settle the affairs of the church in Ireland. In 1691 he received the bishopric of Ely, which he held until his death, May 31, 1707.

PATRON AND CLIENT. Clientage appears to have been an institution of most of the Græco-Italian peoples in early stages of their history; but it is in Rome that we can most easily trace its origin, progress, and decay. Until the reforms of Servius Tullius, the only citizens proper were the members of the patrician or gentile houses; they alone could participate in the solemnities of the national religion, take part in the government and defense of the state, contract quiritarian marriage, hold property, and enjoy the protection of the laws. But alongside of them was a gradually increasing non-citizen population composed of slaves and clients. Some historians class among the latter, as clients of the state, those vanquished communities which, having made an unconditional submission, were allowed to retain a quasi-corporate existence under the protection of Rome. But the name (derived from *cluere*, to obey) was common before Rome had made any conquests, and was usually applied to individuals who had attached themselves in a condition of dependence to the head of the patrician houses as their patrons, in order thereby to secure a *de-facto* freedom. According to Dionysius and Plutarch, it was one of the early cares of Romulus to regulate the relationship, which, by their account of it, was esteemed a very intimate one, imposing upon the patron duties only less sacred than those he owed to his children and his ward, more urgent than any he could be called on to perform toward his kinsmen, and whose neglect entailed the penalty of death. The patron was bound to provide his client with the necessaries of life; and it was a common practice to make him a grant during pleasure of a small plot of land

to cultivate on his own account. Further, he had to advise him in all his affairs; to represent him in any transactions with third parties in which, as a non-citizen, he could not act with effect; and, above all things, to stand by him, or rather be his substitute, in any litigation in which he might become involved. The client in return had not only generally to render his patron the respect and obedience due by a dependent, but, when he was in a position to do so and the circumstances of the patron required it, to render him pecuniary assistance. As time advanced and clients amassed wealth, we find this duty insisted upon in a great variety of forms, as in contributions toward the dowries of a patron's daughters, toward the ransom of a patron or any of his family who had been taken captive, toward the payment of penalties or fines imposed upon a patron, even toward his maintenance when he had become reduced to poverty.

So matters remained during the fourth and fifth centuries. In the sixth a variety of events, social and political, contributed still further to modify the relationship. The rapacity of patrons was checked by the Cincian law, which prohibited their taking actual gifts of money from their clients; marriages between patron and client gradually ceased to be regarded as unlawful or as ineffectual to secure to the issue the status of the patron father; political changes opened to the clients the rural tribes and the higher centuries, and qualified them for the legion, the magistracy, and the senate; hereditary clientage ceased when a client attained to a curule dignity; and, in the case of the descendants of freedmen enfranchised in solemn form, it came to be limited to the first generation. Gradually but steadily one feature after another of the old institutions disappeared, till by the end of the seventh century it had resolved itself into the limited relationship between patron and freedman on the one hand, and the unlimited honorary relationship between the patron who gave gratuitous advice on questions of law and those who came to consult him on the other. To have a large following of clients of this class was a matter of ambition to every man of mark in the end of the republic; it increased his importance, and insured him a band of zealous agents in his political schemes. But amid the rivalries of parties and with the venality of the lower orders, baser methods had to be resorted to in order to maintain a patron's influence; the favor and support of his clients had to be purchased with something more substantial than mere advice. And so arose that wretched and degrading clientage of the early empire, of which Martial, who was not ashamed to confess himself a first-rate specimen of the breed, has given us such graphic descriptions; gatherings of miserable idlers, sycophants, and spendthrifts, at the levees and public appearances of those whom, in their fawning servility, they addressed as lords and masters, but whom they abused behind their backs as close-fisted upstarts—and all for the sake of the *sportula*, the daily dole of a dinner, or of a few pence wherewith to procure one. With the middle empire this disappeared; and, when a reference to patron and client occurs in later times, it is in the sense of counsel and client, the words patron and advocate being used almost synonymously.

PATTESON, JOHN COLERIDGE, bishop of Melanesia, was the eldest son of Justice Patteson and Frances Duke Coleridge, a near relation of Samuel Taylor Coleridge, and was born in London, England, April 2, 1827. He entered Balliol College, Oxford, in 1845, graduated B.A. in 1848, and in 1852 became a fellow of Merton College. In 1853 he became curate of Alington, Devon, and in the following year he was ordained priest and joined the mission to the Melanesian islands in the South Pacific. In 1861 he

was consecrated bishop of Melanesia, and in this capacity did much to promote the Christianization of the islands until his premature death by the hand of a native, September 20, 1871.

PAU, a city of France, formerly the capital of Béarn, and now the chief town of the department of Basses Pyrénées, and the seat of a court of appeal, is situated on the edge of a plateau 130 feet above the right bank of the Gave de Pau (a left-hand affluent of the Adour), at a height of about 620 feet above the sea. The modern importance of Pau is due to its climate, which makes it a great winter health-resort. The most striking characteristic is the stillness of the air, resulting from the peculiarly sheltered situation. The town is built on a sandy soil, and the line of the streets running east and west is favorable to ventilation. The average rainfall is about forty inches, and the mean winter temperature is 44°, the mean for the year being 62°.

Apart from an export flour-trade and some manufactures of chocolate and Béarn linen, the inhabitants of Pau depend entirely on their 4,000 winter-visitors. The castle is bounded on the north and west by the Hédas, on the south by a canal drawn from the Gave, and on the east by a moat thirty feet deep; access is obtained by three bridges, that across the Hédas being of ancient construction.

On the ground-floor is the old hall of the estates of Béarn, eighty-five feet long and thirty-six feet wide, adorned with a white marble statue of Henry IV., and magnificent Flemish tapestries ordered by Francis I. The most interesting room is that in which Henry IV. was born, still containing his mother's bed (from the castle of Richelieu) and his own cradle made of a tortoise-shell. In the keep is a library of 6,000 volumes, mainly of works relating to Henry IV. The population of Pau (about 6,000 at the close of the eighteenth century) was 27,300 in 1871, and 29,971 in 1881.

PAUL. "Saul, who is also (called) Paul," was a "Hebrew of the Hebrews," *i. e.*, of pure Jewish descent unmixed with Gentile blood, of the tribe of Benjamin. In the Acts of the Apostles it is stated that he was born at Tarsus in Cilicia; but in the fourth century there still lingered a tradition that his birthplace was Giscala, the last of the fortress-towns of Galilee which held out against Rome. The fact that he was called by two names has been accounted for in various ways. Saul was a natural name for a Benjamite to give to his son, in memory of the first of Jewish kings; Paul is more difficult of explanation. It is first found in the narrative of the conversion of Sergius Paulus, the proconsul of Cyprus, and it has sometimes been supposed either that Paul himself adopted the name in compliment to his first Gentile convert of distinction, or that the writer of the Acts intended to imply that it was so adopted. Others have thought that it was assumed by Paul himself after the beginning of his ministry, and that it is derived from the Latin *paulus* in the sense either of "least among the apostles" or "little of stature." But these and many similar conjectures may probably be set aside in favor of the supposition that he had a double name from the first, one Aramaic or Hebrew and the other Latin or Greek, like Simon Peter, John Mark, Simeon Niger, Joseph Justus. Whatever be its origin, Paul is the only name which he uses of himself, or which is used of him by others when once he entered into the Roman world outside of Palestine. The Acts speak of his having been a Roman citizen by birth, a statement which also has given rise to several conjectures, because there is no clue to the ground upon which his claim to citizenship is based. Some modern writers question the fact, considering the statement to be part of the general coloring which the writer

of the Acts is supposed to give to his narrative; and some also question the fact, which is generally considered to support it, of the appeal to the emperor. That he received part of his education at Tarsus, which was a great seat of learning, is a possible inference from his use of some of the technical terms which were current in the Greek schools of rhetoric and philosophy; but, since the cultivation of a correct grammatical and rhetorical style was one of the chief studies of those schools, Paul's imperfect command of Greek syntax seems to show that this education did not go very far. That he received the main part of his education from Jewish sources is not only probable from the fact that his family were Pharisees, but certain from the whole tone and character of his writings. According to the Acts, his teacher was Gamaliel, who, as the grandson of Hillel, took a natural place as the head of the moderate school of Jewish theologians; nor, in spite of the objection that the fanaticism of the disciple was at variance with the moderation of the master, does the statement seem in itself improbable. A more important difficulty in the way of accepting the statement that Jerusalem was the place of his education is the fact that in that case his education must have been going on at the time of the preaching and death of Jesus Christ. That he had not seen Jesus Christ during His ministry seems to be clear, for a comparison of 1 Cor. ix. 1, with xv. 8, appears to limit his sight of Christ to that which he had at his conversion, and the "knowing Christ after the flesh" of 2 Cor. v. 16, is used not of personal acquaintance but of "carnal" as opposed to "spiritual" understanding. Like all Jewish boys, he learned a trade, that of tent-making; this was a natural employment for one of Cilician origin, since the hair of the Cilician goat was used to make a canvas (*cilicia*) which was especially adapted for the tents used by travelers on the great routes of commerce or by soldiers on their campaigns. Whether he was married or not is a question which has been disputed from very early times; his expressions in 1 Cor. vii. 8, ix. 5, were taken by Tertullian to imply that he was not, and by Clement of Alexandria and Origen to imply that he had once been, but that he had become a widower.

The beginning of his active life was doubtless like its maturity; it was charged with emotion. He himself gives a graphic sketch of its inner history. His conversion to Christianity was not the first great change that he had undergone. He had lived in his youth a pure and guileless life. He had felt that which is at once the charm and force of such a life, the unconsciousness of wrong. But, while his fellow-disciples in the rabbinical schools had been content to dissect the text of the sacred code with a minute anatomy, the vision of a law of God which transcended both text and comment had loomed upon him like a new revelation. And with the sense of law had come the sense of sin. It was like the first dawn of conscience. He awoke as from a dream. In his outward life the sense of the law of God became to him an overpowering stimulus. The stronger the consciousness of his personal failure the greater the impulse of his zeal. The vindication of the honor of God by persecuting heretics, which was an obligation upon all pious Jews, was for him a supreme duty. He became not only a persecutor but a leader among persecutors. What he felt was a very frenzy of hate; he "breathed threatening and slaughter," like the snorting of a war-horse before a battle, against the renegade Jews who believed in a false Messiah. His enthusiasm had been known before the popular outbreak which led to Stephen's death, for the witnesses to the martyr's stoning "laid down their clothes" at his feet, and he took a prominent place in the persecution

which followed. He himself speaks of having "made havoc" of the community at Jerusalem, spoiling it like a captured city. In the more detailed account of the Acts he went from house to house to search out and drag forth to punishment the adherents of the new heresy. When his victims came before the Jewish courts he tried, probably by scourging, to force them to apostatize; in some cases he voted for their death. The persecution spread from Jerusalem to Judæa and Galilee; but Paul, with the same spirit of enterprise which afterward showed itself in his missionary journeys, was not content with the limits of Palestine. He sought and obtained from the ecclesiastical authorities at Jerusalem letters similar to those which, in the thirteenth century, the popes gave to the "militia Jesu Christi contra hæreticos." The ordinary jurisdiction of the synagogues was for the time set aside; the special commissioner was empowered to take as prisoners to Jerusalem any whom he found to belong to the sect known as "The Way." Of the great cities which lay near Palestine, Damascus was the most promising, if not the only field for such a commission. At Antioch and at Alexandria, though the Jews, who were very numerous, enjoyed a large amount of independence and had their own governor, the Roman authorities would probably have interfered to prevent the extreme measures which Paul demanded. At Damascus, where also the Jews were numerous and possibly had their own civil governor, the Arabian prince Aretas (Haritha), who then held the city, might naturally be disposed to let an influential section of the population deal as they pleased with their refractory members.

On Paul's way thither an event occurred which has proved to be of transcendent importance for the religious history of mankind. He became a Christian by what he believed to be the personal revelation of Jesus Christ. His own accounts of the event are brief, but they are at the same time emphatic and uniform. "It pleased God \* \* \* to reveal His Son in me;" "have I not seen Jesus Christ our Lord;" "last of all He was seen of me also as of one born out of due time." These accounts give no details of the circumstances.

But against all the difficulties and apparent incredibilities of the narratives there stand out the clear and indisputable facts that the persecutor was suddenly transformed into a believer, and that to his dying day he never ceased to believe and to preach that he had "seen Jesus Christ." Nor was it only that he had seen Him; the gospel which he preached, as well as the call to preach it, was due to this revelation.

Of his life immediately after his conversion he himself gives a clear account: "I conferred not with flesh and blood, neither went I up to Jerusalem to them which were apostles before me; but I went away into Arabia." The reason of his retirement, whether it was to the Haurán (Renan) or to the Sinaitic peninsula (Holsten), is not far to seek. A great mental no less than a great bodily convulsion naturally calls for a period of rest; and the consequences of his new position had to be drawn out and realized before he could properly enter upon the mission-work which lay before him. From Arabia he returned to Damascus, and there began not only his preaching of the gospel but also the long series of "perils from his own countrymen," which constitute so large a part of the circumstances of his subsequent history.

It was not until "after three years," though it is uncertain whether the reckoning begins from his conversion or from his return to Damascus, that he went up to Jerusalem; his purpose in going was to become acquainted with Peter, and he stayed with him fifteen days.

From Jerusalem he went "into the regions of Syria and Cilicia," preaching the gospel. How much that brief expression covers is uncertain; it may refer only to the first few months after his departure from Jerusalem, or it may be a summary of many travels, of which that which is commonly known as his "first missionary journey" is a type.

The chief features of these accounts are the formation of a new center of Christian life at Antioch, and a journey which Paul, Barnabas, and for part of the way John Mark took through Cyprus and Asia Minor.

The first of these facts has a significance which has sometimes been overlooked for the history not only of Paul himself but of Christianity in general. It is that the mingling together, in that splendid capital of the civilized East, of Jews and Syrians on the one hand with Greeks and Romans on the other, furnished the conditions which made a Gentile Christianity possible. The religion of Jesus Christ emerged from its obscurity into the full glare of contemporary life. Its adherents attracted enough attention to receive in the common talk and intercourse of men a distinctive name. They were treated, not as a Jewish sect, but as a political party. The narrative of the incidents of the single journey which is recorded in detail, and which possibly did not occupy more than one summer, has given rise to much controversy. Its general credibility is supported by the probability that in the first instance Paul would follow an ordinary commercial route, on which Jewish missionaries as well as Jewish merchants had been his pioneers; for his letters to his Gentile converts all presuppose their acquaintance with the elements of Judaism. They do not prove monotheism, but assume it.

According to the narrative, Paul and his companions went first to Cyprus, the native country of Barnabas, and traveled through the island from its eastern port, Salamis, to its capital, Paphos. At Paphos a Jewish sorcerer, Bar Jesus, was struck with blindness, and the proconsul, Sergius Paulus, was converted. From Cyprus, still following a common route of trade, they went into the southeast districts of Asia Minor, through Pamphylia to Antioch in Pisidia. At Antioch, on two successive Sabbaths, Paul spoke in the synagogue; the genuineness of the addresses which are recorded in the Acts has been disputed, chiefly because the second of them seems to imply that he "turned to the Gentiles," not as a primary and unconditional obligation, but owing to the rejection of the gospel by the Jews. Expelled from Antioch, they went on to Iconium (where the apocryphal "Acts of Paul and Thekla" place the scene of that improbable but not ungraceful romance), and thence to Lystra, where the healing of a cripple caused the simple and superstitious Lycaonians to take them for gods. Their farthest point was the neighboring town of Derbe, whence they returned by the route by which they had come to the seacoast, and thence to Antioch in Syria.

At the end of fourteen years, either from his conversion or from his visit to Peter at Jerusalem, the question of the relation of the communities which he had formed, and of the gospel which he preached, to the original Christian communities, and to the gospel of the Twelve, came to a crisis. His position was unique. He owed neither his knowledge of the gospel nor his commission to preach to any human authority. As Jesus Christ had taught and sent forth the Twelve, so had he taught and sent forth Paul. He was on equal terms with the Twelve. Until a revelation came to him he was apparently at no pains to cooperate with them. But between their respective disciples there was evidently a sharp contention. The Jewish party, the original disciples and first converts, maintained the continued obligation

of the Mosaic law and the limitation of the promises to those who observed it; the Pauline party asserted the abrogation of the law and the free justification of all who believed in Jesus Christ. The controversy narrowed itself to the one point of circumcision. If the Gentiles were without circumcision members of the kingdom of God, why was the law obligatory on the Jews? If, on the other hand, the Gentiles had to be circumcised, the gospel had but a secondary importance. It seemed for a time as though Christianity would be broken up into two sharply divided sects, and that between the Jewish Christianity, which had its seat at Jerusalem, and which insisted on circumcision, and the Gentile Christianity, which had its seat at Antioch, and which rejected circumcision, there would be an irreconcilable antagonism. It was consequently by "revelation" that Paul and Barnabas, with the Gentile convert Titus as their "minister" or secretary, went to confer with the leaders among the original disciples, the "pillars" or "them who were of repute," "James, and Cephas, and John." He put the question to them: Was it possible that he was spending or had spent his labor in vain? He laid before them the "gospel of the uncircumcision." They made no addition to it, but accepted it as Paul preached it, recognizing it as being a special work of God, and as being on the same level of authority with their own. The opposition was no doubt strong; there were "false brethren" who refused to emancipate the Gentile world from the bondage of the law; and there was also apparently a party of compromise which, admitting Paul's general contention, maintained the necessity of circumcision in certain cases, of which the case of Titus, for reasons which are no longer apparent, was typical. But Paul would have no compromise. From his point of view compromise was impossible. "Justification" was either "of faith" or "by the works of the law;" it was inconceivable that it could be partly by the one and partly by the other. And he succeeded in maintaining his position at all points. He received "the right hand of fellowship," and went back to Antioch the recognized head and preacher of the "gospel of the uncircumcision." Within his own sphere he had perfect freedom of action; the only tie between his converts and the original community at Jerusalem was the tie of benevolence. Jew and Gentile were so far "one body in Christ" that the wealthier Gentile communities should "remember the poor."

When Paul returned to Antioch Peter followed him, and for a time the two apostles worked in harmony. Peter "did eat with the Gentiles." He shared the common table at which the Jewish distinctions of meats were disregarded. He thereby accepted Paul's position. But when "certain came from James" he drew back. The position of James was probably that, even if the law had ceased to be valid as a means of justification, it was still valid as a rule of life. For reasons which are not apparent, possibly the wish not to break with the community at Jerusalem, not only Peter but Barnabas and the whole of the Jewish party at Antioch accepted that position, with its subsequent obligation of separation from the Gentile brethren, not only in social life, but probably also in the partaking of the Lord's Supper. Paul showed that the position of Peter was illogical, and that he was self convicted. His argument was that the freedom from the law was complete, and that to attach merit to obedience to the law was to make disobedience to the law a sin, and, by causing those who sought to be justified by faith only to be transgressors, to make Christ a "minister of sin." Obedience to any part of the law involved recognition of the whole of it as obligatory, and consequently "made void the grace of God."

The schism in the community at Antioch was probably never healed. It is not probable that Paul's contention was there victorious; for, while Paul never again speaks of that city, Peter seems to have remained there, and he was looked upon in later times as the founder of its church.

But this failure at Antioch served to Paul as the occasion for carrying out a bolder conception. The horizon of his mission widened before him. The "fullness of the Gentiles" had to be brought in. His diocese was no longer Antioch, but the whole of the Roman empire. The years that followed were almost wholly spent among its great cities, "preaching among the Gentiles the unsearchable riches of Christ." He became the spiritual father of many communities, and he watched over them with a father's constant care.

The first scene of his new activity, if indeed it be allowable to consider the conference at Jerusalem and the subsequent dispute at Antioch as having given occasion for a new departure, was probably the eastern part of Asia Minor, and more particularly Galatia. Some of it he had visited before; and from the fact that the Galatians, though they had been heathens, were evidently acquainted with the law, it may be inferred that he still went on the track of Jewish missionaries, and that here, as elsewhere, Judaism had prepared the way for Christianity. Of his preaching he himself gives a brief summary; it was the vivid setting forth before their eyes of Jesus as the crucified Messiah, and it was confirmed by evident signs of the working of the Spirit. The new converts received it with enthusiasm; he felt for them as a father; and an illness which came upon him (assuming this to have been his first visit) intensified their mutual affection. What we learn specially of the Galatians is probably true also of the other Gentiles who received him; some of them were baptized, they were formed into communities, and they were so far organized as to have a distinction between teachers and taught.

But an imperative call summoned him to Europe. The western part of Asia Minor, in which afterward were formed the important churches of Ephesus, Colossæ, Hierapolis, and Laodicea, was for the present left alone. He passed on into Macedonia.

In Europe, as in Asia, persecutions attended him. He was "shamefully entreated" at Philippi, and according to the Acts the ill-treatment came not from the Jews, but from the Gentile employers of a frenzied prophetess, who saw in Paul's preaching an element of danger to their craft. Consequently he left that city, and passing over Amphipolis, the political capital of the province, but the seat rather of the official classes than of trade, he went on to the great seaport and commercial city of Thessalonica. His converts there seem to have been chiefly among the Gentile workmen, and he himself became one of them. Knowing as he did the scanty wages of their toil, he "worked night and day that he might not burden any of them." But for all his working he does not seem to have earned enough to support his little company; he was constrained both once and again to accept help from Philippi. He was determined that, whatever he might have to endure, no sordid thought should enter into his relations with the Thessalonians; he would be to them only what a father is to his children, behaving himself "holily and righteously and unblamably," and exhorting them to walk worthily of God who had called them. But there, as elsewhere, his preaching was "in much conflict." The Jews were actively hostile. According to the account in the Acts, they at last hounded on the lazzaroni of the city, who were doubtless moved as easily as a Moslem crowd in modern times by any cry of treason or in-

fidelity, to attack the house of Jason, either because Paul himself was lodging there, or because it was the meeting-place of the community. Paul and Silas were not there, and so escaped; but it was thought prudent that they should go at once and secretly to the neighboring small town of Berea. Thither, however, the fanatical Jews of Thessalonica pursued them; and Paul, leaving his companions Silas and Timothy at Berea, gave up his preaching in Macedonia for a time and went southward to Athens.

The narrative which the Acts give of his stay at Athens is one of the most striking, and at the same time one of the most difficult, episodes in the book. What is the meaning of the inscription on the altar? What is the Areopagus? How far does the reported speech give Paul's actual words? What did the Athenians understand by the Resurrection? These are examples of questions on which it is easy to argue, but which, with our present knowledge, it is impossible to decide. One point seems to be clear, both from the absence of any further mention of the city in Paul's writings and from the absence of any permanent results of his visit, that his visit was a comparative failure.

From Athens he went to Corinth, the capital of the Roman province of Achaia, and the real center of the busy life of Greece. It was not the ancient Greek city with Greek inhabitants, but a new city which had grown up in Roman times, with a vast population of mingled races, who had added to the traditional worship of Aphrodite the still more sensuous cults of the East. Never before had Paul had so vast or so promising a field for his preaching; for alike the filthy sensuality of its wealthy classes and the intense wretchedness of its 500,000 paupers and slaves were prepared ground upon which his preaching could sow the seed, in the one case of moral reaction, and in the other of hope. At first the greatness of his task appalled him: "I was with you in weakness, and in fear, and in much trembling." But he laid down for himself from the first the fixed principle that he would preach nothing but "Jesus Christ, and him crucified," compromising with neither the Jews, to whom "the word of the cross," *i.e.*, the doctrine of a crucified Messiah, was "a stumbling-block," nor with the Gentile philosophers, to whom it was "foolishness." It is probable that there were other preachers of the gospel at Corinth, especially among the Jews, since soon afterward there was a Judaizing party; Paul's own converts seem to have been chiefly among the Gentiles.

After having lived probably about two years at Corinth Paul resolved, for reasons to which he himself gives no clue, to change the center of his activity from Corinth to Ephesus. Like Corinth, Ephesus was a great commercial city with a vast mixed population; it afforded a similar field for preaching, and it probably gave him increased facilities for communicating with the communities to which he was a spiritual father. It is clear from his epistles that his activity at Ephesus was on a much larger scale than the Acts of the Apostles indicate. He went about like one condemned to die, upon whom the sentence might at any moment be carried out. Once, at least, it seemed as though the end had actually come, for he had to fight with beasts in the arena; and once, if not on the same occasion, he was only saved by Prisca and Aquila, "who for his life laid down their own necks."

An émeute which took place at Ephesus was, according to the Acts, the occasion if not the cause of his leaving that city; "a great door and effectual had been opened unto him" there, and the growth of the new religion had caused an appreciable diminution in the trade of those who profited by the zeal of the worship-

ers at the temple. He went overland to Troas, where, as at Ephesus, "a door was opened unto him in the Lord," but the thought of Corinth was stronger than the wish to make a new community. He was eager to meet Titus, and to hear of the effect of his now lost letter; and he went on into Macedonia. It is at this point of his life more than at any other that he reveals to us his inner history. At Ephesus he had been hunted almost to death; he had carried his life in his hand; and, "even when we were come into Macedonia, our flesh had no relief, but we were afflicted on every side; without were fightings, within were fears." But, though the "outward man was decaying, yet the inward man was renewed day by day;" and the climax of splendid paradoxes which he wrote soon afterward to the Corinthians was not a rhetorical ideal, but the story of his actual life. But after a time Titus came with news which gladdened Paul's heart. He had been well received at Corinth. The letter had made a deep impression. The admonitions had been listened to. The Corinthians had repented of their conduct. They had rid themselves of "him that did the wrong," and Paul was "of good courage concerning them" (2 Cor. vii. 8-16). He then wrote the second of his extant letters to them, which was sent by Titus and the unknown "brother whose praise in the gospel is spread through all the churches," and who had been elected by the churches to travel with Paul and his company (2 Cor. viii. 18, 19). It was probably in the course of this journey that he went beyond the borders of Macedonia into the neighboring province of Illyricum (Rom. xv. 19); but his real goal was Corinth. For the third time he went there, and, overcoming the scruples of his earlier visits, he was the guest of Gaius, in whose house the meetings of the community took place.

Of the incidents of his visit no record remains; the Acts do not even mention it. But it was the culminating point of his intellectual activity. He resolved to go to Jerusalem and then to the new mission fields of Rome and the still farther West. His departure from Corinth, like that from Ephesus, was probably hastened by danger to his life; and, instead of going direct to Jerusalem, he and his companions took a circuitous route around the Ægean Sea. His course lay through Philippi, Troas, Mitylene, Chios, and Miletus, where he took farewell of the elders of the community at Ephesus. Thence he went, by what was probably an ordinary route of commerce, to the Syrian coast, and at last he reached the Holy City.

The narrative which the Acts give of the incidents of his life there is full of grave difficulties. It leaves altogether in the background that which Paul himself mentions as his chief reason for making the visit; and it relates that he accepted the advice which was given him to avail himself of the custom of vicarious vows, in order to show, by his conformity to prevalent usages, that "there was no truth" in the reports that he had told the Gentiles "not to circumcise their children, neither to walk after the customs."

What coloring of a later time, derived from later controversies, has been spread over the original outline of the history cannot now be told. But it is certain Paul went to Rome.

His life at Rome and all the rest of his history are enveloped in mists from which no single gleam of certain light emerges. Almost every writer, whether apologetic or skeptical, has some new hypothesis respecting it; and the number and variety of the hypotheses which have been already framed is a warning, until new evidence appears, against adding to their number. The chief of the preliminary questions is the genuineness of the epistles bearing Paul's name, which, if they be his, must be

assigned to the later period of his life, viz., those to the Philippians, Ephesians, and Colossians, to Philemon, to Timothy, and to Titus. As these epistles do not stand or fall together, but give rise in each case to separate discussion, the theories vary according as they are severally thought to be genuine or false. The least disputed is the Epistle to Philemon.

But, even if this preliminary question of the genuineness of the several epistles be decided in each instance in the affirmative, there remains the further question whether they or any of them belong to the period of Paul's imprisonment at Rome, and, if so, what they imply as to his history. It is held by many writers that they all belong to an earlier period of his life, especially to his stay at Cæsarea. It is held by other writers that they were all sent from Rome.

The place and manner and occasion of his death are not less uncertain than the facts of his later life. The only fragment of approximately contemporary evidence is a vague and rhetorical passage in the letter of Clement of Rome (c. 5): "Paul \* \* \* \* having taught the whole world righteousness, and having come to the goal of the West, and having borne witness before the rulers, so was released from the world and went to the Holy Place, having become the greatest example of patience." The two material points in this passage, (1) "the limit of the West," (2) "having borne witness," are fruitful sources of controversy. The one may mean either Rome or Spain, the other may mean either "having testified" or "having suffered martyrdom." It is not until toward the end of the second century, after many causes had operated both to create and to crush traditions, that mention is made of Paul as having suffered about the same time as Peter at Rome; but the credibility of the assertion is weakened by its connection in the same sentence with the erroneous statement that Peter and Paul went to Italy together after having founded the church at Corinth. A Roman presbyter named Gaius speaks, a few years later, of the martyrdoms of the two apostles being visible at Rome; but neither this testimony nor that of Tertullian is sufficient to establish more than the general probability that Paul suffered martyrdom. But there is no warrant for going beyond this, as almost all Paul's biographers have done, and finding an actual date for his martyrdom in the so-called Neronian persecution of 64 A.D.

The chronology of the rest of his life is as uncertain as the date of his death. We have no means of knowing when he was born, or how long he lived, or at what dates the several events of his life took place. The nearest approach to a fixed point from which the dates of some events may be calculated is that of the death of Festus, which may probably, though by no means certainly, be placed in 62 A.D.; even if this date were certainly known, new evidence would be required to determine the length of time during which he held office; all that can or could be said is that Paul was sent to Rome some time before the death of Festus in 62 A.D.

Of the writings which are ascribed to him in the current list of the canonical books of the New Testament, and also of the Epistle to the Hebrews, accounts will be found in separate articles under their respective titles. The writings which are ascribed to him outside the canon, and which are all unquestionably pseudonymous, are the following:—(1) *The Epistle to the Laodiceans*. This is supposed to be the letter mentioned in Col. iv. 16; it has been recognized as apocryphal from early times. (2) *A Third Epistle to the Corinthians*, i. e., the letter mentioned in 1 Cor. v. 9. This is found in an Armenian version, together with an equally apocryphal letter of the Corinthians to Paul. (3) *Letters between Paul and Seneca*. These are first mentioned by Jerome

and Augustine, *Epist. 54 (153), ad Macedonium*, and have given rise to interesting discussions as to the possibility of personal relations having actually existed between the two men. The letters will be found in most editions of Seneca. Besides these apocryphal letters there are several apocryphal works which profess to add to our information respecting his life.

PAUL THE DEACON. See PAULUS DIACONUS.

PAUL OF SAMOSATA, bishop of Antioch from about 260 A. D., famous in church history as the author of the last attempt to replace the doctrine of the essential (physical) divinity of Christ by the old view of the human personality of the Redeemer. The effort was not successful even within his own community. About the life of Paul we know scarcely anything. His enemies, indeed, describe him as an unspiritual prelate, an empty preacher, an arrogant man of the world, and a crafty sophist; but this portrait must not be too readily accepted.

PAUL, the name of five popes.

PAUL I., pope from 757 to 767, succeeded his brother Stephen III, on May 29, 757. His pontificate was chiefly remarkable for his close alliance with Pippin, king of France. He died on June 28, 767, and received the honor of canonization, which he seems to have merited by his piety and virtues. His successor was Stephen IV.

PAUL II., Pietro Barbo, pope from 1464 to 1471, was born at Venice, February 28, 1418. He was on the mother's side the great-nephew of Gregory XII. and the nephew of Eugenius IV., to whose favor he owed his elevation to the cardinalate at the early age of twenty-two. He seems, however, to have made no especial figure at the papal court until the death of Calixtus III. in 1458. Upon the death of Pius II. he was unanimously and unexpectedly elected his successor, August 31, 1464. He died very suddenly, probably of apoplexy, on July 28, 1471, and was succeeded by Sixtus IV.

PAUL III., Alessandro Farnese, pope from 1534 to 1549, was born February 28, 1468, of an ancient and noble Roman family. He received an excellent education, but his youth was dissolute and stormy, and he owed his promotion to the cardinalate (September, 1493) to the admiration of Alexander VI. for his beautiful sister Giulia, whence he was derisively nicknamed Cardinal Petticoat. He soon showed himself, however, to be a man of ability and character, and his reputation and influence went on steadily increasing until, upon the death of Clement VII., being at the time senior cardinal of the sacred college, he was unanimously elected pope after a conclave of only two days, having been in a manner nominated by his predecessor (October 13, 1534).

No pope has made so many distinguished cardinals, and his promotions included both men of evangelical piety inclined to the new doctrines like Contarini, and fanatical devotees of the old system like Caraffa. The latter group, though Paul had probably little personal inclination for them, triumphed in his councils. The bull instituting the order of the Jesuits (1540) marks the commencement of the Roman counter-reformation; two years afterward the Roman Inquisition was established. Another memorable measure extorted from Paul by the necessities of his position was the convocation of the council of Trent in 1545; but he soon found means to suspend its sittings, which were not resumed for many years. His brief condemning slavery (1537) ranks among the most honorable actions of his reign. Paul's contemporaries respected and courted him, Italy in general enjoyed tranquillity, and the monster who brought such disgrace upon him acquired the princi-

palities of Parma and Piacenza. After, however, the murder of this unworthy son, the ingratitude of his grandsons broke Paul's heart, and, overcome by a sudden fit of passion, he expired on November 10, 1549—enjoying the rare distinction of being one of the very few popes who have died lamented by their subjects. Julius III. was his successor.

PAUL IV., Giovanni Pietro Caraffa, pope from 1555 to 1559, born June 28, 1476, was the nephew of Cardinal Oliviero Caraffa, by whose interest he became at an early age chamberlain to Pope Alexander VI., and subsequently, though contrary to his own inclination, archbishop of Chieti. He was afterward nuncio in England and Spain, both of which missions he discharged with credit; but in 1524, under the influence of strong religious impressions, he resigned his archbishopric, distributed his goods among the poor, and retired from the world to direct the monastic order of Theatins, founded by himself. In 1536 the fame of his sanctity induced Paul III. to call him to his court and confer the dignity of cardinal upon him. He now became the head of the reactionary party at Rome, bent on crushing all tendencies to religious innovation, while insisting on reforms in discipline and moral deportment. Having taken an important part in two conclaves, he was himself unexpectedly elected pope on May 23, 1555, after the death of Marcellus II., notwithstanding his personal unpopularity and the positive veto of Charles V. Raised to the pontifical throne, Paul showed himself a man of extreme counsels in every respect. His open espousal of the cause of France brought upon him a Spanish invasion which would have destroyed his temporal sovereignty but for the superstition of Philip II. and his general Alva, who embraced the first opportunity of making peace. He called his nephews to court and trusted them with blind confidence, but unhesitatingly disgraced them when convinced of their unworthiness. He refused to acknowledge Ferdinand as emperor of Germany, maintaining that Charles had no right to abdicate or Ferdinand to succeed without his own permission. Amid all these agitations he never lost sight of the main purpose of his life—he struggled incessantly against heresy, and was the first pope to issue a full official *Index Librorum Prohibitorum*. He died on August 18, 1559. He was succeeded by Pius IV.

PAUL V., Camillo Borghese, pope from 1605 to 1621, was born in Rome, September 17, 1552, of a noble family. He followed the study of canon law, and after having filled various important offices was made a cardinal in 1596. He succeeded Leo XI. on May 16, 1605, after an unusually long and stormy conclave. No one, till the last moment, had thought of Borghese, who owed his election to his supposed inoffensiveness and the inability of the leaders of the factions to agree upon any other man. Scarcely had he been elected ere he gave convincing proof that his character had been very much mistaken. He showed himself harsh, domineering, impatient of advice, fanatical in his devotion to the secular as well as the spiritual prerogatives of the church, and inflexible in his resolution to uphold them. He began by successfully repressing numerous encroachments of the civil power in various Roman Catholic countries, and thus became tempted to embark in a contention with the republic of Venice, which inflicted a deeper wound on Rome than anything that had taken place since the Reformation. When the Venetians refused to yield, he launched (April, 1606) a bull of excommunication against them, and placed the whole republic under an interdict. The Venetians set him at defiance, forbidding their clergy to pay the least attention to the papal censures, and banishing those who

disobeyed from their dominions. Throughout the remainder of his long pontificate Paul acted with comparative moderation, maintaining, nevertheless, the character of a zealous pontiff intent on combating heresy, and especially active in his encouragement of foreign missions. He ranks among the popes who have contributed most to the embellishment of Rome; the nave, façade, and portico of St. Peter's were completed by him; he also erected the sumptuous Borghese chapel in Santa Maria Maggiore, and greatly benefited the city by improving streets and constructing public fountains. He died on January 28, 1621, and was succeeded by Gregory XV.

PAUL, emperor of Russia, son of Peter III. and of Catherine, was born on October 2, 1754. During the early part of his life he was treated with great harshness by his mother, who had usurped the throne and did not allow him to take any part in the government. His days were spent in retirement, with the exception of a tour which he made in the west of Europe in the year 1780. He was twice married, first, in 1773, to Augusta, princess of Hesse-Darmstadt, who died three years afterward, leaving no issue; secondly, in 1776, to Dorothea Sophia, princess of Würtemberg, who was received into the Greek Church as Maria Feodorovna. Paul Petrovich ascended the throne on the death of his mother Catherine, November 17, 1796. One of his first acts was to cause the body of his father to be exhumed from the Nevski monastery and buried with the empress his wife in the Petropavlovski church among the rest of the czars. Orloff and the other persons implicated in Peter's assassination were compelled to follow the coffins, and afterward banished the empire forever. The chief ministers of the new emperor were Rostopchin and Arakchéeff. Paul now gave signs of a benevolent disposition; among other acts of generosity he set at liberty Kosciusko, who had been detained a prisoner at St. Petersburg. He, however, revived many obsolete imperial privileges which were offensive to the nobility, and became unpopular by introducing German regulations into the army. Alarmed at the progress of the French Republic, he joined Turkey, England, Austria, and Naples in a coalition against Bonaparte. To command the Russians, the veteran Suwaroff was summoned from his rural retreat. For the campaigns of the Russian general, the article RUSSIA may be consulted. It may suffice to say here that he, triumphant at first, was eventually compelled to retreat, and was recalled by Paul. He died in disgrace in the year 1800. Soon afterward the capricious emperor completely changed his plans. Having been flattered by Bonaparte, he secretly made overtures to him and quarreled with England, seizing English vessels and goods which happened to be in the Russian ports. Bonaparte now entered into an agreement with Paul, whereby they should simultaneously invade the English possessions in India. But the coalition was broken up by the assassination of the Russian emperor in the night of March 23 to 24, 1801, which Bonaparte unjustly declared in the *Moniteur* had been planned by the English. The story of his death is well known: he was strangled in the Mikhailovski Palace by Zouboff, Pahlen, and other conspirators. Their original object appears to have been only to make him abdicate. The empress Maria survived till 1828.

PAUL, ST. VINCENT OF. See VINCENT OF PAUL, ST.

PAULDING, JAMES KIRKE, in his day a successful politician, and a writer of much merit and distinction, was born in Dutchess county, N. Y., on August 22, 1778, and removed to New York city in 1800, to reside with his brother-in-law, William Irving, a brother

of Washington Irving. In connection with the latter Paulding began in 1807 a series of brief, lightly humorous articles, which, under the title of "The Salmagundi Papers," soon became popular, and continued to appear until June 25, 1808, when they terminated with the twentieth number. Six years later he published a political pamphlet, *The United States and England*, which attracted the notice of President Madison, who in 1814 appointed the author secretary to the Board of Navy Commissioners. Subsequently Paulding was for twelve years navy agent in New York city, and from 1837 to 1841 secretary of the navy, under President Van Buren. His marriage in 1818, the death of his wife and his own withdrawal from public life in 1841, with his death on April 5, 1860, comprise the chief remaining facts of his useful, honorable, and uneventful career.

PAULI, REINHOLD, historian, was born at Berlin May 25, 1823. From his mother, who was of Huguenot descent, he derived a vivacious temperament; from his father, a minister of the Reformed Church, sprung of a family of clergymen and theological professors, he inherited strong religious convictions. He spent his boyhood in Bremen, and studied at the university of Berlin (1842-46), where he acquired a lifelong predilection for the Hohenzollerns and for the civil service and army of Prussia. Ranke was young Pauli's model historian, but he had far too much individuality to bind himself slavishly to any school. After having taken his degree and passed the public schoolmaster's examination, he became, in 1847, a private tutor in Great Britain. During 1849-52 he served as private secretary to the Prussian ambassador Bunsen in London. The roots of Great and Greater Britain appeared to him to lie in Anglo-Saxon, not in Celtic, institutions, and therefore his first book was *König Aelfred* (Berlin, 1851). Not without material privations Pauli continued his stay in England, and between 1853 and 1858 published three large volumes, comprising the period from Henry II. to Henry VII. In 1855 he became privat-docent at Bonn, and he obtained a professorship at Rostock in 1857. Thence he removed, in 1859, to Tübingen, where, in 1856, he offended the Würtemberg government by vehemently denouncing its Austrian policy in an essay which appeared during the Prussian war in the *Preussische Jahrbücher*. Exiled to a remote country seminary, he preferred to resign. He now returned to his native country and obtained, in 1867, a post in the university of Marburg, which he once represented in the Prussian Upper House. In 1870 he found an honorable position at Göttingen.

Pauli's later life was chiefly devoted to modern history, and the *Geschichte Englands 1814-52*, in 3 vols. (Leipsic, 1864-75), made his name widely known. He fulfilled his duties as a teacher and examiner and as a fellow of different learned societies with punctual accuracy; he became member of the academies of Göttingen, Munich, and Berlin, and honorary doctor of Oxford and Cambridge. He died June 3, 1882.

PAULICIANS, the name of a religious sect which sprang up in Armenia in the latter half of the seventh century. Their founder was Constantine, belonging to a village near Samosata called Mananalis, where a dualistic, perhaps Marcionite, community had long subsisted.

PAULINUS, ST., OF NOLA. Pontius Meropius Anicius Paulinus, who was successively a consul, a monk, and a bishop, was born at Bordeaux in 353 A. D. His father, præfectus prætorio in Gaul, was a man of great wealth. The literary education of the future saint was intrusted to his elder contemporary and townsman Ausonius, and how considerable was the degree of culture to which he attained as a writer in both

prose and verse can yet be seen from his extant works. In 378 he was raised to the rank of consul suffectus, and in the following year he appears to have been sent as consularis into Campania. From Campania Paulinus returned to his native place and came into correspondence or personal intimacy with men like Martin of Tours and Ambrose of Milan, whose example could not fail to keep before him the claims of Christianity as conceived by them; and ultimately (about 389) he was formally received into the church by Bishop Delphinus of Bordeaux, whence shortly afterward he withdrew with his wife beyond the Pyrenees. The personal asceticism of Paulinus and his liberality toward the poor soon brought him into great repute among all the devout of the region in which he had settled; and while he was spending Christmas at Barcelona the enthusiasm of the people rose to such a pitch that they insisted on his being forthwith ordained to the priesthood. At the next vacancy, not later than 409, he succeeded to the bishopric of Nola, and this office he held with ever-increasing honor until his death, which occurred shortly after that of Augustine in 431. He is commemorated by the Church of Rome on June 22d.

PAULUS, HEINRICH EBERHARD GOTTLOB, the distinguished representative of the rationalistic school of German theologians of the beginning of this century, was born at Leonberg, near Stuttgart, September 1, 1761. The chief exegetical works of Paulus are his *Philologisch-kritischer und historischer Commentar über das Neue Testament* (4 vols., 1800-1804), *Clavis über die Psalmen* (1791), and *Clavis über Jesaias* (1793), and particularly his *Exegetisches Handbuch über die drei ersten Evangelien* (3 vols., 1830-33; 2d ed., 1841-42). His *Life of Jesus* (2 vols., 1828) is a synoptical translation of the Gospels, prefaced by an account of the preparation for the Christ and a brief summary of His history, and accompanied by very short explanations interwoven in the translation. The form of the work was fatal to its success, and the subsequent *Exegetisches Handbuch* rendered it quite superfluous. He died, faithful to his first rationalistic position, a staunch friend of intellectual and political freedom and light, August 10, 1851, in his ninetieth year.

PAULUS, JULIUS. See ROMAN LAW.

PAULUS (or PAULLUS), LUCIUS ÆMILIUS, a distinguished Roman general, of the patrician family of the Æmilii, was born about 229 B.C. His first laurels were won in Further Spain, whither he was sent as prætor in 191. After a period of retirement from public life he was elected consul a second time, for 168, and intrusted with the command in the Macedonian war. Paulus brought the war to a speedy termination by the battle of Pydna, fought on June 22 (Julian calendar), 168. The battle decided the fate of Macedonia, which was henceforward a Roman province. But his public glory was closely attended by private misfortune; of the two sons borne him by his second wife one died a few days before, the other a few days after, his triumph. The veteran was thus left without a son to bear his name; for of his two sons by his first wife Papiria, the elder had been adopted by Quintus Fabius Maximus, Hannibal's great opponent, and the younger by the son of Scipio Africanus. The latter, known as P. Cornelius Scipio Æmilianus, was the conqueror of Carthage and Numantia. Paulus was censor in 164, and died in 160, B.C.

PAULUS ÆGINETA. See ÆGINETA and MEDICINE.

PAULUS DIACONUS, the historian of the Lombard dominion in Italy, flourished in the eighth century (see LOMBARDS). He was born in 720, and spent some years in a monastery, and later went to France. After some years' residence in France, Paulus returned

to Italy and to his convent, and died, probably between 790 and 800, at his beloved Monte Cassino.

PAUPERISM. See POOR LAWS.

PAUSANIAS, the general who led the Greeks to victory at Plataea, was a Spartan and a member of the Agid branch of the royal house. He commanded the united Greek army at the memorable battle of Plataea (479), which forever secured the freedom of Greece against the Persians. After the expulsion of the Persians from Greece Pausanias led a Greek fleet (478 or 477) to Cyprus and thence to Byzantium, which he captured from the Persians. He conceived the design of making himself master of all Greece, and to this end entered into treasonable correspondence with the enemy. Pausanias was recalled to Sparta and tried, but, though convicted and punished for minor offenses, the evidence was insufficient to substantiate the charge of treason, and he was acquitted. Having afterward the folly to return to Byzantium in a private capacity and reopen communications with Persia, he was again recalled and put on his trial. There was strong suspicion of his treason, but no positive evidence. It was known, too, that he had incited the Helots to revolt. But not until they had contrived to overhear a conversation between Pausanias and his messenger were the ephors satisfied of his guilt; and then they proceeded to arrest him. Foreseeing their intention, Pausanias took refuge in the temple of Athene of the Brazen House. The ephors took off the roof, blocked up the doors, and starved him. When on the point of death he was dragged out, that his corpse might not defile the sanctuary. This happened about 467.

PAUSANIAS, a prose writer of Greek traditions, mythical and historical, and a critic of Greek art. His important work, in ten books, usually known as *Pausaniæ Descriptio Græciæ*, has come down to us entire. It is strictly an itinerary through the Peloponnesus, including Attica, Bœotia, and Phocis, with a rather slight mention of the adjacent islands and some of the principal towns on the Asiatic coast. It was evidently compiled by one whose interest was mainly centered in making notes of art-collections as they existed in the Greek temples and public places in the time of the Antonines. Of the personal history of Pausanias nothing is recorded. He lived during the prosperous times of the Roman empire under Hadrian, whom he often mentions by name, and his successors Antoninus Pius and Marcus Aurelius, the latter of whom became emperor in 161 A. D.

PAUSILIPO, or POSILLIPO. See NAPLES.

PAVIA, a city of Italy, the chief town of a province, and a bishop's see, is situated twenty-two and one-half miles by rail south of Milan, on the left bank of the Ticino. The railway from Milan to Genoa, which is there joined by lines from Cremona, etc., crosses the river on a fine bridge constructed in 1865; and, farther down, the city is connected with the suburban village of Ticino by a remarkable brick-built covered bridge dating from the fourteenth century. Though it has lost its importance as a fortified town, and no longer deserves the designation of "City of the Hundred Towers," Pavia is still for the most part surrounded by its ramparts, which in a circuit of about three and one-half miles inclose an area of 400 acres. Several of its buildings are of great architectural interest. The basilica of San Michele is one of the finest specimens extant of the Lombard style, and as it was within its walls that the crown was placed on the head of the "kings of Italy," from whom the house of Savoy claims to be descended, it has received the legal title of Basilica Reale. The cathedral of San Stefano, of which the first stone was laid by Bishop Ascanio Sforza in 1488,

is still unfinished. In the interior is the tomb of St. Augustine, a remarkable specimen of fourteenth-century sculpture, which presents the saint life-size in pontifical robes.

The university of Pavia (formally constituted in 1361 by the emperor Charles IV., but claiming to have its first origin in a school founded by Charlemagne) has faculties of law, medicine, and science. The professors number between forty and fifty, but the students have decreased from 1,475 in 1860 to 604 in 1889. The university library was founded by Maria Theresa in 1754; the famous collection of books which Gian Galeazzo brought together by the aid of Petrarch was carried off to Blois by the French in 1500. The civil hospital of San Matteo is a large and flourishing institution, dating from 1449; like the Borromeo and Ghislieri colleges, it has large landed estates in the circondario. Comparatively few manufactures are prosecuted in Pavia, but there is considerable trade by water as well as by rail, barges being able to pass down the Po to the Adriatic and along the canal to Milan. The population of the city was 27,792 in 1881, or, including the suburbs Ticino, Calvenzano, and Borgorato, 29,836; that of the commune was 29,941 in 1881.

PAVLOGRAD, a town of European Russia, at the head of a district in the government of Ekaterinoslaff. It dates from the latter half of the eighteenth century, and was originally known as Luganskoe Selo. It was made a district town of Ekaterinoslaff in 1784. Its population is 13,000.

PAWPAW, (Malay *papaya*), the fruit of a small American tree (*carica papaya*). The fruit is eaten, but to some it is not palatable, while it is favorite with others. The root of the tree has not a pleasant odor, and the juice of the fruit, before ripening, contains an albuminous substance resembling fibrine. The plant is said to make meat tender. Meat newly killed and covered by the leaves becomes soft and delicate, and certain animals fed on these leaves have very tender flesh.

Pawpaw is the name also given to a North American tree (*Asimina triloba*) which varies in height from ten to twenty feet. There are several smaller species of *Asimina* to which the same term is applied. The roots and bark of these trees give forth an unpleasant odor. The ripe fruit, which is several inches long, is of a yellowish color and much more bulbous than the banana. The pulp is soft and tasteless and contains large seeds. The tree is found in the sandy regions of Georgia and Florida.

PAWTUCKET, a town in Providence county, R. I., four miles northeast of Providence, is situated on both sides of the navigable Pawtucket river (Blackstone river above the falls), which falls about fifty feet at this point, affording abundant water-power. At Pawtucket in 1790, Samuel Slater erected the first water-power cotton-factory in America. In the earlier part of the present century Pawtucket was the seat of shipbuilding and of considerable commerce. It is now a place with nearly 100 different industries, large manufactories of cotton and woolen cloths, steam-engines, fire-engines, etc. The exports and imports amount to several million dollars annually. In 1862 Pawtucket, originally belonging to Massachusetts, became part of Rhode Island. The population in 1880 was 19,030, and in 1890 was 27,633.

PAXO, or PAXOS, one of the IONIAN ISLANDS (*q. v.*) about eight miles south of the southern extremity of Corfu, is a hilly mass of limestone five miles long by two broad, and not more than 600 feet high. Though it has only a single stream and a few springs, and the inhabitants were often obliged, before the Russians and

English provided them with cisterns, to bring water from the mainland. Paxo is well clothed with olives, which produce oil of the very highest quality. Gaion (or, less correctly, Gaia), the principal village, lies on the east coast, and has a small harbor. Toward the center, on an eminence, stands Papandi, the residence of the bishop of Paxo, and throughout the island are scattered a large number of churches. On the west and southwest coasts are some extensive and remarkable caverns.

PAXTON, SIR JOSEPH, architect and ornamental gardener, was born at Milton Bryant, near Woburn, Bedfordshire, England, in 1803, and was educated at the grammar school of that town. Having served his apprenticeship as gardener, he obtained employment at Chiswick, the seat of the duke of Devonshire, and eventually became superintendent of the duke's gardens and grounds at Chatsworth, and manager of his Derbyshire estates. Here he built a grand conservatory, in which he introduced various improvements of great value in construction and arrangements. To this edifice there attaches a peculiar interest from the fact that it formed the model for the Great Exhibition building of 1851. The happy suggestion of Paxton solved a difficulty which threatened to render it impossible to hold the exhibition, and in recognition of his services he received the honor of knighthood. On the formation of the Crystal Palace Company he was invited to prepare the design for the building at Sydenham, and was also appointed director of the gardens and grounds. In 1854 he was chosen M. P. for Coventry, which he continued to represent till his death, which occurred at his residence near the Crystal Palace, June 8, 1865. Paxton was elected in 1826 a Fellow of the Horticultural Society, in 1833 a Fellow of the Linnæan Society, and in 1844 he was made a knight of the order of St. Vladimir by the emperor of Russia.

PAYMENT, in English law, is one of the modes of performance of an obligation, and consists in the discharge of a sum due in money or the equivalent of money. In order that payment may extinguish the obligation it is necessary that it should be made at a proper time and place, in a proper manner, and by and to a proper person. If the sum due be not paid at the appointed time, the creditor is entitled to sue the debtor at once, in spite of the readiness of the latter to pay at a later date, subject, in the case of bills and notes, to the allowance of days of grace. In the common case of sale of goods for ready money, a right to the goods vests at once upon sale in the purchaser, a right to the price in the seller; but the seller need not part with the goods till payment of the price.

Payment may be made at any time of the day upon which it falls due, except in the case of mercantile contracts, where the creditor is not bound to wait for payment beyond the usual hours of mercantile business. If no place be fixed for payment, the debtor is bound to find, or to use reasonable means to find, the creditor, unless the latter be abroad. Payment must be made in money which is a legal tender, unless the creditor waive his right to payment in money by accepting some other mode of payment, as a negotiable instrument or a transfer of credit. If the payment be by negotiable instrument, the instrument may operate either as an absolute or as a conditional discharge. In the ordinary case of payment by check the creditor accepts the check conditionally upon its being honored; if it be dishonored, he is remitted to his original rights. The creditor has a right to payment in full, and is not bound to accept part payment unless by special agreement. Part payment is sufficient to take the debt out of the Statute of Limitations. It is a technical rule of English

law that payment of a smaller sum, even though accepted by the creditor in full satisfaction, is no defense to a subsequent action for the debt. The reason of this rule seems to be that there is no consideration for the creditor foregoing his right to full payment. In order that payment of a smaller sum may satisfy the debt, it must be made by a person other than the person originally liable, or at an earlier date, or at another place, or in another manner than the date, place, or manner contracted for. Payment must in general be made by the debtor or his agent, or by a stranger to the contract with the assent of the debtor. If payment be made by a stranger without the assent of the debtor, it seems uncertain how far English law regards such payment as a satisfaction of the debt. If the debtor ratify the payment, it then undoubtedly becomes a satisfaction. Payment must be made to the creditor or his agent. A *bona fide* payment to an apparent agent may be good, though he has in fact no authority to receive it. Such payment will usually be good where the authority of the agent has been countermanded without notice to the debtor. The fact of payment may be presumed, as from lapse of time. Thus payment of a testator's debts is generally presumed after twenty years. A written receipt is only presumptive and not conclusive evidence of payment. If payment be made under a mistake of fact, it may be recovered, but it is otherwise if it be made under a mistake of law, for it is a maxim of law that *ignorantia legis neminem excusat*. Money paid under compulsion of law, even though not due, cannot generally be recovered where there has been no fraud or extortion.

In the United States the law, as a rule, does not materially differ from English law. In some States, however, money may be recovered, even when it has been paid under a mistake of law. The question of legal tender has been an important one. In 1862 Congress passed an act making treasury notes legal tender. After much litigation, the Supreme Court of the United States finally decided, in 1870, in favor of the constitutionality of this act, both as to contracts made before and after it was passed. These notes are legal tender for all purposes except duties on imports and interest on the public debt. All gold coins, silver dollars, and silver coins below the value of a dollar coined before 1854 are legal tender to any amount. Silver coins below the value of a dollar of 1854 and subsequent years are legal tender for sums not exceeding five dollars. Silver three-cent pieces of the dates 1851 to 1853 are legal tenders for sums not exceeding thirty cents, those of subsequent years for sums not exceeding five dollars. Foreign coins are not legal tender. Postal currency is not legal tender for private debts. It falls exclusively within the jurisdiction of Congress to declare paper or copper money a legal tender. By the constitution of the United States, "no State \* \* \* shall make anything but gold and silver coin a tender in payment of debts."

PAYSANDU, formerly SAN BENITO, a port and departmental town of Uruguay, is situated on the left bank of the river Uruguay, 270 miles by river from Montevideo, and 120 miles by road from Durazno. The long streets run east and west at right angles to the river, and the slope of the ground makes drainage easy. Paysandu has been a great battle-ground: in 1846, for instance, it was held by Oribe and bombarded by Rivera, and in 1865 it was captured by the Brazilians after a twenty-eight days' siege. In 1868 the population was about 9,000, and it has since considerably increased.

PAYTA, or PAITA, a town of Peru, in the province of Piura, with only 2,390 inhabitants, but of importance as the northernmost harbor of the Peruvian coast, the

port of the city of Piara (San Miguel de), with which it is connected by rail, a regular calling-place for steamers, and a great rendezvous for whaling-vessels.

PAZ DE AYACUCHO, LA. See LA PAZ.

PEA (*Pisum*), a genus of *Leguminosæ*, consisting of herbs with compound pinnate leaves ending in tendrils, by means of which the weak stems are enabled to support themselves, and with large leafy stipules at the base. The flowers are typically "papilionaceous," with a "standard" or large petal above, two side petals or wings, and two front petals below forming the keel. The stamens are ten—nine united, the tenth usually free or only slightly joined to the others. The ovary is prolonged into a long, thick, bent style, compressed from side to side at the tip and fringed with hairs. The fruit is a characteristic "legume" or pod, bursting when ripe into two valves, which bear the large globular seeds (peas) on their edges. These seeds are on short stalks, the upper extremity of which is dilated into a shallow cup or aril; the two cotyledons are thick and fleshy, with a radicle bent along their edges on one side. The genus is exceedingly close to *Lathyrus*, being only distinguished technically by the style, which in the latter genus is compressed from above downward and not thick. It is not surprising, therefore, that under the general name "pea" species both of *Pisum* and of *Lathyrus* are included. The common field or gray pea with compressed mottled seeds and two to four leaflets is *Pisum arvense*, which is cultivated in all temperate parts of the globe, but which, according to the Italian botanists, is truly a native of central and southern Italy. The garden pea, *P. sativum*, is more tender than the preceding, and its origin is not known. It has not been found in a wild state anywhere, and it is considered that it may be a form of *P. arvense*, having, however, from four to six leaflets to each leaf and globular seeds of uniform color.

PEABODY, a town in Essex county, Mass., five miles northwest of Salem. Incorporated as South Danvers in 1855, it adopted its present name in 1868 in honor of the philanthropist George Peabody, who was born in the township, and in 1852 erected there the Peabody Institute, which now contains various memorials of its founder, the portrait of herself presented by Queen Victoria, the Congress medal, etc. Peabody contains a large number of leather and morocco factories, and several glueworks, printworks, etc. Its inhabitants numbered 9,028 in 1880, and 10,158 in 1890.

PEABODY, GEORGE, philanthropist, was descended from an old yeoman family of Hertfordshire, England, named Pabody or Pebody, who, six generations before his birth, had emigrated to New England. He was born at Danvers (now Peabody), Mass., February 18, 1795. The only regular education he received was at the district school, and when only eleven years of age he became apprentice at a grocery store. After serving as a volunteer at Fort Warburton in the short war between Great Britain and the United States, in 1812, he became partner with Elisha Riggs in a dry-goods store, Riggs furnishing the capital, while Peabody had the practical management. Through his energy and skill the business increased with rapidity, and on the retirement of Riggs about 1830, Peabody found himself at the head of one of the largest mercantile concerns in the world. About 1837 he established himself in London, England, as merchant and money-broker, and in 1843 he withdrew from the concern in America. It is, however, as a philanthropist that Peabody has made his name a household word. While holding aloof from the strife of politics in the United States, he was ready to give his native country the benefit of his business skill and the aid of his wealth in its financial difficulties. The num-

ber of his great benefactions to public objects is too great for bare mention here. It must suffice to name among the more important a gift of \$125,000 for educational purposes at Danvers; \$500,000 to found and endow an institution for science in Baltimore, a sum afterward increased by a second donation of \$500,000; of various sums to Harvard University; and of \$1,750,000 for the erection of dwelling-houses for the working-classes in London, which sum was increased by his will to \$2,500,000. If this last benefaction has failed to produce the good results anticipated, this has been due to causes for which Peabody was not responsible, and which do not at all detract from the wise beneficence of the gift. He received from the Queen the offer of a baronetcy, but declined it. In 1867 the United States Congress awarded him a special vote of thanks for his many large gifts to public institutions in America. He died at Eaton Square, London, November 14, 1869.

**PEACH.** By Bentham and Hooker the peach is included under the genus *Prunus* (*Prunus persica*), and its resemblance to the plum is indeed obvious; others have classed it with the almond, *Amygdalus*; while others again have considered it sufficiently distinct to constitute a genus of its own under the name *Persica*.

In general terms the peach may be said to be a medium sized tree, with lanceolate, stipulate leaves, borne on long, slender, relatively unbranched shoots, and with the flowers arranged singly, or in groups of two or more, at intervals along the shoots. The flowers have a hollow tube at the base bearing at its free edge five sepals, an equal number of petals, usually concave or spoon-shaped, pink or white, and a great number of stamens. The pistil consists of a single carpel with its ovary, style, stigma, and solitary ovule or twin ovules. This carpel is, in the first instance, free within the flower-tube, but, as growth goes on, the flower-tube and the carpel become fused together into one mass, the flesh of the peach, the inner layers of the carpel, becoming woody to form the stone, while the ovule ripens into the kernel or seed. This is exactly the structure of the plum or apricot, and differs from that of the almond, which is identical in the first instance, only in the circumstance that the fleshy part of the latter eventually becomes dry and leathery and cracks open along a line called the suture.

The nectarine is a variation from the peach, mainly characterized by the circumstance that, while the skin of the ripe fruit is downy in the peach, it is shining and destitute of hairs in the nectarine. That there is no essential difference between the two is, however, shown by the facts that the seeds of the peach will produce nectarines, and *vice versa*, and that it is not very uncommon, though still exceptional, to see peaches and nectarines on the same branch, and fruits which combine in themselves the characteristics of both nectarines and peaches. The blossoms of the peach are formed the autumn previous to their expansion, and this fact, together with the peculiarities of their form and position, requires to be borne in mind by the gardener in his pruning and training operations. The only point of practical interest requiring mention here is the very singular fact attested by all peach-growers, that, while certain peaches are liable to the attacks of a parasitic fungus known as mildew, others are not, showing a difference in constitution analogous to that observed in the case of human beings, some of whom will readily succumb to particular diseases, while others seem proof against their attacks. In the case of the peach this peculiarity is in some way connected with the presence of small glandular outgrowths on the stalk, or at the base of the leaf. Some peaches have globular, others reniform glands, others none at all, and these latter

trees are much more subject to mildew than are those provided with glands.

**PEACOCK** (the first syllable from the Latin *Pavo*), the bird so well known from the splendid plumage of the male, and as the proverbial personification of pride. A native of the Indian peninsula and Ceylon, in some parts of which it is very abundant, its domestication dates from times so remote that nothing can be positively stated on that score. Setting aside its importation to Palestine by Solomon, its assignment in classical mythology as the favorite bird of Hera or Juno testifies to the early acquaintance the Greeks must have had with it; but, though it is mentioned by Aristophanes and other older writers, their knowledge of it was probably very slight until after the conquests of Alexander. Throughout all succeeding time, however, it has never very freely rendered itself to domestication, and, retaining much of its wild character, can hardly be accounted an inhabitant of the poultry-yard, but rather an ornamental denizen of the pleasure-ground or shrubbery; while, even in this condition, it is seldom kept in large numbers, for it has a bad reputation for doing mischief in gardens, it is not very prolific, and, though in earlier days highly esteemed for the table, it is no longer considered the delicacy it was once thought.

As in most cases of domestic animals, pied or white varieties of the ordinary Peacock, *Pavo cristatus*, are not unfrequently to be seen; and, though lacking in proportion the gorgeous resplendence for which the common fowl stands unsurpassed, they are valued as curiosities. Greater interest, however, attends what is known as the "japanned" Peacock, often erroneously named the Japanese or Japan Peacock, a form which has received the name of *P. nigripennis*, as though it were a distinct species. In this form the cock, besides other less conspicuous differences, has all the upper wing-coverts of a deep lustrous blue instead of being mottled with brown and white, while the hen is of a more or less grayish-white, deeply tinged with dull yellowish-brown near the base of the neck and shoulders. It "breeds true;" but occasionally a presumably pure stock of birds of the usual coloration throws out one or more having the "japanned" plumage, leading to the conclusion that the latter may be due to "reversion to a primordial and otherwise extinct condition of the species," and it is to be observed that the "japanned" male has in the coloration of the parts mentioned no little resemblance to that of the second indubitably good species, the *P. muticus* (or *P. spicifer* of some writers) of Burma and Java, though the character of the latter's crest—the feathers of which are barbed along their whole length instead of at the tip only—and its golden-green neck and breast furnish a ready means of distinction.

The Peafowls belong to the group *Gallinæ*, from the normal members of which they do not materially differ in structure; and, though by some systematists they are raised to the rank of a Family, *Pavonidæ*, most are content to regard them as a Subfamily of *Phasianidæ* (PHEASANT), (*q.v.*)

**PEACOCK, GEORGE**, mathematician, was born at Thornton Hall, Denton, near Darlington, April 9, 1791. He was educated at Richmond, Yorkshire, and entered Trinity College, Cambridge, in 1809. He was second wrangler in the mathematical tripos of 1812 (Sir J. F. W. Herschel being senior), was elected fellow of his college in 1814, and became assistant tutor and lecturer in 1815, full tutor in 1823, and sole tutor of "his side" in 1835. Peacock distinguished himself by his business capacity, and by his broad views of the duties and functions of the educational institution in whose management he had so large a share.

In 1837 he was appointed Lowndean professor of astronomy. In 1839 he took the degree of D.D., and the same year was appointed by Lord Melbourne to the deanery of Ely. He improved the sanitation of Ely, published in 1840 *Observations on Plans for Cathedral Reform*, and carried out extensive works of restoration in his own cathedral.

This list by no means exhausts the sphere of Peacock's activity. He was a prime mover in the establishment of the Cambridge Astronomical Observatory, and in the founding of the Cambridge Philosophical Society. He was a fellow of the Royal, Royal Astronomical, Geological, and other scientific societies. In 1838, and again in 1843, he was one of the commissioners for standards of weights and measures; and he also furnished valuable information to the commissioners on decimal coinage, a matter in which he took great interest. He died on November 8, 1858.

PEACOCK, THOMAS LOVE, novelist and poet, was born at Weymouth, England, October 18, 1785. After a brief experience of business he elected to devote himself to study and the pursuit of literature, living with his mother on their private means. His first books were poetical, *The Monks of St. Mark* (1804), *Palmyra* (1806), *The Genius of the Thames* (1810), *The Philosophy of Melancholy* (1812)—works of no great merit. He also made several dramatic attempts, which did not find their way to the stage. In 1812 he became acquainted with Shelley, who made him his executor together with Lord Byron. In 1815 he evinced his peculiar power by writing *Headlong Hall*, the prototype of all his subsequent novels. It was published in 1816, and *Melincourt* followed in the ensuing year. During 1817 he lived at Great Marlow, enjoying the almost daily society of Shelley, and writing *Nightmare Abbey* and *Rhododaphne*, by far the best of his long poems. In 1819 he received the appointment of assistant examiner at the India House. He also contributed to the *Westminster Review* and the *Examiner*. His services to the East India Company, outside the official routine, were considerable. In 1836 he succeeded Mill as chief examiner, and in 1856 he retired upon a pension. During his later years he contributed several papers to *Fraser's Magazine*, including reminiscences of Shelley. He also wrote in the same magazine his last novel *Gryll Grange* (1860), inferior to his earlier writings in humor and vigor, but still a surprising effort for a man of his age. He died January 23, 1866.

PEAR (*Pyrus communis*). The pear has essentially the same floral structure as the apple. In both cases the so-called fruit is composed of the flower-tube or upper end of the flower-stalk greatly dilated, and inclosing within its cellular flesh the five cartilaginous carpels which constitute the "core" and are really the true fruit. From the upper rim of the flower-tube or receptacle are given off the five sepals, the five petals, and the very numerous stamens. The form of the pear and of the apple, respectively, although usually characteristic enough, is not by itself sufficient to distinguish them, for there are pears which cannot by form alone be distinguished from apples, and apples which cannot by superficial appearance be recognized from pears. The main distinction is the occurrence in the tissue of the fruit, or beneath the rind, of clusters of cells, filled with hard woody deposit in the case of the pear, constituting the "grit," while in the apple no such formation of woody cells takes place. The appearance of the tree—the bark, the foliage, the flowers—is, however, usually quite characteristic in the two species. Cultivated pears, whose number is enormous, are without doubt derived from one or two wild species widely distributed throughout Europe and western Asia, and

sometimes forming part of the natural vegetation of the forests. In England, where the pear is sometimes considered wild, there is always the doubt that it may not really be so, but the produce of some seed of a cultivated tree deposited by birds or otherwise, which has degenerated into the wild spine-bearing tree known as *Pyrus communis*.

The cultivation of the pear extends to the remotest antiquity. Traces of it have been found in the Swiss lake dwellings; it is mentioned in the oldest Greek writings, and was cultivated by the Romans. The word "pear" or its equivalent occurs in all the Celtic languages, while in Slavonic and other dialects different appellations, but still referring to the same thing, are found—a diversity and multiplicity of nomenclature which leads De Candolle to infer a very ancient cultivation of the tree from the shores of the Caspian to those of the Atlantic. A certain race of pears, with white down on the under surface of their leaves, is supposed to have originated from *P. nivalis*, and their fruit is chiefly used in France in the manufacture of PERRY (*q.v.*).

PEARL. Pearls are calcareous concretions of peculiar luster, produced by certain molluscs, and valued as objects of personal ornament. It is believed that most pearls are formed by the intrusion of some foreign substance between the mantle of the mollusc and its shell, which, becoming a source of irritation, determines the deposition of nacreous matter in concentric layers until the substance is completely encysted. The popular notion that the disturbing object is commonly a grain of sand seems untenable; according to Dr. Gwyn Jeffreys and some other conchologists, it is in most cases a minute parasite. The experience of pearl-fishers shows that those shells which are irregular in shape and stunted in growth, or which bear excrescences, or are honeycombed by boring parasites, are those most likely to yield pearls.

The substance of a pearl is essentially the same as that which lines the interior of many shells, and is known as "mother-of-pearl."

Although a large number of molluscs secrete MOTHER-OF-PEARL (*q.v.*), only a few of them yield true pearls. The finest are obtained from the so-called "pearl oyster," the *Avicula (Meleagrina) margaritifera*, Linnaeus, while fresh-water pearls are procured chiefly from the "pearl mussel," *Unio (Margaritana) margaritifera*, L. These river-pearls are generally of dull leaden hue, and inferior in beauty to those of marine origin.

It is obvious that if a pearl presents a perfectly spherical form it must have remained loose in the substance of the muscles or other soft tissues of the mollusc. Frequently, however, the pearl becomes cemented to the interior of the shell, the point of attachment thus interfering with its symmetry. In this position it may receive successive nacreous deposits, which ultimately form a pearl of hemispherical shape, so that when cut from the shell it may be flat on one side and convex on the other, forming what jewelers know as a "perle bouton." In the course of growth the pearl may become involved in the general deposit of mother-of-pearl, and be ultimately buried in the substance of the shell. It has thus happened that fine pearls have occasionally been unexpectedly brought to light in cutting up mother-of-pearl in the workshop.

A pearl of the first water should possess, in jewelers' language, a perfect "skin" and a fine "orient;" that is to say, it must be of a delicate texture, free from speck or flaw, and of clear almost translucent white color, with a subdued iridescent sheen. It should also be perfectly spherical, or, if not, of a symmetrical pear-shape. The most perfect pearl in existence is said to be one,

known as "La Pellegrina," in the museum of Zosima in Moscow; it is a perfectly globular Indian pearl of singular beauty, weighing twenty-eight carats. The largest known pearl is one of irregular shape in the South Kensington museum. This magnificent pearl weighs three ounces, has a circumference of four and a half inches, and is surmounted by an enameled and jeweled gold crown, forming a pendant of great value.

The ancients obtained their pearls chiefly from India and the Persian Gulf, but at the present time they are also procured from the Sulu seas, the coast of Australia, the shores of Central America, and some of the South Pacific islands. The ancient fisheries of Ceylon (Taprobane) are situated in the Gulf of Manaar, the fishing banks lying from six to eight miles off the western shore, a little to the south of the isle of Manaar. The Tinnevely fishery is on the Madras side of the strait, near Tuticorin. These Indian fishing-grounds are under the control of government inspectors, who regulate the fisheries, and permit fishing only when they consider the banks to be in a satisfactory condition. The oysters yield the best pearls at about four years of age. Fishing, generally commences in the second week in March, and lasts for from four to six weeks, according to the season. The boats are grouped in fleets of from sixty to seventy, and start usually at midnight so as to reach the oyster-banks at sunrise. Each boat generally carries ten divers.

To facilitate the descent of the diver, a stone of granite weighing about forty pounds is attached to the cord by which he is let down. The divers work in pairs, one man diving while the other watches the signal-cord, drawing up the sink-stone first, then hauling up the baskets of oysters, and finally raising the diver himself. On an average the divers remain under water from fifty to eighty seconds, though some can endure a much longer submergence, and exceptional instances are cited of men remaining below for as long as six minutes. After resting for a minute or two at the surface, the diver descends again; and so on, until exhausted, when he comes on board and watches the rope, while his comrade relieves him as diver.

Since the days of the Macedonians pearl-fishing has been carried on in the Persian Gulf. It is said that the oyster-beds extend along the entire Arabian coast of the gulf, but the most important are on sandbanks off the islands of Bahrein. According to Colonel Polly's report, there are 1,500 boats belonging to Bahrein alone, and the annual profit from the pearl-fishery was about \$2,000,000. There is a small pearl-fishery near Kurrahee on the coast of Bombay.

From the time of the Ptolemies pearl-fishing has been prosecuted along the coast of the Red Sea, especially in the neighborhood of Jiddah and Koseir.

Very fine pearls are obtained from the Sulu Archipelago, on the northeast of Borneo. The pearl-oyster occurs throughout the Pacific, mostly in the clear water of the lagoons within the atolls, though fine shells are also found in deep water outside the coral reefs. The Polynesian divers do not employ sink-stones, and the women are said to be more skillful than the men. Fine pearl-shells are obtained from Navigators' Islands, the Society Islands, the Low Archipelago or Paumotu Isles, and the Gambier Islands.

Pearl-fishing is actively prosecuted along the western coast of Central America, especially in the Gulf of California, and to a less extent around the Pearl Islands in the Bay of Panama. These pearls are obtained from the *Maleagrina californica*, Cpr., and the mother-of-pearl shell is known in commerce as "Panama" or "bullock" shell. Some pearls of rare beauty have been obtained from the Bay of Mulege, near Los Coytes, in

the Gulf of California; and in 1882 a pearl of seventy-five carats, the largest on record from this district, was found near La Paz in California. The coast of Guayaquil also yields pearls. Columbus found that pearl-fishing was carried on in his time in the Gulf of Mexico, and pearls are still obtained from the Caribbean Sea. In the West Indies the best pearls are obtained from St. Thomas and from the island of Margarita, off the coast of Venezuela. From Margarita Philip II. of Spain is said to have obtained, in 1579, a famous pearl of 250 carats.

Of late years pearl-fishing has been started with considerable success in the Australian seas.

River pearls are produced by the fresh-water mussels inhabiting the mountain streams of temperate climates in the northern hemisphere—especially in Scotland, Wales, Ireland, Saxony, Bohemia, Bavaria, Lapland and Canada. They are found in many parts of the United States, and have been systematically worked in the Little Miami river, Warren county, Ohio. The season extends from June to October. Japan produces freshwater pearls, found especially in the *Anodonta japonica*. But it is in China that the culture of the pearl-mussel is carried to the greatest perfection. The Chinese also obtain marine pearls, and use a large quantity of mother-of-pearl for decorative purposes.

Pink pearls are occasionally found in the great conch or fountain shell of the West Indies, *Strombus gigas*, L.; but these, though much prized, are not nacreous, and their tint is apt to fade. Black pearls, which are very highly valued, are obtained chiefly from the pearl-oyster of the Gulf of Mexico.

*Artificial pearls* were first made in western Europe in 1680 by a rosary-maker in Paris, and the trade is now largely carried on in France, Germany, and Italy. Spheres of thin glass are filled with a preparation known as "essence d'orient," made from the silvery scales of the bleak or "ablette," which is caused to adhere to the inner wall of the globe, and the cavity is then filled with white wax. The scales are in some cases incorporated with celluloid. Many imitation pearls are now formed of an opaline glass of nacreous luster, and the soft appearance of the pearl obtained by the judicious use of hydrofluoric acid. Pink pearls are imitated by turning small spheres out of the rosy part of the conch shell, or even out of pink coral.

PEARSON, JOHN, a learned English bishop, was born on February 28, 1612. After attending Eton, he entered Queens' College, Cambridge, June 10, 1631, and was elected a scholar of King's in April following and fellow in 1634. Entering holy orders in 1639, he was collated to the prebend of Nether-Avon, in the church of Sarum. In 1640 he was appointed chaplain to the lord-keeper Finch, by whom he was presented to the living of Thorington in Suffolk during the same year. In 1650 he was made preacher of St. Clement's, Eastcheap, in London. In 1659 Pearson published at London his celebrated *Exposition of the Creed*. The same year he likewise published the *Golden Remains of the Ever-memorable Mr. John Hales of Eton*, to which he prefixed a preface containing a character of that eminent man, with whom he had been acquainted for many years, drawn up with great elegance and force. Pearson had also a principal share in the editing of the *Critici Sacri*, first published in 1660. Soon after the Restoration he was presented by Juxon, then bishop of London, to the rectory of St. Christopher's in that city; and he was also in 1660 created doctor of divinity at Cambridge, in pursuance of the king's letters mandatory, installed prebendary of Ely, archdeacon of Surrey, and made master of Jesus College, Cambridge. In 1661 he was appointed Lady Margaret professor of

divinity in that university; and on the first day of the ensuing year he was nominated one of the commissioners for the review of the liturgy in the conference held at the Savoy. On April 14, 1662, he was elected master of Trinity College, Cambridge, and in August resigned his rectory of St. Christopher's and his prebend of Ely. In 1667 he was admitted a Fellow of the Royal Society. Upon the death of Doctor Wilkins in 1672, Pearson was appointed his successor in the see of Chester. In 1682 his *Annales Cyprianici* were published at Oxford, with Fell's edition of that father's works. Pearson was disabled from all public service by ill health a considerable time before his death at Chester on July 16, 1686.

PEAT. See FUEL.

PECCARY. Under this name are included two species of small pig-like animals forming the genus *Dicotyles* of Cuvier, belonging to the section *Suina* of the Artiodactyle Ungulates. They are peculiar to the New World, and in it are the only surviving members of the large group now represented in the Old World by the various species of swine, babirussas, wart-hogs, and hippopotami.

The teeth of the peccaries differ from those of the true pigs (genus *Sus*) numerically, in wanting the upper outer incisor and the anterior premolar on each side of each jaw, the dental formula being  $i \frac{2}{3}, c \frac{1}{1}, p \frac{3}{3}, m \frac{2}{3}$ , total 38. The upper canines have their points directed downward, not outward or upward as in the boars, and they are very sharp, with cutting hinder edges, and completely covered with enamel until worn. The lower canines are large and directed upward and outward, and slightly curved backward. The stomach is much more complex than in the true pigs, almost approaching that of a ruminant. As in the pigs, the snout is truncated, and the nostrils are situated in its flat, expanded, disk-like termination. The ears are rather small, ovate, and erect; and there is no external appearance of a tail. The surface is well covered with thick bristly hair, and rather behind the middle of the back is a large and peculiar gland, which secretes an oleaginous substance with a powerful musky odor. This was mistaken by the old travelers for a second navel, a popular error which suggested to Cuvier the name of *Dicotyles*. When the animal is killed for food, it is necessary speedily to remove this gland, otherwise it will taint the whole flesh so as to render it uneatable.

There are two species, so nearly allied that they will breed together freely in captivity. Unlike the true pigs, they never appear to produce more than two young ones at a birth. The collared peccary (*D. tajacu*, Linn., *torquatus*, Cuvier) ranges from the Red river of Arkansas through the forest districts of Central and South America as far as the Rio Negro of Patagonia. Generally it is found singly or in pairs, or at most in small herds of from eight to ten, and is a comparatively harmless creature, not being inclined to attack other animals or human beings. Its color is dark gray, with a white or whitish band passing across the chest from shoulder to shoulder. The length of the head and body is about thirty-six inches. The white-lipped peccary or warree (*D. labiatus*, Cuvier) is rather larger, being about forty inches in length, of a blackish color, with the lips and lower jaw white. Its range is less extensive; it is not found farther north than British Honduras or south of Paraguay. It is generally met with in large droves of from fifty to a hundred or more individuals, and is of a more pugnacious disposition than the former species, and capable of inflicting severe wounds with its sharp tusks. A hunter who encounters a herd of them in a forest has often to climb a tree as his only chance for safety. Both species are omnivor-

ous, living on roots, fallen fruits, worms, and carrion; and when they approach the neighbourhood of villages and cultivated lands they often inflict great devastation upon the crops of the inhabitants.

PECS. See FÜNFKIRCHEN.

PEDOMETER is an apparatus in the form of a watch, which, carried on the person of a traveller, indicates the number of paces made, and thereby approximately the distance traveled. The ordinary form has a dial-plate with chapters for yards and miles respectively, but in some, miles and their fractions only are indicated, while others are divided for kilometers, etc. The registration is effected by the fall of a heavy pendulum, caused by the percussion of each step. The pendulum is forced back to a horizontal position by a delicate spring, and with each stroke a fine-toothed ratchet-wheel attached to it is moved round a certain length. The ratchet communicates with a train of wheels which govern the dial-hands. In using the apparatus a measured mile or other known distance is walked, and the indication thereby made on the dial-plate observed.

PEDRO (PETER), the name borne by several sovereigns of Aragon, Castile, and Portugal. Three of them were contemporaries, and, to add to the confusion to which this has given rise, each of them was the son and successor of an Alphonso.

*Aragon.*—PEDRO IV., born in 1317, surnamed "the Ceremonious," succeeded his father Alfonso IV. in 1336, and died at Barcelona on January 5, 1387, and was succeeded by his son John I.

Three other kings of Aragon bore this name. PEDRO I. succeeded his father Sancho Ramirez on the throne of Aragon and Navarre in 1094, and died in 1104. The leading event of his reign was the conquest of Huesca (1096). PEDRO II., born in 1174, succeeded his father Alfonso II. in 1196. He was slain in the disastrous battle of Muret (September 12, 1213). PEDRO III., born in 1236, son of Jayme I. and grandson of Pedro II., succeeded to the crowns of Aragon, Catalonia, and Valencia in 1276. He died in 1285.

*Castile and Leon.*—PEDRO I., commonly surnamed "the Cruel," was born at Burgos on August 30, 1333. He was raised to the throne at Seville by his father's premature death before Gibraltar (March 20, 1350). He was killed in a struggle with his brother in 1369, after a life of debauchery during which he was held in utter detestation for his many vices and cruelties.

*Portugal.*—PEDRO I. born in 1320, was the son of Alfonso IV. and Beatrice of Castile, and in 1339 married Constance, daughter of the duke of Peñafiel and marquis of Villena. The story of his passion for Inez de Castro, of his supposed marriage with her, of her cruel murder in 1355, and of the exhumation and coronation of her dead body, has been told elsewhere (see CASTRO, INEZ DE). He succeeded to the throne in 1357, and died in 1367, after a peaceful and comparatively uneventful reign of ten years. (For other sovereigns bearing this name see BRAZIL and PORTUGAL.)

PEEBLES, a midland county of Scotland, is bounded north and northeast by Midlothian, east and southeast by Selkirk, south by Dumfries and west by Lanark. Its outline is somewhat irregular, the greatest length from north to south being about thirty miles, the greatest breadth about twenty, and the smallest about ten. The area is 226,899 acres, or about 355 square miles. From the fact that the county lies within the upper valley of the Tweed, it is sometimes known as Tweeddale. The surface consists of a succession of hills broken by the vale of the Tweed, which in some parts attains considerable breadth, and by the narrow valleys forming the courses of numerous "waters" and smaller streams. The highest summits are Broad Law (2,754

feet), Cramalt Craig (2,723 feet), and Dollar Law (2,680 feet).

The Tweed has its source in a small fountain named Tweed's Well at the base of a hill on the southwestern border called Tweed's Cross, from the farther side of which flow the Annan and the Clyde.

In the uplands the climate, though colder than that of the Lothians, is generally pure and dry, and remarkably healthy. The annual rainfall is about twenty-nine inches. As may be supposed from its hilly character, the country is pastoral rather than agricultural. Although the county has the advantage of convenient railway communication both by the North British and Caledonian systems, and possesses also abundant water-power, the only textile industries are the weaving of tweeds and shawls at Peebles and Innerleithen. The other manufactures are connected with the immediate wants of an agricultural population. The county includes sixteen parishes, and one royal burgh, the county town. Along with the neighboring county of Selkirk it forms a parliamentary county, which returns one member to parliament. In 1861 the population amounted to 11,408, in 1871 to 12,330, and in 1881 to 13,822, of whom 6,626 were males and 7,196 females. The county includes two towns, Peebles (3,495) and Innerleithen (2,313), and two villages, Walkerburn (1,026) and West Linton (434). The town population in 1881 numbered 5,808, the village 1,460, and the rural 6,554.

PEEBLES, the county town of Peebleshire, is finely situated at the junction of the Eddlestone Water and the Tweed, and on the North British and Caledonian Railways, twenty-two miles south of Edinburgh. The population of the royal burgh in 1881 was 2,609.

PEEKSKILL, a manufacturing village in Cortlandt township, Westchester county, N. Y., lies on the east bank of the Hudson, forty-three miles above New York city, with which it has communication by rail and (in summer) by river. Besides iron-smelting, it carries on the manufacture of railings, stoves, and fire-bricks. A church, dating from 1767, and the Van Cortlandt mansion are among its principal buildings. Incorporated in 1816, Peekskill had 6,560 inhabitants in 1870, and has now (1890) 9,676.

PEEL, SIR ROBERT, twice prime minister and for many years the leading statesman of England, was born February 5, 1788, in a cottage near Bury (Lancashire). He was a scion of that new aristocracy of wealth which sprang from the rapid progress of mechanical discovery and manufactures in the latter part of the eighteenth century. His grandfather, Robert Peel, first of Peel-fold, and afterward of Brookside, near Blackburn, was a calico-printer, who, appreciating the discovery of his townsman Hargreaves, took to cotton-spinning with the spinning-jenny and grew a wealthy man. His father, Robert Peel, third son of the last-named, carried on the same business at Bury with greater success, made a princely fortune, became the owner of Drayton Manor and member of parliament for the neighboring borough of Tamworth, was a trusted and honored, as well as ardent, supporter of Pitt, contributed toward the support of that leader's war policy, was rewarded with a baronetcy, and founded a rich and powerful house, on whose arms he emblazoned, and in whose motto he commemorated, the prosperous industry from which it sprang. The example and precepts of the father took early effect upon his eldest son, whom from the first he destined and prepared to serve his country in public life. At Harrow, according to the accounts of his contemporaries, Peel was a steady, industrious boy, the best scholar in the school. At Christ Church, where he entered as a gentleman commoner, he studied hard, and was the first who, under the new examination statutes, took a first class both in

classics and in mathematics. From his classical studies Robert Peel derived not only the classical, though somewhat pompous, character of his speeches and the Latin quotations with which they were often happily interspersed, but something of his lofty ideal of political ambition. Nor did he ever cease to love these pursuits of his youth; and in 1837, when elected lord rector of Glasgow university, in his inaugural speech he passed a glowing eulogy on classical education.

In 1809, being then in his twenty-second year, he was brought into parliament for the close borough of Cashel, which he afterward exchanged for Chippenham, and commenced his parliamentary career under the eye of his father, then member for Tamworth, who fondly saw in him the future leader of the Tory party. The Tory party was then all-powerful at home; while abroad Europe was at the feet of Napoleon. But Napoleon's fortune was about to turn; and, with the close of the struggle against revolutionary France, political progress in England was soon to resume the march which that struggle had arrested. Young Peel's lot, however, was cast, through his father, with the Tory party. He began official life as Lord Liverpool's private secretary, and shortly afterward, in 1811, was made under-secretary for the colonies by Perceval. In 1812 he was transferred by Lord Liverpool to the more important post of secretary for Ireland. There he was engaged till 1817 in maintaining, by insurrection Acts and other repressive measures, English and Protestant ascendancy over a country heaving with discontent, teeming with conspiracy, and ever ready to burst into rebellion. Peel became, by the necessity of his situation, "Orange Peel," and plied the established engines of coercion and patronage with a vigorous hand. His moderation of tone did not save him from the violent abuse of O'Connell, whom he, young, hot-tempered (though his temper was generally under control), and sensitive on the point of honor, was ill advised enough to challenge—an affair which covered them both with ridicule. In 1817 he obtained the highest parliamentary distinction of the Tory party by being elected member for the university of Oxford—an honor for which he was chosen in preference to Canning on account of his hostility to Catholic emancipation, Lord Eldon lending him his best support. In the following year he resigned the Irish secretaryship, of the odious work of which he had long been very weary, and remained out of office till 1822. But he still supported the ministers with official zeal, even in the question of the "Peterloo massacre." In the affair of Queen Caroline, however, he stood somewhat aloof, disapproving some steps taken by the government, and sensitive to popular opinion; and when Canning retired on account of this affair Peel declined Lord Liverpool's invitation to take the vacant place in the cabinet. During this break in his tenure of office he had some time for reflection, which there was enough in the aspect of the political world to move. At this period he was made chairman of the bullion committee on the death of Horner. He was chosen for this important office by Huskisson, Ricardo, and their fellow-economists, who saw in him a mind open to conviction. Peel was converted to the currency doctrines of the economists, and proclaimed his conversion in a great speech on May 24, 1819, in which he moved and carried four resolutions embodying the recommendations of the bullion committee in favor of a return to cash payments. This laid the foundation of his financial reputation, and his coöperation with the economists tended to give a liberal turn to his commercial principles.

In 1820 Peel married Julia, daughter of General Sir John Floyd, who bore him five sons and two daughters.

Three of his sons, Robert, Frederick, and Arthur, have followed him in holding parliamentary office, the youngest being now (1890) speaker of the House of Commons; while another, William, the sailor, has run a bright course in another sphere, and found a glorious grave.

In 1822 he became home secretary; and in that capacity he had again to undertake the office of coercing the growing discontent in Ireland, of which he remained the real administrator, and had again to lead in the House of Commons the opposition to the rising cause of Catholic emancipation. In 1825, being defeated on the Catholic question in the House of Commons, he wished to resign office, but Lord Liverpool pleaded that his resignation would break up the government. He found a more congenial task in reforming and humanizing the criminal law, especially those parts of it which relate to offenses against property and offenses punishable by death. The five Acts in which Peel accomplished this great work, the first step toward a complete and civilized code, as well as the great speech of March 9, 1826, in which he opened the subject to the House, will form one of the most solid and enduring monuments of his fame.

In 1827 the Liverpool ministry was broken up by the fatal illness of its chief, and under the new premier, George Canning, Peel, like the duke of Wellington and other high Tory members of Lord Liverpool's cabinet, refused to serve.

In January 1828, after Canning's death, the duke of Wellington formed a Tory government, in which Peel was home secretary and leader of the House of Commons. This cabinet, Tory as it was, did not include the impracticable Lord Eldon, and did include Huskisson and three more friends of Canning. Its policy was to endeavor to stave off the growing demand for organic change by administrative reform, and by lightening the burdens of the people. Peel also introduced into London the improved system of police which he had previously established with so much success in Ireland. But the tide ran too strong to be thus headed. First the government were compelled, after a defeat in the House of Commons, to acquiesce in the repeal of the Test and Corporation Acts, Peel bringing over their High Church supporters, as far as he could. Immediately afterward the question of Catholic emancipation was brought to a crisis by the menacing power of the Catholic Association and the election of O'Connell for the county of Clare. Peel expressed to the duke of Wellington his conviction that the Catholic question must be settled; and on March 5, 1829, Peel proposed Catholic emancipation in a speech of more than four hours, which was listened to with unflinching attention, and concluded amid cheers which were heard in Westminster Hall. The apostate was overwhelmed with obloquy. Having been elected for the university of Oxford as a leading opponent of the Catholics, he had thought it right to resign his seat on being converted to emancipation. His friends put him again in nomination, but he was defeated by Sir R. H. Inglis. He took refuge in the close borough of Westbury, whence he afterward removed to Tamworth, for which he sat till his death. This great concession did not save the Tory Government. The French Revolution of July, 1830, gave fresh strength to the movement against them, though, schooled by the past, they promptly recognized King Louis Philippe. The parliamentary reform movement was joined by some of their offended Protestant supporters. The duke of Wellington committed them fatally against all reform, first by cashiering Huskisson for voting in favor of giving the forfeited franchise of East Retford to Birmingham, and then by a violent anti-

reform declaration in the House of Lords. The elections went against them on the demise of the crown; they were compelled, by popular feeling, to put off the king's visit to the city; they were beaten on Sir H. Parnell's motion for a committee on the civil list, and resigned. While in office, Peel succeeded to the baronetcy, Drayton Manor, and a great estate by the death of his father May 3, 1830.

The ability and obstinacy of Sir Robert Peel's resistance to the Reform Bill won back for him the allegiance of his party. His opposition was resolute, but it was temperate. He refused to join the duke of Wellington in the desperate enterprise of forming a Tory Government at the height of the storm, when the Grey ministry had gone out on the refusal of the king to promise them an unlimited creation of peers. By this conduct he secured for his party the full benefit of the reaction which he no doubt knew was sure to ensue. He frankly accepted the Reform Act, stamped it as final, taught his party to register instead of despairing, appealed to the intelligence of the middle classes, whose new-born power he appreciated, steadily supported the Whig ministers against the Radicals and O'Connell, and gained every moral advantage which the most dignified and constitutional tactics could afford.

In 1834, on the dismissal of the Melbourne ministry, power came to Sir Robert Peel before he expected or desired it. He hurried from Rome at the call of the duke of Wellington, whose sagacious modesty knew his superior in politics and yielded him the first place, and became prime minister, holding the two offices of first lord of the treasury and chancellor of the exchequer. He was outvoted on the election of the speaker at the opening of the session of 1835, and, after struggling on for six weeks longer, was finally beaten, and resigned on the question of appropriating the surplus revenues of the church in Ireland to national education.

From 1835 to 1840 he pursued the same course of patient and far-sighted opposition, the end of which, sure though distant, was not only office but power. In 1837 the Conservative members of the House of Commons, with victory now in sight, gave their leader a grand banquet at Merchant Taylors' Hall, where he proclaimed in a great speech the creed and objects of his party. In 1839, the Whigs having resigned on the Jamaica Bill, he was called on to form a government, but failed, through the refusal of the queen, by advice of Lords John Russell and Palmerston, to part with the ladies of her bed-chamber, whom he deemed it necessary to replace by ladies not connected with his political opponents. His time was not even yet fully come. In 1840 he was hurried, it is believed by the ardor of his followers, into a premature motion of want of confidence, which was brought forward by Sir John Yarde Buller and failed. But in the following year a similar motion was carried by a majority of one, and the Whigs were compelled to appeal to the country. The result was a majority of ninety-one against them on a motion of want of confidence in the autumn of 1841, upon which they resigned, and Sir Robert Peel, becoming first lord of the treasury, with a commanding majority in both Houses of Parliament, the country in his favor, and many colleagues of the highest ability and distinction, grasped with no doubtful hold the reins of power.

The great financier took till the spring of 1842 to mature his plans. The result was, in place of a deficit of upward of two millions, a surplus of five millions in 1845, and the removal of seven millions and a half of taxes up to 1847, not only without loss, but with gain to the ordinary revenue of the country. In 1844 another great financial measure, the Bank Charter Act, was

passed and, though severely controverted and thrice suspended at a desperate crisis, has ever since regulated the currency of the country. In Ireland O'Connell's agitation for the repeal of the Union had now assumed threatening proportions, and verged upon rebellion, but the troubles here, as elsewhere, were minimized by Peel's wise policy. The weakest part of the conduct of this great government, perhaps, was its failure to control the railway mania by promptly laying down the lines on a government plan. Abroad it was as prosperous as at home.

Yet there was a canker in all this greatness. There were malcontents in Sir Robert Peel's party whose presence often caused embarrassment and twice collision and scandal. But the fatal question was protection. That question was being fast brought to a crisis by public opinion and the Anti-Corn-Law League. Sir Robert Peel had become in principle a free-trader. The approach of the Irish famine in 1845 decisively turned the wavering balance. The ports must be opened, and, being opened, they could not again be closed upon the same conditions. The Clare election and Catholic emancipation were played over again. Sir Robert proposed to his cabinet the repeal of the corn laws. Lord Stanley and the Duke of Buccleuch dissented, and Sir Robert resigned. But Lord John Russell failed to form a new government. Sir Robert again came into office; and now with the consent of all the cabinet but Lord Stanley, who retired, he in a great speech on January 27, 1846, brought the repeal of the corn laws before the House of Commons. In the long and fierce debate that ensued he was overwhelmed, both by political and by personal enemies, with the most virulent invective, which he bore with his wonted calmness, and to which he made no retorts. His measure was carried; but immediately afterward the offended protectionists, goaded by Lord George Bentinck and Disraeli, coalesced with the Whigs and threw him out on the Irish Coercion bill. He went home from his defeat, escorted by a great crowd, who uncovered as he passed, and he immediately resigned. So fell a Conservative Government which would otherwise have probably ended only with the life of its chief.

Though out of office he was not out of power. He had "lost a party, but won a nation." The Whig ministry which succeeded him leant much on his support, with which he never taxed them. In 1849, in a speech on the Irish Poor Laws, he first suggested, and in the next year he aided in establishing, a commission to facilitate the sale of estates in a hopeless state of encumbrance. The Encumbered Estates Act made no attempt, like later legislation, to secure by law the uncertain customary rights of Irish tenants, but it transferred the land from ruined landlords to solvent owners capable of performing the duties of property toward the people. On June 28, 1850, Sir Robert Peel made a great speech on the Greek question against Lord Palmerston's foreign policy of interference. This speech, being against the Government, was thought to show that he was ready to return to office. It was his last. On the following day he was thrown from his horse on Constitution Hill, and mortally injured by the fall. Three days he lingered in all the pain which the quick nerves of genius can endure. On the fourth (July 2, 1850), he took the sacrament, bade a calm farewell to his family and friends, and died; and a great sorrow fell on the whole land.

PEELE, GEORGE, was one of the group of university poets with whom Shakespeare entered into competition at the beginning of his career. It appears from a deposition made by him at Oxford that he was twenty-five years old in 1583. He took his bachelor's degree

at Oxford in 1577, and his master's degree two years afterward. He died in 1598.

PEERAGE. It was remarked in the article NOBILITY that the existence of the peerage, as that word is understood in the three British kingdoms, is something altogether peculiar to those kingdoms, and that it has actually hindered them from possessing a nobility of the Continental type. In its historical use it takes in all the members or possible members of the House of Lords and no other persons. But modern usage and modern decisions seem to limit the use of the name on one side, and to extend it on another. There is no kind of doubt that, according to the earliest precedents—precedents reaching up to the earliest official use of the word *peer*—the spiritual lords are equally peer with the temporal. But it has been held, at least from the seventeenth century, that the spiritual lords, though lords of parliament equally with the temporal lords, are not, like them, peers.

The special character of the British peerage, as distinguished from privileged orders in any other time or place, springs directly from the fact that the essence of the peerage is the hereditary right of a personal summons to parliament. To determine the origin of the peerage is thus to determine how a certain body of men came to possess this hereditary right of summons.

It has been said above that the holder of a peerage as defined is a lord of parliament *in esse* or *in posse*. It has become necessary during the present and last centuries to add these last words to the definition. For it is plain that, since the successive unions of England and Scotland and of Great Britain and Ireland, an hereditary peerage has not always in practice carried with it a seat in the House of Lords. For since those unions certain persons, namely those peers of Scotland and Ireland who are not representative peers and who do not hold peerages of England, of Great Britain, or of the United Kingdom, have been undoubted peers, they have enjoyed some or all of the personal privileges of peerage, but they have had no seats in the House of Lords. But this is a modern accident and anomaly. The persons spoken of held peerages which entitled their holders to seats in the parliaments of Scotland and Ireland as long as those parliaments were distinct bodies. And their present holders, if not members of the House of Lords *in esse*, are such *in posse*. They have a capacity for being chosen to seats in that House which is not shared by other persons. Their membership of the House is rather suspended than altogether taken away.

The use of the word peers ( *pares*) to denote the members of the House of Lords first appears in the fourteenth century, and it was fully established before the end of that century. The name seems to be rather a direct importation from France than anything of natural English or even Norman growth.

But the thing is more important than the name. Whatever view may be taken of the constitution of the ancient Witenagemót, we may safely assume that that assembly, with whatever change in its constitution, is personally continued in the House of Lords. That house consists of two classes of men who have never lost their right to a personal summons, together with certain other classes who have acquired that right in later times. Two classes of men, namely earls and bishops, have, with a certain interval in the seventeenth century, sat continuously in the councils of the nation from the earliest times. These two classes are those whose presence connects the earliest and the latest English assemblies. From the time when the House of Lords began to take anything like its present shape, other classes of men, spiritual and temporal, were sum-

moned as well as the bishops and earls, but not with the same regularity as they were. Some abbots were always summoned from the beginning, and a few other churchmen afterward obtained the same right. But, while every bishop—except in a few cases of personal enmity on the part of the king—was summoned as a matter of course, there was great irregularity in summoning of abbots. So some barons were always summoned as well as the earls; but, while every earl was—with a few such exceptions as in the case of the bishops—summoned as a matter of course, there was great irregularity in summoning the barons. The bishops and earls in short were personages too great to be left out; so were a few of the greatest abbots. Lesser men, spiritual or temporal, might be summoned or not according to a hundred reasons of convenience, caprice, or accident. But it is only the common tendency of things that the occasional summons should grow into the perpetual summons, and that the perpetual summons should, wherever it was possible, that is, in the case of the temporal lords, grow into the hereditary summons. In other words, the doctrine was gradually established that, when a man was once summoned, a right of summons was created for him and his heirs forever. The establishment of this doctrine called into being a new order of men, of lower rank than the bishops and earls but of equal parliamentary power, namely the class of barons having an hereditary right to seats in parliament. Presently, in the course of the fourteenth and fifteenth centuries, the ranks of the temporal peerage were increased by the invention of new orders, those of duke, marquess, and viscount, the two former classes taking precedence of the ancient earls.

The peerage of the temporal lords came to be looked on as something inherent in the blood, something which could not, like the official seat of the churchman, be resigned or lost by any means except by such legal processes as involved "corruption of blood." The parliamentary powers, the formal precedence, of the spiritual lords were not touched, but the idea silently grew that they were not the peers of the hereditary members of the House. In short, the doctrine grew that the temporal lords alone were peers, as alone having their blood "ennobled," which is the herald's way of saying that they held their seats by hereditary right. The extinction of so many temporal peerages in the Wars of the Roses, the creation of so many new peerages under the Tudors, while in one way they lowered the strength and dignity of the order, in another way helped more and more to mark it out a separate order, distinct from all others.

The growth of the hereditary doctrine pressed hardly, we must allow, on both bishops and judges. But its working on either of those classes has been of small moment indeed compared with the effect on the nation at large. There is no institution for which England has greater reason to be thankful than for her hereditary peerage; for, as we began by saying, it has saved her from the curse of a nobility. Or rather to speak more accurately, the growth of the peerage with its comparatively harmless privileges hindered the real nobility from keeping or winning privileges which would have been anything but harmless.

But, while the growth of the peerage thus hindered the growth of a nobility of which every gentleman should be a member, it was still possible that a real nobility might have grown up out of the peerage itself. That is to say, it might have come about that, while none but the descendants of peers were privileged, all the descendants of peers should be privileged. A nobility might thus have been formed, much smaller than a nobility taking in all lawful bearers of coat-ar-

mor, but still a nobility by no means small. But in England no such nobility has ever grown up. No one has any substantial privilege except the peer himself. No one in short is noble but the peer himself. Even in common speech, though we speak of a noble family, we do not personally apply the word *noble* to any other member of that family, unless, in the case of the higher ranks of the peerage, to a few immediate descendants of the peer. In short, while the blood of the peer is said to be ennobled, it is ennobled with a nobility so high and rare that it cannot pass to more than one at a time even of his own descendants. The oldest son of a duke is legally a commoner; the children of his youngest sons are not only legally but socially undistinguishable from other commoners. That is to say, the hereditary possession of the peer is not nobility at all in the sense which that word bears in other lands. It is a fiction to say that the peer's blood is ennobled, when the inheritors of his blood are not inheritors of his nobility. In short, as there is no nobility outside the families whose heads are peers, neither is there any real nobility within those families. It was then in this way that the peerage, growing out of the hereditary summons to parliament, hindered the growth of any nobility outside the families of peers and by the same means hindered the growth of any real nobility within their families.

PEGASUS, a famous horse of Greek fable, was said to have sprung from the trunk of the Gorgon Medusa when her head was cut off by Perseus. Bellerophon caught him as he drank of the spring Peirene on the Acrocorinthus at Corinth, or (according to another version) received him tamed and bridled at the hands of Athene. Mounted on Pegasus, Bellerophon slew the Chimæra and overcame the Solymi and the Amazons, but when he tried to fly to heaven on his back the horse threw him and continued his heavenward course. Arrived in heaven, Pegasus served Zeus, fetching for him his thunder and lightning. Hence some have thought that Pegasus is a symbol of the thunder-cloud. In later legend he is the horse of Eos, the Morning Pindar and later poets represent him as winged. From his connection with Hippocrene Pegasus has come to be regarded as the horse of the Muses and hence as a symbol of poetry. But this is a modern attribute of Pegasus, not known to the ancients, and dating only from the *Orlando Innamorato* of the Italian poet Boiardo.

PEGU, a division of British Burmah, comprising the districts of Rangoon, Hanthawaddy, Tharawadi, and Prome, has an area of 9,159 square miles, with a population (in 1881) of 1,162,393.

PEGU, an ancient town in the Rangoon district of British Burmah, is situated on the Pegu river, twenty miles west of the Tsit-toung.

PEHLEVI. See PAHLAVÍ.

PEIRCE, BENJAMIN, mathematician and astronomer, was born at Salem, Mass., April 4, 1809. Graduating at Harvard College in 1829, he became mathematical tutor there in 1831 and professor in 1833. After Bowditch's death in 1838 Peirce stood at the head of American mathematicians; but the first work that gave him a wider fame was his computation of the general perturbations of Uranus and Neptune. In 1849 he became consulting astronomer to the American Nautical Almanac, and for this work he prepared new tables of the moon (1852). Another piece of important astronomical work was his discussion of the equilibrium of Saturn's ring, in which he showed that a fluid ring was necessarily unstable as well as a solid one. From 1867 to 1874 he was superintendent of the coast survey; in 1857 he published his largest and most characteristic work, the *System of Analytical Mechanics*. He him-

self, however, seems to have thought most of his *Linear Associative Algebra*. His death took place at Cambridge, on October 6, 1880.

PEKIN, a city of Illinois, capital of Tazewell county, is located on the left bank of the Illinois river, 160 miles southwest of Chicago, fifty-six miles north of Springfield, and a dozen miles below Peoria. It is a prominent railroad center, being the terminus of the Wabash railroad by which it is connected with Decatur, and is an important station on the Chicago and St. Louis; the Ohio, Indiana and Western; Peoria, Decatur and Evansville, and Peoria, Pekin and Union roads, all of which have made large and costly improvements, including depots, warehouses, etc., and add greatly to the amount of business annually transacted there. The city has 9 churches, 2 national banks, 1 daily and 3 weekly papers, 5 hotels, a courthouse and jail, a high school and several school buildings for subordinate grades, electric light works, and a large number of stores. It also contains foundries and machine shops, cigar manufactories, hominy mills, saw mills, sash, door and blind factories, carriage factories and farming implement manufactories, also distilleries, etc. Large invoices of high-wines, grain, and other products are shipped to Pekin, thence to the south and southwest by rail and river, and to other points in the United States. The present population of the city (1890), is 8,000.

PEKING or PEKIN, the capital of the Chinese empire, stands on the northern extremity of the great alluvial delta which extends southward from its walls for 700 miles. For the last nine centuries Peking, under various names and under the dominion of successive dynasties, has, with some short intervals, remained an imperial city.

During different periods the extent and boundaries of the city varied considerably. Under the Kin dynasty the walls extended to the southwest of the Tartar portion of the present city, and the foundations of the northern ramparts of the Khan-balik of Kublai Khan are still to be traced at a distance of about two miles in a northerly direction beyond the existing walls. The modern city consists of two parts, the *nui ch'ing*, or inner city, commonly known to foreigners as the "Tartar city," and the *wai ch'ing*, or outer city, known in the same way as the "Chinese city." These names are somewhat misleading, as the inner city is not inclosed within the outer city, but adjoins its northern wall, which, being longer than the *nui ch'ing* is wide, outflanks it considerably at both ends. The outer walls of the double city contain an area of about twenty-five square miles, and measure thirty miles in circumference. Unlike the walls of most Chinese cities, those of Peking are kept in perfect order. Those of the Tartar portion, which is the oldest part of the city, are fifty feet high, with a width of sixty feet at the base and forty feet at the top, while those of the Chinese city which were built by the emperor Kea-tsing in 1543, measure thirty feet in height, and have a width of twenty-five feet at the base and fifteen feet at the top.

The population of Peking is reckoned to be about 1,000,000, a number which is out of all proportion to the immense area inclosed within its walls. This disparity is partly accounted for by the facts that large spaces, notably in the Chinese city, are not built over, and that the grounds surrounding the imperial palace, private residences, and temples are very extensive.

Viewed from the wall Pekin looks like a city of gardens. Few crowded neighborhoods are visible, and a characteristic feature is the many-patterned roofs of temples, palaces, and mansions, with their blue, green, and yellow tiles scattered among the groves of trees. Among

the striking features of the city are the Drum and Bell towers. The great bell is one of the largest in existence, weighs 120,000 pounds, is fourteen feet high, thirty-four feet in circumference, and nine inches thick. It is struck by a wooden beam, and only at night.

The Purple or "Forbidden city," the central portion of which forms the Imperial Palace, is in the southern division of Pekin. Its halls are probably not to be surpassed anywhere in the magnificence of their proportions and the barbaric splendor of their adornment. It was this beautiful palace, known as the "Summer Palace," that was looted by the French troops in 1860. Just outside the "Forbidden city" is the Temple of Heaven, where every year the emperor offers a sacrifice to the god, Shangkti. The altars of the sun and moon and those of the earth and agriculture are situated in the Chinese city. Next to these in religious importance comes the temple of Confucius. In the southeastern portion of the Tartar city is the observatory built by the order of Kublha Khan in 1296. The streets are wide, but not paved, and are impassable, by reason of mud, in wet weather, and covered with dust in summer. The city has no manufactories, and thus trade is very small. It is essentially the seat of the government and home of the emperor, and aside from its architectural features and antiquarian associations, calls for little comment.

Its situation near the northern frontier recommended it to the Tartar invaders as a convenient center for their power, and its peculiarly fortunate position inclined the Chinese dynasty to accept it as the seat of their force. In the year 986 it was taken by an invading force of Tartars, who named it "Nanking."

PELAGIA, ST. An Antiochene saint of this name, a virgin of fifteen years, who chose death by a leap from the housetop rather than dishonor, is mentioned by Ambrose, and is the subject of two sermons by Chrysostom.

PELAGIUS. Of the origin of Pelagius almost nothing is known. He seems to have been one of the earliest, if not the very earliest, of that remarkable series of men who issued from the monasteries of Scotland and Ireland and carried back to the Continent in a purified form the religion they had received from it. Coming to Rome in the beginning of the fifth century (his earliest known writing is of date 405), he found a scandalously low tone of morality prevalent. From his extant *Commentaries on the Epistles of St. Paul* it may be gathered that men were encouraged to rely on a profession of the Christian creed, and on the magical efficacy of the sacraments, while they entirely neglected to cultivate a Christian character. This state of things Pelagius denounced.

The peculiar tenets of Pelagius, though indicated in the commentaries which he published at Rome previous to 409, might not so speedily have attracted attention had they not been adopted by Cœlestius, a much younger and bolder man than his teacher. When Rome was sacked by the Goths (410) the two friends crossed to Africa. There Pelagius once or twice met with Augustine, but very shortly sailed for Palestine.

An imperial edict was issued at Ravenna April 30, 418, peremptorily determining the theological question and enacting that only Pelagius and Cœlestius but all who accept their opinions shall suffer confiscation of goods and irrevocable banishment. The date of his death is uncertain.

PELAGIUS I., pope from 555 to 560, was a Roman by birth, and first appears in history at Constantinople in the rank of deacon, and as apocrisiarius of Pope Silverius, whose overthrow in favor of Vigilius his intrigues promoted. Pelagius died on March 3, 560, and was succeeded by John III.

PELAGIUS II., a native of Rome, but of Gothic descent, was pope from 578 to 590, having been consecrated successor to Benedict I., without awaiting the sanction of the emperor, on November 27th of the former year. He died in January, 590, and was succeeded by Gregory I.

PELARGONIUM. See GERANIUM.

PELASGI. See GREECE and ITALY.

PELEW ISLANDS, a group in the western Pacific, which is often considered part of the Caroline Archipelago. The name *Islas Palaos*, by which the islands are first designated, is of doubtful but certainly not of native origin, and was originally applied by the Spaniards in an indefinite way to all the islands east of Mindanao (Philippines). The English form "Pelew" may be a corruption either of Palao or of Pelelin (*Pellelew*), the proper name of one of the southern islands.

PELHAM, HENRY, prime minister of England, was the younger brother of Thomas Holles Pelham, duke of Newcastle, and was born in 1696. Through strong family influence and the recommendation of Walpole he was chosen in 1721 a lord of the treasury. The following year he was returned for Sussex county. In 1724 he entered the cabinet as secretary of war, but this office he exchanged in 1730 for the more lucrative one of paymaster of the forces. He became prime minister in 1743. He died March 6, 1754.

PELIAS, PELIADES. Pelias, a celebrated character in Greek fable, was the son of Poseidon and Tyro, daughter of Salmoneus.

The tragic death of Pelias was the subject of Sophocles' drama *Rhizotomoi* (Root-cutters), and in the *Tyro* he treated another portion of legend. *Peliades* was the name of Euripides' first play.

PELICAN, a large fish-eating water-fowl, remarkable for the enormous pouch formed by the extensible skin between the lower jaws of its long, and apparently formidable but in reality very weak, bill. The ordinary Pelican, the *Onocrotalus* of the ancients, to whom it was well known, and the *Pelecanus onocrotalus* of ornithologists, is a very abundant bird in some districts of South-eastern Europe, South-western Asia, and North-eastern Africa, occasionally straying, it is believed, into the northern parts of Germany and France; but the possibility of such wanderers having escaped from confinement is always to be regarded, since few zoological gardens are without examples which are often in the finest condition. Its usual haunts are the shallow margins of the larger lakes and rivers, where fishes are plentiful, since it requires for its sustenance a vast supply of them, pursuing them under water, and rising to the surface to swallow those that it has captured in its capacious pouch. The nest is formed among the reeds that border the waters it frequents, placed on the ground and lined with grass. Therein two eggs, with white, chalky shells, are commonly laid. The young during the first twelvemonth are of a grayish-brown, but this dress is slowly superseded by the growth of white feathers, until when mature almost the whole plumage, except the black primaries, is white, deeply suffused by a rich blush of rose or salmon-color, passing into yellow on the crest and lower part of the neck in front. A second and somewhat larger species, *Pelecanus crispus*, also inhabits Europe, but in smaller numbers. North America has one, *P. erythrorhynchus*, very similar to *P. onocrotalus* both in appearance and in habits, but remarkable for a triangular, compressed, horny excrescence which is developed on the ridge of the male's bill in the breeding season, and falls off without leaving trace of its existence when that is over. Australia has *P. conspicillatus*, easily distinguished by

its black tail and wing-coverts. Of more marine habit are *P. philippensis* and *P. fuscus*, the former having a wide range in Southern Asia, and, it is said, reaching Madagascar, and the latter common on the coasts of the warmer parts of both North and South America.

PELIGNI. See ITALY.

PÉLISSIER, JEAN JACQUES AMABLE, duke of Malakhoff, marshal of France, was born November 6, 1794 at Maromme (Seine Inférieure). He served as aid-de-camp in the Spanish campaign of 1823, and in the expedition to the Morea in 1828-29, at the conclusion of which he received the grand cross. In 1830 he took part in an expedition to Algeria, and on his return was promoted to the rank of major. Nine years later he was again sent to Algeria. On the declaration of war with Russia Péliissier was sent to the Crimea, where on May 16, 1855 he succeeded Marshal Canrobert as commander-in-chief of the French forces before Sebastopol. After the capture of the fortress he was, on September 12th, promoted to be marshal. On his return to Paris he was named senator, created duke of Malakhoff (July 22, 1856), and rewarded with a grant of 100,000 francs per annum. From March 1858 to May 1859 he acted as French ambassador in London, whence he was recalled to take command of the army of observation on the Rhine. In 1860 he was appointed governor-general of Algeria; and he died there May 22, 1864.

PELL, JOHN, mathematician, was born on March 1, 1610, at Southwick, in Sussex, England. He died in 1685.

PELLA. See MACEDONIA.

PELLAGRA (Ital. *pelle agra*, smarting skin) is the name given, from one of its early symptoms, to a peculiar disease, of comparatively modern origin, occurring among the peasantry in Lombardy and other provinces of northern Italy, and in the Asturias (*mal de la rosa*), Gascony, Roumania, and Corfu. It is a progressive disease of nutrition tending toward profound paralytic and mental disorders, and is associated to a very significant extent, if not even invariably, with a staple diet of damaged maize, along with other peculiarly wretched and hopeless conditions of living.

The indications of pellagra usually begin in the spring of the year, declining toward autumn, and recurring with increasing intensity and permanence in the spring seasons following. A peasant who is acquiring the malady feels unfit for work, suffers from headaches, giddiness, singing in the ears, a burning of the skin, especially in the hands and feet, and diarrhoea. At the same time a red rash appears on the skin, of the nature of erysipelas, the red or livid spots being tense and painful, especially where they are directly exposed to the sun. About July or August of the first season these symptoms disappear, the spots on the skin remaining rough and dry. The spring attack of the year following will probably be more severe and more likely to leave traces behind it; with each successive year the patient becomes more like a mummy, his skin shriveled and sallow, or even black at certain spots, as in Addison's disease, his angles protruding, his muscles wasted, his movements slow and languid, and his sensibility diminished. Meanwhile there are more special symptoms relating to the nervous system, including drooping of the eyelid, dilatation of the pupil, and other disorders of vision, together with symptoms relating to the digestive system, such as a red and dry tongue, a burning feeling in the mouth, pain on swallowing, and diarrhoea. A large number of pellagrous peasants end their days in lunatic asylums in a state of driveling wretchedness or raving madness; many more drag out a miserable existence in the communes where their

working years had been spent, sometimes receiving the communal relief to which the law entitles them; while the cases that are reckoned curable are in Italy received into the various endowed hospitals, of which there are a large number. Cases that are rapidly fatal end in delirium or a state of typhoid stupor; the more protracted cases are cut off at last by rapid wasting, colliquative and ill-smelling sweats, profuse diarrhoea and dropsy.

There is hardly any doubt as to the remedy for pelagra, just as there is hardly any doubt as to its cause. The question is mainly one of the social condition of the peasantry, of their food and wages; it is partly, also, a question of growing Indian corn on a soil or in a climate where it will not mature unless with high farming. There is nothing in the resources of medicine proper to cure this disease; as the cause is, so must the remedy be.

PELLICANUS, CONRAD, one of the most interesting minor figures in German theology and scholarship in the great age of the Reformation, was born at Ruffach in Alsace in the winter of 1478. He died in 1556.

PELLICO, SILVIO, Italian dramatist, was born at Saluzzo in Piedmont on June 24, 1788. He died January 31, 1854, and was buried in the Campo Santo at Turin. His writings, whether in prose or verse, are chaste and graceful, but defective in virility and breadth of thought, and his tragedies display neither the insight into character nor the constructive power of a great dramatist.

PELOPIDAS, a distinguished Greek general, who, in conjunction with Epaminondas, raised his native city Thebes to a pitch of power such as she never attained to before or afterward. He was the son of Hippoclus and member of an illustrious Theban family. The large property to which he succeeded in his youth, and which he seems to have increased by a brilliant marriage, was liberally employed by him in the relief of the destitute. When he could not persuade his friend Epaminondas to share his wealth, he imitated that great man in the stern simplicity and frugality of his life and in his cheerful endurance of hardships. Their friendship continued unbroken till death. In 364 the Thessalian towns appealed to Pelopidas for help against their old enemy Alexander of Pheræ. Disregarding an ominous eclipse of the sun, Pelopidas pushed on with a handful of troops, leaving the main body to follow. At the heights of Cynoscephalæ, near Pharsalus, he came up with the tyrant Alexander at the head of a much superior force. The valor of Pelopidas secured another victory, but it was his last—catching sight of his hated foe he rushed on him single-handed and fell covered with wounds. His friend did not long survive him. He too was to die fighting his country's battles in a foreign land. The preëminence of Thebes was the work of these two men alone, and with them it passed away.

PELOPONNESUS. See GREECE.

PELOPS, a hero of Greek mythology, was the grandson of Zeus, son of Tantalus and Dione, and brother of Niobe. His father's home was on Mount Sipylus in Asia Minor, whence Pelops is spoken of as a Lydian or a Phrygian, or even as a Paphlagonian. Tantalus was a friend and companion of the gods, and one day he served up to them his own son boiled and cut in pieces. The gods detected the crime, and none of them would partake except Demeter (according to others Thetis), who, distracted by the loss of her daughter Persephone, ate of the shoulder. The gods restored Pelops to life, and the shoulder consumed by Demeter was replaced by one of ivory. Wherefore the

descendants of Pelops had a white mark on their shoulder ever after.

PELOUZE. THÉOPHILE JULES, French chemist, was born on February 26, 1807, at Valognes in Normandy. He was appointed in 1831 professor of chemistry at the École Polytechnique and at the Collège de France, in 1833 assayer to the mint, and in 1848 president of the Mint Commission. In 1850 he succeeded Gay-Lussac as chemical adviser to the glass-works of St. Gobain. He was elected a member of the Institute of France in 1837. He died, after a short illness, on May 31, 1867.

PELTIER, JEAN CHARLES ATHANASE, was originally a watchmaker, but retired from business about the age of thirty, and devoted himself to experimental and observational science. He was born at Ham (Somme) in February, 1785; his death took place at Paris in October, 1845. His great experimental discovery was the heating or *cooling* of the junctions in a heterogeneous circuit of metals according to the direction in which an electric current is made to pass round the circuit (1834).

PELUSIUM, an ancient city of Egypt, at the mouth of the most easterly (Pelusiac) branch of the Nile, was the key of the land toward Syria and a strong fortress, which, from the Persian invasion at least, played a great part in wars between Egypt and the East. It has not, however, been satisfactorily identified with any place mentioned in the hieroglyphic monuments.

PEMBERTON, an urban sanitary district of Lancashire, England, situated on the Lancashire and Yorkshire Railway, two and a half miles west from Wigan. The population of the urban sanitary district (area 2,894 acres) in 1871 was 10,374, and in 1881 it was 13,762.

PEMBROKE, the most westerly county of South Wales, lies to the west of the counties of Cardigan and Carmarthen, and is bounded on three sides by the ocean—on the south by Bristol Channel, on the west by St. George's Channel, and on the north by Cardigan Bay. Its length from Strumble Head to St. Gowan's Head is about thirty miles, and its average breadth a little over twenty. The area is 393,682 acres, or about 615 square miles.

Flannels are woven in various towns and are the principal textile manufacture of the county; there are also rope and sail works, and hat-making is practiced.

The county includes seven hundreds; the municipal boroughs of Haverfordwest (6,398), Pembroke (14,156) and Tenby (4,750), and part (2,058) of the municipal borough of Cardigan, the remainder of which is in Cardiganshire. In addition to Haverfordwest, Pembroke and Tenby, there are four other market towns—Fishguard (2,009), Milford (3,812), Narberth (2,334) and Newport (1,504). From 56,280 in 1801 the population had increased in 1821 to 74,009, in 1851 to 94,140, but in 1871 it had diminished to 91,998, and in 1881 to 91,824, of whom 43,449 were males and 48,375 females.

PEMBROKE, a municipal and parliamentary borough of South Wales, is picturesquely situated on an elevated ridge at the head of Pennar Mouth Creek, on the south side. The population of the parliamentary borough (area, 6,298 acres) in 1881 was 16,339.

PEMPHIGUS. See SKIN, DISEASES OF.

PEN, an instrument for writing or for forming lines with an ink or other colored fluid. The English word, as well as its equivalents in French (*plume*) and in German (*Feder*), originally means a wing-feather, but in ancient times the implements used for producing written characters were not quills. The earliest writing implement was probably the stylus, a pointed bodkin of metal, bone, or ivory, which, however, was only used

for producing incised or engraved letters. The calamus or arundo, the hollow tubular stalk of grasses growing in marshy lands, was the true ancient representative of the modern pen; hollow joints of bamboo were similarly employed. The use of such pens can be traced to a remote antiquity among the civilized nations of the East, where reeds and canes are to this day in common use as writing instruments.

The quills, formerly in exclusive use, and still largely employed among Western communities as writing instruments, are obtained principally from the wings of the goose. Swan-quills are also highly prized, and for special purposes crow-quills and the wing-feathers of certain other birds are adopted.

Metallic pens, though perhaps not altogether unknown even in classical times, did not come into use till the present century, and indeed did not become common till near the middle of the century.

Fountain pens and penholders in which considerable reservoirs of ink could be carried ready for use were introduced by a patented invention of the ingenious Joseph Bramah. A highly original and comparatively successful form of fountain pen of recent introduction is known as the stylograph, in which the ordinary form of nib is dispensed with, and connected with the barrel or reservoir is a finely-tapered point tipped with iridium pierced with a fine aperture. Into the aperture is fitted an iridium needle or plug attached internally to a delicate gold spring, and the act of writing sufficiently pushes back the needle to allow the escape of the requisite flow of ink by the aperture.

The metal used in the manufacture of the common steel pen consists of rolled sheets of cast steel of the finest quality, made from Swedish charcoal iron. These sheets are cut into strips of suitable width, annealed in a muffle furnace, and pickled in a bath of dilute sulphuric acid to remove the oxidized scale from the surface. The strips so cleaned are next rolled between steel rollers till they are reduced to ribbons the thickness of the pens to be made. At this stage the raw material is ready for the series of manufacturing operations, most of which are performed with the aid of hand fly-presses, moving suitable cutting, stamping and embossing attachments. The pen blanks are first cut out of the ribbon so as to leave as little scrap as possible. These blanks are next pierced, that is, the central perforation and the side or shoulder slits by which flexibility is secured are made at one operation. After again annealing, they are marked and embossed with maker's name, trade-mark, or any of the endless variety of marks by which pens are distinguished from each other. Up to this point the blanks are flat; they are now raised or rounded into the semi-cylindrical form in which pens are used. At this stage the pens are tempered by heating in iron boxes in a muffle, plunging in oil, and heating over a fire in a rotating cylindrical vessel till their surfaces attain the dull blue color characteristic of spring steel elasticity. They are then scoured and polished by being revolved in large tin cylinders, in which they are mixed with sand, pounded crucibles, or such substances. The grinding of the points next follows, an operation performed by small rapidly revolving emery-wheels, on which the points are first ground lengthwise and then across the nib, the object of the process being to increase the elasticity of the point. The slitting process which follows—that is, the cutting of the pen-slit from the perforation to the point—is effected with a chisel-cutter worked by a hand screw-press. On the precision with which the slit divides the point depends the perfection of the pen, to finish which it now only remains to color the surface in a revolving cylinder over a charcoal fire, and to varnish it in a solution of shellac.

**PENANCE.** The word "penance" (*pœnitentia*) has a double signification—its strict legal meaning of a penalty inflicted by the formal sentence of a spiritual authority in punishment of an offense, and with the primary object of amending and so benefiting the offender; and its wider and more popular sense of any ascetic practice adopted, whether voluntarily or under compulsion, for the expiation of sin or for advance in spiritual attainment. Broadly speaking, no trace of such a theory is visible in classical paganism, from which the idea of sin as a moral defilement is almost absent. There are faint marks discernible in the Greek heroic legends of something analogous to penance, when we read of a hero being driven into exile for some crime (most usually unpremeditated homicide), and not permitted to return till he had found some one able and willing to purify him with certain lustral sacrifices. The Oriental religions, contrariwise, teem with the ascetic principle, and personal austerities form a large part of the Zoroastrian, Buddhist and Brahman systems. Islam had originally nothing even remotely like the practices in question, save in so far as the annual fast of Ramadan and the hajj to Mecca and other sacred places necessitated self-denial; and it is even on record that Mohammed himself directly discouraged an ascetic spirit which displayed itself in some of his trustiest companions and disciples, such as 'Omar, 'Alí, Abú-Dharr, and Abú-Horeirah. Nor has the principle of penance ever formed an important integer of the Jewish religion. The Levitical code enjoins the performance of various lustral sacrifices in expiation of certain sins; but the cost of the victims is the only element of penalty, being virtually a money fine on the offender.

The Christian theory of penance ultimately rests on the view that the Christian church is the precise analogue of the Jewish people under the elder dispensation. As the Jews were the one family on earth in direct covenant with God, so that it became necessary for all Gentiles who desired to be brought into the like relation to abandon their own proper nationality and to become Jews by adoption, forsaking their former habits and associations together with their creed; and as various offenses against the law of Moses were punished with temporary or final exclusion from fellowship in the Hebrew polity; so was it from a very early period in the Christian church. One marked difference between the Rabbinical and the Christian discipline is indeed visible from the first, that the former involved the suspension or deprivation of civil rights, whereas the latter, in all the earlier centuries at any rate, was a purely spiritual penalty. And, as it soon came to be accepted that the inward sorrow for sin would be attended with an outward token of that sorrow, involving pain or humiliation in some form or other, there are four distinct stages in the ecclesiastical use of the word "pœnitentia"—first, as denoting the change of mind due to sorrow for sin; next, the external penalty attached to each offense; thirdly, the discipline of the church in dealing with all spiritual offenses; and lastly, any piece of austerity practiced with a religious motive; and the fact of the Latin language having no doublets like the English "penitence" and "penance" to express the distinct though allied ideas of the mental attitude and the outward action has powerfully conditioned Latin theology and practice.

There is naturally but little to be found in the New Testament on the subject of discipline; but the whole principle is provided for and anticipated in one saying of Christ—that which directs that he who neglects to hear the church as arbiter in a dispute shall be regarded as a heathen and a publican, and which goes on to confer upon the apostles the power of binding and

loosing (Matt. xviii. 17, 18)—words which they, with their Jewish experience and associations, must needs have interpreted as authorizing, and even enjoining, the infliction of penalties, and notably that of excommunication, upon members of the new society. The penalties seem at first to have been very simple and lenient, leaving out of account the difficult problem of the phrase “delivering to Satan,” twice found in this connection, which may mean merely relegating to heathen fellowship by exclusion from the society of Christians, but may also cover much more ground.

The main difference between the earlier and later systems lies in the fact that penance was for some centuries restricted to certain very grave sins, to wit, idolatry, adultery, and murder, with such lesser offenses as were closely allied (as, for instance, the delivery of the sacred books to pagan inquisitors, that *traditio* which has given the words “treason” and “traitor” to modern diction); nor does it appear that any distinction was made between the treatment of those penitents whose guilt was notorious and those whose own voluntary confession alone made it manifest. Minor offenses were punished with suspension of communion and with refusal of oblations at the hands of the offender, and many were left wholly to the individual conscience. But the catalogue of canonical offenses was much enlarged at the time when the penitential system was developed and codified— theft, usury, false witness, polygamy, habitual drunkenness, and some others being included among those which had to be publicly expiated. Yet it was this increased severity which led to the almost total abrogation of public penance, because of the scandal given by the publication of the offenses on the new list, whereas the cases under the older rule were necessarily few, however serious.

It is time to speak of the position occupied by penance in the theological systems of the Latin and Greek Churches. Both of them account penance, taken in its widest sense of the method of dealing spiritually with sins by confession, discipline and absolution, as a sacrament, but there are various differences in their theories and methods. The Greek and Armenian Churches are in full agreement with the Latin Church in regarding confession as an integral and essential part of penance, of which they consider it the outward and visible sign, while the spiritual part of the sacrament consists in the form of absolution, whether precatory or declaratory, pronounced by the priest. And they lay down that the external acts of asceticism performed by the penitent are not strictly part of the sacrament itself, but merely the fulfillment of the church's injunctions, and tokens of that repentance which should attend the confession of sins. And confession, though recommended as a religious observance, is not a matter of formal ecclesiastical precept in the Eastern Church, but is left to the individual conscience, though it is usual to practice it at least once a year, prior to the Easter communion. There are also certain public penances sometimes enjoined in the East for sins of exceptional gravity, publicly or legally proved, but they do not form part of the normal system, one part of which, in strict agreement with ancient usage, consists in suspending heinous offenders from communion for some years, during which they can receive only the blessed bread. And in all cases the Easterns deny that penances are in any sense satisfactions or expiations of sins made to appease Divine justice.

PENANG. See PRINCE OF WALES ISLAND.

PENARTH, a seaport of Glamorganshire, Wales, is picturesquely situated on rising ground on the south side of the mouth of the Taff opposite Cardiff, from which it is four miles distant by rail and two by steamer.

PENATES, Roman gods of the store-room and kitchen, derived their name from *penus*, “eatables, food.” The store-room over which they presided was, in old times, beside the *atrium*, the room which served as kitchen, parlor and bedroom in one; but in later times the store-room was in the back part of the house. It was sanctified by the presence of the Penates, and none but pure and chaste persons might enter into it, just as with the Hindus the kitchen is sacred and inviolable. The family hearth, which anciently stood in the *atrium*, was their altar; on it were placed their images, two in number, for the Penates were always in pairs—the name does not occur in the singular. They had no individual names, but were always known under the general designation Penates. Closely associated with the Penates were the Lares, another species of domestic deities, who seem to have been the deified spirits of deceased ancestors (see LARES). But, while each family had two Penates, it had but one Lar. In the household shrine the image of the Lar (dressed in a toga) was placed between the two images of the Penates, which were represented as dancing and elevating a drinking-horn in token of joy and plenty. The three images together were sometimes called Penates, sometimes Lares, and either name was used metaphorically for “home.”

PENCIL (Lat. *penicillus*, small tail), a name originally applied to a small fine-pointed brush used in painting, and still employed to denote the finer camel's-hair and sable brushes used by artists, has, in English, come commonly to signify solid cones or rods of various materials used for writing and drawing. Some method of producing black or colored markings with rods of solid material on parchment, paper, wood and other like smooth surfaces must have been known from time immemorial, but the ordinary so-called black-lead pencil does not possess a very high antiquity. It has been asserted that a manuscript of Theophilus, attributed to the thirteenth century, shows signs of having been ruled with a black-lead pencil; but the first distinct allusion to the common form of the instrument occurs in the treatise on fossils by Conrad Gesner of Zurich (1565), who describes an article for writing formed of wood and a piece of lead, or, as he believed, an artificial composition called by some *stimmi anglicanum* (English antimony).

M. L. Leman, of New York, was the pioneer in the manufacture of lead pencils in the United States in 1830. In 1849 Eberhard Faber came to New York as the agent of A. W. Faber, of Stein, Germany, and in 1881, the centennial of the house, it was determined to establish the industry in America. This was really the start of the pencil industry in this country.

The pencil leads consist of a most intimate mixture of graphite and clay, both first brought to a condition of the finest subdivision. The graphite is reduced to fine powder in a mortar; it is sifted and sometimes treated with mineral acid, to free it from iron, etc., then washed, and thereafter calcined at a bright-red heat. To get it in the condition of fine division, it is mixed with water and poured into a vat, where the heavier particles sink. From this vat the water bearing the lighter particles passes into another at a lower level, and so into one or two more, in each of which the comparatively heavy particles sink, and only the still finer particles are carried over. That which sinks in the last of the series is in a condition of extremely fine division, and is used for pencils of the highest quality. The clay, which must be free of sand and iron, is treated in the same manner and brought to a state of great uniformity and smoothness. Clay and graphite so prepared are mixed in varying proportions from about

equal parts to two of clay for one of graphite according as the pencils are to be hard or soft. They are thoroughly incorporated and ground together, then placed in bags and squeezed in a hydraulic press till they have the consistency of stiff dough, in which condition they are ready for forming pencil rods. For this purpose the plastic mass is placed in a strong upright cylinder of brass, into which a plunger or piston works, moved by a powerful screw-press. The bottom of the cylinder consists of a thick bronze plate having in it a number of small apertures the section and size of the leads to be made. By the application of pressure to the plunger the graphite mixture is squeezed in continuous threads through the holes, and these threads are received and arranged in straight continuous lengths on a board, on which they are left to dry for some hours. For further drying by gentle heat they are placed in straight grooves in a grooved board, covered with another board, in which position they harden to stiff rods. These are afterward cut into lengths for pencils, which are packed with charcoal in a covered crucible and submitted to a high furnace-heat. The two elements which regulate the comparative hardness and blackness of pencils are the proportions of graphite and clay in the leads and the heat to which they are raised in the crucible. According as the proportion of graphite is greater and the heat lower the pencil is softer and of deeper black streak.

The cedar in which pencils are cased is cut into sets of rectangular slips of unequal thickness; but so that a thick and a thin slip put together form in section a square. In the thick or body piece is formed the groove or depression to receive the lead, which perfectly fits and fills it. The thinner covering piece is glued on and the pencil rounded between revolving cutters working at great speed. The cutters leave the rounded surface perfectly smooth, and it only remains to stamp the finished pencil with name and grade, etc.

Black pencils of an inferior quality are made from the dust of graphite melted up with sulphur and run into molds. Such, with a little tallow added to give them softness, are the pencils commonly used by carpenters. Colored pencils consist of a mixture of clay, with appropriate mineral coloring matter, wax, and tallow, treated by the method of making lead pencils. In the indelible and copying pencils which have come into use in recent years, the coloring matter is an aniline preparation mixed with clay and gum. The mixture not only makes a streak which adheres to the paper, but, when the writing is moistened with water, it dissolves and assumes the appearance and properties of an ink.

PENDULUM. See CLOCKS. MECHANICS.

PENELOPE, the faithful wife of the Greek hero Odysseus (Ulysses), immortalized by Homer in the *Odyssey*. She was the daughter of the Spartan Icarus and Peribœa. Shortly before Odysseus left his native island of Ithaca to war against Troy, Penelope bore him a son, Telemachus. When her husband tarried long many chieftains of Ithaca and the islands round about wooed her to wife; they behaved wantonly, wasting the substance of Odysseus, insulting his son, and corrupting the maidservants. The heart of Penelope yearned for Odysseus, and, to rid herself of the importunities of the wooers, she bade them wait till she had woven a winding-sheet for old Laertes, the father of Odysseus. But every night she undid the piece which she had woven by day, so that the web was always unfinished. This she did for three years, till her maids revealed the secret to the wooers. Robbed of her pretext for delay she was in sore straits, till she was relieved by the arrival of Odysseus after an absence of

twenty years. He slew the wooers, and the long-parted husband and wife were united once more.

PENGUIN, the name (of very uncertain origin) of a flightless sea-bird, but, so far as is known, first given to one inhabiting the seas of Newfoundland, as in Hore's "Voyage to Cape Breton," 1536, which subsequently became known as the Great Auk or GAREFOWL; and, though the French equivalent *pingouin* preserves its old application, at the present day, the word penguin is by English ornithologists always used in a general sense for certain birds inhabiting the Southern Ocean, called by the French *Manchots*, the *Spheniscidæ* of ornithologists, which in some respects form perhaps the most singular group of the whole Class, or at least we may say of the Carinate Subclass. The most conspicuous outward character presented by the Penguins is the total want of quills in their wings, which are as incapable of flexure as the flippers of a Cetacean, though they move freely at the shoulder-joint, and some at least of the species occasionally make use of them for progressing on land. In the water they are most efficient paddles, and are usually, if not always, worked alternately with a rotatory action. The plumage which clothes the whole body, leaving no bare spaces, generally consists of small scale-like feathers, many of them consisting only of a simple shaft without the development of barbs; but several of the species have the head decorated with long cirrhous tufts, and in some the tail-quills, which are very numerous, are also long. In standing these birds preserve an upright position, generally resting on the "tarsus" alone, but in walking or running on land this is kept nearly vertical, and their weight is supported by the toes alone.

PENINSULAR CAMPAIGN. The year 1861, the first year of the war between the States, had proven barren of results advantageous to the Union forces. In the fall of that year George B. McClellan was made commander-in-chief of the Federal army as successor to General Scott, retired. During the winter McClellan organized the Army of the Potomac, which in March, 1862, was composed of 180,000 men, divided into four corps. Opposed to this force and menacing the security of Washington was an army of 75,000 Confederate troops under the command of Gen. Joseph E. Johnston. While preparing to inaugurate a campaign having for its objects the raising of the blockade of the Potomac river, the re-opening of communication between Washington and the west (then obstructed at Harper's Ferry) and, finally, the capture of Richmond, capital of the Confederate States, McClellan was directed by the President to open the Baltimore and Ohio road, also to destroy the batteries the Confederates had planted on the banks of the Potomac. While McClellan was occupied in executing that part of the order having reference to the Baltimore and Ohio road, Johnston abandoned the Potomac for the Rapidan, and deprived McClellan's plans of the promise they held out at their inception. The latter, thereupon, selected Fortress Monroe as a base of operations, and formulated a campaign to be conducted in territory bounded by Fortress Monroe, the upper Chickahominy, the James, York and Pamunkey rivers, consisting of the Peninsula proper with a stretch of land extending above Richmond. On March 17, 1862, a portion of McClellan's army rendezvoused at Alexandria to embark for the field of operations.

His removal as commander-in-chief was directed, and the Potomac army reduced to 120,000, the balance of the 180,000 soldiers enlisted under his command being retained at Washington for the defense of that city. On April 6th, following, an army of 119,965 men, with forty-

four batteries of artillery, were assembled at Fortress Monroe, ready for active service, and McClellan had commenced his march up the Peninsula. On the 5th of the same month he arrived opposite Yorktown. The left wing of his army, however, delayed at Warwick's creek, a small stream along which for ten miles or more was Magruder's line of defense. The latter with an army of 11,000 men refused to retire before McClellan's advance, and concluding that his antagonist had been reinforced McClellan determined to postpone an attack until the arrival of McDowell's corps. He was soon after advised that McDowell's three divisions had been withdrawn from immediate service, and that Wool and 15,000 men at Fortress Monroe were to constitute an independent command. To add to the perplexities of the situation, the naval force that was expected to operate on York river was diverted from that purpose on the plea that the *Virginia* demanded close watching. However April 16th witnessed the commencement of active hostilities, but after repeated attempts to capture Yorktown McClellan decided to besiege it. This policy was continued until May 5th, when preparations to bombard the place were concluded. It was discovered that the city as also York river, was evacuated and abandoned. The Confederate army began its retreat to Richmond, pursued by McClellan on land, while Franklin's division of McDowell's corps was ordered to be landed at White House, on the Pamunkey river, east of Richmond.

At Williamsburg, on the west shore of the peninsula, the Confederates had constructed a series of fortifications, at this time defended by Longstreet's corps. Upon the arrival there of the Union forces, Hooker attacked the enemy's right, and a fierce engagement followed. The battle was prolonged and bloody, and Hooker was falling back when Kearney came to his relief. Late in the afternoon, Hancock attacked the enemy's left. He was opposed by Early's brigade, which was, however, put to flight, and hostilities were suspended. During the same night McClellan arrived on the scene, but in the morning when preparations for resuming the battle were making, it was discovered that the enemy had evacuated their defenses and recommenced their retreat to Richmond, a movement pursued and concluded without interruption.

The Army of the Potomac was hurried to White House, where Franklin arrived May 7th, and where McClellan established his depots and by May 21st had his army in *echelon* along the left bank of the Chickahominy. The confederate forces meanwhile were concentrating at Richmond. The destruction of the *Merrimac* and the opening of the James river to the Union forces strengthened McClellan in his purpose of transferring his base to the James and coöperating with Admiral Goldsborough in an attack upon Richmond from the south. The center and right wing of his army remained on the Chickahominy, but as he was about to transfer the remainder of his forces at Bottoms Bridge the authorities at Washington became alarmed at the threatened attitude of Jackson in the valley, countermanded the order theretofore issued to McDowell's corps to join McClellan with 41,000 men and caused an abandonment of the proposed plan. On May 31st General Johnston attacked the Union forces at Fair Oaks and was himself so severely wounded as to compel his temporary retirement from the field. He was succeeded by Gen. Robert E. Lee, who thereafter until the surrender of the confederate army at Appomattox was chief in command.

During the month of June unpropitious weather prevented the continuance of active hostilities. The only incidents of importance were the raids of General Stuart

around the Union lines and on the railroad and White House. About June 25th, news was conveyed to McClellan that Jackson was threatening his rear, and that A. P. Hill, Longstreet and D. H. Hill, were about to effect a junction with the first named, and attack the Union right. Jackson was delayed, but Longstreet and the Hills united their forces and the Battle of Mechanicsville was fought with disastrous results to the Confederates. McClellan now abandoned the north bank of the Chickahominy, and by stationing the divisions of McCall and Porter at Cold Harbor, sought the protection of the railroad by which his army supplies were being carried from White House to the James. On June 27th, was fought the battle of Gaines' Mill. The action began about two o'clock in the afternoon, and the Confederates were defeated. At four o'clock Jackson came into the field, and forming a junction with D. H. Hill and Longstreet, made an attack along the entire Union line. The line yielded at every point, but the timely arrival of French and Meagher's brigades saved the day.

That night the Union forces crossed the river and on the night of June 28th were in motion, with Lee in pursuit. The next morning they were reunited, and the same afternoon while the larger portion was pursuing its way to Malvern Hill by way of White Oak swamp, Sumner's corps repulsed Magruder at Savage's Station. It now became Lee's apparent purpose to attack McClellan's army at its center and defeat it in detail. With this object in view White Oak Swamp was flanked by Longstreet, who hurried forward and forming a junction with A. P. Hill, fought the battle of Frazier's Farm. During that night, the Union army was massed at Malvern Hill, and on the afternoon of July 1st it was attacked by the Confederates. A desperate battle followed, the Confederate force sustaining a fearful loss; the bloody contest raged until darkness brought it to a close. During the same night the Union army was withdrawn to Harrison Landing and the Peninsular campaign passed into history.

The leaders of the opposing forces in this campaign, as also the campaign itself, have been made the subject of critical comment by historians, writers, and speakers for the past quarter of a century. While admitting that McClellan's knowledge of the art of war, of the planning of campaigns and the marshaling of an army was without a superior, the claim is urged that his indecision at critical points, when he should have "imitated the actions of the tiger," lost him opportunities that men differently constituted, though less brilliant than he, would have taken advantage of, and personally profited by. Critics also insist that he was guilty of special errors in the conduct and management of the campaign. And while such have been some of the remarks heard respecting his career as a commander, the universal verdict has been that his retreat to Harrison's Landing was one of the most remarkable achievements of the war.

The losses entailed by the seven days' battles were in round numbers—Union side, 16,000; Confederate side, 20,000. These figures include the killed and wounded and missing.

PENN, WILLIAM, the Quaker, was the son of Admiral William Penn and Margaret Jasper, a Dutch lady, and was born at Tower Hill, London, on October 14, 1644. During his father's absence at sea he lived at Wanstead in Essex, and went to school at Chigwell close by, in which places he was brought under strong Puritan influences.

Until the outbreak of the plague Penn was a student of Lincoln's Inn. For a few days also he served on the staff of his father—now great captain commander—

and was by him sent back in April, 1665, to Charles with dispatches. Returning after the naval victory off Lowestoft in June, Admiral Penn found that, probably from the effect upon his mind of the awful visitation of the plague, his son had become settled in seriousness and Quakerism.

He was sent to Ireland, and on September 3, 1667, he attended a meeting of Quakers in Cork, at which he assisted to expel a soldier who had disturbed the meeting. He was in consequence, with others present, sent to prison by the magistrates. From prison he wrote to Lord Orery, the president of Munster, a letter, in which he first publicly made a claim for perfect freedom of conscience. He was immediately released and at once returned to his father in London, with the distinctive marks of Quakerism strong upon him. Penn now became a minister of the denomination, and at once entered upon controversy and authorship.

His first public discussion was with Thomas Vincent, a London Presbyterian minister, who had reflected on the "damnable" doctrines of the Quakers. In this he appears to have acted as second to George Whitehead. The imputations upon his opinions and good citizenship, made as well by dissenters as by the church, he repelled in *Innocency with her Open Face*. It was now, too, that he published the most important of his books, *No Cross, no Crown*.

An informal reconciliation now took place with his father, who had been impeached through the jealousy of Rupert and Monk (in April, 1668), and whose conduct in the operations of 1665 he had publicly vindicated; and Penn was again sent on family business to Ireland. He returned to London in 1670, and was immediately involved in fresh trouble. Having found the usual place of meeting in Gracechurch Street closed by soldiers, Penn, as a protest, preached to the people in the open street. With William Mead he was at once arrested and indicted at the Old Bailey on September 1st for preaching to an unlawful, seditious, and riotous assembly, which had met together with force and arms.

In the beginning of 1671 Penn was again arrested for preaching in Wheeler Street meeting-house by Sir J. Robinson, the lieutenant of the Tower, formerly lord mayor, and known as a brutal and bigoted churchman. During this imprisonment Penn wrote several works, the most important being *The Great Case of Liberty of Conscience* (February, 1671), a noble defense of complete toleration. Upon his release he started upon a missionary journey through Holland and Germany.

Upon his return home in the spring of 1672 Penn married Gulielma Springett. To this year, 1672, belong the *Treatise on Oaths* and *England's Present Interest Considered*. In the year 1673 Penn was still more active. He secured the release of George Fox, addressed the Quakers in Holland and Germany, carried on public controversies with Hicks, a Baptist, and Faldo, an Independent, and published his treatise on the *Christian Quaker and his Divine Testimony Vindicated*, the *Discourse of the General Rule of Faith and Practice, Reasons against Railing* (in answer to Hicks), *Counterfeit Christianity detected*, and a *Just Rebuke to One-and-twenty Learned Divines* (an answer to Faldo and to *Quakerism no Christianity*). His last public controversy was in 1675 with Richard Baxter, in which, of course, each party claimed the victory. During this year his active sympathies were enlisted on behalf of imprisoned Quakers at Aberdeen. At this point Penn's connection with America begins.

The province of New Jersey, comprising the country between the Hudson and Delaware rivers on the east and west, had been granted in March, 1663-64, by Charles II. to his brother; James in turn had, in June

of the same year, leased it to Lord Berkeley and Sir G. Carteret in equal shares. By a deed, dated March 18, 1673-74, John Fenwick, a Quaker, bought one of the shares, that of Lord Berkeley (Stoughton erroneously says Carteret's) in trust for Edward Byllinge, also a Friend, for \$5,000. This sale was confirmed by James, after the second Dutch war, on August 6, 1680. Disputes having arisen between Fenwick and Byllinge, Penn acted as arbitrator; and then, Byllinge being in money difficulties, and compelled to sell his interest in order to satisfy his creditors, Penn was added, at their request, to two of themselves, as trustee. The disputes were settled by Fenwick receiving ten out of the 100 parts into which the province was divided, with a considerable sum of money, the remaining ninety parts being afterward put up for sale. Fenwick sold his ten parts to two other Friends, Eldridge and Warner, who thus, with Penn and the other two, became masters of West Jersey, West New Jersey, or New West Jersey, as it was indifferently called. The five proprietors appointed three commissioners, with instructions dated from London, August 6, 1676, to settle disputes with Fenwick (who had bought fresh land from the Indians, upon which Salem was built, Penn being himself one of the settlers there) and to purchase new territories, to survey and divide them, and to build a town—New Beverley, or Burlington, being the result. For the new colony Penn drew up a constitution, under the title of "Concessions," which he himself thus describes: "There we lay a foundation for after ages to understand their liberty as men and Christians, that they may not be brought in bondage but by their own consent; for we put the power in the people." The greatest care is taken to make this constitution "as near as may be conveniently to the primitive, ancient, and fundamental laws of the nation of England." But a democratic element is introduced, and the new principle of perfect religious freedom—"that no men, nor numbers of men upon earth, hath power or authority to rule over men's consciences in religious matters"—stands in the first place. Such a constitution, which is in marked contrast with Locke's aristocratic one for Carolina, settled eight years previously, soon attracted large numbers of Quakers to West Jersey.

It was shortly before these occurrences that Penn inherited through his wife the estate of Worthinghurst in Sussex, whither he removed from Rickmansworth. He now (July 25, 1677), undertook a second missionary journey to the Continent along with George Fox, Robert Barclay, and George Keith. Of this journey a full account, published seventeen years later, will be found in his selected works.

In 1678 the Popish Terror came to a head, and to calm and guide Friends in the prevailing excitement Penn wrote his *Epistle to the Children of Light in this Generation*. A far more important publication was *An Address to Protestants of all Persuasions*, by William Penn, Protestant, in 1679. This was succeeded, at the general election which followed the dissolution of the pensionary parliament, by an important political manifesto, *England's Great Interest in the Choice of this New Parliament*. Next came *One Project for the Good of England*, perhaps the most pungent of all his political writings. But he was not merely active with his pen. Encouraged by his success in the New Jersey provinces, he again turned his thoughts to America. In repayment of the debt mentioned above Penn now asked from the crown, at a council held on June 24, 1680, for "a tract of land in America north of Maryland, bounded on the east by the Delaware, on the west limited as Maryland [*i.e.*, by New Jersey], northward as far as plantable;" this latter limit Penn explained to be "three

degrees northward." This formed a tract 300 miles by 160, of extreme fertility, mineral wealth, and richness of all kinds. Disputes with James, and with Lord Baltimore, who had rights over Maryland, delayed the matter until March 24, 1681, when the grant received the royal signature, and Penn was made master of the province of Pennsylvania. His own account of the name is that he suggested "Sylvania," that the king added the "Penn" in honor of his father, and that, although he strenuously objected and even tried to bribe the secretaries, he could not get the name altered. It should be added that early in 1682 Carteret, grandson of the original proprietor, transferred his rights in East Jersey to Penn and eleven associates, who soon afterward conveyed one-half of their interest to the earl of Perth and eleven others. It is uncertain to what extent Penn retained his interest in West and East Jersey, and when it ceased. The two provinces were united under one government in 1699; and Penn was a proprietor in 1700. In 1702 the government of New Jersey was surrendered to the crown.

By the charter for Pennsylvania Penn was made proprietary of the province. He was supreme governor; he had the power of making laws with the advice, assent, and approbation of the freemen, of appointing officers, and of granting pardons. The laws were to contain nothing contrary to English law, with a saving to the crown and the English council in case of appeals. Parliament was to be supreme in all questions of trade and commerce; the right to levy taxes and customs was reserved to England; an agent to represent Penn was to reside in London; neglect on the part of Penn was to lead to the passing of the government to the crown (which event actually took place in 1692); no correspondence might be carried on with countries at war with Great Britain. A clause added at the last moment illustrates curiously both the strength and the jealousy of the Anglican Church at the time. The importunity of the bishop of London extorted the right to appoint Anglican ministers, should twenty members of the colony desire it, thus securing the very thing which Penn was anxious to avoid—the recognition of the principle of an establishment.

Having appointed Colonel Markham, his cousin, as deputy, and having in October sent out three commissioners to manage affairs until his arrival, Penn proceeded to draw up proposals to adventurers, with an account of the resources of the colony. He negotiated, too, with James and Lord Baltimore with the view, ultimately successful, of freeing the mouth of the Delaware, wrote to the Indians in conciliatory terms, and encouraged the formation of companies to work the infant colony in both England and Germany, especially the "Free Society of Traders in Pennsylvania," to whom he sold 20,000 acres, absolutely refusing, however, to grant any monopolies. In July he drew up a body of "conditions and concessions." This constitution, savoring strongly of Harrington's *Oceana*, was framed in consultation with Sidney, though to what extent is doubtful. The inferences drawn by Hephworth Dixon from a single letter of Penn to Sidney, given at length by Stoughton, are quite unjustifiable. This sketch of a constitution was democratical in the purest sense. Until the council of seventy-two (chosen by universal suffrage every three years, twenty-four retiring each year) and the assembly (chosen annually) were duly elected, a body of provisional laws was added.

It was in the midst of this extreme activity that Penn was made a Fellow of the Royal Society. Leaving his family behind him, Penn sailed with a hundred comrades from Deal in the *Welcome* on September 1, 1682.

His *Last Farewell to England* and his letter to his wife and children contain a beautiful expression of his pious and manly nature. He landed at Newcastle on the Delaware on October 27th, his company having lost one-third of their number by smallpox during the voyage. After receiving formal possession, and having visited New York, Penn ascended the Delaware to the Swedish settlement of Upland, to which he gave the name of Chester. The assembly at once met, and on December 7th passed the "Great Law of Pennsylvania." The idea which underlies this law is that Pennsylvania was to be a Christian state on a Quaker model. Only one condition was made necessary for office or citizenship, viz., Christianity. The constitution was purely democratic; all offices, for example, are elective. In many other provisions Penn showed himself far in advance of his time, but in none so much as where the penalty of death was abolished for all offenses except murder. Lawsuits were to be superseded by arbitration, always a favorite idea with Penn. Philadelphia was now founded, and within two years contained 300 houses and a population of 2,500. At the same time an act was passed, uniting under the same government the territories which had been granted by feoffment by James in 1682. His connection with the Indians was one of the most successful parts of his management, and he gained at once and retained through life their intense affection. At his death they sent to his widow a message of sorrow for the loss of their "brother Onas," with some choice skins to form a cloak which might protect her "while passing through the thorny wilderness without her guide."

Penn now wrote an account of Pennsylvania from his own observation for the "Free Society of Traders," in which he showed considerable power of artistic description.

Tales of violent persecution of the Quakers, and the necessity of settling disputes which had arisen with Lord Baltimore, his neighbor in Maryland, carried Penn back to England (October 2, 1684), after an absence of two years. Within five months after his arrival in England Charles II. died, and Penn found himself at once in a position of great influence. His close connection with James, dating from the death of his father, was rendered doubly strong by the fact that, from different causes, each was sincerely anxious to establish complete liberty of conscience.

In 1686, when making a third missionary journey to Holland and Germany, Penn was charged by James with an informal mission to the prince of Orange to endeavor to gain his assent to the removal of religious tests. In 1687 James published the Declaration of Indulgence, and Penn probably drew up the address of thanks on the part of the Quakers.

At the Revolution he behaved with courage. He was one of the few friends of the king who remained in London, and, when twice summoned before the council, spoke boldly in his behalf. He admitted that James had asked him to come to him in France; but at the same time he asserted his perfect loyalty. During the absence of William, in 1690, he was proclaimed by Mary as a dangerous person, but no evidence of treason was forthcoming. It was now that he lost by death two of his dearest friends, Robert Barclay and George Fox. In 1691, again on Fuller's evidence, a proclamation was issued for the arrest of Penn and two others as being concerned in Preston's plot. He might, on the intercession of Locke, have obtained a pardon, but refused to do so. He appears to have especially felt the suspicions that fell upon him from the members of his own body. In 1692 he began to write again, both on questions of Quaker discipline and in defense of the sect.

*Just Measures in an Epistle of Peace and Love, The New Athenians* (in reply to the attacks of the *Athenian Mercury*), and *A Key opening the Way to every Capacity* are the principal publications of this year.

Meantime matters had been going badly in Pennsylvania. No sooner had Penn by a skillful compromise settled matters than the colony was torn by the religious schism caused by George Keith. On October 21, 1692, an order of council was issued depriving Penn of the governorship of Pennsylvania, and giving it to Colonel Fletcher, the governor of New York. To this blow were added the illness of his wife and fresh accusation of treasonable correspondence with James.

In 1694 (February 23d) his wife Gulielma died, leaving two sons, Springett and William, and a daughter, Letitia, afterward married to William Aubrey. Two other daughters, Mary and Hannah, died in infancy. He consoled himself by writing his *Account of the Rise and Progress of the People called Quakers*. In March, 1696, he formed a second marriage, with Hannah Callowhill, his son Springett dying five weeks later. In this year he wrote his work *On Primitive Christianity*, in which he argues that the faith and practice of the Friends were those of the early church. In 1697 Penn removed to Bristol, and during the greater part of 1698 was preaching with great success against oppression in Ireland, whither he had gone to look after the property at Shannangarry. In 1699 he was back in Pennsylvania, landing near Chester on November 30th.

Affairs now again demanded his presence in England. The king had, in 1701, written to urge upon the Pennsylvania Government a union with other private colonies for defense, and had asked for money for fortifications. The difficulty felt by the crown in this matter was a natural one. A bill was brought into the Lords to convert private into crown colonies. The accession of Anne appears to have put an end to the bill in the Lords, and to Penn's troubles on this score. He once more assumed the position of leader of the Dissenters, and himself read the address of thanks for the promise from the throne to maintain the Act of Toleration. He now took up his abode again at Kensington, and published, while here, his *More Fruits of Solitude*.

In 1703 he went to Knightsbridge, where he remained until 1706, when he removed to Brentford, his final residence being taken up, in 1710, at Field Ruscombe, near Twyford. In 1704 he wrote his *Life of Bulstrode Whitelocke*. He had now much trouble from America. Moreover, pecuniary troubles came heavily upon him, while the conduct of his son William, who became the ringleader of all the dissolute characters in Philadelphia, was another and still more severe trial. Difficulties with his government of Pennsylvania continued to harass him. Fresh disputes took place with Lord Baltimore, the owner of Maryland, and Penn also felt deeply what seemed to him the ungrateful treatment which he met with at the hands of the assembly. He therefore, in 1710, wrote, in earnest and affectionate language, an address to his "old friends," setting forth his wrongs. So great was the effect which this produced that the assembly which met in October of that year was entirely in his interests. Penn now, in February, 1712, being in failing health, proposed to surrender his powers to the crown. Before, however, the matter could go further he was seized with apoplectic fits, which shattered his understanding and memory. A second attack occurred in 1713, and from that time until his death his powers gradually failed, although at times his intellect was clear and vigorous. He died May 30, 1718, leaving three sons by his second wife, John, Thomas, and Richard, and was buried along with his first and second wives at Jourdan's meeting-house,

near Chalfont St. Giles, in Buckinghamshire. It has finally to be mentioned that in 1790 the proprietary rights of Penn's descendants were bought up for a pension of £4,000 (\$20,000) a year to the eldest male descendant by his second wife, and that this pension was commuted in 1884 for the sum of \$335,000.

PENNANT, THOMAS, naturalist and antiquary, was descended from an old Welsh family, who for many generations had resided at Downing, Flintshire, where he was born June 14, 1726. He died in 1798.

PENNI, GIANFRANCESCO (born in 1488, died in 1528), Italian painter, surnamed "Il Fattore," from the relation in which he stood to Raphael, whose favorite disciple he was after Giulio Romano, was a native of Florence, but spent the latter years of his life in Naples. He painted in oil as well as in fresco, but is chiefly known for his work in the Loggie of the Vatican.

PENNSYLVANIA, one of the original thirteen States of the North American Union, is 160 miles wide, and more than 300 miles long from east to west. Its northern, southern, and western border-lines were meant to be straight; the eastern follows the course of the Delaware river. It is bounded by the States of New York and New Jersey on the north and east, by Ohio on the west, and by Delaware, Maryland, and West Virginia on the south. Its surface, subdivided into sixty-seven counties, measures nearly 28,800,000 acres or 45,000 square miles; less than one-half of its acreage is in cultivated farms, and only 1,000,000 of the people live in separate farmhouses. Out of a population of 4,283,000, nearly 2,000,000 lived in towns and cities in 1880, and more than 2,000,000 in country hamlets or factory villages, at iron mines and furnaces, at coal-mines and coke-ovens, at lumber-camps and oil-wells, or along the many lines of canal and railroad which traverse the State in all directions.

In physical features Pennsylvania is topographically divisible into three parts—a southeast district, the open country between the South Mountains and the sea; a middle belt of parallel valleys separated by low parallel mountain-ridges; and a northern and western upland, behind the escarpment of the Alleghany Mountains. One and a half millions of its people inhabit the fertile and highly-cultivated southeastern triangle, which is nowhere more than 600 or 700 feet above the level of the sea. One million inhabit the middle belt of higher-lying valleys, rich in iron ore and anthracite coal. One and a half millions occupy the great bituminous coal and oil regions of the northern and western counties, elevated from 1,000 to 2,500 feet above the sea, which constitute at least one-half of the State, and drain, not eastward into the Atlantic, but northward into the St. Lawrence and westward into the Mississippi.

The valleys of the middle belt are of two characters, distinguished by the farming population of the Atlantic States as "rich valleys" and "poor valleys." The former, whether large or small, are completely inclosed and comparatively level areas of limestone land, surrounded by rocky and wooded barriers. Their entire limestone floor has been under cultivation for a century, and the best iron-ore deposits of the State and its oldest mines are situated in them. They are gardens of fertility, yielding heavy crops of wheat, rye, and maize; innumerable caverns ramify beneath the surface; sink-holes receive the drainage of the fields; many of the watercourses appear and disappear beneath sunken arches of limestone; and wells are the chief source of supply. Old orchards and great planted trees abound, and more picturesque landscapes cannot be found. Nittany, the largest of these isolated valleys, occupies the center of the State. Sinking Spring valley is at its

southwestern end, and here it is traversed by the Little Juniata river, along the banks of which runs the Pennsylvania Railroad. A narrow valley, called Canoe valley, leads southward into Morrison's cove, which is half as large as Nittany valley. The next largest limestone valley is Kishicoquilis, forty miles long by five miles wide, ending southward in a point, and split at its north-east end into three. Farther south is McConnell's cove, west of this Friend's cove, and still farther west Millikin's cove. Two little oval holes in the mountains northeast of Nittany valley, Nippenose valley and Oval valley, and two long slit-like depressions in Tuscarora and Black Log mountains conclude the short list of these remarkable limestone thrashing-floors of Pennsylvania.

The eight counties which lie along the face of the South Mountains, in the southeastern region of the State, are in the highest state of cultivation. The region as a whole is divisible into at least four districts, differing as much in population as in soil and situation. The counties of York and Adams, lying west of the Susquehanna river, along the Maryland line, are inhabited by Germans. The counties of Montgomery and Bucks, lying between the Schuylkill and Delaware rivers, have a mingled population of the descendants of Germans, Quakers, and French Huguenots. The hilly district of northern Chester is also partly German. Southern Lancaster, southern Chester, and Delaware counties support a population largely composed of the descendants of Penn's colonists. The district which they inhabit is a veritable fairyland, and its principal town, Westchester, has been for a long time one of the notable centers of scientific life in the State.

The climate of so great a State is necessarily various in character, and is made more variable by its situation on the eastern side of the continent, facing the Gulf Stream. The northwest wind is dry and cold in winter, the southwest wind always mild and rainy, and the southeast ocean wind wet and sultry in summer; but the northeasters of New England lose much of their rigor by the time they reach the Delaware. The northern highlands of the State are buried under four or five feet of snow four months of the year. The southern middle counties enjoy genial weather the whole year round, interrupted only by a few short intervals of intense heat or cold, never lasting more than three consecutive days. The midland valleys are very hot in midsummer and very cold in midwinter, the thermometer ranging between 0° and 100°, with a not infrequent sudden fall after a sultry week of 30° or 40° in a few hours, ending with thunder-storms, and followed by dry, clear, cool weather, with winds from the northwest. The climate of the southwestern counties is comparatively dry and equable, but with a sufficient annual rainfall, and plenty of snow in winter, productive of good river floods in spring. The average annual rainfall ranges from 36 inches in the western counties to 42 inches at Philadelphia.

For unknown geological reasons Pennsylvania is peculiar for exhibiting the Palæozoic system in its maximum development, that is, from the Permian formation down to the base of Murchison's Lower Silurian, with a total thickness of more than 40,000 feet at the eastern outcrops, diminishing to half that amount in the western counties. Near Harrisburg, at Pottsville, and at Mauch Chunk the Carboniferous, Devonian, and Upper Silurian rocks, standing vertical, show a cross section five miles thick. At the Delaware and Lehigh water-gaps the Lower Silurian slates are 6,000 feet thick. In Canoe valley the underlying Lower Silurian limestones have been measured 6,500 feet thick. In the southwestern corner of the State about 1,000 feet of Permian rocks overlie the Coal-measures proper.

The mineral resources of Pennsylvania have never been exaggerated except by those who compare its iron-mines with those of other States. But Pennsylvania has the advantage over other States of a first plant, in both iron-works and coal-mines, and in a consequent multiplication and concentration of capital for these industries, which must keep her *facile princeps* in this respect for a long time to come.

The coal-fields of Pennsylvania are divided into seven anthracite and eight bituminous coal districts, and the productions for the year 1888 were as follows:

## ANTHRACITE.

No. of District.	No. of tons mined.
1.....	9,881,878.06
2.....	5,455,537.51
3.....	8,684,493.00
4.....	4,892,514.00
5.....	4,962,331.00
6.....	4,710,014.54
7.....	2,658,803.00
Total.....	41,225,571.11

## BITUMINOUS.

No. of District.	No. of tons mined.
1.....	2,313,957
2.....	6,228,117
3.....	1,893,845
4.....	4,632,043
5.....	5,240,941
6.....	3,265,596
7.....	4,683,981
8.....	5,513,866
Total.....	33,772,346

The number of working collieries in the anthracite region, that year, was 606, and 591 in the bituminous region, and a total of 177,606 men were employed in both districts during the same period.

The iron industry of Pennsylvania has always competed with the cotton growth of the southern States and the cotton industry of the eastern States for political power in Congress, to save itself against a foreign importation of rolled iron. The ironmasters of Pennsylvania have led in every debate upon a protective tariff. Pennsylvania has always furnished one-half of the total amount of pig-iron cast in the United States. In 1885 it made 2,445,496 tons, out of a total of 4,529,869 tons made in twenty-six States and one Territory. Of these 1,235,248 tons were anthracite pig, 1,198,100 coke and raw coal pig, and only 12,148 were charcoal pig. In like manner Pennsylvania has always rolled more than one-half of the iron and steel rails of American manufacture.

The vegetation of the State corresponds in variety with the variety of elevation and distance from the seaboard. The mountains are clad with forests of pine, hemlock, oak, beech, maple, walnut, wild cherry, cucumber, dogwood, and laurel; cultivated apple, cherry, pear, and peach trees grow in the clearings. Wild grapes grow in sheltered places; wild huckleberries, strawberries, and blackberries flourish. Oats, barley, and timothy grass yield heavy crops. The original forest remains only here and there in secluded spots. In the northwestern counties the discovery of petroleum in 1859 produced a great demand for derrick lumber, and the ephemeral wooden cities which sprang up during the succeeding twenty-five years caused a rapid bringing under cultivation of at least 5,000 square miles, lying between 1,000 and 2,000 feet above the level of the sea.

Two hundred and eighty-four genera and 544 species of plants are enumerated as growing on the plateau of Wayne county, in the northeast corner of the State, a typical portion of the whole upland region, covered with glacial drift-sand and gravel, with innumerable lakes,

ponds, and small swamps, lying at various elevations from 1,100 to 2,000 feet above the sea.

The zoölogy of Pennsylvania exhibits that transition stage of its history in which we live. The elk has disappeared; but the panther (puma) and the small wolf are occasionally met with. The black bear is not by any means extinct, and can always find its way anew into the State from West Virginia. The wildcat is common in the least settled counties. Hedgehogs, groundhogs, weasels, polecats, squirrels of three species, mice of several species, and muskrats abound; but the beaver, which has given name to so many mountains, rivers, creeks, and swamps all over the State, no longer exists. The wild turkey is practically exterminated, but is occasionally shot on the mountains. Owls, wood-doves, thrushes, and other birds are abundant. Harmless snakes of various species are innumerable, especially a constrictor, the black snake, which grows to a length of five or six feet. Two venomous snakes are still numerous, the copperhead in the half-cultivated districts, and the rattlesnake in the mountains. The latter, in spite of all efforts to exterminate it, breeds with incredible rapidity. In summer it descends into the valleys. Poisonous insects are almost unknown; but infinite swarms of gnats torment cattle and men in the forest counties. During a short season in summer mosquitoes abound along the tidal rivers, when the south wind blows. Fleas have only recently been imported; but ticks are common in the lowland woods, and the native bedbug, which breeds under the bark of the hemlock, has become domiciled throughout the State, and is the curse not only of the traveler but of a large part of the resident population.

The constitution of 1874 gives the right to vote to every male citizen over twenty-one years of age who has been a citizen of the United States one month, resident in Pennsylvania one year, and in his election district two months; but, if over twenty-two years old, he must have paid a tax at least two months before the day of election. The legislative power is vested in a general assembly of two houses—50 senators elected by the people for four years and 200 representatives for two years. There are strong constitutional guards against special legislation. The executive department consists of a governor, lieutenant-governor, secretary of internal affairs, elected each for four years, an auditor for three, and a treasurer for two, together with a secretary of state, an attorney-general, and a superintendent of public instruction, each appointed for four years by the governor with consent of the senate. The judiciary consists of a supreme court of seven judges elected for twenty-one years; forty-three district courts of common pleas each with one or more judges elected for ten years, and exercising probate jurisdiction except in cities where there are orphans' courts; and local magistrates of minor jurisdiction. The State sends twenty-seven representatives to the national Congress; and federal courts for the eastern district are held at Philadelphia, and for the western district at Pittsburgh, Williamsport, and Erie.

The population, which in 1755 was figured at 255,000, had increased in 1880 to 4,282,891, and was in 1890 shown by the census to be 5,258,014. During the legislative session of 1887, a resolution was adopted providing for an amendment to the constitution prohibiting the manufacture, sale, or keeping for sale of any intoxicating liquor to be used as a beverage. The question was voted upon in the fall of 1889, and the proposed amendment rejected.

January 1, 1889, there were 2,298 school districts in the State, owning property valued at \$39,998,783.75, represented in part by 21,342 schools, 9,551 of which

were graded. The teachers number 23,681, of whom 14,678 are women, the average monthly wages for men being \$38.54, and for women \$30.16. There were 13 normal schools in 1889 under State patronage. The total school expenditure for 1888 was \$11,012,990, including \$1,500,000 of State aid, given every year. The schools are free to all persons from six to twenty-one years of age; and this "school population" in 1888 numbered 831,367, exclusive of Philadelphia. The average attendance was 573,041. There are 28 colleges giving four-year courses, but only 5 confine themselves strictly to college work, viz., University of Pennsylvania at Philadelphia, Lehigh University at South Bethlehem, Lafayette College at Easton, Haverford College at Haverford, and Dickinson College at Carlisle. The grounds, buildings, and apparatus of twenty institutions are valued at \$3,186,000, and they hold \$3,951,000 in productive funds. Swarthmore College and eight others admit both sexes to equal privileges. The peculiar industries of the State have led to extensive provisions for technical and scientific instruction. There are 17 theological schools, a law department in the university of Pennsylvania, 5 medical colleges, all in Philadelphia, an academy of fine arts, and about 200 academies of various grades. Schools for the education of the orphans of soldiers are also maintained, but by an act of the legislature dated June 2, 1887, admissions thereto after June 1, 1890, were prohibited. The schools were established in 1864, and are prepared to furnish tuition to upward of 3,000 pupils annually.

There are two penitentiaries, the Eastern, at Philadelphia, on the separate-cell system, with about 1,000 convicts, and the Western, at Allegheny, on the congregate system, with about 650 convicts. The reform school at Morganza (cottage system) and the house of refuge at Philadelphia receive youthful offenders, who in both institutions average over 1,000. This latter was in 1888 made the recipient of a large donation of money by two citizens of Philadelphia, and in the year following appropriated the same to the purchase of land upon which a new house of refuge is in progress of construction. An industrial reformatory at Huntingdon has room for 500 youthful criminals sentenced for first offenses.

Pennsylvania has made liberal provision for the care of her insane. Four exclusively State institutions, and one which has been built and largely maintained by State aid, afford accommodation for more than 4,000 inmates. They are severally located at Harrisburg, Danville, Warren, Dixmont, and Norristown, and, with three other establishments, are now largely occupied. In addition to these there are the Pennsylvania Training School for Feeble Minded Children, at Media, Delaware county; the Pennsylvania Institution for the Deaf and Dumb, for the Instruction of the Blind, the Working Home for Blind Men, and the Industrial Home for Blind Women, all located at Philadelphia; the Western Institution for the Deaf and Dumb at Wilkesburg, and the Pennsylvania Institute for the Instruction of the Blind.

Of the 2,000,000 persons in Pennsylvania in all descriptions of occupation about one-fifth, or 400,000 people, are devoted to agriculture. The number of farms is upward of 200,000, of which one-quarter is under improvement. The principal crops are wheat, maize, hay, and tobacco, the latter being largely grown in Lancaster county.

The manufacturing industries have more than doubled since 1860, and at present represent a capital invested approximating \$500,000,000, giving employment to a large army of operatives and annually turning out over one-seventh of the total product of manu-

factures of the United States. Iron and steel are the principal lines conducted, though textile fabrics, such as carpets, woolens, cottons, yarn, hosiery, etc., contribute largely to swell the sum total, and flour and grist mills, lumber-mills, glass factories, and salt-wells are extensively operated.

Connections between the navigable rivers was effected in former years by a system of canals which cost over \$50,000,000, but are now chiefly used for the carriage of coal and subordinate to the mining and railroad corporations, which are closely related. There are nine canal companies in Pennsylvania which make annual reports to the Department of Internal affairs. Their returns for the year 1890 show a paid in capital of \$52,500,000, and a floating and bonded indebtedness of \$47,500,000. The gross shipment of freight was 6,502,103 tons, and the total receipts were \$2,749,533.33. With respect to railways, the report of the Secretary of Internal Affairs for the year ending June 30, 1890, says: The reports of 283 companies show an increase of \$23,920,902.05 in the amount of "capital stock paid in," the amount now being \$799,987,217.65. The funded and unfunded debt is still accruing and will undoubtedly in a year or two reach \$1,000,000,000.00, the amount at present being \$984,123,679.30, or an increase of \$18,400,300.92. The entire cost of roads and equipments is shown to be \$1,311,245,952.80, or about \$327,000,000.00 more than the present reported indebtedness of these corporations. The increase during the year of miles of road operated by companies required by law to report to this department is 1,761.36, or a grand total of mileage of 18,810.32. The companies that do make a specific report show 11,775.46 miles in the state. In 1890 314 miles were added.

Steel rails are fast taking the place of iron. During the past year over 6,500 miles of track were laid with steel rails.

The magnitude of the railway system can be realized when it is known that by the corporations operating lines in whole or in part within this state there is an army of 176,945 persons employed. The total earnings of these corporations for the year was \$270,442,882.80, the total expenses \$235,560,006.19.

The report of the State Treasurer for the fiscal year ending November 30, 1890, showed as follows: Balance on hand at beginning of year, \$3,969,587; total receipts from all sources during year, \$8,625,919, aggregating \$12,595,506. The total payments during the year amounted to \$8,168,861, leaving a balance on hand December 1, 1890, of \$4,426,645. The public debt on December 1, 1890, stood at \$12,349,920, of which sum \$134,220 bears no interest. The sinking fund at the same date was \$3,019,724, leaving a net debt of \$4,330,196.

The annual report of the insurance commissioner, dated April, 1891, submits the amount of business done in the State during 1890, as follows: Premiums for fire and marine insurance \$14,227,730, with total losses paid of \$7,906,955. The total net income of all companies was \$3,105,902, of which \$1,379,676 was paid out in dividends.

The grant of the extensive territory called Pennsylvania, made by Charles II. in 1681 to William PENN (*q.v.*), carried with it full proprietorship and dominion, saving only the king's sovereignty. Penn at once created a quick market for lands by publishing in England and on the continent his liberal scheme of government and his intention to try the "holy experiment" of "a free colony for all mankind." In 1682, when he crossed the sea to take possession, he found the western bank of the Delaware already occupied by nearly 6,000 Swedes, Dutch, and English, the Swedes

having begun a settlement in 1638. To these, as to settlers from all nations, he conceded equal liberties. English Quakers, Scotch and Irish Presbyterians, German Mennonites, French Huguenots, men of all religions, were alike welcome; the population increased for a few years at the rate of one thousand a year; then more rapidly, so that at the end of seventy-five years it exceeded 200,000. Penn twice visited Pennsylvania, staying each time two years. In December, 1682, he summoned delegates to meet him at Upland (now Chester) to confer about government; the land was divided into counties, and in March following representatives chosen by the people of these districts agreed on a constitution, based upon popular suffrage, and guaranteeing liberty of conscience. All magistrates and officers were to be chosen by the people, Penn surrendering all claim for revenue by taxation, and retaining for himself and his deputies only the governorship. (See PENN.) The failure to settle the boundary-line between Pennsylvania and Maryland, in dispute between Lord Baltimore and Penn, long caused great irritation among the settlers, who were liable to double taxation; but in 1750 Lord Hardwick's decree in chancery confirmed the original claims of Penn, and in 1763-67 Mason and Dixon definitely fixed and marked 246 miles of the line between the States of Pennsylvania, Maryland and Delaware.

For over sixty years the predominance of the Quakers in the assembly had prevented any legislation for public defense—of which, indeed, there was little need so long as Indians and whites kept their covenant. But in 1744 the Indians became allies of the French, then at war with Great Britain. The party of non-resistance was overborne by a sense of public danger, which found strong expression in a pamphlet by Franklin, and in 1747 the assembly permitted volunteer organization. One hundred and twenty companies were soon enrolled, ten of them, of a hundred men each, in Philadelphia. But there was no efficient management nor hearty co-operation with adjacent colonies. Braddock's defeat in 1754 intensified the alarm; Fort Duquesne (site of Pittsburgh), which he aimed to reduce, was held by the French till 1758. The peace of Paris in 1763 did not quiet the red men. Pontiac, a famous sachem, united the western tribes in a war of extermination, only ended when the whites had proved their mastery. Though stout against the Stamp Act of 1765 and other parliamentary encroachments, Pennsylvania was not swift to move; a committee of safety seized the reins till the people could speak through a representative convention. The convention espoused the revolution; in September, 1776, a state constitution was promulgated, in 1778 the old charter was formally annulled and the Penn claims silenced by payment of \$650,000. During the war Pennsylvania was the scene of important events—the deliberations of the Congress and the Declaration of Independence in 1776; the battles of Brandywine and Germantown in 1777; the British occupation of Philadelphia, and the encampment of Washington at Valley Forge, in 1777-78. A brief but violent mutiny of the unpaid soldiery of Pennsylvania in 1781 led Congress to adopt a better system of finance, under the wise guidance of Robert Morris of Philadelphia. In 1812, at the outbreak of war with Great Britain, Pennsylvania promptly furnished its quota of troops. At the opening of the war with the Southern States in 1861, in response to the president's call for 14,000 men as the State's quota, Pennsylvania sent 25,975, and during the war furnished a total of 387,284. No other northern state was invaded. At Gettysburg, near the state border, a three days' battle was fought, June 30 to July 3, 1863, resulting in a decisive victory of the Federal

forces. In 1864 Chambersburg was burned by the Confederates.

For more than two centuries Penn's commonwealth has been advancing in population, and prosperity, and the great body of the people have dwelt in peace. There have been five serious local disturbances. Between 1791 and 1794 there was organized resistance to the collection of a Federal tax on distilled spirits, but a strong display of force quelled the insurrection without bloodshed. In 1844 there were riots in Kensington, a suburb of Philadelphia, between "native Americans" and Catholic Irish, resulting in the destruction of thirty dwellings, three churches, one convent, and many lives. Between 1835 and 1861 anti-slavery meetings in Philadelphia were often roughly interrupted, and in 1838 Pennsylvania Hall was burned by a pro-slavery mob. A criminal combination in the anthracite mining region, known as the "Molly Maguires," was broken up in 1876 by due course of law, twenty men being hanged for murder. In 1877 the "railroad riots," an outbreak of dissatisfied railway employes, caused a vast destruction of property at Pittsburgh and vicinity, but were quelled by the military. The constitution has been four times revised—in 1838, 1850, 1857, 1874.

PENRITH, a market-town of Cumberland, England, situated near the river Eamont, and on the Lancaster and Carlisle section of the London and North-Western Railway, eighteen miles south of Carlisle, and five northeast of Ulswater. The town consists chiefly of one long and wide street. The principal public buildings are the grammar school, founded by Queen Elizabeth in 1566, the agricultural hall, the mechanics' institute, and the workingmen's literary institute. There are breweries, tanneries and sawmills, but the town depends chiefly on agriculture. The population of the urban sanitary district, in 1871, was 8,317, and in 1881 it was 9,268, and in 1890 estimated at 10,500.

Old Penrith, the *Bremetenracum* of the Romans, was about five miles north-by-west of the present town. At the Conquest the honor of Penrith was a royal franchise; but it was alternately in the possession of the English and Scottish kings until given to Anthony Beck, bishop of Durham, by Edward I. The town more than once lapsed to the crown. In 1696 it was granted to William Bentinck, earl of Portland, and in 1783 it was sold by the duke of Portland to the duke of Devonshire.

PENSACOLA, a city of the United States, capital of Escambia county, Fla., on the northwest coast of Pensacola Bay. The harbor has recently been improved so as to secure a uniform depth of twenty-four feet. Pensacola is the terminus of several railway lines which connect it with Mobile, Montgomery, Jacksonville, and Millview, the starting-place of steamers plying to Cedar Keys, etc., and the seat of a large trade in lumber (mainly pitch pine), early vegetables, and winter fruits. About seven miles west of Pensacola lies a United States navy-yard. The average annual value of the exports to Great Britain and the British colonies is about \$1,500,000, to other foreign countries \$1,600,000, and to the Northern States \$500,000. The total imports were only \$200,000. In 1850 the population was 2,164, in 1870, 3,347, and in 1880, 6,345; and it has now (1890) increased to 11,751.

Pensacola Bay is said to have been discovered by Narvaez in 1528. French, and afterward Spanish, colonists settled on the site of the town in the close of the seventeenth century. In 1719 it was captured by Bienville, in 1723 restored to the Spaniards, in 1763 occupied by the British, in 1781 captured by General Galvez, in 1814 taken from the British by the United

States general Jackson, and again, in 1818, taken by the same general from the Spaniards. In 1821, according to the treaty of 1819, it became, with the rest of Florida, part of the United States territory.

PENSION SYSTEM OF THE UNITED STATES. The present elaborate and comprehensive pension-system of the United States dates its origin back to the days of the first continental congress. The measures then undertaken in acknowledgment of the nation's obligation to the soldiers, and as an expression of the gratitude felt by the nation for his services, have since been extended to the purposes for which they were inaugurated, until the system has become one of the most responsible and invaluable of any maintained by the general government. Nine years after the passage of the original act, or in 1785, the sums derived by taxation for this fund proved inadequate, and until 1789 the deficiency thus created was made up from appropriations by the States. Upon the adoption of the Federal Constitution legislation was enlisted and the system developed. The acts of 1790-2-3 and 1806 provided for the payment of pensions to beneficiaries during their lives, and extended to the militia and State troops disabled in service against the enemy. Disabled officers and soldiers of the regular army were also provided for. Subsequent legislation in the way of amendments, etc., was had, and the laws then created have since been accepted as authorities on the subject of pensions for injuries received prior to the civil war. The act also provided pensions for the widows and children of officers dying of wounds received in battle; payment to commence from the date of death, and at the rate of one-half the amount paid decedent monthly during his connection with the army. In February, 1871, soldiers of the war of 1812, and widows of deceased soldiers of that war were placed upon the service pension list, and allowed \$8 per month from the date of the passage of the bill; payment, however, being conditioned upon proof of loyalty during the Rebellion, and that marriage occurred prior to the close of the war. By the act of March, 1878, soldiers who had served fourteen days in the army during the Rebellion, or had participated in battle during that war, were granted a pension of \$8 per month, the same sum being also allowed to widows of such soldiers. The latter's pensions were subsequently increased to \$12 per month by act of March, 1886. The year following the benefits of the system were again extended to survivors of the Mexican war who had served sixty days in the army or navy in Mexico, on the coasts or frontier thereof, or *en route* thereto, or engaged in battle in that country and had been honorably discharged. These and the widows of survivors who had attained the age of sixty-two years, and been disabled by some cause covered by the pension laws, were, by the act of January 29, 1887, granted the same increase. On June 7, 1888, an act was adopted for the payment to the widows for the full period of time which had elapsed between the deaths of their husbands and the dates of the commencements of the pensions they were then enjoying. An act was also passed the same year directing the payment of \$30 per month to soldiers who become totally deaf, with a corresponding increase over rates previously paid in cases of partial deafness. At the sessions of congress of 1889-90, there was but limited legislation, the bulk of same being almost entirely confined to the passage of private acts; the Morrill service pension bill, up to June 1, 1890, having failed to become a law.

When the system was first introduced the administration of its affairs was directed by the secretary of war, those relating to the navy by the secretary of the navy, and the laws with reference to bounty lands by the

treasury department. Both the latter branches came under the jurisdiction of the pension department proper March 4, 1840, and January 20, 1843, respectively, and on March 3, 1849, the department was made a separate and independent bureau of the interior department, at that time but recently created. The office since that date has been in charge of a commissioner of pensions, appointed by the president. He has original jurisdiction of matters pertaining to pensions, assisted by two or more commissioners, and a full force of clerks, examiners, legal and medical reviewers, and subordinates.

Those who are entitled to pensions include army, navy, marine, and militia officers, enlisted men disabled by wounds received or contracted while in the service, widows or minor children under sixteen years of age, of officers and soldiers in the army or navy who have died of wounds or disease received or contracted in the service, and the dependent fathers, mothers, brothers or sisters of officers and soldiers in the army or navy, who have died of wounds received or disease contracted as above stated. The father inherits from the mother in case of the latter's death, and the minor brothers and sisters from the father, share and share alike. The first grade named above receive \$72 per month, being regarded as totally disabled; the second grade, which includes those incapacitated from manual labor, are paid \$30; and the third grade, partial disability, \$24 per month.

The growth of the system has been no more wonderful than substantial. During the year closing June 30, 1889, there were 489,725 pensioners on the rolls, of whom 351,484 were invalids, 97,590 widows, minor children, and dependent relatives, 6,813, navy invalids, widows, and dependent relatives, 603 survivors of the war of 1812, 17,065 survivors of the Mexican war, and 6,206 widows of those who served in that war. During the year the rolls were increased by 37,168 pensioners added thereto. There were \$88,275,113.28 paid for pensions, an increase of \$9,499,251.36; and the aggregate annual value of pensions was \$64,246,556.36, in addition to which there were \$203,821.84 disbursed for fees for examining army and navy surgeons. Since July 30, 1860, there have been 1,248,146 applications for pensions filed, of which 789,121 have been allowed, and \$1,052,218,413.17 have been disbursed in pursuance thereof.

Pensions are obtained upon furnishing evidence to the Bureau of the righteousness of the claim, and payment of same is made quarterly, beginning July 1st of each year, at agencies located as follows: Augusta, Me., Boston, Mass., Buffalo and New York city, N.Y., Columbus, Ohio, Concord, N. H., Des Moines, Iowa, Detroit, Mich., Indianapolis, Ind., Knoxville, Tenn., Louisville, Ky., Milwaukee, Wis., Philadelphia and Pittsburgh, Penn., San Francisco, Cal., Topeka, Kan., Washington, D. C., and Chicago, Ill.

**PENTATEUCH AND JOSHUA.** The name Pentateuch, already found in Tertullian and Origen, corresponds to the Jewish חמשה חומשי התורה (the five-fifths of the Torah or law); the several books were named by the Jews from their initial word, though at least Leviticus, Numbers, and Deuteronomy had also titles corresponding to those we use, viz., תורת כהנים, חמש הפקודים (*Ἀμμεσφρακωδειμ*, Origen, in *Eus.*, *H. E.* vi. 25), and משנה תורה. The Pentateuch, together with Joshua, Judges, and Ruth, with which it is usually united in Greek MSS., makes up the Octateuch; the Pentateuch and Joshua together have recently been named the Hexateuch. The date of the division of the Torah into five books cannot be made out; it is probably older than the Septuagint translation.

Moses is already taken for the author of the Penta-

teuch in 2 Chronicles xxv. 4, xxxv. 12 *seq.*; only the last eight verses of Deuteronomy are, according to the rabbins, not from his pen. From the synagogue belief in the Mosaic authorship passed to the church, and is still widely prevalent among Christians. At an early date, indeed, doubts suggested themselves as to the correctness of this view, but it was not till the seventeenth century that these became so strong that they could not be suppressed. It was observed that Moses does not speak of himself in the first person, but that some other writer speaks of him in the third—a writer, too, who lived long after. The expression of Gen. xii. 6, "the Canaanite was then in the land," is spoken to readers who had long forgotten that a different nation from Israel had once occupied the Holy Land; the words of Gen. xxxvi. 31, "these are the kings that reigned in Edom, before there reigned any king over the children of Israel," have no prophetic aspect; they point to an author who wrote under the Hebrew monarchy. Again, the "book of the wars of Jehovah" (Num. xxi. 14) cannot possibly be cited by Moses himself, as it contains a record of his own deeds; and when Deut. xxxiv. 10 (comp. Num. xii.) says that "there arose not a prophet since in Israel like unto Moses," the writer is necessarily one who looked back to Moses through a long series of later prophets.

At the same time attention was drawn to a variety of contradictions, inequalities, transpositions, and repetitions of events in the Pentateuch, such as excluded the idea that the whole came from a single pen. Such observations could not but grievously shake the persuasion that Moses was the author of the Pentateuch, while at the same time they directed criticism to a less negative task—viz., the analysis of the Pentateuch.

Thus the investigation into the composition of the Pentateuch reached a point of rest and a provisional conclusion. The results may be thus summarized. The five books of Moses with Joshua form one whole; and it is not the death of Moses but the conquest of the promised land which forms the true close of the history of the patriarchal age, the exodus, and the wanderings in the wilderness; it is therefore more correct to speak of the Hexateuch than of the Pentateuch. From this whole it is most easy to detach the book of Deuteronomy, and accordingly its independence was very early recognized. Of the other elements, that which has the most marked individuality is the work of the Elohist, which we may call the Priestly Code. This too, like Deuteronomy, is a law-book, but it has a historical setting. Its main stock is Leviticus, with the cognate parts of the adjacent books, Exod. xxv.—xl. (except chaps. xxxii.—xxxiv.) and Num. i.—x., xv.—xix., xxv.—xxxvi. (with some inconsiderable exceptions). This law-book does not, like Deuteronomy, embrace precepts for civil life, but is confined to affairs of worship, and mainly to the esoteric aspect of public worship, that is, to such points as belonged to the function of the priests as distinguished from the worshiping people. The Priestly Code is characterized by a marked predilection for numbers and measures, for arrangement (titles to sections) and formality of scheme, by the poverty and inflexibility of its language, by standing repetitions of certain expressions and phrases such as are not elsewhere found in old Hebrew. Thus its distinguishing marks are very pronounced, and can always be recognized without difficulty. If now Deuteronomy and the Priestly Code are successively subtracted from our present Pentateuch the Jehovistic history-book remains, distinguished from both the others by the fact that it is essentially narrative and not law, and by the pleasure it takes in bringing out details of the historical tradition, so that individual points of the story receive

full justice and are not sacrificed to the interests of the general plan. The patriarchal history belongs almost entirely to this document, and forms the most characteristic part of it; here that history forms no mere epitomized introduction to more important matter, as in the Priestly Code, but is treated in all fullness as a subject of first-rate importance. Legislative elements are incorporated in the Jehovistic narrative only at one point, where they naturally fall into the historical context, viz., in connection with the lawgiving on Sinai.

PENTECOST, a feast of the Jews, was in its original meaning the closing feast of the harvest gladness, at which, according to Lev. xxiii. 17, leavened bread was presented at the sanctuary as the first fruits of the new cereal store. Hence the names "Feast of Harvest," "Day of First Fruits;" but the commoner Old Testament name is "Feast of Weeks," because it fell exactly seven weeks, or, on the Jewish way of reckoning an interval by counting in both termini, just fifty days after the offering of the first sheaf of the harvest at the Feast of Unleavened Bread. Pentecost or "Fiftieth" day is only a Greek equivalent of the last name in the Apocrypha and New Testament. The orthodox later Jews reckoned the fifty days from the sixteenth of Nisan, cutting the ritual sheaf on the night of (that is, on our division of days, the night preceding) that day (see PASSOVER). In Deuteronomy Pentecost, like the other two great annual feasts, is a pilgrimage feast, and so it was observed in later times; but, unlike the others, it lasts but one day, agreeably to its character, as merely the solemn closing day of harvest-time. Like the other great feasts, it came to be celebrated by fixed special sacrifices. The amount of these is differently expressed in the earlier and later priestly law; the discrepancy was met by adding the two lists. The later Jews also extended the one day of the feast to two. Further, in accordance with the tendency to substitute historical for economic explanations of the great feasts, Pentecost came to be regarded as the feast commemorative of the Sinaitic legislation.

To the Christian church Pentecost acquired a new significance through the outpouring of the Spirit. (See WHITSUNDAY.)

PENZA, a government of eastern Russia, bounded on the north by Nijni Novgorod, on the east by Simbirsk, and on the south and west by Saratoff and Tamboff, and having an area of 15,000 square miles. The surface is undulating, with deep valleys and ravines, but even in its highest parts it does not reach more than 600 or 900 feet above sea-level. Chalk, potter's clay, peat, and iron are the chief mineral products, in the north. There are extensive forests in the north, but the south shows the characteristic features of a steppeland. The government is watered by the Moksha, the Sura (both navigable), and the Khoper, belonging respectively to the Oka, Volga, and Don systems. Timber is floated down several smaller streams, while the Moksha and Sura are important means of conveyance for grain, spirits, timber, metals, and oils. The climate is harsh and continental, the average temperature at Penza being only 39.8° (12.2° in January and 68.5° in July). The population was 1,356,600 in 1881.

PENZA, capital of the above province, is situated 440 miles by rail southeast from Moscow. It is mostly built of wood, on the slopes of a plateau 730 feet above the sea, at the confluence of the little Penza with the navigable Sura. The population, in 1881, had reached 41,650.

PENZANCE, a seaport and municipal borough of Cornwall, and the westernmost borough of England, is finely situated on gently rising ground on the northwestern shore of Mount Bay, at the terminus

of the Great Western Railway, ten miles east-northeast of Land's End, and twenty miles west-southwest of Truro. The town has a considerable shipping trade, the total number of vessels which entered the port in 1882 being 1,829 of 197,933 tons burden, the number which cleared 1,774 of 187,569 tons. The exports include tin, copper, granite, serpentine, and fish, and the imports coal, timber, and provisions. Large quantities of pilchard are annually exported to Italy. Fruits, flowers, and vegetables are grown in the neighborhood for the London market. On account of its sheltered situation and its remarkably mild and equable climate, the town has a high repute as a winter residence for persons suffering from pulmonary complaints; and on account of its fine scenery it is also becoming a favorite watering-place. The population of the municipal borough, in 1871, was 10,414, and in 1881 it was 12,409. It has been immortalized by Gilbert and Sullivan's opera *Pirates of Penzance*.

PEONY, a genus of *Ranunculaceæ* remarkable for their gorgeous flowers, constructed almost exactly on the same lines as those of the common buttercup except as regards the pistil, which in the peonies consists of two or more separate carpels each containing several seeds, and surrounded at the base by a fleshy cup or disk, which grows up around the carpels. The receptacle of the flower, moreover, instead of being flattish or somewhat convex, is in peonies a little depressed in the center, so that the stamens become somewhat perigynous as in water-lilies or roses. The carpels when ripe form dry follicles, splitting along one edge so as to expose the numerous shining black seeds, provided with a small fleshy aril. There are but few species, natives of the northern hemisphere of the Old World, and divisible into two main groups—those with herbaceous stems dying down in winter, and those with shrubby stems (Moutan or Tree Peonies). The herbaceous peonies have magnificent cup-like flowers in different varieties, of all shades of color from white to clear yellow, rose-colored, and richest crimson. The Moutan or Tree Peonies have an erect bushy stem, from which the bark peels off in flakes; the foliage is divided as in the commoner kinds, and more or less glaucous. The flowers are remarkable for the extreme delicacy of tint, and botanically by the large development of the disk above mentioned. Moutan Peonies are natives of China.

PEORIA, capital of Peoria county, Ill., is a city of remarkable growth and promise. It is pleasantly located at the south end of Peoria lake, an attractive sheet of water, and on the west bank of the Illinois river, 159 miles south of Chicago, 65 miles north of Springfield, 53 miles east of Galesburg and 43 miles west of Bloomington. It is the third city in the State in population, and in all respects is a model of enterprise, design, and construction. The city is laid out after the most approved plans, with wide streets intersecting each other at right angles, handsomely shaded and brilliantly illuminated with gas and electric lights; the residence, business, and manufacturing districts have been built up with elegant and substantial structures perfectly adapted for the uses to which they are respectively devoted, while the undulating prairies with which the city is surrounded are dotted with evidences of the taste and cultivation of the people. It is a prominent railroad city, being the intersection of the Terre Haute and Peoria; Lake Erie and Western; Ohio, Indiana and Western; Peoria, Decatur and Evansville; Peoria and Pekin Union; Wabash and Western; Central and St. Louis; Toledo, Peoria and Western; Rock Island and Peoria; Chicago, Rock Island and Pacific, and Chicago, Burlington and Quincy, also the terminus of a line of steamboats that

plies between the city and St. Louis. It contains a courthouse, city-hall, five first-class hotels, about thirty churches, the Peoria county normal school, a high school and a number of subordinate schools, nine national, six private and two savings banks, between two and three hundred stores devoted to every line of commercial endeavor, an opera-house and two public halls with an aggregate seating capacity of forty-one hundred. The representative industries embrace enterprises conducting the manufacture of engines and machinery, agricultural implements, trunks, glucose, brass fixtures, cigars, carriages, brushes, brooms, sash, doors and blinds, soap, highwines (special attention being paid to the distillation of whisky which is extensively engaged in) and bitters, patterns, safes, baskets, mantels, coal-drills, saws, metal rope, jewelry, cornices, elevators, stoves and hardware specialties, grain registers, watches, marble mantels, etc., and other intricate mechanical devices. Five daily newspapers, two of which are German, five weeklies and two monthlies are published here, and a heavy business is done annually in the shipment of bituminous coal taken from mines operated on the city's outskirts. The population, which was 22,849 in 1870 and 29,259 in 1880, was in 1890 returned at 41,024.

PEPPER, a name applied to several pungent spices known respectively as Black, White, Long, Red or Cayenne, Ashantee, Jamaica, and Melegueta Pepper, but derived from at least three different natural orders of plants.

*Black Pepper* is the dried fruit of *Piper nigrum*, L., a perennial climbing shrub indigenous to the forests of Travancore and Malabar, whence it has been introduced into Java, Sumatra, Borneo, the Malay Peninsula, Siam, the Philippines, and the West Indies. It is one of the earliest spices known to mankind, and for many ages formed a staple article of commerce between India and Europe—Venice, Genoa, and the commercial cities of central Europe being indebted to it for a large portion of their wealth. The largest quantities of pepper are produced in Penang, the island of Rhio, and Johore, near Singapore—Penang affording on an average about half of the entire crop.

Pepper owes its pungency to a resin, and its flavor to a volatile oil, of which it yields from 1.6 to 2.2 per cent. The oil agrees with oil of turpentine in composition as well as in specific gravity and boiling point. Pepper also contains a neutral crystalline substance, called piperin, to the extent of 2 to 8 per cent., which is largely used in medicine as a stimulant and stomachic.

*White Pepper* is obtained from the same plant as the black, and differs only in being prepared from the ripe fruits.

*Long Pepper* is the fruit-spike of *Piper officinarum*, C. DC., and *P. Longum*, L., gathered shortly before it reaches maturity, and dried.

*Ashantee* or *West African Pepper* is the dried fruit of *Piper Clusii*, C. DC., a plant widely distributed in tropical Africa, occurring most abundantly in the country of the Niam-niam. It differs from black pepper in being rather smaller, less wrinkled, and being attenuated into a stalk, like cubebs, to which it bears considerable resemblance externally.

*Jamaica Pepper* is the fruit of *Pimenta officinalis*, Lindl., an evergreen tree of the myrtle family. It is more correctly termed "pimento," or "allspice," as it is not a true pepper.

*Melegueta Pepper*, known also as "Guinea grains," "grains of paradise," or "alligator pepper," is the seed of *Amomum Melegueta*, Roscoe, a plant of the ginger family; the seeds are exceedingly pungent, and are used as a spice throughout central and northern Africa.

PEPPERMINT, an indigenous perennial herb of the natural order *Labiata* and genus *Mentha*, the specific

name being *Mentha piperita*, Huds., is distinguished from other species of the genus by its stalked leaves and oblong-obtuse, spike-like heads of flowers. It is met with, near streams and wet places, in several parts of England and on the Continent, and is also extensively cultivated for the sake of its essential oil in England, in several parts of continental Europe, and in the United States.

Peppermint oil varies considerably in commercial value, that of Mitcham, England, commanding nearly three times the price of the finest American. The flavor varies to a slight extent even with particular plots of land, badly drained ground being known to give unfavorable results both as to the quantity and quality of the oil. That of the Japanese and Chinese oil also differs slightly from the English, and is thus distinguishable by experts. In America the oil is liable to be injured in flavor by aromatic weeds which grow freely among the crop. When pure the oil is nearly colorless, and has an agreeable odor and powerful aromatic taste, followed by a sensation of cold when air is drawn into the mouth. Oil of peppermint is often adulterated with a third part of rectified spirit, which may be detected by the milkiness when the oil is agitated with water. Oil of rosemary and rectified oil of turpentine are sometimes used for the same purpose. If the oil contains turpentine it will explode with iodine. If quite pure it explodes in its own weight of rectified spirits of wine. In the form in which menthol is imported it bears some resemblance to Epsom salts, with which it is said to be sometimes adulterated. It is usually not entirely free from the essential oil, and consequently undergoes purification and recrystallization. The amount of menthol imported by a large firm at Leipsic between September, 1883, and April, 1884, is stated by them to have been 6,380 pounds, while it is certain that at least an equal quantity is imported into England from Yokohama. Although the Japanese peppermint plant has been imported by a London merchant, no attempt has as yet been made to cultivate the plant in order to manufacture menthol in England. Menthol is now (1890), however, manufactured from *M. Piperita* in the United States, where also *M. arvensis*, var. *piperascens*, is cultivated.

Oil of peppermint is used in medicine as an antispasmodic for the relief of griping pains in the alimentary canal, to expel flatulence, to relieve nausea, to hide the taste of other medicines, and to act as an adjunct to purgatives. The dose is usually from one to three minims. It forms a most valuable remedy in diarrhea, acting as an antiseptic and as a stimulant to the circulation, and as an anodyne. The oil rubbed over the head is used in China to cure sunstroke. Menthol has lately come largely into use as a remedy for neuralgia, being molded by heat into the form of small cones, which are rubbed over the part affected. A small portion placed on the tongue frequently relieves headache, and catarrh and coryza if placed in the nostril. The largest consumption of the oil is in the manufacture of peppermint lozenges.

PEPPER-TREE. The tree usually so called has no real consanguinity with the true pepper (*Piper*), but is a member of the Anacard family known botanically as *Schinus Molle* or *Mulli*, the latter epithet representing, it is said, the Peruvian name of the plant. The resin is used for medicinal purposes by the Peruvians, and has similar properties to mastic. The Japan pepper-tree is *Xanthoxylum piperitum*, the fruits of which have also a hot taste. Along the Riviera the tree known as *Melia Azedarach*, or the "Pride of India," a very ornamental tree with elegant foliage and dense clusters of fragrant lilac flowers, is also incorrectly called the pepper-tree by visitors.

PEPSIN. See NUTRITION.

PEPYS, SAMUEL, of diary fame, was the fifth child of John Pepys and Margaret (Perkins? *Diary*, September 17, 1663), and was born on February 23, 1632 or 1633.

In January, 1659 or 1660, Pepys began to keep his *Diary*. He was at this time living in Axe Yard, Westminster, in a small house with one servant, in straitened circumstances. In March Montagu gave Pepys the post of secretary to the generals at sea. On June 28th he became clerk of the acts of the navy, an office which Montagu had procured for him against powerful competition. On July 23d he became clerk of the privy seal. In this month he took his M.A. degree. On September 24th he was sworn in as J. P. for Middlesex, Essex, Kent, and Southampton.

In 1669 the increasing weakness of his eyesight compelled him to discontinue the *Diary*, his last entry being on May 31st. In June, 1673, he was chosen at a by-election as James' nominee for Castle Rising, a Howard borough, but a vote of the committee of privileges declared the election void. On August 7, 1677, Pepys was elected master of the Clothworkers' Company, who still possess the silver cup he gave them on the occasion. In April, 1680, Pepys attended the king by command to Newmarket, and there took down in shorthand from his own mouth the narrative of his escape from Worcester.

On his return Pepys was again made secretary to the admiralty. In the same year (1684) he was elected president of the Royal Society. At the coronation of James II. he figured as one of the barons of the Cinque Ports; and he sat in James' parliament for his old seat of Harwich along with his former colleague, Sir Anthony Deane. He died on May 26, 1703.

The importance of Pepys' *Diary*, historically speaking, may be summed up by saying that without it the history of the court of Charles II. could not have been written.

PERCEVAL, AMAND-PIERRE CAUSSIN DE, Orientalist, was born at Paris, January 13, 1795. He died during the siege of Paris, January 15, 1871.

PERCEVAL, SPENCER, prime minister of England from 1809 to 1812, was the second son of John, second earl of Egmont, and was born in Audley Square, London, in November, 1762. He was shot by an assassin, perhaps a madman, named Bellingham, in the lobby of the House of Commons, May 11, 1812. Perceval will be chiefly remembered for his strenuous opposition to Catholic emancipation, an opposition due to a conscientious dread of the political evils that might result from it. He was a vigorous debater, specially excelling in replies, in which his thorough mastery of all the details of his subject gave him a great advantage.

PERCH (*Perca fluviatilis*), a freshwater fish generally distributed over Europe, northern Asia, and North America, and so well known as to have been selected for the type of an entire family of spiny-rayed fishes, the *Percidae*, which is represented in European fresh waters by several other fishes such as the pope (*Acerina cernua*) and the pike-perch (*Lucioperca*). It inhabits rivers as well as lakes, but thrives best in waters with a depth of not less than three feet; in large, deep lakes it frequently descends to depths of fifty fathoms and more. It occurs in Scandinavia as far north as the 69th parallel, but does not extend to Iceland or any of the islands north of Europe. In the Alps it ascends to an altitude of 4,000 feet.

PERCIVAL, JAMES GATES, an American writer of many-sided activity, but chiefly remembered by his verses, was born at Berlin, Conn., on September 15, 1795. He died at Hazel Green, Wis., May 2, 1856.

PERCY. This family, whose deeds are so prominent in English history, claimed descent from one Manfred de Perci, who was said to have come out of Denmark into Normandy before the adventure of the famous Rollo. But it is more certain that two brothers, William and Serlo de Percy, came into England with William the Conqueror, who endowed his namesake, the elder, with vast possessions in Hampshire, Lincolnshire, and Yorkshire, among which were Topcliffe in the North Riding and Spofforth in the West Riding, the principal seats of the family for many ages afterward. This William deserves special notice besides, since he reformed the noble abbey of Whitby.

The next important member of the family is Henry de Percy, whom Edward I., after the deposition of John Baliol, appointed governor of Galloway, and who was one of his most active agents in the subjugation of Scotland.

To him succeeded another Henry Percy, a feudal baron like his predecessors, who fought at Crécy during his father's lifetime; and to him another Henry, who was made earl of Northumberland at the coronation of Richard II. Powerful in the south as well as in the north, he was the Lord Henry Percy who protected Wycliffe when cited before the archbishop at St. Paul's. As earl of Northumberland he exhibited his independence of Richard II. in a way characteristic of a northern baron. He was the father of the noted Hotspur.

The whole family of the Percies seem to have felt that their services to Henry of Lancaster were ill requited.

A crisis occurred in the fortunes of the family in the reign of Henry VIII., on the death of the sixth earl, whose two brothers, much against his will, had taken part in the great insurrection called the "Pilgrimage of Grace." A thriftless man, of whom it is recorded that in his youth he was smitten with the charms of Anne Boleyn, but was forced to give her up and marry a woman he did not love, he died childless, after selling many of the family estates and granting the others to the king. The title was forfeited, and was granted by Edward VI. to the ambitious Dudley, earl of Warwick, who was attainted in the succeeding reign. It was restored in the days of Queen Elizabeth to Thomas Percy, who, being a staunch Catholic, was one of the three earls who took the lead in the celebrated "Rising in the North," and was beheaded at York. His brother Henry, who succeeded him, was no less unhappy. Involved in Throgmorton's conspiracy, he was committed to the Tower, and was supposed to have shot himself in bed with a pistol found beside him; but there were grave suspicions that it had been discharged by another hand. His son, the next earl, suffered like his two predecessors for his attachment to the religion of his forefathers. At length, in 1670, the male line of this illustrious family became extinct.

Not one of the English noble houses is so distinguished as the Percies throughout the whole range of English history. It is remarkable alike for its long unbroken line, its high achievements, its general culture of arts and of letters. Preëminent also, as remarked by Sir Harris Nicolas, for its alliances among the peerage, it continues to this day, though represented once more by a female branch. The present dukedom of Northumberland was created in 1766 in the family of Smithson, who assumed the name of Percy and have borne it ever since. Sir Hugh Smithson, who became the first duke, married a granddaughter of a daughter of the last earl.

PERCY, THOMAS, bishop of Dromore, the editor of

the *Percy Reliques*, was born at Bridgnorth, England, April 13, 1729, and died in 1811.

PERDICCAS, son of Orontes, a distinguished Macedonian general under Philip and Alexander the Great, and regent of the empire from the death of the latter till he perished in a mutiny in 321 B.C. (See MACEDONIAN EMPIRE.)

The same name was borne by three kings of Macedonia: PERDICCAS I., whom Herodotus calls the founder of the monarchy of Macedon; PERDICCAS II., the enemy of Athens in the Peloponnesian War (died c. 414 B.C.); and PERDICCAS III., (died 359 B.C.)

PEREKOP, a town of European Russia, in the Crimea, sixty miles southeast of Kherson, on the isthmus which connects the peninsula with the continent, and, as its name (*perekop*, a cutting) indicates, commanding the once defensive ditch and dyke which cross from the Black Sea to the Sivash lagoon. It was formerly an important place, with a great transit trade in salt (obtained from the great salt lakes of the immediate neighborhood), which occupied so large a place in popular estimation that the Tartars of the Crimea were usually styled the "Perekop horde" and their khans the "Perekop khans." Since the opening of the railway route to the Crimea it has greatly declined.

PEREYASLAV, a town of European Russia, in the Poltava government, 175 miles west-northwest of Poltava, at the junction of the Trubezh and the Alta, which reach the Dnieper five miles lower down at the town's port, the village of Andrushki. The population was 10,835 in 1865, and 9,300 in 1870.

PEREYASLAVL, or PERESLAVL (called Zalyesskii, or "Beyond the Forest," to distinguish it from the older town in Poltava after which it was named), is one of the earliest and most interesting cities in northwest Russia, situated in Vladimir government, eighty-seven miles east of Moscow on the road to Yaroslavl, and on both banks of the Trubezh, near its entrance into Lake Pleshtchevo. The population was 6,253 in 1864, 7,210 in 1870, and 8,700 in 1880.

PEREZ, ANTONIO, for some years the favorite minister of Philip II. of Spain and afterward for many more the object of his unrelenting hostility, was an Aragonese. He was born about 1540 and died in comparative obscurity in Paris on November 3, 1611.

PERFUMERY is the art of manipulating odoriferous substances for the gratification of the sense of smell. Perfumes may be divided into two classes, the first of which includes all primitive or simple odoriferous bodies derived from the animal or vegetable kingdom, as well as the definite chemical compounds specially manufactured, while the second comprises the various "bouquets" or "mélanges" made by blending two or more of the foregoing in varying proportions—toilet powders, dentifrices, sachets, and the like. The second class contains the endless combination of tinctures for scenting the handkerchief sold under fancy names which may or may not afford a clue to their composition, such as "comédie française," "eau de senteur," "eau de Cologne," "lavendre ambrée," "blumengeist." These are sometimes made upon a quasi-scientific basis, namely, that of the odophone or gamut of odors of the late Dr. Septimus Piesse. Their numbers may be almost infinite; one large firm is known to manufacture several hundreds.

PERGAMUM, an important city of Teuthrania, a district in Mysia. The name, which is related to the German *burg*, is appropriate to the situation on a lofty isolated hill in the broad and fertile valley of the Caicus, about 120 stadia, less than fifteen miles, from its mouth. According to the belief of its inhabitants, the town was founded by Arcadian colonists, led by

Telephus, son of Heracles. Under the Roman empire Pergamum was one of the chief seats of the worship of Asclepius; invalids came from distant parts of the country to ask advice from the god and his priests. The temple and the curative establishment of the god were situated outside the city. Pergamum was one of the early seats of Christianity, and one of the seven churches enumerated in the Revelation was situated there. Two tributaries of the Caicus, named Selinus and Cetius, flowed through or near the city. The ancient name is still preserved under the form "Bergamo."

PERGOLESI (or PERGOLESE), GIOVANNI BATTISTA, Italian musical composer, was born at Jesi, Ancona, January 3, 1710, and died in 1736.

PERIANDER was born about 665 B.C. and succeeded his father Cypselus as despot of Corinth in 625 B.C. His rule appears to have been at first mild and beneficent, but evil advice or domestic calamity converted him into a cruel tyrant. At last, enfeebled by age, Periander offered to resign the tyranny to his son and to retire himself to Corcyra; but the prospect alarmed the Corcyreans, and they put Lycophron to death. The tyrant took his revenge by sending 300 of the noblest Corcyrean youths to Alyattes, king of Lydia, to be made eunuchs of; they were rescued, however, by the Samians. Periander did not long survive his son; he fell into a deep despondency, and died, either of grief or by violence voluntarily incurred, in 585 B.C., at the age of eighty.

PERICARDITIS, or inflammation of the pericardium, is a disease of frequent occurrence; the result of a large number of post-mortem examinations being to show that about one in twenty-three of all who die at an adult age exhibit traces of recent or old attacks of this disorder. The symptoms of pericarditis are pain in the situation of the heart, increased by a full inspiration, by pressure upon or between the ribs in the cardiac region, and especially by pressure upward against the diaphragm by thrusting the fingers beneath the cartilages of the false ribs; palpitations, a dry cough, and hurried respiration, discomfort or pain on lying on the left side, restlessness, great anxiety of countenance, and sometimes delirium. The pulse usually beats from 110 to 120 in a minute, and is sometimes intermittent, and febrile symptoms are always present. The physical signs are three in number: 1. In consequence of irritation propagated to the muscular tissue of the heart at the commencement of the inflammation of its investing membrane, the ventricles contract with increased force, rendering the sounds of the heart louder and its impulse stronger than in health, or than in the more advanced stages of the disease. 2. When much fluid is effused into the pericardium, dullness on percussion is always observable to a greater degree than in health. This sign, which is very characteristic, is seldom perceived till the disease has continued for two or three days. In extreme cases the dullness may extend over a space whose diameter is seven inches or more. Simultaneous with the increased dullness, there is a diminution of the heart's sounds in consequence of the intervening fluid, and the impulse is often scarcely perceptible. 3. The rubbing of the inflamed and roughened surfaces upon each other gives rise to a sound which is commonly called the friction sound, but which has received various names. Sometimes it closely resembles the noise made by a saw in cutting through a board; sometimes it is more like that occasioned by the action of a file or of a rasp, but its essential character is that of alternate rubbing; it is a to-and-fro sound. This sound is heard early in the disease, before the surfaces of the pericardium are separated by the effusion of fluid. Pericarditis is a

disease which occasionally runs a rapid course, and terminates fatally in forty-eight hours or less. In slight cases it is probable that a true cure, without adhesion, may take place.

PERICLES, a great Athenian statesman, and one of the most remarkable men of antiquity, was the son of Xanthippus, who commanded the Greeks at the battle of Mycale in 479 B.C. The steps by which he rose to the commanding position which he occupied in later life cannot be traced with certainty.

The first public appearance of Pericles of which we have record probably fell about 463. When Cimon, on his return from the expedition to Thasos, was tried on the utterly improbable charge of having been bribed by the Macedonian king to betray the interests of Athens, Pericles was appointed by the people to assist in conducting the prosecution; but, more perhaps from a conviction of the innocence of the accused than, as was said, in compliance with the entreaties of Cimon's sister Elpinice, he did not press the charge, and Cimon was acquitted. Not long afterward Pericles struck a blow at the conservative party by attacking the Areopagus, a council composed of life-members who had worthily discharged the duties of archon. Pericles seems to have deprived it of nearly all its functions, except its jurisdiction in cases of murder. The popular party seems to have immediately followed up its victory over the Areopagus by procuring the ostracism of Cimon, which strengthened the hands of Pericles by removing his most influential opponent (461). Pericles took part in the battle of Tanagra (457) and bore himself with desperate bravery. After the battle Cimon was recalled from banishment, and it was Pericles who proposed and carried the decree for his recall. In 454 Pericles led an Athenian squadron from the port of Pegæ on the Corinthian Gulf, landed at Sicyon, and defeated the inhabitants who ventured to oppose him; then, taking with him a body of Achæans, he crossed to Acarnania, and besieged the town of Cœniadæ, but had to return home without capturing it. Not long afterward Pericles conducted a successful expedition to the Thracian Chersonese, where he not only strengthened the Greek cities by the addition of 1,000 Athenian colonists, but also protected them against the incursions of the barbarians by fortifying the isthmus from sea to sea. This was only one of Pericles' many measures for extending and strengthening the naval empire of Athens. Colonies were established by him at various times in Naxos, Andros, Oreus in Eubœa (in 446), Brea in Macedonia (about 443), and Ægina (in 431).

When Cimon died, in 449, the aristocratic party sought to counterbalance the power of Pericles by putting forward Thucydides, son of Melesias, as the new head of the party. He seems to have been an honest patriot, but, as the event proved, he was no match for Pericles. The Sacred War in 448 showed once more that Pericles knew how to defend the interests of Athens. The peace left Pericles at liberty to develop his schemes for promoting the internal welfare of Athens, and for making it the center of the intellectual and artistic life of Greece. But first he had to settle accounts with his political rival, Thucydides; the struggle was soon decided by the ostracism of the latter in 444. Thenceforward to the end of his life Pericles guided the destinies of Athens alone. The period during which he ruled Athens was the happiest and greatest in her history, as it was one of the greatest ages of the world. Other ages have had their bright particular stars; the age of Pericles is the Milky Way of great men. In his lifetime there lived and worked at Athens the poets Æschylus, Sophocles, Euripides, Cratinus, Crates, the philosophers Anaxagoras, Zeno, Protagoras, Socrates,

the astronomer Meton, the painter Polygnotus, and the painters Myron and Phidias. Contemporary with these, though not resident at Athens, were Herodotus, the father of history; Hippocrates, the father of medicine; Pindar, "the Theban eagle;" the sculptor Polyclitus; and the philosophers Empedocles and Democritus, the latter joint author with Leucippus of the atomic theory. When Pericles died other stars were rising or soon to rise above the horizon—the historians Thucydides and Xenophon, the poets Eupolis and Aristophanes, the orators Lycias and Isocrates, and the gifted but unscrupulous Alcibiades. Plato was born shortly before or after the death of Pericles. Of this brilliant circle Pericles was the center. His generous and richly-endowed nature responded to all that was beautiful and noble not only in literature and art, but in life, and it is with justice that the age of Pericles has received its name from the man in whom, more than in any other, all the various lines of Greek culture met and were harmonized. In this perfect harmony and completeness of nature, and in the classic calm which was the fruit of it, Pericles is the type of the ideal spirit, not of his own age only, but of antiquity. In the autumn of 429 he died.

He was buried among the great dead in the Ceramicus, and in after years Phormio, Thrasybulus, and Chabrias slept beside him. In person he was graceful and well made, save for an unusual height of head, which the comic poets were never weary of ridiculing. In the busts of him which we possess, his regular features, with the straight Greek nose and full lips, still preserve an expression of Olympian repose.

PERIDOTE, a name applied by jewelers to the green transparent varieties of olivine. When yellow, or yellowish-green, the stone is generally known as "chrysolite." The color of the peridote is never vivid, like that of emerald, but is usually some shade of olive, pistachio, or leek green. Although sometimes cut in rose-forms and *en cabochon*, the stone displays its color most advantageously when it is worked in small steps. There can be little doubt that the ancient "topazion" was our peridote or chrysolite, and that the mineral now called topaz was unknown to ancient and mediæval writers.

PÉRIGORD, an old province of France which formed part of the military government of Guienne and Gascony, and was bounded north by Angoumois, east by Limousin and Quercy, south by Agenais and Bazadais, and west by Bordelais and Saintonge. It is now represented by Dordogne and part of Lot-et-Garonne. The capital was PÉRIGUEUX, (*q.v.*)

PÉRIGUEUX, formerly capital of Périgord, now chief town of the department of the Dordogne, France, situated on the slope of an eminence commanding the right bank of the Isle, one of the tributaries of the Dordogne. It is 310 miles by rail south-southwest of Paris and 79 miles east-northeast of Bordeaux. The population, in 1881, was 25,036.

PERINTHUS, a town of Thrace, on the Propontis, twenty-two miles to the west of Selymbria, strongly situated on a small peninsula on the Bay of Perinthus, on the site of the modern Eski Eregli. It is said to have been a Samian colony, and to have been founded about 599 B.C.

PERIODICALS may be broadly divided into two classes, the one chiefly devoted to general literature, apart from political and social news, and the other more exclusively to science and art, or to particular branches of knowledge or trade. The former class, and those of general interest only, will be principally dealt with in this article, where an endeavor is made to trace briefly the history of the rise and progress of that vast

and increasing body of printed matter which, under the different names of reviews, magazines, etc., forms so large a part of current literature.

The first literary periodical in English was the *Mercurius Librarius, or a Faithful Account of all Books and Pamphlets* (1680), a mere catalogue.

After the close of the first quarter of the eighteenth century the literary journal began to assume more of the style of the modern review.

These periodicals had now become extremely numerous, and many of the leading London publishers found it convenient to maintain their own particular organs. It is not a matter of surprise, therefore, that the authority of the reviews should have fallen somewhat in public estimation. The time was ripe for one which should be quite independent of the booksellers, and which should also aim at a higher standard of excellence. As far back as 1755 Adam Smith, Blair, and others had endeavored to carry on such a quarterly without achieving success, and in 1773 Gilbert Stuart and William Smellie issued during three years an *Edinburgh Magazine and Review*. To the northern capital is also due the first high-class critical journal which has kept up its reputation to the present day. The *Edinburgh Review* was established in 1802, by Jeffrey, Scott, Horyer, Brougham, and Sydney Smith. It created a new era in periodical criticism.

Soon after the introduction of the literary journal in England, one of a more familiar tone was started by the eccentric John Dunton in the *Athenian Gazette, or Casuistical Mercury, resolving all the most Nice and Curious Questions* (1689-90 to 1695-96), a kind of forerunner of *Notes and Queries*, being a penny weekly sheet, with a quarterly critical supplement. In the last part the publisher announces that it will be continued "as soon as ever the glut of news is a little over." Defoe's *Review* (1704-13) dealt chiefly with politics and commerce, but the introduction in it of what its editor fittingly termed the "scandalous club" was another step nearer the papers of Steele and the periodical essayists, the first attempts to create an organized popular opinion in matters of taste and manners. These little papers, rapidly thrown off for a temporary purpose, were destined to form a very important part of the literature of the eighteenth century, and in some respects its most marked feature. Although the frequenters of the clubs and coffee-houses were the persons for whom the essay-papers were mainly written, a proof of the increasing refinement of the age is to be found in the fact that now for the first time were women specially addressed as part of the reading public. The *Tatler* was commenced by Richard Steele in 1709, and issued thrice a week until 1711.

As from the "pamphlet of news" arose the weekly paper wholly devoted to the circulation of news, so from the general newspaper was specialized the weekly or monthly review of literature, antiquities, and science, which, when it included essay-papers, made up the magazine or miscellaneous repository of matter for information and amusement. Several monthly publications had come into existence since 1681, but perhaps the first germ of the magazine is to be found in the *Gentleman's Journal* (1691-94) of Peter Motteux, which, besides the news of the month, contained miscellaneous prose and poetry.

The increased influence of this class of periodicals upon the public opinion of our own era was first apparent in *Blackwood's Edinburgh Magazine*, founded in 1817 by the publisher of that name, and carried to a high degree of excellence by the contributions of Scott, Lockhart, Hogg, Maginn, Syme, and John Wilson, the editor. It is still issued, and has always

remained liberal in literature and conservative in politics.

From 1815 to 1820 a number of low-priced and unwholesome periodicals flourished. The *Mirror* (1823-49), a two-penny illustrated magazine, begun by John Limbird, and the *Mechanics Magazine* (1823) were steps in a better direction. The political agitation of 1831 led to a further popular demand, and a supply of cheap and healthy serials for the reading multitude commenced with *Chambers' Edinburgh Journal* (1832), the *Penny Magazine* (1832-45) of Charles Knight, issued under the patronage of the Society for the Diffusion of Useful Knowledge, and the *Saturday Magazine* (1832-44), begun by the Society for Promoting Christian Knowledge.

Recent shilling monthlies began with *Macmillan* (1859), the *Cornhill* (1860), and the *Temple Bar* (1860).

In 1889, apart from political newspapers, there were published in Paris 1,381 periodicals of all kinds. They may be classified in the following order:—Theology 95, jurisprudence 132, reviews 75, popular reading 172, history and geography 37, political economy and finance 243, science generally 26, mathematics 6, medicine 101, natural science 21, military 14, naval 12, fine arts 75, fashion 81, education 46, technology 137, agriculture 46, sport 24, miscellaneous 40.

Periodicals have been specialized in Germany to an extent perhaps unequalled in any other country. Those of a really high class have become very numerous and form a marked feature in the current literature.

There were in Austria, in 1848, 22 literary and 41 special periodicals, and in 1883 110 literary and 413 special periodicals. Germany possessed, in 1848, about 947 periodicals, and in 1884, 1,550. According to the *Deutscher Zeitschriften-Katalog*, 1884, there were published in Austria, Germany, and Switzerland in 1874, 2,219 periodicals in the German language.

Spurred by the success of the *Gentleman's Magazine* in England, Benjamin Franklin printed and published the earliest miscellany in America, under the title of the *General Magazine* (1741), at Philadelphia, which, owing to want of support, expired after six monthly numbers had appeared. Franklin's rival, John Webbe, brought out in opposition the *American Magazine* (1741), which ran only to two numbers. Further attempts at Philadelphia in 1757 and 1769 to revive periodicals with the same name were both fruitless. The other pre-revolutionary magazines were the *Boston American Magazine* (1743-47), an imitation of the *London Magazine*; the *Boston Weekly Magazine* (1743); the *Christian History* (1743-44); the *New York Independent Reflector* (1752-54); the *New England Magazine* (1758-60), a collection of fugitive pieces; the *Boston Royal American Magazine* (1774-75); and the *Pennsylvania Magazine* (1775-76), which, founded by R. Aitken, with the help of Thomas Paine, came to an untimely end upon the commencement of the war. The *Columbian Magazine* (1786-90) was continued as the *Universal Asylum* (1790-92). Matthew Carey brought out the *American Museum* in 1787, and it lasted until 1792. Five or six more magazines ran out a brief existence before the end of the century. One of the most successful of them was the *Farmer's Museum* (1793-99), supported by perhaps the most brilliant staff of writers American periodical literature had yet been able to show, and edited by Dennie, who in 1801 commenced the publication of the *Portfolio*, carried on to 1827 at Philadelphia. The *Literary Magazine* (1803-8) was established at Philadelphia by C. B. Brown, who, with Dennie, may be considered as having been the first American professional man of letters. The *Anthology*

Club was founded at Boston in 1803, by Phineas Adams, for the cultivation of literature and the discussion of philosophy. Ticknor, Everett, and Bigelow were among the members, and were contributors to the organ of the club, the *Monthly Anthology* (1803-11), the forerunner of the *North American Review*. In the year 1810 Thomas (*Printing in America*, ii. 292) informs us that twenty-seven periodicals were issued in the United States. The first serious rival of the *Portfolio* was the *Analectic Magazine* (1813-20), founded at Philadelphia by Moses Thomas, with the literary assistance of W. Irving (for some time the editor), Paulding, and the ornithologist Wilson. In spite of a large subscription list it came to an end on account of the costly style of its production. The first southern serial was the *Monthly Register* (1805) of Charleston. New York possessed no periodical worthy of the city until 1824, when the *Atlantic Magazine* appeared, which changed its name shortly afterward to the *New York Monthly Review*, and was supported by R. C. Sands and W. C. Bryant. For many years *Graham's Magazine*, published in Philadelphia, was the leading popular miscellany in the country, reaching at one time a circulation of about 35,000 copies. The first western periodical was the *Illinois Monthly Magazine* (1830-32), published in Southern Illinois, owned, edited, and almost entirely written by James Hall, who followed with his *Western Monthly Magazine* (1833-36), produced in a similar manner. In 1833 the novelist C. F. Hoffman founded at New York the *Knickerbocker* (1833-60), which soon passed under the control of Timothy Flint and became extremely successful, most of the leading native writers of the next twenty years having been contributors. Equally popular was *Putnam's Monthly Magazine* (1853-57, 1867-69). The *Dial* (1841-44), Boston, the organ of the transcendentalists, was first edited by Margaret Fuller, and subsequently by R. W. Emerson and George Ripley. Among other extinct magazines may be mentioned the *American Monthly Magazine* (1833-38), the *Southern Literary Messenger* (1834), Richmond, the *Gentleman's Magazine* (1837-40), and the *International Magazine* (1850-52), edited by R. W. Griswold. The *Yale Literary Magazine* dates from 1836. The *Merchants' Magazine* was united, in 1871, with the *Commercial and Financial Chronicle*. Foremost among existing magazines come *Harper's Monthly Magazine* (1850) and *Scribner's Monthly* (1870) (now *The Century*), the *Cosmopolitan*, the new *Scribner's*, all famous for their unrivaled wood engraving and literary excellence. Within the last few years the circulation of these two periodicals has increased to a remarkable degree, both at home and abroad. Not less admirable in their way are the *Atlantic Monthly* (1857), *Lippincott's Magazine*, the *Manhattan*, and *Belford's Magazine*.

The first attempt to carry on an American review was made by Robert Walsh, in 1811, at Philadelphia, with the *American Review of History and Politics*, which lasted only a couple of years. Still more brief was the existence of the *General Repository and Review* (1812), brought out at Cambridge by Andrew Norton with the help of the professors of the university, but of which only four numbers appeared. Niles' *Weekly Register* (1811-48) was political, historical, and literary. The *North American Review*, the oldest and most prosperous of all the American reviews, dates from 1815, and was founded by William Tudor, a member of the previously-mentioned Anthology Club. After two years' control Tudor handed over the review to the club, then styled the North American Club, whose most active members were E. T. Channing, R. H. Dana, and Jared Sparks. On his return from Europe, in 1819, Edward Everett became the editor; his elder brother,

Alexander, acquired the property in 1829. The roll of the contributors to this review numbers almost every American writer of note. Since January, 1879, it has been published monthly. The *American Quarterly Review* (1827-37), established at Philadelphia by Robert Walsh, came to an end on his departure for Europe. The *Southern Review* (1828-32), conducted by H. Legaré, S. Elliott, and G. W. Simms in defense of the politics and finance of the South, enjoyed a shorter career. It was resuscitated in 1842, and lived another ten years. These two were followed by the *Democratic Review* (1838-52), the *American Review*, afterward the *American Whig Review* (1845-52), the *Massachusetts Quarterly Review* (1847-50), and a few more. The *New Englander* (1843), the *Biblical Repertory and Princeton Review* (1825), and the *National Quarterly Review* (1860) are still published. The critical weeklies of the past include the *New York Literary Gazette* (1834-35, 1839), *De Bow's Review* (1846), the *Literary World* (1847-53), the *Criterion* (1855-56), the *Round Table* (1863-64), the *Citizen* (1864-73), and *Appleton's Journal* (1869). The leading weeklies of the day include the *Nation* (1865), the *Literary World* (1870), and the *Critic* (1881).

Religious periodicals have been extremely numerous in the United States during the last hundred years. The earliest was the *Theological Magazine* (1796-98). The *Christian Examiner* dates from 1824 and lasted down to 1870. The *Panoplist* (1805), changed to the *Missionary Herald*, still represents the American Board of Missions. The *Methodist Magazine* dates from 1818 and the *Christian Disciple* from 1813. The *American Biblical Repository* (1831-50), a quarterly, was united with the *Andover Bibliotheca Sacra* (1843) and with the *Theological Eclectic* (1865). *Brownson's Quarterly Review* began as the *Boston Quarterly Review* in 1838, and did much to introduce to American readers the works of the modern French philosophical school. Among more recent serials of this class we may notice the *Protestant Episcopal Quarterly Review* (1854), the *Presbyterian Magazine* (1851-60), the *Catholic World* (1865), the *Southern Review* (1867), the *New Jerusalem Magazine* (1827), *American Baptist Magazine* (1817), the *Church Review* (1848), the *Christian Review* (1836), the *Universalist Quarterly* (1844). Among historical periodicals may be numbered the *American Register* (1806-11), Stryker's *American Register* (1848-51), Edwards' *American Quarterly Register* (1829-43), the *New England Historical and Genealogical Register* (1847), the *Historical Magazine* (1857), the *New York Genealogical Record* (1869), and the *Magazine of American History* (1877.)

For many years the leading English periodicals have been regularly reprinted in the United States, and many serial publications have been almost entirely made up of extracts from English sources. Perhaps the earliest example is to be found in *Select Views of Literature* (1811-12). The *Eclectic Magazine* (1844) and *Littell's Living Age* (1844) are still published. On the other hand, the leading American periodicals and some of the journals have English offices of publication, and are there reprinted and published.

In 1817 America possessed only one scientific periodical, the *Journal of Mineralogy*. Professor Silliman established the journal known by his name in 1818. Since that time the *American Journal of Science* has enjoyed unceasing favor. Among other special periodicals of the day may be mentioned the *American Naturalist*, the *American Journal of the Medical Sciences*, the *American Journal of Speculative Philosophy*, the *American Journal of Philology*, the *American Railroad Journal*, the *Banker's Magazine*, the

*Index Medicus*, and the *Journal of the Franklin Institute*.

The number of periodicals devoted to light literature and to female readers has been, and still remains, extremely large. The earliest in the latter class was the *Lady's Magazine* (1792) of Philadelphia. The name of the *Lowell Offering* (1841), written chiefly by factory girls, is well known in England. *Godey's Lady's Book* is still issued. Children's magazines originated with the *Young Misses' Magazine* (1806) of Brooklyn; *St. Nicholas* is a modern high-class representative of this kind; another current example is the *Child's Paper* (1852).

The following estimate of the number of periodicals now appearing in the United States is taken from G. P. Rowell & Co.'s *American Newspaper Record* (1888). Weeklies, and those published more frequently than once a week, are omitted on account of the difficulty of distinguishing them from newspapers. The numbers given are—bi-weeklies, 61; semi-monthlies, 229; monthlies, 1,704; bi-monthlies, 25; quarterlies, 109.

PERIPATETICS was the name given in antiquity to the followers of Aristotle, from their master's habit of walking up and down as he lectured conversationally to his pupils. Others derive the name from the *Peripatos*, or covered walk of the Lyceum. Aristotle's central conception is the correlative opposition of form and matter. This may be called the supreme category under which he views the world; it is the point where, as Zeller puts it, Aristotle's system at once refutes and completes the Platonic doctrine of the "idea" in its relation to phenomena. But Aristotle did not succeed in expelling the dualism which he blamed in Plato. His deity is pure form, and dwells in abstract self-contemplation withdrawn from the actual life of the world. The development of the world remains, therefore, unrelated to the divine subject. In Aristotle's doctrine of man, precisely the same difficulty is experienced in connecting the active or passionless reason with the individual life, the latter being a process of development bound up with sense, imagination, and desire. The soul is originally defined as the entelechy of the body, and, moreover, not of body in general but of its particular body. It is impossible, therefore, from this point of view to speak of soul and body as separate entities. Yet Aristotle holds that besides the individual mind, which is all things potentially—which *becomes* all things—there is superinduced upon the process of development the active or creative reason, the pure actuality which the development presupposes as its necessary *prins*, just as the world-process presupposes God. This reason is "separable," and is said to enter "from without" when it unites itself to the process of individual life. It must, therefore, exist before the individual, and it alone outlasts the death of the body; to it alone properly belong the titles of "immortal" and "divine." But its relation to the universal divine reason was not handled by Aristotle at all. The question was destined to become the *crux* of his commentators. In general it is evident that, if reason in man be identified with the process of natural development (and there is Aristotelian warrant for declaring these to be simply two aspects of the same thing), we drift into a purely naturalistic or materialistic doctrine. On the other hand, the doctrine of the "active reason" may be maintained, but what Aristotle left vague may be further defined. The rational soul of each individual may be explicitly identified with the divine reason. This leads to the denial of individual immortality and the doctrine of one immortal impersonal reason, such as we find, for example, in the rationalistic pantheism of Averoes. A third position is possible, if the statements of Aristotle

be left in their original vagueness. Aristotle may then be interpreted as supporting monotheism and the immortality of separate rational souls. This was the reading adopted by the orthodox scholastic Aristotelians, as well as by those early Peripatetics who contented themselves with paraphrasing their master's doctrine.

Aristotle's immediate successors, Theophrastus, who presided over the Lyceum from 322 to 288 B.C., and Eudemus of Rhodes, were distinguished by a learned diligence rather than by original speculative power. The naturalistic tendency of the school reached its full expression in Strato of Lampsacus, who succeeded Theophrastus as head of the Lyceum, and occupied that position for eighteen years, (287–269 B.C.) His predilection for natural science earned for him in antiquity the title of "the physicist." He is the most independent, and was probably the ablest, of the earlier Peripatetics.

The successors of Strato in the headship of the Lyceum were Lyco, Aristo of Ceos, Critolaus (who, with Carneades the Academic and Diogenes the Stoic, undertook, in 155 B.C., the famous embassy to Rome, more important in its philosophical than in its political bearings), Diodorus of Tyre, and Erymneus, who brings the philosophic succession down to about the year 100 B.C.

From the outset the characteristic of the Aristotelian philosophy had been its disinterested scientific character; but the age was one for which speculation as such had lost its attractiveness. At such a time it was natural, therefore, that the Peripatetic school should suffer more than the others. It had also in practical matters taken up a mediating position, so that it lacked the attractions which, in the case of extreme views, enlist supporters and inspire them with propagandist zeal. The fact, at all events, is not to be denied that, after Strato, the Peripatetic school has no thinker of any note to show for about 200 years. With Strato, moreover, the scientific activity of the school has an end; when it received a new infusion of life its activity took another direction. Strato accuses the Peripatetics of this period of devoting themselves to the tricking out of commonplaces. This seems in great measure true of those who still occupied themselves with philosophy; they cultivated ethics and rhetoric, and were noted for the elegance of their style. But the majority followed the current of the time, and gave themselves up to the historical, philological, and grammatical studies which mark the Alexandrian age.

PERIPATUS. See MYRIAPODA.

PERITONITIS, inflammation of the peritoneum or membrane investing the abdominal and pelvic cavities and their contained viscera. It may exist in an acute or a chronic form, and may be either localized in one part or generally diffused.

*Acute peritonitis* may attack persons of both sexes and of any age. It is sometimes brought on, like other inflammations, by exposure to cold, but it would appear to arise quite as frequently in connection with some antecedent injury or disease in some of the abdominal organs, or with depraved conditions of the general health. The symptoms usually begin by a rigor, together with vomiting and pain in the abdomen of a peculiarly severe and sickening character, accompanied with extreme tenderness, so that the slightest pressure causes a great aggravation of suffering. The patient lies on the back with the knees drawn up, and it will be noticed that the breathing is rapid and shallow and performed by movements of the chest only, the abdominal muscles remaining quiescent, unlike what takes place in healthy respiration. The abdomen becomes swollen by flatulent distension of the intestines, which increases the patient's distress. There is usually con-

stipation. The skin is hot, although there may be perspiration; the pulse is small, hard and wiry; the urine is scanty and high colored, and passed with pain. The patient's aspect is one of anxiety and suffering. These symptoms may subside in a day or two, but if they do not the case is apt to go on rapidly to a fatal termination. In such an event the pain and tenderness subside, the abdomen becomes more distended, hic-cough and vomiting of brown or blood-colored matter occur, the temperature falls, the face becomes pinched, cold and clammy, the pulse exceedingly rapid and feeble, and death takes place from collapse, the patient's mental faculties generally remaining clear till the close. When the peritonitis is due to perforation, as may happen in the case of the gastric ulcer, or the ulcers of typhoid fever, the above-mentioned symptoms and the fatal collapse may all take place in from twelve to twenty-four hours. Further, the puerperal form of this disease, which comes on within a day or two after parturition, is always very serious and is often rapidly fatal. The symptoms are similar to those already described, but in addition there are generally superadded those of septicæmia (blood-poisoning).

*Chronic peritonitis* occurs in two forms:—(1) as a result of the acute attack; (2) as a tubercular disease. In the former case, the acute symptoms having subsided, abdominal pain to some extent continues, and along with this there is considerable swelling of the abdomen, corresponding to a thickening of the peritoneum, and it may be also to fluid in the peritoneal cavity. The tubercular form of peritonitis occurs either alone or associated with tuberculous disease of the lungs or other organs. The chief symptoms are abdominal pain and distension, along with disturbance of the functions of the bowels, there being either constipation or diarrhea, or each alternately. Along with these local manifestations there exist the usual phenomena of tuberculous disease, viz., high fever, with rapid emaciation and loss of strength. Cases of this kind are of grave import, and their tendency is to a fatal termination.

In the treatment of acute peritonitis the remedy upon which most reliance is to be placed is opium, which affords relief to the pain, and appears to exercise a certain controlling influence upon the inflammatory process. It requires to be given in considerable quantity, yet with due care, so as to avoid its narcotic action. The old plan of covering the abdomen with leeches is now seldom resorted to; nevertheless a moderate abstraction of blood by this means in a previously healthy person may contribute to the relief of the pain. Hot fomentations with turpentine or opium applied over the abdomen are of value. The strength must be maintained by milk, soups, and other light forms of nourishment. It is not in general desirable that the bowels should act, and this is one of the benefits obtained by the internal administration of opium. In the simple chronic form the use of iodine externally and of tonics with cod-liver oil internally will be found of service; while in the tubercular form remedies are as a rule of little value, but such symptoms as pain, fever, diarrhea, etc., must be dealt with by palliative measures appropriate to these conditions.

PERIZONIUS, JACOB, classical scholar, the most distinguished member of a learned Dutch family of that name (Voorbrock in the vernacular), was born at Dam, in Groningen, in 1651, and died in 1715. The works of Perizonius both as an author and as an editor were very numerous, and by universal consent entitle him to a place of the highest rank among the scholars of his age.

PERJURY is an assertion upon an oath duly administered in a judicial proceeding, before a competent

court, of the truth of some matter of fact, material to the question depending in that proceeding, which assertion the assertor does not believe to be true when he makes it, or on which he knows himself to be ignorant. In the early stages of legal history perjury seems to have been regarded rather as a sin than as a crime, and so subject only to supernatural penalties. The injury caused by a false oath was supposed to be done not so much to society as to the Divine Being in whose name the oath was taken (see OATH). One of the practical effects of this view was to make perjury so common in the Middle Ages that the probable reason for preserving trial by combat was the difficulty of securing a just cause against the perjury of witnesses. The almost universal existence of compurgation was no doubt another explanation of the frequency of perjury. At common law only a false oath in judicial proceedings is perjury. But by statute the penalties of perjury have been extended to extra-judicial matters, e.g., false declarations made for the purpose of procuring marriage, and false affidavits under the Bills of Sale Act, 1878. False affirmation by a person permitted by law to affirm is perjury. In order to support an indictment for perjury the prosecution must prove the authority to administer the oath, the occasion of administering it, the taking of the oath, the substance of the oath, the materiality of the matter sworn, the falsity of the matter sworn, and the corrupt intention of the defendant. The indictment must allege that the perjury was willful and corrupt, and must set out the false statement or statements on which perjury is assigned.

Subornation of perjury is procuring a person to commit a perjury which he actually commits in consequence of such procurement. If the person attempted to be suborned do not take the oath, the person inciting him, though not guilty of subornation, is liable to fine and punishment. Perjury and subornation of perjury are punishable at common law with fine and imprisonment.

In the United States the common law has been extended by most States to embrace false affirmations and false evidence in proceedings not judicial. Perjury in the United States courts is dealt with by an act of Congress of March 3, 1825, by which the maximum punishment for perjury or subornation of perjury is a fine of \$2,000 or imprisonment for five years. The jurisdiction of the States to punish perjury committed in the State courts is specially preserved by the same act. Statutory provisions founded upon 23 Geo. II., c. 11, have been adopted in some States, but not in others. In the States which have not adopted such provisions, the indictment must set out the offense with the particularity necessary at common law.

PERKINS, JACOB, inventor and physicist, was born at Newburyport, Mass., in 1766. He soon made himself known by a variety of useful mechanical inventions, and in 1818 went over to England with a plan for engraving bank-notes on steel, which, though it did not find acceptance at once, ultimately proved a signal success, and was carried out by Perkins, in partnership with the English engraver Heath, during the rest of his long business life. Perkins continued to be fertile of inventions, and his steam-gun, exhibited in 1824, attracted much attention, though the danger attending the use of highly compressed steam prevented its practical adoption. His chief contribution to physics lay in the experiments by which he proved the compressibility of water and measured it by a piezometer of his own invention. He retired in 1834, and died in London, July 30, 1849.

\* PERM, a government of Russia, on both slopes of the Ural Mountains, with an area of 128,250 square miles. Perm is the chief mining region of Russia,

owing to its wealth in iron, silver, platinum, copper, nickel, lead, chrome ore, and auriferous alluvial deposits. Many rare metals besides, such as iridium, osmium, rhodium, and ruthenium, are found along with the above, as also a great variety of precious stones, such as sapphires, jacinths, beryls, phenacites, chrysoberyls, emeralds, aquamarines, topazes, amethysts, jades, malachite. Salt-springs appear in the west; and the mineral waters, though still little known, are also worthy of mention. The population in 1881 amounted to 2,520,100, of which number 106,500 lived in towns.

PERM, capital of the above government, stands on the left bank of the Kama, on the great highway to Siberia, 930 miles northeast from Moscow. During summer it has regular steam communication with Kazan, 685 miles distant, and it is connected by rail with Ekaterinburg. It is the see of the bishop, and has an ecclesiastical seminary and a military school. The population of Perm, in 1879, was 32,350.

PERNAMBUCO, or RECIFE, a city and seaport of Brazil and the chief town of the extensive province of Pernambuco. As it is situated on the coast, not far from the point where the continent begins to trend toward the southwest, it is naturally the first port visited by steamers from Lisbon to Brazil. The city of Pernambuco lies low, and is surrounded by a swampy stretch of country, with no high ground nearer than the hill on which Olinda is built, eight miles to the north. It used to be considered the most pestilential of Brazilian seaports; but its sanitary condition has greatly improved. The great commercial staple is sugar. Cotton, which was first exported in 1778 and continued a small item till 1781, now holds the second place. Coal began to be imported in 1834. In 1889 the population of the town and immediate suburbs was 105,000.

PARNAU, in Russian PERNOFF, a seaport town and watering-place of European Russia, in the government of Livonia, is situated 155 miles north of Riga, on the left bank of the Pernau or Pernova, which about half a mile farther down enters the Bay of Pernau, the northern arm of the Gulf of Riga. The population was 6,690 in 1863, 9,525 in 1867, and 12,918 in 1881.

PÉRNE, ANDREW, a notable character in sixteenth-century history, was born at East Bilney, in England, in 1519. He is best known as a remarkable example of the tergiversation in reference to religious profession, which, owing to the sudden changes in the prescribed theological belief of the state, was only too common in his age. Doctor Perne died in 1589 while on a visit to Archbishop Whitgift, on whose gratitude he had established a lasting claim by the protection he accorded him during the persecution under Mary.

PÉRONNE, chief town of an arrondissement of the department of the Somme, France, and a fortified place on the right bank of that river, at its confluence with the stream called the Doingt or Cologne, lies ninety-four miles north-northeast of Paris, on the railroad from Paris to Cambrai.

PÉROUSE. See LA PÉROUSE.

PERPETUAL MOTION, or PERPETUUM MOBILE, in its usual significance does not mean simply a machine which will go on moving forever, but a machine which, once set in motion, will go on doing useful work without drawing on any external source of energy, or a machine which in every complete cycle of its operation will give forth more energy than it has absorbed. Briefly, a perpetual motion usually means a machine which will create energy.

The earlier seekers after the "perpetuum mobile" did not always appreciate the exact nature of their quest; for we find among their ideals a clock that would periodically wind itself, and thus go without human inter-

ference as long as its machinery would last. The energy created by such a machine would simply be the work done in overcoming the friction of its parts, so that its projectors might be held merely to have been ignorant of the laws of friction and of the dynamic theory of heat. Most of the perpetual motionists, however, had more practical views, and explicitly declared the object of their inventions to be the doing of useful work, such as raising water, grinding corn, and so on. Like the exact quadrature of the circle, the transmutation of metals, and other famous problems of antiquity, the perpetual motion has now become a venerable paradox. Still, like these others, it retains a great historical interest. Just as some of the most interesting branches of modern pure mathematics sprang from the problem of squaring the circle, as the researches of the alchemist developed into the science of modern chemistry, so, as the result of the vain search after the perpetual motion, there grew up the greatest of all generalizations of physical science, the principle of the conservation of energy.

It was no doubt the barefaced fallacy of most of the plans for perpetual motion that led the majority of scientific men to conclude at a very early date that the "perpetuum mobile" was an impossibility. We find the Parisian Academy of Sciences refusing, as early as 1775, to receive schemes for the perpetual motion, which they class with solutions of the duplication of the cube, the trisection of an angle, and the quadrature of the circle. Stevinus and Leibnitz seem to have regarded its impossibility as axiomatic; and Newton, at the beginning of his *Principia*, states, so far as ordinary mechanics are concerned, a principle which virtually amounts to the same thing.

PERPIGNAN, the ancient capital of Roussillon, and now the chief town of the department of Pyrénées Orientales, France, and a first-class fortress, stands about sixty-six feet above sea-level, on the right bank of the Tet, seven miles above the point where it falls into the Mediterranean. The fortifications of the citadel, which is large enough to contain 2,000 men, are of various times. Perpignan was the seat of a university founded by the kings of Aragon, and the town still possesses an interesting museum of sculptures and pictures, where are to be seen the first photographic proofs produced by Daguerre, a natural history collection, and a library containing 30,000 volumes. The manufactures of Perpignan are cloth making, cork-cutting, tanning, and cooperage, and it has a large trade in wine, brandy, honey, fine wool, fruit, and vegetables. The population, in 1881, was 31,735.

PERRAULT, CHARLES, the most prominent author of France in a specially French kind of literature—the fairy tale—and one of the chief actors in the famous literary quarrel of ancients and moderns, was born at Paris on January 12, 1628. No criticism of his famous productions is necessary, and it is scarcely less superfluous to observe that Perrault has no claim to the invention of the subjects. His merit is that he has treated them with a literary skill in adapting style to matter which cannot possibly be exceeded. He died on May 16, 1703.

PERRONE, GIOVANNI, Roman Catholic theologian, was born at Chieri (Piedmont) in 1794. He died on August 26, 1876. He was the author of numerous dogmatic works, which, as clearly and faithfully reflecting the prevailing tendencies of Roman theology, obtained wide currency and were extensively translated.

PERRY, an alcoholic beverage, obtained by the fermentation of the juice of pears. The manufacture is in all essentials identical with that of CIDER (*q. v.*), though there are some variations in detail arising from the more abundant mucilage of the pear.

PERSEPOLIS. In the interior of Persia proper, some forty miles northeast of Shíráz, and not far from where the small river Pulwár flows into the Kur (Kyrus), there is a large terrace with its east side leaning on Kúhi Rahmet ("the Mount of Grace"). The other three sides are formed by a retaining wall, varying in height with the slope of the ground from fourteen to forty-one feet; and on the west side a magnificent double stair, of very easy steps, leads to the top. On this terrace, which is not perfectly level, stand and lie the ruins of a number of colossal buildings, all constructed of exquisite dark-gray marble from the adjacent mountain. The stones were laid without mortar, and many of them are still *in situ*, although the iron clamps by which they were fastened together have been stolen or destroyed by rust. The mason-work is excellent, and the style of the lofty palaces, colonnades, and vestibules most imposing. Especially striking are the huge pillars, of which a number still stand erect. No traveler can escape the spell of these majestic ruins. It is to be observed that several of the buildings were never finished. Stolze has shown that in some cases even the mason's rubbish has not been removed, and remarks accordingly that in those early times, just as at the present day, an Oriental prince would rather commence a new building of his own than complete the unfinished work of his predecessor.

These ruins, for which the name *Chihil menáre* or "the forty minarets" can be traced back to the thirteenth century, are now known as *Takhti Jamshíd*, "the throne of Jamshíd" (a mythical king). That they represent the Persepolis captured and partly destroyed by Alexander the Great has been beyond dispute, at least since the time of Pietro della Valle.

In the time of its greatest prosperity the Persian metropolis must undoubtedly have covered a great part of the extremely fertile valley of the Pulwár. It is not at all necessary to suppose that its limits are determined by the two heaps of ruins. The great bulk of the houses would, of course, be built in the wretched manner which is all but universal in the East.

The name Persepolis appears to have been first used by Clitarchus, one of the earliest, but unfortunately one of the most imaginative, annalists of the exploits of Alexander. The word was no doubt meant to allude to the "Persians," but apparently he preferred this extraordinary form to the regular "Persopolis" for the sake of a play on the destruction (*persis*) which he relates. Later writers have followed him in the use of the name Persepolis. For information about the capture and treatment of the city by Alexander we are almost entirely dependent on narratives which are based on Clitarchus, since Arrian unfortunately disposes of this episode in a very summary fashion.

Alexander, having crushed the resistance of the Persian army under Ariobarzanes at the "Persian Gates," marched rapidly on the capital. Ariobarzanes had made his way thither with a few followers, but was refused admission by Tiridates, the commandant of the citadel, who had already commenced negotiations with Alexander, and at last surrendered the place with its immense treasures to the conqueror. In a subsequent battle Ariobarzanes was killed. Alexander then ordered a general massacre, and gave up the city to be plundered. In the citadel he placed a garrison of 3,000 men under Nicarchides, and then caused the royal palaces to be set on fire—certainly not in a drunken freak, but apparently with deliberate calculation on the effect it would produce on the minds of the Asiatics.

PERSEUS, a hero of Grecian fable, son of DANAE (*q.v.*) and Zeus. When Perseus was grown to man-

hood Polydectes, the wicked king of Seriphus, cast his eye on Danae; and, that he might rid himself of the son, he exacted of him a promise that he would bring him the head of the Gorgon Medusa. Now the dreadful GORGONS (*q.v.*) dwelt with their sisters the Grææ (the Gray Women) by the great ocean, far away in the west. Guided by Hermes and Athene, Perseus came to the Grææ. They were three hags, with but one eye and one tooth among them, which they handed one to another. Perseus stole the eye and tooth, and would not restore them till the Grææ had guided him to the Nymphs, from whom he received the winged sandals, the wallet, and the cap of invisibility. These he put on, and, being armed by Hermes with a cimeter, came upon the Gorgons as they slept and cut off Medusa's head, while with averted eyes he looked at her image on his brazen shield lest he should be turned to stone. Perseus put the Gorgon's head in his wallet and fled. Coming to Æthiopia he delivered and married ANDROMEDA, (*q.v.*) With her he returned to Seriphus in time to rescue his mother and Dictys from Polydectes, whom he turned to stone along with all his court by showing them the Gorgon's head. The island itself was turned to stone, and was still and lonely ever after; the very frogs of Seriphus (so ran the proverb) were dumb. Perseus then gave the head of Medusa to Athene, who put it on her shield, and with Danae and Andromeda, he hastened to Argos to see his grandfather, Acrisius, once more. But he, fearing the oracle, had gone to Larissa, in Thessaly. Thither his grandson followed him, but at some games given by Teutamias, king of Larissa, he threw a quoit which lighted on his grandfather's foot and caused his death. Ashamed to return to Argos, Perseus gave his kingdom to Megapenthes, and received from him Tiryns in return. There he reigned and founded Midea and the famed Mycenæ, and became the ancestor of the Persides, among whom were Eurystheus and Heracles.

PERSIA, or ÍRÁN. In modern political geography these two terms are synonymous; the kingdom which we call Persia the Persians themselves call Írán.

The name Írán was originally of much wider signification than Persia, and the whole upland country from Kurdistán to Afghánistán may, in accordance with the native use of its ancient inhabitants, be called the Iranian upland. The inhabitants of this upland, together with certain tribes of the same race in adjacent lands, shared with their near kinsmen in India the name of Aryans (Ariya, Airya of the *Avesta*; Sk. Árya).

Modern Írán, or Persia, does not embrace nearly the whole Iranian upland, still less all men of Iranian nationality, that is, all who speak an Iranian dialect akin to Persian. On the other hand, the modern kingdom of Írán has many subjects who are not Iranians ethnographically, but come originally from Central Asia or Arabia, and speak Turkish or Arabic.

The series of the great Iranian monarchies begins for us with the Median empire of Ecbatana. Unfortunately, we possess but little trustworthy information about its history, being almost wholly dependent on what two Greeks, Herodotus and Ctesias, who wrote long after the fall of the kingdom, report from the mouths of Orientals. These two authorities differ so widely that their statements are to a great extent mutually exclusive.

Herodotus says the Medes freed themselves from the Assyrians, and lived for a time without a master till Deioeces obtained the kingly power by stratagem. The duration of the kingdom is exactly a century and a half, divided into two exactly equal portions, each of which is occupied by the reigns of two kings. BOSTON

further, according to Herodotus, the rule of the Medes over Upper Asia, *i.e.*, the land east of the Halys, lasted 128 years, save only the twenty-eight years during which the Scythians ruled. It is easy to see that "save only" means "minus," and that thus the foreign supremacy of the Medes is reckoned at exactly 100 years, or two-thirds of the total duration of the kingdom. Obviously such figures can at most be only approximately correct.

Ctesias' narrative opens with a highly-colored description of a real event, namely, the destruction of Nineveh by the leader of the Medes, called by him Arbaces, with the help of the Babylonian Belesys (the historical Nabopolassar). But the fact that by this event the position of Media as a great power was for the first time assured is mixed up by Ctesias with the beginning of the monarchy itself. In addition, he grossly exaggerates the duration of the empire; so that we arrive at the monstrous result that between 606 or 607, the real date of the destruction of Nineveh, and 550, the year of the fall of the Median supremacy, more than 300 years are supposed to have elapsed.

Down to the destruction of Nineveh we must ignore Ctesias almost completely and follow Herodotus alone.

In perfect harmony with the conditions of development of a small state into a great power is the statement of Herodotus that the second king of the Medes, Phraortes (*Fravarti*; according to Herodotus' reckoning 656-634 [647-625]), extended his sway beyond the limits of Media and first of all subjugated Persis, or Persia proper, the secluded mountain-land southeast of Media. During all this time, indeed, as we learn from Darius' great inscription, Persis had kings of its own; but these were simply vassals of the sultan who had his seat in Ecbatana.

Phraortes' successor, Cyaxares (*Huwakhshatara*; according to Herodotus' reckoning 634-594 [625-585]), brought the empire to the highest pitch of power. He is said to have introduced fixed tactical arrangements into the army. It was to him that the pretenders whom Darins had to overcome traced their descent, as he tells us himself.

Cyaxares marched against Nineveh and destroyed it about 607. Not only Ctesias but also Berosus asserts that the king of the Medes achieved this great success in league with the king of Babylon. After the fall of Nineveh, Nebuchadnezzar, the son of Cyaxares, made himself master of Syria and Palestine, and Cyaxares acquired most of the rest of the Assyrian territory. Probably Assyria proper belonged to him also. When Cyaxares afterward began the war with the Lydians he was already master of Armenia and Cappadocia, though he probably did not acquire them until after he had got rid of the Scythians and destroyed Nineveh. The pretext for the war was afforded by the flight of some Scythians in Cyaxares' service to Alyattes, king of Lydia; but the real cause was doubtless thirst of conquest. The war lasted for five years with varying fortune, and was ended by the battle during which the eclipse of the sun, said to have been predicted by Thales, took place. The terrified combatants saw in this a divine warning and hastily concluded peace.

The Median empire must at this time have reached a tolerably high degree of civilization. The consideration enjoyed by the Median monarch is proved by the fact that in Western lands which never came in contact with it at all its name was so familiar that more than 100 years after its fall the Persians were still mostly called Medes by the Greeks; in particular the wars of independence with the Persians still went at a much later date simply by the name "the Median wars."

Nor was the Median empire properly destroyed by Cyrus; it was only transformed.

We possess three accounts of the mode in which the transition was effected, that of Herodotus, that of Ctesias (of which that of Dinon, preserved only in some fragments and vestiges, is merely a variation), and that of Xenophon in the *Cyropædia*. Though Xenophon had before him the works of both Herodotus and Ctesias, we must, with Niebuhr, regard his book as nothing more than an extremely silly romance; the attempts to employ it as an independent historical source have always failed. Herodotus probably got his charming narrative directly or indirectly from the descendants of Hargagus, a man who undoubtedly played a chief part in transferring the supremacy from the Medes to the Persians. Ctesias' narrative, which we are obliged to piece together from Nicolaus Damascus, Photius, Justin, Polyænus, and Diodorus, is highly colored, but in parts very pretty, and has, in contradistinction to Xenophon's romance, a genuinely Oriental stamp. It appears to be based on the account of a Mede, who gave a marked preference to his own people, and represented the founder of the Persian empire in as unfavorable a light as it was possible for a Persian subject (and probably an official) to do.

Stripped of its romantic features, Herodotus' narrative of the rise of Cyrus is in fundamental harmony with the new document which we possess on the subject, in the shape of annals inscribed on a Babylonian tablet.

After the taking of Ecbatana, which made Cyrus the great king, he must have had enough to do to subdue the lands which had belonged to the Median empire. Little reliance can be placed on Ctesias' account of these struggles. Herodotus states that the Bactrians, who according to Ctesias were soon subdued, were, like the Sacræ, not subjugated until after the conquest of Babylon.

The next war was against the powerful and wealthy king Cræsus of Lydia, who ruled over nearly the whole western half of Asia Minor. It was a continuation of the war between the Medes and Lydians which had been broken off in 585.

The date of Cræsus' fall is not quite certain. It may have been 547 or 546. From that time forward the Lydians never made the slightest attempt to shake off the Persian rule.

But now began that struggle of the Persians with the Greeks which has had so much importance for the history of the world. But Harpagus and other Persian leaders quickly took one Greek town after the other; some, like Priene, were razed to the ground. Some of the Ionians, such as the Teians, and most of the Phocæans, avoided slavery by emigrating. Miletus alone, the most flourishing of all these cities, had early come to an understanding with Cyrus, and the latter pledged himself to lay no heavier burden on it than Cræsus had before him.

Though Cyrus had made, and continued to make, conquests in the interior of Asia, he was still without the true capital of Asia, Babylon, the seat of primeval civilization, together with the rich country in which it lay, and the wide districts of Mesopotamia, Syria, and the border-lands over which it ruled. Before the capture of the city, in the summer of 539, a great battle took place, in consequence of which Cyrus occupied the capital without any further serious fighting, since the Babylonian troops had mutinied against their king. Late in the autumn of 539 Cyrus marched into Babylon, Nabunaid, the king, having previously surrendered himself. According to Berosus, Cyrus appointed Nabunaid governor of Carmania, east of Persis; but in the annals inscribed on the tablet it is said to be recorded that Nabunaid died when the city was taken.

How far to the east Cyrus extended his dominion we do not know, but it is probable that the countries to the east which are mentioned in the older inscriptions of Darius as in subjection or rebellion were already subject in the time of Cyrus.

Different accounts of Cyrus' death were early current. Herodotus gives the well-known didactic story of the battle with Tomyris, queen of the Massagetæ, as the most probable of many which were told.

Cyrus died in the beginning of the year 529. He left behind him two sons, Smerdis (Persian *Bardiya*) and Cambyses (*Kambujiya*); their common mother was according to Herodotus an Achæmenian, according to Ctesias the daughter of the Median king. The great inscription of Darius states that Cambyses caused Smerdis to be put to death without the people being aware of it. From this it follows that the partition of the kingdom between the two brothers, of which Ctesias speaks, can hardly have taken place; for the murder of a king or consort could not have remained concealed. Nothing else is told us about the earlier part of the reign of Cambyses. It is only when we come to his conquest of Egypt that we have more exact information.

It seems that only one great battle was fought, at Pelusium, the gateway of Egypt. The Egyptians, utterly beaten, fled to Memphis, which soon fell into the enemy's hands. Thus Egypt became a province of Persia. This was followed by the submission of the neighboring Libyans and the princes of the Greek cities of Cyrene and Barca. The peculiar religious feelings of the Egyptians were almost as easily wounded as those of the Jews were in later times. The Persians, flushed with victory, recked little of Egyptian wisdom or folly, least of all recked the brutal king. No doubt the Egyptian priests greatly exaggerated the king's wickednesses, but enough remains after all deductions.

The empire was extended in another direction, when Polycrates, the powerful tyrant of Samos and the neighboring islands, sought safety in submission to the great king.

Suddenly, however, the empire rang with the news that the king's brother Smerdis had seized the crown in Persis. We are now in possession of Darius' own account of these events, and can fairly dispense with the Greek narratives; but we may note that here again, in spite of his poetical coloring, Herodotus stands the test much better than Ctesias. Gaumâta, a Magian, gave himself out as Smerdis (spring of 522) and formally assumed the government. Even Darius' account lets us see that Cambyses was very unpopular, and the same thing appears from the fact that everybody sided with the new king. Cambyses seems to have marched against him as far as Syria, but there he put an end to himself—an end plainly affirmed by the great inscription, and quite in keeping with the wildly passionate nature of the man. Gaumâta reigned, universally acknowledged, and, as it seems, beloved, because he granted extensive remissions of taxes. He appeared in the character of Smerdis, son of Cyrus, and therefore as *Persian*. Seven persons conspired against him. The conspiracy was completely successful; and the seven killed Gaumâta in the fortress Sikathahuvati, near Ecbatana, in the land of Nisa, in Media. Darius was then made king.

Darius (*Darayavahu*, in the nominative *Darayavahush*) was then, according to Herodotus (i. 209), about thirty years of age. He acted very energetically and promptly; and the chief provinces were undoubtedly reduced to subjection in the first three years of his reign. The experience gained by Darius in the first unsettled years of his reign must have been in part the occasion of his introducing numerous improvements into the

organization of the empire. Governors with the title of satraps (*khshathrapâvan*, i.e., land-rulers) there had been before, but Darius determined their rights and duties.

Herodotus says that Darius caused the Indus to be explored from the land of the Pactyans (Pakhtu, Afghâns) to its mouth by Scylax, a Greek or rather Carian, and then conquered the country. But in any case this Persian "India" was only one portion of the region of the Indus. If this conquest was somewhat adventurous, much more so was the enterprise against the Scythians. The expedition failed—not through the superior tactics of the Scythians, who behaved just as might be expected of such nomads, with a mixture of timidity and audacious greed of booty—but through the impassable and inhospitable nature of the country, through hunger and thirst, through exhaustion and disease. After sustaining heavy losses Darius was obliged to retreat across the Danube. That the Scythians immediately followed up their enemy, or that they even opened negotiations with the Spartans, as Herodotus states, is not to be supposed. Moreover, Megabyzus, whom Darius on his return left behind in Europe, subdued great districts of Thrace along with the Greek cities on the coast. The king of Macedonia also acknowledged the great king as his liege lord.

The eyes of the Persians were now turned toward Greece proper. While the Greek coast of Asia Minor was indispensable to the power which held the interior, the possession of the mother-country of Hellas was, as we can easily see, not only unnecessary but positively dangerous to the Persians, especially as they were themselves absolutely unfitted for the sea. But to the Persians of those days, absorbed in schemes of universal empire, considerations such as these could not present themselves. The subjugation of the rest of the Greeks of the mainland and islands, as well as of the Carians, now rapidly followed, not without dreadful massacres and devastations. The Phœnicians, who formed the main body of the Persian fleet, seem to have been especially zealous in the work of destruction.

Mardonius cherished great designs. He wished to conquer Greece itself. He did actually conquer Greeks and non-Greeks in the northwest of the Archipelago, but at the promontory of Athos his fleet was shattered by a storm.

The second expedition against Greece was on a greater scale. Under the conduct of the Mede Datis and the younger Artaphernes, son of Darius' brother of the same name, the Persians took Naxos, and destroyed Eretria in Eubœa, the inhabitants of which had sent five ships to help the Ionians at the beginning of the revolt. But at Marathon they were utterly defeated by the Athenians and Plateæans (September or October, 490). It was the first great victory of the Greeks over the Persians in the open field; the moral impression had an immense effect in the sequel, when the danger was much greater.

The southwest of the empire alone had hitherto remained free from rebellion against Darius. Darius, who had been with Cambyses in Egypt, treated the Egyptians with forbearance, and in return loyal priests praised him to fellow-countrymen and Greeks. If a notice of Polyænus is to be trusted, he must have gone in person to Egypt in the year 517, in order to lighten the burdens of the people. Among other measures which promoted the material well-being of the land, he made a canal from the Nile to the Red Sea, as an inscription of the king himself testifies to this day. But the hatred of the Egyptians to the Persians was too great. In the year 486 the first great insurrection of the Egyptians against the Persians took place. Darius

did not live to see the revolt put down, for he died in the following year, 485.

Darius is the most remarkable king of the dynasty of the Achæmenians, and perhaps the most remarkable of all the native kings of Iran. He was as energetic as he was prudent. He was, of course, a despot, and could be ruthless and even cruel, but on the whole he was inclined to be mild. He was succeeded, apparently without any disturbance, by his son Xerxes (*Khshayárshá*) I., who as son of Atossa, elder daughter of Cyrus, had probably always been regarded as heir-apparent. The subjugation of Egypt was effected in 484.

Babylon, too, seems to have again risen in revolt. Ctesias assigns to this date the revolt with which the well-known story of Zopyrus is connected, naming instead of Zopyrus his son Megabyzus. The long siege of which Herodotus speaks does not, as we saw, fit in with the revolt under Darius; it belongs, perhaps, to the time of Xerxes.

Xerxes was firmly resolved to wipe out the disgrace of Marathon, and to bring the whole of Greece under the yoke. His mighty preparations for the march thither had been interrupted by the revolt of Egypt, and, if our conjecture is right, of Babylon. They were now vigorously recommenced; and provision was made for the maintenance of the army, at least within the limits of the Persian domain. Xerxes himself went to Sardis, the first great rendezvous. From there he set forward in the spring of 480. We will not further describe the great expedition, which, after the dearly-bought successes at Thermopylæ and Artemisium, ended with the defeats of Salamis (September, 480) and Plataea (479); all this belongs rather to the history of Greece.

We stand here at the decisive turning point of Persian history. Later Greece may have been coveted and designs against it cherished, but no enterprises were undertaken. The Persians were thrown back upon the defensive. Though they often afterward exercised an influence on the history of Hellas by means of money or diplomacy, still the respect for their fighting power was gone, and so far it is possible to regard Alexander's expedition as a result and continuation of the old struggles, and the saying of Æschylus, "In Salamis the power of the Persians lies buried," may be called prophetic.

About this time Xerxes was assassinated by Artabanus, captain of the body-guard; his youngest son, Artaxerxes, in league with the murderer, put to death his elder brother Darius, who had a better title to the throne.

Artaxerxes (*Artakhshathra*) I. came to the throne in 464. Hardly was Artaxerxes seated on the throne when the second great revolt of Egypt broke out, and the Athenians were rash enough to involve themselves in the struggle (about 460). The Athenians in Egypt were annihilated (probably 455); the same fate befell a reinforcement of fifty ships.

These are the last contests of the Athenians and their allies with the Persians. Peace must have been concluded shortly afterward.

The conclusion of peace did not prevent the Persians, or at least individual satraps, from occasionally supporting enemies of Athens.

During the early years of the Peloponnesian War the Spartans repeatedly held communications with the Persians, whose assistance they desired against Athens. These negotiations were, for the time being, without result. Of the internal state of the empire during the long reign of Artaxerxes I. we know very little.

Artaxerxes died in 424. His successor, Xerxes II., the only one of his eighteen sons who was legitimate, was murdered after a month and a half by his brother Secydianus or Sogdianus. But after six and a half

months the murderer was in his turn overthrown by his brother Oehus, satrap of Hyrcania, and, in violation of solemn oaths, put to death. Oehus assumed the name of Darius, ascending the throne about the beginning of the year 423. Darius II. is called Nothus or Syrus. The king's full brother Arsites, in conjunction with another son of Megabyzus, Artyphius, raised the standard of revolt, probably in Syria. But his Greek soldiers were bribed, and thus he fell into the hands of the royalists, and, in violation of the oath, was put to death at the instigation of Parysatis. The same fate befell some of those who had taken part in the murder of Xerxes II. Darius had presumably come forward from the beginning as his avenger. Soon after 410 the great revolt of the Egyptians was successfully accomplished. The first independent king was called Amyrtæus, and was presumably a grandson or other relative of the former Amyrtæus. The deep decay of the Persian military power is proved by the fact that for sixty years it failed to reduce the unwarlike Egyptians, though the latter were frequently divided among themselves by internal dissension and double rulers.

Pissuthnes, satrap of Sardis, had also revolted. Tissaphernes, who here appears for the first time, put down the rebellion by the usual means of bribery and perjury; the Athenian Lycon, leader of Pissuthnes' Greek mercenaries, plays a far from honorable part in the affair. The events fall after 424, and at least some years before 412. But Pissuthnes' son Amorges continued the revolt in Caria, and was supported therein by the Athenians, perhaps because they already knew for certain that Tissaphernes was preparing to help the Spartans.

When the power of Athens seemed annihilated by the dreadful catastrophe in Sicily, the Persians expected to regain the whole seacoast. Tissaphernes, satrap of Sardis, and his rival Pharnabazus, satrap of Hellespontine Phrygia, vied with each other in invoking the help of the Spartans. The party hostile to Athens in the cities of the mainland and in the islands displayed great zeal in bringing about the alliance.

About the time of the conclusion of peace between Athens and Sparta Darius II. died. Arsicas ascended the throne under the name of Artaxerxes (II). The surname "Mnemon" (the mindful) seems again to have been first mentioned by Dinon. The younger and much abler son, Cyrus, preferred by Parysatis, came with 300 Greek mercenaries, no doubt to seize the throne, but he was too late. Tissaphernes, professedly the friend of Cyrus, warned the king against him, and with good reason. Cyrus was arrested, but at the instance of Parysatis he was released and sent back to his satrapy—a very unwise measure, for his ambition was only inflamed by his imprisonment and by his exasperation against Tissaphernes.

No sooner was Cyrus in his satrapy again than he began to make great encroachments. He gained over the Ionian cities which belonged to the province of Tissaphernes and laid siege to Miletus, which adhered to Tissaphernes. On Orontes, a partisan of the latter, he made open war. Meantime he collected under false pretexts an army of Greek mercenaries, and in 401 set out with the real purpose of seizing the throne. He had with him nearly 13,000 Greek mercenaries commanded by Clearchus, a Spartan exile, and a vast host of Asiatics. Cyrus advanced boldly, confident in the military superiority of the Greeks; but he had some trouble in carrying them with him as far as Syria and Babylonia, for they were not engaged for so distant a goal. He made his way without difficulty into the heart of the empire. Neither the passes of the Taurus leading from Cappadocia into Cilicia nor those of the Amanus from

Cilicia into Syria were blocked. The vassal-prince of Cilicia, Syennesis, put a good face on a bad business, and let him through. Even the line of defense between Babylonia and the Mesopotamian desert was unoccupied. At Cunaxa, 500 stadia from Babylon, they came upon the mighty royalist army. The Greeks carried everything before them; the king proved a miserable coward and fled. But in fighting the Asiatic rabble, Clearchus seems to have adhered too pedantically to the cautious Spartan tactics, and not to have dashed with sufficient rapidity at the enemy's center. Cyrus, however, rushed foolhardily into the *mêlée* and there fell.

Even if we deduct much from Xenophon's idealistic portrait, we must still admit that Cyrus was a very able and in many respects honorable man, far worthier of the throne than his brother. Cyrus' Greeks were an object of terror to the king's troops. All the deception and crimes employed against them had their source in cowardice. The king's hosts were reënforced by the army of Cyrus, which after their leader's fall passed over to the enemy; but all these Asiatics trembled before the dauntless Greek mercenaries, comparatively few in number as they were and strangers to the country. It is characteristic of the state of the empire that Tissaphernes allowed the Greeks to plunder the villages which were the special property of Parysatis; he probably thought that with the death of her favorite son her power was broken, while he himself had succeeded in appearing as the deliverer of the empire. After electing fresh leaders in place of those who were foully assassinated, the "ten thousand" made themselves a way through wild mountains and wild peoples; they had to endure a thousand dangers and hardships, but from the king's forces they experienced no serious hindrance.

This expedition revealed to the Greeks the weakness of the empire and the cowardice of its rulers and defenders. Cyrus had penetrated to its center without striking a blow, and an army of ordinary Greek mercenaries proved itself more than a match for the power of the whole empire. It was perceived how helpless the colossus was; it was perceived that great territories, which had been regarded as royal provinces, were completely independent.

Tissaphernes succeeded to all the privileges of the post which Cyrus had occupied. This could not but hasten the inevitable conflict with Sparta, which now, at the height of her power, could not bring herself to fulfill the treaty and resign to the Persians all the Greek cities of Asia Minor. The Greeks expected to be protected by Sparta against Tissaphernes, who was already enforcing his rights with the strong arm, and the war which the Spartans began in 401 against the Persians in Asia Minor was no doubt popular, but as a land-power with limited resources they were not in a position to conduct much more than a purely predatory war. At the head of the Persian fleet the Athenian admiral, Conon, utterly defeated the Spartans at Cnidus (beginning of August, 394). In a short time nearly all the islands and cities on the Asiatic coast were freed from the Spartan prefects ("harmosts"), and Conon carried his point of nowhere occupying the citadels with Persian garrisons. The Spartan sovereignty of the seas, after lasting ten years, was over forever.

As the land-war in Greece dragged on for a long time, the Spartans had again recourse to diplomacy. The Spartans at last succeeded through their ambassador Antalcidas and through Tiribazus in bringing about a peace, and all the more important states of Greece found themselves obliged to accede to it, however unwillingly. This is the notorious peace of Antalcidas, which Tiribazus laid before the delegates of the Greeks at Sardis or Ephesus in 387.

Thus Greece was split up into a thousand petty communities, which Sparta, who did not dream of extending the independence to her own subjects, could with ease dominate collectively. Through this peace the Spartans gained for about sixteen years a much greater power over the Greek mainland than they had ever possessed before, and they ruthlessly turned it to account. The real gain to Persia by the peace was a firm hold on the seacoast. The domineering attitude toward the other Greeks was a mere appearance. In the following decades the king repeatedly commanded peace, even after Thebes had completely broken the power of Sparta (371). The powers for the time being employed Persian intervention as a means to their own ends, and there were plenty of diplomatic negotiations with the king, but Persia had no advantage from them. Moreover, now one, now another Greek state supported rebel satraps and vassals. They all, the king as well as the rebels, procured mercenaries from Greece.

Meantime another enemy to the Persian supremacy in the west had arisen—an enemy who, if Athens, his friend and sympathizer, had at that time been once more a great naval power with an aggressive policy, might perhaps have excluded the Persians from all the western seas. Evagoras of Salamis had made himself the almost independent lord of Cyprus, relying on the ancestral antagonism of the Greek to the Phoenician element in the island. As early as 390 forces were levied against him. Athens, under obligations to him on Conon's account, supported him openly, although she was at that time still formally leagued with the Persians against Sparta. After the peace of Antalcidas Persia made great efforts to reduce Evagoras again to subjection. He was in league with Egypt, scoured the seas far and wide, and had even for some time maintained a siege of Tyre. The cunning Cypriot also kept up a secret correspondence with the vassal princes of Caria. After a ten years' struggle he had to yield to superior force, but by skillful negotiation with the satraps he was able to procure a tolerable peace. Soon afterward he was murdered, but his descendants long continued to be princes of different towns in Cyprus.

About this time probably the expedition of Artaxerxes against the Cadusians took place, of which Plutarch, after Dinon, has given us a detailed account. The Cadusians are the inhabitants of the modern Gilán, who were probably never completely subdued, and who certainly by their raids inflicted much annoyance on the neighboring territory of the king. Darius II. had taken the field against them shortly before his death, and the repeated mention in the fragments of Ctesias of the Cadusians at the time of the Median empire is presumably a reflex of the state of things in his own day. Artaxerxes' campaign turned out disastrously.

Meanwhile the war with Egypt was never quite at a standstill. Even before the subjugation of Evagoras much fighting took place, but without result. Our knowledge of the particulars, even of the chronology, is very inexact.

The last part of the reign of Artaxerxes II. is filled with revolts of the satraps and chiefs of Asia Minor, of which we have numerous but mostly isolated and, to a large extent, inexact accounts. These revolts, which lasted in part into the reign of Artaxerxes III., must have weakened immensely the imperial power in the western provinces, and prepared the way for the Macedonians.

At the instigation of Parysatis Artaxerxes had married his own daughter Atossa. She used her interest to secure the succession for the energetic and violent Ochus, who is said to have promised to marry her. Soon afterward the aged Artaxerxes died after a reign of

forty-six years (in the course of the year 358). Many stories are told of his mildness and affability, but, even if they are true, they have little significance. The contempt for his brother which Cyrus exhibited was perfectly justified; under the effeminate king the empire gradually fell to pieces.

But his successor Ochus, who took the title of Artaxerxes (III.), was of a different stamp. He was, it appears, one of those great despots who can raise up again for a time a decayed Oriental empire, who shed blood without scruple and are not nice in the choice of means, but who in the actual position of affairs do usually contribute to the welfare of the state as a whole. At the very beginning of his reign he secured himself on the throne by a massacre of his nearest relatives. But for awhile the empire was in a state of absolute dissolution. Artabazus headed a revolt in Phrygia. The revolt of Orontes (or Orontas) fell somewhat later.

The war in Egypt still went on. And now the cities of Phœnicia, previously so trustworthy, also revolted, and so did the kings of Cyprus. Even in Judæa there must have been an insurrectionary movement. Mentor succeeded in everywhere sowing dissension between the Greek mercenaries of the Egyptian king and the Persians; and even more by intimidation than by the sword Egypt was, after long independence, again made a Persian province (344).

Thus by force and policy the old state of the monarchy was restored in all the western lands. Mentor, the real conqueror of Egypt, was splendidly rewarded. He received the satrapy of the west coast of Asia Minor, and quickly removed by cunning and treachery Hermias, tyrant of Atarneus and the friend of Aristotle, who had concluded treaties like an independent prince and stood in suspicious relations to King Philip of Macedonia. Of course no one thought of danger to Asia Minor, much less to the whole empire, but Philip's efforts to secure the mastery of the Bosphorus and Hellespont were enough in themselves to excite grave anxiety.

As early as 350 the story went that Philip had sent an embassy to the king, and it is definitely stated that he concluded a treaty with Ochus. The pacific intentions of the Persians, at least for the moment, were no doubt sincere; not so those of Philip, who had to subdue Greece before he could put into execution his designs on Asia Minor, a circumstance overlooked by the honest but politically short-sighted Isocrates in his exhortation to Philip to attack Persia (347-346). Probably Demosthenes was not alone in perceiving that the safety of Greece now lay in an alliance with the Persians against Philip. Negotiations went on busily between Athens and the king, who at all events sent subsidies repeatedly for the conflict with Macedonia. In the year 340 Persia interfered actively by rescuing, in conjunction with Athens, the town of Perinthus, on the Propontis (and therefore close to Persian territory), which was besieged by Philip; and the Macedonians could perhaps with some right assert that with this step the war between the Persians and them had begun. But the Persians did not see, what to us is obvious from the result, that it was necessary for them to prevent the subjugation of Greece; or, if they saw it, they lacked the energy to act.

Artaxerxes probably did not reach the battle of Chæroneia (August, 338), which made Philip master of Greece. So far as we can judge, however, it was a great misfortune for the empire that this king, the first since Darius I. who had in person energetically conducted a great expedition and restored the empire, died just at this critical moment. Probably he was murdered by Bagoas, who placed Arses, the youngest of the sons of Artax-

erxes, on the throne. But, when Arses was preparing (so it is said) to punish Bagoas, the latter put him and his children to death (355). We know nothing further of this king. Under his reign (spring, 336) a Macedonian army first crossed into Asia, after Philip had previously caused himself to be nominated general of the Greeks against the Persians. The Macedonians gained some not unimportant successes, but the undertaking was checked in the very same year by the assassination of Philip. The commander Parmenio returned to Europe, and Memnon, who after Mentor's death commanded in these regions, probably won back from the Macedonians nearly all their conquests in Asia, though it is likely that Abydus, commanding the passage of the Hellespont, and perhaps one or two more strong places, remained in their hands.

In order to rule securely Bagoas placed on the throne not a near relation of the murdered man, but Codomannus, who reigned as Darius (III.), a great-grandson of Darius II., and a man of about forty-five years of age. But the king-maker was caught in his own snare, for Darius soon put him out of the way.

Over the last of the Achæmenians misfortune has thrown a halo of romance, but sober criticism can see in him only an incapable despot like so many whom the East has produced. It is no reproach that he was not a match for perhaps the greatest general in history, but an Ochus would doubtless have made the task a somewhat harder one, and would scarcely have been guilty of the folly of beheading, in a fit of bad temper, so useful a man as the old condottiere Charidemus, who thoroughly understood the mode of fighting the Macedonians.

The history of Alexander the Great is given under the articles ALEXANDER THE GREAT and MACEDONIAN EMPIRE; here we can only enumerate the chief steps in the downfall of the Persian empire.

After placing a terrible curb on the Greek love of freedom by the destruction of Thebes, Alexander crossed the Hellespont in the beginning of spring, 334. A few weeks later, on the Granicus, he annihilated the great Persian army which should have barred his onward march. Sardis, the capital, at once fell into his hands. At the farthest extremity of Cilicia Darius in person met him at the head of a huge army, but the field of battle was so badly chosen that the numerical superiority of the Persians did not come into full play. The brilliant victory of Issus (about November, 333) and the flight of Darius threw wide regions into the power of Alexander, who, with all his daring, was also cautious, and did not follow the Persian king in his flight into the interior. Egypt welcomed exultingly the Macedonian who freed her from the hated Persians. After the acquisition of Egypt Alexander possessed a territory large and strong enough to be able to survive, if need be, a reverse. In the spring of 331 he left Egypt and marched through Syria and Mesopotamia to Assyria proper, where Darius awaited him at the head of vast masses of troops, and this time in a favorable position. But on October 1, 331, Alexander defeated the king at Gaugamela so decisively that henceforward the Persian empire, as such, was shattered. Darius fled to Media. Without striking another blow Alexander captured the capitals, Babylon and Susa, with their vast treasures. The burning of the royal castle at Persepolis was meant to show the Asiatics that their empire was utterly overthrown, and that Alexander was their only lord.

After the decisive battle of Gaugamela (331 B.C.) Alexander proclaimed himself king of Asia. After Alexander had by his rapid and effective movements taken actual possession of the whole empire, Media was swiftly traversed, but the eastern frontier was not sub-

dued and secured so easily. The Achæmenian power at its climax had never crossed the Indus; Alexander passed the river and pushed into India proper. This adventurous march was undertaken wholly for the sake of prestige, and was specially meant to impress the imagination of the Greeks, to whom India was a land of marvels. Alexander proposed to reach the Ganges and the ends of the habitable earth; and it was sorely against his will that his own soldiers forced him to confine his plans to the rational scope of securing the Indus as his frontier and adding to his realm its commercially important delta. Alexander had now accomplished what, in the eyes of the Arian peoples, was necessary to give the last stamp of legitimacy to the new empire; he had led his armies round all the frontiers and taken personal possession of his lands. To close the circle he had still to march back through Gedrosia and Carmania. But it may well be doubted if he would have faced this last exploit had he known beforehand the full terrors of the burning desert; not a fourth part of the forces that began the march from India survived a journey which has been fitly compared with the retreat from Moscow.

A series of minor expeditions completed the work of the great campaigns by reducing a number of mountain tribes, which had shaken off the weak yoke of the Achæmenians, exacted tribute at the chief passes, and in their irreclaimable savage habits of plunder were like the modern Kurds, the born foes of the Iranian peasant. Such were the Uxians, the Mardians in Persis, and the people of the same name to the south of the Caspian, and finally the Cossæans, whom Alexander disposed of in his last campaign in forty midwinter days. The future obedience of these brigands was secured by planting fortresses at the most difficult points of the roads, and they were compelled to settle down and take to husbandry.

These vast results were only obtained by the aid of continual fresh levies in Europe, and strong garrisons had to be left in the conquered lands. Alexander's work could not last unless the European occupation became permanent; and therefore he planned a great network of new cities, in which colonies of Greek or Macedonian soldiers were planted. According to Plutarch more than seventy cities owed their origin to Alexander; some forty of these can still be traced.

Alexander's capital was Babylon, the natural center of an empire that embraced both Iran and the West, and recommended also by its command of the great lines of international traffic, and by its historical traditions of empire. The Achæmenian system of satrapies was retained; kingships were left only in the exceptional case of India.

To the Greeks a union with a barbarian was no regular marriage; but the Bactrian Roxana was Alexander's queen. His friends were urged to follow his example; eighty of his courtiers married Persians on the occasion of the great wedding at Susa, and 10,000 soldiers who had chosen Asiatic wives received gifts on the occasion. Still more startling was the introduction of polygamy; the king took a second wife, Statira, daughter of Darius, and a third, Parysatis, daughter of Ochus.

Alexander desired to fuse the Greeks and barbarians together, but the practical means directed to this ideal aim were such as brought him into conflict with the natural leaders of the new state. By asking the Greeks as well as the barbarians to worship him as divine he destroyed the whole effect of the theatrical arts in which he was a master, and by which he hoped to recommend his mission as an eminently Hellenic one to the masses; even Callisthenes, the enthusiastic herald of the new era, was bitterly undeceived, and, turning against Alexander, fell a victim to the despotism of the man who

had been his idol. But, what was still more fatal, the net result of his efforts at a fusion of races was not to Hellenize the Persians, but to teach the Macedonians to exchange their old virtues for the effeminacy and vices of the East.

The want of coherence in the empire was seen even while Alexander was in India. Many satraps broke all restraint, renewed the old oppressions of the Persian time, hired mercenaries again, and only awaited a fit moment for open rebellion; the generals of the army that lay in Media committed sacrilege and crimes of every kind; the treasurer Harpalus violated his trust and escaped with his plunder. Alexander, on his return, soon restored order with terrible severity, but the ferment was still at work, especially in the west, and was increased through the disbanded mercenaries of the satraps who returned to the coast.

One Macedonian custom Alexander had retained, that of carousing with his generals. A series of debauches in the malarious climate of Babylon brought on a violent fever, which ended in his death (June 13, 323). The object of his life, the fusion of Macedonians and Persians, was not attained.

Terrible civil wars broke out at once on Alexander's death, and lasted almost unbroken for forty-two years, tearing his work to pieces, and scattering to the winds Macedonia's claims to universal empire. In 312 a victory over Nicanor, who held Media for Antigonos, (the latter having his commission from Antipater the regent), made Seleucus master of Media and the adjoining provinces. Antigonos had still some temporary successes, but at the end of the war Seleucus was acknowledged lord of Babylonia and the upper satrapies.

Instead of the twenty-one Asiatic satrapies of the partitions Seleucus divided his empire into seventy-two, thus diminishing the dangerous strength of the individual governors. But the old arrangement was restored later.

Seleucus had built for himself a new capital, Seleucia on the Tigris, but in process of time his chief attention came to be more and more engrossed by the affairs of the west, and the seat of power was shifted to Antioch in Syria. A kingdom like that of Seleucus could hardly be governed from Syria, which lay so far from its natural center, and about 293 or a little later Seleucus found it advisable to make over the upper satrapies to Antiochus, his son by his first marriage with Apama, daughter of Spitamenes, giving him Seleucia as his capital and his stepmother Stratonice as wife. Seleucus, like Antigonos, dreamed of regaining the whole monarchy of Alexander, and fancied himself within reach of his goal after the fall of Lysimachus, when he was himself removed by assassination. Antiochus Soter (280-261) was prudent enough to be content with what he possessed and acquiesce in the actual division of the empire into three realms, practically corresponding to the three continents.

The heir of the kingdom was his second son, Antiochus II. Theos (261-246), a drunken and dissolute prince, who neglected his realm in the society of unworthy favorites. Under the weak Antiochus II. north-eastern Iran was lost to the empire.

When Antiochus II. died, the horrors that accompanied the succession of his son Seleucus II. Callinicus (246-226) gave the king of Egypt the pretext for a war, in which he overran almost the whole land of the Seleucids as far as Bactria. Meantime a civil war was raging between Seleucus and his brother Antiochus Hierax, for whom the Galatians held, and at the great battle of Ancyra, in 242 or 241, Seleucus was totally defeated and thought to be slain. At this news Arsaces Tiridates, whom the genuine tradition still represents as a brave robber-chief, broke into Parthia at the head

of his Parnians, slew the Macedonian eparch Andragoras, and took possession of the province.

Arsaces Tiridates soon added Hyrcania to his realm and raised a great host to maintain himself against Seleucus, but still more against a nearer enemy, Diodotus of Bactria. On the death of the latter, however, the common interests of the Parthians and Bactrians against the Seleucids brought about an alliance between Arsaces Tiridates and Diodotus II. Tiridates, who on his coins appears first merely as Arsaces, then as King Arsaces, and finally as "great king" (probably in imitation of Antiochus Magnus), reigned thirty-seven years, dying in 211 or 10. His nation ever held his memory in almost divine honor.

Seleucus III. Soter (226-223) died early, and was followed by Antiochus III. Magnus (223-187), who in his brother's lifetime had ruled from Babylon over the upper satrapies.

Antiochus was followed in the kingdom by his sons, first the weak Seleucus IV. Philopator (187-175), and then the gifted Antiochus IV. Epiphanes (175-164).

Now followed the troubled reign of the child-king Antiochus V. Eupator (164-162), which was cut short by Demetrius Soter (162-150).

The true danger for the Macedonian monarchy came from the ever stronger reaction of the Oriental element, of which the little state of Parthia was the most vigorous champion. The kings of Parthia had long kept quiet after the war with Antiochus the Great. Phriapatius, successor of Arsaces II., who reigned fifteen years (c. 191-c. 176), calls himself on his coins "Arsaces Philadelphus," perhaps because he had married a sister, and (first of all Parthian kings) Philhellen. By the last title he presents himself, at a time when the Seleucid power was sinking, as the protector of his present and future Greek subjects. His eldest son and successor, Phraates I. (Arsaces Theopator of the coins), conquered the brave Mardian highlanders and transplanted them to Charax in the neighborhood of the Caspian Gates, a proof that the Parthians had already detached Comisene and Choarene from Media (Strabo, xi. 514), probably just after the death of Antiochus the Great.

About 171 Phraates died and left the crown not to his sons but to his brother Mithradates (Arsaces Epiphanes and apparently also, on tetradrachms of 139, 138, Arsaces Philhellen), a prince of remarkable capacity, who made Parthia the ruling power in Iran. His first conquests, it would seem, were made at the expense of Bactria.

The kingdom of Bactria had made vast advances under Euthydemus, whose son Demetrius crossed the Indian Caucasus and began the Indian conquests, which soon carried the Greeks far beyond the farthest point of Alexander. Demetrius, having succeeded his father, was displaced in Bactria by the able usurper Eucratides, some time between 181 and 171. A thousand cities obeyed Eucratides, and both he and his rival Demetrius sought to extend the Greek settlements, the one founding Eucratidia in Bactria, the other Demetrius in Arachosia. On his way back from the conquest of India Eucratides was murdered by his son and co-regent, probably Heliocles.

In the midst of the civil wars, which became more serious after the death of Eucratides, Mithradates of Parthia began to extend his dominions at the expense of Bactria; even in the lifetime of Eucratides he succeeded in annexing the satrapies of Aspiones and Turiua. These seem to have covered Aria, for the Hindu-Kush is named as the eastern boundary of the Parthians—whence perhaps the mention of Arians among the foes of Eucratides. Another account makes Mithradates

rule as far as India, and declares him to have obtained without war the old kingdom of Porus, or the rule over all nations between the Indus and the Hydraspes.

The change of rule was not well received by the new subjects of Parthia, least of all by the Greeks and Macedonians of the upper provinces.

Mithradates' last campaign was against the king of Elymais. The country was brought under Parthia, but continued to have its own kings. The coins make it likely that Mithradates simply set up a new dynasty, a branch of his own house. Mithradates died in a good old age in 138, or a little later. His memory was revered almost equally with that of the founder of his house, but his real glory was much greater, for it was he who made Parthia a great power. He is praised as a just and humane ruler, who, having become lord of all the lands from the Indian Caucasus to the Euphrates, introduced among Parthians the best institutions of each country, and so became the legislator of his nation.

The complete annihilation of the Macedonian empire in Iran was closely followed by the destruction of Greek independence in eastern Iran, north of the Paropanisus. The last mention of independent Bactria is in 140.

Phraates II., who succeeded his father in 138, and continued his work, wresting Margiana from the Scythians of Bactria in an expedition commemorated on extant coins, had also to meet the last and most formidable attempt to restore the sovereignty of the Seleucids. Antiochus VII., one of the ablest kings of his race, had put down the civil wars in Syria, even taking Jerusalem and compelling the Jews to acknowledge his might by paying him military service, and in 130 he marched eastward at the head of a force of 80,000 combatants, swollen by camp-followers to a total of 300,000. Many of the small princes, on whom the hand of Parthia lay heavy, joined him as they had joined his brother; the enemy was smitten on the Great Zab, and in two other battles; Babylon and then Ecbatana opened their gates to the conqueror; and the subject-nations rose against the Parthians, who, when Antiochus took up his winter quarters in Media, were again confined to their ancient limits. When the snows began to melt, an embassy from Phraates appeared to ask for peace; but the terms demanded by Antiochus—the liberation of Demetrius, the surrender of all conquests, and the payment of tribute for the old Parthian country—were such as could not be accepted without another appeal to the fortunes of war. Demetrius, indeed, was released and sent to Syria, but only to stir up a hostile party in his brother's rear. During the winter the Syrian host had been dispersed over a wide range of cantonments; the disorderly insolence of the soldiers, for which the general Athenæus was held to be mainly responsible, and of the levies raised in the towns had disgusted the natives; the Medes made secret terms with Parthia, and all the cantonments were attacked by concert on a single day. Hastening to relieve the nearest corps, Antiochus was met by the Parthian with a superior force of 120,000 men; he refused the advice of his officers to fall back to the neighboring mountains, and accepted battle on a field too narrow for the evolution of his troops. The Syrian soldiers, enervated by luxury, were readier to imitate the flight of Athenæus than the valor of his master; the whole host was involved in the rout and annihilated. Antiochus himself escaped wounded from the fray, and cast himself from a rock that he might not be taken alive. This catastrophe (February, 129) freed the Parthians for ever from danger from Syria.

Phraates paid funeral honors to the fallen king, and afterward sent his body to Syria in a silver coffin. He entertained his captive family royally, married one of the two daughters, and sent the eldest son Seleucus to

Syria to claim the sovereignty, and so serve future plans of his own; for an attempt to follow and recapture Demetrius, made immediately after the battle, had proved too late. But dangers in the east soon turned the Parthian's attention away from enterprises in the west. In his distress he had bribed the Scythians to send him help; as they arrived too late he refused to pay them, and they in turn began to ravage the Parthian country. Phraates marched against them, leaving his charge at home to his favorite, the Hyrcanian Euhemerus, who chastised the countries that had sided with Antiochus, made war with Mesene, and treated Babylon and Seleucia with the utmost cruelty. But the Scythian war proved a disastrous one; the enemy overran the whole empire, and for the first time for five hundred years Scythian plunderers again appeared in Mesopotamia; in a decisive battle Phraates was deserted by the old soldiers of Antiochus, whom he had forced into his service and then treated with insolent cruelty; the Parthian host sustained a ruinous defeat, and the king himself was slain (spring, 128, or somewhat later).

Artabanus I. (third son of Phriapatius), who now became king, was an elderly man.

His son and successor, Mithradates II. the Great, was the restorer of the empire. We are briefly told that he valiantly waged many wars with his neighbors, added many nations to the empire, and had several successes against the Scythians, so avenging the disgrace of his predecessors.

Artabanus II. was the next monarch, but after him the style of king of kings was taken by the Armenian Tigranes, one of the most dangerous foes Parthia ever had. In 86 it was still a reason for choosing Tigranes as king of part of Syria that he was in alliance with Parthia (Just., xl. 1, 3), but very soon the latter state was so ruined by civil and foreign war that it was no match for Armenia. Of the details in this history we know only the last act. In 77 the Arsacid Sinatruces returned from the land of the Sacaraucae to take the throne at the age of eighty, and reigned seven years.

Phraates III. succeeded his father, Sinatruces, a little before the arrival of Lucullus in the East in 70, and in 69 refused a second invitation to give help against Rome, which Mithradates and Tigranes addressed to him jointly, the latter offering to reward him by giving up all that he had taken from the Parthians. His hatred of Tigranes made him more disposed to alliance with Rome; and after a period of hesitating neutrality Phraates accepted the overtures of Pompey, and prepared to invade Armenia. But the Romans had no further occasion for Parthian help. Immediately afterward Pompey's officer marched into Syria through Mesopotamia, which, by treaty, had been expressly recognized as Parthian. Nevertheless, Phraates at first contented himself with again sending a fruitless embassy to demand that Pompey would observe the treaty and acknowledge the Euphrates as the Parthian frontier.

For a century and a half up to the death of Mithradates the Great there had been an unusual degree of unity in the house of the Arsacids; but the corruptions to which every Eastern dynasty ultimately falls a prey appeared at length. About 57, Phraates, the restorer of the empire, was murdered by his two sons, one of whom, Orodes or Hyrodes I. (Zend, *Huraodha*), took the throne, while his brother Mithradates III. got Media; but the latter ruled so cruelly that he was expelled by the Parthian nobles, and Orodes reigned alone. Mithradates, with a loyal follower, Orsanes, fled to Gabinius, proconsul of Syria, who had already crossed the Euphrates to restore him by force when he was summoned by Pompey to restore Ptolemy XI. to the throne of Egypt (55). Mithradates,

dismissed by the Romans, now tried what he could do without help. Orodes had at first to flee, but soon regained his position, mainly through the help of Surenas, a young noble who had the hereditary right of crowning the king, and was the second person in the empire in point of wealth, nobility, and influence, and the first in courage and political skill. Surenas took Seleucia by storm; Babylon received Mithradates, but was reduced by famine; Mithradates then surrendered to his brother and was killed before his eyes. These events carry us far into the year 54.

Meantime Crassus, hoping for a rich and easy prey, had invaded Mesopotamia without a shadow of pretext, had defeated a small Parthian force at Ichnæ, and occupied a number of large towns, such as Nicephorium, Ichnæ, Carrhæ, whose Greek inhabitants welcomed the Romans as liberators. As Mithradates was at this time in arms in Babylonia, we can understand why Crassus was blamed for a grave error of judgment in not marching direct from Nicephorium on Seleucia and Babylon. Instead of this, he retired to winter quarters in Syria, leaving 7,000 foot and 1,000 horse to garrison the Mesopotamian cities. Thus his hands were tied for the following campaign, and he could not accept the invitation of Artavasdes II. of Armenia to advance through his country and have his coöperation. A Parthian embassy appeared in Syria in spring to remonstrate against the faithlessness of Rome, but at the same time the Parthians were ready for war. At midday, May 6th (June 9th as the calendar then stood) the Romans had crossed the Balissus (Nahr Belik) and met Surenas half way between Carrhæ and Ichnæ, or a little nearer the latter town. Surenas kept the mass of his troops concealed by a wooded hill, showing only the not very numerous vanguard of cataphracts till the Romans were committed to do battle. The Roman cavalry under Publius Crassus, son of the proconsul, charged the enemy, to prevent a threatening flank movement, and were drawn away from the mass of the army by the favorite Parthian maneuver of a simulated flight, and then surrounded and cut to pieces. The mass of the Roman host lost courage at this disaster, and already had suffered terrible loss from the light-armed hordes of Parthian serfs who hovered round the enemy at a safe distance and galled it with arrows shot with deadly precision. The legionaries serried their ranks and covered themselves with their shields; but in this close order they were easily broken by the charge of the Parthian freemen with their long heavy lances and almost impenetrable suits of complete armor. The heat, too, thirst, and dust oppressed the Romans, and this first day would have decided their fate but that the Parthians withdrew before evening, true to their rule of encamping at a distance from the foe. Crassus retired at night, leaving all who were badly wounded behind him, and reached Carrhæ safely; but his army was sadly demoralized, and he himself lost his head, and, though fairly secure at Carrhæ, thought only of immediate retreat to Syria. He marched by night northward toward the mountains; the several divisions lost one another and each sought only to shift for itself. The quæstor Cassius, one of Crassus' best officers, returned to Carrhæ and thence regained Syria in safety. Crassus himself, after getting dangerously entangled in marshy ground, had almost reached the mountains when he was induced, by the despair of his troops rather than by error of his own judgment, to yield to treacherous proposals of Surenas and descend again into the plain. As he mounted the horse which was to convey him to a meeting with the enemy's general the gestures of the Parthians excited suspicions of treachery, a struggle ensued, and Crassus was struck down and slain. Scarcely 10,

000 men out of the whole host reached Syria by way of Armenia; 20,000 had fallen and 10,000 captives were settled in Antioch, the capital of Margiana. The token of victory, the hand and head of Crassus, reached Orodes in Armenia just as he had made peace with Artavasdes and betrothed his eldest son Pacorus to the daughter of the Armenian king. The Roman disaster was due primarily to the novelty of the Parthian way of assault, which took them wholly by surprise, and partly also to bad generalship; but the Romans always sought a traitor to account for a defeat, and in the present case threw the blame partly on Andromachus of Carrhæ, who really did mislead Crassus in his retreat, and was rewarded by the Parthians with the tyranny of his native town, but had no great influence on the disaster, and partly on Abgar, whose advice was no doubt bad, but not necessarily treacherous, while the silence of the older account disposes of Dio's improbable assertion that the men of Orrhoene fell on the rear of the Romans. That the Parthians did not count Abgar their friend and punished him with deposition may be fairly inferred from the list of kings of Edessa given by Dionysius of Telmahar, which shows that the reign of Abgar II. ended in 53, and was followed by a year of interregnum.

Surenas, the victor of Carrhæ, whose fame was now too great for the condition of a mere subject, was put to death a little later, the victim of Orodes' jealousy; the victory itself was weakly followed up. Not till 52 was Syria invaded, and then with forces so weak that Cassius found the defense easy. In July, 51 (Sextilis, according to the old calendar), the attack was renewed with greater forces; the Romans were still weak in troops, their harshness and injustice had alienated the provincials, and some districts—as Judæa—openly sympathized with the foe. Thus all the chances were still favorable to the Parthians, who indeed overran the open country, but were too unskilled in siege to take Antioch. As they drew off, Cassius stopped their way at Antigonia and inflicted on them a defeat in which Osaces, the real leader of their host under the young prince Pacorus, was mortally wounded (August, 51). Pacorus wintered in Cyrrestica, the Romans under the new proconsul Bibulus not venturing beyond the walls of Antioch; but, the satrap of Mesopotamia having raised a revolt against Orodes in the name of Pacorus, the latter was recalled by his father and Syria was entirely evacuated by May, 50.

Orodes avoided the threatened breach with his son by associating Pacorus in the empire; but the Parthians took little advantage of the civil wars that preceded the fall of the Roman republic.

From this point down to 165 the history of Parthia is a continual struggle with Rome. These wars were waged under different kings on the one side, and generals and emperors on the other, until under Cassius in the reign of Marcus Aurelius the overthrow of the Parthian power was completed. The circumstances of its final extinction are as follows:

Volagases III. had designs on Armenia, but an interview between him and Antoninus Pius (spring, 155) delayed for a time the outbreak of war. However, martial preparations went on, and on the death of Antoninus Volagases entered Armenia (162), expelled the Arsacid Sohæmus, who was a client of Rome, and made Pacorus king. The destruction of a Roman legion under the legate of Cappadocia (Ælius Severanus), who fell on his own sword, laid Cappadocia and Syria open to the Parthians; Attidius Cornelianus, legate of Syria, was routed, and the provincials were in such distress that they even began to speak of revolt from Rome. When, late in the year, Ælius Verus

arrived from the capital, he found the troops so demoralized by defeat that he was ready to offer peace; but, when Volagases refused to treat, the able lieutenants whom Verus directed from Antioch soon changed the face of affairs. The war had two theaters, and was officially called the Armenian and Parthian war. Armenia was regained and Sohæmus restored by Statius Priscus and Martius Verus (163, 164), while Avidius Cassius drove Volagases from Syria in a bloody battle at Europus, and, entering north Mesopotamia, took Edessa and Nisibus, though not without serious opposition. At length, deserted by his allies (*i.e.*, by the local kings, who were becoming more and more independent), Volagases abandoned Mesopotamia, and Cassius entered Babylonia, where, on a frivolous pretext, he gave up to rapine and fire the friendly city of Seleucia, still the first city of the East, with 400,000 inhabitants. The destruction of Seleucia was a hideous crime, a mortal wound dealt to Eastern Hellenism by its natural protectors; that Cassius next, advancing to Ctesiphon, razed the palace of Volagases to the ground may, on the other hand, be defended as a symbolical act calculated more than anything else to impair the prestige of the Parthian with his Oriental subjects. Cassius returned to Syria in 165, with his victorious army much weakened through the failure of the commissariat and by the plague, which, breaking out in Parthia immediately after the fall of Seleucia, spread over the whole known world. In the same year Martius Verus won hardly less considerable successes in Media Atropatene, then apparently a separate kingdom. The peace which followed in 166 gave Mesopotamia to Rome. This was the greatest of all wars between Rome and Parthia, alike in the extent of the lands involved and in the energy of attack shown by the Parthians. The Romans used their victory with moderation, but Parthia, after this last effort, continued steadily to sink.

The Romans at the same time made an effort to compete with Parthia for the Chinese trade (especially in silk), which the latter had jealously kept in their own hands, and in 166 an envoy of An-thun (M. Antoninus) reached the court of the emperor Huan-ti, *via* the sea and Tong-king. But the effort to establish a direct trade with China was unavailing, and the trade still flowed in its old channels when a second Roman agent reached China in 226, a little before the fall of the Parthian empire. The Chinese tell us that with India also the Parthians drove a considerable trade.

Volagases III. died in 191, having reigned forty-two years without civil war, and was succeeded by Volagases IV. During the civil troubles of Rome which preceded the establishment of the military empire this prince maintained friendly relations with Pescennius Niger; and his vassal Barsenius of Atra was permitted to supply a force of bowmen, who took part in the fighting against Septimius Severus at Nicæa (194). When Niger's cause declined, however, Volagases allowed his clients of Adiabene to join with Orrhoene, now in revolt against the Roman power. The strongholds of Mesopotamia were taken, and their garrisons put to the sword; Nisibus itself was besieged. In truth, the Parthian could no longer pretend to control the policy of the princes on his frontier, who felt themselves their own masters since they had borne the chief brunt of the last two Roman wars. But in summer, 195, Severus appeared in Mesopotamia, received the submission of Abgar VIII. of Orrhoene, and from Nisibus (which, with true insight into its strategic importance, he raised to a colony and great military station) directed two successful campaigns against Adiabene (196) and the Arabs of the Singara district, incorporating the latter in the province of Mesopotamia. The

Parthians made no movement till Severus was busy with Albinus, when they ravaged Mesopotamia and besieged Laetus in Nisibis; but in 198 Severus was again on the scene of war, and they fell back without fighting, leaving the emperor free to prepare for next year a campaign on a great scale. In 199 a fleet on the Euphrates coöperated with the Roman army, and Severus, taking up an unaccomplished plan of Trajan, dredged out the old Naarmalca canal, through which his ships sailed into the Tigris, and took the Parthians wholly by surprise. Selucia and Coche were deserted by their inhabitants; Ctesiphon was taken by the end of the year with terrible slaughter, 100,000 inhabitants being led captive and the place given up to pillage, for the great king had fled powerless at the approach of the foe. Severus, whose force was reduced by famine and dysenteries, did not attempt pursuit, but drew off up the Tigris. The army was again in its quarters by April 1, 200, and for some time thereafter Severus was occupied in Armenia. But in 201 he undertook a carefully organized expedition against Atra, from whose walls the Romans had been repulsed with great loss when Severus, returning from the Tigris in the previous year, had attempted to carry it by a *coup de main*. This city, which in Trajan's time was neither great nor rich, was now a wealthy place, and the sun-temple contained vast treasures. The classical authors call Atra Arabian, but the king's name is Syriac, Barsenius, *i. e.*, Bar Sîn, son of the moon, and we may suppose that it was really an Aramæan principality, which, like Palmyra, had its strength from the surrounding Arab tribes that it could call into the field. Severus lay before Atra for twenty days, but the enemy's cavalry cut off his foraging parties, the admirable archers galled the Roman troops, a great part of the siege train was burned with naphtha; and, when, in addition, two assaults had been repulsed with tremendous loss on two successive days, the emperor was compelled to raise the siege—a severe blow to Roman prestige in the East, and one that greatly raised the name of Atra and its prince, but did not help the decaying power of Parthia in the least.

In 209 Volagases IV. was succeeded by his son Volagases V., under whom, in 212, the fatal troubles in Persis began, while in 213 his brother Artabanus rose as rival claimant of the kingship; and the civil war lasted for many years. A fresh danger arose when Tiridates, a brother of Volagases IV., who had long been a refugee with the Romans, and had accompanied Severus' campaign of 199, escaped, in company with a Cilician adventurer, the Cynic Antiochus, to the court of his nephew Volagases; for the emperor Antoninus (Caracalla) demanded their surrender, and obtained it only by a declaration of war (215). About the same time Artabanus gained the upper hand, and in 216 he held Ctesiphon and its districts; but Volagases still held out in the Greek cities of Babylonia, as his tetradrachms prove (till 222). Artabanus' strength lay in the north; the Arab histories of the Sásánians make him king of the Median region, and agreeably with this he coins only drachmæ. Presently Artabanus had a war with Rome on his hands; the pretext was that he had refused his daughter to Antoninus, but the emperor was mindful of his father's dying advice to enrich the soldiers and despise all other classes, and saw a prospect of rich booty. In 216 the Romans penetrated to Arbela by way of Carduene and Calachene, and violated the graves of the kings of Adiabene, which they falsely took for those of the Arsacids. Thus far the Parthians, who had been taken by surprise in full peace, had offered little or no resistance, but Antoninus was murdered (April 8, 217), while he was preparing for a new foray, and his successor, Macrinus, at once found that Artabanus was now armed,

and was not the man to let the insult to his territory pass with impunity. An overwhelming Parthian force fell on Mesopotamia and refused to be appeased by the restoration of the captives of the previous year; Macrinus was beaten in two engagements and compelled to retire to Syria, abandoning the Mesopotamian plain; and in the winter of 217-18 he was glad to purchase peace for an indemnity of 50,000,000 denarii (\$8,615,287). In or about 222 Artabanus must also have displaced his brother in Babylonia, for he was a patron of Rab Abba, who became head of the Jewish school of Sura in 219.

Persis, which dealt the last blow to the Arsacids, had through the whole Parthian period held an isolated position, and is so seldom mentioned that our knowledge of its history and native princes is almost wholly due to recently found coins.

#### SÁSÁNIAN EMPIRE.

Of the minor kings who ruled in Persis, in the Arsacid period, in real or nominal allegiance to the Parthian "king of kings" we know some names from coins or ancient writers, but we cannot tell whether they were all of one dynasty. In the beginning of the third century the kings, who then belonged to a dynasty of which the name probably was Bázrangík, had lost much of their power; lesser potentates ruled, in various parts of the land, which, by being all mountainous, falls naturally into ill-connected sections. One of these local princes was Pápak, or, in the more modern pronunciation, Pábak, son or descendant of Sásán, a native of the village of Khír, on the southern margin of the great salt lake east of Shíráz. Pábak overthrew Gózihr, the last prince of the Bázrangík, and became master of the district of Istakhr (Persepolis), and the coins and inscriptions of his son give him the title of king. His legitimate heir was his son, Shápúr, for whom Pábak is said to have asked recognition from the Arsacids; but on Pábak's death a second son, Ardashír, refused to acknowledge his brother, and was in arms against him when Shápúr died suddenly, and hardly by mere accident. That Ardashír's claims were opposed by his brothers and that he put them to death are not to be doubted, as we have these facts from a tradition of strictly legitimist tendency.

Tradition names various local princes conquered by Ardashír for himself or for his father, and perhaps Pábak before his death was already lord of all Persis. Slowly, and not without toil, he rose from king of Persis to be king of the kings of Irán.

The Romans saw with concern the rise of a prince who already directed his aims against their Asiatic possessions, and seems to have had some success in this quarter, till, in 233, he was smitten by Alexander Severus in a great battle. Henceforth, though peace was often made between the two powers, they remained constant rivals—and rivals on equal terms, for, though under able rulers and when the inner condition of the empire was not greatly disturbed, the Europeans of Rome or Byzantium were still too strong for the Asiatics, the tables were not seldom turned, and Rome sustained many a shameful defeat. This struggle fills the chief place in the political history of the Sásánians; and the inner development of the empire, its martial and political institutions, its art and industry, were also most powerfully influenced by the superior civilization of the West.

The nominal capital was always at Istakhr, where, for example, the holy "pyreum" of the royal house stood, and where the heads of conquered foreign kings were hung up. But the real metropolis was the Arsacid capital of Ctesiphon, with Ardashír's new foundation of

Veh-Ardashír, just across the Tigris, on the site of the old Seleucia. The rich alluvial land that surrounded these twin cities was no part of Irán proper, and its inhabitants were mainly Semites; but old example, and probably its vicinity to Roman soil, marked it out for the true seat of government.

The extent of the empire at the time of Ardashír's death is uncertain, for the national tradition ascribes to him some conquests that were really made by his successors, and others which the Sásánians never made at all.

The wars with Rome continued with varying success on both sides down to 546 A.D., when, during the reign of Khosrau, the Romans paid a large sum for a five years' truce, and another five years' truce followed in 553, though Lázistán was excluded from both truces until 556, when the Romans had gained successes there; but during all this time the Persian and Roman Arabs never laid down their arms. At length, about Christmas, 562, a fifty years' peace was concluded, the Romans again promising a considerable yearly subsidy, and the Persians withdrawing their claims on Lázistán, though the possession of the neighboring Suania was left an open question. The treaty also provided for religious freedom to the Persian Christians, while all proselytizing among Zoroastrians was strictly forbidden.

During the truces (546-562) great changes had taken place in the East, where a powerful empire had been formed in the northern steppes by the Turks, whose name then, for the first time, became known in the West. The khákán of the Turks, whom the Greeks call Silzibulos and the Arabs (after the Persians) name Sinjibú, took from the Hephthalites the right bank of the Oxus, while Kosrau (seemingly in alliance with the khákán, whose daughter he wedded) occupied the left bank (c. 560). Thus Bactria, from which the Sásánians had suffered so much, was at length embodied in their empire, and Péróz was fully avenged. But the friendship of Turks and Persians was soon changed to that hostility which has long made the rulers of Turkestán and the deserts appear the natural enemies of the lords of Khorásán.

From the reign of Khosrau (531) down to the reign of Yazdegerd (633), the empire was continually at war with first one then another of its foes — principally the Romans, and in minor affairs with the Turks. The state had also been continually torn with internecine war. On the accession of this prince there seemed reason to predict a change for the better.

Fond hopes could now be entertained that the wounds of the monarchy might be healed under a legitimate prince unstained by descent from the parricide Shéróe, consecrated in the cradle of the monarchy, and upheld by the strong hand of Rustam. Some temporary recovery seems actually to have taken place; but a new foe more dangerous than Julian or Heraclius was already knocking at the gates of the monarchy. That Yemen and some tracts in north Arabia had already been lost by Persia to the Moslems had scarcely been observed at Ctesiphon amid so many greater disasters. But now the Moslems already hovered on the frontier. Mothanná, one of the boldest leaders of those Bedouins who since Dhú Kár had made frequent forays on Persian soil, accepted Islám, and had its strength at his back. These attacks became bolder and bolder. Presently Khálid, in all the prestige of his victory over the revolt of the Arabs against Islám (see MOHAMMEDANISM), appeared with a small force on the lower Euphrates to lead these Bedouins. Persian troops and their Arab allies were repeatedly beaten in small engagements, and soon a number of frontier posts were in the hands of the Moslems. The inhabitants of the western bank of the lower Euphrates, who were all

Christians and had little attachment to Persia, submitted themselves and promised to supply the victors with intelligence. Soon the Arabs ventured to cross the river and plunder the villages west of the Tigris. In the early summer of 634, however, Khálid was called away to Syria; his successor, Abú 'Obaid of Táif, though strengthened by reënforcements, was utterly defeated and slain on his first meeting with a regular Persian host in the hard-fought "battle of the bridge" at the Euphrates, and Mothanná had great difficulty in saving the remains of the army (November 26, 634). Not without hesitation the caliph 'Omar resolved to send a greater force to 'Irák, calling on his Arabs to win for themselves the treasures of the Khosraus and paradise; and now for the first time a considerable Persian army was defeated at Bowaib (635 or 636), with the loss of its general, a prince of the house of Mihrán. In Sa'd ibn Abí Wakkás the Moslems had now an energetic and cautious leader, and the Persian court began to see its danger, especially when the news arrived of the battle of Yarmúk, by which Syria was lost to Heraclius. Rustam in person placed himself at the head of a great army, over which, in sign of the gravity of the enterprise, was borne the venerable sacred banner of the empire (*dirafshi káiviyán*). Sa'd fell back before the Persian advance and posted himself at Kádisiya on the edge of the desert south or southwest of Híra, where the armies lay facing each other for months. The Arab force must have been inferior in strength, for no great army could have long held such a barren post nourished only by forays and what the caliph could send from Medina. At length, toward the close of the year 636, or in 637, battle was joined and raged for several days, Sa'd giving orders to his men in spite of a sickness under which he labored. The Persians were better armed, but the Arabs fought with desperate energy. The elephants, which formed part of every regular Persian army, greatly terrified them at first, but ultimately these huge beasts, getting out of command, only aided the discomfiture of the Persians. Of the mass of a Persian host no great bravery was to be expected; yet it was only after a hard fight that the victory was decided, Rustam slain, and the sacred banner taken.

The battle of Kádisiya virtually decided the fate of the Tigris valley; but there was still some fighting on the plains of Babylonia, at Birs (Borsippa), and Seleucia was not taken without a lengthy siege. Then the Arabs crossed the Tigris and fell on Ctesiphon, Yazdegerd fleeing before them to Holwán on the Medo-Babylonian frontier. At Jalúlá on the road to Holwán the Arabs gained a fresh victory over Rustam's brother, Khorrezádh, and Yazdegerd continued his flight. Meantime another body of Arabs had occupied Lower 'Irák and entered Susiana. A strong and wise leader might still perhaps have saved Irán proper, and 'Omar, as energetic as cautious, was in fact slow to allow his armies to assail the highlands. It was not till some time between 640 and 642 that the "victory of victories," as the Arabs rightly call it, was gained at Nehávend (a little south of the old high road from Babylon to Ecbatana), and the last great army of the Persians was shattered by No'mán, who fell on the field, and the Meccan Hodhaifa. Even now many individual provinces and cities did not yield without stubborn resistance, and in many places rebellion after rebellion had to be crushed, especially in the region around Istakhr, the cradle and sacred hearth of the fallen monarchy. Everywhere the great local barons and even the lesser nobility dealt with the Arabs as independent chiefs, and in many cases came to peaceful terms with them.

Yazdegerd fled from one to another of his lieutenants without venturing himself to strike a blow for his crown and his life. He still retained the forms of sovereignty, and coins were still struck in his name; but one host after another dismissed him as a burdensome guest, and at length he was miserably murdered in the remote district of Merv, not, it would appear, without the connivance of Máhóe, governor of that province (651 or 652).

The region at present laid down on the maps as Persia is bounded on the east by Russia, Afghanistan and Baluchistan; south by the Arabian sea and Persian Gulf; west by Turkey; north by Russia and the Caspian sea. The boundaries of the country are vague and have long been a subject of dispute, both with Russia and with Turkey. Its superficial area is estimated at 610,000 square miles.

#### GEOGRAPHY AND STATISTICS.

Persia of the present day is not only, in the matter of geographical definition, far from the vast empire of Sacred Writ and remote history, but it is not even the less extensive, though very expansive, dominion of the Safawí kings and Nádir Sháh. It may be said, however, to comprise now quite as much settled and consolidated territory as at any period of its political existence of which we can speak with the authority of intimate acquaintance. If it has less extent of land than before its latest disastrous war with Russia, there is certainly within its recognized limits less rebellion and more allegiance. And, if the true interests of Persia, considered as a living power, were only understood by her kings and ministers, she might reasonably seek to attain a state of security which would amply compensate for the loss of precarious and profitless expanse.

There are no sufficient statistics available accurately to estimate the rainfall in Persia, but Sir Oliver St. John, himself a resident of some years in the country, estimated that in no part of it except the watersheds of the Caspian and Persian Gulf (north of 28° latitude) and their immediate reverse slopes, with perhaps the Úrmíya basin, is there an average of ten inches, taking mountain and hill together.

One remarkable feature in the plains of Persia which naturally engaged St. John's attention was the salt-swamp called "kavír." He applied the term to those bogs of slimy mud found in the lowest depressions of the alluvial soil, where the supply of water, though constant, was insufficient to form a lake. In winter they are covered with brine, and in summer with a thick crust of salt. The principal kavír is that in Khurásan, and marked in the maps as the Great Salt Desert.

Other kavírs he finds in the Sarjan or Sayidábád plain west of Karman and in the neighboring valley of Kútrú. Among ordinary kavírs, which are "innumerable," he considers the largest to be on the south of Kháf, and the best known that north of Kúm.

The climate of Persia varies much according to locality. In the Caspian provinces, where the rains fall frequently, it is hot, humid, and unhealthy for the greater part of the year. In the table-lands it is intensely cold in winter, and, though it is hot in summer, its dry, clear heat is temperate in comparison with that of Sind and the Punjab. The spring and autumn are the best seasons. In the south and southwest, toward the Persian Gulf and in Baluchistan, the heat is intense throughout the summer and often in the spring and autumn. The three regions of Nearchus and the old travelers—illustrated by parching heat, sand, and barrenness in the south, a temperate climate, pastures, and cultivation in the center, and severe cold with bare or snow-clad mountains in the north—may still be accepted as con-

veying a fairly accurate description of the tracts lying generally between Bushahr and Tehran; but of course there are seasons and seasons, and it may be very hot as well as very cold in the north as elsewhere.

Where there is irrigation the productiveness of the soil in Persia is remarkable, but, unfortunately, two-thirds of the table-lands of the country are sterile from want of water. The desert is the rule, fertility the exception, and generally in the form of an oasis. Yet wheat, barley, and other cereals are grown in great perfection; there are the sugar-cane and rice also, especially in Mazandaran, where the soil is favorable and water procurable; opium, tobacco, and cotton, madder roots, henna, and other dyes, are as well-known exports as the woolen goods of Persia; and the first may become of importance in its bearing upon the Indian market. In Gílan, famous for its mulberry plantations, silk has been one of the most valuable of products. Yazd and Mazandaran contribute also the same material, but of late years the worm has comparatively failed to do its office, and disease has destroyed crop after crop. The peasants of Gílan recently turned their attention to the cultivation of rice, and though a marked improvement was perceptible in the silk produce, they were not disposed to revert to this branch of culture on the former large scale. Rice was found to suit the cultivators better; it gave them less trouble and provided them with an article of daily food. The production of silk, on the other hand, profited the richer landed proprietors, and subjected the cultivators to oppression.

Vines are abundant, and the Persian grapes are not only of a good flavor and kind, but the wines made from them by the Jews and Armenians have more than a mere local reputation. That of Shíráz is the most universally known and celebrated; but a description of port manufactured at Ispahan is equally palatable and less astringent. It might not, however, bear the vicissitudes of export. A light wine made at Hamadan, diluted with water, is found very drinkable by European visitors and residents. Other cities in Persia could be cited where the juice of the grape is turned to similar account.

Fruits and flowers are abundant, and are fully appreciated in Persia. Of fruits the variety is great, and the quality, though not always the best, is in some cases unrivaled. There is, perhaps, no melon in the world superior to that of Nusrabad, a village between Kashan and Kúm. It were easier to name the few English fruits—such as the gooseberry, strawberry, raspberry, currant, and medlar—that are seldom, if at all, seen, than the many that are commonly enjoyed by Persians. Apples and pears, filberts and walnuts, muskmelons and watermelons, grapes, peaches, plums, nectarines—all these are to be had in profusion and so cheap as to be within reach of the poorest inhabitant.

Among the flowers are roses of many kinds, the marigold, chrysanthemum, hollyhock, narcissus, tulip, tuberose, convolvulus, aster, wallflower, dahlia, white lily (much valued), hyacinth, violet, larkspur, pink, and many ornaments of the European parterre. Of the roses, Lady Sheil observes that they are so profuse during the spring at Tehran that some are cultivated in fields as an object of trade to make rose-water. The double-colored orange rose at Níshápúr is exceptionally attractive and fragrant.

As with fruits and flowers, so also with vegetables for the table. If the parsnip be excepted, which is probably not found because not wanted, all those commonly used in England are to be had in Persia.

Irrespective of scientific classification and detail, it may be stated that among the tame animals of Persia

the horse, mule, and camel occupy an important position; and, jointly perhaps with oxen (used for tilling purposes), are first and foremost in usefulness to man. The Persian-Gulf Arab, though not equal to the pure Arabian, is a very serviceable animal, and has always a value in the Indian market. Among others, the Kashgais, or those wandering semi-Turkish tribes brought down from Turkestan to the neighborhood of Shíráz, have the credit of possessing good steeds. The Turkman horse of Khurásan and the Atak is a large, bony, and clumsy-looking quadruped, with marvelous power and endurance. Col. C. E. Stewart speaks of a "splendid breed of camels" in the northeastern district, of which Radkan, a small town of 4,000 inhabitants with a deputy-governor, is the capital. He also states that the Khurásan camel is celebrated for its size and strength, that it has very long hair, and bears cold and exposure far better than the ordinary Arabian or Persian camel, and that while the ordinary Persian camel only carries a load of some 320 pounds and an Indian camel one of some 400 pounds, the Khurásan camel will carry from 600 to 700 pounds. The best animals, he notes, are a cross between the Bactrian or two-humped and the Arabian one-humped camel. Sheep, goats, dogs, and cats are good of their kind; but not all the last are the beautiful creatures which, bearing the name of the country, have arrived at such distinction in Europe. Nor are these to be obtained, as supposed, at Angora or in Asia Minor. Lake Van or Ispahan is a more likely habitat. The cat at the first place, called by the Turks "Van kedisi," has a certain local reputation.

Among the wild animals are the lion, tiger, leopard, lynx, wolf, jackal, fox, hare, wild ass, wild sheep, wild cat, mountain-goat, gazelle, and deer. The tiger is peculiar to the Caspian provinces.

Poultry is good and plentiful, and the game birds, if not of many varieties, have admirable representatives in the "durráj" (black partridge), and the three kinds of partridge called respectively the "kabk," the "kabk darah," and "tihú." The "hubára," a kind of bustard, is well known to the sportsmen of northern India.

The comparative failure of silk has given an impetus to the cultivation of opium, the greater part of which, when prepared for the market, is shipped to China. Carpets have found new favor in Europe, and the value of those exported is estimated at ten times the amount of former days.

According to the latest information obtained, Persia is found to be portioned out into four large divisions and six smaller governments, of which governors-general or governors are appointed by the king. The four divisions are: (1) Adarbajjan (Azerbaijan) in the west; (2) the North Central Districts; (3) Khurásan in the east, including Sistan; (4) Southern Persia, or from the Shattu'l-'Arab to the Mashkid. The minor governments are: (5) Astrábád, (6) Mazandaran, (7) Gilan, (8) Khansah with Zanjan, (9) Kazvín, (10) Gerrus.

Persia is peopled by men of various races. A very great proportion of the population is composed of wandering tribes, that is, of a large number of families who pass a portion of the year on the hills. It is in this sense only that they can be considered wanderers. They invariably occupy the same pasture-grounds one year after another. Their chiefs are possessed of great authority over the tribesmen, and all dealings between the Government and the tribes are carried on through heads of these divisions. Through the chief the taxes, whether in money or in kind, are paid, and through him the regiments which his tribe may furnish are recruited. The office of chief is hereditary. The tents in which the tribesmen dwell are for the most part com-

posed of a light framework of the shape of a beehive. This is covered with a coating of reeds, and above it is placed a thick black felt. It has but one door, and no window or chimney. This is the Turkman tent, which is used by the Shahsavand and other tribes, but the Íliyats in Central Persia make use of tents of another construction, with flat or slightly sloping roofs.

The inhabitants of Persia may be divided into two classes—those who inhabit the towns and villages, and those who dwell exclusively in tents. The former class remain stationary during the greater part of the year, the richer orders only leaving the towns for two months during the summer heats, when it is possible to obtain cool air in the hills or upper grounds close by. The tribes who dwell in tents move from place to place with the varying seasons of the year. In the springtime they drive their flocks and herds to their accustomed pasture-grounds, and if they have a right to the pasture of mountains which are inaccessible in spring, they move up to their summer quarters as soon as the snow disappears. Winter finds them on the plains, prepared, in their black tents, to brave its utmost rigor. These Íliyát tribes serve each a separate chief. For the Íliyáts of Fars there is an hereditary chief called the Ílkhání, to whom they all owe allegiance; from whom they receive the laws that rule their conduct; and to whom they pay the revenue imposed upon them. They contribute a certain number of soldiers to the Shah's army. Very little is known as to the numbers and the peculiarities of these nomads. The Íliyát tribes of Turkish descent have an Ílkhání appointed by the Shah. Besides these tribes there are wanderers who are less numerous, and who occupy a less prominent position—the gipsies common to so many countries.

It is difficult to form an estimate of the population of Persian towns or districts. In the first place, opinion is divided upon the approximate figure to be accepted for the kingdom at large. According to St. John, the discrepancy is between 10,000,000 and 4,000,000; and if the smaller one were made a basis there would be but a scanty number indeed for partition among the cities and principal centers. The famine of 1870 was, moreover, severe and fatal enough to cause a considerable diminution in the totals calculated prior to its occurrence. When returning through Mashhad in the spring of 1872 the British commissioner for the Sístan boundary settlement was informed that no less than 100,000 persons had been carried off within the limits of the prince-governor's rule, of whom 24,000 were from the city itself, where exclusive of passing pilgrims, reckoned by thousands, a population of 70,000 might well be supposed. In Yazd and Ispahan losses were also very great, and must have sensibly affected the figures.

The official estimate for 1881 is recorded as follows:—inhabitants of cities, 1,963,800; wandering tribes, 1,909,800; inhabitants of villages and country, 3,780,000; total, 7,653,600. It is probable that 8,000,000 would be a fair estimate in round numbers; and this should include the comparatively new accessions of the territory in Sístan and western Baluchistan.

The population of certain cities may be recorded as follows:—Tehran, 100,000; Astrábád (city), 8,000—in the province, 26,000 (Lovett, 1881); Tabríz, 120,000; Úrumíya, 40,000; Hamadan, 30,000; Karmansháh, 25,000; Rasht, 20,000; Kazvín, 25,000; Zanjan or Zanjaánah, 20,000; Kúm, 20,000; Ispahan, 60,000; Shíráz, 30,000; Bushahr, 11,000; Yazd, 40,000; Karman, 40,000; Birjand, 12,000; Ardakan (Khurásan desert), 20,000; Bam, 6,000.

The sháh is regarded as the vicegerent of the Prophet, and, as such, claims implicit obedience so long as his commands do not go against the Koran and

the sacred law. The executive government is carried on by a ministry of which the *personnel* is subject to constant change, and the distribution of duties depends much upon the standing in royal favor of individual ministers. It may be said, as a rule, that those who fill the more important functions and do the most real work are better known by their family names than the official titles accorded them. The somewhat common prefix "mirza" is usually taken by high functionaries of state—a work which invariably denotes a member of the royal house when used as an affix.

The division of the country for administrative purposes has been mentioned above. Provinces are further subdivided into districts under "hákins," or chiefs, who collect the revenue as well as exercise a general superintendence. In villages the "katkhudá," or magistrate, administers justice.

Of the Armenians under Persian rule there are said to be 43,000, chiefly in Julfa near Ispahan, and of Nestorians and Chaldeans 23,000, chiefly in Úrumíya and Salmas. There are probably 70,000 Christians of every denomination. The number of Jews given is 19,000, and of Gabars (Guebres) or Parsís 8,000. Perhaps the Nestorians have been under-estimated; but the Parsís have greatly diminished in recent years. However tolerant the declared principles of the government toward aliens in religion, there is no doubt that much could yet be done to improve the condition of the sháh's non-Moslem subjects in respect of taxation, civil and social rights, and general treatment by local authorities. Efforts on behalf of the Nestorians have from time to time been made in late years, with the support of the British Government, and special agents have been deputed to Úrumíya to report upon supposed grievances with a view to their alleviation or removal. The temporary appointment of a Christian governor was an indication of the sháh's good wishes, but can hardly be said to have attained the desired end. It is just possible that the desire awakened in England in the second half of the nineteenth century to know more of the eastern churches may result in the exercise of a beneficial influence over the fortunes of a people who have suffered various forms of oppression for five centuries or more. (See NESTORIANS, where statistics, etc., are given.)

The value of imports in 1885 was 125,300,000 francs, that of the exports 72,200,000 francs. The leading imports are cottons, glassware, paper, iron, copper, sugar, and tea. The principal articles of export are silk, tobacco, skins, carpets, and opium.

The Persian army, according to official returns of the minister of war, numbers 105,500 men, of whom 5,000 form the artillery, 53,900 the infantry, 31,000 the cavalry, regular and irregular, and 7,200 militia. Of these troops, however, only one-third are employed in active service, the standing army of Persia consisting, on the peace footing, of a total of 30,000 men.

The receipts of the treasury are about 43,750,000 francs (\$9,000,000) per annum, of which 6,600,000 (\$1,300,000) proceed from customs. The expenditure amounts to 40,750,000 francs (\$8,000,000), of which 21,250,000 francs (\$4,250,000), are for the army, and 7,500,000 francs (\$1,500,000) for the royal household.

The character of the Persian is that of an easy-going man with a wish to make things pleasant generally. He is hospitable, obliging, and specially well disposed to the foreigner. His home virtues are many; he is very kind and indulgent to his children, and, as a son, his respect for both parents is excessive, developed in a greater degree to his father, in whose presence he will rarely sit, and whom he is in the habit of addressing and speaking of as "master." The full stream of

his love and reverence is reserved for his mother; he never leaves her to starve, and her wishes are laws to him. The mother is always the most important member of the household, and the grandmother is treated with veneration. The presence of the mothers-in-law is coveted by their sons-in-law, who look on them as the guardians of the virtue of their wives. The paternal uncle is a much nearer tie than with us; while men look on their first cousins on the father's side as their most natural wives.

Black slaves and men-nurses or "lallaks" are much respected; the "dyah" or wet nurse is looked on as a second mother and usually provided for for life. Persians are very kind to their servants; a master will often be addressed by his servant as his father, and the servant will protect his master's property as he would his own. A servant is invariably spoken to as "bacha" (child). The servants expect that their master will never allow them to be wronged. The slaves in Persia have a good time; well fed, well clothed, treated as spoiled children, given the lightest work, and often given in marriage to a favorite son or taken as "segah" or concubine by the master himself, slaves have the certainty of a well-cared-for old age. They are looked on as confidential servants, are intrusted with large sums of money and the conduct of the most important affairs, and seldom abuse their trust. The greatest punishment to an untrustworthy slave is to give him his liberty and let him earn his living. They vary in color and value: the "Habshi" or Abyssinian is the most valued; the Suháli or Somáli, next in blackness, is next in price; the Bombassi, or coal-black negro of the interior, being of much less price, and usually only used as a cook. The prices of slaves in Shiráz are, a good Habshi girl of twelve to fourteen \$200, a good Somáli same age, half as much; while a Bombassi is to be got for \$70, being chosen merely for physical strength. They are never sold, save on importation, though at times they are given away. A Persian is seldom unkind to his own horse or his slave, and when overtaken by poverty he will first sell his shirt, *then* his slave.

In commercial morality, a Persian merchant will compare not unfavorably with the European generally. To the poor, Persians are unostentatiously generous; most of the rich have regular pensioners, old servants, or poor relations who live on their bounty; and though there are no workhouses, there are in ordinary times no deaths from starvation; and charity, though not organized, is general. Procrastination is the attribute of all Persians, "to-morrow" being ever the answer to any proposition, and the "to-morrow" means indefinite delay. A great dislike is shown generally to a written contract binding the parties to a fixed date; and, as a rule, on breaking it the Persian always appeals for and expects delay and indefinite days of grace.

Persians are clean in their persons, washing themselves and their garments frequently. The Persian always makes the best of his appearance; he is very neat in his dress, and is particular as to the sit of his hat and the cut of his coat. All Persians are fond of animals, and do not treat them badly when their own property.

Cruelty is not a Persian vice; torture and punishment of an unusual and painful nature being no part of their judicial system. There are no vindictive punishments, such as a solitary confinement, penal servitude for long terms of years, etc. Seldom, indeed, is a man imprisoned more than twelve months, the rule being that there is a general jail delivery at the New Year. Royal clemency is frequently shown, often, perhaps, with want of judgment.

PERSIGNY, JEAN GILBERT VICTOR FIALIN, DUC DE, the most devoted servant of Napoleon III., who

with the duc de Morny and Marshal Saint-Arnaud formed the triumvirate which established the second empire, was born at Saint-Germain Lespinasse (Loire), January 11, 1808. He had two qualities which gave him ascendancy over the young prince, fidelity and audacity. He it was who planned the attempt on Strasburg in 1836, and that on Boulogne in 1840. For his share in the last escapade he was sentenced to imprisonment in a fortress for twenty years, which was commuted into detention at Versailles. When the Revolution of 1848 broke out he labored indefatigably for the Bonapartist cause, securing the election of Louis Napoleon to the Constituent Assembly in June and in September, 1848, and to the presidency in December, 1848. His own prosperity was now secured; he was made aide-de-camp to the prince president, and elected to the Legislative Assembly in May, 1849, for the department of the Loire. He then became one of the secret plotters of the *coup d'état*, and was at first designed for the office of minister of the interior, but a man of more capacity, De Morny, was chosen for this post, and Persigny only accompanied Colonel Espinasse to take possession of the hall of the assembly. On securing the throne Napoleon III. hastened to reward his most faithful personal adherent. Persigny became minister of the interior in the place of De Morny in January, 1852, and a senator in December, 1852. He resigned office in 1854 and became ambassador in London, with but one short interval (1858-59), from May, 1855, to November, 1860, when he again became minister of the interior. His second tenure of office lasted till June, 1863, when he resigned. As a minister he showed very little capacity, and when the empire fell in 1870 escaped to England. He did not long survive the overthrow of the idea which he had so strenuously supported, and died at Nice, January 11, 1872. Fialin de Persigny was certainly only an adventurer, but he had one merit, which the other founders of the second empire did not possess, fidelity to his master.

PERSIMMON, the name given to the fruits of *Diospyros virginiana* in the United States. The tree which bears them belongs to the order *Ebenaceæ*. The astringency renders the green fruit unpalatable, but, after it has been subjected to the action of frost, or has become partially rotted or "bletted" like a medlar, its flavor is improved. In some of the southern States the fruit is kneaded with bran, made into cakes, and baked. From the cakes a fermented liquor is made with the aid of yeast. The tree is cultivated in England, but rarely, if ever, ripens its fruit.

PERSIUS (A. PERSIUS FLACCUS) stands third in order of time of those recognized by the Romans as their four greatest satirists. Of these four representatives of the most distinctly national branch of Roman literature—Lucilius, Horace, Persius, and Juvenal—Persius is the least important.

Well born and well connected, and the inheritor of a good estate, Persius lived the uneventful life of a student, and was chiefly remarkable for his affection for his friends, his teachers, and his family. He was a native of Etruria, a district which contributed less than any other in Italy to the literary distinction of Rome. And it is noticeable that, while Persius has all the characteristic moral fervor of the more serious Roman writers, he shows less, compared with those who have an important place in the national literature, of that sensuous vivacity and susceptibility to beauty in art and nature with which the purely Italian race was preeminently endowed. He was born at Volaterræ in the year 34 A.D., and died in 62 A.D.

PERSONAL ESTATE. Strictly speaking, the term ESTATE (*q.v.*) is confined in English law to the

extent of interest which can exist in real property. But "personal estate" is a term often conveniently, if not accurately, applied to all property that is not real property. The division of property into real and personal represents in a great measure the division into immovable and movable incidentally recognized in Roman law and generally adopted since. "Things personal," according to Blackstone, "are goods, money, and all other movables which may attend the owner's person wherever he thinks proper to go." This identification of things personal with movables, though logical in theory, does not, as will be seen, perfectly express the English law, owing to the somewhat anomalous position of chattels real.

Personal estate is divided in English law into *chattels real* and *chattels personal*; the latter are again divided into *choses in possession* and *choses in action*. Chattels real are personal interests in real estate, which, though they are annexed to land, still descend in the same manner as personal estate. Examples are a term of years, the next presentation to a benefice, an estate *pur autre vie*, and money due upon a mortgage. Under the head of chattels personal fall all kinds of property other than real estate and chattels real. In cases of bequest to a charity the terms pure and impure or mixed personalty are often used. The latter class is almost conterminous with chattels real. A *chose in action* denotes the right of recovery by legal proceedings of that which, when recovered, becomes a *chose in possession*.

Interest in personal property may be either absolute or qualified. The latter case is illustrated by animals *feræ naturæ*, in which property is only coëxtensive with detention. Personal estate may be acquired by occupancy (including the *accessio, commixtio, and confusio* of Roman law), by invention, as patent and copyright, or by transfer, either by the act of the law (as in bankruptcy, judgment, and intestacy), or by the act of the party (as in gift, contract, and will).

There are several cases in which, by statute or otherwise, property is taken out of the class of real or personal to which it seems naturally to belong. By the operation of the equitable doctrine of conversion money directed to be employed in the purchase of land, or land directed to be turned into money, is in general regarded as that species of property into which it is directed to be converted.

The law in the United States agrees in most respects with that of England. Heirlooms are unknown, one reason being, no doubt, that the importance of title-deeds is much less than it is in England, owing to the operation of the Registration Acts. Long terms in some States have annexed to them the properties of freehold estates. Thus in Massachusetts, if the original term be a hundred or more years, it is deemed a fee as long as fifty years remain unexpired. In the same State estates *pur autre vie* descend like real property. In New York and New Jersey an estate *pur autre vie* is deemed a freehold only during the life of the grantee; after his death it becomes a chattel real. In other States the heir has a *scintilla* of interest as special occupant. In some States railway rolling-stock is considered as purely personal, in others it has been held to be a fixture, and so to partake of the nature of real property. Shares in some of the early American corporations were, like New River shares in England, made real estate by statute, as in the case of the Cape Sable Company in Maryland. In Louisiana animals employed in husbandry are, and slaves were, regarded as immovables. Pews in churches are generally real property, but in some States they are made personal property by statute, *e.g.*, in Massachusetts. The assignment of *choses in action* is generally permitted,

and is in most States regulated by statute. The circuit court has no jurisdiction in the case of an assigned *chose in action* unless a suit might have been prosecuted in that court if no assignment had been made.

PERSPECTIVE. See PROJECTION.

PERTH, an inland county of Scotland, is situated almost in the center of the country. The larger part of its border-line is formed of natural boundaries, the Grampians separating it on the west and north from Argyll, Inverness, and Aberdeen, while the Ochils and the Firth of Tay in the southeast divide it from Kinross, Clackmannan, and Fife. In the south the river Forth forms a large portion of the boundary with Stirling, but the boundary with Forfar in the northeast is almost at no point defined either by rivers or by mountains. The county is of an irregular circular form, the diameter being about seventy miles. A small portion in the southeast is separated from the main portion at the junction of Clackmannan and Fife, and another small portion is surrounded by Stirlingshire. Perthshire is the fourth largest county in Scotland, the total area being 1,617,808 acres, or 2,528 square miles. The lochs and rivers abound in salmon and varieties of trout; and scarcely any of the streams have been perceptibly injured by the pollution of manufactures. About four-fifths of the surface of the county, chiefly in the west and northwest, is occupied by the Grampians, or encroached on by their ridges or by isolated summits. The Ochils, occupying a considerable area in the southeast, attain in many cases a height of over 2,000 feet, and the Sidlaws, practically a continuation of the Ochils running into Forfarshire, reach a height of about 1,500 feet. The lowland districts consist chiefly of the straths and river valleys, as Strath-tay; Strathmore, extending into Forfarshire; Strathearn, stretching across the county from west to east, and bounded on the south by the Ochils, the district of Menteith between the Teith and the Forth; and the Carse of Gowrie between the Sidlaws and the Firth of Tay.

The climate and soil of Perthshire present greater varieties than are known in any other county of Scotland. In the higher western regions it is very moist; and long stretches of exposed uplands alternate with finely-sheltered valleys. The arable land is chiefly in the drier eastern districts. For the most part the soil is sharp and fertile. The county, agriculturally, may be classed in four divisions:—deer-forests, chiefly the wilder mountain districts; grazing and pasture lands on the hills, embracing about four-fifths of the total area; light soils in the lower undulating districts, including the north portion of Menteith and the upper portion of the principal river-valleys, specially suited for oats, barley, turnips, and potatoes; clay and carse land, chiefly in the Carse of Gowrie, which extends to about 100,000 acres, in the Carse of Stirling north of the Forth, and in the lower part of Strathearn below and above Bridge of Earn. A considerable area is occupied by orchards, the light quick soil on Tayside and in the upper districts of Menteith being admirably adapted for apples.

The manufacture of coarser linen fabrics is largely carried on in the towns and villages, and there are a considerable number of flour mills.

Perthshire embraces eighty-one parishes in its limits and contains three ancient cities—Perth, formerly the capital of Scotland, and Dunkeld and Dunblane, formerly the seats of bishoprics, as was also Abernethy. The population of the county in 1831 was 142,166, which by 1851 had diminished to 138,660, and by 1871 to 127,768; but in 1881 it had increased to 129,007, of whom 61,552 were males and 67,455 females.

PERTH, an ancient city, a royal and parliamentary

burgh, and the chief town of the above county, is beautifully situated at the foot of Kinnoul Hill, chiefly on the west bank of the Tay, about forty miles north of Edinburgh and about twenty west of Dundee.

PERTH, a city of Australia, capital of the colony of Western Australia, is picturesquely situated on the Swan river, 12 miles above Freemantle and 1,700 west-northwest of Melbourne. Perth was founded in 1829, received a municipal constitution in 1856, and was created a city in 1880. The population of the city, including the military, in 1871 was 5,007, and in 1881 it was 5,044.

PERTH AMBOY, a city of Middlesex county, N. J., also a port of entry, is located on Raritan River where that stream empties into Raritan Bay, at the south end of Staten Island Sound, opposite Tottenville, N. Y. It is connected with the latter point by ferry, and is twenty-two miles from New York city. The city contains eight churches, two banks, three hotels, two newspaper offices, two public schoolhouses, a young ladies' seminary, custom-house, postoffice and telegraph office. It also has a cork factory, emery-mills, terracotta works, foundry and machine-shop, cigar manufactory, electric-light works, oil refinery, chemical works, and manufactures of fire and glazed brick, and drain-tiles. It is the terminus of a branch road connecting the city with Rahway, and is a prominent station on the New York and Long Branch Road. The population, in 1890, was 9,512.

PERTHES, FRIEDRICH CHRISTOPH, German publisher, was born at Rudolstadt on April 21, 1772. He was an ardent patriot, and during the period of Napoleon's supremacy he distinguished himself by his steady resistance to French pretensions. His zeal for the national cause led him to issue (in 1810-11) *Das Deutsche Museum*, to which many of the foremost publicists in Germany contributed. Perthes died at Gotha on May 18, 1843.

PERTINAX, HELVIUS, Roman emperor, was the son of a charcoal-burner, and was born in 126 A.D., in Liguria, or at Villa Martis, among the Apennines. From being a teacher of grammar he rose through many important offices, both civil and military, to the consulate, which he held twice. Chosen on December 31, 192, to succeed the murdered Commodus, he was himself assassinated in a mutiny of the soldiers after a reign of eighty-six days.

PERTURBATIONS, in Physical Astronomy, are the disturbances produced in the simple elliptic motion of one heavenly body about another, by the action of a third body, or by the non-sphericity of the principal body. Thus, for instance, were there no bodies in space except the earth and moon, the moon would describe accurately an ellipse about the earth's center as focus, and its radius-vector would pass over equal areas in equal times; but only if both bodies be homogeneous and truly spherical, or have their constituent matter otherwise so arranged that they may attract each other as if each were collected at some definite point of its mass. The oblateness of the earth's figure, therefore, produces perturbations in what would otherwise be the fixed elliptic orbit of the moon.

PERTZ, GEORG HEINRICH, editor of the *Monumenta Germaniæ Historica*, was born at Hanover on March 28, 1795, and died at Munich, October 7, 1876.

PERU has, in different periods, included areas of territory of varying extent. The empire of the Yncas and the Spanish viceroyalty were not conterminous with the modern republic nor with each other. The republic of Peru is situated between the equator and the Tropic of Capricorn, yet, owing to the differences of elevation,

it includes regions with every variety of climate. It lies between the parallels of  $3^{\circ} 21'$  S. and  $19^{\circ} 10'$  S. and between  $68^{\circ}$  and  $81^{\circ} 20' 45''$  W. longitude, and has an area of about 480,000 square miles. The length along the Pacific coast is 1,240 miles, while the width ranges from 300 to 400 miles.

The republic is bounded on the west by the Pacific Ocean, on the east by Brazil and Bolivia, on the north by Ecuador, and on the south by Chili.

Peru is divided longitudinally into three well-defined regions, the coast, the sierra, and the montaña. The coast, extending from the base of the Maritime Cordillera to the Pacific Ocean, consists of a sandy desert crossed at intervals by rivers, along the banks of which there are fertile valleys. The sierra is the region of the Andes, and is about 250 miles in width. It contains stupendous chains of mountains, elevated plains and table-lands, warm and fertile valleys, and ravines. The montaña is the region of tropical forests within the valley of the Amazon, and skirts the eastern slopes of the Andes.

The coast has been upraised from the ocean at no very distant geological epoch, and is still nearly as destitute of vegetation as the African Sahara. It is, however, watered by fifty streams which cross the desert at intervals. Half of these have their origin in the summits of the Andes, and run with a permanent supply of water into the ocean. The others, rising in the outer range, which does not reach the snow-line and receives less moisture, carry a volume of water to the sea during the rainy season, but for the rest of the year are nearly dry. The absence of the rain here is caused by the action of the lofty uplands of the Andes on the trade-wind. The southeast trade-wind blows obliquely across the Atlantic Ocean until it reaches Brazil. By this time it is heavily laden with vapor, which it continues to bear along across the continent, depositing it and supplying the sources of the Amazons and La Plata. Finally, the trade-wind arrives at the snow-capped Andes, and here the last particle of moisture is wrung from it that the very low temperature can extract. Coming to the summit of that range, it rushes down as a cool and dry wind on the Pacific slopes beyond. Meeting with no evaporating surface, and with no temperature colder than that to which it is subjected on the mountain-tops, this wind reaches the ocean before it becomes charged with fresh moisture. The constantly prevailing wind on the Peruvian coast is from the south. From November to April there are usually constant dryness, a clear sky, and considerable, though by no means oppressive, heat. From June to September the sky is obscured for weeks together by fog, which is often accompanied by drizzling rain called "garua."

The deserts between the river valleys vary in extent, the largest being upward of seventy miles across. On their western margin steep cliffs generally rise from the sea, above which is the "tablazo" or plateau, in some places slightly undulating, in others with ridges of considerable height rising out of it; the whole apparently quite bare of vegetation. The surface is generally hard, but in many places there are great accumulations of drifting sea-sand. The sand usually forms isolated hillocks, called "medanos," of a half-moon shape, having their convex sides toward the trade-wind. They are from ten to twenty feet high, with an acute crest, the inner side perpendicular, the outer with a steep slope. Sometimes, especially at early dawn, there is a musical noise in the desert, like the sound of distant drums, which is caused by the eddying of grains of sand in the heated atmosphere, on the crests of the "medanos." Apparently the deserts are destitute of all vegetation; yet three kinds of herbs exist, which bury them-

selves deep in the earth, and survive long periods of drought. One is an amaranthaceous plant, whose stems ramify through the sand-hills; the other two are a *Martynia* and an *Aniseia*, which maintain a subterranean existence during many years, and only produce leafy stems in those rare seasons when sufficient moisture penetrates to the roots.

The valleys form a marvelous contrast to the surrounding desert. A great mass of pale-green foliage is usually composed of the "algarrobo" trees, while the course of the river is marked by lines or groups of palms, by fine old willows (*Salix Humboldtiana*), fruit-gardens, and fields of cotton, maize, sugar, and lucerne. In some valleys there are expanses of sugar-cane, in others cotton, while in others vineyards and olive-yards predominate. The woods of "algarrobo" are used for pasture, cattle and horses greedily enjoying the pendulous yellow pods.

The coast of Peru has few protected anchorages, and the headlands are generally abrupt and lofty. These and the few islands are frequented by myriads of sea-birds, whence come the guano deposits, the retention of ammonia and other fertilizing properties being due to the absence of rain. The islets off the coast are all barren and rocky.

The more common sea-birds, which haunt the islets and headlands in countless myriads, are the *Sula variegata* or guano-bird, a large gull called the *Larus modestus*, the *Pelecanus thajus*, and the *Sterna Ynca*, a beautiful tern with curved white feathers on each side of the head. The rarest of all the gulls is also found on the Peruvian coast, namely, the *Xema furcatum*. The immense flocks of birds as they fly along the coast, appear like clouds, and one after another is incessantly seen to plunge from a height into the sea to devour the fishes, which they find in extraordinary numbers. The guano-deposits are in layers from forty to fifty feet thick, of a grayish-brown color outside, and more and more solid from the surface downward, owing to the gradual deposit of strata and evaporation of fluid particles. Sea-lions (*Otaria fosteri*) are common on the rocky islands and promontories. These large creatures frequent particular islets for the purpose of breathing their last, the wounded or aged being helped there by their companions.

The Maritime Cordillera, overhanging the Peruvian coast, contains a long line of volcanic mountains, most of them inactive, but their presence is probably connected with the frequent and severe earthquakes, especially in the southern section of the coast. Since the year 1570 there have been seventy violently destructive earthquakes recorded on the west coast of South America, but the register is of course incomplete in its earlier part. The most terrible was that of 1745, which destroyed Callao.

The most important part of Peru is the region of the cordilleras of the Andes divided into "puna" or lofty uninhabited wilderness, and "sierra" or inhabitable mountain slopes and valleys. This great mountain system, running southeast to northwest with the line of the coast, consists of three chains or cordilleras. The two chains which run parallel, and near each other on the western side, are of identical origin, and have been separated by the action of water during many centuries. On these chains are the volcanoes and many thermal springs. The narrow space between them is for the most part, but not always, a cold and lofty region known as the "puna," containing alpine lakes—the sources of the coast rivers. The great eastern chain, rising from the basin of the Amazon and forming the inner wall of the system, is of distinct origin. These three chains are called the Maritime Cordillera, the

Central Cordillera, and the Andes. Paz Soldan and other Peruvian geographers give the name of Andes, *par excellence*, to the eastern cordillera.

The Peruvian Maritime Cordillera contains a regular chain of volcanic peaks overlooking the coast region of Tarapaca, which attain a height of 16,000 to 18,000 feet. In most parts of the Peruvian Andes the line of perpetual snow is at 16,400 feet above the sea; but on the Cordillera Nevada, above the Callejon de Huaylas, it sinks to 15,400 feet. This greater cold is obviously caused by the intervention of the Cordillera Negra, which intercepts the warmth from the coast.

The Central Cordillera is the true water-parting of the system. No river, except the Marañon, breaks through it either to the east or west, while more than twenty coast-streams rise on its slopes and force their way through the maritime chain. The Central Cordillera consists mainly of crystalline and volcanic rocks, on each side of which are aqueous, in great part Jurassic, strata thrown up almost vertically. In 14° 30' S. latitude the central chain is connected with the Eastern Andes by the transverse mountain-knot of Vilcañota, the peak of that name being 17,500 feet above the sea. The great inland basin of Lake Titicaca is thus formed. The central chain continues to run parallel with the Maritime Cordillera until, at Cerro Pasco, another transverse knot connects it with the Andes in 10° 30' S. latitude. It then continues northward, separating the basins of the Marañon and Huallaga; and at the northern frontier of Peru it is at length broken through by the Marañon flowing to the eastward.

The Eastern Andes is a magnificent range in the southern part of Peru, of Silurian formation, with talcose and clay slates, many quartz veins, and eruptions of granitic rocks. The whole range is highly auriferous, and the thickness of the strata is not less than 10,000 feet. It is nowhere disturbed by volcanic eruptions, except at the very edge of the formation near Lake Titicaca, and in this respect it differs essentially from the Maritime Cordillera.

The third division of Peru is the region of the tropical forests, at the base of the Andes, and within the basin of the Amazons. It is traversed by great navigable rivers. The sub-tropical section is important from the value of its products, and interesting from the grandeur and beauty of its scenery. Long spurs run off from the Andes, gradually decreasing in elevation, and it is sometimes a distance of sixty to eighty miles before they finally subside into the vast forest-covered plains of the Amazon basin. Numerous rivers flow through the valleys between these spurs, which are the native home of the quinine-yielding cinchona trees. In the warm valleys there are large plantations of coca (*Erythroxylon Coca*), or CUCA, the annual produce of which is stated at 15,000,000 pounds. The other products of these warm valleys are most excellent coffee, cocoa, sugar, tropical fruits of all kinds, and gold in great abundance. In the vast untrodden forests farther east there are timber-trees of many kinds, incense-trees, a great wealth of india-rubber trees of the *Hevea* genus, numerous varieties of beautiful palms, sarsaparilla, vanilla, ipecacuanha, and copaiba. The abundant and varied fauna is the same as that of the Brazilian forests.

The earliest reliable enumeration of the people of Peru was made in the year 1793, when there were 617,700 Indians, 241,225 mestizos (Indian and white), 136,311 Spaniards, 40,337 negro slaves, and 41,404 mulattoes, giving a total of 1,076,977 souls, without counting the wild Indians of the montaña. The ecclesiastics numbered 5,496, including 1,260 nuns. This tells a sad story of depopulation since the fall of

the Yncas, to which the abandoned terraces on the mountain-sides, once highly cultivated, bear silent testimony. In 1862 the population was officially estimated at 2,487,716. The latest census was taken in 1876 with much care. The result was 2,673,075 souls (males 1,352,151, females 1,320,924); of these 57 per cent. were Indians, 23 per cent. mestizos, and 20 per cent. of Spanish descent, negroes, Chinese, and foreigners; so that Peru is still the country of the Ynca people.

The principal towns on the coast, except those of Payta, Callao, and Arica, are always situated some distance from the seashore. San Miguel de Piura, founded by Pizarro in 1532, is on the river of the same name. The towns in all parts of Peru are built on the same plan where the ground will allow of it, in squares or "quadras," with the streets at right angles, and a quadrangular open space or "plaza," one side being occupied by the principal church, near the center. Piura is a town of this class. Farther south are the cities of Lambayeque, Chiclayo, and Saña. Truxillo, founded by Pizarro in 1535, is of more importance. Truxillo is the most important city north of Lima.

To the north of Lima there are five principal ports and thirteen smaller ones. Payta has a good anchorage and exports the cotton of the Chira and Piura valleys, the anchorages of Tumbes to the north and Sechura to the south being subsidiary to it. Pimentel is the port for the valleys of Lambayeque and Chiclayo, and Eten for that of Ferreñafe, the older port of San José having been abandoned as more dangerous. Pacasmayo, also a precarious anchorage, is the port which taps the rich valley of Jequetepeque. Farther south Malabrigo is the port for the valley of Chicama. Huanchaco was formerly the port for Truxillo, but Salaverry, a few miles to the south, has been substituted as affording a safer anchorage. Santiago de Chao and Guañape, in the Viru district, are lesser ports, the latter being resorted to by ships loaded with guano at the adjacent islands. Chimbote, in the bay of Ferrol, has a good anchorage, and is important as the principal outlet for the Santa valley and the department of Ancachs. Farther south are the lesser ports of Santa, Samanco, Casma, Huarmey, Supé, Huacho, Chancay, and Ancon.

LIMA, the capital (*q.v.*), according to the census of 1876, had a population of 100,046, of whom 33,020 were of European descent, 23,010 half-castes, 19,630 Indians, 15,378 foreigners, and 9,008 negroes. South of Lima are the cities of Chíncha and Yca, with the principal seaport of Pisco, whence the wines and spirits of the adjacent valleys are exported. The small ports of Cerro Azul and Tambo Mora export the sugars of the Cañete and Chíncha valleys. Farther south the exposed port of Chala, with a bad anchorage, is used for the valley of Acari and the province of Parinacochas in the mountains. Southeast of Yca are the charming agricultural towns of Palpa and Nasca. AREQUIPA (*q.v.*), the most important coast city south of Lima, was founded by Pizarro in 1536. South of Arequipa is the littoral province of Moquegua, with a pleasant town, the center of a vine-growing industry. The cities of Tacna, Arica, and Iquique are in the Chilian province of Tarapaca. The ports of Arequipa were formerly Quilca, then Islay, and now Mollendo. Ylo and Pacocha, in the same bay, are the ports of Moquegua; Saña, under the lofty headland of the same name, is a port where landing is impossible except in "balsas," and it is little used. Arica was a very important port before the Chilian invasion, as through it passed all the trade to Bolivia. Iquique and Pisagua are the chief ports of Tarapaca, the others being Junin, Mexillones, Molle, Chucumata, Patillos. The principal interior towns in the north of Peru are Caxamarca, Huaraz, Huanuco, Cerro Pasco, the center of

the great silver-mining industry, 13,200 feet above the sea, Tarma and Xauxa. Huancavelica owed its existence to the famous quicksilver mine. Ayacucho, formerly Guamanga, founded by Pizarro in 1539, is a charming abode amid lovely scenery. Between Ayacucho and Cuzco are the pleasant towns of Andahuaylas and Abancay. CUZCO (*q.v.*), the center of Peru, the old capital of the Yncas, lies at the foot of the famous hill of Sacsahuaman. South of Cuzco are many delightful places in the vale of Vilcamayu, and the towns in the Collao, the chief being Puno, on the shore of Lake Titicaca.

Universities and colleges were founded in Peru very soon after the conquest, and there was intellectual progress both among the Indians and in the families of Spanish descent. The university of San Marcos, at Lima, is the most ancient in the New World, having been created by order of Charles V. in 1551. The college of San Carlos was founded in 1770, and the school of medicine in 1792. At Cuzco the university of San Antonio Abad was founded in 1598, and the college of San Geronimo at Arequipa in 1616. Since the independence there has been very considerable intellectual and educational progress in the country. There is a university of the first rank at Lima, 5 lesser universities, 33 colleges for boys and 18 for girls, 1,578 schools for boys and 729 for girls, besides private schools.

The early inhabitants of Peru originally consisted of several distinct nations, subdivided into many tribes, which were eventually combined in the empire of the Yncas. The principal race was that of the imperial Yncas themselves, inhabiting the two central sections of the sierra, from the Knot of Cerro Pasco to that of Vilcañota, a distance of 380 miles. Six nations originally peopled this central mountain region—the Yncas in the valley of the Vilcamayu and surrounding plateaus, the Canas round the sources of the Apurimac, the Quichuas along the upper courses of the Pachachaca and the Apurimac, the Chancas, a very warlike people, from Guamanga to the Apurimac, the Huancas in the valley of the Xauxa, and the Rucanas round the summits and on the slopes of the Maritime Cordillera. These six nations were divided into "ayllus" or tribes, the most distinct of which were the still famous Morochucos and Yquichanos, brave mountaineers of the Chanca nation.

In the basin of Lake Titicaca there was another race, anciently called Colla, but now better known as Aymara. Their language survives, and, though closely allied grammatically, the vocabulary differs from that of the Yncas.

The Peruvian coast appears originally to have been inhabited by a diminutive race of fishermen called Changos, a gentle and hospitable people, never exceeding five feet in height, with flat noses. They fished in boats made of inflated sealskins, lived in sealskin huts, and slept on heaps of dried seaweed.

The Ynca or Quichua tribes of the Andes of Peru average a height of five feet to five feet six inches. They are of slender build, but with well-knit, muscular frames, and are capable of enduring great fatigue. Their complexions are of a fresh olive-color, skin very smooth and soft, beardless, hair straight and black, the nose aquiline. They are good cultivators, and excel as shepherds by reason of their patience and kindness to animals. They are naturally gentle, most affectionate to their families, with an intense love of home; but at the same time they are enduring and brave. The Aymaras are more thick-set than the Yncas, and their chief physical peculiarity is that the thigh, instead of being longer, is rather shorter than the leg. The whole build is admirably adapted for mountain-climbing.

The great Ynca Huayna Ccapac died in 1527, the year when Pizarro first appeared on the coast. His consolidated empire extended from the river Ancasmayu north of Quito to the river Maule in the south of Chili. The Yncas had an elaborate system of state-worship, with a ritual and frequently recurring festivals. History and tradition were preserved by the bards, and dramas were enacted before the sovereign and his court. Roads with posthouses at intervals were made over the wildest mountain ranges and the bleakest deserts for hundreds of miles. A well-considered system of land-tenure and of colonization provided for the wants of all classes of the people. The administrative details of government were minutely and carefully organized, and accurate statistics were kept by means of the "quipus" or system of knots. The edifices displayed marvelous building skill, and their workmanship is unsurpassed. The world has nothing to show, in the way of stone-cutting and fitting, to equal the skill and accuracy displayed in the Ynca structures of Cuzco. As workers in metals and as potters they displayed infinite variety of design, though not of a high order, while as cultivators and engineers they in all respects excelled their European conquerors.

On March 10, 1526, the contract for the conquest of Peru was signed by Almagro and Luque, Gaspar de Espinosa supplying the funds. In 1527 Francisco Pizarro, after enduring fearful hardships, first reached the coast of Peru at Tumbez. In the following year he went to Spain, and on July 26, 1529, the capitulation with the crown for the conquest of Peru was executed. Pizarro sailed from San Lucar with his brothers in January, 1530, and landed at Tumbez in 1532. The civil war between Huascar and Atahualpa, the sons of Huayna Ccapac, had been fought out in the meanwhile, and the victorious Atahualpa was at Caxamarca on his way from Quito to Cuzco. On November 15, 1532, Francisco Pizarro with his little army entered Caxamarca and in February, 1533, his colleague Almagro arrived with reinforcements. The murder of the Ynca Atahualpa was perpetrated on August 29, 1533, and November 15 Pizarro entered Cuzco. He allowed the rightful heir to the empire, Manco, the legitimate son of Huayna Ccapac, to be solemnly crowned on March 24, 1534. Almagro then undertook an expedition to Chili, and Pizarro founded the city of Lima on January 18, 1535. In the following year the Yncas made a brave attempt to expel the invaders, and closely besieged the Spaniards in Cuzco during February and March. But Almagro, returning from Chili, raised the siege on April 18, 1537. Immediately afterward the dispute arose between the Pizarros and Almagro as to the limits of their respective jurisdictions. An interview took place at Mala, on the seacoast, on November 13, 1537, which led to no result, and Almagro was finally defeated in the battle of Las Salinas, near Cuzco, April 26, 1538. His execution followed. His adherents recognized his young half-caste son, a gallant and noble youth generally known as Almagro the Lad, as his successor. Bitterly discontented, they conspired at Lima and assassinated Pizarro on June 26, 1541. Meanwhile Vaca de Castro had been sent out by the emperor, and on hearing of the murder of Pizarro he assumed the title of governor of Peru. On September 16, 1542, he defeated the army of Almagro the Lad in the battle of Chupas, near Guamanga. The ill-fated boy was beheaded at Cuzco.

Charles V. enacted the code known as the "New Laws" in 1542. "Encomiendas," or grants of estates on which the inhabitants were bound to pay tribute and give personal service to the grantee, were to pass to the crown on the death of the actual holder; a fixed sum

was to be assessed as tribute; and forced personal service was forbidden. Blasco Nunez de Vela was sent out, as first viceroy of Peru, to enforce the "New Laws." Their promulgation aroused a storm among the conquerors. Gonzalo Pizarro rose in rebellion, and entered Lima on October 28, 1544. The viceroy fled to Quito, but was followed, defeated, and killed at the battle of Anaquito on January 18, 1546. The "New Laws" were weakly revoked, and Pedro de la Gasca, as first president of the Audiencia (court of justice) of Peru, was sent out to restore order. He arrived in 1547, and on April 8, 1548, he routed the followers of Gonzalo Pizarro on the plain of Xaquixaguana, near Cuzco. Gonzalo was executed on the field. La Gasca made a redistribution of "encomiendas" to the loyal conquerors, which caused great discontent, and left Peru before his scheme was made public in January, 1550. On September 23, 1551, Don Antonio de Mendoza arrived as second viceroy, but died at Lima in the following July. The country was then ruled by the judges of the Audiencia, and a formidable insurrection broke out, headed by Francisco Hernandez Giron, with the object of maintaining the right of the conquerors to exact forced service from the Indians. In May, 1554, Giron defeated the army of the judges at Chuquinga, but he was hopelessly routed at Pucara on October 11, 1554, captured, and on December 7th executed at Lima. Don Andres Hurtado de Mendoza, marquis of Cañete, entered Lima as third viceroy of Peru on July 6, 1555, and ruled with an iron hand for six years. The next viceroy was the Conde de Nieva (1561-64). His successor, the licentiate Lope Garcia de Castro, who only had the title of governor, ruled from 1564 to 1569. From this time there was a succession of viceroys until 1824. The viceroys were chief magistrates, but they were not supreme. In legal matters they had to consult the Audiencia of judges, in finance the Tribunal de Cuentas, in other branches of administration the Juntas de Gobierno and de Guerra.

In their legislation the Spanish kings and viceroys showed a desire to protect the people from tyranny, but they were unable to prevent the rapacity and lawlessness of distant officials. The country was depopulated by the illegal methods of enforcing the mita, and an air of sadness and desolation spread over the land.

Peru was the center of Spanish power, and the viceroy had his military strength concentrated at Lima. Consequently the more distant provinces, such as Chili and Buenos Ayres, were able to throw off the yoke first. But the destruction of the viceroy's power was essential to their continued independent existence. The conquest of the Peruvian coast must always depend on the command of the sea. A fleet of armed ships was fitted out at Valparaiso, in Chili, under the command of Lord Cochrane and officered by Englishmen. It convoyed an army of Argentine troops, with some Chilians, under the command of the Argentine general San Martin, which landed on the coast of Peru in September, 1820. San Martin was enthusiastically received, and the independence of Peru was proclaimed at Lima on his entrance, after the viceroy had withdrawn (July 28, 1821). On September 20, 1822, San Martin resigned the protectorate, with which he had been invested, saying that the "presence of a fortunate soldier is dangerous to a newly constituted State," and on the same day the first congress of Peru became the sovereign power of the State. After a short period of government by a committee of three, the congress elected Don José de la Riva Agüero to be first president of Peru, on February 26, 1823. He displayed great energy and capacity as an administrator, but the aid of the Colombians under Bolivar was sought, and the native ruler was unwisely

deposed. Bolivar arrived at Lima on September 1, 1823, and began to organize an army to attack the Spanish viceroy in the interior. On August 6, 1824, the cavalry action at Junin was fought with the Spanish general Canterac, near the shores of the lake of Chin-chay-cocha. It was won by a gallant charge of the Peruvians under Colonel Suarez, at the critical moment. Soon afterward Bolivar left the army to proceed to the coast, and the final battle of Ayacucho (December 9, 1824) with the viceroy and the whole Spanish power was fought by his second in command, General Sucre. The Spaniards were completely defeated. The viceroy and all his officers were taken prisoners, and Spanish power in Peru came to an end.

General Bolivar now showed that he was actuated by personal ambition; he intrigued to impose a constitution on Peru, with himself as president for life. He failed, and left the country on September 3, 1826, followed by all the Colombian troops in March, 1827. General Lamar, who commanded the Peruvians at Ayacucho, was elected president of Peru on August 24, 1827, but was deposed, after waging a brief but disastrous war with Colombia, on June 7, 1829. General Gamarra, who had been in the Spanish service, and was chief of the staff in the patriot army at Ayacucho, was elected third president on August 31, 1829.

For fifteen years, from 1829 to 1844, Peru was painfully feeling her way to a right use of independence. The officers who fought at Ayacucho, and to whom the country felt natural gratitude, were all-powerful, and they had not learned to settle political differences in any other way than by the sword. From 1837 to 1839 there was a lawless and unprincipled intervention on the part of Chili which increased the confusion. Three men, during that period of probation, won a prominent place in their country's history, Generals Gamarra, Salaverry, and Santa Cruz. Gamarra, born at Cuzco in 1785, never accommodated himself to constitutional usages; too often he made his own will the law; but he attached to himself many loyal and devoted friends, and, with all his faults, which were mainly faults of ignorance, he loved his country and sought its welfare according to his lights. Salaverry was a very different character. Born at Lima in 1806, of pure Basque descent, he joined the patriot army before he was fifteen and displayed his audacious valor in many a hard-fought battle. Feeling strongly the necessity that Peru had for repose, and the guilt of civil dissension, he wrote patriotic poems which became very popular. Yet he, too, could only see a remedy in violence. He seized the supreme power, and perished by an iniquitous sentence on February 18, 1836. Andres Santa Cruz was an Indian statesman. His mother was a lady of high rank, of the family of the Yncas, and he was very proud of his descent. Unsuccessful as a general in the field, he nevertheless possessed remarkable administrative ability and for nearly three years (1836-39) realized his lifelong dream of a Peru-Bolivian confederation. But Peruvian history is not confined to the hostilities of these military rulers. Three constitutions were framed, in 1828, 1833, and 1839. There were lawyers, statesmen, and orators who could defend the rights and liberties of the people. On November 7, 1832, Doctor Vijil, the deputy for Tacna, rose in his place in congress and denounced the unconstitutional acts of President Gamarra in a memorable speech of great eloquence. Nor should a much humbler name ever be omitted in writing the history of republican Peru. Juan Rios, a private soldier, was sentry at the door of congress when Gamarra illegally sent his troops to disperse the members. He defended his post against two companies, and fell mortally wounded.

In 1844 General Ramon Castilla restored peace to Peru, and was elected constitutional president on April 20, 1845. Ten years of peace and increasing prosperity followed. In 1849 the regular payment of the interest of the public debt was commenced, steam communication was established along the Pacific coast, and a railroad was made from Lima to Callao. After a regular term of office of six years of peace and moral and material progress Castilla resigned, and General Echenique was elected president. But the proceedings of Echenique's government in connection with the consolidation of the internal debt were disapproved by the nation, and after hostilities which lasted for six months, Castilla returned to power in January, 1855. From December, 1856, to March, 1858, he had to contend with and subdue a local insurrection headed by General Vivanco, but, with these two exceptions, there was peace in Peru from 1844 to 1879, a period of thirty-five years. The existing constitution was framed in 1856, and revised by a commission in 1860. Slavery and the Indian tribute were abolished; by its provisions the president is elected for four years, and there are two vice-presidents. The congress consists of a senate and chamber of deputies. The senators are elected by departments and the deputies by the people, every 30,000 inhabitants having a representative. When congress is not sitting there is a permanent commission of the legislature, elected at the end of each session, and consisting of seven senators and eight deputies. The chamber of deputies may accuse the president of infractions of the constitution and the senate passes judgment. The president appoints the prefects of departments and sub-prefects of provinces; the prefects nominate the governors of districts. In each province there is a judge; a superior court of justice sits at the capital of each department; and there is an appeal to the supreme court at Lima. Castilla retired at the end of his term of office in 1862, and died in 1868. On August 2, 1868, Colonel Balta was elected president. Before his time the public debt had been moderate, amounting to \$21,826,464, and the interest had been regularly paid since 1849. But Balta's government increased it to \$245,000,000, the payment of the interest of which from the ordinary revenues was simply impossible. The creditors, as security, had the whole of the guano and nitrate deposits assigned to them. With the vast sum thus raised, President Balta commenced the execution of public works, principally railroads on a gigantic scale. His period of office was signalized by the opening of an international exhibition at Lima. He was succeeded (August 2, 1872) by Don Manuel Pardo, an honest and enlightened statesman, who did all in his power to retrieve the country from the financial difficulty into which it had been brought by the reckless policy of his predecessor, but the conditions were not capable of solution. He regulated the Chinese immigration to the coast-valleys, which, from 1860 to 1872, had amounted to 58,606. He paid great attention to statistics, promoted the advance of education, and encouraged literature. He was the best president Peru has ever known, and his death in 1878 was a public calamity. On August 2, 1876, General Prado was elected, and his term of office saw the commencement of that calamity which has since overwhelmed his country.

On April 5, 1879, the republic of Chili declared war upon Peru, the alleged pretext being that Peru had made an offensive treaty, directed against Chili, with Bolivia, a country with which Chili had a dispute; but the publication of the text of this treaty made known the fact that it was strictly defensive and contained no just cause for war. The true object of Chili was the conquest of the rich Peruvian province of Tarapaca,

the appropriation of its valuable guano and nitrate deposits, and the spoliation of the rest of the Peruvian coast.

After the capture of the *Huascar* off Point Angamos on October 8, 1879, by two Chilean ironclads and four other vessels, the Peruvian coast was at the mercy of the invaders, and Tarapaca, surrounded by trackless deserts, yet open to the sea, though bravely defended for some time by the Peruvian army, fell into the hands of the enemy after the hotly-contested battle of Tarapaca, on November 17, 1879.

Chili then landed an army farther north, and on May 26, 1880, the battle of Tacna was fought, followed by the capture of the port of Arica on June 7th. In these combats the Peruvians lost 147 officers alone. The possession of the sea enabled the Chilean ships to desolate the whole coast; and, the Peruvian army having been almost annihilated, only a force of volunteers and raw recruits could be assembled for the defense of the capital. After the two desperately-contested battles of Chorrillos and Miraflores on January 13th and 15th, 1881, Lima was entered on the 17th, and was not evacuated by the invaders until October 22, 1883. During that period General Caceres, the hero of the defense, carried on a gallant but unequal struggle in the sierra. At last a provisional government, under General Iglesias, signed a treaty with the Chileans on October 20, 1883, by which the province of Tarapaca was ceded to the conquerors, Tacna and Arica were to be occupied by the Chileans for ten years, and then a vote by plebiscitum is to decide whether they are to belong to Peru or Chili; and there are clauses respecting the sales of guano; while all rights to the nitrate deposits, which are hypothecated to the creditors of Peru, have been appropriated by the Chilean conquerors. This most disastrous war has brought ruin and misery on the country, and has thrown Peru back for many years. The country contains the elements of recovery, but it will be a work of time.

PERU, the county seat of Miami county, Ind., is located on the north bank of the Wabash river and on the Wabash and Erie canal. It is one of those busy, bustling, go-ahead cities indigenous to the West, and equally illustrative of the enterprise and progressive character of the inhabitants of that section. The Wabash Western Railroad passes through the city, to which it is also an important feeder, and, with the transportation conveniences afforded by that line and its connections, Peru is placed in close communication with Indianapolis, Logansport, Fort Wayne and other cities in the State, besides those at a distance. The city contains seven churches, a high school and a well arranged and appointed union school, courthouse, and county buildings, three daily papers, two national banks, three hotels, and many large and handsome stores. In the line of manufactures, it is the location of the Indiana Manufacturing Company's plant, having in addition a large woolen-mill, three planing-mills, three steam saw-mills, one grist-mill, three foundries, two cigar manufactories, one soap factory, one tile factory, one basket factory, gasworks and electric-light works, with other undertakings of a productive character. The city is lighted by electric lights and natural gas, the latter being also employed as a substitute for fuel for domestic, heating, and manufacturing purposes, an innovation upon the established order of things of comparatively recent date, found to be effective, economical and a source of attraction for the removal of industrial enterprises to Peru from distant points. The city's population, in 1890, was 6,731.

PERUGIA, a city of Italy, the chief town of the province of Perugia (formerly Umbria), lies 1,550 feet

above the sea on a beautiful and green-clad hill, which affords a magnificent view over a wide sweep of the Apennines and the great Umbrian plain through which the Tiber flows. Woolens, silks, wax candles, and liqueurs are manufactured on a small scale. The population of the city was 16,708 in 1871, and 17,395 in 1881; that of the commune 49,503 and 51,354 respectively.

PERUGINO, PIETRO, whose correct family name was VANNUCCI, one of the most advanced Italian painters immediately preceding the era of Leonardo da Vinci and Raphael, was born in 1446 at Città della Pieve, in Umbria. Gradually Perugino rose into notice, and in the course of some years he became extremely famous not only throughout all Italy, but even beyond her bounds. He was one of the earliest Italian painters to practice oil-painting, in which he evinced a depth and smoothness of tint which elicited much remark; he transcended his epoch in giving softness to form and a graceful spaciousness to landscape-distances, and in perspective he applied the novel rule of two centers of vision. The Florentine school advanced in amenity under his influence. Some of his early works were extensive frescoes for the Ingesati fathers in their convent, which was destroyed not many years afterward in the course of the siege of Florence; he produced for them also many cartoons, which they executed with brilliant effect in stained glass.

The painting of that part of the Sixtine Chapel which is now immortalized by Michelangelo's *Last Judgment* was assigned to him by the pope; he covered it with frescoes of the *Assumption*, the *Nativity*, and *Moses in the Bulrushes*. These works were ruthlessly destroyed to make place for his successor's more colossal genius, but other works by Perugino still remain in the Sixtine Chapel—*Moses and Zipporah* (often attributed to Signorelli), the *Baptism of Christ*, and *Christ giving the keys to Peter*. The last work is more especially noted, and may be taken as a typical example both of Perugino's merits and of his characteristic defects—such as formal symmetry of composition, set attitudes, and affectation in the design of the extremities. Perugino's last frescoes were painted for the monastery of S. Agnese in Perugia, and in 1522 for the church of Castello di Fontignano hard by. Both series have disappeared from their places, the second being now in the South Kensington Museum. He was still at Fontignano in 1524, when the plague broke out, and he died. He was buried in unconsecrated ground in a field, the precise spot now unknown.

PERUVIAN BARK. See CINCHONA and QUININE.

PERUZZI, BALDASSARE, architect and painter of the Roman school, was born at Ancajano, in 1481. He died in 1536, and was buried by the side of Raphael in the Pantheon.

PERVIGILIUM. See VIGIL.

PERVIGILIUM VENERIS, the Vigil of Venus, a short Latin poem, in praise of spring as the season of love and flowers. Written professedly in early spring on the eve of a three-nights festival (Vigil) in honor of Venus (probably April 1-3), it describes in warm and poetical language the annual awakening of the vegetable and animal world in spring through the all-pervading influence of the foam-born goddess, whose birth and connection with Rome and the Cæsars are also touched upon. The joyous tone which runs through the poem passes suddenly at the close into one of lyric sadness: "The nightingale is singing, but I am silent. When comes my spring?" It consists of ninety-three verses in trochaic tetrameter catalectic, and is divided into strophes of unequal length by the refrain, "Cras amet

qui nunquam amavit; quique amavit cras amet." The author, date, and place of composition are unknown.

PESARO, a city and seaport of Italy, the capital of the province of Pesaro and Urbino, lies on the coast of the Adriatic, thirty-six miles north of Ancona and twenty and one-half south of Rimini, on the right bank of the Foglia, the ancient Pisaurus. The population of the city and port in 1870 was 11,952 and in 1880 12,913; that of the commune 19,691 and 20,909 in the same years.

PESHAWAR, or PESHAWUR, a district in the lieutenant-governorship of the Punjab, with an area of 2,504 square miles, situated in the extreme northwestern corner of British India. The district is naturally fertile and well watered, and the valley is entirely drained by the Cabul river. The temperature ranges from a minimum of 17° in February to a maximum of 137° in July. The average rainfall is about fourteen inches. According to the census of 1881 the population was 592,674. Out of the total area of 2,504 square miles 1,414 are cultivated and 470 are returned as cultivable.

Peshawar in 1881 had five towns with a population exceeding 5,000, namely, Peshawar (see below); Nowshera, 12,963; Tangi, 9,037; Maira Parang, 8,874; and Char-sadda, 8,363.

PESHAWAR, chief town in the above district, is about fourteen miles east of the Khyber Pass, and distant from Lahore 276 miles and from Cabul 190 miles. Its population in 1881 was 79,982 (50,322 males, 29,660 females).

PESSIMISM is a word of very modern coinage, employed to denote a mode of looking at and estimating the world, and especially human life, which is antithetical to the estimate designed by the term (a much older one) "Optimism." Both terms have a general as well as a special application. In their non-technical usage they denote a composite and ill-defined attitude of mind which gives preponderating importance to the good or to the evil, to the joys or to the sorrows, respectively, in the course of experience. The optimist sees everything in *couleur de rose*; the pessimist always turns up the seamy side of things. But in their special and technical employment, optimism and Pessimism denote specific theories elaborated by philosophers—the former to show that the world is the work of an author of infinite goodness and wisdom, and is, all things considered, conducive to the happiness of its sentient life; the latter, that existence, when summed up, has an enormous surplus of pain over pleasure, and that man in particular, recognizing this fact, can find real good only by abnegation and self-sacrifice. As a speculative theory optimism is chiefly associated with the *Théodicée* of Leibnitz (1710), while Pessimism is the work of Schopenhauer and Von Hartmann. In either case, however, the modern doctrines have their predecessors. The Stoics and the Neoplatonists were earlier laborers in the cause of optimism, in their attempt to exhibit the adaptations in nature for the welfare of its supreme product, man. And in the metaphysical dogmas of Brahmanism, as well as in the practical philosophy of the Buddhists, the creed of the modern pessimist, that the world is vanity and life only sorrow, is found precluded with startling sameness of tone. Though later as a philosophical creed in the European world, Pessimism is far earlier than optimism as a mood of feeling in mankind at large.

The pessimistic theories of modern times are in part a commendable protest against the common compromises which slur over the antithesis between the moral and the natural. They show tolerably conclusively that the world is not a felicitous institution, and that he who makes happiness the aim of his life is on the wrong track. But, when they proceed to dogmatize that ex-

istence has a root of bitterness and life is a burden of pain, they fall into the common error of exaggerating a statement relatively true into an absolute principle. You cannot tell if life is worth living, so long as life is held to be the sum or difference of pains and pleasures. If pains and pleasures were only and always such, the argument might be admitted; if they were permanent real entities, not liable to be transformed into each other, not constantly associated in the same act, it might be possible to treat them as ultimate and irreversible standards for our estimate of life and the guidance of our conduct. If pleasure and pain are unequally and unfairly distributed, it is probable that this is a fault which human agency can cure to an unspeakable degree, quite without the desperate remedy of self-torture or cosmic suicide. If Pessimism can teach the world that the highest reward of virtue is self-respect, and that there is no pleasure available anywhere to bribe us to be good, it has done well. It has also done well if it points out the barriers to happiness in this world, so long as these barriers prevent true life and can be removed by wise methods. But in the meanwhile, till the burden of existence has become universally unbearable, it may be well to remember that we shall be as likely to benefit the Absolute by doing our work well as by macerating ourselves, and that the sum of existence is a big thing, of which it were rash to predicate either that it is altogether and supremely good or altogether and supremely bad.

PESSINUS, or PESINUS, an ancient city of Galatia, in Asia Minor, situated on the southern slope of Mount Dindymus. It stood on the left bank of the river Sangarius, about 150 stadia (17 miles) from its source, and 16 miles south of Germa on the road from Ancyra to Amorium. It was the capital of the Tolistobogii, and the chief commercial city of the district. It was famous for its worship of the mother of the gods (Cybele), who here went by the name of Agdistis. The modern town of Sevri-Hissar is built at the height of about 3,000 feet on the southern base of a steep granite rock, half-way up which are the ruins of a castle.

PESTALOZZI, JOHANN HEINRICH, was born in 1746, and died in 1827. (See EDUCATION.)

PESTH, the chief town of Hungary, and the second of the Austrian-Hungarian monarchy, is situated on the left bank of the Danube, 140 miles to the southeast of Vienna. Since 1873 it has formed one municipality with BUDA (*q.v.*) on the opposite bank, and the joint city, officially styled Budapest (Ger. *Pest-Ofen*), is the capital of Hungary, the second residence of the Austrian emperor, the seat of the Hungarian ministry, diet, and supreme courts, and the headquarters of the commander of the Honveds or Hungarian landwehr. On one side of the Danube is a flat sandy plain, in which lies Pesth, modern of aspect, regularly laid out, and presenting a long frontage of handsome white buildings to the river. On the other the ancient town of Buda straggles capriciously over a series of small and steep hills, commanded by the fortress and the Blocksberg, and backed by spurs of the vine-clad mountains beyond. The Danube is crossed by three bridges.

In commerce and industry Budapest is by far the most important town in Hungary, and in the former, if not also in the latter, it is second to Vienna alone in the Austrian-Hungarian monarchy. The chief articles of manufacture are machinery, railway plant, carriages, gold and silver wares, chemicals, cutlery, starch, tobacco, and the usual articles produced in large towns for home consumption. The great staple of trade is grain, of which about four and half million bushels are brought into the town annually. One-fourth of this amount merely passes through Pesth, while most of

the remainder is ground into flour and exported in this form. Other important articles of commerce are wine, wool, cattle, timber, hides, honey, wax, and "slivovitz," an inferior spirit made from plums. The imports, so far as they do not belong to the transit trade, consist chiefly of manufactured articles and colonial produce. The four annual fairs, formerly attended by many thousand customers, have now lost much of their importance.

Few European towns have grown so rapidly as Pesth during the present century, and probably none has witnessed such a thorough transformation in the last twenty years. In 1889 the population of Budapest was 452,907 souls, including a garrison of 10,000 men; more than 70,000 Jews are included in the population, and the Jewish synagogue is the handsomest place of worship in the city.

PETALUMA, a city in Sonoma county, Cal., is located on Petaluma creek, at the head of navigation, and on the San Francisco and North Pacific road. It is situated forty-two miles north of San Francisco, sixteen miles south of Santa Rosa, ten miles west of the village of Sonoma, and about the same distance east of the Pacific ocean and north of San Pablo bay. Its location, surroundings, etc., have combined to make the city an attractive resort for tourists and strangers, not only from the East and abroad, but from all portions of the adjoining States and Territories. The climate is hospitable and the bracing breezes from the Pacific serve to temper the visitations of heat and cold which intrude upon the locality at intervals. It is also well adapted to the cultivation of grapes and fruit, and the beautiful and fertile valleys of the vicinity are productive and highly cultivated. The city contains seven churches, large graded-school buildings, high-school building, one savings and one national bank, five hotels, three flouring-mills, two planing-mills, one sawmill, one foundry, one brewery, a woolen-mill, a daily and weekly newspaper, and superior warehouse facilities. Steamers ply daily between the city and San Francisco, and lumber, dairy products, and cereals are the chief articles of export. Population, in 1890, 5,500.

PETAU, DENYS, better known in some departments of literature under the Latin form of his name as DIONYSIUS PETAVIUS, a highly distinguished Catholic theologian and one of the most learned men of the seventeenth century, was born on August 21, 1583, at Orleans. His death took place on December 11, 1652.

PETER. Simon Peter was "an apostle of Jesus Christ." His two names are both found in two forms: of the one the full form is Symeon (Συμεών, Συμεών),

which is found in the speech of James, Acts xv. 14, and in most MSS. of 2 Peter i. 1), the shorter and more usual form being Simon; the other is found both in its Greek form Peter (Πέτρος) and in the Græcized form Cephas (Κηφᾶς) of the Aramaic Kepha (כִּפְיָ).

Simon is the name by which he is always addressed by Jesus Christ; Peter is that by which he is most commonly spoken of in the Synoptic Gospels, the Acts of the Apostles, and subsequent ecclesiastical literature; the combined name, Simon Peter, is found once in St. Matthew, once in St. Luke, and frequently in St. John; sometimes Peter is expressly stated to be a surname. In John i. 44 he is said to have been of Bethsaida, which was possibly the place of his birth; but it appears from Mark i. 29 that he and his brother Andrew had a house together at Capernaum. With the same brother, and with James and John as partners, he was engaged in what was probably the thriving business of a fisherman on the Lake of Gennesaret; and from the fact that he went back to his business after the resurrection it has been inferred that, at least up to that time, he had

never wholly left it. That he was married is clear from the mention of his wife's mother, and that his wife accompanied him when he finally left his home to preach the gospel is implied by St. Paul; there is an early tradition, which is not inconsistent with probability, that she also suffered martyrdom, and that Peter called out to her as she was being led away, "O wife, remember the Lord!" The statement that he had children is probably only an inference from the fact of his having been married.

Of the beginning of his discipleship there are two accounts which have sometimes, though without sufficient reason, been supposed to be inconsistent with each other.

(1) According to St. John, he was brought to Jesus by his brother Andrew, who had been a follower of John the Baptist, but who, after the Baptist's testimony, recognized in Jesus the promised Messiah.

(2) According to St. Matthew and St. Mark, it was at the beginning of the Galilæan ministry that Jesus called Simon and Andrew to become "fishers of men." The manner of the call seems to imply a previous acquaintance, and is consequently not out of harmony with that of St. John.

From the time of his call Peter has a place in most of the important events of the Gospel narrative. The most important incident which is recorded of him between his call and the crucifixion is that which happened at Cæsarea Philippi. Around the words which St. Matthew records many controversies have raged; nor does it seem possible, with the existing means of investigation, to fix to the sentence "upon this rock I will build My church" a meaning that will be beyond dispute. Whatever may be its precise meaning, it seems at any rate to be in harmony with other passages of the Synoptic Gospels, which indicate, not only that Peter was foremost among the apostles by virtue of natural force of character, but that he was also their ordinary leader and representative.

In the earliest account of the resurrection (that of St. Paul, 1 Cor. xv. 5) it is mentioned that Jesus appeared to Peter before and separately from the twelve; and the last chapter of the Fourth Gospel gives him an especial prominence. These facts undoubtedly confirm the general picture of the relations of Peter to the early church which is drawn in the Acts of the Apostles; at the same time no part of the New Testament has been more strongly attacked by modern writers than the first twelve chapters of that book, in which the "Acts of Peter" are contained, partly on the speeches and partly on the narrative. It is alleged that the Petrine speeches form no exception to the general uniformity of phraseology and style which characterizes the Acts, and that they ignore the marked differences in the conception of Christianity between Peter and Paul. It must be admitted that the coincidences are such as to render it probable that the author of the Acts dealt freely with his materials, but at the same time the peculiarities are sufficiently numerous to support the view that these speeches contain a true representation of the primitive teaching. At the great crisis of early Christianity which is known as the conference or council of Jerusalem Peter advocated (according to the Acts), or accepted (according to Paul), the policy of conciliation. Afterward he went to Antioch, where Paul had preceded him, and there he carried out his acceptance of Gentile Christianity to the further point of eating at the common meals at which Gentiles were present. For this step the members of the original community at Jerusalem were not prepared; and, when a deputation from them came to Antioch, Peter "drew back and separated himself." Thereupon followed an argument and a remon-

strance on the part of Paul which has been fruitful of results to both ancient and modern Christianity. Peter was "withstood to the face" because of (1) inconsistency, (2) practical calumny of Christ, (3) transgression of the law, (4) making void the gift of God. It is altogether too much to assume that this remonstrance led to a permanent alienation of the two apostles from one another; it is more probable that with a character such as Peter's, which had more energy than steadiness of resolution, it may even have been effectual. But it is upon the assumption of such an alienation that the Jewish party in the ancient church pictured Peter as the champion and hero of the faith, and Paul as its vanquished opponent, and also that in modern times the Tübingen school have endeavored to reconstruct not only early church history but also the New Testament.

This incident at Antioch is the last that is certainly known of Peter. The prophecy recorded in John xxi. 18, 19, is in harmony with early tradition in pointing to a violent death. But of the time and place of that death we know nothing with even approximate probability. The only historical mention of him for more than a hundred years afterward is in Clement of Rome, who sets before the Corinthians the example of "Peter, who through zeal undertook not one or two but numerous labors, and so having borne witness went to the place that was due to him." It is sometimes supposed that an indication of the place in which he "bore witness" or "suffered martyrdom" is afforded by the phrase "among us," *i.e.*, among the Romans, in the next chapter; but this, though possible, is quite uncertain. Outside this statement, which if it were more definite would be conclusive, there is only the doubtful interpretation of "Babylon" in 1 Peter v. 13 as meaning "Rome," and the echo of a vague tradition in the apocryphal *Petri et Pauli Prædicatio*.

PETER, EPISTLES OF. 1 *Peter*.—The first of the two canonical epistles which bear the name of St. Peter is addressed "to the elect who are sojourners of the dispersion in Pontus, Galatia, Cappadocia, Asia, and Bithynia." Most commentators in both ancient and modern times (*e.g.*, of the former Athanasius, Jerome, Ephiaphanius; of the latter, Lange, Weiss, and Bey-schlag) have interpreted this phrase to refer primarily to Jewish Christians. But this interpretation creates a difficulty.

The epistle was evidently written at a time when the Christians of Asia Minor were both calumniated and persecuted. It exhorts those to whom it was addressed not only to bear their trials patiently, and even to rejoice inasmuch as they were "partakers of the sufferings of Christ," but also to give no occasion to the hostile world which surrounded them to reproach them as evil-doers, and it specializes this exhortation to well-doing by addressing separately servants, wives, and husbands. This fact that Christianity had come to be persecuted, and also the fact, which is manifested in its whole tone, that Christians were in danger of retrograding, show that the epistle cannot be placed in the earlier part of the apostolic age. The time of the Neronian persecution is the earliest that will satisfy the required conditions, and some have thought that even this is too early for these conditions, and that it must be referred to the time of Trajan.

2 *Peter*.—The second epistle is addressed to a wider circle than the first, *i.e.*, to Christians in general. Its aim is mainly polemical; it is directed partly against a tendency toward libertinism which was growing up and which took for one of its supports the Pauline doctrine of Christian freedom, and partly against the reaction which had set in against the earlier eschatology. It protests in powerful language against the separation of

Christianity from holy living, maintaining that Christianity without holy living is worse than no living at all; and it reasserts the reality of the Second Coming, resting it upon the reality of the supernatural evidence of the First Coming.

The differences of style which distinguish the second from the first epistle have been noted since the time of Jerome. They are sometimes explained on the ground of the epistles having had different purposes, or having been written at different times; they are more commonly used as indications of a difference of authorship; and, although the argument from differences of style in comparatively short documents cannot be held to be decisive where the external evidence in their favor is strong, such is not the case with this epistle. The external evidence for it is singularly weak.

PETER OF BLOIS, otherwise known as PETRUS BLESSENSIS, a writer of the twelfth century, was born at Blois in France about the year 1120. Peter died about 1200. His writings, which cover all the fields of intellectual activity then accessible, show him to have been one of the most widely and deeply learned men of his age.

PETER THE HERMIT, the apostle of the first crusade, was born of good family, it is supposed, in the diocese of Amiens about the year 1050. After the failure of the expedition headed by him in 1096, he founded and became first prior of the abbey of Neufmoustier at Huy, in the diocese of Liège, where he died July 7, 1115.

PETER I., ALEXEIEVICH, surnamed THE GREAT, czar of Russia, was born at Moscow June 11, 1672. His mother, Natalia Narishkina, was the second wife of the czar Alexis. He was taught reading and writing, and the limited range of subjects which then constituted education in Russia, by the deacon Nikita Zotoff. He came to the throne in the year 1682, on the death of his elder brother Feodore. There was another brother, Ivan, who was six years his senior, but he was weak in both body and mind, and a compromise was made whereby Ivan and Peter were to reign jointly. On the death of Ivan in 1696 Peter became sole ruler.

With the aid of Lefort, a Swiss adventurer, and other foreigners, Peter commenced his remarkable reforms, for which see RUSSIA. The czar died January 28, 1725.

The character of Peter exhibits a strange congeries of opposed qualities. According to some he "knouted" Russia into civilization; others see in him the true "father of his country" and the founder of Russian greatness. In spite of his errors, no one will deny that he was a man of great genius; his was the "fiery soul that, working out its way," exhausted prematurely a vigorous physical organization. Although frequently cruel, on many occasions he showed humanity and tenderness, and even in his most violent fits of temper was amenable to advice, as he evinced in enduring the rebukes of Prince James Dolgoruki. All Russia seems but the monument of this strange colossal man. He added six provinces to her dominions, gave her an outlet upon two seas, a regular army trained in European tactics in lieu of the disorderly militia previously existing, a fleet, and a naval academy, and, besides these, galleries of painting and sculpture and libraries. The title of "Great" cannot justly be refused to such a man.

PETER II., ALEXEIEVICH, son of Alexis and grandson of Peter the Great, was born at St. Petersburg in 1715, and ascended the throne in 1727. He was under the guardianship of Menshikoff, to whose daughter Mary he was betrothed. The faction of the Menshikoffs was overthrown, however, by the Dolgorukis, to a daughter of whose house the czar was now to be married. All these political plans were rudely broken

by the death of Peter in January, 1736. During his short reign this youth showed reactionary tendencies, and it seemed as if the capital of Russia was again to be transferred to Moscow. The young czar was buried in the cathedral of the Archangel in that city.

PETER III., FEODOROVICH, was son of Anna, daughter of Peter the Great, who had married the duke of Holstein. He was born at Kiel in 1728, his real name being Karl Peter Ulrich; he went to Russia in 1742 on being named heir to the throne. In 1745 he married Sophia Augusta, princess of Anhalt-Zerbst, who, on entering the Greek Church, took the name of Catherine. They lived very unhappily together. In January, 1762, the czarina Elizabeth died and Peter succeeded her. He soon became unpopular on account of his fondness for the Prussians and the introduction of German regulations in the army. His wife took advantage of his unpopularity and caused herself to be crowned empress, July, 1762. Peter showed great want of energy, and only attempted to stem the insurrection when it was too late. He was removed to Ropsha, in the government of St. Petersburg, and, after having been forced to sign a renunciation of all rights to the throne, was strangled by Orloff and others. He was first buried in the Alexandro-Neviski monastery, but his remains were removed in 1796 by Paul to the Petropavlovski church.

PETERBOROUGH, a city and municipal and parliamentary borough, chiefly in Northamptonshire, but partly in Huntingdonshire, is situated on the river Nene, seventy-six miles north of London by the Great Northern Railway. The town is also a station on the London and Northwestern, the Great Eastern and the Midland systems. It is built chiefly along the river on the north side, the streets being straight and wide, and containing many good houses.

The modern prosperity and growth of the town are chiefly due to the trade caused by the junction of so many railway lines. Adjoining the town are extensive works and sheds connected with the Great Northern and Midland Railways. Important cattle markets and fairs are held, and there is a large transit of meat and cattle to London and elsewhere. An extensive trade in corn, coal, and timber is also carried on. The principal manufacture is that of agricultural implements. The entire parliamentary city of Peterborough has an area of 6,558 acres (of which 6,310 are in Northamptonshire), with a population of 22,394 (of whom 20,123 are in Northamptonshire). The population of the municipal borough (area, 1,818 acres) in 1871 was 16,310, and in 1891 it was 25,172. Since 1841 it has more than trebled.

PETERBOROUGH, capital of the county of Peterborough, in the Province of Ontario and Dominion of Canada, is located on the navigable Otonabee river, and is a station on the Midland railway, thirty miles north of Port Hope, and ninety-five miles northeast of Toronto. It is also on the Canadian Pacific and Grand Trunk roads, and is connected with Ashburnham, on the opposite side of the Otonabee, by a substantial bridge. The city is handsomely laid out and built, the streets being broad, smooth and well maintained, while the structures that line these thoroughfares, particularly in the business and residence districts, are attractive features of the city's growth, as also testimonials to the enterprise and public spirit of citizens. Besides the county buildings, the city contains six churches, four banks, two newspaper offices, some ninety stores and other commercial depots, ten hotels, gas and electric-light works, school buildings public and private, hospitals, etc., etc. The manufacturing resources include broom, mattress, furniture and hosiery factories, sash,

door and blind factories, pottery-works, woolen and planing mills, fanning-mill and pump works, foundries and machine shops, carriage-works, saw and grist mills, and leather and woodenware manufactories. The city does a large export trade in grain, pork and lumber, and in 1890 was credited with a population of 10,000.

**PETERBOROUGH AND MONMOUTH, CHARLES MORDAUNT, EARL OF**, a man whose whole life was passed in the turmoil of excitement, was born about 1658. His father died June 5, 1675, and Charles Mordaunt succeeded to the peerage. On his return from the second expedition to Tangier he plunged into active political life as a zealous Whig and an unswerving opponent of the duke of York. But his continued hostility to James II. forced him to retire to Holland, when he proposed to William of Orange to invade England. His plan was rejected, though the prudent prince of Orange deemed it judicious to retain his fiery adherent by his side. When William sailed to Torbay his friend accompanied him, and when the Dutch prince was safely established on the throne of England honors without stint were showered upon Lord Mordaunt.

From this time till 1735, under the reign of two sovereigns, dignities both civil and military were at his command. In 1705 he was made commander of the allied Dutch and English forces in Spain, in which country he remained for two years, when, indignant at the conduct of other leaders, he quitted the country and went home.

On his return to England he allied himself with the Tories, and received his reward in being contrasted, much to his advantage, with the Whig victor of Blenheim and Malplaquet. A few months before the close of Queen Anne's reign (November, 1713) he was dispatched as ambassador-extraordinary to the king of Sicily, but was recalled by the Whigs as soon as they obtained the reins of power. With the accession of George I. Lord Peterborough's influence was gone. Hatred of Marlborough became the ruling passion of his mind. His last twenty years of life were passed with the recollection of disappointed hopes and with the continual presence of disease. Worn out with suffering, he died at Lisbon, October 25, 1735. His remains were brought to England and buried at Turvey in Bedfordshire, November 21st.

**PETERHEAD**, a seaport, market town, burgh of barony, and parliamentary burgh of Aberdeenshire, Scotland, is situated on a rocky peninsula on the North Sea, about thirty miles north-northeast of Aberdeen and two north of Buchan Ness. It has railway communication by a section of the Great North of Scotland line, opened in 1852. Formerly it was bonding subport to Aberdeen, but was made independent in 1832. The general trade is of considerable importance. The chief exports are herrings, granite, cattle, and agricultural produce. The town possesses ship and boat building yards, sawmills, an iron foundry, cooperages, agricultural-implement works, woolen manufactories, breweries, and a distillery. In the neighborhood there are extensive granite and polishing works. The limits of the police burgh and the parliamentary burgh are identical, with a population in 1871 of 8,535, and in 1891 of 12,198.

**PETERHOF**, a town of European Russia, in the government of St. Petersburg, and eighteen miles west of the capital, on the south coast of the Gulf of Finland, has grown up round the palace built by Peter the Great in 1711, was constituted a district town in 1848, and has increased its population from 7,647 in 1866 to 14,298 in 1881. It is almost exclusively a residential town, but is garrisoned by a cavalry regiment and has

the military schools lodged in its barracks for six weeks in the summer.

**PETERSBURG**, a city of Dinwiddie county, Va., also a port of entry, is advantageously located on the right bank of the Appomattox river, ten miles from its mouth. The river is navigable for vessels of moderate tonnage, while consignments for Petersburg carried in bottoms of more than 100 tons are unladen at City Point and Port Walthal. Petersburg is one of the oldest cities in the State, having been settled by the English in 1733. During the Revolutionary war it was made a rendezvous for the state troops, and when Virginia at the close of hostilities became identified with the Federal Union, Petersburg was regarded with favor as a location for the capital of that commonwealth. Thenceforward, its growth, while not rapid, was permanent, and in 1860 the city contained a population of 18,266 souls. While the civil war lasted Petersburg, on account of its advantages of location, transportation facilities, etc., was esteemed as a coign of vantage by the opposing armies, but remained nearly the entire period in the possession of the Confederates. It was fortified with exceptional care, and the forts and redans of the works resisted all attacks. In June, 1864, a movement against Petersburg was commenced, and after several days' sharp fighting the city was invested by the army of the Potomac. The siege thus inaugurated was conducted with varied success. During the latter part of June, General Burnside began running a mine from the center of his front beneath the Confederate lines, opposite. This was completed in July and ordered to be charged and exploded on the 30th of that month. It was 500 feet long, intersected by a cross gallery 80 feet in length and extending under the enemy's lines. Its explosion followed, as directed, but the effort, according to General Grant, was "a stupendous failure," none of the results anticipated having been realized. The siege, however, was maintained, less vigilance doubtless being exercised by the Union army on account of their successes in the Shenandoah Valley and the Southwest. Early in 1865 hostilities were renewed against the city, continuing until April 3d, when it was evacuated by the Confederates, and taken possession of by the Union army.

It is an important point on the Norfolk and Western, Richmond and Petersburg, and Petersburg and Weldon railroads, contains sixteen churches, one savings, one national, and one private bank, one daily and three weekly papers, a custom-house, public library, city hall, two female colleges, the Petersburg and the Southern, and five hotels. Extensive water-power is furnished by the river, and manufactures of every description are successfully operated, including iron, cotton, lumber, tobacco, sumac, sash, doors, and blinds, straw goods, blank-books, brooms, bags, fireworks, clothing, trunks, soap, baskets, etc. The municipal government is vested in a mayor and board of aldermen, who direct the management of the several city departments, over each of which is an authorized head, responsible for the execution of the trust committed to his custody. During 1889 the total receipts of the city treasurer were \$329,248.74, and the disbursements \$320,667.15, of which \$7,308 were paid for the support of the fire department, \$15,511.98 for the maintenance of the police, \$24,500 for the schools and \$5,000 for charities; the almshouse, electric lights, water-works, etc., being supported by funds appropriated to each service respectively. The bonded debt of the city was, January 1, 1890, \$1,223,200; the value of property listed for taxation, \$9,706,445; and the rate \$1.60 per \$100. The population of the city at the last census was 22,650.

**PETERS, or PETER, HUGH**, a man whose name has

for three centuries been rarely mentioned except in terms of infamy, was the son of Thomas Dyckwoode, *alias* Peters, by Martha, daughter of John Treffry of Fowey, Cornwall, and was baptized in Fowey parish church, June 29, 1598. His shrewd judgment, his ready wit, and his zeal for the cause of the Parliament endeared him to the army and its leaders; he accompanied Fairfax and Cromwell on their campaigns, and described their achievements in numerous letters to the House of Commons. To the adherents of the vanquished cause Hugh Peters always lent his good offices. At the Restoration he was seized and imprisoned in the Tower of London, where he composed his affecting tract, "A Dying Father's Last Legacy to an Only Child." His trial as a regicide took place on October 13, 1660, and he was, of course, condemned to death. Four days later he was drawn on a sledge to Charing Cross and there hanged and quartered, his head being set on a pole on London Bridge.

PETERWARDEIN, a town and strong fortress of Hungary, is situated on a promontory formed by a loop of the Danube, forty-five miles to the northwest of Belgrade. It is connected with Neusatz, on the opposite bank, by a bridge of boats 800 feet long. The fortifications consist of the upper fortress, on a lofty serpentine rock rising abruptly from the plain on three sides, and of the lower fortress at the northern base of the rock. The latter includes the town, which contains (1890) 3,603 inhabitants, engaged in wine-growing, agriculture, and the manufacture of liqueurs (*rosoglio*), and vinegar. The two fortresses can accommodate a garrison of 10,000 men. The arsenal contains interesting trophies of the Turkish wars.

PÉTION DE VILLENEUVE, JÉRÔME, was the son of a *procureur* at Chartres, where he was born in 1753. He himself became an *avocat* in his native place in 1778, and when the elections to the States-General took place in 1789 he was elected a deputy to the Tiers État for Chartres. Both in the assembly of the Tiers État and in the Constituent Assembly Pétion showed himself a radical leader. After the last meeting of the assembly on September 30, 1791, Robespierre and Pétion were made the popular heroes and were crowned by the populace with civic crowns. On November 14, 1791, he was elected second mayor of Paris in succession to Bailly. In his mayoralty he exhibited clearly his republican tendency and his hatred of the old monarchy, especially on June 20, 1792, when he allowed the mob to overrun the Tuilleries and insult the royal family. He was still mayor of Paris when the massacres of September in the prisons took place, and must bear the blame of not having endeavored to interfere. He was elected to the convention for Eure-et-Loire, and became its first president. His jealousy of Robespierre allied him to the Girondin party, as did also his assiduous attention at Madame Roland's salon. With the Girondins he voted for the king's death and for the appeal to the people, as one of them he was elected to the first committee of general defense in March, 1793, as their representative he attacked Robespierre on April 12th, and it is no matter of wonder, therefore, that his name was among those of the twenty-two Girondin deputies proscribed on June 2d. Pétion was one of those who escaped to Caen and raised the standard of provincial insurrection against the Convention; and when the Norman rising failed he fled with Gaudet, Buzot, Barbaroux, Salle, and Louvet to the Gironde, and hid in a grotto at St. Émilion. At last, but a month before Robespierre's fall in June, 1794, the escaped deputies felt themselves tracked down, and deserted the grotto; Louvet found his way to Paris, Salle and Gaudet to Bordeaux, where they were soon

taken; Barbaroux committed suicide; and the bodies of Pétion and Buzot were found in a field, half-eaten by wolves.

PETIS DE LA CROIX, FRANÇOIS, the best representative of Oriental learning in France during the last decades of the seventeenth century and the beginning of the eighteenth century, was born in Paris about 1653. In capacity of interpreter he conducted the negotiations with Tunis and Tripoli in 1685 and those with Morocco in 1687; and the zeal, tact, and linguistic knowledge he manifested in these and other transactions with Eastern courts were at last rewarded in 1692 by his appointment to the Arabic chair in the Collège Royal de France, which he filled until his death in 1713.

PETITION is an application for redress by a person aggrieved to an authority capable of relieving him. It may be made in the United Kingdom to the crown or its delegate, or to one of the houses of parliament.

The right of petitioning the crown was recognized indirectly as early as Magna Charta in the famous clause, *Nulli vendemus, nulli negabimus aut differemus, recitum aut justitiam*, and directly at various periods later. Petitions to the crown appear to have been at first for the redress of private and local grievances, or for remedies beyond those possessed by the courts. As equity grew into a system, petitions of this kind tended to become superseded by bills in chancery (see CHANCERY).

In the United States the right of petition is secured by Art. I of the amended Constitution, which enacts that "Congress shall make no law abridging \* \* \* the right of the people peaceably to assemble and to petition the Government for a redress of grievances."

*Petitions to a Court of Justice.*—Strictly speaking these are no doubt an indirect mode of petitioning the crown, for in the theory of English law the crown is the fountain of justice. But it is more convenient to treat them separately, as they now form a part of the practice of the courts. Appeals to the House of Lords and the privy council are prosecuted by petition of appeal. The House of Lords has now no original jurisdiction in judicial matters; the original jurisdiction of the privy council in such matters is confined to petitions under certain statutes, such as the Endowed Schools Acts 1867 and 1873, the Public Schools Act 1868, the Universities Act 1877, and the Patents Act 1883. In most cases the petitions are referred to the judicial committee of the privy council. Petitions may be addressed to the lord chancellor in a few instances, such as the sealing of patents and the removal of coroners and county court judges. The most important use of petitions in England is in the Chancery Division of the High Court of Justice. They may be presented either as interlocutory proceedings in the course of an action, or as original proceedings where no litigation exists—a petition being generally a more cheap and speedy form of remedy than an action. Petitions in the course of an action are usually presented to the court in which the action is brought.

In the United States petitions can be presented to the courts under much the same circumstances as in England. It is a general rule in such cases that an affidavit should be made that the facts therein contained are true as far as known to the petitioner, and that those facts which he states as knowing from others he believes to be true.

*Petition of Right* is a term confined to English law. It is used in two senses. (1) It denotes the statute 3 Car. I. c. 1, a parliamentary declaration of the liberties of the people. (See ENGLAND.) (2) It denotes a mode of prosecuting a claim against the crown by a subject. This remedy is said to owe its origin to Edward I. It lies as a rule for obtaining possession of real or personal

property, or for breach of contract, not for breach of public duty, as failure to perform treaty obligations, or for trespass, or for negligence of crown servants.

PETRA, the capital city of the NABATÆANS (*q.v.*), and the great center of their caravan trade, is described as lying in a level place, well supplied with water for horticulture and other uses, but encircled by a girdle of rocks, abrupt toward the outer side. The surrounding country was barren, especially toward Judæa; the distance from Jericho was from three to four days' journey, and from Phœnicum on the Red Sea coast five. According to Pliny the little valley of Petra is not quite two miles across, and lies at the junction of two roads, from Palmyra and Gaza respectively, 600 miles from the latter. These and other ancient notices leave no doubt as to the identity of the site with the modern Wády Músá, in the mountains which form the eastern wall of the great valley between the Dead Sea and the Gulf of Akaba. Wády Músá lies just north of the watershed between the two seas.

The Nabatæans, as we see from Diodorus, used Petra as a place of refuge and a safe storehouse for their treasures of frankincense, myrrh, and silver before they gave up their nomadic habits. But Petra was not only safe and well watered, it lay close to the most important lines of trade. Thus Petra became a center for all the main lines of overland trade between the East and West, and it was not till the fall of the Nabatæan kingdom that PALMYRA (*q.v.*) superseded it as the chief emporium of North Arabia. Many Roman and other foreign merchants were settled here even in the time of Strabo, and he describes the caravans which passed between it and Leuce Come on the Red Sea coast as comparable to armies.

PETRARCH. Francesco Petrarca, eminent in the history of literature both as one of the four classical Italian poets, and also as the first true reviver of learning in mediæval Europe, was born at Arezzo on July 20, 1304.

Petrarch's real name, according to Tuscan usage, was Francesco di Petracco. But he altered this patronymic, for the sake of euphony, to Petrarca, proving by this slight change his emancipation from usages which, had he dwelt at Florence, would most probably have been imposed on him. Notwithstanding Petrarch's firm determination to make himself a scholar and a man of letters rather than a lawyer, he so far submitted to his father's wishes as to remove, about the year 1323, to Bologna, which was then the headquarters of juristic learning. There he stayed with his brother Gherardo until 1326, when his father died, and he returned to Avignon.

On April 6, 1327, happened the most famous event of Petrarch's history. He saw Laura for the first time in the church of St. Clara, at Avignon. Who Laura was remains uncertain still. That she was the daughter of Audibert de Noves and the wife of Hugh de Sade rests partly on tradition and partly on documents which the abbé de Sade professed to have copied from originals in the last century.

Petrarch's inner life after this date is mainly occupied with a passion which he celebrated in his Italian poems, and with the friendships which his Latin epistles dimly reveal to us.

It was some time in the year 1337 that he established himself at Vacluse and began that life of solitary study, heightened by communion with nature in her loneliest and wildest moods, which distinguished him in so remarkable a degree from the common herd of mediæval scholars. A desire for glory was one of the most deeply-rooted passions of his nature, and one of the points in which he most strikingly anticipated the

humanistic scholars who succeeded him. It is not, therefore, surprising to find that he exerted his influence in several quarters with the view to obtaining the honors of a public coronation. The result of his intrigues was that on a single day in 1340, September 1st, he received two invitations, from the university of Paris and from King Robert of Naples respectively. He chose to accept the latter, journeyed in February, 1341, to Naples, was honorably entertained by the king, and, after some formal disputations on matters touching the poet's art, was sent with magnificent credentials to Rome. There, in the month of April, Petrarch assumed the poet's crown upon the Capitol from the hand of the Roman senator amid the plaudits of the people and the patricians.

With the coronation in Rome a fresh chapter in the biography of Petrarch may be said to have begun. Henceforth he ranked as a rhetorician and a poet of European celebrity, the guest of princes, and the ambassador to royal courts. In January, 1343, his old friend and patron Robert, king of Naples, died, and Petrarch was sent on an embassy from the papal court to his successor Joan. The notices which he has left us of Neapolitan society at this epoch are interesting, and it was now, perhaps, that he met Boccaccio for the first time.

In the month of May, 1347, Cola di Rienzi accomplished that extraordinary revolution which for a short space revived the republic in Rome, and raised this enthusiast to titular equality with kings. Petrarch, who in politics was no less visionary than Rienzi, hailed the advent of a founder and deliverer in the self-styled tribune. Without considering the impossibility of restoring the majesty of ancient Rome, or the absurdity of dignifying the mediæval Roman rabble by the name of *Populus Romanus*, he threw himself with passion into the republican movement, and sacrificed his old friends of the Colonna family to what he judged a patriotic duty.

Petrarch built himself a house at Parma in the autumn of 1347. Here he hoped to pursue the tranquil avocations of a poet honored by men of the world and men of letters throughout Europe, and of an idealistic politician, whose effusions on the questions of the day were read with pleasure for their style. But in the course of the next two years this agreeable prospect was overclouded by a series of calamities. Laura died of the plague on April 6, 1348. Francisco degli Albizzi, Mainardo Accursio, Roberto de' Bardi, Sennuccio del Bene, Luchino Visconti, the cardinal Giovanni Colonna, and several other friends followed to the grave in rapid succession. All of these had been intimate acquaintances and correspondents of the poet. Friendship with him was a passion; or what is more true perhaps, he needed friends for the maintenance of his intellectual activity at the highest point of its effectiveness. Therefore he felt the loss of these men acutely. We may say with certainty that Laura's death, accompanied by that of so many distinguished associates, was the turning-point in Petrarch's inner life.

When the jubilee of 1350 was proclaimed, Petrarch made a pilgrimage to Rome, passing and returning through Florence, where he established a firm friendship with Boccaccio. It has been well remarked that, while all his other friendships are shadowy and dim, this one alone stands out with clearness. Each of the two friends had a distinguished personality. Each played a foremost part in the revival of learning. Boccaccio carried his admiration for Petrarch to the point of worship. Petrarch repaid him with sympathy, counsel in literary studies, and moral support which helped to elevate the younger poet's over-sensuous nature. To

ward the close of the long struggle between Genoa and the republic of St. Mark, the Genoese entreated Giovanni Visconti to mediate on their behalf with the Venetians. Petrarch was intrusted with the office; and on November 8th he delivered a studied oration before the doge, Andrea Dandolo, and the great council. His eloquence had no effect; but the orator entered into relations with the Venetian aristocracy, which were afterward extended and confirmed. Charles IV. passed through Mantua in the autumn of 1354. There Petrarch made his acquaintance, and, finding him a man unfit for any noble enterprise, declined attending him to Rome. When Charles returned to Germany, after assuming the crowns in Rome and Milan, Petrarch addressed a letter of vehement invective and reproach to the emperor who was so negligent of the duties imposed on him by his high office. This did not prevent the Visconti sending him on an embassy to Charles in 1356. Petrarch found him at Prague, and, after pleading the cause of his masters, was dispatched with honor and the diploma of count palatine. His student's life at Milan was again interrupted, in 1360, by a mission on which Galeazzo Visconti sent him to King John of France.

The remaining years of Petrarch's life, important as they were for the furtherance of humanistic studies, may be briefly condensed. On May 11, 1362, he settled at Padua, from the neighborhood of which he never moved again to any great distance. On July 18, 1374, his people found the old poet and scholar dead among his books in the library of that little house which looks across the hills and lowlands toward the Adriatic.

As an author Petrarch must be considered from two points of view—first as a writer of Latin verse and prose, secondly as an Italian lyricist. In the former capacity he was speedily outstripped by more fortunate scholars. His eclogues and epistles and the epic of *Africa*, on which he set such store, exhibit a comparatively limited command of Latin meter. His treatises, orations, and familiar letters, though remarkable for a prose style which is eminently characteristic of the man, are not distinguished by purity of diction. With regard to his Italian poetry Petrarch occupies a very different position.

PETREL, the name applied in a general way to a group of birds (of which more than 100 species are recognized) from the habit which some of them possess of apparently walking on the surface of the water as the apostle St. Peter (of whose name the word is a diminutive form) is recorded to have done. For a long while the Petrels were ranked as a Family, under the name of *Procellariidæ*, and thought to be either very nearly allied to the gulls, *Laridæ*, or intermediate between that Family and the *Steganopodes*; but this opinion has gradually given way, and it is now hard to resist the conclusion that they have to be regarded as an "Order," to which the name *Tubinares* has been applied.

Petrels are dispersed throughout all the seas and oceans of the world, and some species apparently never resort to land except for the purpose of nidification, though nearly all are liable at times to be driven ashore, and often very far inland, by gales of wind. It would also seem that during the breeding-season many of them are wholly nocturnal in their habits, passing the day in holes of the ground, or in clefts of the rocks, in which they generally nestle, the hen of each pair laying a single white egg, sparsely speckled in a few species with fine reddish dots. Of those species that frequent the North Atlantic, the common Storm-Petrel, *Procellaria pelagica*, a little bird which has to the ordinary eye rather the look of a swift or swallow, is the "Mother Carey's chicken" of sailors, and is widely believed to be

the harbinger of bad weather; but seamen hardly discriminate between this and others nearly resembling it in appearance, such as Leach's or the Fork-tailed Petrel *Cymochorea leucorrhœa*, a rather larger but less common bird, and Wilson's Petrel, *Oceanites oceanicus*, the type of the Family *Oceanitidæ* mentioned above, which is more common on the American side. But it is in the Southern Ocean that Petrels most abound, both as species and as individuals.

PETRIE, GEORGE, Irish antiquary, was the son of James Petrie, a native of Aberdeen, who had settled in Dublin as a portrait and miniature painter. He was born in Dublin, in January, 1790, and died January 17, 1866.

PETROLEUM. The word "petroleum" (*rock-oil*) is used to designate the forms of bitumen that are of an oily consistence. It passes by insensible gradation into the volatile and ethereal naphthas on the one hand and the semi-fluid malthas or mineral tars on the other.

*History*—Petroleum has been known by civilized man from the dawn of history. Herodotus wrote of the springs of Zacynthus (Zante), and the fountains of Hit have been celebrated by the Arabs and Persians. Pliny and Dioscorides describe the oil of Agrigentum, which was used in lamps under the name of "Sicilian oil," and mention is made of petroleum springs in China in the earliest records of that ancient people. Petroleum was observed and described as early as 1814 in Washington county, Ohio, in wells at that time being bored for brine. In 1819 a well bored for brine in Wayne county, Ky., yielded so much black petroleum that it was abandoned. It has continued to yield small quantities until the present time. In 1829 a well drilled for brine near Burkesville, Cumberland county, Ky., yielded such a flow of petroleum that it was regarded as a wonderful natural phenomenon. This well is estimated to have yielded, up to 1860, 50,000 barrels of oil, the larger part of which was wasted. Of the rest a few barrels were bottled and sold as a liniment in the United States and Europe under the name of "American oil."

About the year 1847 E. W. Binney, of Manchester, England, called attention to the petroleum discovered at Riddings, near Alfreton, in Derbyshire, and a few years later he, together with James Young and others, commenced the manufacture of illuminating and other oils from it. The supply of crude material from this source soon became inadequate, and they then commenced distilling the Boghead mineral that had been found near Bathgate in Scotland. The success attending this enterprise soon attracted attention in the United States of America, and a number of establishments were in operation in the course of a few years, some of them being licensed under Young's patents. In 1851, when petroleum on Oil Creek was worth seventy-five cents a gallon in the crude state, it was tested as a crude material for the manufacture of illuminating oil by Messrs. William and Luther Attwood, and Joshua Merrill, at the United States Chemical Manufacturing Company's works at Waltham, near Boston, Mass., and its merits for that purpose fully established. But its scarcity at that time prevented its use in commercial quantities, and the establishments at Boston and at Portland, Me., under the charge of Messrs. Merrill and William Attwood, continued to use Boghead mineral and albertite for a number of years after petroleum was produced in sufficient quantity. Petroleum was refined and offered for sale in Pittsburgh, Penn., as early as 1855, but the quantity was too small to influence even the local trade; it, however, created a small demand for the crude oil. The well-known fact that brine-wells often produced petroleum led those

who sold the "American oil" to embellish the label on the bottles with a derrick and other accompaniments of a brine-well; and the story is told that the projector of the first well drilled exclusively for petroleum was led to undertake it through reflecting upon this picture. Some oil from one of the natural springs near Titusville, Penn., was sent to Prof. B. Silliman, Jr., of Yale College, and he made a report upon it which has become a classic in the literature of petroleum. This report was so satisfactory that a company was organized in New Haven, and E. L. Drake was sent to drill a well upon land that was leased in the valley of Oil Creek, a short distance below the spot where the city of Titusville now stands. The region was then almost a wilderness, and many delays were experienced before he succeeded in getting his men and machinery in operation. He was at first thwarted by quicksands and water, but he finally drove an iron pipe thirty-six feet down to the rock. This device, said to have been original with Drake, has been of great value in artesian boring ever since he used it. After drilling thirty-three feet on August 28, 1859, the drill fell suddenly six inches into a crevice, and was left until the next day, when the drill-hole was found to be nearly filled with petroleum. No spot in the entire territory where petroleum has since been obtained could have been selected where the oil was to be obtained nearer the surface. The success of this enterprise led to the immediate drilling of other wells, first in the valley of Oil Creek and its tributaries, and later over the higher land between Oil Creek and the Alleghany river below Tidioute. As this territory began to be exhausted, the region of the lower Alleghany, in Butler and Clarion counties, yielded wells of great richness, and finally the Bradford field in McKean county became the center of production. A careful comparison of the situations of some of the most productive wells led to the discovery that the areas yielding oil were not irregular in outline, but extended across the country in narrow belts, without regard to the present configuration of the surface. The areas of these belts were in general parallel, and extended in a northeast and southwest direction, 15° to 20° from the meridian. As the exhaustion of the oil-fields of Butler and Clarion counties led producers to seek a more productive locality, lines were run by compass on the supposed axis of the oil-belt over forest-covered hills for many miles, until they reached the town of Bradford, near which wells had previously been drilled without success. Deeper wells were drilled, and oil was obtained, resulting in the development, since 1875, of the most uniformly productive and extensive oil-territory yet discovered.

In the province of Ontario, Canada, principally in the vicinity of Enniskillen, a territory of limited extent but great productiveness has been under development for the last twenty years. In the region about Baku and in the valley of the Kuban, at the eastern and western extremities of the Caucasus, petroleum has been obtained for an unknown period, and is now being produced from artesian borings in large quantities. In Galicia and Roumania it is also obtained in commercial quantities. These regions, with the United States, furnish the petroleum of commerce. Japan, China, Burmah, and Italy have yielded petroleum in quantities sufficient to supply a local demand, but the vast quantity of the American oil and low prices at which it is furnished have rendered the production in these countries unprofitable.

*Geographical Distribution.*—Petroleum "was found about one hundred years since in making the duke of Bridgewater's tunnel at Worsley, at Wigan, and West Leigh in the Lancashire coal-fields. at Coalbrookdale

and Wellington in Shropshire and Riddings in Derbyshire, two other coal-fields; also in a peat-bog at Down Holland, near Ormskirk, in Lancashire, but never in commercial quantities. The greatest supply has not been more than fifty gallons a day, and even that soon diminished." A tar-spring was known at Coalport, in Shropshire, early in the present century. Although there are extensive deposits of solid bitumen in eastern France and Switzerland, the petroleum springs that occur at Saint Boès, Basses Pyrénées, are unimportant. In Alsace, at Lobsann and Bechelbronn, petroleum has been obtained for many years for local uses. Although reported from many localities in Germany, the only point that has promised to be of any importance is the Lüneburg heath, south of Hamburg. Petroleum is also reported near Hölle, in Dithmarschen, Schleswig-Holstein. On the eastern shores of the Adriatic—in Dalmatia and Albania—and in the Ionian Islands, petroleum springs have been mentioned by the writers of classical antiquity. In Armenia and Persia petroleum has been used for unknown centuries, and it appears to be widely distributed in the mountains that surround the table-land of Iran. In Algeria, Egypt, Kashmir, the Punjab, Assam, Java, and other East Indian islands petroleum is reported. In North America the successful development of the petroleum-fields of northwest Pennsylvania following the completion of Drake's well led in a few years to the drilling of wells in a great many localities where petroleum springs had been observed. The following so-called "petroleum-fields" have, according to last census, produced oil in commercial quantities more or less valuable:—

NAME.	Maximum production in	Yield in barrels to 1880.
Oil Creek, Venango county, Penn.....	1862	35,517,297
Pithole, Venango county, Penn.....	1866	8,816,289
Central Alleghany, Venango county, Penn.	1871	6,182,900
Lower Alleghany, Butler and Clarion counties, Penn.....	1874	37,342,978
Tidioute, Venango and Warren counties, Penn.....	1874	4,674,345
Bullion, Venango county, Penn.....	1877	2,312,090
Bradford, McKean county, Penn.....	1881	44,574,921
Warren, Warren county, Penn.....	1878	448,213
Smith's Ferry, Beaver county, Penn.....	1879	339,631
Mecca, Trumbull county, Ohio.....	} A continuous small production since 1865. No record.	
Grafton, Lorain county, Ohio.....		
Macksburg, Washington county, Ohio...		
Horse Neck, Pleasants county, W. Va...		
Volcano, Wood county, W. Va.....		
Burning Spring, Wirt county, W. Va ...		
Glasgow, Barren county, Ky.....		
Santa Clara Valley, Ventura county, Cal.		

Besides these localities petroleum has been observed over an area 1,500 miles long by an unknown breadth in the valleys of the Mackenzie and its tributaries, and in New Brunswick, Newfoundland, and other portions of eastern Canada. It also occurs at many different points along the Appalachian system of mountains from Point Gaspé, on the St. Lawrence, to northern Alabama. It has been noticed in Kansas, Missouri, Wyoming, Colorado, and Texas in the United States, in southern Mexico, in the West India Islands, and in the northern states of South America. Petroleum is one of the most widely distributed substances occurring in nature, but an examination of the geographical localities in which it chiefly occurs will show them to be intimately connected with the principal mountain-chains of the world.

In both Galicia and the Caucasus, which, with Canada and the United States, now furnish the petroleum of commerce, the ancient methods of production are being

rapidly superseded by those employed in America. In the United States the development of oil-territory has acquired a habit that has become well defined, and has been repeatedly exemplified during the last twenty years. The first step is the sinking of a test or "wildcat" well outside the limits of any proved productive territory, the progress of such well being eagerly watched not only by those who pay for it but also by many others who hope to profit by the experiment. The striking of oil in such a well is the signal for a grand rush, and a speculative floating population invades the place. After a time the speculative phase is succeeded by that of settled development. The oil-territory has become outlined. The sagacious ones have secured control of the most profitable tracts, while the floating element has moved on to a new field. Between the period of active development and absolute exhaustion comes that of decay, when the derricks are rotting and falling to wreck, and when property that has ceased to be productive has been sold at an extravagant price, and after accumulating debts has been abandoned. Finally the wave passes over and nature restores as she restores after the ruin of battle-fields. A visit to Pithole City, which in 1865 was, next to Philadelphia, the largest postoffice in Pennsylvania, showed in 1881 fields of maize and timothy where some of the most famous wells had been, and of the city a score of houses tumbling to decay and not an inhabitant. It is not to be inferred, however, that any of the sections into which the oil regions have been divided entirely cease to produce oil. There are wells now producing within sight of the spot where Drake drilled the first well; but large tracts cease to be centers of speculative investment, the old wells cease to be remunerative, and the new wells no longer hold out the possibilities of a grand lottery.

*Technology.*—The technology of petroleum is quite simple. In the crude state it enters largely into mixtures with other oils, tallow, lead, soap, graphite, etc., that are chiefly used for lubrication. Crude petroleum is also filtered through charcoal. Crude oils that are too fluid for lubrication are reduced to the required consistency by partial evaporation, both by exposure to the sun in shallow tanks and also by distillation of the more volatile portion in stills. Such oils are called "reduced oils."

*Lubricating Oils.*—Crude petroleum and the heavy distillates from petroleum, finished either by treatment or by filtration, have been slowly winning their way with consumers of lubricating oils for the last twenty years, and may now be said to have a recognized value. This result has been due as much to improved processes of manufacture, and consequently to improved quality of the products, as to a recognition of their merits. When properly prepared, and exempt from volatile matter and offensive odor, they are found to be possessed of great endurance, to be free from a tendency to gum, and to be incapable of spontaneous combustion. When mixed with animal and vegetable oils liable to spontaneous combustion, these oils prevent it. They are therefore now in large demand, a demand which is likely to increase as new applications are found for them and their quality is improved.

*Illuminating Oils.*—Oils of this class manufactured from petroleum have nearly superseded the use of other illuminating fluids throughout the world. They are largely sold in Great Britain under the name of "paraffin oils;" in the United States they are called "kerosene," and on the European continent "refined petroleum." The different qualities are known as "water white," "standard," and "prime," and are further distinguished as "low test" and "high test" oils. The characters chiefly relied on in the trade are "color" and

"test." The color should be as light and free from opalescence as possible. Color is, however, a matter of little importance, except as it indicates unskillful manufacture of the oil. The "test" is of paramount importance, and indicates the temperature Fahr. at which the oil will give off a sufficient amount of vapor to ignite explosively when the oil is properly tested.

*The Uses of Naphtha.*—The lightest products obtained from petroleum are rhigolene, which is used in surgery, and cymogene, which is used as the volatile fluid in ice-machines. Gasolene is the lightest fluid obtained in considerable quantity, and is used in automatic gas-machines for the carburation of gas or air. The question of increasing the illuminating power of gas (see GAS) by causing it to absorb fluid hydrocarbons, was discussed as early as 1832, but it was only after petroleum furnished a cheap and suitable fluid that inventors succeeded in securing results of any value. While hundreds of machines have been patented in England, America, and continental Europe for accomplishing this purpose, it is only quite recently that an American inventor, Dr. Walter M. Jackson, has succeeded in constructing a machine that satisfactorily meets all the requirements of the problem. His metrical carbureter measures both the fluid and the gas or air in such a manner that the least amount of the hydrocarbon fluid required to produce the effect sought is furnished to the gas, and the whole is immediately absorbed. By this means a uniform carburation is secured, furnishing a gas of uniform quality, that never contains a sufficient amount of fluid to admit of condensation in any part of the apparatus. Both crude petroleum and the products of its manufacture have been used as a material for the manufacture of gas by distillation. The different qualities of naphtha are used in mixing paint, in the manufacture of oil-cloths for floors and of varnishes, as a solvent for gums and resins, in the preparation of alkaloids, in the manufacture of india-rubber, in washing wool, and in removing oils and grease from seeds and textile fabrics.

*Petroleum as Fuel.*—In the region of the Caucasus and on the Caspian Sea, where other fuel is scarce and dear and petroleum is plentiful and cheap, the latter is used with complete success on both steamships and locomotives. Petroleum and its products have been used with practical success in the manufacture of iron in the United States. Both illuminating oil and naphtha are now very widely used in stoves; but naphtha-stoves are extremely dangerous, and their use should be prohibited by law. In the valley of the Euphrates, near Mosul, petroleum is used as a fuel in burning lime.

*Petroleum in Medicine.*—Although petroleum has been used as a remedial agent for an unknown period in the countries where it is a natural product, its physiological effects have never been fully investigated. Barbados tar, Haarlem oil, Seneca oil, and American oil, all consisting wholly or in large part of crude petroleum, were sold by apothecaries for years before petroleum was obtained by boring. They were mainly used as liniments for external application, particularly in rheumatism. The oil of the Alleghany valley early had a local reputation as an internal remedy for consumption, and it has lately been prescribed for bronchitis. The most volatile product of petroleum obtained by distillation, called rhigolene, has been used to produce local insensibility, by means of the intense cold resulting from its rapid evaporation; and the same fluid when inhaled as vapor or the gas escaping from fresh oil will produce an intoxication or insensibility resembling the effects of laughing-gas, resulting in death if its action is prolonged. The products of petroleum that have proved most valuable in medicine are the filtered paraffin residues sold

under the names of cosmoline, vaseline, etc., that are now so widely used as ointments, either plain or medicated. They are of about the consistence of butter, with very little taste or odor, and will keep indefinitely without becoming rancid. These valuable properties have caused them to almost entirely supersede all other preparations containing animal or vegetable fat.

Looking toward the past, it may be said that petroleum has attained universal diffusion as a lighting agent; it is fast displacing animal and vegetable oils as a lubricator on all classes of bearings, from railroad-axles to mule-spindles, and also where other oils are liable to spontaneous combustion; it is very largely used as fuel for stoves, both for heating and cooking; it is very successfully used for steam purposes when other fuel is scarce and petroleum plentiful; it is likely to be used for the production of pure iron for special purposes; and it has become a necessity to the apothecary as petroleum ointment. Looking toward the future, what assurance have we that these varied wants, the creation of a quarter of a century, will be satisfied? While it is not probable that the deposits of petroleum in the crust of the earth are being practically increased at the present time, there is reason to believe that the supply is ample for an indefinite period. Yet the fact is worthy of serious consideration that the production of petroleum as at present conducted is everywhere wasteful in the extreme.

PETROLOGY. See ROCKS.

PETRONIUS. Petronius Arbiter, although excluded from the list of classical writers available for the purposes of education, is one who enjoyed a great reputation, especially in France, at a time when Latin authors were more read as literature than they are in the present day. A recent critic of Petronius has stated, though with evident exaggeration, that no ancient writer except Aristotle has found so many interpreters as has his *Satire*. But there is perhaps none about whose history and era there has been so much controversy, nor is the controversy yet settled with absolute certainty. His place of residence, in his later years at least, was not Marseilles but Rome. There is nothing, however, in what Tacitus says incompatible with the supposition that Marseilles was his birthplace.

The account given of C. Petronius is "that he spent his days in sleep, his nights in attending to his official duties or in amusement, that by his dissolute life he had become as famous as other men by a life of energy, and that he was regarded as no ordinary profligate, but as an accomplished voluptuary. His reckless freedom of speech, being regarded as frankness, procured him popularity. Yet during his provincial government, and later when he held the office of consul, he had shown vigor and capacity for affairs. Afterward returning to his life of vicious indulgence, he became one of the chosen circle of Nero's intimates, and was looked upon as an absolute authority on questions of taste in connection with the science of luxurious living." This excited the jealousy of Tigellinus, and led to his condemnation. Petronius' death is then described, which was in keeping with his mode of life and character. He selected the slow process of opening his veins and having them bound up again, while in conversing with his friends he avoided the serious subjects natural at such a time, and listened to their recitation of light odes and trifling verses. He then dined luxuriously, slept for some time, and, so far from imitating the practice of others by flattering Nero or Tigellinus in his will, he wrote, sealed, and sent to the emperor a document which professed to give, with the names of the partners of his vices, a detailed account of the scandalous life of the court.

PETROPAVLOVSK, a district town of western Siberia, in the government of Akmolinsk, is situated on

the right bank of the Ishim river, 185 miles to the west of Omsk. The fertile steppes to the east, west, and south of the town largely supply it with corn and cattle, and at the same time give great facilities for trade with the Kirghiz, with Turkestan, and with Bokhara. The town has several tallow-melting houses, tanneries, and glue and soap works; and its industries are steadily increasing. The population (7,850 in 1865) now exceeds 11,500.

PETROPOLIS, a town of Brazil, in the province of Rio de Janeiro, lies at a height of 2,400 feet above the sea on a beautiful and healthy plateau, surrounded by the wooded heights of the Serra da Estrella, which lie between it and the coast region. It is about twenty-five miles almost due north from Rio de Janeiro, and is reached by a railway (twenty-two miles) from Maua; the last ten and one-half miles are on the Rigi system. Founded by the emperor of Brazil as a colony for distressed German immigrants, Petropolis has grown into an elegant and thriving town of 8,000 or 10,000 inhabitants, and, besides the royal palace and park, has a number of good hotels and public buildings.

PETROVSK, a town of European Russia, in the province of Saratoff, lies on both banks of the Medveditza, a tributary of the Don, sixty-four miles north-northwest of Saratoff on the Volga by the highway to Moscow. It was founded by Peter I. in 1698 to defend the district from the encroachments of the Kuban Tartars, and by the beginning of the nineteenth century it had become a place of 6,921 inhabitants, with ten churches and a monastery (St. Nicholas). In 1864 the population was 10,128, and it has since increased to upward of 15,000.

PETROZAVODSK, a town of Russia, capital of the government of Olonetz, lies on the western shore of Lake Onega, 300 miles to the northeast of St. Petersburg. The government cannon-foundry can turn out annually more than 5,000 tons of pig-iron, and the same weight of guns, gun-carriages, and ammunition, but its actual production is subject to great fluctuations. Within the district there are a few private iron-works as well as important sawmills. The inhabitants engage in agriculture and fishing, and there is some trade with St. Petersburg—timber, fish, and furs being exported in exchange for corn, groceries, and manufactured wares. The population (11,027 in 1865) was 11,970 in 1881.

PETTY, SIR WILLIAM, statistician and political economist, and author of the *Down Survey of Irish Lands*, was born on May 26, 1623. His first publication was a letter to Samuel Hartlib in 1648, entitled *Advice for the Advancement of some Particular Parts of Learning*. In 1649 he obtained the degree of doctor of physic, and was soon after elected a fellow of Brasenose College. He gained some notoriety in 1650 by restoring to life a woman who had been hanged for infanticide. In 1663 he attracted much notice by the success of his invention of a double-bottomed ship, which twice made the passage between Dublin and Holyhead, but was afterward lost in a violent storm. He was one of the first members of the Royal Society, and sat on its council. He died at London on December 16, 1687, and was buried in the church of his native place.

PETUNIA. See HORTICULTURE.

PEUTINGER, CONRAD, born in 1465, died in 1547, a prominent and useful citizen of Augsburg, remembered for his services to the new learning. He was one of the first to publish Roman inscriptions, and his name remains associated with the famous *Tabula Peutingeriana*, which was in his hands when he died, and was found again among his MSS. in 1714.

PEWTER is a generic term for a variety of alloys

which all agree in this, that tin forms the predominating component. The finest pewter (sometimes called "tin and temper") is simply tin hardened by the addition of a trifle of copper. Ordinary pewter is tin alloyed with lead, which latter ingredient is added chiefly on account of its cheapness, and therefore often in excessive proportion. The law of France restricts the percentage of lead to 16.5, with a toleration of 1.5 per cent. of error, an alloy of this or higher degree of richness in tin being, according to an old investigation by Vauquelin, as proof against sour wine or vinegar as pure tin is. Higher percentages of lead are dangerous, and besides spoil the appearance of the alloy. The composition of an alloy containing only these two components can be ascertained approximately by determining the specific gravity.

Plate Pewter is a hard variety much used for plates and dishes; a good quality is composed of 100 parts of tin, 8 of antimony, 2 of bismuth, and 2 of copper. Closely allied to it is the silver-white alloy called "Britannia metal," which is much used in Great Britain for the making of teapots more especially.

PFAFF, CHRISTIAN HEINRICH (born 1773, died 1852), chemist and physicist, younger brother of J. F. Pfaff, noticed below, took his degree as doctor of medicine at Stuttgart, in 1793. His work in chemistry was chiefly analytical and mineralogical. In physics he was distinguished as one of the earlier experimenters with the voltaic current, and had a considerable share in the experimental investigation of its properties. He also made important researches on the carrying power of magnets, more particularly on the effect of the extent of the attracting surface.

PFAFF, JOHANN FREIDRICH, German mathematician, was born December 22, 1765, at Stuttgart. In 1788 Pfaff became professor of mathematics in Helmstädt, and so continued until that university was abolished in 1810. From that time till his death (April 20, 1825), he held the chair of mathematics at Halle.

Another brother of this family, JOHANN WILHELM ANDREAS PFAFF, who was born in 1774 and died in 1835, was professor of pure and applied mathematics successively at Dorpat, Nuremberg, Würzburg, and Erlangen.

PFALZBURG, a town of German Lorraine, lies high on the west slopes of the Vosges, twenty-five miles to the north-northwest of Strasburg. In 1880 it contained 3,379 inhabitants (mainly Roman Catholics).

PFEIFFER, FRANZ, an eminent writer on mediæval German literature, and on old forms of the German language, was born at Solothurn, Switzerland, on February 27, 1815. In 1857, having established his fame as one of the foremost authorities on his special subject, he was appointed professor of German literature and language at the university of Vienna; and in 1860 he was made a member of the Imperial Academy of Sciences. He died on May 29, 1868.

PFEIFFER, IDA LAURA, traveler, was born at Vienna, the daughter of a merchant named Reyer, October 14, 1797. Ida was the only sister of six brothers, and in her youth acquired masculine habits. Her training was Spartan, and accustomed her to the endurance of hardships and deprivations. On May 1, 1820, she married Doctor Pfeiffer, a prosperous advocate of Lemberg, twenty-four years older than herself. In 1842 Madame Pfeiffer visited Egypt and Palestine, and, with considerable hesitation, published an account of her journey in three small volumes, *Reise einer Wienerin in das Heilige Land*, in 1845. In the same year she set out again, this time to Scandinavia and Iceland, describing her tour in two volumes. In 1846 she started on her first journey round the world. The results were

published in three volumes at Vienna in 1850, under the title *Eine Frauenfahrt um die Welt*. For her next and most extensive journey she received the support of the Austrian Government to the small extent of \$625. Starting in 1851 she reached home in 1854. Her narrative, *Meine zweite Weltreise*, was published in four volumes at Vienna in 1856. After being detained by her sufferings in Mauritius for some months, Ida returned by England to Vienna, where she died October 27, 1858. The *Reise nach Madagascar* was issued in 1861, with a biography by her son.

PFORZHEIM, one of the chief industrial towns in the grand-duchy of Baden, is pleasantly situated at the confluence of the Nagold, the Würm and the Enz, on the northern margin of the Black Forest, fifteen miles to the southeast of Carlsruhe. The staple industry is the manufacture of gold and silver ware and jewelry, which gives employment to nearly 10,000 workmen, besides which there are iron and copper works, and manufactures of chemicals, paper, leather, cloth, and other articles. A brisk trade is maintained in timber, cattle, and agricultural produce. In 1890 the population was 29,508.

Pforzheim (Porta Hercyniæ) is of Roman origin, and has belonged to Baden for 600 years.

PIÆDRUS, the author of five books of Latin fables in verse, lived in the reigns of Augustus, Tiberius, Caligula, and Claudius. To his literary vanity we owe most of our scanty knowledge of his life. He was born on the Pierian Mountain, in Macedonia, but seems to have been brought at an early age to Italy, for he mentions that he read a verse of Ennius as a boy at school. According to the heading of the chief MS. he was a slave and was freed by Augustus. He incurred the wrath of Sejanus, the powerful minister of Tiberius, but on what grounds is not known. Devoting himself to literature, he lived in poverty and died at an advanced age.

PHAETHON ("the shining one"), in Homer an epithet of the sun, and used by later writers as a name for the sun, is more generally known in classical mythology as a son of the Sun and the ocean nymph Clymene. He persuaded his father to let him drive the chariot of the sun across the sky, but he lost control of the horses, and driving too near the earth scorched it; mountains were set on fire, rivers and seas dried up, Libya became a desert, and the Æthiopians were blackened by the heat. To save the earth from utter destruction Zeus killed Phaethon with a thunderbolt. He fell to earth at the mouth of the Eridanus, a river of northern Europe (identified in later times with the Po), on the banks of which his weeping sisters were transformed into poplars and their tears into amber.

PHAGEDÆNA (Gr. from φαγείν, *phagein*, to eat or corrode) designates a variety of ulceration in which there is much infiltration, and at the same time rapid destruction of the affected part. The sore presents an irregular outline, and a yellowish surface; it gives off a profuse bloody or ichorish discharge, and is extremely painful. It usually attacks persons whose constitutions are vitiated by scrofula, by congenital syphilis, by the abuse of mercury, by intemperance, etc. It not very infrequently appears in the throat after scarlatina in a severe form. If relief is not afforded by the internal administration of opium (to allay the pain), and of quinia, or some other preparation of cinchona, wine, beef-tea, etc., to improve the tone of the constitution, together with astringent and sedative local applications, subacetate of lead, kino, tannate of iron, etc., recourse must be had to the destruction of the part by chloride of zinc (Canquoin's paste) or in some cases actual cautery (white-hot iron). Nitric acid should not be used, as it frequently induces phagedæna, and care should be taken that all parts of the ulcer are cauterized, else the

uncauterized portions will speedily reinfect the whole sore.

**PHALANGER.** Phalangers as a whole are small woolly-coated animals, with long, powerful, and often prehensile tails, large claws, and, as in the American opossums, with opposable nailless great toes. Their expression seems in the day to be dull and sleepy, but by night they appear to decidedly greater advantage. They live mostly upon fruit, leaves, and blossoms, although some few feed habitually upon insects, and all relish, when in confinement, an occasional bird or other small animal. Several of the phalangers possess flying membranes stretched between their fore and hind limbs, by the help of which they can make long and sustained leaps through the air, like the flying squirrels; but it is interesting to notice that the possession of these flying membranes does not seem to be any indication of special affinity, the characters of the skull and teeth sharply dividing the flying forms, and uniting them with other species of the non-flying groups. Their skulls are as a rule broad and flattened, with the posterior part swollen out laterally, owing to the numerous air-cells situated in the substance of the squamosals. The dental formula is very variable, especially as regards the pre-molars, of which some at least in each genus are reduced to mere functionless rudiments, and may even vary in number on the two sides of the jaw of the same individual. The incisors are always  $\frac{3}{1}$ , the lower one very large and proclivous, and the canines normally  $\frac{1}{1}$ , of which the inferior is always minute, and in one genus generally absent. The true molars number either  $\frac{4}{3}$  or  $\frac{3}{3}$ .

The true phalangers, or opossums as they are called by the Australian colonists, consist of four or five hardly separable species, of which the best known is the Vulpine Phalanger (*Ph. vulpecula*), so common in zoölogical gardens, where, however, it is seldom seen, owing to its nocturnal habits. It is of about the size and general build of a small fox, whence its name; its color is gray, with a yellowish-white belly, white ears, and a black tail. It is a native of the greater part of the continent of Australia, but is replaced in Tasmania by the closely allied Brown Phalanger (*Ph. fuliginosa*). Its habits are very similar to those of the Yellow-bellied Flying-Phalanger (*Petaurus australis*), except that, of course, it is unable to take the wonderful flying leaps so characteristic of that animal. Like all the other phalangers, its flesh is freely eaten both by the natives and by the lower class of settlers.

**PHALARIS**, a Greek tyrant, who ruled Agrigentum (Acragas), in Sicily, for sixteen years (probably between c. 571 and 549 B.C.), was the son of Laodamas, and his family belonged to the Dorian island of Astypakæa, near Cnidus. As a leading man in the new city (for Agrigentum had been founded by the neighboring city of Gela only a few years before, 582 B.C.), Phalaris was intrusted with the building of the temple of Zeus Atabyrius on the citadel, and he took advantage of his position to make himself master of the city. Under his rule Agrigentum seems to have attained a considerable pitch of external prosperity.

**PHALLUS**, a representation of the male generative organs, used at certain Dionysian festivals in ancient Greece as a symbol of the powers of procreation. The bearers of the phallus, which generally consisted of red leather, and was attached to an enormous pole, were the Phallophoroi. Phalli were on those occasions worn as ornaments around the neck, or attached to the body. Phalli were often attached to statues, and of a prodigious size; sometimes they were even movable.

**PHARAOH**, which the Old Testament often uses as if it were a proper name, applicable to any king of

Egypt, though sometimes such a distinguishing name as Hophra or Nechoh (Nekos) is added, is really an Egyptian title of the monarch (Perāa or Phuro), often found on the monuments. Apart from Hophra and Necho the Biblical Pharaohs cannot, in the present state of Hebrew and Egyptian chronology, be identified with any certainty.

**PHARISEES**, the Jewish party of the scribes, the opponents of the Sadducees. (See ISRAEL and MESSIAH.)

**PHARMACOPŒIA** (lit. the art of the drug compounder) in its modern technical sense denotes a book containing directions for the identification of simples and the preparation of compound medicines, and published by the authority of a government or of a medical or pharmaceutical society. The name has also been applied to similar compendiums issued by private individuals.

National pharmacopœias now exist in the following countries:—Austria, Belgium, Denmark, France, Germany, Great Britain, Greece, Holland, Hungary, India, Mexico, Norway, Portugal, Russia, Spain, Sweden, and the United States. The Argentine Republic, Chili, and Japan have each a pharmacopœia in preparation. All the above-mentioned were issued under the authority of government, and their instructions have the force of law in their respective countries, except those of the United States and Mexico, which were prepared by commissioners appointed by medical or pharmaceutical societies, and have no other authority, although generally accepted as the national textbooks. Italy has no national pharmacopœia, the authorities used in the different States prior to the unification being still retained. Sardinia, for example, has a pharmacopœia dating from 1853; Modena, Parma, and Piacenza have one in common, published in 1839; in the States of the Church as well as in Tuscany and Lucca, an unofficial compilation is in use entitled *Orosi Farmacologia technica practica ovvero Farmacologia Italiana*; Naples has its *Ricettario Farmaceutico Napolitano* (1859); and Lombardy and Venice use the Austrian pharmacopœia. Although Switzerland has a national pharmacopœia, this does not possess government authority, the French *Codex* being recognized in Geneva, and the canton of Ticino having a pharmacopœia.

The French *Codex* has probably a more extended use than any other pharmacopœia outside the limits of its own country, being, in connection with Dorvault's *L'Officine*, the standard for druggists in a large portion of Central and South America; it is also official in Turkey. The sum-total of the drugs and preparations it contains is about 2,000, or more than double the average of other modern pharmacopœias. The progress of medical knowledge during the last two hundred years has led to a gradual but very perceptible alteration in the contents of the various pharmacopœias. The original very complex formulæ have been gradually simplified until only the most active ingredients have been retained, and in many cases the active principles have to a large extent replaced the crude drugs from which they were derived. From time to time such secret remedies of druggists or physicians as have met with popular or professional approval have been represented by simpler official preparations.

*International Pharmacopœia.*—The increased facilities for travel during the last fifty years have brought into greater prominence the importance of an approach to uniformity in the formulæ of the more powerful remedies, such as the tinctures of aconite, opium, and nux vomica, in order to avoid danger to patients when a prescription is dispensed in a different country from that in which it was written. Attempts had been made during the

last few years by international pharmaceutical and medical conferences to settle a basis on which an international pharmacopœia could be prepared, but, owing to national jealousies and the attempt to include too many preparations in such a work, it had not as yet been produced. At the fifth International Pharmaceutical Congress, held in London in 1881, however, a resolution was passed to the effect that it was necessary that such a pharmacopœia should be prepared, and a commission, consisting of two delegates from each of the countries represented, was recommended to be appointed in order to prepare within the shortest possible time a compilation in which the strength of all potent drugs and their preparations should be equalized—the work, when complete, to be handed over to their respective governments or to their pharmacopœia committees. This has since been done and the various tinctures and fluids are now of uniform strength.

**PHEASANT**, Middle-English *Fesaunt* and *Fesaun*, German *Fasan* and anciently *Fasant*, French *Faisan*—all from the Latin *Phasianus* or *Phasiana* (*sc. avis*), the bird brought from the banks of the river Phasis, now the Rioni, in Colchis, where it is still abundant, and introduced by the Argonauts, it is said, in what passes for history, into Europe. As a matter of fact nothing is known on this point.

Within recent years the practice of bringing up Pheasants by hand has been extensively followed, and the numbers so reared vastly exceed those that are bred at large. The eggs are collected from birds that are either running wild or kept in a mew, and are placed under domestic hens; but, though these prove most attentive foster-mothers, much additional care on the part of their keepers is needed to insure the arrival at maturity of the poults; for, being necessarily crowded in a comparatively small space, they are subject to several diseases which often carry off a large proportion, to say nothing of the risk they run by not being provided with proper food, or by meeting an early death from various predatory animals attracted by the assemblage of so many helpless victims. As they advance in age the young pheasants readily take to a wild life, and indeed can only be kept from wandering in every direction by being plentifully supplied with food, which has to be scattered for them in the coverts in which it is desired that they should stay.

Of the many other species of the genus *Phasianus*, two only can be dwelt upon here. These are the King-necked Pheasant of China, *P. torquatus*, easily known by the broad white collar, whence it has its name, as well as by the pale grayish-blue of its upper wing-coverts and the light buff of its flanks, and the *P. versicolor* of Japan, often called the Green Pheasant from the beautiful tinge of that color that in certain lights pervades almost the whole of its plumage, and, deepening into dark emerald, occupies all the breast and lower surface that in the common and Chinese birds is bay barred with glossy black scallops. Both of these species have been to a considerable extent introduced into England, and cross freely with *P. colchicus*, while the hybrids of each with the older inhabitants of the woods are not only perfectly fertile *inter se*, but cross as freely with the other hybrids, so that birds are frequently found in which the blood of the three species is mingled. The hybrids of the first cross are generally larger than either of their parents, but the superiority of size does not seem to be maintained by their descendants. White and pied varieties of the common Pheasant, as of most birds, often occur, and with a little care a race or breed of each can be perpetuated. A much rarer variety is sometimes seen; this is known as the Bohemian Pheasant.

**PHENOL**. See CARBOLIC ACID.

**PHERECRATES**, one of the chief poets of the Old Attic Comedy, was a contemporary of Cratinus, Crates, and Aristophanes, being older than the last and younger than the two former. At first an actor, he seems to have gained a prize for a play in 438 B. C. The only other ascertained date in his life is 420, when he produced his play *The Wild Men*. Like Crates, whom he imitated, he abandoned personal satire for more general themes.

**PHERECYDES OF SYROS**, one of the earliest Greek philosophers, was the son of Babys and a native of the island of Syros. The dates of his life are variously stated, but there seems to be no doubt that he lived in the sixth century B. C.; among his contemporaries were Thales and Anaximander. He was sometimes reckoned one of the Seven Wise Men, and a very uniform tradition represented him as the teacher of Pythagoras.

**PHIDIAS**, the most famous of Greek sculptors, was born about 500 B. C., and began his artistic career, probably under the guidance of his father, Charmides of Athens, with the study of painting, an art which at that time had attained a singular largeness and dignity of style, while in sculpture these qualities were as yet being sought for with only a somewhat bold and rude result, as may be seen from the remains of it now at Olympia.

To obtain something like a fair judgment of the style of Phidias it is to the sculptures of the Parthenon now in the British Museum that we must turn. Though executed in what was to him an inferior material, marble, it yet happened that the elevated position which these sculptures were to occupy on the temple was such as to give scope for the highest powers of composition, and so far they may be regarded as a worthy monument of his genius. He must, however, have found finer opportunities in the colossal statues of gold and ivory, where the greater difficulty of duly distributing light and shade was rewarded with greater splendor of effect. In these statues the nude parts, such as the face, hands, and feet, were of ivory, the drapery of gold; and in the statue of *Zeus* at Olympia the gold was enriched with enameled colors, and the impression of the whole is described by ancient writers with unbounded praise. Of the *Athena* in the Parthenon there exist two small copies in marble found in Athens, but so rude in execution as to be of no service in conveying a notion of the style of the original. On the acropolis, and not far from the Parthenon, stood a colossal bronze statue of *Athena Promachos* by Phidias, the attitude and to some extent the type of which may be gathered from the small bronze found at Athens. In Elis he executed a statue of *Aphrodite* in gold and ivory, and at Plataea a colossal *Athena* of wood gilt, with the face, hands, and feet of Pentelic marble. Bright but simple colors had been traditional in art before the time of Phidias. It is not supposed that he had sought to refine upon them as a colorist. What he did was to combine with their simplicity and brightness the ideal largeness and dignity of conception which he shared with the great painters of his day, and the perfection of execution which he shared with the greatest of contemporary sculptors.

**PHIGALIA**, a city in the southwest angle of Arcadia, situated on an elevated rocky site, among some of the highest mountains in the Peloponnesus—the most conspicuous being Mount Cotylium and Mount Elæum; the identification of the latter is uncertain.

**PHILADELPHIA**, the name of several cities of antiquity, of which the two most important have been noticed under ALA-SHEHR and AMMONITES.

**PHILADELPHIA**, the chief city of Pennsylvania, and the third city in the United States, is situated on the west bank of the Delaware river, 96 miles

from the Atlantic and in a direct line 125 miles northeast of Washington, D. C., and 85 miles southwest of the city of New York. Its greatest length north-northeast is 22 miles, its breadth from 5 to 10 miles, and its area 82,603 acres, or about 129 square miles (greater than that of any other city in America except Chicago). The surface of the city between the rivers Delaware and Schuylkill—the latter running parallel with the Delaware and dividing the city about in half, east and west—is remarkably level. It varies, however, in elevation from 24½ feet above the sea to 440 feet, the latter in the northern and suburban sections. The eastern and western sections of the city are connected by eight bridges. The length of the river-front on the Delaware is nearly twenty miles, and the length of wharves five miles. On both sides of the Schuylkill, to Fairmount dam, the front is sixteen miles and the length of wharves four miles. The mean low-water mark of the Delaware is twenty-four feet, and the tide rises six feet, while the average depth of water at the city wharves is fifty feet. The wharf-line, which varies from fourteen feet to sixty-eight feet, gives extraordinary accommodation for shipping. The Delaware is navigable at all seasons of the year for vessels of the heaviest burden, and Philadelphia affords one of the best protected harbors in the country. The substratum of the city is a clay soil mixed with more or less sand and gravel.

The site of the present Philadelphia was originally settled by the Swedes, and so Penn found it when he came to lay out the city; and many of the original patentees for town lots under him were descendants of these first settlers. The original city limits were from east to west 10,922 feet 5 inches, and from north to south 5,370 feet 8 inches, or more than two square miles. The boundaries were Vine street on the north, Cedar (now South) street on the south, the Delaware river on the east, and the Schuylkill river on the west. And this was the city of Philadelphia from its foundation until February 2, 1854, when what is known as the Consolidation Act was passed by the legislature of the State, and the old limits of the city proper were extended to take in all the territory embraced within the then county of Philadelphia. This legislation abolished the districts of Southwark, Northern Liberties, Kensington, Spring Garden, Moyamensing, Penn, Richmond, West Philadelphia, and Belmont; the boroughs of Frankford, Germantown, Manayunk, White-Hall, Bridesburg, and Aramingo; and the townships of Passyunk, Blockley, Kingsessing, Roxborough, Germantown, Bristol, Oxford, Lower Dublin, Moreland, Bybery, Delaware, and Penn; and it transferred all their franchises and property to the consolidated city of Philadelphia under one municipal government. The present boundaries of the city are: on the east the Delaware, on the northeast Bucks county, on the north-northwest and west Montgomery county, and on the west and south Delaware county and the Delaware. The greater part is laid out in parallelograms, with streets at right angles to each other. Each main parallelogram contains about four acres, or is 400 feet on each of its sides, divided by one or more small thoroughfares. Upon the city plans there are plotted 191,928 square town lots. The main streets running north and south are numbered from First or Front to Sixty-third street, and those running east and west were formerly named after the trees and shrubs found in the province. Thus, while the principal street in the city is named Market street, other main streets are named Chestnut, Walnut, Spruce, Pine, etc. The main streets of Philadelphia are 50 feet wide, with some few exceptions; Broad or Fourteenth street is 113 feet wide, and Market

street is 100 feet wide. The streets are generally paved with rubble stone, although square or Belgian blocks of granite are being extensively introduced. There are laid down on the city plans upward of 2,000 miles of streets, but at present (1884) only 1,060½ miles are opened, of which 573.54 miles are paved and 44.28 macadamized. The pavements are chiefly of brick, but some of the more prominent streets have flagstone sidewalks. Market street and Chestnut street, below Eighth street, and Front street are the localities where the main wholesale business of the city is located. Most of the retail stores are situated in the upper part of Chestnut street and Eighth street. The principal banking institutions are in Chestnut street, between Second and Fifth streets, and in Third street between Walnut and Chestnut streets. Walnut street in the southern section of the city, and Spring Garden and Broad streets in the northern section of the city, are the chief streets for large and luxurious private residences. There is not a street of any consequence which has not a tramway along it; and the tramway system has done a great deal to increase building, until now Philadelphia is emphatically "the city of homes." There are upward of 160,000 dwelling-houses, of which at least 110,000 are owned by the occupants. According to the returns for the census of 1880, there were 146,412 dwelling-houses in the city, which, taking the population as given by that census, 847,170, gave 5.79 persons to each house, while the number of dwellings in New York to the population gave 16.37 to each house. On the original plan of the city five squares, equidistant, were reserved for public parks. One of these, called Center square, situated at the intersection of Broad and Market streets, has been taken for the erection of the city-hall, and the remaining four, situated at Sixth and Walnut, Sixth and Race, Eighteenth and Walnut, and Eighteenth and Race, and named respectively Washington, Franklin, Rittenhouse, and Logan, have a combined area of 29.06 acres. There are six other public squares in the city, with a total area of 18.90 acres. In addition to these public squares, Fairmount Park, with an area of 2,791 1-5 acres, including 373 acres of the water-surface of the Schuylkill river, is the most extensive public park in the United States. It lies in the northwestern section of the city, and the Schuylkill river and Wissahickon creek wind through the greater portion of it. In the park Horticultural Hall and Memorial Hall remain as mementoes of the Centennial Exhibition held there in 1876. The garden of the Zoölogical Society, covering 33 acres, on the outskirts of the park, was opened July 1, 1874, as the pioneer of such enterprises in the United States. Until within the last score of years the buildings in Philadelphia bore a singular resemblance to each other, especially the dwelling-houses. The predominant material for building was, and is, red brick, the soil affording the finest clay for brick found in the United States. The desire for uniformity in buildings, in both style and material, has happily undergone a change in recent years, although the danger now is of running to the other extreme, and thus giving the streets a decidedly bizarre appearance.

*Buildings.*—The old brick Swedes Church in Swanson street in the southeastern section, dedicated on the first Sunday after Trinity, 1700, is the oldest building of character now standing in the city. When it was completed it was looked upon as a great masterpiece, and nothing was then equal to it in the town. The four other colonial buildings of importance still standing are Christ (Protestant Episcopal) Church, the State House (Independence Hall), the Pennsylvania Hospital and Carpenter's Hall, all of them built of red brick with

black glazed headers. Dr. John Kearsley, a physician, was the architect of the first-mentioned, and Andrew Hamilton, a lawyer, the architect of the second. Christ Church stands on the west side of Second street between Market and Arch streets, and its erection was begun in 1727, but it was not finished, as it now appears with tower and spire, until 1754. It was built on the site of a still older Christ Church, which was also of brick, erected in 1695. Queen Anne in 1708 presented a set of communion plate to the church, which is now used on great occasions. During his presidency Washington worshiped at this church, and his pew is still preserved, as is also that of Franklin. In 1882 the interior of the church was restored to its ancient character at an expense of about \$10,000. The nave is 75 feet long by 61 feet in width and 47 feet high; the chancel is 15 feet by 24; and the spire is 196 feet 9 inches high. The old State House or Independence Hall, on the south side of Chestnut street between Fifth and Sixth streets, was commenced in 1731, and was ready for occupancy by the Assembly toward the close of 1735. It was the scene of almost all the great civil events of the Revolutionary War. It is 100 feet in length on Chestnut street by 44 feet in depth; and prior to the Centennial celebration its exterior and interior were restored as nearly as possible to their original appearance. The Pennsylvania Hospital occupies the square of ground bounded by Spruce, Pine, Eighth, and Ninth streets, and the cornerstone of the building was laid on May 28, 1755. Carpenter's Hall, where the first Congress met, stands back from Chestnut street, east of Fourth street, and was begun in January, 1770. These four buildings are all very simple in their construction, but substantial and imposing, and are interesting specimens of colonial architecture. Among the notably fine buildings in Philadelphia are the old United States bank, now the United States custom-house, the Girard bank, the United States mint, and the Girard College, all of which, with the exception of the last-named, were built more than half a century ago. They are all of white marble and of the different orders of Grecian architecture, with porticoes and high fluted columns. Other fine buildings are the Masonic Temple, the Ridgway branch of the Philadelphia library, the Pennsylvania Academy of Fine Arts, and the Academy of Natural Sciences. There are also many very beautiful churches. The two newest buildings of magnitude are the new United States postoffice, at the corner of Ninth and Chestnut streets, which was completed in 1884, at the cost of \$8,000,000, and the new municipal buildings for the city, at the intersection of Broad and Market streets. The postoffice, which is Romanesque, is of granite, and was more than ten years in building, from October, 1873, to March, 1884. It has a frontage of 425 feet, a depth of 175 feet, and a height of 164 feet. The annual sales of stamps amount to \$1,600,000. About half a million of letters, etc., pass through the post-office each day. The new public building, as it is called, or city-hall, forms the largest single building in America. It covers an area, including courtyards, of nearly four and one-half acres, the dimensions being 470 feet east and west, and 486 feet north and south. The building contains 520 rooms, and the topmost point of the dome, on the tower, is 537 feet 4 inches above the courtyard, one of the highest artificial constructions in the world. The architecture is rather rococo in character.

*Population.*—Previous to the census of 1830 Philadelphia was the most populous American city, but since then New York has taken the first place. In 1683 it was estimated that Philadelphia had 80 houses and 500 inhabitants. The next year the population in-

creased 2,000, and by the beginning of the last century there were 700 dwelling-houses and 4,500 people. In 1800 there were 9,868 dwellings and 81,009 inhabitants, and in 1820, the last census when Philadelphia stood first, she had a population of 119,325. By the census of 1880 the population of the city was placed at 847,170 (males 405,022, females 441,181), while in 1870 it was 674,022, and in 1860 565,529. About one-third of the population in 1880 were foreign-born. The enumerated population in 1890 is 1,046,964. The city has 644 places of worship, viz., Baptist 83, Hebrew 11, Lutheran 32, Methodist 131, Moravian 5, Presbyterian 110, Protestant Episcopal 96, Quaker 15, Reformed Dutch 20, Reformed Episcopal 10, Roman Catholic 47, Swedenborgian 3, Unitarian 3, Universalist 4, and 74 among 23 other different denominations. There are 183 cemeteries and burial-grounds in the city.

*Municipal Government.*—By Penn's charter of October 25, 1701, Philadelphia was first created a borough city with a government of its own, separate from that of the province and county. Under this charter, with many modifications, the city was governed until the act of the legislature of the State incorporating the city was passed, March 11, 1789. This is the fundamental law governing the city to-day, but with such changes as have become necessary by the altered condition of affairs and the development of the entire country. The most important change was the Consolidation Act of February 2, 1854, already mentioned, whereby the old county of Philadelphia became the city of Philadelphia, the county of Philadelphia being at the same time continued as one of the counties of the State. The city is divided territorially and politically into thirty-three wards, and is governed by a mayor, elected by the people for four years, and by two bodies, called the select and common council. The upper branch is composed of one member from each ward elected for three years, who must have attained the age of twenty-five years and have been a citizen and inhabitant of the State for four years next before his election, and the last year thereof an inhabitant of the ward for which he shall be chosen. Each ward has a member of common council, elected for two years, for every 2,000 taxable inhabitants; he must be twenty-one years of age and have the other qualifications required for the upper body. The mayor has the right of veto upon the acts of the councils. Councils in joint meeting appoint all heads of department not elected, establish the rate at which all taxes shall be levied that are authorized by law, and fix the salaries of all municipal officers elected by the people, as well as those they appoint. The city can make no binding contract or incur any debt unless authorized by law or ordinance and an appropriation sufficient to pay the same be previously made by councils. The present city charter came in force April 1, 1887. Under this the executive power is vested in the mayor and departments. The mayor is elected for four years, and is not eligible for reëlection. The funded debt of the city on January 1, 1889, was \$57,146,095. The revenues from all sources in 1889 were \$20,529,146, and the expenditures for all purposes were \$20,667,681. The city builds up each year about one square mile, and great improvements are made each year in public buildings, paving, and lighting. The electric system is being placed underground. In 1889 there were 12,000 building permits issued. The city owns its water-works, and within the past three years has greatly improved the service and quality. Edward Shippen was named in the charter of 1701 as first mayor of the city. The last mayor under the English crown was Samuel Powel, elected October 3, 1775, and he was also the first mayor under the United

States, being reelected April 13, 1789. During the interim of the Revolutionary War the municipal government was suspended, and the affairs of the city were carried on by the councils of safety and other local bodies.

*Police, Fire, Water.*—The mayor is the nominal head of the police of the city, and all the appointments and removals are in his hands. The force consists of 1,717 men, of whom 1,425 are patrolmen. There are 4 captains and 1 chief of police; and the fire marshal is attached to the police department.

The fire department is governed by a board of fire commissioners elected by councils, and consists of a chief engineer, 6 assistant engineers, and 502 men. They are divided into 40 steam engine-companies and 10 hook and ladder companies, with the addition of hose and hose-carriage to each.

The largest portion of Philadelphia is supplied with water from the Schuylkill, and it was in great part for the preservation of the purity of this water-supply that Fairmount Park was created. The park has not, however, served its purpose in this respect, and of recent years improvements have been made. The supply also is hardly adequate to the demand, and many other sources have been suggested. The capacity of the present water-works allows a daily average pumpage of 116,500,000 gallons, and the nine reservoirs have a total capacity of 891,491,454 gallons. The dwellings are charged for water according to the number and character of appliances in use, irrespective of the amount of water used or the number of the occupants of the house. The streets have a number of fountains, erected by the Philadelphia Fountain Society, for the use of horses, dogs, and men; and there are also hydrants for the use of the fire department.

The various trust funds of the city are under the control of a board of directors of city trusts, composed of twelve prominent citizens appointed by the judges of the Court of Common Pleas. The board has charge of the Girard Fund; the Wills Hospital Fund, for the relief of indigent blind and lame; the Franklin fund, for aiding young married artificers; and sundry funds for furnishing the poor with fuel and other purposes.

*Finances.*—There are 32 national banks in Philadelphia, with an aggregate capital of \$17,578,000. In addition to the national banks there are 6 banks chartered by the State with an aggregate capital of \$714,600; 8 trust and safe deposit companies, where deposits are received and a *quasi* banking business done, with a total capital of \$8,625,000, and 3 saving funds without any capital, but where all the depositors are interested in the profits. Philadelphia has numerous joint-stock fire insurance companies, joint-stock fire and marine companies, mutual fire insurance companies, and life insurance companies. In addition to these there are a real-estate-title insurance company and a plate-glass insurance company, their objects being expressed in their titles.

*Commerce.*—Until within the last sixty years Philadelphia was the commercial emporium of the United States, but since that time her commerce has been gradually declining, until now she ranks sixth in the order of ports, being preceded by New York, Boston, Chicago, San Francisco, and New Orleans. At the same time her manufactures have been steadily increasing, until she has become the great manufacturing center of the country. Lines of steamers run to Liverpool, Glasgow, New York, Boston, Baltimore, Savannah, Charleston, and other ports. Philadelphia is also the center of the three great internal carrying lines of the State, the Pennsylvania Railroad, the Lehigh Valley Railroad, and the Reading Railroad. The last two are principally coal-roads from the great anthracite coal-fields of Pennsylvania, while the first, with its numerous branches, is

the main artery from the west for the transportation of its agricultural products.

*Industries.*—The largest single classes of manufactures are the iron and steel and the textile industries. The first-named includes all forms of machinery and of iron and steel articles. The manufactures of wool, cotton, silk, etc., employ over 60,000 persons in 1,018 establishments, producing textile fabrics to the value of \$102,087,128; and these figures are rather below than above the actual facts. In the carpet manufacture alone, for which there are 216 establishments, there are 35,000,000 yards of carpet made annually. The census for 1880 gave Philadelphia 8,567 manufacturing establishments, with a capital of \$187,148,857, employing 185,527 hands and producing articles valued at \$324,342,935 per annum. The seven classes producing over \$10,000,000 a year were—sugar-refineries (11), \$24,294,929; factories of woolen goods (89), \$21,349,810; men's clothing manufactories (426), \$18,506,748; cotton-mills (145), \$14,268,696; carpet manufactories (170), \$14,263,510; foundry and machine shops (226), \$13,455,238; drug and chemical manufactories (54), \$11,804,793. Since then, however, Philadelphia has made great strides. The large and important industry of brick-making, for which there are 63 yards, produces annually about 350,000,000 bricks, of a market value of at least \$3,500,000. The fine "pressed brick" of Philadelphia is used in all parts of the country, and of late years molded bricks of various designs and of any size have been extensively and successfully made.

*Charities.*—There are not less than 300 charities proper in Philadelphia, leaving out institutions of learning which come within the legal definition of the word. A few of them are municipal, but the majority are wholly private in their origin and conduct. Among the former may be classed the Blockley Almshouse for the care of the indigent poor of the city, and the house of correction, employment and reformation at Holmesburg. This last is a mixed institution, being a work-house for both criminals and paupers. The city bath-houses are another important municipal charity. There are twenty-two hospitals in Philadelphia, the most important being the Pennsylvania Hospital, projected in 1751 by Benjamin Franklin and Dr. Thomas Bond. It is governed principally by the Quakers, and is supported wholly by voluntary contributions. It has a capacity for 230 patients, and recent accident cases are always admitted. The insane department of this hospital is located at Haverford road, and was opened in 1841. In addition to this hospital for the insane there is an insane department attached to the City Hospital at the Almshouse, and a Friends' Asylum for the Insane at Frankford. Other important charities are the Philadelphia Dispensary, Home for Consumptives, Home for Incurables, Preston Retreat (lying-in charity), Orphans' Society, Philadelphia Working Home for Blind Men, Sheltering Arms for Infants, the Sick Diet Kitchen, and the House of Refuge for Juvenile Delinquents. This last receives children committed by the Court of Oyer and Terminer upon conviction of a criminal offense, also vagrant, incorrigible, or vicious children committed by magistrates on complaint of the parent or any other person that the parent or guardian is incapable or unwilling to control them.

*Education.*—Penn, in his frame of government, provided that a committee of manners, education, and art should be appointed, so that all "wicked and scandalous living may be prevented, and that youth may be trained up in virtue, and useful arts and knowledge." The first school in Philadelphia of which we have knowledge was opened the year following the foundation of the colony. At a meeting of the provincial

council, held in Philadelphia "ye 26th of 10th month, 1683," the governor and council, "having taken into serious consideration the great necessity there is of a schoolmaster for the instruction—and sober instruction—of youth in the town of Philadelphia, sent for Enoch Flower, an inhabitant of the said town, who for twenty years past hath been exercised in that care and employment in England," and engaged him to instruct the youth of the city. In the year 1689 the first public school in Pennsylvania was established at Philadelphia under the care of the celebrated George Keith. It was incorporated by the provincial council February 12, 1698, and was entitled "The Overseers of the Public Schools founded in Philadelphia at the request, costs, and charges of the people of God called Quakers," and in 1711 received a charter from Penn. This school, although supported by the Quakers, was open to all, and for more than sixty years continued to be the only public place for instruction in the province. It thrived and was held in high estimation, and its legitimate successor is still in operation in Philadelphia, where it maintains its ancient reputation. In 1749 Franklin published his *Proposals Relative to the Education of Youth in Pennsylvania*, which resulted the next year in the establishment of the academy and charitable school, which became a college in 1755, and in 1779 was incorporated as the University of Pennsylvania. The university at present occupies a site in Woodland avenue, in what was formerly West Philadelphia, and gives instruction in ten departments (Arts, Music, Medicine, Law, Dentistry, Philosophy, Auxiliary of Medicine, Veterinary Medicine, Towne Scientific School, and Wharton School of Finance and Economy). The faculty consists of 132 professors, lecturers, and instructors in the various departments.

The public school system of Pennsylvania was not really firmly fixed until 1818, when by an act of the legislature Philadelphia was made the first school district of Pennsylvania with a distinct educational system from that of the State in general. This district is governed by a board of education composed of thirty-one members, one from each ward of the city, who are appointed, one-third each year for three years, by the Judges of the Courts of Common Pleas of the county. They have the financial control and general supervision of schools, the selection of the books to be used, the oversight of the teachers, and the building of the schoolhouses. In addition to this board there are the directors of the public schools, twelve from each ward, who have the local supervision of the schools in their respective sections. They are elected by the people, one-third each year for three years. The schools are divided into primary, secondary, and grammar schools, in addition to which there is a central high school, a finishing school for boys, and a normal school which is a finishing school for girls, and where they can also be qualified to become teachers. There are 465 public schools in Philadelphia and 236 school buildings of a value of \$4,186,200. Another noted educational institution in Philadelphia is Girard College for orphans, endowed by Stephen Girard in 1831 for the benefit of poor white male orphan children. By the will a preference is given first to orphans born in Philadelphia, second to those born in Pennsylvania, third to those born in New York City, and fourth to those born in New Orleans. To be qualified for admission the orphans must be between six and ten years of age; and a child without a father, while the mother is living, is held to be an orphan entitled to admission. The buildings cost \$1,933,821.78, and were formally opened in January, 1848. At Philadelphia are also the Pennsylvania Institution for the Instruction of the Deaf and

Dumb; the Pennsylvania Institution for the Instruction of the Blind; the Pennsylvania Academy of the Fine Arts, founded in 1805, and the first art school in America; the School of Design for women; the Pennsylvania Museum and School of Industrial Art; and the Jefferson Medical College.

*Libraries.*—Philadelphia was for many years not only the first city commercially in the country, but it was also the seat of letters. When the poet Moore visited America in 1804 he wrote to his mother, of Philadelphia, "it is the only place in America that can boast of a literary society." Unfortunately it has much degenerated in this respect in eighty years and to-day but little attention is paid by its people to letters and literature. To Franklin, again, its first library is due. It grew out of the Junto, and in 1731 the Library Company of Philadelphia was established. In 1769 it absorbed the Union Library Company, which had been formed some few years before; and in 1792 the Loganian Library, a valuable collection of classical and other works provided under the will of James Logan, a friend of Penn, was transferred to the Philadelphia library. It subsequently acquired, by bequest, the libraries of the Rev. Samuel Preston of London and of William Mackenzie of Philadelphia. Among the rarities in the latter was a copy of Caxton's *Golden Legend*, 1486. In 1869 it was made the beneficiary, under the will of Dr. James Rush, of an estate valued at over a million dollars. It has two library buildings and possesses about 145,000 volumes, as well as valuable manuscripts and broadsides. The Mercantile Library Association is the popular circulating library of the city, and contains 149,000 volumes. Other libraries are the Athenæum, Apprentices' Library, Library of the Law Association, and Friends' Library.

*Learned Societies.*—The American Philosophical Society is the oldest organized body for the pursuit of philosophical investigation in its broadest sense in America. It was founded also by Franklin, May 25, 1743, and incorporated March 15, 1780, with its founder as president. It began the publication of its transactions in 1773, and the twenty-second volume has been recently issued. The publication of the proceedings of this society was commenced in 1838, and still continues. Its library contains about 23,000 volumes, and the society also possesses valuable manuscript correspondence of Franklin. The Academy of Natural Sciences was organized in 1812, and its ornithological collection, which contains over 25,000 specimens, is claimed to be the finest in the world. It has a fine library of works on the natural sciences, and publishes a journal and its proceedings. The Franklin Institute for the promotion of the mechanic arts started in 1824. It has a valuable library of over 20,000 volumes devoted to mechanics and kindred subjects, and has ever since its organization published a monthly journal. The Historical Society of Pennsylvania was founded in 1824, and is devoted to the preservation of material relating to the history of the State. Its collections are of great historical value, and its library contains more than 20,000 volumes. The Numismatic and Antiquarian Society of Philadelphia, founded in 1858, was the first organization on the American continent to engage in the pursuit of numismatic science. It has a fine collection of coins and a good library. Another notable body is the College of Physicians and Surgeons with a medical library of 23,000 volumes and a fine museum of prepared specimens.

*Newspapers.*—The *American Weekly Mercury* was the first newspaper published in Philadelphia and the third in the colonies. It was started on December 22, 1719, by Andrew Bradford, a son of William Bradford,

the first printer in the middle colonies, and this paper was the first newspaper in the same section. On September 21, 1784, the first daily newspaper in the United States was issued at Philadelphia. It was the *American Daily Advertiser*, subsequently published as *Poulson's Daily Advertiser*, and later merged into the *North American and United States Gazette*, which is thus by succession the oldest daily newspaper in the United States. There are at present twenty daily newspapers published in Philadelphia, eight of them being afternoon papers, with an average circulation of 375,000, and seventy-seven weekly newspapers, chiefly religious and Sunday secular papers.

*Social Life.*—Among Philadelphia's claims to priority she has in her midst one of the oldest purely social clubs in existence—the Colony or State in Schuylkill, which was formed in 1732. The other purely social clubs in the city are the Philadelphia Club, Social Art Club, and University Club. The Union League (Republican) and Commonwealth (Democratic) are mixed social and political clubs. There are some organizations of a mixed social and charitable character, such as the St. George Society (1772), the St. David Society (1729), the St. Andrew Society (1749), and the Sons of St. Patrick or Hibernian Society (1771). The First Troop of Philadelphia City Cavalry, formed in 1774, is a military organization of high social standing. There are also a gentlemen's driving park or racecourse and innumerable cricket and boat clubs. There is an opera-house capable of accommodating 3,500 persons, and five first-class theaters, but Philadelphia as a community seems not to be a theater-going people.

*History.*—Down to the War of Independence the history of Philadelphia is virtually that of PENNSYLVANIA, (*q.v.*) The patent granted to William Penn (see PENN) for the territory embraced within the present Commonwealth of Pennsylvania was signed by Charles II. on March 24, 1681, and in the autumn of that year Penn appointed three commissioners to proceed to the new province and lay out a great city. This seems to have been his chief thought in settling the province, and his instructions to his commissioners were to select a site on the Delaware where "it is most navigable, high, dry, and healthy; that is where most ships can best ride, of deepest draught of water, if possible to load or unload at the bank or key side without boating or lightering of it." These commissioners were William Crispen, Nathaniel Allen, John Bezar, and William Heage. Crispen, who was a kinsman of the proprietor, died on the voyage out, and the remaining commissioners arrived toward the close of the year. They had been preceded by Penn's cousin, Capt. William Markham, as deputy-governor, and were soon followed by the surveyor-general of the province, Thomas Holme, who, as may be understood from his office, was one of the most important men in the early history of the city and State. The site of the city was speedily determined upon, and Holme proceeded to lay it out according to the modified instructions of Penn, and his *Portraiture of the City of Philadelphia in the Province of Pennsylvania in America* was published and sold by Andrew Sowle in Shoreditch, London, in 1683. This plan shows the old part of the city as it is to-day, covering between 1,200 and 1,300 acres. Unfortunately no date can be fixed, even approximately, for the founding of the city; nor is the date known of Penn's first visit to the capital of his province. He landed at Newcastle, on the Delaware, on October 27, 1682, and two days later came up as far as Upland, now Chester, thirteen miles south of Philadelphia. He probably did not remain long so near his pet scheme

without viewing it, but when he did first come to Philadelphia is now unknown.

The seat of government was fixed in Philadelphia by the meeting of the governor and council on March 10, 1683, and the General Assembly met two days later. For 117 years the city continued to be the capital of Pennsylvania, and was the most important town, commercially, politically, and socially, in the colonies during nearly the whole of this period. In October, 1685, the first printing press established in the middle colonies was set up here by William Bradford; the earliest specimen of his work which has survived to our day is his *Kalendarium Pennsylvaniense or America's Messenger, being an Almanack for the year of Grace 1686*. The printing press was followed in 1690 by a paper-mill, erected by William Rittenhouse, a Mennonite preacher, on the Wissahickon creek, a locality which has ever since remained a favorite for the manufacture of paper. The one man, next to William Penn, whose influence was most deeply impressed upon Philadelphia as upon the affairs of the colony, was Benjamin Franklin, whose power was felt almost on his first landing in October, 1723, when in his eighteenth year, and its impress is seen to-day. Four years after he settled here he formed a club for mutual improvement, which he called the "Junto," out of which subsequently grew the American Philosophical Society for the promotion of useful knowledge, and the Library Company of Philadelphia. He also originated the present University of Pennsylvania, organized the first fire-engine company in the city, and was instrumental in founding the Pennsylvania Hospital. In March, 1753, the first Arctic expedition ever sent out from America sailed from Philadelphia. The vessel, called the *Argo*, was commanded by Captain Swaine, but her voyage accomplished nothing of importance. In 1770 the first factory for the manufacture of fine porcelain in the colonies was established at Philadelphia by a Swiss and an Englishman, but the difficulty of obtaining competent workmen forced its abandonment two years later. During the war of the revolution Philadelphia was the virtual capital of the colonies and the scene of all the prominent civil events of those stirring times. The first Congress met at Carpenter's Hall on September 4, 1774; on May 24, 1775, Congress reconvened in the old State House and here continued its sittings, except when the city was threatened by the enemy and in his possession. On July 2, 1776, the "resolutions respecting independency" were passed, and on July 4, 1776, Philadelphia was the scene of the adoption of the Declaration of Independence; and the old State House became ever afterward Independence Hall. On July 9, 1778, "the articles of confederation and perpetual union between the independent States of America" were here adopted and signed, and in the same place the convention to frame a constitution for the United States of America met on May 14, 1787, with Washington as presiding officer, and continued its sessions until September 17th, when the work was finished and the fundamental law of the land given to the world. The affairs of state were thus placed on a firm foundation, while the affairs of the church had received the attention of the people the previous year. In June, 1786, the clerical and lay delegates from the Protestant Episcopal churches in the United States met in Philadelphia and formally organized "the Protestant Episcopal Church in North America." The Congress of the United States had held its opening session in New York, but in December, 1790, it reassembled at Philadelphia; and for ten years the seat of government was at Philadelphia, until it was permanently removed to the District of Columbia. Here Washington delivered his farewell

address to the people of the United States, and here he retired from public life. As in Philadelphia the first bank in the colonies had been opened—the bank of North America in 1781—so in Philadelphia the first mint for the coinage of the money of the United States was established in 1792. Both of these institutions are still in full operation. In April, 1816, Congress incorporated the bank of the United States, which was the second banking institution of that name chartered by the government, and fixed it at Philadelphia. The affairs of this institution form a very important chapter in the history of the city, as indeed in the history of the whole country. It had an unsettled existence, until the final blow came from President Jackson, in the beginning of his second term of office, in 1833. Being opposed to the continuance of the bank, he withdrew the public deposits, amounting to about \$8,000,000, the result of which was widespread ruin and business depression, not only in Philadelphia but elsewhere.

The two events of greatest note which have taken place in the city in recent years have been the centennial celebration of the independence of the colonies in 1876, and the bi-centennial celebration of the landing of William Penn in 1882. The centennial celebration was of the greatest moment, owing to the Exposition of the Industries of all Nations, which was open from May 10th to November 10th; the total admissions reached the number of 9,910,966 persons.

PHILÆ. See EGYPT.

PHILEMON, the oldest poet of the New Attic Comedy, was the son of Damon, and was born at Soli in Cilicia, or, according to others, at Syracuse; but early in life he settled at Athens. Since he died in 262 B.C. at an age variously stated at from 96 to 101 years, he must have been born somewhere about 360. In its absence of poetical idealism and restriction to the prosaic realism of daily life the New Comedy stands to the Old somewhat as the comedies of Molière or Sheridan stand to those of Shakespeare. Its repertoire was limited to a few stock characters—the imprudent lover, the designing fair, the stingy father, the greedy parasite, the blustering swashbuckler—and its plots rang the changes on the well-worn theme of thwarted but faithful love, rescued from its difficulties by the discovery of a long-lost relative and ending in marriage. In the many fragments of Philemon preserved by Stobæus, Athenæus, and other writers there is much wit and good sense.

PHILEMON, EPISTLE TO. This, which is the shortest of the extant epistles of St. Paul, stands to the other books of the New Testament in a relation similar to that of the book of Ruth to the other books of the Old Testament. It is an idyl of domestic life. Onesimus, the slave of one of Paul's converts in Asia Minor, had run away from his master, probably, as was often the case with runaways, after stealing some of his money. He had come to Paul, more probably at Rome than, as some have thought, at Cæsarea, and Paul had converted him. Paul sends him back to his master, begging that he may be kindly treated as being now a brother Christian, and formally undertaking to repay what he owed. The epistle is addressed not only to Philemon but to Apphia, who was probably his wife, to Archippus (possibly the head of the community at Colossæ or Laodicea, Col. iv. 17), and to the community which either, like some of the Roman *collegia*, consisted of Philemon's household or held its meetings in his house. The genuineness of the epistle is almost universally admitted.

PHILETAS, a distinguished poet and critic of the Alexandrian school, was the son of Telephus, and a na-

tive of the island of Cos. He lived in the reigns of Philip, Alexander the Great, and Ptolemy I. of Egypt, the last of whom appointed him tutor to his son Ptolemy Philadelphus. The story runs that he died from the excessive assiduity with which he sought the answer to the sophistical problem called "The Liar" (*i.e.*, If a man says he is telling a lie, does he speak truly or falsely?). A bronze statue of him was erected in Cos.

The fame of Philetas rested chiefly on his elegiac verses, in which, however, he was esteemed inferior to the younger poet Callimachus.

PHILIDOR, FRANÇOIS ANDRÉ DANICAN, was born in 1726, and died in 1795. See CHESS.

PHILIP, one of the twelve apostles, mentioned fifth in all the lists, is a mere name in the Synoptists, but a figure of some prominence in the Fourth Gospel. There he is said to have been "of Bethsaida, the city of Andrew and Peter," and to have received his call to follow Jesus at Bethany, having previously been, it would seem, a disciple of the Baptist. Philip was at that time the means of bringing Nathanael to Jesus, and at a later date he, along with Andrew, carried the request of the inquiring Greeks to the Master. Philip and Andrew alone are mentioned by name in connection with the feeding of the 5,000, and Philip is also one of the few interlocutors in John xiv. After the resurrection he was present at the election of Matthias as successor to Judas, but he does not again appear in the New Testament history; it is, however, implied that he still continued in Jerusalem after the outbreak of the first persecution.

PHILIP, "the evangelist," is first mentioned in the Acts as one of "the seven" who were chosen to attend to certain temporal affairs of the church in Jerusalem in consequence of the murmurings of the Hellenists against the Hebrews. After the martyrdom of Stephen he went to Samaria, where he preached with much success, Simon Magus being one of his converts. He afterward instructed and baptized the Ethiopian eunuch on the road between Jerusalem and Gaza; next he was "caught away" by the Spirit and "found at Azotus" (Ashdod), whence "passing through he preached in all the cities till he came to Cæsarea." Here some years afterward, according to Acts xxi. 8, 9, he entertained Paul and his companion on their way to Jerusalem; at that time "he had four daughters which did prophesy."

PHILIP, tetrarch of Ituræa. See HEROD PHILIP.

PHILIP, the name of five kings of Macedon. The greatest of those was PHILIP II. (382–336 B.C.), the first founder of the MACEDONIAN EMPIRE, (*q.v.*) After the death of Alexander the Great, Arrhidæus, a bastard of Philip II., reigned as PHILIP III., till he was put to death by Olympias in 317. PHILIP IV., son of Cassander, reigned only for a few months in 296. PHILIP V., the last but one of the kings of Macedon and son of Demetrius II., was born in 237, and came to the throne on the death of his uncle, Antigonus Doseon, in 220.

PHILIP I., king of France, was the son of Henry I. and Anne of Russia, and was born in 1052. He was associated with his father on the throne in 1059, the consecration taking place at Rheims (May 23d), and he succeeded to the undivided sovereignty in the following year (August 4, 1060), first under regency of his mother, and afterward from 1062 to 1067, under that of Baldwin V. count of Flanders. In 1100 he made his son Louis (afterward Louis VI.) joint king, and his death took place at Melun July 29, 1108. (See FRANCE.)

PHILIP II., surnamed "Augustus," king of France, was the son of Louis VII. and was born in August, 1165. When fifteen years old he was crowned joint king at Rheims on November 1, 1179. In the following year he was again crowned along with his newly wedded wife, Margaret of Hainault, at St. Denis (May

29, 1180); the death of his father took place a few months afterward. For an account of Philip's character and of the leading events of his reign the reader is referred to FRANCE. He died at Mantua July 14, 1223.

PHILIP III., surnamed "the Rash," king of France, was born in 1245 and succeeded his father Louis IX. on August 25, 1270, at Tunis, where, after continuing the siege for some time, he made a truce of ten years and embarked for France in the following November. He was twice married, first to Isabella of Aragon in 1258, and subsequently to Mary of Brabant. He died at Perpignan on October 5, 1285. See FRANCE.

PHILIP IV., surnamed "the Fair," son of the preceding, was born at Fontainebleau in 1268, was married to Joanna, queen of Navarre, in 1284, accompanied his father into Aragon in 1285, and was proclaimed king of France at Perpignan on October 6th of that year. See FRANCE. He died at Fontainebleau November 29, 1314.

PHILIP V., surnamed "the Tall," second son of the preceding, born in 1293, succeeded his elder brother, Louis X., in January, 1317, and was succeeded by his younger brother, Charles IV., in January, 1322.

PHILIP VI. was the eldest son of Charles, count of Valois, the younger brother of Philip IV., and was born in 1293. He succeeded his cousin, Charles IV., in 1328, and died at Nogent-le-Roi, near Chartres, on August 22, 1350. (See FRANCE.)

PHILIP I., of Castile and Aragon, surnamed "the Handsome," was the son of the emperor Maximilian I. and Mary, the only child of Charles the Bold, last prince of the house of Burgundy, and was born at Bruges on July 22, 1478. Philip died (September 25, 1506) at Burgos.

PHILIP II., king of Spain, was the son of the emperor Charles V. and Isabella of Portugal, and was born at Valladolid on May 21, 1527. He was brought up in Castile under the care of his mother, who died when he was twelve years old. As Philip grew up, his father, though he rarely saw his son, watched carefully over his education and strove to fit him for political life. In 1543 Philip married Mary of Portugal, who died in 1545, soon after the birth of a son, Don Carlos. In 1548 Charles V. summoned Philip to Brussels, that he might gain some experience of the peoples whom he would be called upon to rule. He was not, however, popular with his future subjects. He had already formed his character upon the model of Spanish haughtiness. He was cold, reserved, punctilious about decorum, and wanting in geniality. The Italians did not care for him, the Flemings disliked him, the Germans hated him. His appearance and manner did not further his father's plan of securing his election to the empire. The scheme failed, and Philip's presence was in no way helpful. In 1551 he returned to the more congenial task of governing Spain.

The death of Edward VI. of England opened out to Charles V. new prospects for his son. Queen Mary regarded the emperor as her only friend, and submitted herself entirely to his guidance. She received with joy a proposal for her marriage with Philip. The English opposition broke down with the failure of Wyatt's rebellion, and in 1554 Philip came to England to claim his bride. Charles V. resigned to him Naples and Sicily that he might not come as a needy prince. Philip was well supplied with Spanish gold, and was charged by his father to spare no pains in conciliating the English. He tried his best; but his cold, ungenial manner was a hopeless obstacle to his success. Mary was devotedly attached to her husband, who exercised a moderating influence over the queen's zeal for the re-establishment of Catholicism. Charles V. wished to

secure England as an ally, and subordinated religious to political considerations. Philip was not naturally fitted for conciliatory action, and was not happy in England. He found that his wife was destined to be childless and that he had no prospect of succeeding to the English crown. At the end of 1555 he joyfully obeyed his father's summons to go to Brussels. Charles V., worn out by the fatigue of a long reign, resolved to abdicate in favor of his son, and this he did on January 16, 1556.

Philip began his reign with glory, and Europe saw that Charles V. had no unworthy successor. Yet Philip was not anxious for military glory. His finances were embarrassed and he felt the need of a period of peace. For the purpose of maintaining his political supremacy he proposed to continue his English alliance by marrying Elizabeth when she succeeded Mary on the English throne. Elizabeth did not at once reject the proposal; but she gradually entered upon a religious policy which made marriage with Philip impossible. The Spanish king rapidly changed his plans and cemented his alliance with France by a union (June 24, 1559) with Isabella, daughter of Henry II. He made arrangements for the government of the Netherlands, and at the end of 1559 returned to Spain, where he remained for the rest of his life.

The policy of Philip was steadily directed toward welding his dominions together in dependence on himself, and extending his influence over Europe. The power of Charles V. had had no definite center. The emperor had recognized the claims of his separate dominions upon him, and had striven to be neither German, Spanish, Flemish, nor Italian. Philip identified himself entirely with Spain. Castile was to be the seat of his monarchy, and that monarchy was to be absolute. He was devoted to Catholicism, and during his reign superseded the pope as the head of the Catholic party in Europe. But the interests of Catholicism were in his mind identified with his own personal interests, and under the cover of zeal for the church he pursued the aggrandizement of Spain. In Spain itself his care for the maintenance of the Catholic faith accorded with the temper of the people. The long continuance of war against the Moors had identified orthodoxy with purity of race, and heresy was regarded as a taint in the blood. The rigor of the Inquisition preserved the national honor; the *auto-da-fé* was a means of ridding the land of dangerous elements. This uncompromising spirit of Spain in religious matters its king wished to extend to the rest of his dominions. He died at the Escorial in September, 1598.

PHILIP III., king of Spain, son of Philip II. by his fourth wife, Anne of Austria, was born at Madrid on April 14, 1578, succeeded his father on September 13, 1598, married Margaret of Austria on April 18, 1599, and died at Madrid on March 31, 1621.

PHILIP IV., king of Spain, son of Philip III., was born at Valladolid on April 8, 1605, was married to Isabella of France on November 25, 1615, succeeded his father on March 31, 1621, and died on September 17, 1665.

PHILIP V., king of Spain, was the second son of the French dauphin, Louis, by his wife Maria Anna of Bavaria, and was born at Versailles on December 19, 1683. In 1702 he married Maria Louisa, daughter of Victor Amadeus, duke of Savoy; shortly after her death in February, 1714, which he felt deeply, he married Elizabeth Farnese (December). Philip died on July 9, 1746, and was succeeded by his son, Ferdinand VI. (See SPAIN.)

PHILIP. For the dukes of Burgundy of this name, surnamed respectively "the Bold" (1342-1404) and "the

Good" (1396-1467), see BURGUNDY and FRANCE. For Archduke Philip, "the Handsome," see PHILIP I. of Castile and Aragon.

PHILIP OF SWABIA, rival of the emperor OTHO IV. (*q.v.*), and younger son of the emperor Frederick I., was born about 1170 A.D. The coronation of Otho at Aix-la-Chapelle in July was soon followed by that of his rival at Mainz, and a civil war ensued, which, carried on with varying fortunes for ten years, was only brought to an end by the murder of Philip by Otho of Wittelsbach, at Bamberg, on June 21, 1208.

PHILIPPI, a city of ancient Macedonia, on a steep hill near the river Gangites (now the Angista), overlooking an extensive plain and at no great distance from the coast of the Ægean, on the highway between Neapolis (Kavalla) and Thessalonica. Originally called Crenides, or "Fountains," it took the name by which it has become famous from Philip of Macedon, who made himself master of the neighboring gold-mines of the Hill of Dionysus, and fortified the city as one of his frontier towns. Octavius and Antony having, in 42 B.C., gained a great victory over Brutus and Cassius in the plain of Philippi, the place received a Roman colony, *Colonia Julia Philippensis*, which was probably increased after the battle of Actium.

PHILIPPIANS, EPISTLE TO THE. This is one of the most characteristic of the letters of St. Paul. It was addressed to the community at PHILIPPI (see above), the first important European city which St. Paul had visited, where he had formed a community with the apparently new organization of "bishops" and "deacons," and with which he had relations of especial intimacy. The immediate occasion of his writing the letter was his receipt of money which the Philippians had sent by Epaphroditus to supply St. Paul's personal wants. They were probably wealthier than some of the other communities which he had founded, and consequently he had not the reluctance which he felt elsewhere to receive money from them; the money so sent was no doubt part of the offerings of the community which constituted the Christian sacrifice, a fund which was administered by the officers of administration, *i.e.*, the bishops and deacons. It was consequently to those officers that he especially addressed his acknowledgment of it.

The genuineness of the epistle was attacked by Baur on three grounds, which he himself states to be (1) the appearance of gnostic ideas in ii. 6-11, (2) the want of anything distinctively Pauline, (3) the questionableness of some of the historical data. The attack has been renewed by one section of his followers; but it is generally admitted, even by critics who reject the epistles to the Ephesians and Colossians, that the attack upon this epistle has failed. The doctrinal importance of the epistle is considerable.

PHILIPPICUS, or PHILEPICUS, emperor of Constantinople from December, 711, to June, 713, was the son of the patrician Nicephorus, and became distinguished as a soldier under Justinian II. The short reign of Philippicus was brought to a close through a conspiracy headed by two of his generals, who caused him to be blinded in the hippodrome in June, 713. Of the remainder of his life nothing is known. He was succeeded by his secretary, Artemius, known as Anastasius II.

PHILIPPINE ISLANDS (Span. *Islas Filipinas*), PHILIPPINES, an archipelago in the southeast of Asia. On the west and northwest it is separated by the China Sea from China and the Indo-Chinese peninsula; toward the east lies the Pacific; on the north a number of smaller islands stretch out toward Formosa; and on the south, while a double connection with Borneo is formed by the lines of the Palawan and Balabac and

the Sulu Islands, the basin of the Celebes Sea, with a central depth of from 1,000 to 2,600 fathoms, extends, for a distance of 300 miles, between its southernmost island (Mindanao) and Celebes. As the number of the Philippines is believed to exceed 1,400, and the larger islands are in several cases only beginning to be properly explored, it is impossible to give a definite statement of their aggregate land-area. A measurement on Dommann's map (1882) resulted in 114,356 square miles. Nor is it in regard to the area alone that our knowledge is defective. Though for three centuries the greater part of the territory has been nominally in Spanish possession, the interior of some of the larger islands has never been surveyed; several of the native tribes, especially in Mindanao, are altogether independent. The geology of Luzon, the best known of all the archipelago, is to a large extent matter of conjecture; and the visit of a passing botanist or naturalist is enough to add facts of primary importance to the register of flora and fauna. While none of the summits, with the exception, perhaps, of Apo in Mindanao, exceed 9,000 feet—the loftiest probably being Halcon in Mindoro (8,865 feet), Malindang in Mindanao (8,685 feet), Mayon in Luzon (8,275 feet), and Malaspina in Negros (8,190 feet)—all the islands may be described in general as mountainous and hilly. The principal ranges have a tendency to run north and south, with a certain amount of deflexion east or west, as the case may be, so that the orographic diagram of the archipelago as a whole would have a certain similarity to a fan with northern Luzon as its center of radiation.

Volcanic forces have had a great share in shaping the archipelago, and a large number of the mountains bear the stamp of their former activity. But those that still have the credit of being working volcanoes are comparatively few.

Earthquakes are sufficiently frequent and violent in the Philippines to affect the style adopted in the erection of buildings; in 1874, for instance, they were very numerous throughout the archipelago, and in Manila and the adjacent provinces shocks were felt daily for several weeks. The most violent earthquakes on record in the Philippines occurred in July, 1880, when the destruction of property was immense, both in the capital and in other important towns of central Luzon.

*Minerals.*—Though hitherto little advantage has been taken of its existence, there appears to be in several of the islands a fair amount of mineral wealth. Two coal-fields are known to exist, one beginning in Caransan in the south of Luzon, and probably extending southward across the Strait of San Bernardino to Catbalongan in Samar, and another occupying the western slopes of Cebu and the eastern slopes of Negros, and thus probably passing under the Strait of Tañon. Iron-ore of excellent purity occurs in various parts of Luzon, in Laguna, Bulacan, Pampanga, Camarines, Norte, and notably in the Camachin mountains between the Bulaon and the Garlan; but, with the exception of a few small foundries in Bulacan province, there are no iron-works in the country. In this department there was actually more activity a century ago. Copper-mines are worked at Mancayan, Suyuc, Bumucum, and Agbao in the province of Lepanto, by the Cantabro-Philippine Company, founded in 1862; and the heathen natives of that region (perhaps having learned the art from Chinese or Japanese strangers) appear to have long been accustomed to manufacture copper utensils for their own use and for sale in the Christian settlements.

*Climate.*—As the north part of Luzon is as far from the south of the Sulu Islands as the north of England from the south of Italy, and as the archipelago is

divided by the line of the ecliptic, the climate of one region differs considerably from that of another, though the general characteristics are everywhere tropical. The northern islands lie in the region of the typhoons. Three seasons are usually recognized—a cold, a hot, and a wet. The first extends from November to February or March; the winds are northerly, and, though there is no need for fire, woolen garments can be worn with comfort in the mornings; the sky is for the most part clear and the atmosphere bracing; and Europeans look forward to this period as the most enjoyable of the year. The hot season lasts from March to June, and the heat becomes very oppressive before the beginning of the southerly monsoon. Thunder-storms, often of terrific violence, are of frequent occurrence in May and June. The wet season is usually ushered in by the heavy rains locally known as “collas.” During July, August, September, and October the rain comes down in torrents, and large tracts of the lower country are flooded.

*Fauna.*—The mammals of the Philippines are strikingly few, especially when contrasted with those of such an island as Java; but their number may yet be slightly increased, and nine-tenths of them are peculiar species. Since *Cynopithecus niger* was struck out of the list, the only monkey known to science is *Macacus cynomolgus* (chongo of the Tagals), found in all the islands; but there are also pure white monkeys (not albinos) in Mindanao, and specimens are occasionally sold at Manila. The lemuroids are represented by the strange little *Tarsius spectrum*, the insectivora proper by *Galeopithecus philippensis* and a “tupaia,” or squirrel-shrew. Of carnivora there are three species, two civets and a wild cat, as well as the ordinary domestic animal. The rodents comprise only a few squirrels, *Sciurus philippensis*, etc., a porcupine, and two or three rats. Of bats there are between twenty and thirty species. The wild boar is regularly hunted in all the islands; the natives throughout the archipelago keep large numbers of black pigs; and the Babuyanes group take their name from *babuy*, “a pig.” Of deer there are three species, *Cervus mariannus*, *C. philippensis*, and *C. Alfreddi*; and a chevrotain or mouse-deer (*Tragulus*) is found, more especially in Bataan. Tapa, or sun-dried deer's flesh, is a favorite food with the natives. The statement that the horse has become wild in the interior of several islands is founded on a mistake. The ordinary domestic variety, probably of Spanish, Chinese, and Japanese origin, is “generally small, but well shaped and hardy, the largest and best breeds coming from Batangas, Albay, and Camarines, the smallest and probably the hardiest from Ilocos.” For all kinds of fieldwork the buffalo (“carabao”) is employed; ordinary cattle and goats are common enough, and some of the former are of great excellence. As there is a Tagalog name for it, it has been supposed that the elephant was at one time to be met with in the Philippines; and in the Sulu Islands, at least, it is said to have existed in the seventeenth century.

The birds of the Philippines proper show the isolated character of the group by the absence of a large number of ordinary Malayan forms, and at the same time there is a considerable proportion of genera from Australia, India, and China. Viscount Warden found the known species numbered 219, and R. B. Sharpe, by the assistance of Professor Steere's collections, brought the total up to 287 species, of which 151 were peculiar to the Philippines. To these must be added several species hitherto only found in the Sulu Islands. Palawan has a strong Bornean element. It is enough here to mention a number of peculiar woodpeckers, beautiful little parakeets (*Loriculus*), a number of pigeons (including

at least one peculiar genus, *Phapitreron*), cockatoos, mound-builders, and a peculiar hornbill, *Penelopides*, known from its note as “calao” to the natives, who frequently tame it. The principal game bird is the jungle-fowl (*Gallus bankiva*).

Alligators abound in some of the lakes and rivers; and turtles, tortoises, and various kinds of lizards are familiar enough forms; one of the last, the “chacon,” is believed by the natives to be a defense against earthquakes. The beauty and variety of the butterflies and the destructiveness of the termites are obtrusive features of the insect life; the land-shells are peculiar, numerous, and remarkable for delicacy of form and color. Some of the mollusks attain gigantic dimensions; the “taclobo” shell sometimes weighs 200 pounds, and is used for baptismal fonts. One of the most valuable kinds of fish is the “dalag” (*Ophiocephalus vagus*), and one of the most peculiar the *Hemiramphus vivipara*.

*Flora.*—The flora of the Philippines is essentially Malayan, intermixed with a Chinese element, but with sufficient individuality to constitute a sub-region. According to Llanos' edition of Manuel Blanco's *Flora de Filipinas*, 4,479 species are known, belonging to 1,223 genera and 155 orders.

*Products.*—Mangoes, plantains, mangosteen, jack-fruit, medlars, and in general most of the Malayan fruits are to be met with; the lanzon occurs in the north, and the durian in the south, more especially in the Sulu Islands. Rice is the staple food of the natives, but, though it is extensively cultivated, the supply is not always equal to the demand. Sweet potatoes (camote), a kind of yam (palawan), the groundnut, and gourds are pretty generally grown, as well as occasionally peas, potatoes, and in the higher regions even wheat. The plants which are of primary commercial importance are tobacco, Manila hemp, sugar-cane, coffee, and cocoa.

Tobacco was made a government monopoly by Captain-General José Basco y Vargas in 1781, and remained so till July 1, 1882. Though it was free to anyone to grow the plant to any extent he pleased, the government was the only purchaser, fixed its own price, and, paying its debts according to its own convenience, was sometimes three or four years in arrear. Besides, certain districts were bound to furnish a certain quantity of the leaf, and the peasant was thus often forced under severe penalties to devote himself to the tobacco crop when he would have obtained better results from something else. The best tobacco comes from the provinces of Isabel and Cagayan, and it is there that the cultivation is most systematically carried on; but the plant is also grown in other provinces of Luzon (Union, Ilocos, Lepanto, etc.), as well as in the Visayas Islands. Abacá, or MANILA HEMP (*G. v.*), is best grown in the south-east of Luzon, in Samar, Leyte and Bohol. Coffee was introduced, probably from Brazil, in the latter part of the eighteenth century, but the first plantation on a large scale was formed only in 1826. Sugar is extensively cultivated, and the export had increased from 1,399,434 piculs in 1871 to 3,382,664 in 1881.

*Trade.*—Before the conquest there was considerable commercial intercourse between the Philippines and China and Japan, but this, which would naturally have developed enormously if the Spanish trade between Manila and America (Navidad and Acapulco) had been left free, was interrupted, and at times almost completely stopped, by a series of absurd restrictions, devised in the supposed interest of the trade between Spain and America. For a long period only a single galleon, under government supervision, was allowed to proceed yearly from Manila to Acapulco, the value of the cargo each way being bound not to exceed a certain sum. Direct trade with Europe *via* the Cape was commenced

in 1764; but, as if the exclusion of all except Spanish ships was not sufficient, a practical monopoly of this field of enterprise was, in 1785, bestowed on the Royal Company of the Philippines. With the close of the eighteenth century a certain amount of liberty began to be conceded to foreign vessels; the first English commercial house was established at Manila in 1809; and in 1834 the monopoly of the Royal Company expired. Manila remained the only port for foreign trade till 1842, when Cebu was also opened; Zamboanga (Mindanao), Iloio (Panay), Sual (Luzon); Legazpi or Albay (Luzon), and Tacloban (Leyte) are now in the same category, but only Manila, Iloilo, and Cebu have proved of real importance, as they are the only ports where foreign-bound vessels have hitherto loaded.

*Administration, Etc.*—The Philippines are subject to a governor-general with supreme powers, assisted by (1) a "junta of authorities" instituted in 1850, and consisting of the archbishop, the commander of the forces, the admiral, the president of the supreme court, etc.; (2) a central junta of agriculture, industry, and commerce (dating from 1866); and (3) a council of administration. In the provinces and districts the chief power is in the hands of *alcaldes mayores* and civic-military governors. The chief magistrate of a commune is known as the *gobernadorcillo* or captain; the native who is responsible for the collection of the tribute of a certain group of families is the *cabeça de barangay*. Every Indian between the ages of sixteen and sixty subject to Spain has to pay tribute to the amount of \$1.17—descendants of the first Christians of Cebu, new converts, *gobernadorcillos*, etc., being exempted. Chinese are subject to special taxes; and by a law of 1883 Europeans and Spanish half-castes are required to pay a poll-tax of \$2.50.

Ecclesiastically the Philippines comprise the archbishopric of Manila and the suffragan bishoprics of Nueva-Caceres, Nueva-Segovia, Cebu, and Santa Isabel de Jaro, which were all constituted by the bull of Clement VIII., August 14, 1595, with the exception of the last, whose separation from Cebu dates only from the bull of Pius IX., May 27, 1865. The Agustinos Calzados were established in the Philippines in the year 1565, the first prelate being Andres Urdaneta, and they have convents in Manila, Cebu, and Guadalupe. The Franciscans date from 1577, and have convents at Manila and San Francisco del Monte; the Dominicans (1587) at Manila and San Juan del Monte; the Recollects or strict Franciscans (1606) at Manila, Cavite, and Cebu. The Jesuits, restored in 1852, maintain the missions of Mindanao and Sulu; and they have charge in Manila of the municipal athenæum, the normal school for primary teachers, and an excellent meteorological observatory. There are also Sisters of Charity, and nuns of the royal monastery of Santa Clara, founded in 1621.

*Education.*—A good deal has been done for the diffusion of primary education among the natives (every pueblo is bound to have a school), but the standard is not a high one. The press is under strict civil and ecclesiastical control, and all discussion of Spanish or general European politics is forbidden. Several daily papers, however, are published at Manila, *El Diario de Manila* dating from 1848.

There are no accurate statistics of the whole population of the Philippines; and even the number of the Spanish subjects was, up till 1877, only estimated according to the number of those who paid tribute. Diaz Arenas in 1833 stated the total at 3,153,290, the ecclesiastical census of 1876 at 6,173,632, and the civil census of 1877 at 5,561,232. Moya y Jimenez, founding on certain calculations by Del Pan, and admitting an an-

nual increase of 2 per cent., brings the number up to 10,426,000 in 1882.

*History.*—The Philippine or, as he called them, the St. Lazarus Islands were discovered by Magellan March 12, 1521, the first place at which he touched being Jomonjol, now Malhou, an islet in the Strait of Surigao, between Samar and Dinagat. By April 27th, he had lost his life on the island of Mactan off the coast of Cebu. The surrender of the Moluccas by Charles V., in 1529, tended to lessen the interest of the Spaniards in the *Islas de Poniente*, as they generally called their discovery, and the Portuguese were too busy in the new southern parts of the Indian Archipelago to trouble about the *Islas de Oriente*, as they preferred to call them. Villalobos, who had sailed from Navidad in Mexico with five ships and 370 men in February, 1543, accomplished little (though it was he who suggested the present name of the archipelago by calling Samar Filipina); but in 1565 Legazpi founded the Spanish settlement of San Miguel at the town of Cebu, which afterward became the Villa de Santissimo Nombre de Jesus, and in 1571 determined in large measure the future lines of conquest by fixing the capital at Manila. It is in a letter of Legazpi's in 1567 that the name *Islas Filipinas* appears for the first time. The subjugation of the islands, thanks to the exertions of the Roman Catholic missionaries and to the large powers which were placed in their hands by Philip, was effected, not, of course, without fighting and bloodshed, but without those appalling massacres and depopulations which characterized the conquest of South America. Contests with frontier rebellious tribes, attacks by pirates and reprisals on the part of the Spaniards, combine with volcanic eruptions, earthquakes, and tornadoes to break the comparative monotony of the subsequent history. Manila was captured by the English under Draper and Cornish in 1762, and ransomed for \$5,000,000; but it was restored in 1764.

PHILIPPOPOLIS, FILIPPOPEL, and (Turkish) FELIBE, a city of Thracia, previous to 1878 the chief town of a sanjak in the Turkish vilayet of Adrianople, and now the capital of the independent province of Eastern Roumelia and the chief town of one of the six departments, lies 112 miles west-northwest of Adrianople by rail and thus 309 miles from Constantinople, mainly on the right bank of the Maritza (the ancient Hebrus). The population, estimated at 24,000 to 28,000, consists of Bulgarians, and, in smaller proportions, of Greeks, Turks, Armenians, Jews and Gipsies.

PHILIPPSBURG, a small town of the grand-duchy of Baden, situated on a sluggish arm of the Rhine, fifteen miles to the north of Carlsruhe, was formerly an important fortress of the German empire, and played a somewhat conspicuous part in the wars of the seventeenth century. The population in 1880 was 2,549.

PHILIPPUS, M. JULIUS, Roman emperor from 244 to 249 A.D., often called "Philip the Arab," was a native of Bostra or the Trachonitis, who exchanging the predatory life of the Arabs who hung on the desert borders of the empire for Roman military service, rose to be prætorian prefect in the Persian campaign of Gordian III., and inspiring the soldiers to mutiny and to slay the young emperor, was raised by them to the purple (244). Of his reign little is known except that he celebrated the secular games with great pomp in 248.

PHILIPS, AMBROSE, English man of letters, was born of a good Leicester family in 1671. He died in 1749.

PHILIPS, JOHN, English man of letters, son of Dr. Stephen Philips, archdeacon of Salop, was born at Bampton, in Oxfordshire, in 1676. He died in 1708.

**PHILISTINES**, the name of a people which, in the latter part of the age of the Judges and up to the time of David, disputed the sovereignty of Canaan with the Israelites (see ISRAEL). The Philistine country embraced the rich lowlands on the Mediterranean coast (the Shephelah) from somewhere near Joppa to the Egyptian desert south of Gaza, and was divided between five chief cities, Ashdod or AZOTUS (*q.v.*), GAZA (*q.v.*), and Askelon (Ashkelon, ASCALON, *q.v.*) on or near the coast, and GATH (*q.v.*) and EKRON (*q.v.*) inland. The five cities, of all of which except Gath the sites are known, formed a confederation under five "lords" (Serānīm). Ashdod was probably the foremost city of the confederation in the time of Philistine supremacy; for it heads the list in 1 Sam. vi. 17, and it was to the temple of Dagon in Ashdod that the ark was brought after the battle of Aphek or Ebenezer. Hebrew tradition recognizes the Philistines as immigrants into Canaan within historical times, like the Israelites and the Aramæans, but unlike the Canaanites. They came, according to Amos, from Caphtor, and Deut. ii. 23 relates that the Caphtorim from Caphtor displaced an earlier race, the 'Avvīm, who were not city-dwellers like the Canaanites, but lived in scattered villages. The very name of Philistines probably comes from a Semitic root meaning "to wander;" the Septuagint calls them "aliens." The date of their immigration cannot be determined with certainty.

**PHILLIP, JOHN**, subject and portrait painter, was born at Aberdeen, Scotland, on April 19, 1817. In 1857 Phillip was elected an associate of the Royal Academy, and in 1859 a full member. In the end of 1866 his excessive application to work for the next year's exhibition induced an attack of bilious fever, which was succeeded by paralysis, and the genial and talented artist expired at London on February 27, 1867, at the age of fifty.

**PHILLIPS, JOHN**, one of the foremost of the early geologists of England, was born December 25, 1800, at Marden, in Wiltshire. From school he went to the house of the Rev. B. Richardson, an accomplished naturalist, in whose charge he remained a year, and from whom he obtained not only much knowledge but the strong bent toward the study of nature which henceforth became the master-pursuit of his life. His uncle, "Strata Smith," at that time lived in London, where he exercised the profession of a civil and mining engineer, though a very large part of his time and earnings were given to the preparation of those maps of England and the English counties on which his fame now rests. A youth so trained could not fail to become a geologist. In the spring of 1824 Smith went to York to deliver a course of lectures on geology, and his nephew accompanied him. This was the starting-point in Phillips' career. His extensive knowledge of natural science and especially of fossils was now turned to account. He accepted engagements in the principal Yorkshire towns to arrange their museums and give courses of lectures on the collections contained therein. York became his residence, where he obtained the situation of keeper of the Yorkshire Museum and secretary of the Yorkshire Philosophical Society. From that center he extended his operations to other towns beyond the county; and in 1831 he included University College, London, in the sphere of his activity. In that year the British Association for the Advancement of Science was founded at York, and Phillips was one of the active minds who organized its machinery.

This arrangement lasted for six years, until, in 1840, he resigned his charge of the York Museum and was appointed one of the staff of the Geological Survey of Great Britain under De la Beche. Nine years later, on

the death of Strickland, who had acted as substitute for Doctor Buckland in the readership of geology in the university of Oxford, Phillips succeeded to the post of deputy, and eventually, at the dean's death, became himself reader, a post singularly congenial to him, and which he held up to the time of his own death, which was almost tragic in its suddenness. He dined at All Souls' College on April 23, 1874, but in retiring slipped and fell headlong down a flight of stairs. Paralysis at once ensued, and he expired on the afternoon of the next day. In 1864 he had been elected president of the British Association.

**PHILLIPS, SAMUEL**, an industrious and successful *littérateur*, was the son of a Jewish tradesman in Regent street, London, and was born in 1815, and died in 1854.

**PHILLIPS, THOMAS**, portrait and subject painter, was born at Dudley, in Warwickshire, on October 18, 1770, and died in 1845.

**PHILLIPS, WILLIAM**, an able British mineralogist and geologist, who did much to foster in Britain the study of the sciences to which he was devoted, was born May, 1775, and died in 1828.

**PHILLIPSBURG**, a city of the United States, on the Delaware river, in Warren county, N. J., is opposite Easton, Penn., and at the western terminus of the Morris canal, about fifty miles to the northwest of Trenton, the capital of the State. It is also on the Belvidere division of the Pennsylvania Central, which here connects with the Morris and Essex and the Central Railroad of New Jersey, and on the Philadelphia and Reading, Lehigh Valley, and Delaware, Lackawanna and Western roads, all of which occupy separate depots. The river at this point is crossed by two fine bridges, owned by the railway interests located here. The principal business of the city is connected with manufacturing industries, which are of a varied and comprehensive character, embracing sheet and malleable iron works, tileworks, sawmills, stoveworks, carriage factories, silkmills, locomotive and boiler works, furniture factories, pulpmills, foundries and machine-shops, brick and marble works, and mower and reaper factories. It contains six churches, high-school and graded-school buildings, two banks, a newspaper office, twelve hotels, and between one and two hundred stores, wholesale and retail. Iron-ore and limestone are mined in close proximity to the city. The population, in 1890, was 8,644.

**PHILO**, often called **PHILO JUDÆUS**, Jewish philosopher, appears to have spent his whole life at Alexandria, where he was probably born *c.* 20-10 B.C. His brother Alexander was alabarch or arabarch (that is, probably, chief farmer of taxes on the Arabic side of the Nile), from which it may be concluded that the family was influential and wealthy. Jerome's statement that he was of priestly race is confirmed by no older authority. The only event of his life which can be exactly dated belongs to 40 A.D., when Philo, then a man of advanced years, went from Alexandria to Rome, at the head of a Jewish embassy, to persuade the emperor Caius to abstain from claiming divine honor of the Jews. Of this embassy Philo has left a full and vivid account. Various fathers and theologians of the church state that in the time of Claudius he met St. Peter in Rome; but this legend has no historic value, and probably arose because the book *De vita contemplativa*, falsely ascribed to Philo, in which Eusebius already recognized a glorification of Christian monasticism, seemed to indicate a disposition toward Christianity.

Though we know so little of Philo's own life, his numerous extant writings give the fullest information as to his views of the universe and of life, and his religious and scientific aims, and so enable us adequately to esti-

mate his position and importance in the history of thought. He is quite the most important representative of Hellenistic Judaism, and his writings give us the clearest view of what this development of Judaism was and aimed at.

PHILO. A Jewish Hellenist of this name is the author of an epic poem in Greek hexameters on the history of Jerusalem, and lived at an earlier date than the philosopher, Alexander Polyhistor quoting several passages of his book about 80-60 B.C.

PHILO BYBLIUS, *i.e.*, Philo of Byblus (Gebal, Jubeil), was born, according to Suidas, in 42 A.D., and lived into the reign of Hadrian, about which he wrote a book now wholly lost. He was a grammarian by profession and author of many books, of which those oftenest cited are: (1) a work *About Cities and the Famous Men they have Produced*, which was epitomized by Serenus, and (2) *Phœnician History*.

PHILO OF BYZANTIUM, author of a treatise on mechanics, of which only two books now remain, flourished in the second or third century A.D.

PHILOLAUS, next to Archytas the most illustrious of the Pythagorean philosophers, was born at Tarentum or, according to Diogenes Laertius, at Crotona. He was said to have been intimate with Democritus, and was probably one of his teachers.

Philolaus was the first to propound the doctrine of the motion of the earth; some, however, attribute this doctrine to Pythagoras, but there is no evidence in support of their view. Philolaus supposed that the sphere of the fixed stars, the five planets, the sun, moon, and earth, all moved around the central fire, which he called the hearth of the universe, the house of Zeus, and the mother of the gods; but as these made up only nine revolving bodies he conceived, in accordance with his number theory, a tenth, which he called counter-earth. He was the first who published a book on the Pythagorean doctrines, a treatise of which Plato made use in the composition of his *Timæus*.

PHILOLOGY. *Part I. Science of Language in General.*—Philology is the generally accepted comprehensive name for the study of the word; it designates that branch of knowledge which deals with human speech, and with all that speech discloses as to the nature and history of man. Philology has two principal divisions, corresponding to the two uses of "word" or "speech," as signifying either what is said or the language in which it is said, as either the thought expressed—which, when recorded, takes the form of literature—or the instrumentality of its expression: these divisions are the literary and the linguistic.

Philology, in all its departments, began and grew up as classical; the history of our civilization made the study of Greek and Latin long the exclusive, still longer the predominant and regulating, occupation of secular scholarship. The Hebrew and its literature were held apart, as something of a different order, as sacred. It was not imagined that any tongue to which culture and literature did not lend importance was worthy of serious attention from scholars. The first essays in comparison, likewise, were made upon the classical tongues, and were as erroneous in method and fertile in false conclusions as was to be expected, considering the narrowness of view and the controlling prejudices of those who made them; and the admission of Hebrew to the comparison only added to the confusion. The change which this century has seen has been a part of the general scientific movement of the age, which has brought about the establishment of so many new branches of knowledge, both historical and physical, by the abandonment of shackling prejudices, the freedom of inquiry, the recognition of the dignity of all knowledge, the

wide-reaching assemblage of facts and their objective comparison, and the resulting constant improvement of method. Literary philology has had its full share of advantage from this movement; but linguistic philology has been actually created by it out of the crude observations and wild deductions of earlier times, as truly as chemistry out of alchemy, or geology out of diluvianism.

The study of language is a division of the general science of anthropology, and is akin to all the rest in respect of its objects and its methods. Man as we now see him is a two-fold being; in part the child of nature, as to his capacities and desires, his endowments of mind and body; in part the creature of education, by training in the knowledge, the arts, the social conduct, of which his predecessors have gained possession. And the problem of anthropology is this: how natural man has become cultivated man; how a being thus endowed by nature should have begun and carried on the processes of acquisition which have brought him to his present state.

How long man, after he came into being such as he now is, physically and intellectually, continued to communicate with imitative signs of direct significance, when the production of traditional signs began, how rapidly they were accumulated, and how long any traces of their imitative origin clung to them—these and the like questions it is at present idle to try to answer even conjecturally; just as it is to seek to determine when the first instruments were used, how soon they were shaped instead of being left crude, at what epoch fire was reduced to service, and so on. The stages of development and their succession are clear enough; to fix their chronology will doubtless never be found practicable. There is much reason for holding, as some do, that the very first items of culture were hardest to win and cost most time, the rate of accumulation (as in the case of capital) increasing with the amount accumulated. Beyond all reasonable question, however, there was a positively long period of purely imitative signs, and a longer one of mixed imitative and traditional ones, the latter gradually gaining upon the former, before the present condition of things was reached, when the production of new signs by imitation is only sporadic and of the utmost rarity, and all language-signs besides are traditional, their increase in any community being solely by variation and combination, and by borrowing from other communities.

Of what nature, in various respects, this earliest language-material was is sufficiently clear. The signs, in the first place, were of the sort that we call "roots." By this is only meant that they were integral signs, significant in their entirety, not divisible into parts, of which one signified one thing and another another thing, or of which one gave the main significance, while another was an added sign of a kind or relation. In a language of developed structure like our own, we arrive at such "roots" mainly by an artificial stripping-off of the signs of relation which almost every word still has, or can be shown to have once had.

Of what phonetic form were the earliest traditional speech-signs is, so far as essentials are concerned, to be inferred with reasonable certainty. They were doubtless articulate: that is to say, composed of alternating consonant and vowel sounds, like our present speech; and they probably contained a part of the same sounds which we now use. All human language is of this character; there are no sounds in any tongue which are not learned and reproduced as easily by children of one race as of another; all dialects admit a like phonetic analysis, and are representable by alphabetic signs; and the leading sounds, consonant and vowel, are even

practically the same in all; though every dialect has its own (for the most part, readily definable and imitable) niceties of their pronunciation, while certain sounds are rare, or even met with only in a single group of languages, or in a single language. Articulate sounds are such as are capable of being combined with others into that succession of distinct yet connectable syllables which is the characteristic of human speech-utterance. The name "articulate" belongs to this utterance, as distinguished from inarticulate human sounds and cries, and from the sounds made by the lower animals. The word itself is Latin, by translation from the Greek, and, though very widely misunderstood, and even deliberately misapplied in some languages to designate all sound, of whatever kind, uttered by any living creature, is a most happily chosen and truly descriptive term. It signifies "jointed," or broken up into successive parts, like a limb or stem; the joints are the syllables; and the syllabic structure is mainly effected by the alternation of closer or consonant sounds with opener or vowel sounds. The simplest syllabic combination (as the facts of language show) is that of a single consonant with a following vowel; and there are languages even now existing which reject any other. Hence there is much plausibility in the view that the first speech-signs will have had this phonetic form, and been monosyllabic, or dissyllabic only by repetition (reduplication) of one syllable, such as the speech of very young children shows to have a peculiar ease and naturalness.

As regards their significant value, the first language-signs must have denoted those physical acts and qualities which are directly apprehensible by the senses; both because these alone are directly signifiable, and because it was only they that untrained human beings had the power to deal with or the occasion to use. Such signs would then be applied to more intellectual uses as fast as there was occasion for it. The whole history of language, down to our own day, is full of examples of the reduction of physical terms and phrases to the expression of non-physical conceptions and relations; we can hardly write a line without giving illustrations of this kind of linguistic growth. So pervading is it, that we never regard ourselves as having read the history of any intellectual or moral term till we have traced it back to a physical origin. And we are still all the time drawing figurative comparisons between material and moral things and processes, and calling the latter by the names of the former. There has never been any difficulty in providing for new knowledge and more refined thought by putting to new uses the earlier and grosser materials of speech.

As a matter of course, whatever we now signify by our simple expressions for simple acts, wants, and the like was intended to be signified through the first speech-signs by the users of them. But to us, with our elaborated apparatus of speech, the sentence, composed of subject and predicate, with a verb or special predicative word to signify the predication, is established as the form of expression, and we regard everything else as an abbreviated sentence, or as involving a virtual sentence. With a view to this, we must have "parts of speech:" that is, words held apart in office from one another, each usable for such and such a purpose and no other, and answering a due variety of purposes, so that when they are combined they fit together, as parts composing a whole, and the desired meaning is made clear. Inflections, too, lend their aid; or else auxiliary words of various kinds answering the same purpose—namely, of determining the relations of the members of the sentence. But all our success in understanding the earliest stages of language depends upon

our power to conceive a state of things where none of these distinctions were established, where one speech-sign was like another, calling up a conception in its indefinite entirety, and leaving the circumstances of the case to limit its application. Such a language is far below ours in explicitness; but it would suffice for a great deal of successful communication: indeed, there are many languages even now in existence which are little better off. So a look of approval or disgust, a gesture of beckoning or repulsion, a grunt of assent or inquiry, is as significant as a sentence, means a sentence, is translatable into a sentence, and hence may even in a certain way be called a sentence; and in the same way, but only so, the original roots of language may be said to have been sentences. In point of fact, between the holophrastic gesture or uttered sign and the sentence which we can now substitute for it—for example, between the sign of beckoning and the equivalent sentence, "I want you to come here"—lies the whole history of development of inflective speech.

What has been this history of development, how the first scanty and formless signs have been changed into the immense variety and fullness of existing speech, it is of course impossible to point out in detail, or by demonstration of facts, because nearly the whole process is hidden in the darkness of an impenetrable past. The only way to cast any light upon it is by careful induction from the change and growth which are seen to have been going on in the recent periods for which we have recorded evidence, or which are going on at the present time. Of some groups of related languages we can read the life for 3,000 or 4,000 years back, and by comparison can infer it much farther; and the knowledge thus won is what we have to apply to the explanation of periods and languages otherwise unknown. Nothing has a right to be admitted as a factor in language-growth of which the action is not demonstrable in recorded language.

*Part II. Comparative Philology of the Aryan Languages.*—The study of Aryan comparative philology has from its outset necessarily been in close connection with the study of Sanskrit, a language unparalleled among its cognates in antiquity and distinctness of structure, and consequently the natural basis of comparison in this field. It is therefore not to be wondered at that we find no clear views of the mutual relationship of the individual members of the Aryan family or their position with regard to other languages until Sanskrit began to attract the attention of European philologists, or that the introduction of Sanskrit as an object of study was closely followed by the discovery of the original community of a vast range of languages and dialects hitherto not brought into connection at all, or only made the objects of baseless speculations. We meet with the first clear conception of this idea of an Indo-European community of languages in the distinguished English scholar Sir William Jones, who, as early as 1786, expressed himself as follows: "The Sanskrit language, whatever may be its antiquity, is of wonderful structure; more perfect than the Greek, more copious than the Latin, and more exquisitely refined than either, yet bearing to both of them a stronger affinity, both in the roots of verbs and in the forms of grammar, than could have been produced by accident; so strong that no philologist could examine all the three without believing them to have sprung from some common source which, perhaps, no longer exists. There is a similar reason, though not quite so forcible, for supposing that both the Gothic and the Celtic, though blended with a different idiom, had the same origin with the Sanskrit." But neither Sir William Jones nor any of his older contemporaries who had arrived at similar con-

clusions ever raised this important discovery from a brilliant *aperçu* into a valid scientific theory through a detailed and systematic comparison of the languages in question. To have achieved this is the undoubted merit of the German, Franz BOPP (*q.v.*), the founder of scientific philology of the Aryan languages, and subsequently through this example also the founder of comparative philology in general. Next to him Jacob GRIMM (*q.v.*) must be mentioned here as the father of historical grammar. The first part of his famous *Deutsche Grammatik* appeared in 1819, three years after Bopp had published his first epoch-making book, *Ueber das Conjugations-system der Sanskritsprache*. Bopp's results were here at once utilized, yet Grimm's whole system was entirely independent of that of Bopp, and had no doubt been worked out before Grimm knew of his illustrious predecessor. In fact, their scientific aims and methods were totally different. Bopp's interest was not concentrated in comparison as such, but chiefly inclined toward the explanation of the origin of grammatical forms, and comparison to him was only a means of approaching that end.

In this more or less speculative turn of his interest Bopp showed himself the true son of a philosophical period when general linguistics received its characteristic stamp from the labors and endeavors of men like the two Schlegels and Wilhelm von Humboldt. Jacob Grimm's aims were of a less lofty character than those of Bopp, whose work, to his own mind, was crowned by his theory of the origin of inflection through agglutination. In confining his task to a more limited range than the vast field of Aryan languages embraced in Bopp's researches, and thus fixing his attention on a group of idioms exhibiting a striking regularity in their mutual relationship, both where they coincide and where they differ, he made it his foremost object to investigate and illustrate the continuous progress, subject to definite laws, by which these languages had been developed from their common source. He thus raised the hitherto neglected study of the development of sounds to an equal level with the study of grammatical forms, which had so far almost exclusively absorbed all the interest of linguistic research. Grimm's discovery of the so-called "Lautverschiebung," or Law of the Permutation of Consonants in the Teutonic languages (which, however, had been partly found and proclaimed before Grimm by the Danish scholar Rask), became especially important as a stimulus for further investigation in this line. Grimm's influence on comparative philology (which is secondary only to that of Bopp, although he was never a comparative philologist in the sense that Bopp was, and did not always derive the benefit from Bopp's works which they might have afforded him) is clearly traceable in the work of Bopp's successors, among whom Friedrich August Pott is universally judged to hold the foremost rank. In his great work, *Etymologische Forschungen auf dem Gebiete der indo-germanischen Sprachen, mit besonderem Bezug auf die Lautumwandlung im Sanskrit, Griechischen, Lateinischen, Littauischen, und Gothischen* (Lemgo, 1833-36), we find Indo-Germanic etymology for the first time based on a scientific investigation of general Indo-Germanic phonology. Among Pott's contemporaries Theodor Bensey deserves mention on account of his *Griechisches Wurzellexicon* (Berlin, 1839), a work equally remarkable for copiousness of contents and power of combination, yet showing no advance on Bopp's standpoint in its conception of phonetic changes.

The most prominent achievement of the researches of Bopp and his followers was to prove that the majority of the European languages and dialects, together with a certain number of important languages spoken in Asia, form one great family—that is, that they have

sprung from one common source or parent-language. The name now mostly used in England for this community is *Aryan languages*. American and French scholars generally prefer to say *Indo-European languages*, while the name of *Indo-Germanic languages* is still almost universally used in Germany. It is hard to decide for or against any of these names from a scientific point of view. The word *Indo-Germanic* was not inappropriately coined by combining the names of the most easterly and westerly members of the family, the Indian and the Germanic or Teutonic group. *Indo-European* seems to be a less lucky invention, as this combination of geographical names would erroneously point to all the languages of India and Europe as the constituents of our family, while a large number both of Indian and European idioms belong to entirely unrelated groups of languages. *Aryan* would no doubt be the best name in itself, for it seems that the primitive forefathers of the Aryan nations used the word *Aria* as a national name themselves. We find at least the Sanskrit *Ārya* thus used in India, and similarly the Old Persian *Ariya* (in the cuneiform inscriptions of Darius), Zend *Airya* in Persia (whence the later *Ērān*, *Īrān*), and perhaps *Ériu*, gen. *Érenn*, as the national name for Ireland. But before the word *Aryan* came to be applied in the sense defined above it had for some time been used, and it is still largely used, in a more restricted sense as the special collective name for the languages of the Indian and Persian or Iranian groups of the Indo-Germanic family. This ambiguity renders the use of the word *Aryan* less recommendable than it would be had its name been properly fixed from the beginning. It seems that outside of England *Aryan* will hardly gain ground; some recent attempts to introduce the name into Germany have utterly failed, and in the same way the other nations who share in scientific research in this demesne cling to the older names.

This large Indo-Germanic or Aryan family, then, to revert to our principal task, consists of ten groups or sub-families of languages, three of which are located in Asia, while the rest belong to Europe.

1. The *Indian Family*, in which Sanskrit, especially in its oldest form, preserved in the Vedic texts, stands foremost in rank. Of the older stages of the language Prākṛit and Pāli may be mentioned here—the former, in its various branches, being the mother of the modern Indian dialects of Aryan descent (including also the Gipsy language), the latter (see Pāli) the idiom of the sacred books of the southern Buddhists.

2. The *Iranian or Persian Family*, represented in the earliest period by Old Persian, scanty remnants of which have come down to us in the Achæmenian cuneiform inscriptions, and Zend, or, as it is also called, Old Bactrian, the language of the *Zend-Avesta*, the sacred books of the Zoroastrians. The chief modern representatives of this group are Persian, Afghan, Kurdish, and Ossetic.

3. The *Armenian Family*, consisting of the different living dialects of Armenian. Armenian has but recently been proved to be an independent member of the Aryan family. It partakes of many peculiarities of the Iranian group, but at the same time shares several important characteristics of the European languages, so that it cannot be classed as a subdivision of either of these groups.

4. The *Greek Family*, comprising the various old dialects of Greek, and the modern Romaic idioms, which have been developed out of the later *Koine* that had gradually superseded the old dialectal varieties.

5. A fifth family, which may once have had a far larger extension, is now only represented by one surviving member, the *Albanian language*. As we have no old

sources for this idiom, and only know it in its modern state of utter decay, it is extremely difficult to obtain definite results concerning its origin and position relatively to the surrounding languages. Bopp seems to have proved, however, that Albanian actually is an Aryan idiom. It is also certain that it belongs to the European type of Aryan, yet it is not particularly closely allied with Greek, as has often been assumed, but shows some remarkable coincidences with the northern European languages.

6. The *Italic Family*. Its most important representative is Latin, from which the modern Romance languages have sprung. Closely connected with Latin was the Faliscan dialect, which is preserved in a few inscriptions only. A second branch of Italic is formed by Umbrian and Oscan, both of which soon became extinct through the overpowering influence of Latin, like the other less widely diffused idioms once spoken in Italy.

7. The *Celtic Family*, once covering a large part of western Europe, but now reduced to comparatively scanty remnants in the northwest of France and in the British islands. Among its extinct members the language of the Galatians in Asia Minor may be mentioned, of which little more is known than that it was Celtic. The earliest documents of Celtic speech we possess are some inscriptions in the idiom of the Gallic inhabitants of France and northern Italy. The surviving branches of Gallic show a clear division into two groups: the Northern or Gaelic group, formed by Irish, Gaelic or Scotch, and Manx, and a Southern or Brittonic group, consisting of Welsh or Cymric, Cornish (extinct since 1778), and Armorican or Bas Breton in Brittany.

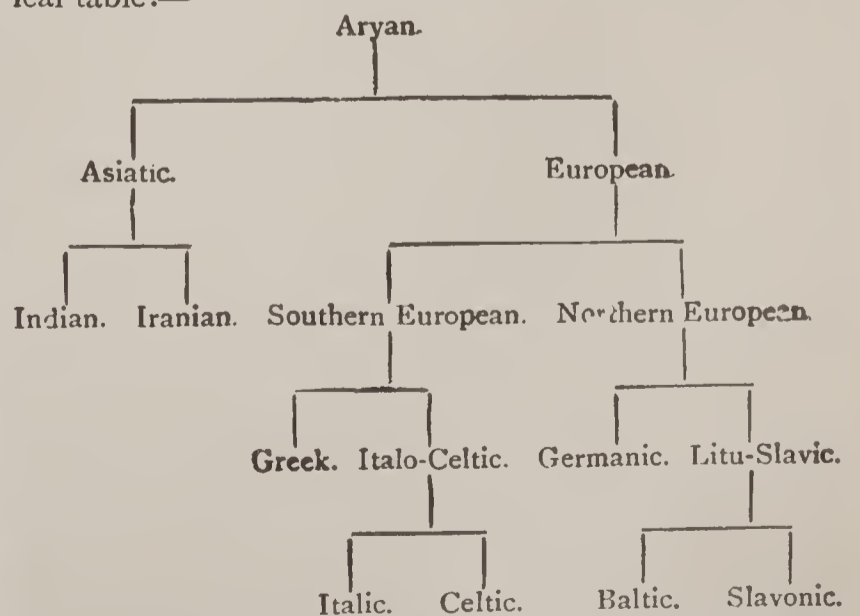

8. The *Germanic or Teutonic Family*. This well developed family is divided into two main groups, which are now commonly denoted Eastern and Western Germanic. The members of the former are Gothic (see GOTHIC LANGUAGE) and Scandinavian, with an eastern and western subdivision, the former comprising Swedish and Danish, the latter Norse and Icelandic. Western Germanic, on the other hand, consists of English, Frisian (these two seem to form a separate branch), Saxon or Low German, Frankish (including Dutch), and Upper German (see article GERMAN LANGUAGE). The dialects of the numerous other Teutonic tribes not mentioned here have died out without leaving sufficient materials for linguistic classification.

9. The *Baltic Family*, comprising three distinct idioms—Prussian, Lithuanian, and Lettish. Prussian became extinct in the sixteenth century.

10. The *Slavonic Family*. There are two main branches of Slavonic. The so-called Southern or Southeastern branch embraces Russian, Ruthenian (in Galicia), Bulgarian, Servian, Croatian, and Slovenian. The second branch is generally designated by the name of Western Slavonic. It is chiefly represented by Cechish or Bohemian and Polish. With the former the Sorbian dialects spoken in Lusatia are very closely connected. Polish, again, is subdivided into Eastern Polish or Polish Proper and Western Polish, a few remnants of which now survive in the Kassubian dialects of Prussia.

The mutual relationship of these ten families may be shortly characterized by saying that they are dialects of the primitive Aryan parent-speech, which at an early period of its existence must have formed a linguistic unity, but subsequently became dissolved into these subdivisions. This fundamental view now seems to be universally admitted to be correct. But it is extremely difficult to go beyond it in attempts to trace out the history of the process of dissolution. One problem offering itself at the very outset of such an attempt (although

more of an ethnological than philological character) must at once be dismissed as insoluble—the question of the original home of our Aryan forefathers and the directions of the wanderings that brought the single members of the great original tribe to the seats occupied in historical times by the several Aryan nations. There exist, indeed, no means for deciding whether they came from the northeastern part of the Iranian plateau near the Hindu-Kush Mountains, as was once generally assumed, or whether Europe may boast of being the mother of the Aryan nationality, as some authors are now inclined to believe. The chief philological difficulty lies in the fact that some of these ten families stand in closer relationship with certain others than with the rest, so that they seem to form separate independent groups, and yet these groups cannot be severed from the rest without overlooking important linguistic facts which seem to speak for the existence of a closer connection between single members of one group and single members or the whole of another. Before attention was drawn to this latter point it was easy enough to account for the origin of the grouping alluded to. If everything that is common to all Aryan languages must have originated in the common parent-speech—and the correctness of this assumption can hardly be doubted—then everything that is common to all the families of one particular group, but strange to the others, must be assigned to a period when these families formed a unity by themselves and were disconnected with the other stock. The fact, for instance, that all the European languages possess the three vowels *a*, *e*, *o*, where the Indian and Iranian group show the uniform *a*, which was then believed to be the primitive sound, seemed to indicate that the primitive Aryan stock had once been split into two halves, one of which remained in Asia and retained the primitive *a*-sound, while the other half emigrated to Europe and there developed the new vowel-system, before any new divisions took place. The Aryan parent-speech would thus appear to have been split into a European and an Asiatic “base-language.” Similar facts in the history of the single European languages then led to the further assumption of a southern European base as the parent of Greek, Italic, and Celtic, and a northern European base for Germanic, Baltic, and Slavonic, and, with further subdivision, an Italo-Celtic and a Litu-Slavic base for Italic and Celtic on the one hand and for Baltic and Slavonic on the other. The prehistoric development of Aryan, according to this genealogical theory (which makes division of language dependent on division of nations), may be illustrated by the following genealogical table:—

It may still be admitted that at least the mutual position of the ten families is not the same in all cases. It can

not be doubted that Indian and Iranian resemble each other more than either of them does any other family. The same may also be said of Baltic and Slavonic, and even of Italic and Celtic, however different the latter two may appear to be at first sight. But it is impossible to carry this system of genealogical grouping through. It will be observed that not all the ten families are represented in the genealogical tree given above; Albanian and Armenian have not found a place in it, nor could they be introduced without disturbing the entire table. If we look at Armenian, for instance, we find that its structure and phonology on the whole follow the Asiatic type, and yet Armenian shares the European vowel-system alluded to before; compare, for instance, Armenian *berem*, "I bear," with Greek *fero*, Latin *fero*, Old Irish *berim*, Gothic *baira* (pronounced *bëra*) Lith. *berù*, Slavonic *bera*, against Sanskrit *bhārāmi*, Zend *barāmi*. Armenian, then, is half European, half Asiatic, and if such an intermediate idiom exists it is impossible to make a strict distinction between Asiatic and European. Let us take another instance. All the Asiatic languages have changed the original palatal *k* into sibilants, and the same change we find again in Slavonic and Baltic, both of which otherwise clearly belong to the European type; compare, for instance Sanskrit and Zend *daçan*, "ten," Armenian *tasn*, Slavonic *desetŭ*, Lith. *dëszimt*, with Greek *dëka*, Latin *decem*, Old Irish *deich*, Gothic *taihun*. In a similar way Litu-Slavic and Germanic are connected by the formation of a plural dative in *m*, as in Gothic *wulfam*, Lith. *vilkans*, Slavonic *vlükomŭ*, against the Sanskrit *-bhyas*, Latin *-bus*, Irish *-b*; and so all around. The consequence is that every attempt at grouping the Aryan families of speech on the genealogical basis must fail, because it would have to cut asunder some of the natural ties that hold the single families together. It is true that some of the coincidences falling under this head may be due to mere chance, especially those in phonology; for we often see the same phonetic processes going on in languages which stand in no connection whatever at the time. Yet in the case before us the number of the actual coincidences is too large to allow of such an explanation, and the fact of their existence is made all the more striking from the circumstance that it is each pair of *neighboring* families which shows these connecting links. If they prove anything (and it cannot be doubted that they do), we must necessarily come to the conclusion that every such link is a witness for at least a temporary connection between the two languages or families it holds together. To assume such temporary connections in the time after a true division of nations had taken place (that is, to assume, for instance, that Slavonic had come into contact with the Asiatic languages after the Europeans had migrated from Asia to Europe, or the forefathers of the present Asiatic nations from Europe to Asia, as the case may be) seems impossible. It is likewise highly improbable that connections intimate enough to leave distinct marks in language existed at a time when the original tribe had spread over the wide regions now covered by the Aryans, even supposing this spreading to have been so gradual as not to cause any break in the continuity of the Aryan population. And, even if we concede this, how are we to account for the fact that we have no longer the supposed continuity of speech, but well-defined single languages, whose separation must, after all, be due to breaks in the continuity of intercourse between the respective speakers? These and similar reasons point to the assumption that the origin of the phenomena alluded to must be sought in a remote period, when the Aryan tribe had an extension small enough to permit con-

tinuity of intercourse, and yet large enough to allow of dialectic variations in its different districts. In other words, when the actual break-up of the Aryan tribe into different nations came to pass the Aryan parent-speech was no longer a homogeneous idiom, but the development of dialects had begun. On their following wanderings, then, those tribes or clans would naturally cling together which had until then lived in the closest connection both of intercourse and dialect (for community of intercourse and of speech always go together), or, as we might also say, the old unity would naturally be broken up into as many parts as there had been dialectic centers. Transition dialects, which might have been spoken in the outlying parts of the old dialectic districts, would also naturally be then reduced to a common level in consequence of the general mixture of speakers that could not but have taken place on wanderings so extensive as those of the Aryan tribes must have been.

Such an assumption would indeed solve most of the difficulties mentioned above, especially the peculiar way in which the single families of Aryan are linked together. Each of these would then correspond to one of the main dialects of the parental language, and their mutual affinities would therefore be of the same kind as those of neighboring dialects, say, of any living speech. And in these nothing is more common, nay even more characteristic, than the gradual transition from one to the other, so that each dialect of an intermediate position partakes of some of the peculiarities of its neighbors to the right and left.

PHILOMELA. See NIGHTINGALE.

PHILOPEMEN, "the last of the Greeks" as he was called by an admiring Roman, was a leading champion of the Achæan League, which preserved in Peloponnesus a last shred of Greek freedom. Sprung from an illustrious Arcadian family, he was born at Megalopolis in Arcadia in 252 B.C. He was elected general of the Achæan League eight times, and upon being captured after putting down a revolt in Messene was put to death by poison 183 B.C. His murderers were obliged to kill themselves. His body was buried and his bones conveyed to Megalopolis with every mark of respect and sorrow; they were almost hidden in garlands.

PHILOSOPHY is a term whose meaning and scope have varied considerably according to the usage of different authors and different ages; and it would hardly be possible, even having regard to the present time alone, to define and divide the subject in such a way as to command the adhesion of all the philosophic schools. A specific sense of the word first meets us in Plato, who defines the philosopher as one who apprehends the essence or reality of things in opposition to the man who dwells in appearance and the shows of sense. Logic, ethics, and physics, psychology, theory of knowledge, and metaphysics are all fused together by Plato in a semi-religious synthesis. It is not till we come to Aristotle that we find a demarkation of the different philosophic disciplines corresponding, in the main, to that still current. In Socrates and Plato, the start is made from a consideration of man's moral and intellectual activity; but knowledge and action are confused with one another, as in the Socratic doctrine that virtue is knowledge. To this correspond the Platonic confusion of logic and ethics and the attempt to substitute a theory of concepts for a metaphysic of reality. Aristotle became the founder of logic, psychology, ethics, and æsthetics, as separate sciences, but it was only in the Alexandrian period that the special sciences attained to independent cultivation. Nevertheless, as the mass of knowledge accumulated, it naturally came

about that the name "philosophy" ceased to be applied to inquiries concerned with the particulars as such. The details of physics, for example, were abandoned to the scientific specialist, and philosophy restricted itself in this department to the question of the relation of the physical universe to the ultimate ground or author of things.

The aim of philosophy is to exhibit the universe as a rational system in the harmony of all its parts; and accordingly the philosopher refuses to consider the parts out of their relation to the whole whose parts they are. Philosophy corrects in this way the abstractions which are inevitably made by the scientific specialist, and may claim, therefore, to be the only concrete science, that is to say, the only science which takes account of all the elements in the problem, and the only science whose results can be claimed to be true in more than a provisional sense.

A fact is nothing except in its relation to other facts; and as these relations are multiplied in the progress of knowledge the nature of the so-called fact is indefinitely modified. Moreover, every statement of fact involves certain general notions and theories, so that the "facts" of the separate sciences cannot be stated except in terms of the conceptions or hypotheses which are assumed by the particular science. Thus mathematics assumes space as an existent infinite, without investigating in what sense the existence or the infinity of this "Uding," as Kant called it, can be asserted. In the same way, physics may be said to assume the notion of material atoms and forces. These and similar assumptions are ultimate presuppositions or working hypotheses for the sciences themselves. But it is the office of philosophy, or theory of knowledge, to submit such conceptions to a critical analysis, with a view to discover how far they can be *thought out*, or how far, when this is done, they refute themselves, and call for different form of statement, if they are to be taken as a statement of the ultimate nature of the real. The first statement may frequently turn out to have been merely provisionally or relatively true; it is then superseded by, or rather inevitably merges itself in, a less abstract account. In this the same "facts" appear differently, because no longer separated from other aspects that belong to the full reality of the known world. There is no such thing, we have said, as an individual fact; and the nature of any fact is not fully known unless we know it in all its relations to the system of the universe, or, in Spinoza's phrase, "*sub specie æternitatis*." In strictness, there is but one *res completa* or concrete fact, and it is the business of philosophy, as science of the whole, to expound the chief relations that constitute its complex nature.

The last abstraction which it becomes the duty of philosophers to remove is the abstraction from the knowing subject which is made by all the sciences, including the science of psychology. The sciences, one and all, deal with a world of objects, but the ultimate fact as we know it is the existence of an object for a subject. Subject-object, knowledge, or, more widely, self-consciousness with its implicates—this unity in duality is the ultimate aspect which reality presents. It has generally been considered, therefore, as constituting in a special sense the problem of philosophy. Philosophy may be said to be the explication of what is involved in this relation, or, in modern phraseology, a theory of its possibility. Any would-be theory of the universe which makes its central fact impossible stands self-condemned.

PHILOSTRATUS, the eminent Greek sophist, was probably born in Lemnos between 170 and 180 A.D. From his incidental statements respecting himself we

learn that he studied at Athens, and was afterward attached to the court of the empress Julia Domna, consort of Severus. It seems to be implied that Philostratus resided in Rome, and, according to Suidas, he lived until the reign of Philip (244–249). His works now extant are a biography of Apollonius of Tyana, *Lives of the Sophists*, *Heroicon*, *Imagines*, and *Epistles*.

PHILOXENUS, one of the last of the dithyrambic poets of Greece, was born in 435 B.C., in the island of Cythera. When the island was conquered by the Athenians in 424, Philoxenus was sold as a slave to Agesylas, who gave him the name of Myrmex ("ant"). On the death of Agesylas he was bought by the dithyrambic poet Melanippides. Philoxenus afterward resided in Sicily, at the court of Dionysius, tyrant of Syracuse, whose bad verses he declined to praise, and was in consequence sent to work in the quarries. Being fetched back again and asked by the tyrant how he liked his verses now, the poet made no reply but "Take me away to the quarries." From Sicily he seems to have gone to Tarentum, and thence perhaps to Corinth. He visited Colophon in Asia Minor, and died at Ephesus in 380. According to Suidas, Philoxenus composed twenty-four dithyrambs and a lyric poem on the genealogy of the Æacidæ.

PHLEBITIS, or INFLAMMATION OF THE VEINS (Gr. φλέβις, *phlebs*, a vein), although seldom an original or idiopathic disease, is a frequent sequence of wounds, in which case it is termed traumatic phlebitis (from the Gr. *trauma*, a wound), and is not uncommon after delivery. The disease is indicated by great tenderness and pain along the course of the affected vessel, which feels like a hard knotted cord, and rolls under the fingers. The hardness is, however, sometimes obscured by the swelling of the limb beyond and about the seat of the disorder, partly in consequence of the effusion of serum caused by the obstruction to the return of the venous blood (which thus gives rise to a local dropsy), and partly in consequence of the propagation of the inflammation to the surrounding tissues. With the return of the circulation, the swelling subsides, and the patient gradually recovers. If, however, the disease advances, suppuration takes place within the coagulum, and one of two things happens; either abscesses are formed along the veins, or the pus gets into the current of blood and contaminates the circulation, giving rise to the perilous disease known as *pyæmia*. Either condition is dangerous; the latter preëminently so. The use of leeches along the affected vein is recommended, and that they should be repeated over and over again if the symptoms of inflammation persevere, the subsequent application of cold lotions, and the internal use of mercury pushed to a moderate salivation.

PHLEBOLITES (Gr. φλέβις, *phlebs*, a vein; and λίθος, *lithos*, a stone), are calcareous concretions formed by the degeneration of coagulations in veins, or occasionally originating in the coats of the vessel. They are seldom detected till after death, although cases are on record in which, occurring in subcutaneous veins, they have given rise to external tumors of considerable size.

PHLEGMASIA ALBA DOLENS, or MILK-LEG, is a disease which is most common in women, after parturition, especially if they have lost much blood, but sometimes occurs in unmarried women and occasionally in males. It usually commences about a week or ten days after delivery with a feeling of pain in the loins or lower part of the abdomen, whence it extends to the groin and down the thigh and leg. The pain soon becomes severe, and principally follows the course of the internal cutaneous and crural nerve of the thigh and of the posterior tibial in the leg. The limb soon begins to

swell, and, in the course of a couple of days, is sometimes twice its ordinary size, and as the swelling develops itself, the acuteness of the pain diminishes. The limb is partly flexed, and lies motionless; any movement aggravates the pain. The swelling extends uniformly over the limb, which is pale and shining, and hot and firm to the touch, seldom pitting on pressure. The femoral vein may usually be felt like a hard cord, and this symptom, taken with the swelling, clearly indicates that this affection is essentially *crural phlebitis*. The uniformity of the cord is interrupted by nodules, arising either from inflamed cellular tissue, or from clots within the vein. Both legs are seldom attacked at the same time, and the left thigh is the most common seat of the disease. This affection usually terminates favorably, the acute symptoms disappearing in about ten days. The swelling, however, often continues for a long time, and sometimes lasts for life. There is no doubt that the disease is inflammation originating in the veins of the genital tract, and extending to those of the lower extremity. The treatment is the same as for phlebitis generally. Warm poppy fomentations, or bran poultices sprinkled with laudanum, may be applied externally at the beginning of the attack, after which, flannel saturated with a liniment composed of one part of laudanum to two parts of soap liniment, may be applied around the limb in the form of a bandage, applied not so tightly as to occasion pain. If necessary, the bowels must be gently opened with castor oil, and opium given to allay pain and induce sleep.

PHLEGON, of Tralles in Asia Minor, a Greek writer of the second century, was a freedman of the emperor Hadrian. His chief work was the *Olympiads*, a universal history in sixteen books, from the first down to the 229th Olympiad, (776 B.C. to 137 A.D.) Portions of another work of Phlegon, *On Marvels*, along with parts of another *On Long-lived Persons*, and the opening parts of his *Olympiads*, are extant in a Heidelberg MS. of the tenth century.

PHLOX, a considerable genus of *Polemoniaceæ*, chiefly consisting of North American perennial plants, with entire, usually opposite, leaves and showy flowers generally in terminal clusters. Each flower has a tubular calyx with five lobes, and a salver-shaped corolla with a long, slender tube and a flat limb. The five stamens are given off from the tube of the corolla at different heights and do not protrude beyond it. The ovary is three-celled with one to two ovules in each cell; it ripens into a three-valved capsule. The garden varieties fall under three groups—the annuals, including the lovely *P. Drummondii* from Texas and its many forms; the perennials, including a dwarf section of alpine plants (forms of *P. subulata*), suitable, by reason of their prostrate habit and neat mode of growth, for the rockery; and the taller-growing decussate phloxes which contribute so much to the beauty of gardens in late summer, and which have probably originated from *P. paniculata*. The range of color in all the groups is from white to rose and lilac.

PHOCÆA, in ancient geography, was one of the cities of Ionia, on the western coast of Asia Minor. It was the most northern of the Ionian cities, and was situated on the coast of the peninsula that separates the Gulf of Cyme. Its advantageous position between two good harbors, called Naustathmus and Lampter, is pointed out by Livy, and was probably the cause which led the inhabitants to devote themselves from an early period to maritime pursuits. They established friendly relations with Arganthonius, king of Tartessus, Spain, who even invited them to emigrate in a body to settle in his dominions, and, on their declining this offer, presented them with a large sum of money. When the

Ionian cities were attacked by Cyrus in 546, mistrusting their power of ultimate resistance, they determined to abandon their city, and, embarking their wives and children and most valuable effects, to seek a new home in the western regions, where they had already founded several flourishing colonies. A large part of the emigrants, however, relented, and, after having proceeded only as far as Chios, returned to Phocæa, where they submitted to the Persian yoke. Phocæa continued to exist under the Persian government, but greatly reduced in population and commerce, so that, although it joined in the revolt of the Ionians against Persia in 500, it was only able to send three ships to the combined fleet that fought at Lade. Nor did it ever again assume a prominent part among the Ionian cities, and it is rarely mentioned in Greek history.

PHOCAS, emperor of the east from 602 to 610, was a Cappadocian of humble origin, and was still but a centurion when chosen by the army of the Danube to lead it against Constantinople. A revolt within the city soon afterward resulted in the abdication of the reigning emperor MAURICE (*q.v.*) and in the speedy elevation of Phocas to the vacant throne (November 23, 602). By the representations of Theodosius, Maurice's supposed son, and of Narses, the Byzantine commander-in-chief on the Persian frontier, Chosroes (Khosrau) II. was induced to take up arms against the emperor in 604 (see PERSIA), and the appearance of the Persian armies as far west as Chalcedon in 609-610 made his deposition by HERACLIUS (*q.v.*) an easy task. He was beheaded by his successful rival on October 4, 610.

PHOCION, an Athenian statesman, born about 402 B.C., and in his youth a pupil of Plato. He saw service under the distinguished general Chabrias, whose temper, by turns sluggish and impetuous, he alternately stimulated and repressed. He thus won the regard of his good-natured commander, and was introduced by him to public notice and employed on important services. He was among the last of the Athenian leaders who combined the characters of statesman and soldier. In 351 Phocion and Evagoras, lord of the Cyprian Salamis, were sent by Idrieus, prince of Caria, with a military and naval force to put down a revolt which had broken out against the Persians in Cyprus. The task was successfully accomplished. Next year Phocion commanded a force which the Athenians sent to Eubœa in support of the tyrant Plutarch of Eretria. In 341 he returned to the island and put down Clitarchus, whom Philip, king of Macedonia, had set up as tyrant of Eretria. In spite of the successful issue of his expedition to Byzantium Phocion advised the Athenians to make peace with Philip. But the war party led by Demosthenes prevailed, and the battle of Chæronea (August, 338), in which Philip overthrew the united armies of Athens and Thebes, converted Greece into a province of Macedonia.

After the revolt of Thebes and its destruction by Philip's son and successor Alexander the Great, Athens, having been implicated in the movement, was called on by Alexander to surrender the orators of the anti-Macedonian party, including Demosthenes (335). Phocion advised the men to give themselves up, but nevertheless by his intercession he induced the conqueror to relent. Phocion led out a force and defeated a body of Macedonian and mercenary troops under Nicion, and after the battle of Crannon (322) Phocion's personal influence induced the victorious Antipater to spare Attica the misery of invasion. However, the Athenians were required by Antipater to surrender the chief members of the anti-Macedonian party, among them Demosthenes and Hyperides. Hyperides was executed, Demosthenes died by his own hand, and over

12,000 citizens lost the franchise, many of them going into exile. These disfranchised citizens had afterward an important influence on Phocion's fate. For some years Athens dwelt in peace, if not in honor, under the shadow of Macedonia. Phocion had the direction of affairs and filled the magistracies with respectable men. By his intercession with Antipater he procured for many of the exiles a repeal or mitigation of their sentence, but he declined to petition Antipater to withdraw the garrison from Munychia. After the death of Antipater, Alexander, son of Polyperchon, arrived in Attica at the head of an army and seized the ports of Piræus and Munychia to be held for his father. To this step, it was reported, he was instigated by Phocion. The latter fled to Alexander, who in response to the petition of an Athenian embassy surrendered him for trial upon a charge of having betrayed his country. He was condemned to die with the companions who had accompanied him in his flight. His death by poison occurred 317 B.C.

PHOCIS was in ancient times the name of a district of central Greece, between Bœotia on the east and the land of the Ozolian Locrians on the west. It adjoined the Gulf of Corinth on the south, while it was separated on the north from the Malian gulf by the ridge of Mount Cnemis and the narrow strip of territory occupied by the Epicnemidian and Opuntian Locrians.

Phocis was for the most part a rugged and mountainous country. In the center of it rose Mount Parnassus, attaining to the height of 8,068 feet, and an underfall of this, Mount Cirphis (4,130 feet), sweeps around to the Gulf of Corinth on the south, separating the Gulf of Crissa from that of Anticyra, both of which were included in the Phocian territory. The range of Mount Cnemis on its northern frontier was of less elevation (about 3,000 feet), but rugged and difficult of access, while the upper valley, or plain of the Cephissus, constituted the only considerable tract of fertile and level country comprised within the limits of Phocis. The little basin adjoining the Crissæan gulf, though fertile, was of limited extent, and the broad valley which led into the interior thence to Amphissa (now Salona) belonged to the Ozolian Locrians. Besides the Cephissus, the only river in Phocis was the Pleistus, which rose in Mount Parnassus, and, after flowing past Delphi, descended through a deep ravine to the Crissæan gulf.

Phocis possessed importance in a military point of view, not only from its central position with regard to the other states of northern Greece and its possession of the great sanctuary of Delphi, but from its command of the pass which led from the Malian gulf across Mount Cnemis to Elatea in the valley of the Cephissus, and afforded the only access for an invader who had already passed Thermopylæ into Bœotia and Attica.

The important city in Phocis after Delphi was Elatea; next to this came Abæ, also in the valley of the Cephissus, near the Bœotian frontier, celebrated for its oracle of Apollo. In the same neighborhood stood Danlis and Ambrysus; while farther south, toward the Corinthian gulf, lay Anticyra, on the gulf of the same name. Crissa, which had been in early times one of the chief cities of Phocis, and had given name to the Crissæan gulf, was destroyed by order of the Amphictyonic council in 591, and never rebuilt. The other towns of Phocis were places of no importance, and their names scarcely appear in history.

PHŒBUS (the bright or pure), a common epithet of APOLLO, (*q.v.*) Artemis in like manner is called Phœbe, and in the Latin poets and their modern followers "Phœbus" and "Phœbe" are often used simply for the sun and the moon respectively.

PHŒNICIA forms part of the seaboard of SYRIA (*q.v.*), extending along the Mediterranean (sometimes called the Phœnician Sea) from the mouth of the Eleutherus in the north to Mount Carmel in the south, a distance of rather more than two degrees of latitude. Formed partly by alluvium carried down by perennial streams from the mountains to the east, and fringed by great sand-dunes thrown up by the sea, Phœnicia is covered by a very fertile vegetable soil. It is only at Eleutherus in the north, and near Acre (Akka) in the south, that this strip of coastland widens out into plains of any extent; a smaller plain is found at Beirût (Beirut). For the most part the mountains approach within not many miles of the coast, or even close to it, leaving only a narrow belt of lowland, which from remote antiquity has been traversed by a caravan-route. To the south of Tyre the cliffs sometimes advance so close to the sea that a passage for the road had to be hewn out of the rocks, as at Scala Tyriorum. The mountains are not rich in mineral products; but it may be mentioned that the geologist Fraas has recently discovered indubitable traces of amber-diggings on the Phœnician coast. The purple-shell (*Murex trunculus* and *brandaris*) is still found in large quantities. The harbors on the Phœnician coast are nearly all silted up, and, with the exception of that of Beirût, there is no safe port for the large vessels of modern times. A few bays, open toward the north, break the practically straight coast-line, and there are a certain number of small islands off the shore.

The ethnographic relations of the Phœnicians have been the subject of much debate. Many investigators are of opinion that, in spite of their purely Semitic language, the Phœnicians were a distinct race from the Hebrews. In favor of the opposite and more probable view, that the Phœnicians are an early offshoot from the Semitic stock, it may be urged (1) that the account in Gen. x. is not framed on strict ethnographic lines, and (2) that the absence from Phœnicia of all trace of an original non-Semitic form of speech cannot be reconciled with the theory of an exchange of language. Inscriptions, coins, topographical names preserved by classical writers, proper names of persons, and the Punic passages in the *Pœnulus* of Plautus combine to show that the Phœnician language, like Hebrew, belonged to the north Semitic group. Even the Phœnician which survived as a rustic dialect in north Africa till the fifth century of our era was very closely akin to Hebrew.

Considering the great part which the Phœnicians played in the movements of ancient civilization, it is singular how fragmentary are our sources of knowledge for all the most essential elements of their history. What we are told of their religion is only in appearance an exception to this rule. The two triads of Hannibal's oath to Philip of Macedon—Sun, Moon, and Earth, and Rivers, Meadows, and Waters—contain the objects on which all Phœnician worship is based. Rivers were generally sacred to gods, trees to goddesses; mountains, too, were revered as nearer than other places to heaven; and bœtylia or meteoric stones were held sacred as divine messengers.

The oldest towns were held to have been founded by the gods themselves, who presumably also placed the Phœnicians in them. Imitating the Egyptians, the race claimed an antiquity of 30,000 years, yet they retained some memory of having migrated from older seats on an Eastern sea. Herodotus understood this of the Persian Gulf; the companions of Alexander sought to prove by learned etymologies that they had actually found here the old seats of the Phœnicians. But all this rested on a mere blunder, and the true form of the

tradition is preserved by Trogus, who places the oldest seats of the Phœnicians on the Syrium stagnum or Dead Sea, and says that, driven thence by an earthquake, they reached the coast, and founded Sidon.

In historical times the Phœnicians called themselves Canaanites and their land Canaan, the latter applying equally to the coast which they themselves held and the inland highlands which the Israelites occupied; and it is a singular fact that alike in the Old Testament and in Homer, in the time of Tyre's greatest might, we constantly read of Sidonians and not of Tyrians. Hence we may conjecture that during the flourishing period of Phœnicia, Sidon and Tyre formed a single state whose kings reigned first in Sidon and then in Tyre, but whose inhabitants continued to take their name from the old metropolis.

The towns of the Phœnician coast were active from a very early date in various manufactures. Glass-work, for which the sands of the Belus gave excellent material, had its chief seat in Sidon; embroidery and purple-dyeing were favored by the prevalence of the purple-giving murex all along the coast. The ancients ascribed to the Phœnicians the invention of all three industries. The Phœnicians, however, brought these arts to perfection and spread the knowledge of them. To them as the great trading nation was ascribed the invention of arithmetic, measure, and weight, which are really Babylonian in origin, and also of writing, although it is not even quite certain that it was the Phœnicians who adapted the Egyptian hieroglyphic alphabet to Semitic use. Yet here again the Phœnicians have undisputedly the scarcely inferior merit of having communicated the art to all the nations of the Mediterranean basin.

The beginnings of navigation lie beyond all human memory, but the ancients made this also an invention of the Phœnicians. Even in later times Greek observers noted with admiration the exact order kept on board Phœnician ships, the skill with which every corner of space was utilized, the careful disposition of the cargo, the vigilance of the steersmen and their mates. They steered by the pole-star, which the Greeks therefore called the Phœnician star; and all their vessels had a speed which the Greeks never rivaled. It was they, in fact, who from the earliest time distributed to the rest of the world the wares of Egypt and Babylon.

The great center of Phœnician colonization was the western half of the Mediterranean and the Atlantic coasts to the right and left of the straits. In especial the trade with Tarshish, that is, the region of the Tartessus (Guadalquivir), was what made the commercial greatness of the Phœnicians; for here they had not only profitable fisheries (tunny and murena) but above all rich mines of silver and other metals, to which the navigable rivers Guadiana and Guadalquivir gave easy access. Next the Phœnicians ventured farther on the ocean and drew tin from the mines of northwest Spain or the richer deposits of Cornwall; the tin islands (Cassiterides) were reached from Brittany, and are always distinguished from the British mainland, so that the old view which makes them the Scilly Islands is probably right. Amber, too, was brought in very early times from the farthest north. The rich trade with Spain led to the colonization of the west. Strabo dates the settlements beyond the Pillars of Hercules soon after the Trojan War, in the time, that is, of Tyre's first expansion. Lixus in Mauretania was older than Gades and Gades a few years older than Utica, which again was founded 1101 B.C. Ophelas may exaggerate when he speaks of 300 cities on the Mauretanian coast beyond the Pillars of Hercules; but the colonists and the Carthaginians after them stamped west Africa with a thor-

oughly Phœnician character, and their language was dominant, at least in the cities, far beyond the limits of their nationality, just as was the case with Latin and Arabic in later times.

The trading connections of the Phœnicians reached far beyond their most remote colonies, and it must have been their knowledge of Africa which encouraged Pharaoh Necho to send a Phœnician expedition to circumnavigate Africa. This greatest feat of ancient seamanship was actually accomplished in 611-605 B.C., at a time when the mother-country had already lost its independence, and the colonial empire had but a shadow of its former splendor. The power of Tyre rested directly on her colonies, which, unlike the Greek colonies, remained subject to the mother-city. Colonies paid tithes of all their revenues and sometimes also of booty taken in war to the Tyrian Hercules, and sent envoys to Tyre for his chief feast. But Tyre was too remote long to exercise as effective a control over her dependencies as was possible to the more favorably placed Carthage; the relation gradually became looser, and the more substantial obligations of the colonies ceased to be discharged; yet Carthage certainly paid tithes to the Tyrian Hercules as late as the middle of the sixth century B.C.

PHŒNIX. Herodotus, speaking of the animals in Egypt, mentions a sacred bird called "Phœnix" which he had only seen in a picture, but which the Heliopolitans said visited them once in 500 years, on the death of its father. The story of the Phœnix is repeated with variations by later writers, and was a favorite one with the Romans. The most familiar form of the legend is that in the *Physiologus*, where the Phœnix is described as an Indian bird which subsists on air for 500 years, after which, lading his wings with spices, he flies to Heliopolis, enters the temple there, and is burned to ashes on the altar. Next day the young Phœnix is already feathered; on the third day his pinions are full-grown, he salutes the priest and flies away. The period at which the Phœnix reappears is very variously stated, but 500 years is the period usually named; and Tacitus tells us that the bird was said to have appeared first under Sesostris, then under Amasis, again under Ptolemy III., and once more in 34 A. D.

PHŒNIXVILLE, a borough in the United States, in Schuylkill township, Chester county, Penn., is situated 27½ miles northwest of Philadelphia by the Philadelphia and Reading Railroad, on the right bank of the Schuylkill river, which is there joined by French Creek, crossed by eight fine bridges. Phœnixville is best known as the seat of the blast-furnaces and mills of the Phœnix Iron Company, which had its origin in a rolling and slitting mill erected in 1790 by Benjamin Longstreth, and long ranked as the largest in the country. The works cover 150 acres and employ sometimes 2,500 men. Phœnixville also contains a pottery, a sash and planing mill, a shirt-factory, and needle-works; and iron, copper, and lead are all mined in the neighborhood. The vicinity of the borough is noted for its large number of magnificent iron bridges. The population was 2,670 in 1850, 4,886 in 1860, 5,292 in 1870, 6,682 in 1889, and 8,514 in 1890.

PHONETICS, the matters pertaining to the voice, is the science and art of the production of sounds, including cries, by means of the organs of speech in man and their analogues in other animals.

In a more restricted sense, applied solely to human beings and to articulate significant sounds, the term "phonetics" is used to designate a work on the enumeration, evaluation, relations, classification, analysis, and synthesis of SPEECH-SOUNDS (*q.v.*)—that is, of the sounds actually used in speech for conveying and record-

ing thought by different nations and tribes, together with a means of fixing them by visible signs.

In a still more restricted and popular sense the term "phonetics" has been recently used for attempts to construct a new practical alphabet for English or other individual languages, or for several such languages simultaneously, with a view either of superseding the alphabets at present in use, or of improving their employment, or, at any rate, of facilitating the generally very difficult tasks of teaching and learning to read and write.

**PHONOGRAPH.** This apparatus, invented in 1877 by Thomas A. Edison, is designed to obtain a record of the sound vibrations resulting from articulate speech that can be mechanically reproduced at a distance of time. The instrument consists of a sender and a receiver or recorder. The sender consists of a tube having an open mouthpiece at one end, and bearing at the other end a thin diaphragm of metal or other substance, with a sharp point or stylus affixed to the center of its outer surface. The second apparatus consists of a cylinder, about four inches in diameter, having on its periphery a V-shaped groove cut spirally from end to end. Over this grooved cylinder a sheet of wax is placed, and the sender is advanced till the point of the style lightly touches the wax, over the opening of the V-shaped cut. While the words to be recorded are spoken or sung, the cylinder is turned rapidly, the apparatus for moving it giving a lateral as well as a circular motion. The point of the style thus traverses the wax spirally from end to end, and the vibrations in the diaphragm caused by the sounds result in a series of indentations in the wax. To reproduce the sounds in the transcriber (or in the sender) the cylinder is again presented to a style attached to a diaphragm, the style being pressed against the wax by a slight spring. The cylinder is now made to revolve, and the motion of the style upon the inequalities in the indented wax produces vibrations in the diaphragm corresponding to the sound-caused vibrations originally created in the instrument by the voice. The sounds are thus reproduced with great exactness, even the character of the voice being so perfectly rendered as to be recognized by anyone familiar with it. The record of sung or spoken sounds may be sent to a distance, or kept for an indefinite length of time, and the original sounds can be reproduced on applying to the proper instrument. In this manner messages have been sent back and forth from this country to Europe and repeated, by simply putting the tablet into the machine and turning the cylinder. Rubbings in wax may be taken from a plaster-cast of the original indented slip, so that copies may be sent to different persons, all of whom can thus reproduce the sounds so long as their wax copy remains intact.

**PHORMIUM, or NEW ZEALAND FLAX** (also called "New Zealand hemp"), is a fiber obtained from the leaves of *Phormium tenax* (ord. *Liliaceæ*). The plant is a native of New Zealand, the Chatham Islands, and Norfolk Island; it is now cultivated as an ornamental garden-plant in Europe, and for economic purposes it has been introduced into the Azores. The leaves grow from three to six and even nine feet in height and from two to three inches in breadth, springing from the extremity of a rhizome. After the tuft of leaves has continued growing for about three years a flowering stalk springs up to the height of about sixteen feet, and when it comes to maturity the whole plant dies down. Among the Maoris the fiber has always been an article of considerable importance, yielding cloaks, mats, cordage, fishing-lines, etc., its valuable properties having attracted the attention of traders even before colonists settled in the islands. The leaves, for fiber-yielding

purposes, come to maturity in about six months, and the habit of the Maoris is to cut them down twice a year, rejecting the outer and leaving the central immature leaves. Phormium is prepared with great care by native methods, only the mature fibers from the under-side of the leaves being taken. No means have yet been devised for producing by mechanical or chemical means fiber in the perfect condition it shows when selected and prepared by Maoris. Phormium is a cream-colored fiber with a fine silky gloss, capable of being spun and woven into many of the heavier textures for which flax is used, either alone or in combination with flax. It is, however, principally a cordage fiber, and in tensile strength it is second only to Manila hemp; recently it has come into use as a suitable material for the bands of self-binding reaping-machines.

**PHOSPHORESCENCE**, a name given to a variety of phenomena due to different causes, but all consisting in the emission of a pale more or less ill-defined light, not obviously due to combustion. In addition to phosphorescence after insolation many minerals exhibit this property under other circumstances: (*a*) on heating to a temperature much below what is known as a "red heat;" (*b*) on friction, as in the case of fused calcium chloride (Homberg's phosphorus); (*c*) on cleavage, a property manifested by mica, the two split portions becoming electrified—the one positive, the other negative; (*d*) on crystallization, as boracic acid after fusion, or water on rapid freezing. A few meteorological phenomena may also be mentioned. Rain has been seen to sparkle on striking the ground, and waterspouts and meteoric dust have presented a luminous appearance. The *ignis fatuus*, or will-o'-the-wisp, seen in marshy districts, has given rise to much difference of opinion. The vegetable kingdom has furnished few instances of the property under consideration; the earliest on record took place in the year 1762, when a daughter of Linnæus saw luminous emanations from a species of *Tropæolum*, since which time a like appearance has been noticed in *Helianthus annuus*, *Lilium bulbiferum*, *Calendula officinalis*, *Tagetes patula*, and *T. erecta*, all of which are red or orange-colored flowers. There are also a number of small marine phosphorescent organisms (*Pyrocystis*, *Peridinium*), concerning which it is impossible to say with certainty whether they should be referred to the animal or vegetable kingdom. But the most brilliant as well as the most varied and interesting cases of phosphorescence belong to the animal world, and there is not one of the larger groups which does not furnish some instances of it.

The light emitted by different animals varies very much in color: green has been noticed in the glow-worm, fireflies, some brittle-stars, centipedes, and annelids; blue is seen in the Italian firefly (*Luciola italica*); and this and light green are the predominant colors exhibited by marine animals, although the beautiful Girdle of Venus and some species of *Salpa* and *Cleodora* appear red, and *Pavonaria* and other gorgonoids lilac. The curious lantern-fly (*Fulgora pyrorhynchus*) has a purple light. One very remarkable instance is mentioned of an *Appendicularia* in which the same individual appeared first red, then blue, and finally green. In the lowest forms of life and in many jellyfish there seem to be no organs specially set apart for the production of light, this being emitted from the whole surface of the body. In other groups of animals the localization of the photogenic property in certain organs or tissues is universal, and these present the utmost variety in structure and situation.

Dead and putrescent animals are not infrequently phosphorescent; this fact has most commonly been observed in fish, though instances are not wanting in

which the property has been manifested by mollusks and other animals, and even by the human body. Furthermore a few startling but apparently well-authenticated instances are on record in which human beings have been luminous while yet alive owing to certain states of disease. The fact that the nervous system is often closely connected with the luminous organs indicates that the exhibition of the light is either dependent on the volition of the animal or is the reflex result of the stimulation of sensory nerves (Panceri). In the glow-worm the distribution of tracheæ (air-tubes) throughout the photogenic apparatus, and the fact that carbonic acid extinguishes the light while oxygen intensifies it, suggests that it is due to some form of slow combustion, while the fatty contents of the luminous cells of this and many other animals point to the probability that a fat containing free phosphorus is the active agent in the process. Since a large number of luminous organs retain their power after the death of the animal, and even after desiccation and subsequent moistening, there seems no necessity to adopt the theory that we have to deal with an instance of the direct transformation of vital into radiant energy. The well-known phosphorescence of the sea is due to the animals which inhabit it, except a few cases in which it has been ascribed to putrescent matter.

The service rendered by this property to its possessors is in many cases by no means obvious; indeed it would seem certain that to crustacean larvæ and other surface-organisms surrounded by voracious enemies phosphorescence must be a "perilous gift." The fact that so many deep-sea animals are phosphorescent, coupled with the discovery that many fish from those regions have large and normally-developed eyes while others have organs which appear to be adapted for the production of light, has led to the belief that this source of light becomes of great importance in the depths of the ocean where no sunlight penetrates—a hypothesis which is known as the "abyssal theory of light."

**PHOSPHORUS AND PHOSPHATES.** "Phosphorus" (light-bringer) had currency in chemistry as a generic term for all substances which shine in the dark without burning, until the name came to be monopolized by a peculiar kind of "phosphorus" which was discovered, some time previous to 1678, by the German alchemist Brand of Hamburg. Brand, hoping to obtain thereby an essence for the "ennobling" of silver into gold, subjected urine-solids to dry distillation. In lieu of the hoped-for essence he obtained as part of the distillate a wax-like, easily fusible solid, which, besides being phosphorescent, readily caught fire, to burn with a dazzling light into a white solid acid. The new phosphorus naturally excited universal interest; but it was, and remained, only a rather costly chemical curiosity until Scheele, in 1771, starting from the discovery of Gahn that bone-ash is the lime-salt of a peculiar non-volatile acid, proved that this acid is identical with the one formed in the combustion of phosphorus, and that the latter, being only "phlogisticated" bone-ash acid, can be obtained from it by distillation with charcoal at a high temperature. This method of Scheele's is used to the present day for the manufacture of phosphorus, and even the theoretical notion on which it rests is recognized as correct as far as it goes, anhydrous bone-ash acid being a compound of phosphorus with oxygen, the formation of which involves the liberation of part of the *energy* ("phlogiston") of each in the kinetic form of heat. That phosphorus is an elementary substance was originally a surmise, which, however, has been confirmed by all subsequent experiences. In comparatively recent times it was found that Brand's phosphorus is susceptible of passing (by mere loss of energy) into two

allotropic modifications, known as "red" and "metallic" phosphorus respectively, so that the name "phosphorus" has again come to assume a generic meaning, being used for these three substances and the element as such conjointly.

Recently purified phosphorus is a slightly yellowish or colorless solid of about the consistence of beeswax. At low temperatures it is brittle; specific gravity = 1.83 at 10° C. It fuses at 44.3° C. into a strongly light-refracting liquid of 1.743 (Kopp) specific gravity. Neither in the solid nor in the liquid state does it conduct electricity. When heated further (in an inert atmosphere such as hydrogen or carbonic-acid gas) it boils at 290° C., and assumes the form of a colorless vapor which at 1040° C. is 4.5 times as heavy as air or 65.1 times as heavy as hydrogen, whence it follows that its molecular weight is  $2 \times 65.1 = 130.2 =$  very nearly *four* times the atomic weight of phosphorus (31.0). Phosphorus is insoluble in water, more or less sparingly soluble in alcohol, ether, fatty oils, and oil of turpentine, and very abundantly soluble in bisulphide of carbon. When exposed to the air, and especially to moist air, it suffers gradual oxidation into phosphorus and phosphoric acids with evolution of a feeble light. Phosphorus does not phosphoresce in the *absence* of oxygen. Singularly, it does not phosphoresce in pure oxygen either, unless the tension of the gas be reduced to some point considerably below one atmosphere. Phosphorus is a most dangerous poison; doses of as little as 0.1 gram (= 1.5 grains) are known to have been fatal to adults. The heads of a few lucifer matches may suffice to kill a child. Phosphorus is used chiefly for the manufacture of lucifer matches (see MATCHES), and also in the manufacture of iodide of methyl and other organic preparations used as auxiliary agents in the tar-color industry. Phosphorus-paste, made by working up a small proportion of phosphorus melted under water in a hot mortar with flour, is used as poison for vermin.

**PHOTIUS**, patriarch of Constantinople from 857 to 867 and again from 877 to 886 A.D., the most eminent literary and ecclesiastical character of his age, was probably born between 820 and 825. At the height of glory and success he was suddenly precipitated from his dignity by a palace revolution. Archbishop Theodore Santabaren, his confidant and favorite, had accused Basil's son, Leo, of a conspiracy against his father. Leo owed his liberty and eyesight to Photius' entreaties; nevertheless, on his accession, in 886, he involved his benefactor in the ruin of his accuser. Arrested, degraded from the patriarchate, banished to the monastery of Bordi in Armenia, Photius, as if by magic, disappears from history. No letters of this period of his life are extant, which leads to the inference that his imprisonment was severe. The precise date of his death is not known, but it is said to have occurred on February 6, 891.

**PHOTOGRAPHY.** It would be somewhat difficult to fix a date when what we now know as "photographic action" was first recorded. We may take it that Scheele, the Swedish chemist, was the first to enter upon a scientific investigation of the darkening action of sunlight on silver chloride. He found by experiment that when silver chloride was exposed to the action of light beneath water there was dissolved in the fluid a substance which, on the addition of caustic (silver nitrate), caused the precipitation of new silver chloride, and that on applying liquor ammonia to the blackened chloride an insoluble residue of metallic silver was left behind. He also noticed that of the rays of the spectrum the violet most readily blackened the silver chloride. In Scheele, then, we have the first who applied combined chemical and spectrum analysis to the science of photography.

To England belongs the honor of first producing a photograph by the utilization of Scheele's observations on chloride of silver.

The first to found a process of photography which gave pictures that were subsequently unaffected by light was Nicéphore de NIEPCE, (*q.v.*) His process, which he called provisionally "héliographie, dessins, et gravures," consists in coating the surface of a metallic plate with a solution of asphaltum in oil of lavender and exposing it to a camera image. In his description he recommends that the asphaltum be powdered and the oil of lavender dropped upon it in a wine-glass, and that it be then gently heated. A polished plate is covered with this varnish, and, when dried, is ready for employment in the camera. After requisite exposure, which is very long indeed, a very faint image, requiring development, is seen. Development is effected by diluting oil of lavender with ten parts in volume of white petroleum. After this mixture has been allowed to stand two or three days it becomes free from turbidity and is ready to be used. The plate is placed in a dish and covered with the solvent. By degrees the parts unaffected by light dissolve away, and the picture, formed of modified asphaltum, is developed. The plate is then lifted from the dish, as much as possible of the solvent being allowed to drain away. It is next placed on an inclined support and carefully freed from all the remaining solvents by washing in water. Subsequently, instead of using oil of lavender as the asphaltum solvent, Niepce employed an animal oil, which gave a deeper color and more tenacity to the surface-film than did his original agent.

Later still, Daguerre and Niepce used as a solvent the brittle residue obtained from evaporating the essential oil of lavender dissolved in ether or alcohol—a transparent solution of a lemon-yellow color being formed. This solution was used for covering glass or silver plates, which, when dried, could be used in the camera. The time of exposure varied somewhat in length. Daguerre remarked that "the time required to procure a photographic copy of a landscape is from seven to eight hours, but single monuments, when strongly lighted by the sun, or which are themselves very bright, can be taken in about three hours." Perhaps there is no sentence which could be quoted that illustrates more forcibly the advance made in photography from the days when this process was described. The ratio of three hours to  $\frac{1}{15}$  of a second is a fair estimate of the progress made since Niepce.

*Daguerreotype.*—We have already noticed in the joint process of Daguerre and Niepce that polished silver plates were used, and we know from the latter that among the chemical agents tried iodine suggested itself. Iodine vapor or solution applied to a silvered plate would cause the formation of silver iodide on those parts not acted upon by light. The removal of the resinous picture would leave an image formed of metallic silver, while the black parts of the original would be represented by the darker silver iodide. This was probably the origin of the daguerreotype process.

Daguerreotype pictures were originally taken on silver-plated copper, and even at the present day the silvered surface thus prepared serves better than electro-deposited silver of any thickness. An outline of the operations is as follows:—A brightly-polished silver plate is cleaned by means, first of finely-powdered pumice and olive oil, then of a dilute nitric acid, and a soft buff is employed to give it a brilliant polish, the slightest trace of foreign matter or stain being fatal to the production of a perfect picture. The plate, thus prepared, is ready for the iodizing operation. Small fragments of iodine are scattered over a saucer, covered

with gauze. Over this the plate is placed, face downward, resting on supports, and the vapor from the iodine is allowed to form upon it a surface of silver iodide, which is the sensitive compound. It is essential to note the color of the surface-formed iodide at its several stages, the varying colors being due to interferences caused by the different thicknesses of the minutely thin film of iodide of silver. The stage of maximum sensitiveness is obtained when it is of a golden orange color. In this state the plate is withdrawn and removed to the dark side of the camera, ready for exposure. Long exposures were required, varying in Paris from three to thirty minutes. The length of the exposure was evidently a matter of judgment, more particularly as over-exposure introduced an evil which was called "solarization," but which was in reality due to the oxidation of the iodide, itself altered by prolonged exposure to light. As a matter of history it may be interesting to remark that the development of the image by means of mercury vapor is said to be due to a chance discovery of Daguerre.

The first great improvement in the daguerreotype process was the resensitizing of the iodized film by bromine vapor. Mr. Goddard published his account of the use of bromine in conjunction with iodine in 1840, and M. Claudet employed a combination of iodine and chlorine vapor in 1841. In 1844 Daguerre published his improved method of preparing the plates, which is in reality based on the use of bromine with iodine.

*Fox-Talbot Process.*—In January, 1839, Fox Talbot described the first of his processes, photogenic drawing, in a paper to the Royal Society. He states that he began experimenting in 1834, and that in the solar microscope he obtained an outline of the object to be depicted in full sunshine in half a second. We must turn, however, to the *Philosophical Magazine* for the account of the full details of his method, which consisted essentially in soaking paper in common salt, brushing one side only of it with about a 12 per cent. solution of silver nitrate in water, and drying at the fire. Fox Talbot stated that by repeating the alternate washes of the silver and salt—always ending, however, with the former—greater sensitiveness was attained. This is the same in every respect as the method practiced by Wedgwood in 1802; but, when we come to the next process, which he called "calotype" or "beautiful picture," we have a distinct advance. This process Talbot protected by a patent in 1841. It may be briefly described as the application of iodide of silver to a paper support. Carefully-selected paper was brushed over with a solution of silver nitrate (100 grains to the ounce of distilled water), and dried by the fire. It was then dipped into a solution of potassium iodide (500 grains being dissolved in a pint of water), where it was allowed to stay two or three minutes until silver iodide was formed. In this state the iodide is scarcely sensitive to light, but is sensitized by brushing "gallo-nitrate of silver" over the surface to which the silver nitrate had been first applied. This "gallo-nitrate" is not a chemical compound, but merely a mixture, consisting of 100 grains of silver nitrate dissolved in two ounces of water, to which is added one-sixth of its volume of acetic acid, and immediately before applying to the paper an equal bulk of a saturated solution of gallic acid in water. The prepared surface is then ready for exposure in the camera, and, after a short isolation in the dark, develops itself, or the development may be hastened by a fresh application of the "gallo-nitrate of silver." The picture is then fixed by washing it in clean water and drying slightly in blotting paper, after which it is treated with a solution of potassium bromide, and again washed and dried. Here there is no mention made of hyposulphite of soda

as a fixing agent, that having been first used by Sir J. Herschel in February, 1840.

*Albumen Process on Glass.*—It was a most decided step in advance when Niepce de St. Victor, a nephew of Nicéphore de Niepce, employed a glass plate and coated it with iodized albumen. The originator of this method did not meet with much success. In the hands of M. Blanquart Évrard it became more practicable; but it was carried out in its greatest perfection by M. Le Gray. The outline of the operations is as follows:—The whites of five fresh eggs are mixed with about one hundred grains of potassium iodide, about twenty grains of potassium bromide, and ten grains of common salt. The mixture is beaten up into a froth with an egg-whisk or fork, and allowed to settle for twenty-four hours, when the clear liquid is decanted off. A circular pool of albumen is poured on a glass plate, and a straight rule (its ends being wrapped with waxed paper to prevent its edge from touching the plate anywhere except at the margins) is drawn over the plate, sweeping off the excess of albumen, and so leaving an even film. The plate is first allowed to dry spontaneously, a final heating being given to it in an oven or before the fire. The heat hardens the albumen, and it becomes insoluble and ready for the nitrate-of-silver bath. One of the difficulties is to prevent crystallization of the salts held in solution, and this can only be effected by keeping them in defect rather than in excess. The plate is sensitized for five minutes in a bath of nitrate of silver, acidified with acetic acid, and exposed while still wet, or it may be slightly washed and again dried and exposed while in its desiccated state. The image is developed by gallic acid in the usual way. After the application of albumen many modifications were introduced in the shape of starch, serum of milk, gelatin, all of which were intended to hold iodide *in situ* on the plate; and the development in every case seems to have been by gallic acid.

*Collodion Process.*—A great impetus was given to photography in 1850, rendering it easy of execution and putting it into the hands of the comparatively untrained. This was the introduction of collodion, a vehicle which up to the present day holds its own against the more rapid processes on account of the facility with which the plates are prepared, and also because it is a substance totally unaffected by silver nitrate, which is not the case when any other organic substance is employed, and, it may be said, inorganic as well in many instances.

In 1844, Hunt introduced another reducing agent, which has continued to be the favorite down to the present time, viz., ferrous sulphate. By its use the time of necessary exposure of the plate is reduced, and the image develops with great rapidity.

*Dry Plates.*—It would appear that the first experiments with collodion dry plates were due to M. Gaudin. In *La Lumière* of April 22 and May 27, 1854, he describes his researches on the question; while in England, Mr. G. R. Muirhead, on August 4, 1854, stated that light acts almost as energetically on a dry surface as on a wet after all the silver has been washed away from the former previous to desiccation. Doctor Taupenot, however, seems to have been the first to use a dry-plate process that was really workable. His original plan was to coat a plate with collodion, sensitize it in the ordinary manner, wash it, cause a solution of albumen to flow over the surface, dry it, dip it in a bath of silver nitrate, acidified with acetic acid, and wash and dry it again. The plate was then in a condition to be exposed, and was to be developed with pyrogallic acid and silver.

A great advance was made in all dry-plate processes by the introduction of what is known as the "alkaline developer," which is, however, inapplicable to all plates

on which silver nitrate is present in the free state. The introduction of this developer is believed to be of American origin; and it is known that in the year 1862 Major Russell used it with the dry plates he introduced. An alkaline developer consists of an alkali, a reducing agent, and a restraining agent. These bodies, when combined and applied to the solid bromide or chloride of silver, after being acted upon by light, as when a plate was exposed to the camera image, were able to reduce the sub-bromide or sub-chloride, and to build up an image upon it, leaving the unaltered bromide intact, except so far as it was used in the building up.

The alkalis used embraced all the alkalis themselves and the mono-carbonates. The sole reducing agent up till recent times was pyrogallic acid. In the year 1880 Abney found that hydrokinone was even more effective than pyrogallic acid, its reducing power being stronger. Various other experimentalists tried other kindred substances, but without adding to the list of really useful agents. In 1884, however, Herr Egli and Arnold Spiller brought out hydroxylamin as a reducing agent, which promises to be of great use if it can be prepared cheaply enough.

*Collodion Emulsion Processes.*—In 1864 Bolton and Sayce published the germ of a process which revolutionized photographic manipulations, and by a subsequent substitution of gelatin for collodion gave an impetus to photography which has carried it to that state of perfection at which it has arrived at the present time (1890). The outline of the method was to dissolve a soluble bromide in plain collodion, and add to it drop by drop an alcoholic solution of silver nitrate, the latter being in excess or defect according to the will of the operator. To prepare a sensitive surface the collodion containing the emulsified sensitive salt was poured over a glass plate, allowed to set, and washed till all the soluble salts resulting from the double decomposition of the soluble bromide and the silver nitrate, together with the unaltered soluble bromide or silver nitrate, were removed, when the film was exposed wet, or allowed to dry and then exposed. The rapidity of these plates was not in any way remarkable, but the process had the great advantage of doing away with the sensitizing nitrate-of-silver bath, and thus avoiding a tiresome operation. The plates were developed by the alkaline method, and gave images which, if not primarily dense enough, could be intensified by the application of pyrogallic acid and silver nitrate as in the wet collodion process.

*Gelatin Emulsion Process.*—The facility with which collodion emulsion plates could be prepared had turned all investigation into this channel, and collodion was not the only vehicle that was tried for holding the sensitive salts in suspension. As early as September, 1871, Dr. R. L. Maddox had tried emulsifying the silver salt in gelatin, and had produced negatives of rare excellence. In November, 1873, Mr. King described a similar process, getting rid of the soluble salts by washing. Efforts had also been made in this direction by Mr. Burgess in July, 1873. Mr. R. Kennett, in 1874, may be said to have been the first to put forward the gelatin emulsion process in a practical and workable form, as he then published a formula which gave good and quick results. It was not till 1878, however, that the great capabilities of silver bromide when held in suspension by gelatin were fairly known; in March of that year Mr. C. Bennett showed that by keeping the gelatin solution liquid at a low temperature for as long as seven days extraordinary rapidity was conferred on the sensitive salt. It may in truth be said that the starting-point of rapid plates was 1878, and that the full credit of this discovery should be allotted to Mr. C. Bennett.

The warming process introduced by Bennett was soon superseded. Col. Stuart Wortley in 1879 announced that, by raising the temperature of the vessel in which the emulsion was stewed to 150° Fahr., instead of days being required to give the desired sensibility only a few hours were necessary. A further advance was made by boiling the emulsion, first practiced, we believe, by Mr. Mansfield in 1879. Another improvement was effected by Mr. W. B. Bolton by emulsifying the silver salt in a small quantity of gelatin and then raising the emulsion to boiling point, boiling it for from half an hour to an hour, when extreme rapidity was attained. It would be impossible to enumerate many minor improvements in this process that have from time to time been made; it is sufficient to state in historical sequence the different important stages through which it has passed. It may be useful to give an idea of the relative rapidities of the various processes we have described.

Daguerreotype, originally.....	half an hour's exposure.
Calotype .....	2 or 3 minutes' exposure.
Collodion.....	10 seconds' exposure.
Collodion emulsion.....	15 seconds' exposure.
Rapid gelatin emulsion.....	1-15 second's exposure.

By this it will be seen what advances have been made in the art of photography during the fifty years of its existence.

*Photo-Lithography.*—Reference has already been made to the effect of light on gelatin impregnated with bichromate of potash, whereby the gelatin becomes insoluble, and also incapable of absorbing water where the action of the light has had full play. It is this last phenomenon which occupies such an important place in photo-lithography. In the spring of 1859, Asser, of Amsterdam, produced photographs on a paper basis in printer's ink. Being anxious to produce copies of such prints mechanically, he conceived the idea of transferring the greasy ink impression to stone, and multiplying the impressions by mechanical lithography. Following very closely upon Asser, J. W. Osborne, of Melbourne, made a similar application; his process is described by himself in the *Photographic Journal* for April, 1860, as follows:—"A negative is produced in the usual way, bearing to the original the desired ratio. \* \* \* A positive is printed from this negative upon a sheet of (gelatinized) paper, so prepared that the image can be transferred to stone, it having been previously covered with greasy printer's ink. The impression is developed by washing away the soluble matter with hot water, which leaves the ink on the lines of print of the map or engraving." The process of transferring is accomplished in the ordinary way. Early in 1860, Col. Sir H. James, R.E., F.R.S., brought forward the Southampton method of photo-lithography, which had been carefully worked out by Captain de Courcy Scott, R.E.

**PHOTOGRAPHIC ENGRAVING, or PHOTO-ENGRAVING.** In one of these processes a steel plate, such as is prepared for engravers, is first dipped into a solution containing acetic and sulphuric acids; it is then coated with a mixture containing a solution of fine gelatin and bichromate of potash. This is impressed with the image of a photographic negative by exposure in the copying frame, and washed. The film of gelatin is previously yellow, but the action of the light through the light parts of the photograph change it dark brown, but the remainder is unaffected; consequently, a picture is produced of a light yellow color on a dark ground. The action of the light is to reduce the bichromate of potash, and, consequently, to render the gelatin combined with it insoluble; while those portions which have been protected from the action of the light by the dark parts of the negative are still readily soluble in

water, and can be removed by soaking; the insoluble portion thus forms a raised picture, which is submitted to a solution containing bichloride of patina in certain proportions, with a little free acid and water, which etches out the exposed parts of the plate, and renders it fit for engraving from. An ingenious method of giving to the whole picture the appearance of an engraving consists in spreading over the gelatinized plate, when nearly dry, a piece of fine muslin, and evenly pressing it so as to leave an impression of the cross-lines of the textile material upon the surface. A modification of this system is that, instead of washing, the gelatinized surface is thinly but evenly covered with finely powdered copal or other resin, and the under-side of the plate exposed to sufficient heat to melt the resin, so as to make a thin varnish over the whole. The etching fluid is then poured on, and, notwithstanding the resin coating, it acts through to the metal, and eats in wherever the gelatin has not been rendered insoluble by the action of the bichromate of potash and the light. When sufficiently etched, it is washed in clean water, and the plate is freed from the resin and the gelatin. The same processes, with some modifications, applied to zinc, constitute Photo-zincography, and to stone, Photo-lithography, both of which are largely practiced.

**PHOTOMETER** (Gr. *phos*, light; *metron*, measure), an instrument for measuring the intensity of light. The instrument consists of a screen of thin paper placed vertically, and behind it, at the distance of a few inches, is placed a cylindrical stick, or any other similar body. When the intensity of light from two flames is to be compared, they are placed behind this stick in such a way that each casts a separate shadow of the stick upon the paper screen. The observer stands in front of the screen, and directs the removal of the two lights either to or from the stick, till the shadows which are cast upon the screen are equally obscure. The distance of each light from the shadow it casts on the screen is then measured; and the squares of these distances give the relative intensities of the two lights. This photometer may also be modified by employing, instead of a cylindrical stick, a second screen parallel to the first, but of greater thickness, and having an aperture cut in its center.

**PHOTOMETRY, CELESTIAL.** The earliest records that have come down to us regarding the relative positions of the stars in the heavens have always been accompanied with estimations of their relative brightness. With this brightness was naturally associated the thought of the relative magnitudes of the luminous bodies from which the light was assumed to proceed. Hence in the grand catalogue of stars published by Ptolemy (c. 150 A.D.), but which had probably been formed 300 years before his day by Hipparchus, the 1,200 stars readily visible to the naked eye at Alexandria were divided into six classes according to their luster, though instead of that term he used the word "magnitude;" the brightest he designates as being of the first magnitude, and so downward till he comes to the "least visible," to which he assigns the sixth. These magnitudes he still further divides each into three. He does not, indeed, tell us the precise process by which these divisions were estimated, but the principle involved is obvious. The eye was here made the natural photometer, and it is certain that even in the instances where modern instrumental appliances are called into requisition the ultimate appeal is made to perception by the eye. Moreover, it is one of the many remarkable instances of the acuteness and precision of the Greek mind that for upward of 1,500 years no real improvement was made in these estimations of luster by any of Ptolemy's numerous successors in this field of research.

Flamsteed was the first astronomer who extended the estimation of magnitude to stars visible only by the telescope.

It was not till the year 1796 that any real advance was made in stellar photometry. Sir W. Herschel, instead of assigning a particular magnitude to stars, arranged them in small groups of three or four or five, indicating the order in which they differed from each other in luster at the time of observation. This method was admirably adapted to the discovery of any variations in brightness which might occur in the lapse of time among the members of the group. Sir William observed in this way some 1,400 stars.

It is to Sir John Herschel that we are indebted for the first successful attempt at stellar photometry by what may be termed "artificial" means. By the aid of appliances of the simplest kind he deflected the light of the moon (by means of the internal reflection of a rectangular prism) through a small lens 0.12 inch in diameter and of very short focus, 0.2253 inch, so as to form a sort of artificial star in its focus. By the instrumentality of strings and a wooden pole he could move this artificial star of comparison so as to be in the same line of sight with any actual star whose light he proposed to measure. Other strings enabled him to remove this microscopic lunar image to such a distance from the eye that its light was adjudged to be sensibly the same as that of the star compared. The distance of the short focused lens with the image contiguous to it was measured with a graduated tape, and the inverse squares of these distances afforded relative numerical measures of the brightness of the several stars thus brought into ocular juxtaposition with the equalized light of the tiny lunar image. In this way he proceeded with the observations of a considerable number of stars, and these, by appropriate methods, were reduced so as to afford the means of the comparison of their relative brightness when set side by side with results obtained by means of his "sequences," and with the estimated magnitudes of preceding astronomers. Sir John, however, did not go on to the formation of a complete "uranometria." Various other methods have been proposed and used by different observers. The most recent and probably the most successful device for a stellar photometer on the *principle of equalizing lights* is that invented by Professor Pickering of Harvard College. He deflects the light of Polaris, or of some other star such as *Lambda Ursæ Minoris*, by means of prismatic reflection, and he contrives to form an image of it contiguous to the image of any other star selected on the meridian. The equalization of the lights is then effected by the intervention of a polarizing apparatus, such as that adopted by Zöllner. Thus the artificial and in many respects objectionable lamp-star of Zöllner is dispensed with. Professor Pickering, with singular inventive power, has devised many other forms of stellar photometers on virtually the same principle. Unlike his eminent predecessors, the American astronomer is persevering in the formation of a complete catalogue of star-magnitudes.

PHOTOPHONE is the name of an apparatus which may be said to transmit articulate speech to a distance along a beam of light. In the photophone found most serviceable the transmitter is a plane mirror of silvered microscope glass or thin mica; the receiver, fixed at a distance, without any connection, is a parabolic reflecting mirror, in the focus of which is placed a sensitive selenium cell, connected in local circuit with a battery and telephone. When the apparatus is used, a strong beam of light is concentrated by a lens in the plane mirror; the speaker directs his voice against the back of this mirror, which is thrown into vibrations corresponding

with those of the voice. The reflected beam of light, to which similar vibrations are also communicated, is directed through a lens to the receiving mirror, and creates in the selenium cell a rapidly intermittent current, which at the end of the telephone attached becomes audible again as vocal sound. The rays of the oxyhydrogen light, or of an ordinary kerosene lamp, suffice for transmitting articulate speech.

PHOTO-SCULPTURE, invented by M. Willème in 1867, is an ingenious use of photography to assist a sculptor in modeling portrait statues, or fac-similes and reduced reproductions of other statues. The subject stands in the center of a circular chamber, and is simultaneously photographed by no less than twenty-four cameras, arranged at equal distances around the chamber. The twenty-four photographs are subsequently made available in the sculptor's studio, where the clay model is arranged on a frame capable of being turned around. A magic lantern throws the outline of photograph No. 1 on a screen in front of the artist, who by means of a pantograph brings this outline to bear on the clay in its first position. The model is then turned around  $\frac{1}{24}$  of a revolution, and the outline of photograph No. 2 is taken advantage of. Thus the modeler works his way, in twenty-four changes, around the model, and the likeness or fac-simile or reduced figure of the original is or should be complete.

PHRENOLOGY. This name was given by Forster in 1815 to the empirical system of psychology formulated by Gall and developed by his followers, especially by Spurzheim and Combe. At first it was named "cranioscopy," "craniology," "physiognomy," or "zoöonomy," but Forster's name was early adopted by Spurzheim, and became that whereby the system is now known. The principles upon which it is based are four: (1) the brain is the organ of the mind; (2) the mental powers of man can be analyzed into a definite number of independent faculties; (3) these faculties are innate, and each has its seat in a definite region of the brain; (4) the size of each of these regions is the measure of the power of manifesting the faculty associated with it. While Phrenology is thus, on the one hand, a system of mental philosophy, it has a second and more popular aspect as a method whereby the disposition and character of the individual may be ascertained. These two sides of the subject are distinct from each other, for, while it can only serve as a reliable guide for reading character on the assumption of its truth as a philosophic system, yet the possibility of its practical application does not necessarily follow from the establishment of the truth of its theoretic side.

Early in the thirteenth century Albertus Magnus gave a detailed description of the distribution of mental and psychical faculties in the head. The anterior region he assigned to judgment, the middle to imagination, and the posterior to memory. A somewhat similar allocation was made by Gordon, professor of medicine in Montpellier (1296), who assigned common sensation and the reception of impressions to the anterior cornua of the lateral ventricles, *phantasia* to the posterior, this power being twofold (*imaginativa* and *cogitativa*), judgment or *astimativa* to the third ventricle, and memory to the fourth. Figures of a similar division were given by Petrus Montagnana and Lodovico Dolce, still later by Ghiradelli of Bologna and by Theodore Gall of Antwerp. That the "vital spirits" resided in the ventricles was doubted by many, and refuted by a few of the anatomists of the seventeenth century. Bauhin, in 1621, attacked the old view, and Hoffmann of Altorf showed that, as the ventricles were closed cavities, they could not transmit any material fluid. That these spirits existed at all was doubted by Alex-

ander Benedictus, Plater, and a few others; but they were believed in by the great majority of seventeenth and even of eighteenth century medical writers.

Of later writers three deserve special notice as having largely prepared the way for the more modern school of Phrenology. Unzer of Halle in his work on physiology extended the preëxisting theories of localization. Metzger, twenty years before the publication of Prochaska's work, had proposed to make a series of observations on the anatomical characteristics of the brains of persons of marked intellectual peculiarity; but it is not known to the present writer whether he ever carried this into effect. In a more special manner Prochaska of Vienna may be looked upon as the father of Phrenology, as in his work on the nervous system, published in Vienna in 1784, are to be found the germs of the later views which were propounded in that city twelve years later.

The system formulated by Gall is thus a modern expansion of an old empirical philosophy, and its immediate parentage is easily traced, although, according to Gall's account, it arose with him as the result of independent observations. These, he tells us, he began to make at an early age, by learning to correlate the outward appearances and mental qualities of his school-fellows. Gall's first published paper was a letter in the *Deutscher Merkur* of December, 1798, but his principal expositions were oral, and attracted much popular attention, which largely increased when, in 1802, he was commanded by the Austrian Government, at the instance of the ecclesiastical authorities, to discontinue his public lectures. In 1804 he obtained the coöperation of Spurzheim (1776-1832), a native of Longwich, near Treves, who became his pupil in 1800, and proved a powerful ally in promulgating the system. Master and pupil first taught in harmony, but they found it advisable to separate in 1813; and we find Spurzheim, several years after their parting, declaring that Gall had not introduced any new improvements into his system since their separation. "My philosophical views," he also says, "widely differ from those of Gall."

The popularity of Phrenology has waned, and few of the phrenological societies survive; the cultivation of the system is confined to a few enthusiasts such as will be found attached to any cause, and some professional teachers who follow Phrenology as a vocation. Like many similar systems, it has a much larger following in America than in Europe. Based, like many other artificial philosophies, on an admixture of assumption and truth, certain parts will survive and become incorporated into scientific psychology, while the rest will in due course come to be relegated to the limbo of effete heresies.

*The Faculties and their Localities.*—The system of Gall was constructed by a method of pure empiricism, and his so-called organs were for the most part identified on slender grounds. Having selected the place of a faculty, he examined the heads of his friends and casts of persons with that peculiarity in common, and in them he sought for the distinctive feature of their characteristic trait. Gall marked out on his model of the head the places of twenty-six organs as round inclosures with vacant interspaces. Spurzheim and Combe divided the whole scalp into oblong and conterminous patches. Other methods of division and other names have been suggested by succeeding authors, especially by Cox, Sidney Smith (not Sydney), Toulmin Smith, Carus of Dresden, Don Mariano Cubi i Solar, Powell of Kentucky, Buchanan of Cincinnati, Hittel of New York. Some, like the brothers Fowler, raise the number of organs to forty-three; but the system of Spurzheim and Combe is that which has always been most popular in Britain.

Spurzheim separated the component faculties of the human mind into two great groups, and subdivided these as follows:

- I. Feelings, divided into—
  1. Propensities, internal impulses inviting only to certain actions.
  2. Sentiments, impulses which prompt to emotion as well as to action.
    - A. Lower—those common to man and the lower animals.
    - B. Higher—those proper to man.
- II. Intellectual faculties—
  1. Perceptive faculties.
  2. Reflective faculties.

Even though no fault could be found with the physiology and psychology of Phrenology, it would not necessarily follow that the theory could be utilized as a practical method of reading character. For although the inner surface of the skull is molded on the brain and the outer surface approximates to parallelism thereto, yet the correspondence is sufficiently variable to render conclusions therefrom uncertain. The spongy layer or diploe which separates the two compact tables may vary conspicuously in amount in different parts of the same skull as in the cases described by Professor Humphrey (*Journ. of Anat.*, vol. viii., page 187). The frontal sinus that opprobrium phrenologicum, is a reality not infrequently of large size and may wholly occupy the regions of five organs, the centers of ossification of the frontal and parietal bones, the muscular crests of these and the occipital bones, also, differ in their prominence in different skulls. Premature synosposes of sutures mold the brain without doing much injury to its parts. Artificial malformations alter the apparent skull shape considerably and affect the relative development of the brain but little. All these and other cogent reasons of a like kind, whose force can be estimated by those accustomed to deal with the component soft parts of the head, should lead phrenologists to be careful in predicting relative brain power from skull shape. Psychology, physiology, and experience alike contribute to discredit the system and to show how worthless the so-called diagnoses of character really are. Its application by those who are its votaries is seldom worse than amusing, but it is capable of doing positive social harm, as in its proposed application to the discrimination or selection of servants and other subordinate officials. It has even been proposed to use it for the purposes of the guaranteeing society and for the selection of parliamentary representatives. The sarcastic suggestion which originated with Christopher North of molding children's heads so as to suppress the evil and foster the good was actually repeated in good faith by a writer on Phrenology, but experience of the effects of malformation leads one to be skeptical as to the feasibility of this mode of producing a social Utopia. The application of Phrenology to the art of painting and sculpture has been suggested, but a careful examination of some of the best pictures of the best masters who were close observers of nature, shows that no phrenological principles were accepted by them in their works. An application to ethnology has also been proposed, but although there are in most cases well marked racial characteristics presented by the skull, yet all attempts at correlating national characteristics therewith have been groundless and worthless. For further particulars on allied subjects see PHYSIOGNOMY.

There is a large weight of evidence which can not be explained away, in favor of the existence of some form of localization of function. So little is known of the physical changes which underlie psychical phenonoma, or indeed of the succession of the psy-

chical processes themselves, that we can not as yet judge as to the nature of the mechanism of these centers. So much of the psychic work of the individual life consists in interpretation of sensations and translation of these into motions that there are strong *a priori* grounds for expecting too much of the material of the nerve centers occupied with this kind of work, but in the present conflict of experimental evidence it is safer to suspend judgment. That these local areas are not centers in the sense of being indispensable parts of their respective motor apparatuses is clear; as the function abolished by ablation of a part returns, though tardily, so that whatever superindendence the removed region exercised apparently becomes assumed by another part of the brain. Experimental physiology and pathology, by suggesting other functions for much of the brain service are thus directly subversive of much of the Phrenology of Gall and Spurzheim.

PHRYGIA was the name of a large country in Asia Minor, inhabited by a race which the Greeks called *Phryges*, *Freemen*. Roughly speaking, Phrygia comprised the western part of the great central plateau of Anatolia, extending as far east as the river Halys; but its boundaries are vague, and varied so much at different periods that a sketch of its history must precede any account of the geography. According to unvarying Greek tradition the Phrygians were most closely akin to certain tribes of Macedonia and Thrace; and their near relationship to the Hellenic stock is proved by all that is known of their language and art, and is accepted by almost every modern authority. The country named Phrygia in the better known period of history lies inland, separated from the sea by Paphlagonia, Bithynia, Mysia, and Lydia. Yet we hear of a Phrygian "thalassocracy" at the beginning of the ninth century B.C. The Troad and the district around Mount Sipylus are frequently called Phrygian, as also is the seaport Sinope; and a district on the coast between Sestus and the river Cius was regularly named Little Phrygia. Again, the wide currency of names like Mygdones, Doliones, and Phryges or Briges both in Asia Minor and in Europe has been pointed out, and many other examples may be added. The inference has been generally drawn that the Phrygians were a stock wide-spread in the countries which lie around the Ægean Sea. There is, however, no decisive evidence, and no agreement among modern scholars, as to whether this stock came from the East over Armenia, or whether it was European in origin and crossed the Hellespont into Asia Minor.

It is impossible to fix a date for the beginning of the Phrygian kingdom. It appears to have arisen on the ruins of an older civilization, whose existence is revealed to us only by the few monuments which it has left.

The downfall of the Phrygian monarchy can be dated with comparative accuracy. Between 680 and 670 the Cimmerians in their destructive progress over Asia Minor overran Phrygia; the king Midas in despair put an end to his own life; and from that time the history of Phrygia is a story of slavery, degradation, and decay, which contrasts strangely with the earlier legends. The catastrophe seems to have deeply impressed the Greek mind, and the memory of it was preserved. The date of the Cimmerian invasion is fixed by the concurrent testimony of the contemporary poets Archilochus and Callinus, of the late chronologers, Eusebius, etc., and of the inscriptions of the Assyrian king Essar-haddon. The Cimmerians were finally expelled from Asia Minor by Alyattes before his war with the Medes under Cyaxares, (590-585 B.C.)

Alexander the Great placed Phrygia under the command of Antigonus, who retained it when the empire was broken up. When Antigonus was defeated and

slain at the decisive battle of Ipsus, Phrygia came under the sway of Seleucus. As the Pergamenian kings grew powerful, and at last confined the Gauls in eastern Phrygia, the western half of the country was incorporated in the kingdom of Pergamum. Under the Roman empire Phrygia had no political existence under a separate government, but formed part of the vast province of Asia. In autumn, 85 B.C., the pacification of the province was completed by Sulla, and throughout the imperial time it was common for the Phrygians to date from this era.

When the Roman empire was reorganized by Diocletian, at the end of the third century, Phrygia was divided into two provinces, distinguished at first as Prima and Secunda, or Great and Little, for which the names Pacatiana and Salutaris soon came into general use. Pacatiana comprised the western half, which had long been completely pervaded by Græco-Roman manners, and Salutaris the eastern, in which the native manners and language were still not extinct. Each province was governed by a "præses" about 412 A.D., but shortly after this date an officer of consular rank was sent to each province, (Hierocles, *Synecd.*) About 535 Justinian made some changes in the provincial administration: the governor of Pacatiana was henceforth a "comes," while Salutaris was still ruled by a "consularis." When the provinces of the Eastern empire were reorganized and divided into "themata" the two Phrygias were broken up between the Anatolic, Opsician, and Thracesian themes, and the name Phrygia finally disappeared. Almost the whole of the Byzantine Phrygias is now included in the vilayet of Broussa or Khodavendikya, with the exception of a small part of Parorius and the district about Themisonium (Karayuk Bazar) and Ceretapa (Kayadibi), which belong to the vilayet of Koniye, and the district of Laodicea and Hierapolis, which belongs to Aidin. The principal modern cities are Kutayah (Cotyæum), Eski Sheher (Dorylæum), Afum Kara Hissar (near Prynnessus), and Ushak (near Trajanopolis).

PHRYNE, a celebrated Greek courtesan, flourished in the time of Alexander the Great, (fourth century B.C.) She was born at Thespiæ in Bœotia, but seems to have lived at Athens. On the occasion of a festival of Poseidon at Eleusis she laid aside her garments, let down her hair, and stepped into the sea in the sight of the people, thus suggesting to the painter Appelles his great picture of Aphrodite rising from the Sea, for which Phryne sat as model. The sculptor Praxiteles was one of her lovers, and she is said to have been the model of his celebrated Cnidian Aphrodite, which Pliny declared to be the most beautiful statue in the world. Being accused of impiety by Euthias, she was defended by the orator Hyperides, one of her lovers. When it seemed that the verdict was about to be against her, he rent her robe and displayed her lovely bosom, which so moved her judges that they acquitted her.

PHRYNICHUS, the name of a number of distinguished Greeks, of whom the most prominent were the following:—

I. PHRYNICHUS, one of the earliest tragic poets of Athens, was the son of Polyphradmon, and a pupil or follower of Thespiis, who is commonly regarded as the founder of tragedy. But such were the improvements introduced by Phrynichus that some of the ancients regarded him as its real founder. He flourished, according to Cyrillus and Eusebius, in 483 B.C., but he gained a poetical victory (probably his first) as early as 511. His famous play, the *Capture of Miletus*, was probably composed shortly after the conquest of that city by the Persians (494). He wrote numerous other works.

According to Suidas it was Phrynichus who first introduced female characters on the stage (played by men in masks).

2. PHRYNICHUS, a poet of the Old Attic Comedy and a contemporary of Aristophanes, is said by Suidas to have been an Athenian, but according to the scholiast on Aristophanes (*Frogs*, 13) he was satirized as a foreigner. His first comedy was exhibited in 429 B.C. (according to Suidas, as corrected by Clinton and Meineke). He composed ten plays, of which the *Solitary* ("Monotropos") was exhibited in 414 along with the *Birds* of Aristophanes and gained the third prize, and the *Muses* carried off the second prize in 405, Aristophanes being first with the *Frogs*. He was not included by the Alexandrian critics in their canon of the best poets. The remains of his works, which have been edited with the other fragments of the Attic Comedy by Meineke and Bothe, are too scanty to allow us to judge of their merits.

3. PHRYNICHUS ARABIUS, a grammarian of Bithynia, lived in the reigns of the emperors Marcus Antoninus and Commodus (second century A.D.)

PHTHALIC ACID. This name was given by Laurent to a di-basic acid,  $C_8H_6O_4$ , which he obtained by the oxidation of naphthalin or its tetra-chloride with nitric acid. Schunck subsequently obtained the same acid by boiling alizarin with nitric acid, but failed to recognize its identity with Laurent's.

PHTHISIS or CONSUMPTION. This term, although applicable to several forms of wasting disease, is commonly used to designate a malady having for its chief manifestations progressive emaciation of the body and loss of strength, occurring in connection with morbid changes in the lungs and in other organs.

Few diseases possess such sad interest for humanity as consumption, both on account of its widespread prevalence and of its destructive effects, particularly among the young; and in every age of medicine the subject has formed a fertile field for inquiry as to its nature, its cause, and its treatment. On all these points medical opinion has undergone numerous changes with the advance of science and the application of more accurate methods of investigation; yet, notwithstanding the many important facts which within recent years have been brought to light, it must be admitted that our knowledge of this disease is still far from complete.

In the early part of the present century the study of the diseases of the chest received a great impetus from the labors of Laennec, whose discovery of the stethoscope led to greater minuteness and accuracy in investigation (see AUSCULTATION). This physician held that phthisis depended on the development of tubercles in the lungs, which, undergoing various retrograde changes, led to the breaking down and excavation of these organs—in short, produced the whole phenomena of consumption; and, further, that this tuberculous formation affected various other parts and organs, and was the result of a morbid constitutional condition or diathesis. This doctrine, which was generally taught during the first half of the century, and even longer, was to some extent superseded by that to which the greatest prominence was given by Niemeyer and others, namely, that the majority of cases of phthisis had their origin in an inflammation of the lung (catarrhal pneumonia), but that tubercle—the existence of which was freely admitted—might occasionally be evolved out of this condition. This view has had wide acceptance, but has been modified in a variety of ways, especially by its extension to inflammation in other parts besides the lungs, the unabsorbed products of which are held to be capable of producing tubercle by infection from within the system. Still more recently there has arisen

another doctrine in connection with the discovery by Koch of the micro-organism or bacillus of tubercle, which can be cultivated, and which, when inoculated, appears capable of producing tubercular disease, namely, the doctrine of the infectiveness of phthisis by means of this "microbe" received into the system from without. This view, which is supported by many striking facts and arguments, has been extensively adopted as furnishing in all probability a rational basis of the pathology of tubercular consumption. Yet it has not been universally accepted, being held by many to be insufficient to account for the origin and course of the disease in numerous instances and in certain of its forms. It is impossible to deny an important place in the course of the disease to inflammatory processes. Even in those cases where the lungs are infiltrated with tubercular deposit evidence of inflammation is abundantly present, while, on the other hand, it would seem that in not a few instances the process is inflammatory throughout. That phthisis, therefore, is not the same process in all cases, but that there are distinct varieties of the disease, is made clear by the morbid anatomy of the lungs no less than by other considerations.

Whatever be the form, the common result of the presence of these disease-products is to produce consolidations in the affected portions of the lungs, which, undergoing retrograde changes (cassation), break down and form cavities, the result being the destruction in greater or less amount of lung-substance. These changes most commonly take place at the apex of one lung, but with the advance of the disease they tend to spread throughout its whole extent and to involve the other lung as well. When the disease is confined to a limited area of a lung it may undergo arrest—even although it has advanced so far as to destroy a portion of the pulmonary tissue, and a healing process may set in and the affected part cicatrize. This is, however, exceptional, the far more common course being the progress of the destructive change either by the spread of the inflammatory process or by infection through the lymphatics, etc., from the existing foci of diseased lung-tissue. Various morbid changes affecting the lungs themselves or other organs frequently arise in the course of phthisis, complicating its progress and reducing the chance of recovery. Of these the more common are affections of the pleura, stomach, liver, kidneys, and especially the intestines, which in the later stage of the disease become ulcerated, giving rise to the diarrhœa which is so frequent and fatal a symptom at this period.

The causes influential in producing phthisis are numerous and varied, but they may for general consideration be embraced under two groups, namely, those which are *predisposing* and operate through the constitution as a whole, and those which are *exciting* and act immediately upon the organs implicated. These two sets of causes may be more or less distinctly associated in an individual case; but, on the other hand, one may appear to act in both ways—as predisposing and exciting. The following may serve to illustrate some of the conditions of a predisposing kind. A constitutional tendency to scrofula and its manifestations lends itself readily to the production of phthisis. This morbid constitution is characterized, among other things, by a liability to low chronic forms of inflammation affecting gland-textures, mucous membranes, etc., the products of which show little readiness to undergo absorption, but rather to degenerate. Inflammations of this character affecting the lungs, as is not uncommon, have a special tendency to lead to the breaking down of lung-texture and formation of phthisical cavities. Many high authorities hold that tubercle-formation may be evolved out of scrofulous inflammations of glands, such as those of the neck, by an

infective process, like that already referred to. The mention of this constitutional state naturally suggests another powerful predisposing cause, namely, hereditary transmission. The extent to which this influence operates as a cause of consumption has been differently estimated by writers, owing, probably, to the various aspects in which the matter is capable of being viewed. It is impossible to deny that the children of parents one or both of whom are consumptive are liable to manifest the disease—that is, they inherit a constitution favoring its development under suitable exciting causes. But a similar constitutional proclivity may be induced by other influences acting through the parents. Should either or both of them be enfeebled by previous disease or by other weakening cause, they may beget children possessing a strong predisposition to consumption. Marriages of near relatives are held by some to induce a consumptive tendency—probably, however, owing to the fact that any constitutional taint is likely to be intensified in this way. Phthisis is a disease of early life, the period between fifteen and thirty-five being that in which the great majority of the cases occur, and of these by far the larger proportion will be found to take place between the ages of twenty and thirty. The influence of sex is not marked. Occupations, habits, and conditions of life have a very important bearing on the development of the disease apart altogether from inherited tendency. Thus occupations which necessitate the inhalation of irritating particles, as in the case of stone-masons, needle-grinders, workers in minerals, in cotton, flour, straw, etc., are specially hurtful, chiefly from the mechanical effects upon the delicate pulmonary tissue of the matter inhaled. No less prejudicial are occupations carried on in a heated and close atmosphere, as is often the case with compositors, gold-beaters, seamstresses, etc. Again, habitual exposure to wet and cold or to sudden changes of temperature will act in a similar way in inducing pulmonary irritation which may lead to phthisis. Irregular and intemperate habits are known predisposing causes; and overwork, over-anxiety, want of exercise, insufficient or unwholesome food, bad hygienic surroundings such as overcrowding and defective ventilation, are all powerful agents in sowing the seeds of the disease. Consumption sometimes arises after fevers and other infectious maladies, or in connection with any long-continued drain upon the system, as in over-lactation. The subject of climate and locality in connection with the causation of phthisis has received considerable attention, and some interesting facts have been ascertained on this point. That phthisis is to be met with in all climes, and it would seem fully as frequently in tropical as in temperate regions, is evidence that climate alone exercises but little influence. It is very different, however, with locality, elevation appearing to affect to a considerable extent the liability to this disease.

Cases of phthisis differ widely as regards their severity and their rate of progress. Sometimes the disease exhibits itself as an acute or galloping consumption, where from the first there is high fever, rapid emaciation, with cough and other chest symptoms, or with the comparative absence of these, and a speedily fatal termination. In such instances there would probably be found extensive tuberculization of the lungs and other organs. In other instances, and these constitute the majority, the progress of the disease is chronic, lasting for months or years, and along with periods of temporary improvement there is a gradual progress to a fatal issue. In other cases, again, the disease is arrested and more or less complete restoration to health takes place.

All modern treatment has been directed to the de-

struction of the bacilli, and various modes of doing this have been proposed. One plan proposed is the inhalation of very hot dry air, it being held possible to thus kill the micrococci without injuring the patient. Other methods look to the introduction into the system of various drugs inimical to the life of bacteria. This is proposed to be accomplished in various ways—such as injection under the skin, per rectum, etc. Great attention and anxiety are now centered around these experiments.

The treatment of phthisis has received much attention from physicians as well as from empirics, by the latter of whom chiefly many so-called cures for consumption have from time to time been given forth. It need scarcely be stated that many authorities assert there is no "cure" for this disease; but while this may be true, it is no less true that by the adoption of certain principles of treatment under enlightened medical guidance a very great deal may now be done to ward off the disease in those who show a liability to it, and to mitigate and retard, or even arrest, its progress in those who have already become affected by it. The preventive measures include careful attention to hygienic conditions, both personal and surrounding. In the case of children who may inherit a consumptive tendency or show any liability to the disease much care should be taken in bringing them up to promote their general health and strengthen their frames. Plain, wholesome food with fatty ingredients, if these can possibly be taken, milk, cream, etc., are to be recommended. Exercise in the open air and moderate exercise of the chest by gymnastics and by reading aloud or singing are all advantageous. An ample supply of fresh air in sleeping apartments, schools, etc., is of great importance, while warm clothing and the use of flannel are essential, especially in a climate subject to vicissitudes. The value of the bath and of attention to the function of the skin is very great. The like general hygienic principles are equally applicable in the case of adults. When the disease has begun to show any evidence of its presence its treatment becomes a matter of first importance, as it is in the early stages that most can be done to arrest or remove it. Special symptoms, such as cough, gastric disturbances, pain, etc., must be dealt with by the physician according to the individual case; but it is in this stage of the disease that the question of a change of climate in the colder seasons of the year arises among those whose circumstances render such a step practicable. There can be no doubt that the removal of patients threatened by or already suffering from consumption to some mild locality, either in the country or abroad, proves in many instances most salutary. The object aimed at is to obtain a more equable climate, where the atmosphere may have a soothing influence on the respiratory organs, and where, also, open-air exercise may be taken with less risk than at home. Of like value and in a similar class of cases are long sea-voyages. Nevertheless, there is no doubt that consumptive patients are often sent abroad manifestly to die. It may be stated generally (although doubtless there may be exceptions) that where the disease exhibits a decidedly acute form, even in its earlier stages, any distant change is rather to be discouraged; while in the advanced stages, where there is great prostration of strength, with colliquative symptoms, the removal of a patient is worse than useless, and frequently hastens the end.

Throughout the whole course of the malady the nutrition of the patient forms a main part of the treatment, and tonics which promote the function of the digestive organs are especially helpful. Cod-liver oil has long been held to be of eminent value, as it appears not merely to possess all the advantages of a food but to

exert a retarding effect on the disease. Where it is well borne, not only will the weight of the body be found to increase, but the cough and other symptoms will markedly diminish. The oil is as a rule best administered at first in small quantity. The frequently employed substitutes, such as malt extract, tonic syrups, etc., although not without their uses, are all inferior to cod-liver oil. The occasional employment of counter-irritation to the chest in the form of iodine or small blisters is of service in allaying cough and relieving local pains. Respirators to cover the mouth and nose, and so constructed as to contain antiseptic media through which the air is breathed, are sometimes found to lessen cough and other symptoms of chest-irritation.

Among the most serviceable drugs in the treatment of the symptoms of phthisis are the preparations of opium. Administered along with such agents as hydrocyanic acid and expectorants, they are eminently useful in soothing severe cough; along with astringents they are equally valuable in controlling diarrhea; while with quinine, digitalis, etc., they aid in allaying fever and restlessness and in procuring sleep. But besides these many other medicinal agents, too numerous to mention here, are employed with much advantage. Each case will present its own features and symptoms calling for special attention and treatment, and details upon these points must be left to the advice of the medical attendant.

PHYLACTERY is the name given in the New Testament to the *tefillin* or "prayer-thongs" of the Jews. Every Jew wears at prayer two of these thongs—(1) the hand-tefilla, a leather thong wound around the left arm and supporting a small case containing a parchment strip with the passages Exod. xiii. 1-10, 11-16, Deut. vi. 4-9, xi. 13-21 written in four columns; (2) the head-tefilla, a similar thong with the four passages inscribed on four separate slips of parchment, and worn around the head so that the box with the texts rests on the forehead. The use of these phylacteries is justified by a literal interpretation of expressions in the passages above cited, and they form, together with the *zizith* or "fringe" and the *mezûza* above the door, the three sets of visible signs by which the Israelite is constantly reminded of his duty to God.

PHYSICAL GEOGRAPHY. See GEOGRAPHY.

PHYSICAL SCIENCES. According to the original meaning of the word, physical science would be that knowledge which is conversant with the order of nature—that is, with the regular succession of events whether mechanical or vital—in so far as it has been reduced to a scientific form. The Greek word "physical" would thus be the exact equivalent of the Latin word "natural." In the actual development, however, of modern science and its terminology these two words have come to be restricted each to one of the two great branches into which the knowledge of nature is divided according to its subject-matter. Natural science is now understood to refer to the study of organized bodies and their development, while Physical Science investigates those phenomena primarily which are observed in things without life, though it does not give up its claim to pursue this investigation when the same phenomena take place in the body of a living being.

What is commonly called "physical science" occupies a position intermediate between the abstract sciences of arithmetic, algebra, and geometry, and the morphological and biological sciences. The principal physical sciences are as follows:—

A. *The Fundamental Science of Dynamics, or the*

*doctrine of the motion of bodies as affected by force.*—

The divisions of dynamics are the following:—(1) Kinematics, or the investigation of the kinds of motion of which a body or system of bodies is capable, without reference to the cause of these motions. This science differs from ordinary geometry only in introducing the idea of motion—that is, change of position going on continuously in space and time. Kinematics includes, of course, geometry, but in every existing system of geometry the idea of motion is freely introduced to explain the tracing of lines, the sweeping out of surfaces, and the generation of solids. (2) Statics, or the investigation of the equilibrium of forces—that is to say, the conditions under which a system of forces may exist without producing motion of the body to which they are applied. Statics includes the discussion of systems of forces which are equivalent to each other. (3) Kinetics, or the relations between the motions of material bodies and the forces which act on them. Here the idea of matter as something capable of being set in motion by force, and requiring a certain force to generate a given motion, is first introduced into physical science. (A) Energetics, or the investigation of the force which acts between two bodies or parts of a body, as dependent on the conditions under which action takes place between one body or part of a body and another so as to transfer energy from one to the other.

The science of dynamics may be divided in a different manner with respect to the nature of the body whose motion is studied. This forms a cross division. (1) Dynamics of a particle; including its kinematics or the theory of the tracing of curves, its statics or the doctrine of forces acting at a point, its kinetics or the elementary equations of motion of a particle, and its energetics, including, as examples, the theory of collision and that of central forces. (2) Dynamics of a connected system, including the same subdivisions. This is the most important section in the whole of Physical Science, as every dynamical theory of natural phenomena must be founded on it. The subdivisions of this, again, are—*a.* dynamics of a rigid system, or a body of invariable form; *b.* dynamics of a fluid, including the discussion ( $\alpha$ ) of its possible motion, ( $\beta$ ) of the conditions of its equilibrium (hydrostatics), ( $\gamma$ ) of the action of force in producing motion (hydrodynamics, not so unsatisfactory since Helmholtz, Stokes, and Thomson's investigations), and ( $\delta$ ) of the forces called into play by change of volume; *c.* dynamics of an elastic body; *d.* dynamics of a viscous body.

B. *The Secondary Physical Sciences.*—Each of these sciences consists of two divisions or stages. In the elementary stage it is occupied in deducing from the observed phenomena certain general laws, and then employing these laws in the calculation of all varieties of the phenomena. In the dynamical stage the general laws already discovered are analyzed and shown to be equivalent to certain forms of the dynamical relations of a connected system (*A*, 2), and the attempt is made to discover the nature of the dynamical system of which the observed phenomena are the motions. This dynamical stage includes, of course, several other stages rising one above the other; for we may successfully account for a certain phenomenon, say the turning of a weathercock toward the direction of the wind, by assuming the existence of a force having a particular direction and tending to turn the tail of the cock in that direction. In this way we may account not only for the setting of the weathercock but for its oscillations about its final position. This, therefore, is entitled to rank as a dynamical theory. But we may go on and discover a new fact, that the air exerts a pressure and that there is a greater pressure on that side of the cock on which

the wind blows. This is a further development of the theory, as it tends to account for the force already discovered. We may go on and explain the dynamical connection between this inequality of pressure and the motion of the air regarded as a fluid. Finally, we may explain the pressure of the air on the hypothesis that the air consists of molecules in motion, which strike against each other and against the surface of any body exposed to the air.

The dynamical theories of the different Physical Sciences are in very different stages of development, and in almost all of them a sound knowledge of the subject is best acquired by adopting, at least at first, the method which we have called "elementary"—that is to say, the study of the connection of the phenomena peculiar to the science without reference to any dynamical explanations or hypotheses. Thus we have—

(1) Theory of gravitation, with discussion of the weight and motion of bodies near the earth, of the whole of physical astronomy, and of the figure of the earth. There is a great deal of dynamics here, but we can hardly say that there is even a beginning of a dynamical theory of the method by which bodies gravitate toward each other.

(2) Theory of the action of pressure and heat in changing the dimensions and state of bodies. This is a very large subject and might be divided into two parts, one treating of the action of pressure and the other of heat. But it is much more instructive to study the action of both causes together, because they produce effects of the same kind, and therefore mutually influence each other. Hence the term "thermodynamics" might be extended to the whole subject were it not that it is already restricted to a very important department relating to the transformation of energy from the thermal to the mechanical form and the reverse. The divisions of the subject are seven. (a) Physical states of a substance—gaseous, liquid, and solid; elasticity of volume in all three states; elasticity of figure in the solid state; viscosity in all three states; plasticity in the solid state; surface-tension, or capillarity; tenacity of solids; cohesion of liquids; adhesion of gases to liquids and solids. (b) Effects of heat in raising temperature, altering size and form, changing physical state. (c) Thermometry. (d) Calorimetry. (e) Thermodynamics, or the mutual convertibility of heat and work. (f) Dissipation of energy by diffusion of matter by mixture, diffusion of motion by internal friction of fluids, diffusion of heat by conduction. (g) Theory of propagation of sound, vibrations of strings, rods, and other bodies.

(3) Theory of radiance. (a) Geometrical optics; theory of conjugate foci and of instruments. (b) Velocity of light in different media. (c) Prismatic analysis of light—spectroscopy, radiant heat, visible radiance, ultra-violet rays, calorescence, etc., fluorescence, etc. (d) Colors of thin plates, diffraction, etc. (d') Proof of the existence of wave-lengths and wave-periods (preparation for dynamical theory). (e) Polarized light, radiant heat, etc. (é) The disturbance is transverse to the ray. (f) Quantity of energy in the total radiation from a hot body; Prévost's theory of exchanges, etc. (g) Theory of three primary colors.

(4) Electricity and magnetism. (a) Electrostatics, or distribution and effects of electricity in equilibrium. (b) Electrokinematics, or distribution of currents in conductors. (c) Magnetism and magnetic induction, (diamagnetism, etc.) (a) Electromagnetism, or the effects of an electric current at a distance. Under (b) we may discuss electro-chemistry, or the theory of electrolysis; under (c) terrestrial magnetism and ship's magnetism; and after (d) comes electrokinetics, or electromagnetic phenomena considered with reference to the fundament-

al science of dynamics. There is also Faraday's discovery of the effect of magnetism on light, and the electromagnetic theory of light.

Chemistry is not included in this list, because, though dynamical science is continually reclaiming large tracts of good ground from the one side of chemistry, chemistry is extending with still greater rapidity on the other side into regions where the dynamics of the present day must put her hand upon her mouth. Chemistry, however, is a physical science, and a physical science which occupies a very high rank.

PHYSIOGNOMY. By the act of Parliament 17 George II., c. 5, all persons pretending to have skill in Physiognomy were deemed rogues and vagabonds, and were liable to be publicly whipped, or sent to the house of correction until next sessions. The pursuit thus stigmatized as unlawful is one of great antiquity, and one which in ancient and mediæval times had an extensive though now almost forgotten literature. Physiognomy was regarded by those who cultivated it as a twofold science—(1) a mode of discriminating character by the outward appearance, and (2) a method of divination from form and feature. It was very early noticed that the good and evil passions by their continual exercise stamp their impress on the face, and that each particular passion has its own expression. Thus far physiognomy is a branch of physiology, and from a very early age of human thought it attracted philosophic attention. But in its second aspect it touched astrology, of which Galen says that the physiognomical part is the greater, and this aspect of the subject bulked largely in the fanciful literature of the Middle Ages. The name originated with the Greeks.

The first systematic treatise about Physiognomy which has come down to us is that attributed to Aristotle, in which he devotes six chapters to the consideration of the method of study, the general signs of characters, the particular appearances characteristic of the dispositions, of strength and weakness, of genius and stupidity, of timidity, impudence, anger, and their opposites, etc. Then he studies the Physiognomy of the sexes, and the characters derived from the different features, and from color, hair, body, limbs, gait, and voice. He compares the varieties of mankind to animals, the male to the lion, the female to the leopard.

The Latin classics, too, occasionally refer to Physiognomy.

Hitherto the Physiognomy of the schools had been chiefly descriptive; in the succeeding period the astrological side, whose gradual development may be noted, becomes the most important part. Hence in the subsequent or second stage of history chiromancy is specially predictive in character, and attains an importance it had not originally possessed. The treatises also contain occasional digressions on onychomancy, alectoromancy, clidomancy, coscinomancy, podoscopy, spasmatomancy, etc.

Along with the medical science of the period the Arabians took up the study of Physiognomy: 'Alí b. Ragel wrote a book on nævi; Rhazes (1040) devoted several chapters of his medical work to it; and Averroes (1165) made many references to it in his *De Sanitate*. Avicenna also makes some acute physiognomical remarks in his *De Animalibus*. Albertus Magnus (born 1205) devotes much of the second tract of his *De Animalibus* to the consideration of Physiognomy. There is, however, nothing original in the treatise, which largely consists of extracts from Aristotle, Polemon, and Loxus. The famous sage of Balwearie, Michael Scott, while court astrologer to the emperor Frederick II., wrote his treatise *De hominis phisionomia* (c. 1272), much of which is physiological and of curious interest. In 1335

Petrus de Abano of Padua delivered in Paris a course of lectures on this subject (afterward edited by Blondus, 1544), a few years before he was burned for heresy. Shortly after the introduction of printing in the fifteenth century a large number of works on Physiognomy were produced.

The sixteenth century was particularly rich in publications on Physiognomy. Not only were the classical works printed, but additions were made to the literature by authors too numerous to mention.

The rise of the study of anatomy served largely to bring Physiognomy into discredit by substituting real facts for fictions; hence in the seventeenth century its literature, while not smaller in quantity, was less important in quality.

The eighteenth century shows a still greater decline of interest in Physiognomy. The few straggling works which have since appeared are scarcely deserving of notice, the rising attraction of phrenology having given to pure Physiognomy the *coup de grâce* by taking into itself whatever was likely to live of the older science.

The physiological school of Physiognomy was foreshadowed by Parsons and founded by Sir Charles Bell, as his *Essay on the Anatomy of Expression*, published in 1806, was the first really scientific study of expression. He was one of the first who accurately correlated the motions expressive of the passions with the muscles which produce them, and in the latter editions of his work these descriptions are much enlarged and improved. Shortly after the appearance of the first edition of Bell's *Essay* Moreau published his first edition of Lavater along somewhat the same lines (1807). The experiments of Duchenne (Paris, 1862) showed that by the use of electricity the action of the separate muscles could be studied and by the aid of photography accurately represented. These tested and confirmed by experimental demonstration the hypothetic conclusions of Bell. The machinery of expression having thus been clearly followed out, the correlation of the physical actions and the psychical states was made the subject of speculation by Spencer (*Psychology*, 1855), and such speculations were first reduced to a system by Darwin (*Expression of Emotions*, 1872), who formulated and illustrated the following as fundamental principles:—

(1) Certain complex acts are of different or indirect service under certain conditions of the mind in order to relieve or gratify certain sensations or desires, and whenever the same state of mind is induced the same set of actions tend to be performed even when they have ceased to be of use.

(2) When a directly opposite state of mind is induced to one with which a definite action is correlated, there is a strong and involuntary tendency to perform a reverse action.

(3) When the sensorium is strongly excited nerve force is generated in excess and is transmitted in definite directions depending upon the connections of nerve cells and on habit.

It follows from these propositions that the expression of emotion is for the most part not under the control of the will, and that those striped muscles are the most expressive which are the least voluntary. The philosophy of Physiognomy may be formulated upon this definite theoretic basis.

(1) The actions we look upon as expressive of emotions are such as at some time were serviceable in relieving or gratifying the desires or sensations accompanying emotion.

(2) Such actions become habitually associated with the mental condition and continue even where their utility is lost.

(3) Certain muscles which produce these actions

become from habitual action strengthened, and when the skin diminishes in fullness and elasticity with advancing age the action of the muscle produces furrows or wrinkles in the skin at right angles to the course of the fibers of the muscle.

(4) As the mental disposition and proneness to action are inherited by children from parents, so the facility and proneness to expression are similarly developed under the law of heredity.

(5) To some extent habitual muscular action, and the habitual flow of nerve force in certain directions may alter the contour of such bones and cartilages as are thereby acted upon by the muscles of expression.

PHYSIOLOGUS, the most common title of a collection of some fifty Christian allegories much read in the Middle Ages, and still existing in several forms and in about a dozen Eastern and Western languages. As nearly all its imagery is taken from the animal world, it is also known as the *Bestiary*.

That the substance of the *Physiologus* was borrowed from commentaries on Scripture is confirmed by many of the sections opening with a text, followed up by some such formula as "but the Physiologus says." When zoölogical records failed, Egypto-Hellenic ingenuity was never at a loss for a fanciful invention distilled from the text itself, but which, to succeeding copyists, appeared as part of the teaching of the original Physiologus.

At the later period, when the church had learned to look with suspicion upon devotional books likely to provoke the scoffing of some and lead others into heresy, a work of this kind could hardly meet with her approval. A synod of Pope Gelasius, held in 496, passed censure, among others, on the "Liber Physiologus."

PHYSIOLOGY. The word "Physiology" may be used either in a general or in a more restricted sense. In its more general meaning it was used largely of old, and is still occasionally used in popular writings, to denote all inquiry into the nature of living beings. A very slight acquaintance, however, with the phenomena of living beings shows that these can be studied from two, apparently very different, points of view.

In its older sense Physiology embraced certain morphological problems, and corresponded to what is now called BIOLOGY (*q.v.*); in its more modern sense Physiology leaves these matters on one side and deals only with the actions of living beings on their surroundings (the study of these necessarily involving the correlative study of the effect of the surroundings on the living being), and appeals to matters of form and structure only so far as they throw light on problems of action. Looking forward into the far future, we may perhaps dimly discern the day when morphology and Physiology will again join hands, and all the phenomena of living beings, both those which relate to form and those which relate to action, will be seen to be the common outcome of the same molecular processes. But that day is as yet most distant; and, though occasionally even now the two sciences cross each other's path, action explaining form and form in turn explaining action, the dominant ideas of the two are so distinct, the one from the other, that each must for a long time yet be developed along its own line. It is proposed to treat in the following pages of Physiology in this narrower, more restricted sense.

If anyone at the present day, making use of the knowledge so far gathered in, were to attempt a rough preliminary analysis of the phenomena of action of a living being—for instance of one of the more complex, so-called higher animals, such as man—he might proceed in some such way as the following:—

One of the first, perhaps the first and most striking

fact about man is that he moves: his body moves of itself from place to place, and one part of the body moves on another. If we examine any one of these movements, such as the bending of the forearm on the arm, we find that it is brought about by certain masses of flesh, called muscles, which from time to time contract, that is, shorten; and these muscles are so disposed that, when they shorten, and so bring their ends nearer together, certain bones are pulled upon and the arm is bent. Upon further examination it will be found that all the gross movements of the body, both the locomotion of the whole body and the movements of parts upon parts, are carried out by the contraction or shortening of muscles. The muscles, together with bones, tendons, and other structures, are arranged in various mechanical contrivances, many of them singularly complex; hence the great diversity of movement of which an animal or man is capable; but in all cases the central fact, that which supplies the motive-power, is the contraction of a muscle, a shortening of its constituent fibers whereby its two ends are brought for a while nearer together.

When, pushing the analysis farther, we attempt to solve the question, Why do muscles contract? we find that the muscles of the body are connected with what is called the central nervous system by certain strands of living matter called nerves; and we further find that, with some few exceptions, which need not concern us now, the contractions of muscles are brought about by certain occult invisible changes called nervous impulses which travel along these nerves from the central nervous system to the muscles. Hence, when a nerve is severed, the muscle to which the nerve belonged, thus cut adrift from the central nervous system, no longer stirred by impulses reaching it therefrom, ceases to contract, and remains motionless and as it were helpless. Pushing the problem still farther home, and asking how these impulses originate in the central nervous system, we find that this central nervous mass is connected, not only with the muscles by means of nerves which, carrying impulses outward from itself to the muscles and so serving as instruments of movement, are called motor or efferent nerves, but also with various surfaces and parts of the body by means of other nerves, along which changes or impulses travel inward to itself in a centripetal fashion. Moreover, the beginnings or peripheral endings of these and other nerves appear to be so constituted that various changes in the surroundings of the body, or internal changes in the body itself, give rise to impulses, which, thus originated, travel inward to the central nervous system; hence these nerves are spoken of as sensory or afferent. Such sensory impulses reaching the central nervous system may forthwith issue as motor impulses leading to movement; but on many occasions they tarry within the central mass, sweeping backward and forward along particular areas of its substance, thus maintaining for awhile a state of molecular agitation and leading to movement at some subsequent period only. Moreover, we have reason to think that molecular disturbances may arise within the central nervous system apart from the advent, either past or present, of any impulses along sensory nerves. Lastly, the presence of these molecular agitations in the central nervous system, whether the immediate result of some new afferent impulse, or the much delayed and complicated outcome of some impulse which arrived long ago, or the product of internal changes apparently independent of all disturbance from without and so far spontaneous, may be indicated by corresponding phases of what we speak of as consciousness. We are thus led to conceive of the central nervous system as, chiefly at least, the seat of a molec-

ular turmoil maintained by multitudinous afferent impulses streaming in along the various afferent nerves, a turmoil which makes itself felt within as changes of consciousness, and produces effects without by movements wrought through motor nerves and muscles. And one large part of Physiology has for its task the unraveling of the laws which govern this turmoil, which determine, in relation to the advent of afferent impulses and the occurrence of intrinsic changes, the issue of motor impulses, and thus the characters of the resulting movements.

The movements of man or of an animal are not, however, the only salient facts of his existence. Equally characteristic of him are the facts, (1) that he from time to time eats, and must eat in order to live, and (2) that a supply of fresh air containing a certain quantity of oxygen is indispensable to his remaining alive. Viewed from a chemical point of view, an animal body, whether dead or alive, is a mass of complex unstable chemical substances, combustible in nature, *i.e.*, capable of being oxidized, and of being reduced by oxidation to simpler, more stable substances, with a setting free of energy. Combustible in the ordinary sense of the word an animal body is not, by reason of the large excess of water which enters into its composition; but an animal body thoroughly dried will in the presence of oxygen burn like fuel, and, like fuel, give out energy as heat. The material products of that combustion are fairly simple, consisting of water, carbonic acid, some ammonia or nitrogen compounds, and a few salts. And these same substances appear also as the products of that slower combustion which we call decay; for, whether the body be burnt swiftly in a furnace or rot away slowly in earth, air, or water, the final result is the same, the union of the complex constituent substances with the oxygen furnished from the air, and their reduction thereby to the above-named products, with a development of heat, which either as in the first case is rapid and appreciable, or as in the second is so slow and gradual as to be with difficulty recognized. Moreover, during life also the same conversion, the same oxidation, the same reduction of complex substances to simpler matters, the same setting free of the energy present in the former but absent in the latter, may be noted. The animal body dies daily, in the sense that at every moment some part of its substance is suffering decay, is undergoing combustion; at every moment complex substances full of latent energy are by processes of oxidation reduced to simpler substances devoid of energy or containing but little.

This breaking down of complex substances, this continued partial decay, is indeed the source of the body's energy; each act of life is the offspring of an act of death. Each strain of a muscle, every throb of the heart, all the inner work of that molecular turmoil of the nervous system of which we spoke above, as well as the chemical labor wrought in the many cellular laboratories of glands and membranes, every throw of the vital shuttle, means an escape of energy as some larger compacted molecule splits into smaller simpler pieces. Within the body the energy thus set free bears many shapes, but it leaves the body in two forms alone, as heat and as the work done by the muscles of the frame. All the inner labor of the body, both that of the chemical gland-cells, of the vibrating nerve-substance with its accompanying changes of consciousness, and of the beating heart and writhing visceral muscles, is sooner or later, by friction or otherwise, converted into heat; and it is as heat that the energy evolved in this labor leaves the body. Manifold as seems the body's energy, it has but one source, the decay of living material, *i.e.*, the oxidation of complex substances diversely built up into various living

matters, and but two ends, heat and muscular work. The continued setting free of energy which thus marks the living body, entailing as it does the continued breaking up and decay of living substance, constitutes a drain upon the body which must be met by constantly-renewed supplies, or otherwise the body would waste away and its energy flicker out. Hence the necessity on the one hand for that which we call food, which, however varied, is essentially a mixture of complex combustible energy-holding bodies, and on the other hand for that other kind of food which we call breath, and which supplies the oxygen whereby the complex oxidizable substances may be oxidized to simpler matters and their potential energy made to do work. Thus food supplies the energy of the body, but in quantity only, not in quality. The food by itself, the dead food, can exhibit energy as heat only, with intervening phases of chemical action; before its energy can be turned into the peculiar grooves of nervous and muscular action it needs to be transmuted into living substance, and in that transmutation there is a preliminary expenditure of part of the food's store of energy.

Here, then, we have a second view of physiological labor. To the conception of the body as an assemblage of molecular thrills—some started by an agent outside the body, by light, heat, sound, touch, or the like; others begun within the body, spontaneously as it were, without external cause: thrills which, traveling to and fro, mingling with and commuting each other, either end in muscular movements or die away within the body—to this conception we must add a chemical one, that of the dead food continually being changed and raised into the living substance, and of the living substance continually breaking down into the waste matters of the body by processes of oxidation, and thus supplying the energy needed both for the unseen molecular thrills and for the visible muscular movements.

Hence the problems of Physiology may in a broad sense be spoken of as threefold. (1) On the one hand, we have to search the laws according to which the complex unstable food is transmuted into the still more complex and still more unstable living flesh, and the laws according to which this living substance breaks down into simple, stable waste products, void or nearly void of energy. (2) On the other hand, we have to determine the laws according to which the vibrations of the nervous substance originate from extrinsic and intrinsic causes, the laws according to which these vibrations pass to and fro in the body, acting and reacting upon each other, and the laws according to which they finally break up and are lost, either in those larger swings of muscular contraction whereby the movements of the body are effected, or in some other way. (3) And lastly, we have to attack the abstruser problems of how these neural vibrations, often mysteriously attended with changes of consciousness, as well as the less subtle vibrations of the contracting muscles, are wrought out of the explosive chemical decompositions of the nervous and muscular substances, that is, of how the energy of chemical action is transmuted into and serves as the supply of that vital energy which appears as movement, feeling, and thought.

Even a rough initial analysis, however, such as we have just attempted to sketch, simple as it seems with our present knowledge, is an expression of the accumulated and corrected inquiries of many ages; the ideas which it embodies are the results of long-continued investigations, and the residue of many successive phases of opinion.

In the natural hierarchy of the sciences, Physiology follows after chemistry, which in turn follows physics, molar and molecular; and in a natural development, as

indeed is evident from what we have just seen, the study of the two latter should precede that of the former. At a very early age, however, the exigencies of life brought the study of man, and so of Physiology, to the front before its time; hence the history of Physiology consists to a large extent, especially in its opening chapters, of premature vain attempts to solve physical and chemical problems before the advent of adequate physical or chemical knowledge. But no ignorance of these matters could hide from the observant mind, even in quite early times, two salient points which appear also in the analysis just given, namely, that, while some of the phenomena of living beings seem due to powers wholly unknown in things which are not living, other phenomena, though at first sight special to living beings, appear to be in reality the peculiar outcome of processes taking place as well in things not alive. It was further early seen that, while the former are much more conspicuous, and make up a greater part of the life of the individual in those living beings which are called animals, especially in man, and in animals more closely resembling man, than in those which are called plants, the latter are common to both divisions of living things. Both sets of phenomena, however, were at first regarded as the products of certain special agencies; both were spoken of as the work of certain spirits; and the distinction between the two was formulated by speaking of the spirits as being in the former case *animal* and in the latter *vital*.

From the very outset even the casual observer could not fail to be struck with the fact that many of the processes of living beings appear to be the results of the various contrivances or machines of which a living body is largely built up. This, indeed, was evident even before the distinction between animal and vital spirits was recognized; and, when that differentiation was accepted, it was seen that the part played by these machines and contrivances in determining the actions of living beings was much more conspicuous in the domain of vital than of animal spirits. As inquiry was pushed forward the prominence and importance of this machinery became greater and greater, more especially since the phenomena supposed to be due to the agency of vital spirits proved more open to direct observation and experiment than those attributed to the animal spirits. It was found that the most fruitful path of investigation lay in the direction of studying the structure and independent action of the several constituent machines of the body, and of unraveling their mutual relations.

These machines received the names of organs, the work or action of an organ being at a later period spoken of as its function. And, when it became clear that many of the problems concerned with what was supposed to be the work of the vital spirits could be solved by the proper appreciation of the functions of certain organs, it was inferred that the more difficult problems belonging to the animal spirits could be solved in the same way. Still later on it was found that the conception of organs and functions was not only quite separable from, but indeed antagonistic to, the hypothesis of the entities called spirits.

In this way the first great phase, as it may be called, of the science of Physiology was evolved—a phase which lasted till quite recent times. Under this conception every living being, plant or animal, was regarded as a complex of organs, each with its respective function, as an engine built up of a number of intricately contrived machines, each performing its specific work. The whole animal body was parceled out into organs, each of which was supposed to have its appropriate function; and the efforts of investigators were directed, on the

one hand, to a careful examination of the structural features of an organ with the view of determining by deduction what its function must be, and, on the other hand, to confirming or correcting by observation and experiment the conclusions thus reached by the anatomical method. And the fruitfulness of this line of inquiry proved so great that the ideas directing it became absolutely dominant. In many cases the problem to be worked out was in reality a purely mechanical one. This was notably so in the great question of the circulation so brilliantly solved by Harvey. Putting aside for awhile the inquiry as to the origin of the force with which the walls of the heart press on the blood contained in its cavities, accepting the fact that the blood is thus pressed at each beat of the heart, all the other truths of the circulation which Harvey demonstrated are simply the outcome of certain mechanical conditions, such as the position and arrangement of the valves, the connection of various patent tubes, and the like. And many other problems—as, for instance, those connected with respiration—proved to be similarly capable of solution by the application of ordinary mechanical principles to anatomical facts.

So fruitful, and consequently so adequate, seemed this conception of living beings as built up of contrivances or organs, in contrast with the lifeless world in whose monotonous masses no such structural disposition could be recognized, that the word "organic" came into use as a term distinctive of living things. The phrase was especially adopted by the chemists, who for a long time classified their material into "organic" substances, *i.e.*, substances found only in living beings, and into "inorganic" substances, that is, substances occurring in lifeless bodies as well. Indeed, this nomenclature has not even yet been wholly abandoned. Triumphant, however, as was this mode of inquiry in these and similar instances, there remained in every investigation an unsolvable residue, like the question of the origin of the force exerted by the heart referred to above in speaking of Harvey's work; and in many other instances the questions which could not be solved on mechanical principles formed a great part of the whole problem. Thus in the case of the liver careful dissection showed that minute tubes starting from all parts of the liver joined into one large canal, which opened into the small intestine, and observation and experiment taught that these tubes during life conveyed from the liver to the intestine a peculiar fluid called bile, which appeared on the one hand to originate in the liver, and on the other to be used up for some purposes in the intestine. But here the mere mechanical flow of the bile along the gall-ducts, instead of being of primary, was merely of secondary importance, and the problem of how the bile was generated and made its way into the small beginnings of the ducts was the greater part of the whole matter. This latter problem was left unsolved, and indeed for awhile unattempted. Nevertheless the success in other directions attending the conception of organs and functions encouraged physiologists to speak of the liver as an organ whose function was to secrete bile, and, further, led them to ignore to a large extent the great unsolved portion of the problem, and to regard the mere enunciation of the function as the chief end of physiological inquiry.

Moreover, whenever attempts were made to unravel these obscurer problems, the efforts of investigators were mainly confined to a fuller and more complete elucidation of the supposed function of an organ, and the method of inquiry adopted was in most cases one which regarded the finer elements of the part studied as minute organs making up the whole gross organ, and which sought to explain the functions of these smaller

organs on the same mechanical principles which had proved so successful in the case of the whole organ. When the improvements in the microscope opened up a new world to the anatomist, and a wholly fresh mechanical analysis of the structure of living bodies became possible, great hopes were entertained that the old method applied to the new facts would soon solve the riddles of life by showing how the mysterious operations of the living substances out of which the grosser organs were built were the outcome of structural arrangements which had hitherto remained invisible, were in fact the functions of minute component organs. A vision of a grand simplicity of organic nature dawned upon the minds of physiologists. It seemed possible to conceive of all living beings as composed of minute organic units, of units whose different actions resulted from their different structural characters, whose functions were explicable by, and could be deduced from, their anatomical features, such units being built up into a number of gross organs, the functions of each of which could in turn be explained by the direction which its mechanical build gave to the efforts of its constituent units. Such a view seemed to have touched the goal, when, in the first half of this century, the so-called "cell-theory" was enunciated as a physiological generalization.

Long before, in the previous century, the genius of Caspar Wolff had led him to maintain that the bodies of living beings may be regarded as composed of minute constituent units, which, being in early life all alike and put together as an unformed mass, gradually differentiate and are ultimately arranged into the tissues and organs of the adult being. But, though Wolff was not unaware of the physiological bearing of his conception, his mind was chiefly bent toward morphological views, and his cell-theory is essentially a morphological one. The cell-theory, however, which became famous in the third decade of the present century, and to which the twin names of Schwann and Schleiden will always be attached, was essentially a physiological one. The chief interest which these authors felt in the ideas that they put forth centered in the conviction that the properties of the cell as they described it were the mechanical outcome of its build; and for a time it seemed possible that all physiological phenomena could be deduced from the functions of cells, the anatomical characteristics of the various kinds of cells determining in turn their special functions. In the cell-theory the conception of organs and functions reached its zenith; but thenceforward its fall, which had been long prepared, was swift and great. Two movements especially hurried on its decline.

It had long been a reproach to physiologists that, while to most organs of the body an appropriate function had been assigned, in respect to certain even conspicuous organs no special use or definite work could be proved to exist. Of these apparently functionless organs the most notorious instance was that of the spleen, a large and important body, whose structure, though intricate, gave no sign of what its labors were, and whose apparent uselessness was a stumbling-block to the theological speculations of Paley. While in the case of other organs a definite function could be readily enunciated in a few words, and their existence therefore easily accounted for, the spleen remained an opprobrium, existing, as it appeared to do, without purpose, and therefore without cause.

The progress of discovery during the present century, by a cruel blow, instead of pointing out the missing use of the spleen, rudely shook the confidence with which the physiologists concluded that they had solved the riddle of an organ when they had allotted to it a special

function. From very old times it had been settled that the function of the liver was to secrete bile; and the only problems left for inquiry as touching the liver seemed to be those which should show how the minute structure of the organ was adapted for carrying on this work. About the middle of this century, however, the genius of Claude Bernard led him to discover that the secretion of bile was by no means the chief labor of the liver. He showed that this great viscus had other work to do than that of secreting bile, had another "function" to perform, but a function which seemed to have no reference whatever to the mechanical arrangements of the organ, which could never have been deduced from any inspection, however complete, of its structure, even of its most hidden and minute features, and which therefore could not be called a function in the old and proper sense of that word. By a remarkable series of experiments, which might have been carried out by one knowing absolutely nothing of the structural arrangements of the liver beyond the fact that blood flowed to it along the portal vein, and from it along the hepatic vein, he proved that the liver, in addition to the task of secreting bile, was during life engaged in carrying on a chemical transformation by means of which it was able to manufacture and store up in its substance a peculiar kind of starch, to which the name of *glycogen* was given. Bernard himself spoke of this as the glycogenic function of the liver, but he used the word "function" in a broad, indefinite sense, simply as work done, and not in the older and narrower meaning as work done by an organ structurally adapted to carry on a work which was the inevitable outcome of the form and internal build of the organ. In this glycogenic function organization, save only the arrangements by means of which the blood flows on from the portal to the hepatic channels in close proximity to the minute units of the liver-substance, the so-called hepatic cells appeared to play no part whatever; it was not a function, and in reference to it the liver was not an organ, in the old sense of the words. This discovery of Bernard's threw a great flash of light into the darkness hitherto hiding the many ties which bound together distant and mechanically isolated parts of the animal body. Obviously the liver made this glycogen, not for itself, but for other parts of the body; it labored to produce, but they made use of, the precious material, which thus became a bond of union between the two.

The glycogenic labors of the simple hepatic substance carried out independently of all intricate structural arrangements, and existing in addition to the hepatic function of secreting bile, being thus revealed, men began to ask themselves the question, may not something like this be true of other organs to which we have allotted a function, and thereupon rested content? And further, in the cases where we have striven in hope, and yet in vain, to complete the interpretation of the function of an organ, by finding in the minute microscopic details of its structure the mechanical arrangements which determine its work, may we not have followed throughout a false lead, and sought for organization where organization in our sense of the word does not exist? The answer to this question, and that an affirmative one, was hastened by the collapse of the cell-theory on its physiological side, very soon after it had been distinctly formulated.

The "cell," according to the views of those who first propounded the cell-theory, consisted essentially of an envelope or "cell-membrane," of a substance or substances contained within the cell-membrane, hence called cell-contents, and of a central body or kernel called the "nucleus," differing in nature from the rest

of the cell-contents. And, when facts were rapidly accumulated, all tending to prove that the several parts of the animal or vegetable body, diverse as they were in appearance and structure, were all built up of cells more or less modified, the hope arose that the functions of the cell might be deduced from the mutual relations of cell-membrane, cell-contents, and nucleus, and that the functions of an organ might be deduced from the modified functions of the constituent modified cells. Continued investigation, however, proved destructive of this physiological cell-theory. It soon became evident that the possession of an investing envelope or cell-membrane was no essential feature of a cell, and that even the central kernel or nucleus might at times be absent. It was seen, in fact, that the anatomical unit need have no visible parts at all, but might be simply a minute mass, limited in various ways, of the material spoken of as cell-contents. Under the cell-theory, the cell was supposed to be the first step in organization, the step by which a quantity of formless unorganized plasm became an organized unit; this plasm was further supposed still to form the chief part of the cell-contents, and soon became recognized under the name of protoplasm. Hence the destructive anatomical researches which deprived the cell of its cell-membrane, and even of its nucleus, left nothing except a mass of protoplasm to constitute an anatomical unit. For such a unit the word "cell" was a misnomer, since all the ideas of organization denoted by the word had thus vanished; nevertheless it was retained with the new meaning, and up to the present time the definition of a cell is that of a limited mass of protoplasm, generally but not always containing a modified kernel or nucleus.

With this anatomical change of front the physiological cell-theory was utterly destroyed. The cell was no longer a unit of organization; it was merely a limited mass of protoplasm, in which, beyond the presence of a nucleus, there was no visible distinction of parts. It was no longer possible to refer the physiological phenomena of the cell to its organization; it became evident that the work done by a "cell" was the result not of its form and cellular structure but simply of the nature and properties of the apparently structureless protoplasm which formed its body. A new idea pressed itself on men's minds, that organization was a concomitant and result of vital action, not its condition and cause; as Huxley in one of his earliest writings put it, "They [cells] are no more the producers of the vital phenomena than the shells scattered in orderly lines along the sea beach are the instruments by which the gravitative force of the moon acts upon the ocean. Like these, the cells mark only where the vital tides have been, and how they have acted." Hence arose the second of the two movements mentioned above, that which may be called the "protoplasmic" movement, a movement which, throwing overboard altogether all conceptions of life as the outcome of organization, as the mechanical result of structural conditions, attempts to put Physiology on the same footing as physics and chemistry, and regards all vital phenomena as the complex products of certain fundamental properties exhibited by matter, which, either from its intrinsic nature or from its existing in peculiar conditions, is known as living matter—mechanical contrivances in the form of organs serving only to modify in special ways the results of the exercise of these fundamental activities and in no sense determining their initial development.

Long before the cell-theory had reduced to an absurdity the "organic" conception of Physiology, the insight of the brilliant Bichat, so early lost to science, had led him to prepare the way for modern views by developing his doctrine of "tissues." That doctrine

regarded the body as made up of a number of different kinds of living material, each kind of material having certain innate qualities proper to itself as well as certain structural features, and the several kinds of material being variously arranged in the body. Each of these body-components was spoken of as a tissue, muscular tissue, nervous tissue, and the like; and the varied actions of the body were regarded as the result of the activities of the several tissues modified and directed by the circumstance that the tissues were to a great extent arranged in mechanical contrivances or organs which largely determined the character and scope of their actions.

The imperfection of microscopic methods in Bichat's time, and, we may perhaps add, his early death, prevented him from carrying out an adequate analysis of the qualities or properties of the tissues themselves. During the middle portion of this century, however, histological investigation, *i.e.*, inquiry into the minute structure of the tissues, made enormous progress, and laid the basis for a physiological analysis of the properties of tissues. In a short time it became possible to lay down the generalization that all the several tissues arise, as far as structure is concerned, by a differentiation of a simple primitive living matter, and that the respective properties of each tissue are nothing more than certain of the fundamental properties of the primordial substance thrown into prominence by a division of labor running to a certain extent parallel to the differentiation of structure. Developed in a fuller manner, this modern doctrine may be expounded somewhat as follows:—

In its simplest form a living being, as illustrated by some of the forms often spoken of as *amœbæ*, consists of a mass of substance in which there is no obvious distinction of parts. In the body of such a creature even the highest available powers of the microscope reveal nothing more than a fairly uniform network of material, a network sometimes compressed, with narrow meshes, sometimes more open, with wider meshes, the intervals of the meshwork being filled, now with a fluid, now with a more solid substance or with a finer and more delicate network, and minute particles or granules of variable size being sometimes lodged in the open meshes, sometimes deposited in the strands of the network. Sometimes, however, the network is so close, or the meshes filled up with material so identical in refractive power with the bars or films of the network, and at the same time so free from granules, that the whole substance appears absolutely homogeneous, glassy or hyaline. Analysis with various staining and other reagents leads to the conclusion that the substance of the network is of a different character from the substance filling up the meshes. Similar analysis shows that at times the bars or films of the network are not homogeneous, but composed of different kinds of stuff; yet even in these cases it is difficult, if not impossible, to recognize any definite relation of the components to each other such as might deserve the name of structure; and certainly in what may be taken as the more typical instance, where the network seems homogeneous, no microscopic search is able to reveal to us a distinct structural arrangement in its substance. In all probability optical analysis, with all its aids, has here nearly reached its limits; and, though not wholly justified, we may perhaps claim the right to conclude that the network in such case is made up of a substance in which no distinction of parts will ever be visible, though it may vary in places or at times in what may be spoken of as molecular construction, and may carry, lodged in its own substance, a variety of matters foreign to its real self. This remarkable network is often

spoken of as consisting of protoplasm, and though that word has come to be used in several different meanings, we may for the present retain the term. The body of an *amœba*, then, or of a similar organism consists of a network or framework which we may speak of as protoplasm, filled up with other matters. In most cases it is true that in the midst of this protoplasmic body there is seen a peculiar body of a somewhat different and yet allied nature, the so-called nucleus; but this we have reason to think is especially concerned with processes of division or reproduction, and may be absent, for a time at all events, without any injury to the general properties of the protoplasmic body.

Now such a body, such a mass of simple protoplasm, homogeneous save for the admixtures spoken of above, is a living body, and all the phenomena which we sketched out at the very beginning of this article as characteristic of the living being may be recognized in it. There is the same continued chemical transformation, the same rise and fall in chemical dignity, the same rise of the dead food into the more complex living substance, the same fall of the living substance into simpler waste-products. There is the same power of active movement, a movement of one part of the body upon another giving rise to a change of form, and a series of changes of form resulting eventually in a change of place. In what may be called the condition of rest the body assumes a more or less spherical shape. By the active transference of part of the mass in this or that direction the sphere flattens itself into a disk, or takes on the shape of a pear, or of a rounded triangle, or assumes a wholly irregular, often star-shaped or branched, form. Each of these transformations is simply a rearrangement of the mass, without change of bulk. When a bulging of one part of the body takes place there is an equivalent retraction of some other part or parts; and it not infrequently happens that one part of the body is repeatedly thrust forward, bulging succeeding bulging, and each bulging accompanied by a corresponding retraction of the opposite side, so that, by a series of movements, the whole body is shifted along the line of the protuberances. The tiny mass of simple living matter moves onward, and that with some rapidity, by what appears to be a repeated flux of its semi-liquid substance.

The internal changes leading to these movements may begin, and the movements themselves be executed, by any part of the uniform body; and they may take place without any obvious cause. So far from being always the mere passive results of the action of extrinsic forces, they may occur spontaneously, that is, without the coincidence of any recognizable disturbance whatever in the external conditions to which the body is exposed. They appear to be analogous to what in higher animals we speak of as acts of volition. They may, however, be provoked by changes in the external conditions. A quiescent *amœba* may be excited to activity by the touch of some strange body, or by some other event—by what in the ordinary language of Physiology is spoken of as a stimulus. The protoplasmic mass is not only mobile, but sensitive. When a stimulus is applied to one part of the surface a movement may commence in another and quite distant part of the body; that is to say, molecular disturbances appear to be propagated along its substance without visible change, after the fashion of the nervous impulses we spoke of in the beginning of this article. The uniform protoplasmic mass of the *amœba* exhibits the rudiments of those attributes or powers which in the initial sketch we described as being the fundamental characteristics of the muscular and nervous structures of the higher animals.

These facts, and other considerations which might be

brought forward, lead to the tentative conception of protoplasm as being a substance (if we may use that word in a somewhat loose sense) not only unstable in nature but subject to incessant change, existing indeed as the expression of incessant molecular, that is, chemical and physical change, very much as a fountain is the expression of an incessant replacement of water. We may picture to ourselves this total change which we denote by the term "metabolism" as consisting on the one hand of a downward series of changes (*katabolic* changes), a stair of many steps, in which more complex bodies are broken down with the setting free of energy into simpler and simpler waste bodies, and on the other hand of an upward series of changes (*anabolic* changes), also a stair of many steps, by which the dead food, of varying simplicity or complexity, is, with the further assumption of energy, built up into more and more complex bodies. The summit of this double stair we call "protoplasm." Whether we have a right to speak of it as a single body, in the chemical sense of that word, or as a mixture in some way of several bodies, whether we should regard it as the very summit of the double stair, or as embracing as well the topmost steps on either side, we cannot at present tell. Even if there be a single substance forming the summit, its existence is absolutely temporary; at one instant it is made, at the next it is unmade. Matter which is passing through the phase of life rolls up the ascending steps to the top, and forthwith rolls down on the other side. But to this point we shall return later on. Further, the dead food, itself fairly but far from wholly stable in character, becomes more and more unstable as it rises into the more complex living material. It becomes more and more explosive, and when it reaches the summit its equilibrium is overthrown and it actually explodes. The whole downward stair of events seems in fact to be a series of explosions, by means of which the energy latent in the dead food and augmented by the touches through which the dead food becomes living protoplasm, is set free. Some of this freed energy is used up again within the material itself, in order to carry on this same vivification of dead food; the rest leaves the body as heat or motion. Sometimes the explosions are, so to speak, scattered, going off as it were irregularly throughout the material, like a quantity of gunpowder sprinkled over a surface, giving rise to innumerable minute puffs, but producing no massive visible effects. Sometimes they take place in unison, many occurring together, or in such rapid sequence that a summation of their effects is possible, as in gunpowder rammed into a charge, and we are then able to recognize their result as visible movement, or as appreciable rise of temperature.

These various phenomena of protoplasm may be conveniently spoken of under the designation of so many properties, or attributes, or powers of protoplasm, it being understood that these words are used in a general and not in any definite scholastic sense. Thus we may speak of protoplasm as having the power of *assimilation*, *i. e.*, of building up the dead food into its living self; of movement, or of *contractility* as it is called, *i. e.*, of changing its form through internal explosive changes; and of *irritability* or *sensitiveness*, *i. e.*, of responding to external changes, by less massive internal explosions, which, spreading through its mass, are not in themselves recognizable through visible changes, though they may initiate the larger visible changes of movement.

These and other fundamental characteristics, all associated with the double upward and downward series of chemical changes, of constructive and destructive metabolism, are present in protoplasm wherever found; but a very brief survey soon teaches us that specimens of protoplasm existing in different beings or in different

parts of the same being differ widely in the relative prominence of one or another of these fundamental characteristics. On the one hand, in one specimen of protoplasm the energy which is set free by the series of explosions constituting the downward changes of destructive metabolism may be so directed as to leave the mass almost wholly in the form of heat, thus producing very little visible massive change of form. Such a protoplasm consequently, however irritable and explosive, exhibits little power of contractility or movement. In another specimen, on the other hand, a very large portion of the energy similarly set free may be spent in producing visible changes of form, the protoplasm in this instance being exquisitely mobile. Such differences must be due to different internal arrangements of the protoplasm, though, since no vision, however well assisted, can detect these arrangements, they must be of a molecular nature rather than of that grosser kind which we generally speak of as structural. It is true that, as the differences in properties become more and more prominent, as the protoplasm becomes more and more specialized, features which we can recognize as structural intervene; but even these appear to be subsidiary, to accompany and to be the result of the differences in property, or to be concerned in giving special directions to the activities developed, and not to be the real cause of the differences in action. We are thus led to the conception of protoplasm as existing in various differentiated conditions while still retaining its general protoplasmic nature, a difference of constitution making itself felt in the different character of the work done, in a variation of the results of the protoplasmic life. We have a division of physiological labor going hand in hand with a differentiation of material, accompanied ultimately by morphological results which may fairly be spoken of as constituting a differentiation of structure.

Some of the simpler and earlier features of such a division and differentiation may be brought out by comparing with the life of such a being as the *amœba* that of a more complex and yet simple organism as the *hydra* or freshwater polyp. Leaving out certain details of structure, which need not concern us now, we may say that the *hydra* consists of a large number of units or cells firmly attached to each other, each cell being composed of protoplasm, and in its broad features resembling an *amœba*. The polyp is in fact a group or crowd of *amœba*-like cells so associated together that, not only may the material of each cell, within limits, be interchanged with that of neighboring cells, but also the dynamic events taking place in one cell, and leading to exhibitions of energy, may be similarly communicated to neighboring cells, also within limits. These cells are arranged in a particular way to form the walls of a tube, of which the body of a *hydra* practically consists. They form two layers in apposition, one an internal layer called the *endoderm*, lining the tube, the other an external layer called the *ectoderm*, forming the outside of the tube. And, putting aside minor details, the differences in structure and function observable in the organism are confined to differences between the *ectoderm* on the one hand, all the constituent cells of which are practically alike, and the *endoderm* on the other, all the cells of which are in turn similarly alike. The protoplasm of the *ectoderm* cells is so constituted as to exhibit in a marked degree the phenomena of which we spoke above as irritability and contractility, whereas in the *endoderm* these phenomena are in abeyance, those of assimilation being prominent. The movements of the *hydra* are chiefly brought about by changes of form of the *ectoderm* cells, especially of tail-like processes of these cells, which, arranged as a longitudinal

wrapping of the tubular body, draw it together when they shorten, and lengthen it out when they elongate, and it is by the alternate lengthening and shortening of its body, and of the several parts of its body, that the hydra changes its form and moves from place to place. Inaugurating these changes of form, the products of contractility, are the more hidden changes of irritability; these also are especially developed in the ectoderm cells, and travel readily from cell to cell, so that a disturbance originating in one cell, either from some extrinsic cause, such as contact with a foreign body, or from intrinsic events, may sweep from cell to cell over the surface of the whole body. The animal feels as well as moves by means of its ectoderm cells. In the endoderm cells the above phenomena, though not wholly absent, are far less striking, for these cells are almost wholly taken up in the chemical work of digesting and assimilating the food received into the cavity, the lining of which they form.

Microscopic examination further shows that these two kinds of cells differ from each other to some extent in visible characteristics; and, though, as we have seen, the differences in activity appear to be dependent on differences in invisible molecular arrangement rather than on gross visible differences such as may be called structural, still the invisible differences involve or entail, or are accompanied by, visible differences, and such differences as can be recognized between endoderm and ectoderm, even with our present knowledge, may be correlated to differences in their work; future inquiry will probably render the correlation still more distinct.

The ectoderm cells together constitute what we have spoken of above as a tissue, whose function in the modern sense of the word is movement and feeling, and the endoderm cells constitute a second tissue, whose function is assimilation; and the phenomena of the whole being result from the concurrent working of these two functions. Of organs, in the old sense of the word, of mechanical contrivances, there is hardly a trace. The performances of the being are, it is true, conditioned by its being molded in the form of a long tubular sac with a crown of like tubular arms, but beyond this the explanation of every act of the hydra's life is first to be sought in the characteristics of the endoderm and ectoderm. The physiology of the hydra is, for the most part, a series of problems, dealing on the one hand with the intimate nature of the ectodermic protoplasm and the changes in that protoplasm which give rise to movement and feeling, as well as with the laws whereby those changes are so regulated that movement and feeling come and go as the needs of the organism may require, and on the other hand with the intimate nature of the endodermic protoplasm and the changes in that protoplasm whereby the dead food is, also according to the needs of the economy, transformed into living substance. Whereas the older Physiology dealt almost exclusively with mechanical problems, the Physiology of to-day is chiefly busied with what may be called molecular problems.

The physiology of the higher animals, including man, is merely a development of the simpler physiology of the hydra, which has been rendered more complex by a greater division of physiological labor, entailing greater differentiation of structure, and been varied by the intercalation of numerous mechanical contrivances.

In the hydra each ectoderm cell—for, broadly speaking, they are all alike—serves three chief purposes of the body. (1) It is sensitive, that is, it is thrown into peculiar molecular agitations, with expenditure of energy, when acted upon by external agents. In man and the higher animals certain cells of the original ectoderm of the embryo are differentiated from their

fellows (which, losing to a large extent this sensitiveness, remain as a mechanical covering to the body) by a more exquisite development of this power of reaction, and moreover are differentiated from each other in their relative sensitiveness to different agents, so that one set of cells becomes peculiarly susceptible to light, another set to pressure, and the like. Thus the uniform ectoderm of the hydra, uniformly susceptible to all agencies, is replaced by a series of special groups of cells forming the basis of sensory organs, each group being specially sensitive to one agent, and having the nature of its constituent cells correspondingly modified. (2) In each ectoderm cell of the hydra the agitations primarily induced by the exciting agent become so modified by changes taking place in the cell that the outcome is not always the same. According to processes taking place in the cell, movement of one kind or another, or no movement at all, may result, and such movement as results may take place immediately or at some other time; it may be at a time so distant that the connection with the exciting disturbance is lost, and the movement appears to be spontaneous. In man and the higher animals these more complex "neural" processes are carried on, not by the simple sensory cells which receive the primary impression, but by a group of cells set apart for the purpose. These cells constitute a central nervous system, in which a still further division of labor and differentiation of structure takes place, the simple neurotic processes of the hydra, with its dim volition and limited scope of action, being developed in a complex manner into processes which range from simple elaboration of the initial additional agitation of the sensory cell into what we speak of as intelligence and thought. (3) Each ectoderm cell, by its tail-like prolongation, or by its whole body, contributes to the movement of the animal while still carrying on the two other actions just described. In man and the higher animals the material of the sensory cell and of the central nervous cells is too precious to be wasted in movements; these accordingly are carried out by groups of cells constituting the muscular tissue, in which both the sensitiveness and the higher neurotic processes of the primitive cell are held in abeyance; indeed, the latter have almost disappeared in order that the energy of the protoplasm may be more completely directed to producing those changes of form which determine the movements of the animal.

Further, the separation in space of these three groups of cells or tissues necessitates the introduction of elements whereby the agitations set up in the sensory cell should be communicated to the central nervous cells, where these agitations are further elaborated, as well as of elements whereby the muscular tissue may receive vibrations from the central nervous cells, so that the movements of the body may be determined by these. Hence strands of irritable protoplasm whose energy is not spent in movement, but wholly given up to the rapid and easy transmission of molecular vibrations, unite, as sensory nerves, the sensory cells with the central nervous cells, and, as motor nerves, these with the muscles.

Lastly, for the adequate carrying out of complex movements, the contractile cells, elongated into specially constructed fibers and constituting the muscles, are arranged, with inert tissues such as bones, cartilages, tendons, and the like (tissues of mechanical virtues, manufactured by an active protoplasm, but themselves passive, no longer active), into various mechanical contrivances. Similarly the sensory cells, as notably those of the eye and the ear, set apart to be acted upon by special agents, are provided with special mechanisms in order that the agent may act with more complete pre-

cision. Thus the sensory cells constituting the retina of the eye, in which alone sensory, visual impulses are generated, are provided with an intricate dioptric mechanism, formed partly of inert tissues such as the lens, partly of peculiarly arranged muscular and nervous elements.

In this way the simple ectoderm of the hydra is replaced by a complicated system composed of organs, some of them of extremest intricacy. But the whole system may be reduced to two sets of factors. On the one hand there are organs in the old sense of the word, that is, mechanical arrangements, some connected with muscles and others connected with the sensory cells, organs whose functions have for the most part to be interpreted on mechanical principles, since their most important factors, putting aside intervening muscular and nervous elements, are the inert products of protoplasm doing simple mechanical work. On the other hand there are organs in the latter sense of the word, namely, sensory cells differentiated to be sensitive to special influences, central nervous cells differentiated to carry on the inner nervous work, muscles differentiated to contract, and nerves differentiated to bind together these three other factors. The work of these latter organs is dependent on the nature of their protoplasm; mechanical arrangements play but little part in them; and the results of their activity can in no way be explained on simple mechanical principles.

Corresponding with this differentiation of the ectoderm cells runs a somewhat similar differentiation of the endoderm cells. In the hydra each endoderm cell appears to receive some of the food bodily into itself and there to elaborate it into what may be spoken of as prepared nutritive material. Some of this material the cell retains within itself in order to renew its own protoplasm; the rest oozes out to the ectoderm cells, the replenishment of whose protoplasm is thereby effected with a saving of labor. In the higher animals the preparation of food is far more complicated. The endodermic sheet of the alimentary canal is folded and arranged into organs called glands, with the mechanical advantage that a large amount of surface is secured within a small bulk; and the constituent endodermic cells of their glands pour out, or secrete, as is said, divers fluids into the cavity or the canal, so that much preliminary preparation of digestion of the food takes place before the food really enters the body. Further, these secreting glandular cells are so differentiated as to pour out special juices acting on special constituents of a meal, and the food subjected in turn to the action of these several juices becomes thoroughly prepared for reception into the body. This reception is carried out by other endoderm cells, which in receiving the digested food probably act upon it so as still further to heighten its nutritive value; and the absorbed food, before it is presented to the muscular and nervous tissues, for whose use it is largely, though of course not exclusively, intended, is subjected to the action of other cells, such as those forming the lymphatic glands and the liver, in order that it may be still further elaborated, still further prepared for the final conversion into living protoplasm.

As in the case of the tissues and organs of ectodermic origin, so also here, the wide separation in space of the masses of differentiated cells constituting tissues necessitates the introduction of mechanical contrivances for the carriage of material from place to place. In the simple minute hydra the nutritive material can permeate the whole body by simply oozing from cell to cell. In the higher animal a hydraulic system for the distribution of nutritive material is introduced. A fluid is distributed in a ceaseless flow all over the body by a mechanical arrangement, consisting of a pump with branching

tubes, worked on mechanical principles, and capable of being imitated artificially, save that the power which drives the machine is the energy set free by living muscle. As this circulating fluid or blood rushes past the endoderm cells which have gorged themselves from the rich contents of the alimentary canal, it receives from them some of the material which they have absorbed and elaborated, and carries this, the nutritive supply, to muscles, nerves, and all parts of the body. Similarly it carries away from muscle, nerves, and other tissues of waste-products of their activity those broken fragments of simpler stuffs into which, as we have seen, the complex protoplasm, wherever it exists, is forever splitting up, and bears them back to differentiated endoderm and other cells, whose work has become, so to speak, inverted, since their activity is directed to casting things out of the body, instead of receiving things into the body. And lastly, by a special arrangement, by a peculiar property of those red corpuscles which make blood red, this circulating material at one and the same time carries to each corner of the body, not only the nutritive material required for building up protoplasm, but also the oxygen by which the constructed protoplasm may suffer oxidation, and in being oxidized set free that energy the manifestation of which is the token of life. Blood is in fact the medium on which all the various parts of the body live. Just as an amœba finds in the water which is its home both the food with which it builds itself up and the oxygen with which it breaks itself down, and returns to the water the waste-products of its continued disintegration, so each islet of the living substance of the higher animal, be it muscle or nerve or gland, draws its food and its oxygen from the red blood-stream sweeping past it, finding therein all its needs, and sheds into the same stream the particles into which it is continually breaking up, and for which it has no longer any use. Hence the blood becomes, as it were, a chemical epitome of the body; from it each tissue takes something away; to it each tissue gives something back. As it sweeps by each tissue, losing and gaining, it makes the whole body common, and when working aright brings it about that each tissue is never in lack of the things which it wants, never choked up with the things with which it has done.

This vascular system, consisting of a force-pump and branching tubes, constitutes, as we have said, a mechanical arrangement worked on mechanical principles. Nevertheless occult protoplasmic processes intervene as factors in its total work. Not only is the force-pump itself a living muscular organ, not only are the walls of the tubes muscular in nature, so that the mere mechanical working of the system is modified by changes not of mechanical origin taking place in them, but the living material which lines the tubing throughout, especially in the minuter channels, finds work to do, also not of a mechanical nature. The gross phenomena of the flow of blood through the capillary channels may (see VASCULAR SYSTEM) be interpreted on simple hydraulic principles; but no appeal to the ordinary physical laws of dead material will explain the phenomena of the interchange between the blood on the inside of a capillary wall and the tissue-elements on the outside. In every tissue, be it gland, muscle, or nerve, the blood, so far from being actually in contact with the active protoplasmic units of the tissue, is separated by the protoplasmic film of the capillary wall, and by a space or spaces, greater or smaller, filled with the fluid called lymph and lined to a greater or less extent with protoplasmic cells, which lining, often at least, parts the tissue-units from the lymph. Hence the tissue lives upon the lymph, while the lymph is replenished from the blood; and the

interchange between the tissue-unit and the blood is determined, not only by the direct action of the tissue-unit on the lymph, but also by the relations of the lymph to the blood, as regulated by the capillary wall and the cellular lining of the lymph-spaces. We may speak of the interchange as broadly one of diffusion or osmosis through filmy membranes; but diffusion is not the lord in the matter: it is rather a humble servant directed hither and thither by occult molecular processes in the protoplasmic structures concerned.

The foregoing rough analysis leads to a conception of the physiology of the animal body which may be expressed somewhat as follows:—The body is composed of different kinds of matter; each kind of matter, arranged in units more or less discrete, constitutes a tissue; and the several tissues, though having a common likeness in token of their origin from a common primordial protoplasm, have dissimilar molecular constitutions, entailing dissimilar modes of activity. Nor is each tissue homogeneous, for two parts of the body, though so far alike as to be both examples of the same general tissue, may be different in molecular constitution, more or less distinctly expressed by microscopic differences of structure, and correspondingly different in action. Thus a liver-cell and a kidney-cell, though both examples of glandular tissue, are quite distinct; so also several varieties of muscular tissue exist; and in the dominant nervous tissue we have not only a broad distinction between nerve-fibers and nerve-cells, but the several groups of nerve-cells which are built up into the brain and spinal cord, and indeed probably the single nerve-cells of these, though all possessing the general characters, in both structure and function, of nervous protoplasm, differ most widely from each other. These several tissues of diverse constitution and activity, ranging as regards the rapidity of the molecular changes taking place in them from the irritable, unstable, swiftly-changing nerve-cell to the stable, slowly-changing, almost lifeless tendon or bone, are disposed in the body in various mechanical arrangements constituting organs or machines, whereby the activities of the constituent tissue-elements are brought to bear in special directions. These organs range from those in which the mechanical provisions are dominant, the special activity of the tissue-elements themselves being in the background, and supplying only an obscure or even unimportant factor, as in the organs of respiration, to those in which the mechanical provisions are insignificant, as in the central nervous system, where the chief mechanical factor is supplied by the distribution in space of the nerve fibers or cells.

Hence it is obvious that almost every physiological inquiry of any large scope is, or sooner or later becomes, of a mixed nature. On the one hand, investigation has to be directed to the processes taking place in the actual tissue-elements, in the protoplasmic cells and modifications of cells. These are essentially of a molecular, often of a chemical or chemico-physical, nature; in the problems thus raised matters of form and structure, other than that of molecular structure, which no microscope can ever reveal, are of a secondary moment only, or have no concern in the matter at all. These may be spoken of as the purely physiological or as the molecular problems. On the other hand, the natural results of these tissue-activities are continually being modified by circumstances whose effect can be traced to the mechanical arrangements under which the tissue in question is acting, whence arise problems which have to be settled on simple mechanical principles.

We may take as an illustration the physiology of the kidney. In the old language the function of the kidney is to secrete urine. When we come to inquire into the

matter, we find, in the first place, that the secretion of urine—that is, the quantity and quality of the urine escaping from the duct of the kidney in a given period—is partly determined by the quantity of blood passing through the kidney and the circumstances of its passage. Now the quantity of blood reaching the kidney at any one time is dependent partly on the width of the renal arteries, partly on the general pressure of the blood in the arterial system. The width of the renal arteries is in turn dependent on the condition of their muscular walls, whether contracted or relaxed; and this condition is determined by the advent of nervous impulses, the so-called vaso-motor impulses, arising in the central nervous system and passing down to the renal arteries along certain nerves. The emission of these vaso-motor impulses from the central nervous system is further determined, on the one hand by the condition of certain parts of the central nervous system, the so-called vaso-motor centers, and on the other by the passage of certain afferent sensory impulses to those vaso-motor centers from sensory surfaces such as the skin. Similarly the general blood-pressure is dependent on the condition, patent or narrowed, of the small arteries generally, this being likewise governed by the vaso-motor system and on the coincident work done by the heart in driving blood into the great blood-vessels, this work being also governed by the nervous system. Hence in attacking such a problem as to how any particular event, such as the exposure of skin to the cold, influences the flow of blood through the kidney and thus the secretion of urine, the investigator, without staying to inquire into the nature of nervous impulses, or into the nature of changes taking place in vaso-motor centers, etc., directs his attention to determining what impulses are generated under the circumstances, what paths they take, to what extent they are quantitatively modified, how far they and their effects react upon each other, and so on. His inquiry in fact takes on to a large extent the characteristics of an attempt to unravel an intricate game, in which the counters are nervous impulses, muscular contractions, and elastic reactions, but in which the moves are determined by topographical distribution and mechanical arrangements.

But there are other problems connected with the physiology of the kidney of quite a different nature. The kidney is, broadly speaking, constructed of living protoplasmic cells so arranged that each cell is on one side bathed with blood and lymph, and on the other forms the boundary of a narrow canal, which, joining with other canals, ultimately opens into the urinary bladder. Here the question arises how it is that these protoplasmic cells, having nothing to draw upon but the common blood, which is distributed to other organs and tissues as well, are able to discharge on the other side of them into the canal the fluid urine, which is absolutely distinct from blood, which contains substances wholly unknown in blood, as well as substances which, though occurring in blood, are found there in minute quantities only, and, moreover, are not found to escape from the blood into any other tissues or organs. In attempting to answer this question we come upon an inquiry of quite a different nature from the preceding, an inquiry for the solution of which mechanical suggestions are useless. We have to deal here with the molecular actions of the protoplasmic cell. We must seek for molecular explanations of the questions, why a current sets across the cell from blood-capillary and lymph-space to the hollow canal; why the substances which emerge on the far side are so wholly unlike those which enter in on the near side; why, moreover, the intensity of this current may wax and wane, now flooding the canal with urine, now nearly or quite drying up; why

not only the intensity of the current but also the absolute and relative amount of the chemical substances carried along it are determined by events taking place in the cell itself, being largely independent of both the quantity and quality of the blood which forms the cell's only source of supply. These and other like questions can only be solved by looking with the mind's eye penetrating through careful inferences, into those inner changes which we call molecular, and which no optical aid will ever reveal to the physical eye.

*Nervous System.*—However complex may be the anatomical arrangements in man and the higher animals, the nervous system consists essentially of three portions: (1) *central* masses of nervous matter, or *ganglia*, constituting the brain and spinal cord, and containing invariably nerve-cells; (2) *peripheral* or *terminal* arrangements, existing in the organs of sense, in muscle, and in electric organs; and (3) *nerves*, or internuncial cords connecting the central with the peripheral organs. The nerves may be regarded as conductors of a mode of energy which, for want of a better term, is termed "nerve-force," originating either in the nerves themselves on the application of a stimulus or in the terminal organs or in the central organs. Thus, if a nerve be irritated at any point of its course, a change is set up in the nerve-fibers at the point of irritation, and this change is propagated along the nerve-fibers to a central or terminal organ, thus producing a characteristic phenomenon—it may be a sensation of pain or of pleasure, an involuntary movement, the contraction of a muscle, or a discharge of electricity. Again, the stimulus may act on a terminal organ, such as the retina, setting up a change which is then propagated or conveyed to the brain by the optic nerve, there giving rise to a sensation of light or color. Finally, the nervous action may originate in a central organ, as is the case when a voluntary movement is made. The voluntary impulse, in this instance, originates in the brain; a change passes along nerve-fibers from the brain to the muscles, and as a result the muscles contract.

*Part III. Physiology of Plants.*—The body of a plant, like that of an animal, consists of one or more structural units which are termed "cells," and in plants, as in animals, the cell consists essentially of an individualized mass of protoplasm.

The cell or cells constituting the body of a plant present, in most cases, the important peculiarity that the protoplasm is inclosed in a membrane termed the "cell-wall." This membrane does not consist of protoplasm, but of a substance, cellulose, belonging to the group of the carbohydrates. All cell-walls do not, however, consist exclusively of this substance, though this is probably always the case at their first formation; but the cell-wall may undergo considerable modification during the life of the cell. It may, for example, undergo lignification; it then comes to consist largely of a substance termed "lignin," which is much richer in carbon than is cellulose; this takes place typically in those cells which form woody or sclerenchymatous tissue. Or it may undergo cuticularization, when it comes to consist largely of a substance termed "suberin" or "cutin," which, like lignin, is richer in carbon than cellulose. Or, again, it may become gummy or mucilaginous. These chemical differences are accompanied by differences in the physical properties of the cell-wall. A cellulose cell-wall is extensible, capable of swelling from taking up water into itself by imbibition, and is readily traversed by water. A lignified or cuticularized cell-wall is more rigid and less capable of swelling by imbibition; moreover, a cuticularized cell-wall is almost impermeable to water. A gummy or mucilaginous cell-

wall is more extensible and more capable of swelling by imbibition.

The structure of the plant-cell is not the same at all periods of its life. When a cell is young the protoplasm occupies the whole of the cavity inclosed by the cell-wall. But in the course of growth the increase in bulk of the protoplasm is not nearly so great as the increase in surface of the cell-wall, so that in the mature cell the protoplasmic contents form merely a rather thin layer known as the *primordial utricle*, which lies in close contact with the internal surface of the cell-wall at all points. There thus comes to be a relatively large cavity in the cell, the *vacuole*, which is filled with a liquid, the *cell-sap*, consisting of water holding various substances, organic and inorganic, in solution. The structure of a mature living cell is then this: it consists of a cell-wall, lined with a layer of protoplasm, which incloses the vacuole, filled with cell-sap.

The protoplasm of plants is endowed with all those fundamental properties which are possessed by that of animals. When a plant is unicellular these properties are all exhibited, so far as they are necessary to the maintenance of the organism, by its protoplasm; in other words, all the necessary vital functions are performed by the protoplasm of the single cell of which the plant consists. The performance of all the necessary vital functions by the protoplasm of one cell obtains also in the case of not a few multicellular plants—in those, namely, in which all the cells are similar to each other in structure and contents. In the great majority of multicellular plants, however, the functions are distributed to a greater or less extent; there is more or less complete physiological division of labor. In these plants the cells are not all similar in appearance, and their diversity is to be ascribed to their adaptation in different ways to the performance of particular functions. Further, the cells which have undergone modifications in some particular direction for the performance of some particular function are grouped together in certain parts of the plant, and these parts are spoken of as "organs." Thus the roots of one of the higher plants are the organs for the absorption from the soil of water and substances in solution; the leaves are the organs for the absorption of gases from the air, and, in virtue of the green coloring-matter chlorophyll, which their cells contain, they are also the organs in which certain important constructive processes are carried on. But the extent to which physiological division of labor is carried out in plants is not nearly so considerable as it is in animals, and accordingly the protoplasm of the different cells of plants exhibits only in a very slight degree that specialization of structure which is so conspicuous in animals.

*Absorption of Water and Substances in Solution.*—The bodies of plants, unlike those of the great majority of animals, do not contain any internal cavity into which the food may be taken as a preliminary to its being absorbed by the tissues. The materials of the food of plants are therefore taken up directly from without into the cells of the absorbent organs. The cells which are especially concerned in absorption are, in the higher and subaërial plants, the *root-hairs*—thin-walled, unicellular, unbranched filaments which are developed from the epidermal cells some way behind the growing-point of the root; in the lower plants, and even in those of the higher plants which lie submerged, all the cells of the plant may take part in absorption. Since the food is directly absorbed by the cells, and since the cells all possess a cell-wall, the materials of the food must be taken up in solution. Salts and other substances are, as a matter of fact, taken up by the absorbent cells in the form of watery solutions. Sub-

stances which are soluble in water are dissolved in the water which is present in a greater or smaller proportion in all soils, and of those which are not soluble in water many are brought into solution by the acid sap which saturates the walls of the root-hairs. The actual process of absorption is an instance of diffusion through a membrane—that is, of osmosis. Only such substances can be absorbed by a root-hair, for instance, as are capable of diffusing not only through the cell-wall but also through the protoplasmic primordial utricle. Further, only such substances can be absorbed by the root-hair as are present in larger proportion in the water to be absorbed than they are in the cell-sap of the root-hair; this inequality between the proportion of any substance in solution in the liquid on the one side and in that of a membrane on the other is a necessary condition of osmosis. Hence, in order that the absorption of any particular substance by the root-hairs may be continuous, it is necessary that the substance in question should not accumulate in the cell-sap; this accumulation is prevented either by the actual consumption (*i.e.*, chemical decomposition) of the substance in the cell or by the withdrawal of it to supply the needs of adjacent cells. In fact, so far as the process of absorption is concerned, the cell-sap of the internal cells of the root stands in the same relation to the cell-sap of the root-hairs as the cell-sap of the root-hairs does to the external liquid; and, as this relation exists between the successive internal layers of cells, there is set up a current of absorbed substances which travels from the surface toward the center.

It appears from the foregoing considerations that the amount of any particular salt absorbed in a given time depends upon (1) its diffusibility and (2) its consumption in the plant. Of these two conditions the second is the one which is of real physiological importance, and, if only the given time is sufficiently long, the first condition may be neglected. For instance, let us suppose that a plant is absorbing by its roots two salts—the one (*A*) being very diffusible, the other (*B*) much less diffusible—and that, while the former undergoes no change in the plant after absorption, the latter is at once decomposed. Now, if the time of observation is short, it may happen that the amount absorbed of the salt *A* will be found to be greater than that of the salt *B*; but, if the time be extended, the amount absorbed of the salt *B* will certainly be found to be greater than that of the salt *A*. The explanation is that the salt *A* would at first be absorbed very rapidly, on account of its high diffusibility; but the absorption of it would gradually diminish, in consequence of the accumulation of it in the cell-sap of the plant, until it ceased altogether. The absorption of the salt *B*, on the other hand, if less active at first than that of *A*, would be continuous, and thus, over a relatively long period of time, the amount of it absorbed would come to be much greater than that of *A*.

As a matter of fact, it has been ascertained that when different salts or other substances are presented to the root of a plant they are absorbed in different quantities. And further, it has been ascertained that the different salts are absorbed in different proportions by the roots of different plants; it is, in fact, upon this that the necessity for the "rotation of crops" depends.

The gases principally absorbed by plants are oxygen and carbon dioxide. The former is absorbed by every living cell, and at all times; the latter is absorbed exclusively by cells which contain chlorophyll, and by them only when exposed to light. In the more highly organized plants the cells which contain chlorophyll are confined almost entirely to the leaves, so that the

leaves may be regarded as the organs by which these plants absorb carbon dioxide.

Besides oxygen and carbon dioxide other gases are also absorbed by plants, but to a small extent only. Nitrogen is absorbed in small quantities merely in virtue of its solubility and diffusibility; it is not in any way acted upon by the cells after its absorption. It appears that ammonia may be absorbed from the air in the form of gas by the leaves, and that, when thus absorbed, it contributes to the nutrition of the plant. Other gases, such as sulphur dioxide, sulphureted hydrogen, and hydrochloric acid, which are occasionally present in the air as impurities, are absorbed by the leaves, as is shown by the pernicious effects which they produce.

*Circulation.*—It is obviously necessary, in multicellular plants in which certain cells only are in a position to absorb food-materials from without, that these food-materials should be conveyed from the absorbent cells to the remainder of the plant. In no plant is there any organ comparable to the heart of animals by means of which a distribution throughout the tissues of absorbed food-materials is effected. The distribution is accomplished by purely physical means, principally by osmosis. When the cell-sap of a cell becomes charged, by absorption from without or from neighboring cells, with any substance, diffusion-currents are at once set up between this cell and any adjacent cells the cell-sap of which may contain the substance in question in smaller proportion, and these currents will persist until osmotic equilibrium, as far as this substance is concerned, is established. The diffusion-currents do not flow in any definite direction, but their course is determined simply by inequalities in the chemical composition of the cell-sap of the cells in different parts of the plant. Since in subaërial plants the roots are as a rule the only organs which absorb substances from the soil, and since the cell-sap of their cells is therefore relatively rich in absorbed food-materials, the general direction of the diffusion-currents is from the roots upward into the stem and leaves.

In cellular plants—that is, in plants which possess no vascular tissue—the distribution of absorbed food-materials is effected solely by osmosis. Many of these plants are small, so that the distribution is effected from cell to cell with sufficient rapidity by this means. Those of them that are large have a very considerable absorbent surface, many of them being aquatic in habit, so that the absorbed substances have no great distance to travel. In vascular plants, more particularly in those which are subaërial in habit, the distribution of the water, holding substances in solution, which is absorbed by the roots, is effected to a considerable extent by means of the vascular system. The forces by which the flow of liquid through the vascular tissue is maintained are the following:—The first is the *root-pressure*. It is a matter of common observation that, when the stems of vascular plants are cut across, particularly in the spring, an escape of water takes place from the surface of that portion of the stem which still remains connected with the root, an escape which may persist for some considerable time. It has been ascertained that this outflow of water takes place under considerable pressure; for instance, Hales observed, in the case of a vine, that the pressure was sufficiently great to support a column of mercury thirty-two and a half inches in height. But the root-pressure not only manifests itself by causing a flow of water from the cut surfaces of stems, it also causes in many plants the exudation of drops of water at the free surface. Drops may commonly be seen on the surface of certain fungi, which are exuded in consequence of the hydrostatic pressure set up in the plant by the active absorption effected by

the organs (rhizoids) which here perform the functions of roots. Again, drops are frequently to be found on the margins and at the apices of the leaves, especially the younger ones, of many plants, such as grasses, aroids, alchemillas, saxifrages, etc. That the formation of these drops depends upon the forcing of water upward through the vessels by the root-pressure is proved by the fact that, if the stem be cut off from the root and then placed with its cut end in water, no more drops will appear on the leaves. The water thus forced into the vascular system is not pure water, but a watery solution of various substances, principally salts absorbed by the roots. It is therefore obvious that the root-pressure assists in the distribution of these substances throughout the plant.

In order to understand how the root-pressure is set up it will be necessary to give a brief description of the general structure of the root. It consists of a central fibro-vascular cylinder which is surrounded by several layers of parenchymatous cells, the most external of these layers being in contact with the epidermal layer, certain cells of which are developed into root-hairs. Water is absorbed by the root-hairs and passes from them by osmosis into the subjacent parenchymatous cells. It is obvious, however, that osmosis cannot take place between the cells of the innermost layer and the vessels, for the conditions of osmosis are not fulfilled, inasmuch as the vessels at first contain no liquid. The passage of water from the cells into the vessels can only take place by filtration. For this a certain pressure is necessary, and this pressure is set up by the absorbent activity of the root-hairs and of the parenchymatous cells. The system of cells absorbs large quantities of water, more indeed than the cells can contain, so that at length the resistance of the cell-walls is overcome at what is presumably the weakest point, and water filters into the cavities of the vessels of the wood. There it collects, and it may, under certain circumstances, fill the whole vascular system; then, since absorption is still going on at the surface of the roots, sufficient pressure is set up to cause that exudation of drops on the leaves to which allusion has been made, and, if the stem be cut across, to cause "bleeding" at the cut surface. From the foregoing account it is apparent that the root-pressure is the expression of the absorbent activity of the root-hairs.

But the vessels of the wood do not always contain water. Hales observed that, whereas a vine will bleed freely if its stem be cut across in the month of April, no bleeding is observed if it be cut in July. And yet it cannot be doubted that the plant is absorbing water by its roots more actively in July than in April. The explanation of these facts is that, although in July the plant is absorbing water actively by its roots, yet it is losing so much in the form of vapor from its leaves that water does not accumulate in the cavities of the vessels. This loss of water in the form of vapor from the general surface of the plant exposed to the air is termed "transpiration." The parts of the plant which are more especially concerned in transpiration are the leaves. By their structure they are peculiarly adapted for this purpose. The tissue of a leaf is penetrated in all directions by intercellular spaces, which communicate directly with the external air by means of the stomata in the epidermis. In this way a very large surface of moist and thin cell-wall is brought into contact with the air, a condition most favorable to evaporation.

The activity of transpiration is very much affected by external conditions—the moister the air, the smaller will be the transpiration; and conversely, the drier the air and the higher the temperature, the greater will be the amount of water transpired. Light, too, has a remark-

able influence: it has been ascertained by a great number of observers that transpiration is more active in light than in darkness. It seems probable that this is to be attributed largely to the influence of light upon the stomata. Each stoma is usually bounded by two cells, termed "guard-cells," which are capable of so altering their form as to close or to open the aperture between them. The form of the guard-cells is dependent upon the amount of water which they contain. When they hold comparatively little water, and are flaccid, their adjacent free surfaces are straight and in contact with each other; the stoma is then closed. When, however, they contain so much water that their cell-walls are under considerable pressure from within—in a word, when the guard-cells are turgid—they curve so that their adjacent free surfaces are no longer in contact, but a space is left between them; the stoma is then open. It appears that the guard-cells become turgid under the influence of light; and it is probably to this open condition of the stomata that the greater transpiration of leaves when exposed to light is to be ascribed.

It is obvious that the effect of transpiration upon the distribution of water through the plant is very great. It sets up a rapid current, known as the "transpiration-current," which travels from the roots upward toward the leaves.

It has been conclusively proved that the channel along which the transpiration-current travels is the fibro-vascular tissue, and that it is the xylem or woody portion of a fibro-vascular bundle which is the conducting tissue. In the case of plants like conifers and dicotyledons, in which there is a formation of secondary xylem or wood from a cambium-layer, it is the younger wood, the alburnum, along which the transpiration-current passes. The older wood, the duramen, it is true, usually contains water, but it does not serve as a conducting channel, only as a reservoir.

*Distribution of Organic Nutrient Substances.*—In vascular plants the distribution of the organic nutrient substances is, like the conduction of substances absorbed by the roots, assisted by the vascular tissue; but, whereas it is the wood which is the conducting tissue in the latter case, in the former it is the bast or phloem, and more especially the bast-vessels or sieve-tubes. These vessels consist of elongated cells placed end to end, the septa between the adjacent cells being perforated so as to admit of a direct continuity between their protoplasmic contents.

The importance of the wood and of the bast respectively as conducting tissues is well illustrated by the "ringing" experiments which have been repeatedly made on plants, such as dicotyledons and conifers, which have the fibro-vascular bundles arranged in a ring in the stem. When a ring of tissue, extending inward as far as the cambium-layer, is removed from the stem of a dicotyledonous plant the following facts are to be observed: (1) that the leaves which are borne on branches arising from the stem above the level at which the ring of tissue has been removed will not exhibit any signs of withering; (2) that the part of the stem below the incision will not increase in thickness to nearly the same extent as the part above the incision. From these facts it is clear (1) that the operation in question has not materially affected the conduction of water and food-materials in solution upward to the leaves, and, since the wood is the only unimpaired tissue, it is obviously in the wood that the upward current travels; and (2) that the operation has materially affected the conduction of organic nutrient substances to the parts below the incision, the diminished growth of these parts being the result of inadequate nutrition; this effect of

the operation is to be ascribed, principally at least, to the destruction of the continuity of the bast-tissue.

In various families of vascular plants, and in some cellular plants also (certain fungi), there are to be found cells, forming what is known as "laticiferous tissue," which probably assist in distributing both food-materials and organic nutrient substances throughout the plant. In some plants the cells are quite distinct from each other, and extend from one end of the plant to the other, growing with its growth, so that they attain a very considerable size, and are much branched; these are spoken of as "laticiferous cells." In other plants the cells are comparatively small, and fuse together to form an intricate network; these are spoken of as "laticiferous vessels." The cells of the laticiferous tissue contain a milky liquid, termed "latex," which consists of water holding inorganic salts, sugar, gum, extractives and proteids, in solution, and holding in suspense resinous and fatty bodies. The cells contain protoplasm in addition, and not uncommonly starch-granules.

*Food of Plants.*—A rough idea of the nature of its food can be obtained by analyzing a plant. It is found that, in the process of incineration, a considerable weight of its dry solid is burned up and given off in the form of gas; this represents the combustible or organic portion of the plant. The incombustible residue, the ash, is found to be of a mineral or inorganic nature. The gases given off are carbon dioxide, watery vapor, and nitrogen, showing that the combustible portion of the plant contained the elements carbon, hydrogen, and nitrogen. In the ash occur a number of elements, of which the principal are sulphur, phosphorus, potassium, calcium, magnesium, iron, sodium, chlorine, and silicon. But it does not necessarily follow that, because any given chemical element can be detected in a plant, that element is to be regarded as part of the food of the plant, for, as has been already pointed out, plants may absorb substances which in no way contribute to their nutrition, or which are even injurious. When an element enters into the chemical composition of the substances of which the organized structure of the plant consists, then it is clear that this element must form part of the food; but, when an element does not thus contribute to the building up of the organized substance of the plant, its admission to the rank of a food-material must be the subject of direct experiment. It has been ascertained that many elements, though, so far as is known, they are not essential constituents of the organized structure of the plant, are nevertheless essential to the maintenance of its life; they may not, indeed, go to build up the plant-substance, but in some way or other they promote the metabolic processes.

The method which has afforded the most valuable results bearing upon the relative physiological importance of various food-materials is that which is known as "water-culture." It consists in growing plants with their roots immersed in water holding certain salts in known quantities in solution. The mixture of salts can, of course, be varied at pleasure, and the effect upon the plant of the absence of certain elements, as of their presence in smaller or larger quantities, can be observed. Further, by an analysis of that portion of the solution which remains unabsorbed at the close of the experiment, the proportion in which the various salts have been absorbed can be ascertained.

The elements of the food of plants may be conveniently classified into two groups, the first consisting of those which enter into the composition of organized plant-substance, the second consisting of those which, without actually entering into the structure of the plant, are essential to the proper performance of the

metabolic processes. To the first group belong the elements C, H, O, N, S, P; to the second, K, Ca, Mg, Fe, Cl (?).

PIACENZA, a city of Italy, a bishop's see, and the chief town of a province, lies on the Lombard plain, 217 feet above sea-level, not far from the right bank of the Po, just below the confluence of the Trebbia. By rail it is forty-three miles southeast of Milan and thirty-five and a half northwest of Parma. Formerly a place of considerable strength, it is still surrounded by walls with bastions and fosse in a circuit of four miles. The population of the commune (which in this case is almost exactly identical with the city) was 34,985 in 1871 and 34,987 in 1881.

PIANOFORTE. The group of keyed stringed instruments, among which the pianoforte is latest in order of time, has been invented and step by step developed with the modern art of music, which is based upon the simultaneous employment of different musical sounds. In the tenth century the "organum" arose, an elementary system of accompaniment to the voice, consisting of fourths and octaves below the melody and moving with it; and the organ, the earliest keyed instrument, was, in the first instance, the rude embodiment of this idea and convenient means for its expression. There was as yet no keyboard of balanced key levers; batons were drawn out like modern draw-stops, to admit the compressed air necessary to make the pipes sound. About the same time arose a large stringed instrument, the organistrum, the parent of the now vulgar hurdy-gurdy; as the organ needed a blower as well as an organist, so the player of the organistrum required a handle-turner, by whose aid the three strings of the instrument were made to sound simultaneously upon a wheel, and, according to the well-known sculptured relief of St. George de Boscherville, one string was manipulated by means of a row of stoppers or tangents pressed inward to produce the notes. The other strings were drones, analogous to the drones of the bagpipes, and differing in effect from the changing "organum" of the organ. In the eleventh century, the epoch of Guido d'Arezzo, to whom the beginning of musical notation is attributed, the Pythagorean monochord, with its shifting bridge, was used in the singing-schools to teach the intervals of the plain-song of the church. Jean de Muris (*Musica Speculativa*, 1323) teaches how true relations may be found by a single-string monochord, but recommends a four-stringed one, properly a tetrachord, to gain a knowledge of unfamiliar intervals. He describes the musical instruments known in his time, but does not mention the clavichord or monochord with keys, which could not have been then invented.

A keyboard of balanced keys may have been first introduced in the little portable organ known as the regal so often represented in old carvings, paintings, and stained windows. It derived its name regal from the rule (*regula*) or graduated scale of its keys, and its use was to give the singers in religious processions the note or pitch.

The earliest known record of the clavichord occurs in some rules of the minnesingers, dated 1404, preserved at Vienna.

The next instrument described by Viridung is the virginal (*virginalis*, proper for a girl), a parallelogram in shape, with a projecting keyboard and compass of keys the same as the clavichordium.

There would be no difference between the clavicimbalum and the virginal were it not for a peculiarity of keyboard compass, which emphatically refers itself to the Italian "spinetta," a name unnoticed by Viridung or by his countryman Arnold Schlick, who, in the same year, 1511, published his *Spiegel der Orgelmacher* ("Organ-

PIANOS.

Spinetta Tavola (Virginal). 1568; collection of M. Terme

builders' Mirror"), and named the clavichordium and clavicimbalum as familiar instruments. After this date there are frequent references to spinets in public records and other documents, and we have fortunately the instruments themselves to put in evidence, preserved in public museums and in private collections. The oldest spinet we can point out is in the Conservatoire, Paris. It is a pentagonal instrument made by Francesco di Portalupis at Verona, 1523.

Mersenne gives three sizes for spinets—one two and a half feet wide, tuned to the octave of the "ton de chapelle" (in his day a half tone above the present English medium pitch), one of three and a half feet, tuned to the fourth below, and one of five feet, tuned to the octave below the first—the last being, therefore, tuned in unison to the chapel pitch. He says his own spinet was one of the smallest it was customary to make, but from the lettering of the keys in his drawing it would have been of the second size, or the spinet tuned to the fourth.

Thomas Hitchcock (for whom we have a date 1703 upon a spinet jack in an instrument of older model with two cut sharps by Edward Blunt) and his son John made a great advance in constructing spinets, giving them the wide compass of five octaves, from G to G, with very fine keyboards in which the sharps were inlaid with a slip of the ivory or ebony, as the case might be, of the naturals. Their instruments, always numbered, and not dated as has been sometimes supposed, became models for the contemporary and subsequent English makers.

We have now to ask what was the difference between Scaliger's harpichordum and his clavicymbal. Galilei, the father of the astronomer of that name (*Dialogo della Musica Antica e Moderna*, Florence, 1581), says that the harpichord was so named from having resembled an "arpa giacente," a prostrate or "couched" harp,—proving that the clavicymbal was at first the trapeze-shaped spinet; and we should therefore differentiate harpichord and clavicymbal as, in form, suggested by or derived from the harp and psaltery, or from a "testa di porco" and an ordinary trapeze psaltery. We are inclined to prefer the latter. The Latin name "clavicymbalum," having early been replaced by spinet and virginal, was in Italy and France bestowed upon the long harpichord, and was continued as clavicembalo (gravecembalo, or familiarly cembalo only) clavecin. Much later, after the restoration of the Stuarts, the first name was accepted and naturalized in England as harpsichord, which we will define as the long quill instrument shaped like a modern grand piano, and resembling a wing, from which it has gained the German appellation "Flügel."

Double keyboards and stops in the long cembalo or harpsichord came into use in the Netherlands early in the sixteenth century. We find them imported into England.

After the Antwerp make declined, London became preëminent for harpsichords—the representative makers being Jacob Kirckmann and Burckhard Tschudi, pupils of a Flemish master, one Tabel, who had settled in London, and whose business Kirckmann continued through marriage with Tabel's widow. The first idea of pedals for the harpsichord to act as stops appears to have been John Hayward's (?Haward) as early as 1676, as we learn from Mace's *Musick's Monument*. The French makers preferred a kind of knee-pedal arrangement known as the "genouillère," and sometimes a more complete muting by one long strip of buff leather, the "sourdine." As an improvement upon Plenius' clumsy swell, Shudi in 1769 patented the Venetian swell, a framing of louvres, like a Venetian blind, which

opened by the movement of the pedal, and, becoming in England a favorite addition to harpsichords, was early transferred to the organ, in which it replaced the rude "nag's-head" swell. A French harpsichord-maker, Marius, whose name is remembered from a futile attempt to design a pianoforte action, invented a folding harpsichord, the "clavecin brisé," by which the instrument could be disposed of in a smaller space. One, which is preserved at Berlin, probably formed part of the camp baggage of Frederick the Great.

It was formerly a custom with kings, princes, and nobles who were well-disposed toward music to keep large collections of musical instruments—not, as now, for beauty of decoration, form, and color, or historical associations, but for actual playing purposes in the domestic and festive music of their courts. There are records of their inventories, and it was to keep such a collection in playing order that Prince Ferdinand dei Medici engaged a Paduan harpsichord-maker, Bartolommeo Cristofori, the man of genius who invented and produced the pianoforte. We fortunately possess the record of this invention in a literary form from a well-known writer, the Marchese Scipione Maffei; his description appeared in the *Giornale dei letterati d'Italia*, a publication conducted by Apostolo Zeno. The date of Maffei's paper was 1711. Rimbault reproduced it, with a technically imperfect translation, in his *History of the Pianoforte*. We learn from it that in 1709 Cristofori had completed four "gravecembali col piano e forte"—keyed-psalteries with soft and loud—three of them being of the long or usual harpsichord form. A synonym in Italian for the original cembalo (or psaltery) is "salterio," and if it were struck with hammers it became a "salterio tedesco" (the German *hackbrett*, or chopping board), the latter being the common dulcimer. Now the first notion of a pianoforte is a dulcimer with keys, and we may perhaps not be wrong in supposing that there had been many attempts and failures to put a keyboard to a dulcimer or hammers to a harpsichord before Cristofori successfully solved the problem. There are two pianofortes by Cristofori in Florence, dated respectively 1720 and 1726, which show a much improved, we may even say a perfected, construction, for the whole of an essential piano movement is there. The earlier instrument has undergone some restoration, but the 1726 one, which is in the Kraus Museum, retains the original leather hammerheads. To Cristofori we are indebted not only for the power of playing *piano* and *forte*, but for the infinite variations of tone, or *nuances*, which render the instrument so delightful.

Cristofori died in 1731. He had pupils, but did not found a school of Italian pianoforte-making, perhaps from the peculiar Italian conservatism in musical instruments we have already remarked upon.

It has been repeatedly stated in Germany that Frederici of Gera, in Saxony, an organ-builder and musical-instrument maker, invented the square or table-shaped piano, the "forte bien" as he is said to have called it, about 1758-60. No square piano by this maker is forthcoming, but M. Victor Mahillon of Brussels has acquired a Frederici "upright grand" piano, dated 1745. In Frederici's upright grand action we have not to do with the ideas of either Cristofori or Schroeter; the movement is practically identical with the hammer action of a German clock.

Another piano action had, however, come into use about that time, or even earlier, in Germany. The discovery of it in the simplest form is to be attributed to M. Mahillon, who has found it in a square piano belonging to M. Henri Gosselin, painter, of Brussels. The principle of this action is that which was later perfected by the addition of a good escapement by Stein of

Augsburg, and was again later experimented upon by Sebastian Erard. Its origin is perhaps due to the contrivance of a piano action that should suit the shallow clavichord and permit of its transformation into a square piano; a transformation, Schroeter tells us, had been going on when he wrote his complaint. It will be observed that the hammer is, compared with other actions, reversed, and the axis rises with the key, necessitating a fixed means for raising the hammer, in this action effected by a rail against which the hammer is jerked up. It was Stein's merit to graft the hopper principle upon this simple action; and Mozart's approbation of the invention, when he met with it at Augsburg in 1777, is expressed in a well-known letter addressed to his mother. No more "blocking" of the hammer, destroying all vibration, was henceforth to vex his mind. He had found the instrument that for the rest of his short life replaced the harpsichord. M. Mahillon has secured for his museum the only Johann Andreas Stein piano which is known to remain. It is from Augsburg, dated 1780, and has Stein's escapement action, two unisons, and the knee-pedal, then and later common in Germany.

The first square piano made in France is said to have been constructed in 1776 by Sebastian Erard, a young Alsatian. In 1786 he went to England, and founded the London manufactory of harps and pianofortes bearing his name. He did not, however, succeed in producing his famous repetition, or double escapement action, until 1821; it was then patented by his nephew, Pierre Erard, who, when the patent expired in England in 1835, proved a loss from the difficulties of carrying out the invention, which induced the House of Lords to grant an extension of the patent.

Although some great pianists have been opposed to double escapement, notably Kalkbrenner, Chopin, and Dr. Hans von Bülow, Erard's action, in its complete or a shortened form as introduced by Herz, is now more extensively used than at any former period. Erard invented, in 1808, an upward bearing to the wrest-plank bridge, by means of agraffes or studs of metal through holes in which the strings are made to pass, bearing against the upper side. The wooden bridge with down-bearing strings is clearly not in relation with upward-striking hammers, the tendency of which must be to raise the strings from the bridge, to the detriment of the tone. A long brass bridge on this principle was introduced by William Stodart in 1822. A pressure-bar bearing of later introduction is claimed for the French maker, M. Bord, and is very frequently employed, by German makers especially. The first to see the importance of iron sharing with wood (ultimately almost supplanting it) in pianoforte framing was a native of England, and a civil engineer by profession, John Isaac Hawkins, who has been best known as the inventor of the ever-pointed pencil. He was living at Philadelphia, Penn., when he invented and first produced the familiar cottage pianoforte—"portable grand," as he then called it. He patented it in America, his father, Isaac Hawkins, taking out the patent for him in England in the same year, 1800.

The next important addition to the grand piano in order of time was the harmonic bar of Pierre Erard, introduced in 1838.

The introduction of iron into pianoforte structure has been differently and independently effected in America, the fundamental idea here being a single casting for the metal plate and bars, instead of forging or casting them in separate pieces. Alphæus Babcock was the pioneer to this kind of metal construction. He also was bitten with the compensation notion, and had cast an iron ring for a square piano in 1825, which is

not said to have succeeded, but gave the clew to a single casting resistance framing, which was successfully accomplished by Conrad Meyer, in Philadelphia, in 1833, in a square piano which still exists, and was shown in the Paris Exhibition of 1878. Meyer's idea was taken up and improved upon by Jonas Chickering of Boston, who applied it to the grand piano as well as to the square, and brought the principle up to a high degree of perfection—establishing by it the independent construction of the American pianoforte.

The chief centers of the pianoforte trade are London, Paris, Berlin, Leipsic, Dresden, Stuttgart, Hamburg, Vienna, St. Petersburg, Brussels, New York, Boston, Chicago, and Baltimore. The greatest centralizations are found in London and Paris—very few pianofortes being made in the United Kingdom or France, excepting perhaps at Marseilles, out of those cities. But in Germany and the United States there are pianoforte-makers in many towns besides those we have named. Pianofortes are made in Italy at Turin, Milan, Florence, Naples, and Palermo, and in Spain at Barcelona (principally), Madrid, and Saragossa. The large export trade belonged formerly to England and France, but it has been weakened of late years by the commercial activity of the Germans, who have besides copied successfully and with the advantage of much lower wages recent American models. German pianofortes are now much found in Great Britain, where free trade has favored their introduction, and in the Australian colonies; they have also outrivalled the French in Holland; but we believe France still keeps the trade of Southern Europe, as the United States mainly supply Canada. English exports of good makers will be found all over the world; but some important markets have been lost through the inferior instruments consigned or sold because they were cheap, and were supposed to be good enough.

The United States and Germany appear to employ the greatest number of workmen in the pianoforte handicraft, Germany producing the largest numbers of instruments. In adopting, however, the statistics given, we must not forget to take into account that custom of advertising which leavens nearly every statement. There are said to be upward of 8,000 workmen employed in piano-making in America. The Messrs. Steinway claim for America an annual production of 25,000 pianofortes of all kinds, and it may be more. We hardly feel disposed to allow Germany 73,000, with a less number of workmen, viz., 7,834; but such is the statement put forward by a semi-official source, the *Deutsche Consulats-Zeitung*. It must be borne in mind that machinery adds its power indefinitely to the number of men employed, but this occurs more in America than in Germany. A recent strike in Paris represented the pianoforte trade society as consisting of 5,000 members; and we may safely credit that city with a production of 20,000 instruments yearly. The number made in London annually may be taken as reaching at least 35,000; it is probably larger.

PIARISTS, the popular name of the "clerici regulares scholarum *piarum*," the Pauline Congregation of the Mother of God, which was founded by Joseph Calasanza (Josephus a Matre Dei) at Rome in the beginning of the seventeenth century. Calasanza, a native of Calasanz, in the province of Huesca, in Aragon, was born on September 11, 1556; studied at Lerida and Alcala, and after his ordination to the priesthood removed to Rome. Here he became zealously interested in the education of poor and orphan children, and with this end he organized, in 1607, a brotherhood which ultimately, in 1617, became an independent congregation, numbering at that time fifteen priests, under Cal-

asanza as their head. To the three usual vows they added a fourth, that of devotion to the gratuitous instruction of youth. Calasanza, who died on August 22, 1648, was beatified in 1748, and canonized in 1767.

PIATRA, a town of Roumania (Moldavia), at the head of the department of Neamtsu, on the left bank of the Bistritza, an affluent of the Sereth. It is about forty-five miles by road from Roman, a station on the railway from Galatz. Population, 13,890.

PIAZZA ARMERINA (Sicilian, *Chiazza*), a city of Italy, in the province of Caltanissetta, Sicily, on a hill thirty-nine miles by road east-southeast of the city of that name, and thirty miles north of Terranova on the coast. Population, 17,038.

PIAZZI, GIUSEPPE. See ASTRONOMY.

PICARDY, one of the old feudal provinces of France, was bounded north by Hainault, Artois, and the English Channel, east by Champagne, south by Île-de-France, and west by Normandy and the Channel. Northern Picardy (subdivided into Upper and Lower Picardy) was formed into one of the great military governorships of the kingdom, while Southern Picardy was included in the governorship of Île-de-France. The territory is now divided among the departments of Pas-de-Calais, Somme, Aisne, Oise, and Nord.

PICCINI, or PICCINNI, NICCOLA, musical composer, was born at Bari in 1728, and educated, under Leo and Durante, at the Conservatorio di San Onofrio in Naples. His first opera, *Le Donne Dispettose*, produced in 1754, won him a high reputation, which he maintained creditably until 1760, when he composed, at Rome, the *chef d'œuvre* of his early life, *La Cecchina, ossia la Buona Figliuola*, an *opera buffa*, which attained a European success, little less remarkable than that of Pergolesi's *Serva Padrona*. Six years after this Piccini was invited to Paris. All his next works were successful; but, unhappily, the directors of the Grand Opéra conceived the mad idea of deliberately opposing him to Gluck, by persuading the two composers to treat the same subject—*Iphigénie en Tauride*—simultaneously. Gluck's masterly *Iphigénie* was first produced on May 18, 1779. Piccini's *Iphigénie* followed on January 23, 1781, and, though performed seventeen times, was afterward consigned to oblivion. He died at Passy, May 7, 1800.

PICENUM. See ITALY.

PICHEGRU, CHARLES, the conqueror of Holland, was born at Arbois, in the Jura, on February 16, 1761. In 1783 he entered the first regiment of artillery, where he rapidly rose to the rank of adjutant-sub-lieutenant. In 1793, when Dumouriez had deserted, and all generals of noble birth had been superseded, Carnot and Saint Just were sent to find *roturier* generals who could be successful; Carnot discovered Jourdan, and Saint Just discovered Hoche and Pichegru. In December, 1793, he superseded Hoche, became commander-in-chief of the united armies of the Rhine and Moselle, whence he was summoned to succeed Jourdan in the army of the North in February, 1794. It was now that he fought his three great campaigns of one year. The English and Austrians held a strong position along the Sambre to the sea. After vainly attempting to break the Austrian center, Pichegru suddenly turned their left, and defeated Clerfayt at Cassel, Menin, and Courtrai, again at Rouselaer and Hooglede.

Pichegru began his second campaign by crossing the Meuse on October 18th, and, after taking Nimeguen, drove the Austrians beyond the Rhine. On December 28th he crossed the Meuse on the ice, and stormed the island of Bommel, then crossed the Waal in the same manner, and, driving the English before him, entered Utrecht on January 19th, and Amsterdam on January 20th, and soon occupied the whole of Holland. Hon-

ored by the Republicans, and with the greatest military reputation in France, Pichegru then took command of the armies of the North, the Sambre and Meuse, and the Rhine, and crossing the Rhine in force took Mannheim in May, 1795. When his fame was thus at its height he became a traitor, and for the promise of a marshal's baton, the governorship of Alsace, the castle of Chambord, 1,000,000 francs in cash, and 200,000 francs a year, sold his army and his country. He allowed Jourdan to be beaten before Mannheim, and betrayed all his plans to the enemy. His intrigues were suspected, and when he offered his resignation to the Directory in October, 1795, it was to his surprise promptly accepted. He went to Paris in August, 1803, with Georges Cadoudal to head a royalist rising against Napoleon; but, betrayed by a friend, he was arrested on February 28, 1804, and on April 15th was found strangled in prison.

PICKLES. The term pickle was originally applied to herrings preserved in salt brine, and by a pickle is still meant any preservative solution for either animal or vegetable food, that for flesh and fish being a brine of common salt, usually with saltpeter, sugar, and certain spices added, while for vegetable substances vinegar is the principal pickling medium.

PICO, GIOVANNI, OF MIRANDOLA, was born in 1463, the youngest son of Giovanni Francesco Pico, prince of Mirandola, a small territory about thirty Italian miles west of Ferrara, afterward absorbed in the duchy of Modena. The family was illustrious and wealthy, and claimed descent from Constantine. Like most men with brilliant faculties of acquisition and assimilation, Pico was constitutionally an eclectic; and he owes his place in the history of learning and thought to the indefatigable spirit of inquiry which left him dissatisfied with current teaching and drove him to studies then new and strange. His learned wanderings ended at Rome, where he set forth for public disputation a list of 900 questions and conclusions in all branches of philosophy and theology. The pope prohibited the little book in which they were contained, and Pico had to defend the impugned theses in an elaborate *Apologia*. His personal orthodoxy was, however, finally vindicated by a brief of Alexander VI., dated June 18, 1493. He died at Florence in 1494.

PICTOR, FABIVS. See FABIVS PICTOR; also LIVY.

PICTS. See SCOTLAND.

PIEDMONT, a region of northern Italy, bounded north by Switzerland, west by France, south by Liguria, and east by Lombardy. Physically it may be briefly described as the upper gathering-ground and valley of the river Po, inclosed on all sides except toward the Lombard plain by the vast semicircle of the Pennine, Graian, Cottian, Maritime, and Ligurian Alps. In 1859 it was divided into the four provinces of Alessandria, Cuneo, Novara, and Torino (Turin), which still remain as provinces of the kingdom of Italy. In 1889 its population was 3,297,157.

The name of Lombardy was used as inclusive of the upper valley of the Po as late as 1091, when the house of Savoy lost most of its Italian possessions by the death of Adelaide; but in the time of Thomas I. (1177-1233), duke of Savoy, while the name Savoy was applied more especially to the ducal territory on the French side of the Alps, that of Piedmont came into use as a collective term for the territory on the Italian side.

PIERCE, FRANKLIN, fourteenth president of the United States, was descended from an old yeoman family of New England, and was born at Hillsboro, N. H., November 23, 1804. His father, Benjamin Pierce, served through the Revolutionary war, after

ward attaining the rank of major-general, and became governor of his State. The son entered Bowdoin College, Brunswick, Me., in 1820. After leaving college in 1824 he studied law and came to the bar in 1827. From the first he was a zealous supporter of the Democratic party, and he took an active part in promoting the election of Andrew Jackson to the presidency. In 1829 he was elected by his native town to the State legislature, of which he was speaker in 1832-33. In the latter year he was chosen a member of Congress, and in 1837 he was elected to the senate of the United States. In 1842 he resigned his seat in the senate, and returned to the practice of the law. His reputation at the bar was very high, his success being largely due to his power of identifying himself with his client's cause, and his strong personal influence over a jury. In 1846 he was offered the position of attorney-general of the United States, but declined it. On the outbreak of the Mexican War he joined as a volunteer one of the companies raised in Concord. He was soon after appointed colonel of the ninth regiment, and in March, 1847, brigadier-general. At the battle of Contreras on August 19th he was severely injured by the fall of his horse. At the close of the war in December, 1847, he resigned his commission. In 1850 he was president of the convention for revising the constitution of New Hampshire. In 1852, as candidate of the Democratic party, he was elected president of the United States by 254 electoral votes against 42 given to Gen. Winfield Scott. The special feature of his inaugural address was the support of slavery in the United States, and the announcement of his determination that the Fugitive Slave Act should be strictly enforced. This was the keynote of his administration, and pregnant with vital consequences to the country. From it came during his term the Ostend conference and "manifesto," the repeal of the Missouri compromise, and the troubles in Kansas and Nebraska, which crystallized the opposing forces into the Republican party, and led later to the great rebellion. President Pierce, surrounded by an able cabinet, among them Jefferson Davis as Secretary of War, firmly adhered throughout his administration to the pro-slavery party. He failed, notwithstanding, to obtain renomination, but was succeeded by James Buchanan, March 4, 1857, and retired to his home in Concord, N. H., after spending some years in Europe. During the war of 1861-65 his sympathies were wholly with the South, but, with the exception of delivering a strong speech at Concord in 1863, he took no very active part in politics. He died October 8, 1869.

PIERO (or PIETRO) DE' FRANCESCHI, a leading painter of the Umbrian school, was born in 1415. The earliest trace that we find of Piero as a painter is in 1439, when he was an apprentice of Domenico Veneziano. In 1451 he was by himself, painting in Rimini, where a fresco still remains. His most extensive extant series of frescoes is in the choir of S. Francesco in Arezzo—the *History of the Cross*, beginning with legendary subjects of the death and burial of Adam, and going on to the entry of Heraclius into Jerusalem after the overthrow of Chosroes. This series is, in relation to its period, remarkable for effect, movement, and mastery of the nude. He died in October, 1492.

PIERRÉ, the capital of South Dakota and the county seat of Hughes county, is situated on the Missouri, at the mouth of the Bad river. Originally there was an Indian post here but the town was settled several years ago and after a stubborn contest Pierre was designated as the permanent capital of the new State of South Dakota. Buildings for the accommodation of the legislature and State officers are being erected and Pierre is rapidly extending. Population, 3,660.

PIETISM. Pietism is the name of an exceedingly influential, instructive, and interesting movement in the Lutheran church which arose toward the end of the seventeenth and continued during the first half of the following century. The direct originator of the movement was Philip Jacob Spener by religious meetings at his house (*Collegia pietatis*). These meetings were largely attended, produced a great sensation, and were soon imitated elsewhere. They gave rise to the name "Pietists."

PIETRO. See PIERO.

PIG. See SWINE.

PIGALLE, JEAN BAPTISTE, French sculptor, was born at Paris on January 26, 1714. Although he failed to obtain the Great Prize, after a severe struggle he entered the Academy and became one of the most popular sculptors of his day. He died on August 21, 1785.

PIGAULT-LEBRUN, CHARLES ANTOINE GUILLAUME, sometimes called PIGAULT DE L'ÉPINOY, the chief fiction writer of the first empire, and the most popular light novelist of France before Paul de Kock, was born at Calais on April 8, 1753. His youth was decidedly stormy. He twice carried off young ladies of some position, and was in consequence twice imprisoned by *lettre de cachet*. His first love, a Miss Crawford, the daughter of an English merchant whose office Pigault had entered, died almost immediately after her elopement; the second, Mademoiselle de Salens, he married. Although he had tried dramatic writing, he does not seem to have attempted prose fiction till he was forty, but from that time he was a fertile writer of novels for nearly thirty years. In his old age he took to graver work, and executed an abridgment of French history in eight volumes, besides some other work. His *Œuvres Complètes* were published in twenty volumes between 1822 and 1824. He died on July 24, 1835.

PIGEON (see also POULTRY). The word Pigeon, doubtless of Norman introduction as a polite term, seems to bear much the same relation to dove, the word of Anglo-Saxon origin, that mutton has to sheep, beef to ox, veal to calf, and pork to bacon. Perhaps the best-known species to which the name is exclusively given in common speech is the Wild Pigeon or Passenger-Pigeon of North America, *Ectopistes migratorius*, which is still plentiful in many parts of Canada and the United States, though no longer appearing in the countless numbers that it did of old. The rapid and sustained flight of these Pigeons is also as well-established as their former overwhelming abundance. The Passenger Pigeon is about the size of a common turtle-dove, but with a long, wedge-shaped tail. The male is a dark slate-color above, and purplish-bay beneath, the sides of the neck being enlivened by gleaming violet, green, and gold. The female is drab-colored above and dull white beneath, with only a slight trace of the brilliant neck-markings.

Among the multitudinous forms of Pigeons is the Wonga-wonga or White-fleshed Pigeon of Australia, *Leucosarcia picta*, a bird larger than the ring-dove, of a slaty-blue color above and white beneath, streaked on the flanks with black. It is said to be excellent for the table. As regards flavor, however, those who have been so fortunate as to eat them declare that the Fruit-Pigeons of the genus *Treron* (or *Vinago* of some authors) and its allies surpass all birds. These inhabit tropical Africa, India, and especially the Malay Archipelago. Hardly less esteemed are the Pigeons of the genus *Ptilopus* and its kindred forms, which have their headquarters in the Pacific Islands, though some occur far to the westward, and also in Australia. Among them are found the most exquisitely-colored of the

whole family. There may be mentioned the strange Nicobar Pigeon, *Calanas*, an inhabitant of the Indian Archipelago, about half a dozen species of the genus *Goura* and known as Crowned-Pigeons, which belong to New Guinea and the neighboring islands.

At least 500 species of Pigeons have been described, and many methods of arranging them suggested; but a new monograph of the Pigeons, containing all the recent discoveries, is much wanted.

PIGMENTS are colored powders which, when mixed with oil, water, or other fluids, in which they are insoluble, form paints. They are distinguished from dyes and washes by their entire insolubility in the media in which they are mixed, whereas dyestuffs are tinctorial substances applied in solution. Insoluble colors, when used in printing textile fabrics, are distinguished as pigment colors. The sources of materials available as pigments are numerous; many are native colored earths, others are separated from native metallic compounds and other mineral substances; a large number are artificially prepared from inorganic—principally metallic—sources; an important class consist of animal and vegetable coloring principles, forming with earthy bodies insoluble powders called lakes; and the dyestuffs artificially obtained from organic sources are also similarly utilized. But there are many qualities practically essential in a pigment which limit the range of available substances. A consideration of the first importance is the "body" or covering power of a pigment—that is, the property of fully covering and concealing with an opaque coating the surface over which it is spread. It is also important that the material should work well in, and be unaffected in appearance and constitution by the medium with which it is made into a paint, and that it should spread in an even, uniform coat, which should dry well and quickly in the air and adhere firmly to the surface to which it is applied. When dry it should possess durability and resist change under the action of weather and other influences to which paint is exposed. On their artistic side, as decorative and pictorial materials, pigments should possess purity and brightness of color with intensity of tinting power, capacity for mixing or coming into contact with other colors without injuriously affecting these or being themselves deteriorated, and permanence and unalterability of tone after long exposure.

PIKE, freshwater fishes generally distributed over the rivers and lakes of Europe, northern Asia, and North America, and forming a small family (*Esocidae*) of soft-rayed fishes. They are readily recognized by their elongate compressed body covered with small scales, a long head, long and spatulate snout, and very large mouth armed with strong and long teeth in the jaws and broad bands of smaller teeth on the palate and tongue. The teeth point backward or can be depressed so as to offer no obstruction to any object entering the gape, but prevent its withdrawal in the opposite direction. The dorsal and anal fins are placed far back on the tail, thus greatly increasing the propelling power of the fish, and, although Pike are bad swimmers and lead rather a sedentary than a roving life, they are excelled by no other freshwater fish in rapidity of motion when, by a single stroke of their tail, they dash upon their prey or dart out of reach of danger. The European species occurs also in North America, and is common in the eastern United States southward to northern Ohio. But North America is tenanted by other species of Pike besides, of which the largest is the Muskelunge or Maskinonge of the Great Lakes (*Esox nobilior*); it commonly attains to the large size which is exceptionally recorded of *Esox lucius*. The other American Pike are of smaller size, and generally named "pickrel." The European Pike, like its

brethren, is the most voracious of freshwater fishes; it probably exceeds the shark, to which it has been compared by many writers, in the relative quantity of food it consumes. Pike are wholesome food, and much esteemed in inland countries—the smaller (of 20 to 24 inches in length) being preferred to the larger individuals. They are prolific, and not easily exterminated, in a water in which they have been once allowed to spawn. According to season and climate they spawn in April or May, and sometimes as early as February.

PIKE-PERCH (*Lucioperca*), freshwater fishes closely allied to the perch, but with strong canine teeth standing between the smaller teeth of the jaws and palate. In Europe two species occur, the more celebrated being the "Zander" of North Germany or "Schiel" of the Danube (*Lucioperca sandra*). In North America several Pike-Perches have been described, but in the most recent works only two are distinguished, viz., *Lucioperca americana*, which grows to a weight of twenty pounds, and the much smaller *Lucioperca canadensis*; both are abundant in the Canadian lakes and upper Mississippi, and the latter also in the Ohio.

PILATE, PONTIUS, the fifth Roman procurator or "governor" of Judæa, Samaria, and Idumæa, succeeded Valerius Gratus in 26 A.D. By rank he was a Roman eque, possibly of Samnite extraction; his official appointment he owed to the influence of Sejanus. His ordinary residence as procurator was at Cæsarea, the capital, but from time to time he visited Jerusalem, especially at the greater feasts, and on these occasions he had his *bema* in the magnificent palace of Herod the Great, hence called the *prætorium*. Apart from the supreme (to him, likely enough, most trivial) incident in his life ("suffered under Pontius Pilate") the few facts that are known of him indicate a somewhat exceptional recklessness about awakening Jewish fanaticism, and unscrupulousness as to the means used in quelling its manifestations. According to Eusebius (*H. E.*, ii. 7) he was banished to Vienne in Gaul, where various misfortunes caused him at last to commit suicide; the *Chronicle* of Malalas alleges, with less probability, that he was beheaded under Nero. Later legend (see, for example, the apocryphal *Mors Pilati*, "Death of Pilate") has a good deal more to say: his suicide was anticipatory of Caligula's sentence; the body was thrown into the Tiber, and there caused disastrous tempests and floods; it afterward produced similar effects in the Rhine at Vienna, and finally had to be consigned to a deep pool among the Alps. The fact that Pilate allowed Jesus to be crucified is by no means out of keeping with what we know of his indifference to the claims alike of justice and of mercy; that he obviously wished to spare him if this could be done without too much inconvenience to himself has, however, gained him in some quarters very generous recognition; thus Tertullian speaks of him as "jam pro sua conscientia Christianum," the Copts regard him as a martyr, and the Abyssinian Church has given him a place in its calendar (June 25). This view is reflected in the spurious *Paradosis Pilati*. Pilate's wife, known to tradition as Procla or Claudia Procula, is represented as having been a proselyte of the gate and a secret disciple of Jesus. She is commemorated as a saint in the Greek Church (October 27th).

PILCHARD (*Clupea pilchardus*), a fish of the herring family (*Clupeidae*), abundant in the Mediterranean and on the Atlantic coasts of Europe, northward to the British Channel. Sardine is another name for the same fish, which on the coast of Brittany and Normandy is also called *Célan* or *Céléren*.

The Pilchard is so nearly like the herring that they

can with difficulty be distinguished from one another. In the early spring they are found in immense shoals off the coast of Cornwall, where they are caught by the inhabitants and used for food, but principally for exportation. These shipments are made chiefly to Sicily and Sardinia, whence they are returned to Europe as sardines.

PILES. See HÆMORRHOIDS.

PILGRIMAGE (see CRUSADES). The word Pilgrimage denotes the act of journeying to some place deemed sacred, for the purpose of discharging a religious obligation, or to obtain some supernatural assistance or benefit. The practice is common to many religions, and counts back to prehistoric ages. It is ultimately traceable to the nature of tribal religion, in its early form of worship of a deity regarded as purely local in the sphere of his special influence.

The first Pilgrimages of which we have any trustworthy knowledge are those of ancient Egypt. Herodotus notices that, instead of having but one yearly national festival, the Egyptians had six, the principal of which was that of Artemis (*i.e.*, Bast or Sekhet) at Bubastis, to which the pilgrims went in boats crowded with both sexes, playing on castanets and flutes, and singing to this accompaniment. Next to this ranked the festival of Isis at Busiris, attended with ceremonies of mourning, most probably in memory of the sufferings of Osiris. Third in order was the feast of Athene (Neith) at Sais, celebrated at night, with illuminations. Fourth was the festival of the Sun (Ra) at On or Heliopolis; fifth that at Buto in honor of Latona (Buto or Uat).

Among the Phoenicians there are clear traces of at least two great Pilgrimages in honor of Ashtoreth, one to Aphaca (probably the Apek of Scripture), celebrated for a yearly miracle of a ball of fire appearing on the mountain summit, and thence falling into the sea. The obscene rites for which this temple was famous led to its destruction by Constantine the Great (Euseb., *Vit. Const.*, iii. 56). The other great Ashtoreth pilgrimage was to Hierapolis in Syria, frequented by votaries from all the Semitic races except the Jews.

Directing our attention to an entirely different region of the world, we learn that in 1519, when Cortes entered Cholula in Mexico, he found it a great resort of pilgrims to the huge temple of Quetzalcoatl, then of unknown antiquity, as founded by a race earlier than the Aztecs, and built upon a colossal mound, vying in dimensions with the largest pyramids of Egypt. And what is yet more curious, besides this principal shrine, there were subsidiary tribal temples in the city, restricted to the uses of the several allied or kindred nations, who desired to have their own sanctuary in the holy city, precisely as churches of different nationalities are found in Jerusalem and in Rome to-day. And similarly in Peru, the great Temple of the Sun at Cuzco, with its encircling girdle of chapels dedicated to minor deities, was visited by pilgrims from all parts of the empire; nay, it was even regarded as a misfortune to fail in accomplishing the journey.

India, however, is above all others the land of Pilgrimages, for it has observed them during a longer unbroken period than any other country of which we possess sufficient records, and for frequency and multitude it would be difficult to find any parallel. The most celebrated of them are those to the temple of Jagan-nâth at Puri in Orissa, Benares, Hurdwar, Ganga-Sagara, Gangotri, Jumnotri, Prayâga (Allahabad), Râmêswara, Gaya in Behar, and Ayodhya or Oudh. Apart from the motives, common to all pilgrims, of acquiring religious merit or expiating sins, these Indian shrines are frequented for the performance of *sradâha* ceremonies in honor of

deceased ancestors or as votive acts for the recovery of the sick, or, again, to carry the ashes of deceased kindred to be scattered in the waters of some sacred or purifying river.

In China Pilgrimages are made to several of the more sacred spots by both Buddhists and Confucianists. Wutaishan in Shan-si is the chief resort of Buddhist pilgrims, and Tai-shan, the mountain sacred to Confucius, that of Confucianists (Williamson, *Journeys in North China*). In Japan both the older Shintô nature-worship and the newer Buddhist creed have their several sanctuaries and Pilgrimages. The principal Shintô Pilgrimages are those to Isé in the department of Watarai, and to the sacred mountain Fuji. There are two temples at Isé, ranking in sanctity first of all Shintô shrines, and the special seat of the worship of Ten-shôkô-daigin, the Sun-Goddess, from whom the Mikado is held to descend.

Under the judges and the kings we find many traces of Pilgrimage, not only to the sanctuary of the ark at Shiloh, and afterward to Jerusalem, but to local high places, such as Ophrah, Mizpeh, Dan, Bethel, and Beersheba. In truth, it is not till the post-exilic period that the supremacy of one national sanctuary is assured (though a Pilgrimage even after the destruction of the temple is recorded in Jeremiah xli. 5, showing that the mere sight was held sacred), for the local devotion of the high places resisted all the efforts of the reforming party under Hezekiah and Josiah even in the kingdom of Judah itself. There is properly only one Moslem Pilgrimage of obligation, that to Mecca, which still often draws an annual contingent of from 70,000 to 80,000 pilgrims (see MECCA). It is in truth a pagan survival which proved too powerful for extirpation by Mohammed. The Kaaba had been constituted the national sanctuary of Arabia about 100 B.C., and contained, besides the famous Black Stone, some 360 idols of various Bedouin tribes, united in one pantheon, exactly as with the Capitol of Rome; and though it was possible to sweep the idols out of the Kaaba, it was not so easy to deconsecrate the spot, but far more convenient to give it a new sanction.

Christian Pilgrimages were at first limited to Jerusalem and its immediate neighborhood, including Bethlehem. But this is matter of conjecture rather than of knowledge. There is no actual proof of very early Christian Pilgrimage to the holy places, though the belief was already current at the close of the fourth century that the custom had prevailed unbroken from apostolic times, as is distinctly asserted by Paula and Eustochium in their letter to Marcella, written in 386, wherein they state also that of which they are more trustworthy witnesses, that pilgrims then flocked from Armenia, Persia, India, Ethiopia, and even Gaul and Britain, to visit the cradle of Christianity. But another kind of pilgrimage, destined to be more powerful than that to Jerusalem, began to be popular nearly at the same time, that to the tombs of distinguished martyrs or confessors. So much did the notion begin to prevail that Pilgrimage was almost a necessity of religion, and that prayer could be heard more assuredly in particular places, that warnings against error of the kind were uttered by teachers whose own acts had helped to propagate the opinion in question.

What makes the devotion to the tombs of saints such a powerful factor in ecclesiastical history is that, after the Holy Sepulcher itself, no grave had such a hold on Christian imagination as that where the bodies of the two chief apostles, St. Peter and St. Paul, were held to rest in Rome. And consequently, as the division of the empire lessened the intercourse between East and West, as the decay of the old lines of communication made

traveling more difficult, and as the advance of Mahomedanism in Syria and Palestine made it more dangerous also in that direction, Rome gradually supplanted Jerusalem to a great degree in the West as the goal of Pilgrimage, and the enthusiasm of the visitors did much to consolidate the papal monarchy over Latin Christendom. Nowhere was the Pilgrimage to Rome more popular than in Saxon England, and among the crowds of penitents who made the journey were four kings, Ceadwalla, Ine, Coinred, and Offa, all of whom died in Rome, two of them as monks. The Pilgrimage to Jerusalem received fresh stimulus in the ninth century by the first occurrence of the alleged miracle of the heavenly fire on Easter Eve at the Holy Sepulcher, and continued to be frequented till checked by the fanaticism of the caliph Hakem-Biamr'illah about 1018, and more severely and permanently by the Seljukian Turks on their conquest of Syria, which occasioned those armed Pilgrimages, the crusades, to whose history this branch of the subject thenceforward belongs. Meanwhile, a third class of sanctuaries had been steadily coming into notice and popularity, consisting neither of the seats of great historical events nor of the ascertained resting-places of eminent saints. One of the earliest and most famous of these was that of Compostella, where the relics of St. James the Great were said to be discovered in 816, and, after being again hidden for many centuries, to have been discovered afresh in 1884. This was one of the most frequented by English pilgrims, no fewer than 2,460 licenses being granted for the journey in the one year 1434. Another, which became the Bethlehem of the West, as Rome had become its Jerusalem, was Loreto, where, ever since 1295, the Santa Casa, declared to be the home of the Holy Family, miraculously transported from Nazareth, has been frequented by pilgrims till very recent times, when its popularity has waned. Other famous shrines, some few of which even still attract yearly crowds of pilgrims, are Einsiedeln in Switzerland; Assisi, Oropa, Varese, and Vicovaro in Italy; Monserrat and Guadalupe in Spain; Mariazell in Austria; Oetting and Eberhardsclausen in Germany; Walsingham, Becket's shrine at Canterbury, Peterborough, St. Davids, and Holywell in England and Wales; St. Andrews in Scotland; Chartres, Notre Dame de Liesse, Notre Dame de Rocamadour, and Notre Dame des Victoires, Ste. Anne d'Auray in Brittany, with Lourdes in France; and Hal in Belgium.

There is a further small class of Pilgrimages, differing from all others in being neither permanent nor yearly, but periodical at various long intervals. They are usually connected with the exposition of the principal relic or relics in some important church, an event which rarely occurs. Such are the Pilgrimages of Cologne, to the shrine of the Three Kings, and that of Treves, where the alleged seamless coat of Christ has been displayed for popular devotion, and has been visited by vast crowds of pilgrims.

Pilgrims in the Middle Ages were known by a peculiar garb and various badges, the hood and cape, the staff and scrip and water-bottle, and the low-crowned hat, turned up in front, and fastened with strings, being common to all, while the palm specially marked a pilgrim from the Holy Land; a shell, one from Compostella; a bottle or bell, one from Canterbury, and so forth. They had many privileges and advantages. Nevertheless they declined in repute, not only by reason of the feigned devotees who joined them for purposes of vagrancy and mendicancy, and even from worse motives, but because many notorious criminals were customarily sent on Pilgrimage as a punishment, with no care to isolate them from their innocent companions.

**PILLORY.** This was a mode of punishment by

public exposure of the offender on a platform or scaffold long used in most countries of Europe, originating probably with the Anglo-Saxons, one of whose methods of punishment as described by Strutt is nearly identical with the instrument which eventually became known as the pillory.

**PILOT.** The English Merchant Shipping Act of 1854 defines a pilot as being a person duly licensed by any pilotage authority to conduct ships to which he does not belong as one of the crew. Pilots are in fact taken on board to superintend the steering of the vessel, where the navigation is difficult and dangerous, in consequence of their special knowledge of particular waters; and it is to this class alone that the term now applies, whereas in early times the pilot was the steersman, or the individual who conducted the navigation of a ship across the ocean and out of sight of land. The word seems to be of Dutch origin, and to mean primarily a person who conducts a ship by the sounding line (*peillood*); Cowell (*Law Dict.*), describing *lodemanage*, speaks of it as the hire of a pilot for conducting a vessel from one place to another—a *lodesman* (Ang. Sax. *lad-man*, a leader) being a pilot for harbor and river duty. The laws of pilotage in the United States are regulated by the individual States according to the Acts of Congress.

**PILOT-FISH**, a pelagic fish of the family of Horse-Mackerels, well known to sailors from its peculiar habit of keeping company with ships and large fishes, especially sharks. It occurs in tropical and sub-tropical seas, and is common in the Mediterranean, but becomes scarcer in higher latitudes. In summer pilots will follow ships as far north as the south coast of England into port, where they are generally speedily caught. It is, however, extremely doubtful whether the pilot's connection with a shark serves a more special purpose than its temporary attachment to a ship. It accompanies both on account of the supply of food which it derives from them, picking up the crustaceans, cirripeds, or other marine animals swarming about the ship's bottom or parasitic on the shark, offal thrown overboard, or smaller pieces of flesh which are left unnoticed by the shark when it tears its prey.

**PILPAY.** See BIDPAI.

**PILSEN**, the second town of Bohemia, lies at the confluence of the Radbasa and the Mies, fifty miles to the southwest of Prague. It consists of the town proper, which is regularly built and surrounded with promenades on the site of the old ramparts, and of three suburbs. The staple article of manufacture and commerce is beer, of which about 6,000,000 gallons are brewed here annually. Other industrial products are machinery, enameled tinware, leather, alum, paper, earthenware, stoves, and spirits, while a tolerably brisk trade is carried on in wool, feathers, cattle, and horses. In the neighborhood are several coal-pits, iron-works, and glass-works, as well as large deposits of kaolin. The population in 1880 was 38,883, consisting of Germans and Czechs in nearly equal proportions, and is now (1890) about 44,000.

**PIMENTO**, also called **ALLSPICE** and **JAMAICA PEPPER**, is the dried immature fruit of *Eugenia Pimenta* or *Pimenta officinalis*, an evergreen tree about thirty feet high, belonging to the natural order *Myrtaceæ*. It is indigenous in the West India Islands, growing on limestone hills near the sea.

**PIN.** A pin is a small spike, usually of metal, with a bulbed head, or some other arrangement for preventing the spike passing entirely through the cloth or other material it is used for fastening together. The ordinary domestic pin had become in the fifteenth century an article of sufficient importance in England to warrant legislative

notice, as in 1483 the importation of pins was prohibited by statute. At that time pins of good quality were made of brass; but a large proportion of those against which the legislative enactment was directed were made of iron wire blanché, and passed as brass pins. In 1636 the pinmakers of London formed a corporation, and the manufacture was subsequently established at Bristol and Birmingham, the latter town ultimately becoming the principal center of the industry. So early as 1775 the attention of the enterprising colonists in Carolina was drawn to the manufacture by the offer of prizes for the first native-made pins and needles. At a later date several pin-making machines were invented in the United States. During the war of 1812, when the price of pins rose enormously, the manufacture was actually started, but the industry was not fairly successful till about the year 1836. Previous to this an American, Mr. Lemuel W. Wright, of Massachusetts, had in 1824 secured in England a patent for a pin-making machine, which established the industry on its present basis. (See BROOCH.)

PINDAR, the greatest lyric poet of ancient Greece whose work is represented by large remains, was born about 522 B.C.; his birthplace the village of Cynoscephalæ near Thebes in Bœotia. He is said to have received his first lessons in flute-playing from one Scopelinus at Thebes, and afterward to have studied at Athens under the musicians Apollodorus (or Agathocles) and Lasus of Hermione. In his youth, as the story went, he was defeated in a poetical contest by the Theban Corinna—who, in reference to his use of Theban mythology, is said to have advised him "to sow with the hand, not with the sack." The facts that stand out from these meager traditions are that Pindar was precocious and laborious.

His versatility as a lyric poet is one of the characteristics remarked by Horace (*Carm.* iv. 2), and is proved by the fragments, though the poems which have come down entire represent only one class of compositions—the *Epinicia*, or odes of victory, commemorating successes in the great games. The lyric types to which the fragments belong, though it cannot be assumed that the list is complete, are at least numerous and varied. Pindar's genius was boldly original and his place in Greek literature is regarded as leading that of all contemporaries in the domain of lyric poetry. He is said to have died at Argos at the age of seventy-nine 443 B.C.

PINE (*Pinus*), a name given by the ancients to some of the resinous cone-bearing trees to which it is now applied, and, as limited by modern botanists, the designation of a large genus of true conifers (*Abietinæ*), differing from the firs in their hard woody cone-scales being thickened at the apex, and in their slender needle-shaped leaves growing from a membranous sheath, either in pairs or from three to five together—each tuft representing an abortive branch, springing from the axil of a partially deciduous scale-leaf, the base of which remains closely adherent to the stem. The numerous male catkins are generally arranged in dense whorls around the bases of the young shoots; the anther-scales, surmounted by a crest-like appendage, shed their abundant pollen by longitudinal slits; the two ovules at the base of the inner side of each fertile cone-scale develop into a pair of winged seeds, which drop from the opening scales when mature—as in the allied genera.

The pines are widely distributed over the north temperate zone, in the southern portions chiefly confined to the mountains, along which in Central America, a few are found within the tropics; in more northern regions they frequently form extensive forests, sometimes hardly mingled with other trees. Their soft,

straight-grained, resinous, and often durable wood gives to many kinds a high economic value, and some are among the most esteemed of timber trees.

Of the two-leaved species, *P. sylvestris*, the pine of northern Europe, may be taken as a type. When growing in perfection it is one of the finest of the group, and perhaps the most picturesque of forest trees; attaining a height of from 70 to 120 feet, it is of conical growth when young, but in maturity acquires a spreading cedar or mushroom-like top with a straight trunk of from two to four feet in diameter at the base, and gnarled twisted boughs, densely clothed at the extremities with glaucous green foliage, which contrasts strongly with the fiery red-brown bark. The leaves are rather short, curved, and often twisted; the male catkins, in dense cylindrical whorls, fill the air of the forest with their sulphur-like pollen in May or June, and fecundate the purple female flowers, which, at first sessile and erect, then become recurved on a lengthening stalk; the ovate cones, about the length of the leaves, do not reach maturity until the autumn of the following year, and the seeds are seldom scattered until the third spring. *P. sylvestris* is found in greater or less abundance, from the hills of Finmark and the plains of Bothnia to the mountains of Spain, and even the higher forest-slopes of Etna, while in longitude its range extends from the shores of the North Sea to Kamchatka.

In Britain natural forests of Scotch fir of any extent are only now found in the Highlands, chiefly on the declivities of the Grampians, and most of the great woods have been much curtailed in recent times, while the larger trees are generally felled as soon as they attain a timber size. The Scotch fir is a very variable tree, and certain varieties have acquired a higher reputation for the qualities of their timber than others. The heart-wood of the finer kinds of Scotch fir is of a deep brownish-red color, abounding in the resin to which its durability is probably due. For all indoor and most outdoor purposes it is as lasting as oak, and for ship planking is perhaps little inferior; from its lightness and elasticity it is well adapted for the construction of yachts and other small fast-sailing craft, and is said to be the best of all wood for masts and large spars; its weight varies from thirty to forty pounds the cubic foot.

The pine is an important tree in the economy of the northern nations of Europe. In Scandinavia and Russia houses are chiefly constructed of its timber, and log-huts are made of the smaller trunks, and lined and roofed with the bark. The inner bark is twisted into ropes, and, like that of the spruce, is kiln dried, ground up, and mixed with meal in times of scarcity; in Kamchatka it is macerated in water, then pounded, and made into a kind of substitute for bread without any admixture of flour. In recent days the fiber of the leaves has been extracted in some quantity and applied to textile purposes under the name of *waldwolle*, both in Germany and in Sweden. It is prepared by boiling the needles in a solution of soda to remove the resin, which process loosens the fiber and renders its separation easy; it has some resemblance to coarse wool, and is spun and woven into blankets and garments that are said to be warm and durable; it is also used for stuffing cushions; an essential oil, obtained by a previous distillation of the leaves, has medicinal virtues attributed to it by some German practitioners.

Large quantities of turpentine are extracted from this pine in Sweden and Russia, also in the Carolinas, Florida, and Georgia, by removing a strip of bark, terminating below in a deep notch cut in the wood, into which the turpentine runs, and from which it is

scooped as it accumulates; but the product is not equal to that of the silver fir and other species. Tar is prepared largely from *P. sylvestris*; it is chiefly obtained from the roots, which, mingled with a few logs, are arranged in a conical or funnel-shaped hollow made on the steep side of a hill or bank; after filling up, the whole is covered with turf and fired at the top, when the tar exudes slowly and runs into an iron vessel placed below, from the spout of which it is conveyed into barrels. Most of the so-called Stockholm tar is thus prepared, chiefly in the province of Bothnia.

Closely allied to the Scotch pine is the dwarf *P. pumilio*, the "krumholz" or "knieholz" of the Germans. The Red Pine of Canada and New England (so-called from the color of its bark), *P. resinosa*, is a tree of considerable size, sometimes attaining the dimensions of *P. sylvestris*. The tree is of quick growth and the wood strong and resinous, but it is less durable than Scotch fir, though much employed in shipbuilding; according to Emerson, trunks exist in Maine four feet in diameter. Red pines abound in Nova Scotia and Newfoundland, and the tree is rather widely distributed over the northern parts of the continent; it rarely forms extensive woods, but grows chiefly in clumps among other trees, at least in its more southern habitats. Nearly allied is *P. Banksiana*, the Gray or Labrador Pine, sometimes called the Scrub Pine; it is the most northerly representative of the genus in America, and is chiefly remarkable for its much recurved and twisted cones, about two inches long. The trunks are too small to be of great economic value, but the light wood is used by the natives for their canoes.

*P. Laricio*, the Corsican Pine, is one of the noblest trees of this group, growing to a height of 100 or even 150 feet, with a straight trunk and branches in regular whorls, forming in large trees a pyramidal head. This pine abounds in Corsica, and is found in more or less abundance in Spain, southern France, Greece, and many Mediterranean countries; it occurs on the higher mountains of Cyprus. The tree is of very rapid growth, but produces good timber, much used in southern dockyards and very durable, though less strong than that of *P. sylvestris*; the heart-wood is of a brownish tint.

The Black Pine, *P. austriaca*, derives its name from the extreme depth of its foliage tints—the sharp, rigid, rather long leaves of a dark green hue giving a somber aspect to the tree. The light-colored, glossy, horizontal cones are generally in pairs, but sometimes three or four together. The tree is conical when young, but when old forms a spreading head; it often attains a large size. Southern Austria and the adjacent countries are the natural habitats of this pine; it seems to flourish best on rocky mountain sides, but in England grows well on sandy soils. The timber is valued in its native country, and is said to be durable and to stand exposure to the weather well; various resinous products are extracted from it. *P. pyrenaica* is a handsome species of pyramidal form, attaining a large size on the mountains of northern Spain. The leaves are long and of a bright green; the cones are solitary, oblong, conical, and of a yellow tint. The timber is used in Spanish dockyards, but opinions vary as to its quality.

*P. Pinaster*, the Cluster Pine or Pinaster, is an important species from its vigorous growth in the sand-drifts of the coast, especially on the dunes of the Bay of Biscay. Growing to a height of from forty to seventy feet, the deeply-furrowed trunk occasionally reaches a diameter of three feet or more at the base, where, like most sand trees, it usually curves upward gradually, a form that enables the long tap-roots to withstand better the strain of the sea gale; when once established, the tree is rarely overthrown even on the loosest sand.

These forests of pinaster, apart from the production of timber, have a great economic value as a source of turpentine, which is largely obtained from the trees by a process analogous to that employed in its collection from *P. sylvestris*. In England the cluster-pine has been largely planted on sandy districts near the sea, and has become naturalized in Purbeck and other wild tracts in the southern counties, but the summer heat is too small to permit of its resinous products acquiring any value; *P. bruttia*, the Calabrian Pine, a kindred form, is remarkable for its numerous densely clustered radiating cones; its wood is considered good in southern Italy.

*P. Pinea* is the Stone-Pine of Italy; its spreading rounded canopy of light green foliage, supported on a tall and often branchless trunk, forms a striking feature of the landscape in that country, as well as in some other Mediterranean lands.

The tree has been naturalized in many warm countries, even in China; in England it seldom attains any large size, as the deficient summer heat prevents the wood from maturing; but trees occur occasionally in plantations twenty or thirty feet in height; the wood, though soft and deficient in the resin that gives durability to the timber of some species, is valued by the southern carpenter and cabinetmaker for its lightness, its fineness of grain, and the ease with which it is worked. *P. mitis*, the Yellow Pine of the northern and middle States of America, is rather allied to the three-leaved section, but the leaves are mostly in pairs. It is a tree of large size, often attaining a height of seventy feet and upward, though rarely more than two feet in diameter at the root; the lower branches spread horizontally, the upper, converging toward the trunk, give the tree somewhat the aspect of a spruce, hence it is called in some districts the "spruce-pine." The yellow pine is one of the most important timber trees of the genus; the heart-wood being very durable is largely employed in shipbuilding and for house timber, being nearly equal to that of *P. sylvestris*; large quantities are exported to Britain under the name of "New York yellow pine;" the sapwood is perishable. The three-leaved group includes several of the most valuable trees of America; among them is *P. rigida*, the Pitch-Pine of the northern States, a tree of from forty to fifty feet in height with rugged trunk; occasionally three feet in diameter. The wood is very hard and abounds with resin, but on swampy land is of inferior quality and of little value except for fuel, for which the pitch-pine is highly prized; on drier ground the grain is fine from the numerous knots. Large quantities of tar and pitch are obtained from this species. The tree is one of the few that will flourish in salt marshes. *P. australis* is the "Georgia Pitch-Pine," or Yellow Pine of the southern States; it abounds on the sandy soils that cover so much of Georgia, the Carolinas, and Florida, and on those dry lands attains its highest perfection, though occasionally abundant on moist ground, whence it is sometimes called *P. palustris*. The most marked feature of the tree is its long tufted foliage—the leaves, of a bright green tint, springing from long white sheaths, being often a foot in length. The tall columnar trunk furnishes the most valuable pine timber of the States; close-grained and resinous, it is very durable and polishes well; it is largely employed in American shipyards, and immense quantities are exported, especially to Britain and the West India Islands. This tree yields an abundant supply of tar and turpentine of good quality, which products are collected and manufactured in the "pine-barrens" on a large scale.

*P. Teda*, the "Loblolly Pine" of the backwoodsman, a tall tree with straight trunk and spreading top, covers

great tracts of the "pine-barrens" of the Southern States, but also frequently spreads over deserted arable lands that have been impoverished by long and bad farming. It is a fine species 80 or 90 feet high, having sometimes a girth of 6 or 8 feet, with a broad spreading head. The timber of this pine is indifferent, but the forests of it are of importance from the quantity of turpentine they yield; the trees also furnish much firewood of good quality. *P. ponderosa*, a pine of western America belonging to this section, is a fine timber tree; deserving of notice from the extreme density of its wood, which barely floats in water; it abounds in some parts of the western range of the Rocky Mountains. In Oregon and California several large pines of this group are found. *P. Coulteri*, or *macrocarpa*, is remarkable for its enormous cones (sometimes a foot long, six inches in diameter, and weighing more than four pounds). Nearly related to this is *P. Sabiniana*; the Nut-Pine of California, the cones of which are of nearly equal size, also with hooked scales; the large nut-like seeds are eaten by the Indians; the tree is one of the largest of the section, sometimes attaining a height of 120 feet and upward, while trunks have been found, it is said, 10 or 12 feet in diameter. *P. longifolia* is a Nepal species, known in India as the "Cheer-Pine;" the wood is good, resinous, and moderately durable; the tree is common on the foot-hills of the Himalayas. *P. Gerardiana*, another Nepal species, is a large tree with a conical head, growing on the more elevated parts of the mountain range; it furnishes edible seeds. *P. canarinesis*, which forms forests on the mountains of Grand Canary and Teneriffe, growing at an elevation of 6,000 feet, also belongs to this group. The beautiful Monterey-Pine, *P. insignis*, distinguished by the brilliant color of its foliage, has been planted in the southwestern parts of England, but is scarcely hardy. The pines with five leaves in each tuft have generally deciduous sheaths. The most important economic species is the well-known White Pine, *P. Strobus*, from its large growth and abundance, as well as the soft even grain of its white wood, one of the most valuable of American trees. The tree abounds from Canada to Georgia, and is also found in British Columbia, but in the eastern States has been so long sought for by the lumberer that most of the old trees have long disappeared, and large white pine timber is now only found in quantity in the Canadian Dominion. Formerly Maine and Vermont were celebrated for the size of their pines, but few of these great trees now exist in New England; one that stood near the banks of the Merrimack in New Hampshire is said to have had a trunk nearly 8 feet in diameter, and Michaux measured a stump 6 feet across. On a deep rich soil *P. Strobus* attains a height of 150 or even 200 feet, and trunks without a branch are sometimes found 80 or 90 feet long; in the earlier stages of growth it has a pyramidal form, in open glades the lower boughs often touching the ground, but in old age it acquires a wide almost cedar-like top. The wood of the white pine is durable for indoor use, especially when protected by paint, but when exposed to moist air it rapidly decays, and it is very liable to dry rot; it is said to be best when grown on sandy soils. Immense quantities are still exported, especially from Canada, its smooth easily-worked grain rendering it a favorite wood for the house-carpenter and joiner; it weighs about twenty-eight pounds per cubic foot. Nearly approaching this is *P. excelsa*, the Bhotan Pine. It is found in Kumaon and Bhotan and on some of the Nepal ranges, but does not grow in the moist climate of the Sikkim Himalayas; it is found at a height of 6,000 to 7,000 feet, and attains large dimensions; the wood is highly resinous, and is said to be durable;

great quantities of a white clear turpentine exude from the branches when injured. The Bhotan pine is quite hardy in southern England, and has been largely planted of late as an ornamental tree.

*P. Lambertiana*, the Giant Pine or Sugar-Pine of California, is the largest of the genus, rising to the height of 200 feet, with a trunk 20 to 30 feet in girth, and, it is said, occasionally attaining much larger dimensions. The head is of a pyramidal form, the lower branches drooping like those of a Norway spruce; its foliage is of a light bright green color. The pendant cones are very large, sometimes eighteen inches long and four inches in diameter, with large nut-like seeds, which, pounded and baked, are eaten by the Indians. The tree abounds in some sandy districts, but more generally occurs singly or in small groups dispersed through the woods, attaining its greatest dimensions in light soils. The wood is soft and nearly white, but contains much resin, which when fire has run through the forest exudes, and, having in this half-burnt condition a sweetish taste, has given the common name to the tree; the wood seems to be formed slowly; from its smooth grain it is valued for indoor carpentry; the saccharine burnt resin is used as a laxative in California. *P. Cembra* is the Stone-Pine of Siberia and central Europe. It abounds on the Alps, the Carpathians, and the Siberian ranges, in Switzerland being found at an altitude of 6,800 feet in some localities. It is a straight-growing tree, with gray bark and whorls of horizontal branches, growing often from the ground, giving a cylindro-conical outline. The growth of *P. Cembra* is slow, but the wood is of remarkably even grain, and is employed by the Swiss wood-carvers in preference to any other. The *Cembra* is the "zirbel" or "zirbel-kiefer" of the Germans, and is known locally in Switzerland as the "aroile," "aloies," and "arve." *P. occidentalis*, a five-leaved pine with pale green foliage and small ovate cones, is found on the high mountains of St. Domingo. Many members of the group occur on the Mexican isthmus, one of which, *P. cembroides*, produces edible seeds. *P. Ayacahuite*, a large tree growing on the mountains of Guatemala, with glaucous foliage like *P. Strobus*, yields a valuable resin. *P. filifolia* and *P. macrophylla*, likewise natives of Central America, are remarkable for the extreme length of their leaves; the former is said to attain a large size.

PINE-APPLE. The pine-apple so-called consists in reality of the inflorescence of the plant, the originally separate flowers of which, together with the bracts supporting them, become fleshy and consolidated into one mass. The pine, *Ananassa sativa*, is a member of the Bromeliad family, supposed to be of tropical American origin, and has been found wild in Mexico, Central America, Guiana, and Brazil, but is now widely dispersed in all tropical and semitropical countries.

PINE BLUFFS, the capital of Jefferson county, Ark., is conspicuously located on a bluff on the right bank of the Arkansas river, 120 miles from its junction with the Mississippi. It is also on the Little Rock, Mississippi and Texas Railway, 46 miles south of Little Rock, and enjoys substantial advantages by reason of the means of rapid communication with St. Louis, Chicago, Memphis, Vicksburg, and New Orleans, afforded by rail and water. Owing to these and other causes the city has developed rapidly, and its progress has been almost phenomenal. It contains a number of churches and schools, a Jewish synagogue, the Pine Bluff normal institute, 2 papers, 2 banks, 4 hotels, upward of 100 stores; also a court-house and high school. In addition to the Pine Bluff iron works, one of the leading industries of the State, there are 2 saw-mills, 1 shingle-mill, 1 planing, sash, door and blind factory, 2 carriage fac-

ories, 1 ice manufactory, 1 machinery manufacturing works, 1 furniture factory, 1 mill and elevator company, water works, electric light works, and lines of street railway, besides flour mills, cotton seed oil works, and brick-yards. It is the shipping point for the cotton raised in the surrounding country, and its population in 1890 was returned at 9,952.

PINEL, PHILIPPE, a distinguished French physician, was born at the chateau of Rascas, Saint-André, in the department of Tarn, France, on April 20, 1745. He studied at Lavour and afterward at the university of Toulouse, where he took his doctor's degree in 1773. From Montpellier, where he taught mathematics and at the same time carried on his medical studies, he removed in 1778 to Paris, engaging there chiefly in literary work connected with his profession. He died at Paris, October 26, 1826.

PINEROLO, a city of Italy, in the province of Turin (Piedmont), is built in a straggling manner on a hill-side just above the junction of the valleys of the Chisone and the Lemina, at a height of 1,237 feet above the sea, twenty-three and one-half miles by rail southwest of Turin. It is the terminus of the branch railway from Turin by Sangone or Nichellino, and has steam tramways running up to Perosa (twelve miles) and south to Saluzzo. Cotton, silk, wool, and hemp are among the local manufactures. The population of the city in 1889 was 13,000.

PINK. As usually applied this word corresponds to a genus of *Caryophyllaceæ*, the *Dianthus* of botanists. It is characterized by the presence of opposite simple leaves proceeding from thickened nodes, a cymose inflorescence, a tubular calyx surrounded by a number of overlapping bracts, a showy corolla of five free long-stalked petals, ten stamens proceeding, together with the petals, from a short stalk supporting the ovary, which latter has two styles and ripens into an oblong pod which splits by two valves. It is a native chiefly of southern Europe and the Mediterranean region, a few being found in temperate Asia and South Africa. One species only is native to America, and that only in the northwest. Four species are wild in Britain, with two others which are more or less naturalized. These two are the more interesting as being the originals of the pinks and of the carnations and picotees of English gardens.

PINKERTON, JOHN, archæologist, numismatist, historian, geographer, and miscellaneous writer in prose and verse, was born at Edinburgh, February 17, 1758, and died in 1826.

PINSK, a district town of the government of Minsk, Russia, is situated in a marshy region at the confluence of the Strummen and Pina Rivers, 172 miles to the southwest of Minsk. It has a population in 1890 estimated at 26,950.

PINTO, FERNÃO MENDES, a noted Portuguese adventurer, was born in 1509 or 1510 at Montemor-o-Velho, near Coimbra, and died near Lisbon, July 18, 1583.

PINTURICCHIO, whose full name was BERNARDINO DI BETTI, the son of a citizen of Perugia, Benedetto or Betto di Biagio, was one of a very important group of painters who inherited the artistic traditions and developed the style of the older Perugian painters such as Bonfigli and Fiorenzo di Lorenzo. According to Vassari he was a pupil of Perugino. He painted a large number of frescoes, including *The Annunciation*, *Nativity*, *Magi*, *Resurrection*, etc., and died in 1513.

PINZON, a family of wealthy Spanish navigators, of Palos de Moguer, in Andalusia, three members of which—Alonzo, Francesco, and Vicente, brothers—were associated with Columbus in his great discovery.

MARTIN ALONZO PINZON, born about the middle of

the fifteenth century. In the expedition of 1492 Alonzo commanded the *Pinta*, on board of which his brother Francesco was pilot; another brother, Vicente Yañez, had command of the *Nina*. It was at Alonzo's persuasion that on October 7th the course of the expedition was changed to the southwest; the island of Guanahani or San Salvador, four days after, was sighted. On November 21st, off the coast of Cuba, Alonzo separated himself from the expedition, hoping to be the first to arrive at the land of gold of which they had heard the natives speak. After an absence of six weeks he rejoined Columbus, who accepted the excuses he gave for his absence. On the return journey Alonzo again separated from his leader, probably by design, and when Columbus arrived at Palos on March 15, 1493, he learned that Alonzo had already landed at Bayona in Galicia. If his object was to forestall Columbus and obtain the credit of being the discoverer of the New World, his intentions were foiled; he was refused the audience which he craved of the sovereigns, and very shortly after died, it is supposed of chagrin.

VICENTE YANEZ PINZON, who commanded the *Nina*, remained loyal to his leader throughout. In after years he made important discoveries on his own account. After 1523 all traces of Vicente are lost.

PIOMBO, SEBASTIANO DEL. See SEBASTIANO.

PIOTRKÓW, the chief town of a government of the same name in Russian Poland, and formerly the seat of the high court of Poland, is situated on the railway from Warsaw to Vienna, ninety miles by rail to the southwest of the capital, five miles to the west of the river Pilica. In April, 1889, it had 23,050 inhabitants, including 3,000 military. Its manufactures are still insignificant; it has a few flour-mills, saw-mills, soap-works, and breweries.

PIOZZI, HESTER LYNCH, the daughter of John Salisbury, of Bodville, Carnarvonshire, was born there, as it would appear from a protracted dispute between Croker and Macaulay, January 27, 1741. After an education which extended considerably beyond that given to most ladies of her period, she was married in 1763 to Henry Thrale, a brewer of Southwark, whose house was at Streatham, on the southeast corner of Tooting Beck Common. In this retreat she drew around her many of the most distinguished men of letters of the age. She was introduced to Johnson by Arthur Murphy in the year after her marriage, and for nearly twenty years the sage remained on the closest intimacy with her. At the time of Mr. Thrale's death Doctor Johnson was in declining health, and he soon began to think himself slighted, nor was his indignation abated at the announcement in the spring of 1783 of her engagement to Piozzi, an Italian musician. For a time the engagement was broken off, but it was quickly resumed, and on July 25, 1784, they were married. The union provoked the resentment of her children, and the undying denunciations of Doctor Johnson; but, when her husband was found to be a man of quiet and inoffensive manners and a careful guardian of his wife's resources, her children acquiesced in the marriage and most of her friends returned to her. Baretti, always her enemy, abused her, and Boswell ridiculed her, but her character has survived the insinuations of the one and the open malevolence of the other, as well as the satiric attacks of Peter Pindar. Piozzi died of gout at Brynbella, March 1809, and she at Clifton, May 2, 1821.

PIPE (see MUSIC and ORGAN). Strutt, in his *Sports and Pastimes of the People of England*, gives representations of the pipe and tabor as used in England in the fourteenth century to accompany a dancing-dog, a cock on stilts, a horse rearing, etc.

PIPE, TOBACCO. The smoking of tobacco in pipes is a custom which prevailed in America for a period of

unknown duration previous to the discovery of that continent by Columbus. The most ancient pipes of which remains exist have been found in mounds or tumuli called pipe mounds, principally in the States of Ohio, Indiana, Illinois, and Iowa. These mound pipes, which are carved in porphyry and other hard stones, are very uniform in type. In the commonest forms the bowl is a simple cylinder or urn, but in many cases remarkable artistic skill has been displayed in carving the bowls into miniature figures of birds, mammals, reptiles, and human heads, often grotesque and fantastic, but always vigorously expressed. These mound or platform pipes with carved human and animal forms are objects of the highest ethnographic interest and importance, being among the most characteristic remains of the ancient inhabitants of the Mississippi valley. The wide area over which they, as well as remains of baked clay pipes, are found throughout the American continent testifies to the universal prevalence of smoking in the pre-Columbian era. Many of the ancient clay pipes found in Mexico, etc., are elaborately molded and ornamented, while others show considerable similarity to the early clay pipes of Europe. Among the North-American Indian tribes the tobacco pipe occupies a position of peculiar symbolic significance in connection with the superstitious rites and usages of the race. The favorite material for Indian pipe bowls is the famous red pipe stone (catlinite), a fine-grained easily-worked stone of a rich red color of the Côteau des Prairies, west of the Big Stone Lake in Dakota. The Babeen Indians of the British-Columbian coast carve from a soft blue clay slate very elaborate and massive pipes with intricate pierced work and fantastic animal forms, the pipe tube being pierced from some protruding part of the sculpture.

There is considerable dispute as to whether pipes for smoking were at all known in Europe previous to the discovery of America. Throughout Great Britain and Ireland small clay pipes are frequently dug up, in some instances associated with Roman relics. The introduction of the tobacco-pipe into Europe is generally ascribed to Ralph Lane, first governor of Virginia, who in 1586 brought an Indian pipe to Sir Walter Raleigh, and taught that courtier how to use the implement. The pipe-makers of London became an incorporated body in 1619, and from England the other nations of Europe learned the art of making clay pipes.

The regular pipe-making industries divide into many branches, of which the more important are the clay pipe, meerschaum (real and artificial), and wooden bowl trades. Clay pipes are made in prodigious numbers by hand labor with an iron mold and a steel wire for forming the tube of the stem. The pipes are very lightly fired, so as to keep them soft and porous; and so cheaply made are they that the commoner kinds can be retailed at a profit for one-half cent each. The principal center of the clay-pipe industry in England is at Broseley, in Staffordshire, where the trade has been established since the early part of the seventeenth century, and in the United States in Powhatan county, Va., the product of which locality has a reputation superior to all other clay pipes made, usually costing 15 to 25 cents each. Meerschaum pipes (see MEERSCHAUM) are the expensive luxury of the European smoker, but modern ingenuity has succeeded in providing a remarkably clever imitation of both meerschaum and amber; so that a large portion of the so-called meerschaum pipes are factitious.

PIPE-FISHES, small marine fishes, which with the sea-horses form a distinct family, *syngnathidæ*, of the order of Lophobranchiate fishes. The name is derived from the peculiar form of their snout, which is produced

into a more or less long tube, ending in a narrow and small mouth which opens upward and is toothless. The body and tail are long and thin, snake-like, incased in hard integuments which are divided into regularly arranged segments. Pipe-fishes are abundant on such coasts of the tropical and temperate zones as offer by their vegetation shelter to these defenseless creatures. They are very bad swimmers, slowly moving through the water by means of the rapid undulatory movement of the dorsal fin. Their tail, even when provided with a caudal fin, is of no use in swimming, and not prehensile as in sea-horses.

PIPIT, French *Pipit*, cognate with the Latin *Pipio*, the name applied by ornithologists to a group of birds having a great resemblance in both habits and appearance to the LARKS (*q.v.*), with which they were formerly confounded by systematists as they are at the present day in popular speech, but differing from them in several important characteristics, and, having been first separated to form the genus *Anthus*, which has since been much broken up, are now generally associated with the WAGTAILS (*q.v.*) in the family *Motacillidæ*. Pipits, of which over fifty species have been described, occur in almost all parts of the world, but in North America are represented by only two species—*Neocorys spragueii*, the prairie-lark of the northwestern plains, and *Anthus ludovicianus*, the American titlark, which last is very nearly allied to the so-called water-pipit of Europe, *A. spipoletta*.

PIPPI, GIULIO, the head of the Roman school of painting in succession to Raphael. This prolific painter, modeler, architect, and engineer is currently named GIULIO (or JULIO) ROMANO, from the place of his birth—Rome, in the Macello de' Corbi. His name in full was Giulio di Pietro di Filippo de' Giannuzzi—Giannuzzi being the true family name, and Pippi (which has practically superseded Giannuzzi) being an abbreviation from the name of his grandfather Filippo.

The date of Giulio's birth is a little uncertain. Visari (who knew him personally) speaks of him as fifty-four years old at the date of his death, November 1, 1546; thus he would have been born in 1492. Other accounts assign 1498 as the date of birth.

PIPPIN, or PEPIN, a name borne by several members of the Carolingian family. (1) Pippin of Landen, or Pippin the Old, mayor of the palace, died 639. (2) His grandson, Pippin of Heristal, the father of Charles Martel, died 714. (3) Martel's son, Pippin, the Short, king of the Franks, died 768. (4) Pippin, son of Charles the Great (776-810), was his father's deputy in Italy, and as such was anointed "king for Italy" by Pope Adrian I. in 781. (5) Pippin, second son of Louis the Pious, appointed king of Aquitaine by his father in 817, died in 838, after a reign spent in the family conflicts of the period. (6) The son of the last-named Pippin was called to the throne by the Aquitanians on his father's death, and maintained himself with varying fortunes against Charles the Bald, to whom Louis had given the vacant throne, till, in 864, he was taken by treachery, and soon died in confinement.

PIQUA, a city of Miami county, Ohio, is situated in a rich agricultural district on the Miami river, on the Miami and Erie Canal; and on the Pittsburgh, Cincinnati and St. Louis and the Cincinnati and Michigan railways, about ninety miles north-by-east of Cincinnati. Beside a large agricultural trade the city has woolen manufactures, iron foundries, and agricultural machine works. The population, 3,277 in 1850, was 5,967 in 1870, 6,131 in 1880, and 9,090 in 1890.

PIQUET, a game at cards. The name, of uncertain etymology, is probably from *pique* (the spade-suit). The Germans had formerly a *Schwerter* game, the packs

used being like piquet packs. The *pique* of French cards corresponds to the *spade* (sword) of Italian, and to the *espadas* of Spanish cards. Hence *piquet* may be the *sword game*.

Piquet is played by two persons, with a pack of thirty-two cards—the sixes, fives, fours, threes, and twos being thrown out from a complete pack. Until recently the *partie* was the best of five games of 100 up (a player not obtaining fifty losing a double game). But now the *partie* is generally determined in six hands, the player making the largest aggregate score being the winner. The number of points won is the difference between the two scores, with 100 added for the game. If, however, the loser fails to make 100 in six hands, the number of points won is the two scores added together, with 100 for the game. Piquet played in this way is called *Rubicon Piquet*.

PIRACY. Sir Edward Coke describes a pirate (Latin *pirata*) as *hostis humani generis*, and as a rover and robber upon the sea. Piracy may be defined in law as an offense which consists in the commission of those acts of pillage and violence upon the high seas which on land would amount to felony.

PIRÆUS. See ATHENS.

PIRANESI, GIOVANNI BATTISTA, an eminent Italian engraver of ancient architectural subjects, was born in the former half of the eighteenth century, and studied his art at Rome. He did not slacken in his exertions till his death in 1778. The plates of Piranesi, in which the severity of burin work is largely supplemented by the freer lines of the etching-needle, were collected and preserved by his son and coadjutor Francesco. They were published, to the number of about 2,000, in 29 vols. fol., Paris, 1835-37.

PIRMASENS, a small manufacturing town of the Bavarian palatinate, lies in a hilly district, nearly forty miles west-by-south of Spire.

PIRNA, an ancient town of Saxony, lies on the left bank of the Elbe, on the margin of the "Saxon Switzerland," eleven miles above Dresden.

PIRON, ALEXIS, the foremost epigrammatist of France, was born at Dijon on July 9, 1689, and died in 1773.

PISA, which has always been one of the most important cities of central Italy, is situated on the banks of the Arno at a short distance from the sea, in the midst of a fertile plain backed by marble mountains wooded with pines and other forest trees.

The origin of Pisa is very ancient, and is involved in obscurity. The Romans believed it to date from the days of Troy, and also gave a legendary account of its foundation by colonists from Greece. Galileo Galilei was a native of Pisa; he taught in its university; he made his first experiments in gravity from its bell tower, discovered, by observing the swing of the cathedral lamp, the law of the oscillation of the pendulum, and began there his stupendous reform of natural philosophy.

As to Pisa, it is enough to mention that its population within the walls had been reduced in 1551 to 8,574 souls, and that by 1745 it had only risen to the number of 12,406. Under the house of Lorraine, or more correctly during the reign of that enlightened reformer Pietro Leopoldo (1765-1790), Pisa shared in the general prosperity of Tuscany, and its population constantly increased. By 1840 it contained 21,670 souls, exclusive of the suburbs and outlying districts. At the present day Pisa is again one of the most flourishing cities of Tuscany. Population, 37,704.

PISA, LEONARDO OF. See PISANUS.

PISANELLO. See PISANO, VITTORE.

PISANO, ANDREA. Andrea da Pontadera, generally known as Andrea Pisano, the chief pupil of GIO-

VANNI PISANO (*q.v.*), was born about 1270, and first learned the trade of a goldsmith, as did many other afterward celebrated artists. In 1347 he was appointed architect to the duomo of Orvieto, which had already been designed and begun by Lorenzo Maitani. The exact date of his death is not known, but it must have been shortly before the year 1349.

PISANO, GIOVANNI, son of NICCOLA PISANO (see below), born about 1250, was but little inferior to his father either as an architect or as a sculptor. He died in 1330.

PISANO, NICCOLA, one of the chief sculptors and architects of mediæval Italy, was born about 1206, and died in 1278. Though he called himself *Pisanus*, from Pisa, where most of his life was spent, he was not a Pisan by birth.

PISANO, VITTORE, commonly called PISANELLO, the greatest of Italian medalists, was a native of San Vigilio sul Lago in the territory of Verona, and was born in 1380. During the latter portion of his life he lived in Rome, where he enjoyed great repute. He died in 1456.

PISANUS, LEONARDUS (Leonardo of Pisa), an Italian mathematician of the thirteenth century who has left the stamp of his name on a whole period in the history of the science. Of Leonardo's personal history few particulars are known. In 1202 Leonardo Fibonacci (*i.e.*, son of Bonaccio) was in Italy and published his great work *Liber Abaci*. Leonardo certainly was in relation with some persons belonging to that circle when he published in 1220 another more extensive work, *De Practica Geometriæ*, which he dedicated to the imperial astronomer Dominicus Hispanus. Some years afterward (perhaps in 1228, as is related by an author on the authority of a manuscript only once seen by him) Leonardo dedicated to another courtier, the well-known astrologer Michael Scott, the second edition of his *Liber Abaci*. We know nothing of Leonardo's fate after he issued that second edition.

PISCICULTURE. This art as at present pursued is not limited to those animals which are grouped by zoölogists in the class of *Pisces*. "Fishery" is now understood to signify the exploitation of all products of the sea, lake, and river, the capture of whales, turtles, pearls, corals, and sponges, as well as of fish proper. The purpose of fish-culture (or *aquiculture*, as it is in France more appropriately named) is to counteract by reparative and also by preventive measures the destructive effects of fishery.

The possibility of exterminating aquatic animals within the restricted limits of a lake or a river cannot be doubted; authorities are decidedly at variance, however, as to the extent of the influence of man upon the abundance of life in the open seas.

Fishes in ponds, lakes, or streams are quickly exterminated unless the young be protected, the spawning season undisturbed, and wholesale methods of capture prohibited. Salmon and trout streams are preserved in all countries of northern Europe; and in Canada also a large service of fishery wardens is maintained. In the United States there are in many of the older commonwealths excellent codes of laws for the preservation of fish and game, which are enforced by anglers' clubs. A river may quickly be emptied of its anadromous visitors, salmon, shad, and alewives, by over-fishing in the spawning season, as well as by dams which cut off the fish from their spawning-grounds. Numerous rivers in Europe and America might be named in which this has occurred. In the same way, sea fishes approaching the coasts to spawn in the bays or upon the shoals may be embarrassed, and the numbers of each school decimated—particularly if, as in the case of the herring, the

eggs are adhesive and become entangled in nets. Sea fishes spawning in estuaries are affected much in the same manner as the salmon in rivers, though in a less degree, by wholesale capture in stationary nets. The shad and alewife fisheries of the United States are protected by an extensive code of laws, varying in the several States and in the different rivers of each State. The most satisfactory laws appear to be those which regulate the dates when fishery must commence and end, and prescribe at least one day in each week, usually Sunday, during which the ascent of the fish may not be interrupted. Migratory, semi-migratory, or wandering fishes, ranging singly or in schools over broad stretches of ocean, the mackerels, the tunnies, the sardines or pilchards, the menhaden, the bluefish, the bonitoes, and the squeteague, stand apparently beyond the influence of human agency, especially since, so far as is known, they spawn at a distance from the coast, or since the adults, when about to spawn, cannot be reached by any kind of fishery apparatus. Their fecundity is almost beyond comprehension, and in many instances their eggs float free near the surface, and are quickly disseminated over broad areas. The conclusions gained by Professor Baird, United States commissioner of fisheries, agree exactly with those of Professor Huxley, that the number of any given kind of oceanic fish killed by man is perfectly insignificant when compared with the destruction effected by their natural enemies. Almost any body of water, be it a bay or sound, or be it the covering of a ledge or shoal at sea, may be over-fished to such a degree that fishing becomes unprofitable, especially if fishing be carried on in the spawning season. In this manner, no doubt, have the coasts of England been robbed of the formerly abundant supplies of turbot and sole.

The character of the various destructive influences which man brings to bear upon the inhabitants of the water and their effects having thus been briefly noticed, the student of fish culture is confronted by the question, What can be done to neutralize these destructive tendencies? There are evidently three things to do:—(1) to preserve the fish waters, especially those inland, as nearly as it may be possible in their normal condition; (2) to prohibit wasteful or immoderate fishing; and (3) to put into practice the art of fish breeding—(a) to aid in maintaining a natural supply, (b) to repair the effects of past improvidences, and (c) to increase the supply beyond its natural limits rapidly enough to meet the necessities of a constantly increasing population.

The preservation of normal conditions in inland waters is comparatively simple. A reasonable system of forestry and water-purification is all that is required; and this is needed not only by the fish in the streams but by the people living on the banks. It has been shown that a river which is too foul for fish to live in is not fit to flow near the habitations of man. Obstructions, such as dams, may, in most instances, be overcome by fish ladders. The salmon has profited much by those devices in Europe, and the immense dams in American rivers have been made passable even for shad and alewives by the new system of fishway construction devised by Colonel McDonald, and now being applied on the Savannah, James, and Potomac, and other large rivers.

The protection of fish by law is what legislators have been trying to effect for many centuries, and the success of their efforts must be admitted to have been very slight indeed. Great Britain has at present two schools of fishery-economists—the one headed by Professor Huxley, opposed to legislation, save for preservation of fish in inland waters; the other, of which Dr. Francis Day is the chief leader advocating a strenuous legal regula-

tion of sea fisheries also. Continental Europe is by tradition and belief committed to the last-named policy. In the United States, on the contrary, public opinion is generally antagonistic to fishery legislation; and Professor Baird, the commissioner of fisheries, after carrying on for many years, with the aid of a large staff of scientific specialists, investigations upon this very question, never became satisfied that laws are necessary for the perpetuation of the sea fisheries, nor has he ever recommended to congress the enactment of any kind of fishery laws.

The salmon rivers of the Pacific slope of the United States, the shad rivers of the east, and the whitefish fisheries of the lakes are now so thoroughly under control of the fish-culturist that no one will contradict the proposition that it is cheaper to make fish plentiful by culture than to protect those already existing.

Fish-culture in a restricted sense must sooner or later be resorted to in all densely populated countries, for, with the utmost protection, nature unaided can do but little to meet the natural demand for fish to eat. Pond-culture (*Teichwirthschaft*), has been practised for many centuries, and the carp and the gold-fish have become domesticated like poultry and cattle. The culture of carp is an important industry in China and in Germany, though perhaps not more so than it was in England three or four centuries ago; the remains of ancient fish-stews may be seen upon almost every large estate in England, and particularly in the vicinity of old monasteries. Strangely enough, not a single well-conducted carp-pond exists in England to-day to perpetuate the memory of the tens of thousands which were formerly sustained, and the carp, escaping from cultivation, have reverted to a feral state and are of little value. Until improved varieties of carp are introduced from Germany, carp-culture can never be made to succeed in England. Carp-culture is rapidly coming in favor in the United States; a number of young scale carp and leather carp were imported in 1877 for breeding purposes, and the fish commission has since distributed them to at least 30,000 ponds. Two railway cars especially built for the purpose are employed during the autumn months delivering cargoes of carp, often making journeys of over three thousand miles, and special shipments have been made to Mexico and Brazil. The carp is not recommended as a substitute for the salmon, but is especially suited to regions remote from the sea where better-flavored fish cannot be had in a fresh condition.

A kind of pond-culture appears to have been practised by the ancient Egyptians, though in that country as in ancient Greece and Rome, the practice seems to have been similar to that now employed in the lagoons of the Adriatic and of Greece, and to have consisted in driving the young fish of the sea into artificial inclosures or vivaria, where they were kept until they were large enough to be used.

The discovery of the art of artificially fecundating the ova of fish must apparently be accredited to Stephen Ludwig Jacobi of Hohenhausen in Westphalia, who, as early as 1748, carried on successful experiments in breeding salmon and trout. The importance of this discovery was thoroughly appreciated at the time, and from 1763 to 1800 was a fruitful subject of discussion in England, France, and Germany. George III. of England in 1771 granted to Jacobi a life pension.

Fish-culture in Britain was inaugurated in 1837 by Mr. John Shaw, gamekeeper to the duke of Buccleuch at Drumlanrig, who, in the course of ichthyological investigations, had occasion to fecundate the eggs of salmon and rear the young; and, as regards France, an illiterate fisherman, Joseph Remy, living in the mountains of the Vosges, rediscovered, as it is claimed, or at

any rate successfully practised, in association with Antoine Gehin, the culture of trout in 1842. The originality and practical influence of Remy and Gehin's work appear to have been exaggerated by French writers. On the other hand the establishment in 1850 at Huningue (Hünigen) in Alsace by the French Government of the first fish-breeding station, or "piscifactory," as it was named by Professor Coste, is of great significance, since it marks the beginning of public fish-culture. The art discovered in Germany was practised in Italy as early as 1791 by Baufalini, in France in 1820, in Bohemia in 1824, in Great Britain in 1837, in Switzerland in 1842, in Norway under government patronage in 1850, in Finland in 1852, in the United States in 1853, in Belgium, Holland, and Russia in 1854, in Canada about 1863, in Austria in 1865, in Australasia, by the introduction of English salmon, in 1862, and in Japan in 1877.

The distinction between private and public fish-culture must be carefully observed. The maintenance of ponds for carp, trout, and other domesticated species is an industry to be classed with poultry-raising and bee-keeping, and its interest to the political economist is but slight. The proper function of public fish-culture is the stocking of the public waters with fish in which no individual can claim the right of property. This is being done in the rivers of the United States, with salmon, shad, and alewives, and in the lakes with whitefish. The use of steamships and steam machinery, the construction of refrigerating transportation cars, two of which, with a corps of trained experts, are constantly employed by the United States Fish Commission, moving fish and eggs from Maine to Texas, and from Maryland to California, and the maintenance of permanent hatching stations, seventeen in number, in different parts of the continent, are forms of activity only attainable by government aid. Equally unattainable by private effort would be the enormous experiments in transplanting and acclimatizing fish in new waters—such as the planting of Californian salmon in the rivers of the east, land-locked salmon and smelt in the lakes and rivers of the interior, and shad in California and the Mississippi valley, and the extensive acclimatization of German carp; the two last-named experiments carried out within a period of three years have met with successes beyond doubt, and are of the greatest importance to the country; the others have been more or less successful, though their results are not yet fully realized. It has been demonstrated, however, that the great river fisheries of the United States, which produced in 1880 48,000,000 pounds of alewives, 18,000,000 pounds of shad, 52,000,000 pounds of salmon, besides bass, sturgeon, and smelt, and worth "at first hand" between \$4,000,000 and \$6,000,000, are entirely under the control of the fish-culturist to sustain or to destroy, and are capable of immense extension.

Public fish-culture exists only in the United States and Canada. European fish-culturists have always operated with only small numbers of eggs. The hatchery of Sir James Maitland at Howieton near Stirling, Scotland, may be specially mentioned in this connection, since it is undoubtedly the finest private fish-cultural establishment in the world. It is described in one of the Conference papers of the International Fishery Exhibition.

PISEK, a small town of Bohemia, fifty-five miles to the south of Prague, lies on the right bank of the Wotawa, which is here crossed by an interesting stone bridge of great antiquity.

PISIDIA, in ancient geography, was the name given to a country in the south of Asia Minor, immediately north of Pamphylia, by which it was separated from the Mediterranean, while it was bounded on the north by

Phrygia, on the east by Isauria, Lycaonia, and Cilicia, and on the west and southwest by Lycia and a part of Phrygia. It was a rugged and mountainous district, comprising some of the loftiest portions of the great range of Mount Taurus, together with the offshoots of the same chain toward the central tableland of Phrygia.

PISISTRATUS, citizen and afterward tyrant of Athens, was the son of Hippocrates, through whom he traced his pedigree to Meleus and Nestor, princes of Messene in the Heroic Age. One day, not long after a violent dispute with Megacles in the public assembly, Pisistratus drove into the market-place, himself and his mules bleeding from wounds which he had inflicted with his own hand, but which he pretended to have received from his political enemies. The indignant people decreed a guard for the protection of their champion. Of this guard the champion soon availed himself in order to seize the Acropolis and make himself master of Athens (560). Megacles and the Alcæonidæ fled, but Solon remained and continued to lift his voice against the usurper, who, however, treated the old man with the utmost deference, as a valued friend and counsellor. Solon did not long survive his country's freedom; he died in the next year (559). The government of Pisistratus was marked by great moderation; he maintained the existing laws, to which he exacted obedience from all, and set the example of it himself. Being once accused of murder, he appeared in court like a private citizen to answer the charge, which, however, the accuser did not venture to press. He was twice driven out of Athens, but each time returned and repossessed himself of the tyranny, which he thenceforward held till his death.

The well-known story that Pisistratus was the first to collect and publish the poems of Homer in their present form rests on the authority of late writers (Cicero being the earliest), and seems to be sufficiently disproved by the silence of all earlier authorities (see HOMER).

PISTACHIO NUT, see NUT. The pistachio nut is the species named in Gen. xliii. 11 (Heb. פִּסְטָאִיּוֹת, Ar.

*botm*) as forming part of the present which Joseph's brethren took with them from Canaan, and in Egypt it is still often placed along with sweetmeats and the like in presents of courtesy.

PISTOIA, or PISTOJA, a well-walled ancient city, twenty-one miles northwest of Florence, on a slight eminence near the Ombrone, one of the tributaries of the Arno; it now contains about 12,500 inhabitants.

PITCAIRN, or PITCAIRN'S ISLAND, an island of the eastern Pacific, in 25° 4' N. latitude and 130° 8' W. longitude, may be considered as a member or appendage of the Paumotu, Tuamotu, Low or Dangerous Archipelago, but is nearly 100 miles south of Oeno. It is not more than three miles long from east to west and about two miles broad. The island was settled by mutineers from the ship *Bounty*—some of their descendants yet living on the island.

PITCAIRNE, ARCHIBALD, a distinguished Scottish physician, born at Edinburgh in 1652, and died in 1713.

PITCH. See TAR.

PITCHER PLANTS. See INSECTIVOROUS PLANTS.

PITHOM, a city of Egypt, mentioned in Exod. i. 11, along with RAMESES, (*q.v.*)

PITHOU, PIERRE, lawyer and scholar, was born at Troyes, France, on November 1, 1539, and died in 1596.

PITT, WILLIAM, FIRST EARL OF CHATHAM. See CHATHAM.

PITT, WILLIAM, the second son of William Pitt, earl of Chatham, and of Lady Hester Grenville, daughter of Hester, Countess Temple, was born on May 28, 1759. He inherited a name which, at the

time of his birth, was the most illustrious in the civilized world. The child's genius and ambition displayed themselves with a rare and almost unnatural precocity. At seven the interest which he took in grave subjects, the ardor with which he pursued his studies, and the sense and vivacity of his remarks on books and on events amazed his parents and instructors. Before the lad had completed his fifteenth year his knowledge both of ancient languages and of mathematics was such as very few men of eighteen then carried up to college. He was therefore sent toward the close of the year 1773, to Pembroke Hall, in the university of Cambridge. At seventeen he was admitted, after the bad fashion of those times, by right of birth, without any examination, to the degree of master of arts.

One of the young man's visits to the House of Lords was a sad and memorable era in his life. He had not quite completed his nineteenth year when, on April 7, 1778, he attended his father to Westminster. A great debate was expected. It was known that France had recognized the independence of the United States. The duke of Richmond was about to declare his opinion that all thought of subjugating those States ought to be relinquished. Chatham had always maintained that the resistance of the colonies to the mother country was justifiable. But he conceived, very erroneously, that on the day on which their independence should be acknowledged the greatness of England would be at an end. Though sinking under the weight of years and infirmities, he determined, in spite of the entreaties of his family, to be in his place. His son supported him to a seat. The excitement and exertion were too much for the old man. In the very act of addressing the peers, he fell back in convulsions.

His eldest son, now earl of Chatham, had means sufficient, and barely sufficient, to support the dignity of the peerage. The other members of the family were poorly provided for. William had little more than \$1,500 a year. It was necessary for him to follow a profession. In the spring of 1780 he came of age. He then quitted Cambridge, was called to the bar, took chambers in Lincoln's Inn, and joined the western circuit. In the autumn of that year a general election took place; and he offered himself as a candidate for the university; but he was at the bottom of the poll. He was, however, at the request of an hereditary friend, the duke of Rutland, brought into parliament by Sir James Lowther for the borough of Appleby.

On February 26, 1781, he made his first speech in favor of Burke's plan of economical reform. Fox stood up at the same moment, but instantly gave way. The readiness and fluency of the youth created a great impression, and called forth the plaudits of both Fox and Burke. On two subsequent occasions during that session Pitt addressed the House, and on both fully sustained the reputation which he had acquired on his first appearance. In the summer, after the prorogation, he again went the western circuit, held several briefs, and acquitted himself in such a manner that he was highly complimented by Buller from the bench, and by Dunning at the bar.

To Pitt was offered, through Shelburne, the vice-treasurership of Ireland, one of the easiest and most highly paid places in the gift of the crown; but the offer was without hesitation declined. The young statesman had resolved to accept no post which did not entitle him to a seat in the cabinet; and a few days later he announced that resolution in the House of Commons. In 1782 Lord Rockingham died and the ministry went to pieces, Fox and Burke resigning. In the new cabinet, Pitt, then only twenty-three years of age, became chancellor of the exchequer. In January, 1783, the pre-

liminary treaty of peace with the new government of the United States was presented, and the Shelburne ministry were beaten and resigned; Pitt going into opposition with his party. After an interregnum of several weeks the famous "coalition" ministry was formed. The duke of Portland was its nominal head; Fox and North secretaries of state with power ostensibly equal, but Fox was the real Prime Minister, although not such in name.

Pitt now turned his attention to the great question of parliamentary reform, in the advocacy of which he seems to have been in earnest, but his proposal for an increase of county and metropolitan members and the disfranchisement of rotten boroughs was half a century too early for the legislature. In November of 1783, the coalition proposed a measure for the government of India, which contemplated the abolition of the East India Company and the transfer of all power to seven commissioners to be named by parliament and not to be removable by the crown. This bill was rejected by the peers at the instance of the king; Fox and North resigned, and Pitt, at the age of twenty-five, became first lord of the treasury and chancellor of the exchequer. At the general election which followed in March, 1784, the supporters of the coalition were routed, horse, foot, and dragoons, and Pitt, returned at the head of the poll for the university of Cambridge, found himself with a solid parliamentary backing which was to support him in office for seventeen long years. He was the favorite at once of the king, the parliament, and the people, and wielded a power greater than that ever held in England by a subject.

The eight years which followed the general election of 1784 were tranquil and prosperous as any in the history of England. Trade increased and manufactures flourished, there was contentment at home and peace abroad. The taxes resulting from the great war debt were heavy, but the people were content to believe that in some mysterious way Pitt's sinking-fund scheme would pay the debt without calling upon the taxpayer for any additional subscriptions. France and Spain were compelled to peace, and even Ireland ceased to disturb the equanimity of the British. But in 1788 King George developed actively his latent mental defect, and the proposition was made by the Whigs that his son should assume the regency with full powers. This Pitt opposed to the utmost, and succeeded in carrying his bill for a limitation of the power of the Regent. However, the king temporarily recovered. At this point, according to Macaulay, Pitt was at the zenith of his power. Not yet thirty years of age, he ruled England by the strength of an overwhelming parliamentary majority, backed by the sentiment of practically the entire people. During the period which elapsed from this date to the stirring times of the 1792 Revolution in France, Pitt did his best work. He made another essay at parliamentary reform, and in connection with Fox he succeeded in passing a law securing to some extent the liberties of the press against arbitrary prosecutions. In 1789 occurred the fall of the Bastille, and this event had a great effect upon the English people. At first the reforms in France were welcomed, but as they became more threatening of vested interests, the Tories, and Pitt with them, grew to be intolerant opponents of what they styled Jacobinism. The reaction against license abroad degenerated into a proscription of liberty at home, and Pitt went with the majority. He may have striven at first to stem the current of intolerance, but he yielded to it at last, and after 1793 he became the leader and director of the retrograde party. He plunged into the war with France, which was to grow into a war against Europe,

and he showed himself absolutely incompetent to manage the army or to save it from continuous defeats. Macaulay says: "The English army under Pitt was the laughing-stock of Europe. The English navy no mismanagement could ruin."

Meantime, in spite of the scores of successive defeats in battle and the enormous drain which the war caused upon the resources of the country, Pitt retained his ascendancy over the House of Commons. There was no want of vigor in his domestic policy, however weak and incapable he might show himself in dealing with the affairs of Europe. Obsolete statutes against sedition were revived, press prosecutions multiplied, and it was only because juries refused to be brow-beaten by Tory judges that men who advocated peaceable reforms escaped the dread penalties which follow a conviction for high treason. In 1798 came the rebellion in Ireland, suppressed with merciless severity. Pitt followed up his military operations against the rebels in the field by his corrupt scheme for the union between England and Ireland, and the extinction of the Irish parliament. By bribery of the most flagrant kind the sworn guardians of Irish liberty were induced to sign away the last vestiges of freedom, and to Pitt belongs all the odium which should attach to the manipulator of this villainous scheme.

It is claimed by his apologists that he intended to accompany the Act of Union by a bill for removing the political disabilities of Roman Catholics, and it is true that he resigned the premiership when the King refused to consent to the bill. Thus after seventeen years of unshackled power Pitt went into retirement, leaving the nation bankrupt in the midst of a war which threatened its very existence.

The new ministry had at its head Henry Addington, a weak man who surrounded himself with mediocrities. He made peace with France, and he abandoned Pitt's repressive domestic policy. Pitt sulked in retirement for many months, but when Napoleon again declared war the "great commoner" was once more called to assume direction of affairs. His second administration was of brief duration and full of disaster. The French were victorious at all points on land, and the Austrian defeat and surrender at Ulm broke Pitt's heart. Four days later the situation was temporarily redeemed by the tremendous naval victory of Trafalgar, but this was offset by the Napoleonic triumph at Austerlitz, followed in December, 1805, by the dissolution of the European coalition. As the new year opened it was evident that Pitt's days were numbered, and on January 23, 1806, he died. The day of his death was the twenty-fifth anniversary of his entry into parliament. He was in his forty-seventh year, and for nineteen years he had ruled England. He was given a public funeral in Westminster Abbey, and the House of Commons voted £40,000 to pay his debts.

Even the fact that although he had for many years enjoyed an income of \$50,000 a year, with an official residence and other advantages, yet had lived and died hopelessly bankrupt, was held to be to his honor. He never married, nor had he any entangling female alliances, had no election bills to pay, and was never known to bestow a penny in charity. But engrossed in his grand task of "managing" the House of Commons, and retaining himself in power, he permitted his servants to rob him in the most scandalous manner. He enjoyed, as a great poet said, the distinction of ruining Great Britain *gratis*, and while his character for honesty was beyond reproach, it yet seems strange that his bigoted adherents should attribute his very carelessness to him as an additional virtue.

Pitt was undoubtedly the greatest Englishman of his

time—the most prominent figure in English history from Cromwell to Gladstone. A Whig by birth, education and instinct, imbued even with liberal notions, as in the case of electoral reform and in the matter of freeing the Roman Catholics from their political disabilities, he yet persecuted pamphleteers who dared to advocate reform measures milder than his own, and became the administrator and obedient servant of a king whose blind and bigoted Toryism amounted to fatuity. He is spoken of as a great financier, probably because he added hundreds of millions sterling to the national debt, and as a successful statesman, it must be supposed, because he held office half his life. Yet he was a man of great talents and honest intentions, eminently qualified for the part of a parliamentary leader. But he was dwarfed by his education; he knew everything of books and nothing of men, and when called upon to face the greatest crisis of modern times he proved himself weak, irresolute, and unable to grasp the situation. We have said that under Pitt the battle record of England shows only one long series of disasters, redeemed solely by Nelson's naval victory, and it was not until after Pitt had passed from power and from life that the innate stubborn fighting qualities of Wellington's troops redeemed the reputation of England.

Pitt's foreign policy was, it is true, forced upon him by George III. and by the aristocracy in whose hands then lay all political power. To them Napoleon was the embodiment of anarchy and plunder; the restoration of the Bourbons to France and the maintenance of the balance of power in Europe the one political end worth striving for. This compelled Pitt to form his coalitions with the despotic Austrian, the barbarous Russian, and the other already condemned reminiscences of feudalism who at that time disgraced the thrones of Europe. At another time and under different auspices the gigantic powers of this phenomenal man might have been utilized to the good not only of England but of the world. As it was he wasted his vast strength in the attempt to bolster up a rotten system and died a broken and unsuccessful man.

PITTA, in Ornithology, from the Teluga *Pitta*, meaning a small bird, Latinized by Vieillot in 1816 (*Analyse*, p. 42) as the name of a genus, and since adopted by English ornithologists as the general name for a group of birds, called by the French *Brèves*, and remarkable for their great beauty. They were sometimes spoken of by English writers as "water thrushes" and "ant thrushes," although there was no evidence of their possession of aquatic habits, or of any special fondness on their part for ants as an article of diet. There are more than fifty species of Pittas in China, India and Australia, and they are abundant in the islands of the Malayan archipelago.

PITTACUS of Mytilene in Lesbos, one of the seven sages of Greece, was born in 651 B.C. About 611 B.C. Pittacus, along with the brothers of the poet Alcæus, overthrew Melanchrus, tyrant of Lesbos. In 589 his fellow-citizens intrusted Pittacus with despotic power for the purpose of protecting them against the exiled nobles, at the head of whom were Alcæus and Antimenides. He resigned the government after holding it for ten years, and died ten years later (569 B.C.)

PITTSBURG is a rising city of the United States, being in Pittsburg township, Mitchel county, Kan., and has grown into wealth and prominence within the past ten years. Its resources, manufacturing, mercantile, and in other particulars, are large in number and importance, and the business transacted is steadily augmenting in volume and value. The city contains public buildings, including schools, churches, and those used for banking and society purposes, several hotels, between

ninety and one hundred substantial commercial houses, roller and planing mills, two foundry and machine shops, two cigar factories, one carriage works, one bottling works, one zinc works, one zinc smelter, one agricultural implement works, gas works, and other facilities for rapid and economical production. The population in 1890 in round numbers approximated 8,000.

PITTSBURGH, the second largest city of Pennsylvania, and the leading iron, steel, and glass manufacturing center of the United States, lies at the confluence of the Allegheny and the Monongahela, which unite here to form the Ohio, 250 miles west-by-north of Philadelphia. The business quarter of the city is built on a nearly level triangular plain, between the two rivers, measuring about three-quarters of a mile on each side back to the hills which rise to the east.

The manufacturing establishments stretch for a distance of seven miles up the Allegheny, seven up the Monongahela, and two down the Ohio, and occupy the strip of low ground usually a few hundred feet broad between the river banks and the hills which generally face them. The slope of the hills to the east of the business quarter is closely built with residences and retail stores for the distance of a mile and a half, but the summits, 400 or 500 feet high, are partially unoccupied. Beyond the hills extends a rolling country which, for a space of about five miles long by two wide is occupied by the villas of the citizens. The hills facing the rivers are generally precipitous, and vary in height from 300 to 600 feet, but at different points they recede from the river banks and afford sites for the suburbs of Lawrenceville (on the Allegheny), Hazlewood, and Birmingham (on the north and south banks respectively of the Monongahela), which are within the municipality of Pittsburgh, and (on the north bank of the Allegheny and Ohio) for the city of Allegheny, which with its separate municipal government, is commercially and socially a part of Pittsburgh. The two cities together cover an irregular space of nine miles between the extreme eastern and western points, with a breadth varying from two to four miles.

From the character of its site, Pittsburgh would naturally be very attractive to the eye, but the free use of the bituminous coal, which was for a long time the principal agent in its development, brought upon it the, at one time, well-deserved epithet of the "Smoky City." Up to a very few years ago a sooty pall, evolved from the factories, rolling-mills, and glass-works, hung over the peninsula upon which Pittsburgh stands. From the hills along the Monongahela all that was visible was a pillar of cloud by day, a pillar of fire by night. The introduction of natural gas for use as fuel in the furnaces, factories, business houses, and even private residences has changed all that. To those who knew Pittsburgh a dozen years ago, and who revisit it at this time, the metamorphosis is wonderful. The really fine public buildings—the municipal hall, the new post-office and United States court house (1884), the new county court house, also built in 1884—present a striking appearance, and the eye is no longer offended by the unsightly discolorations which of old time marked the houses of the business district. Pittsburgh communicates with its sister city of Allegheny and its suburbs on the Monongahela river by means of ten public bridges and four railway viaducts, while six inclined-plane railways afford access to the summits of the hills, Mount Washington, Mount Oliver, and others. Seen from these hills Pittsburgh presents by night or day a most unique and picturesque appearance. The three rivers with their flotilla of steamers and the marked characteristics of the buildings unite to form a panorama of much beauty.

Pittsburgh is of historical interest from the struggle (1755-1758) for its possession between England and France in the Seven Years' War, and the fact that the public and military career of George Washington was commenced with those campaigns (see WASHINGTON). With the termination of that struggle in the capture of the ruins of Fort Duquesne by the British, the history of the place becomes that of an ordinary frontier town. A new fort was erected and named Fort Pitt in honor of the prime minister whose energy had urged the war forward to its capture, and wrested the Ohio valley and Canada from French control. After one or two Indian wars, in which the post was threatened, and on one occasion nearly taken, Fort Pitt lost its military character and became a trading town. The first streets were laid near the fort in 1764, and in 1769 the first survey of the unsettled lands in the vicinity was made for the proprietors, the heirs of William Penn, under the name of the manor of Pittsburgh. After the termination of the revolution, the legislature of Pennsylvania incorporated Pittsburgh as a village on April 22, 1794, and on March 18, 1816, its charter as a city was granted. During the colonial period a dispute arose between Virginia and Pennsylvania as to the possession of the territory surrounding the town, and in the first few years of its history under the United States it attracted attention from its proximity to the famous "Whisky Insurrection" of Western Pennsylvania. After it had attained a population of 30,000, it was visited on April 10, 1845, by a disastrous conflagration, in which the buildings in the business center, covering a space of fifty-six acres, and valued at \$5,000,000, were consumed.

In the Pittsburgh of to-day there is little besides names of streets, hills, and suburbs to recall the struggle which decided the Anglo-Saxon character of the country. The locality known as the Point, where Fort Duquesne stood, is covered with thickly built factories and dingy tenements. In a squalid and obscure court a portion of the wall of a blockhouse erected in 1763 by Colonel Boquet, one of the British commanders of Fort Pitt, still forms a part of a building, and on the wall of the staircase of Municipal Hall is a stone bearing the inscription with which that officer commemorated its erection. Immediately across the Monongahela a range of precipitous hills some 500 feet high bears the names of Mount Washington and Duquesne Heights. On the first hill rising to the east of the level part of the city, a red granite court-house, to cost \$2,000,000, is in process of construction near the spot where Major Grant was defeated and slain, and the new building will replace the brown stone structure which for many years fronted on the street bearing that unfortunate officer's name. Twelve miles away, the suburb long known as Braddock's Field and now as Braddock's, attracts attention chiefly by the roar and glare of its great steel manufacturing establishment.

Deriving its early importance in commerce from its position at the head of the Ohio, which was until 1855 the principal route between the middle States and the west and southwest, Pittsburgh has since obtained its greatest growth from the coal which underlies nearly all Western Pennsylvania. This has made the city and its immediate suburbs the most important manufacturing district in America, in both pig and bar iron and in steel, glass, and copper. The blast furnaces and rolling-mills of Pittsburg employ a capital of \$23,910,000 and 21,190 workmen, the steel industry \$10,170,000 and 7,060 workmen. Next in importance is the glass manufacture, in which seventy-five establishments are engaged, twenty-four making table ware, twenty-four window glass, ten green glass bottles, and nine lamp chimneys. The capital invested in them is \$5,985,000. They em-

ploy 6,442 hands, and the value of their last reported annual production is \$6,832,683. The coal and coke industry of the district, which is controlled mainly by Pittsburgh, comprises a capital of \$26,406,500, employs 23,621 miners and other laborers, and makes an annual output of 7,720,000 tons of coal and 2,760,000 tons of coke, valued at \$16,600,000. The total of all the manufacturing industries of the city is 1,380 establishments, with \$105,401,481 of capital, employing 85,936 workmen of all kinds, and producing to the value of \$149,721,619. The wholesale trade of the city is much less important than its manufacturing industries, and with a few exceptions is confined to the immediate vicinity. It includes ninety firms with an aggregate capital of \$11,206,000 and total sales of \$125,390,472. Within the last few years a new and unique industry has been developed. By drilling in the earth to a depth of 1,200 to 2,000 feet, what is practically the fire-damp of the coal mine is tapped in such quantity that it comes to the surface in great force. It has been found to be useful as a fuel for all the purposes of coal except the smelting of ores in blast furnaces; and, as it is cheaper both for making steam and for the heating of the iron and glass furnaces, its adoption has been general among the manufacturers.

As the railway system has developed, the important boating interest of Pittsburgh has become confined to the transportation of coal from the Monongahela river mines to the down-river cities. The coal is only taken out when freshets have raised the river, and at that time fleets of steamers, each towing from eight to fifteen barges, covering acres in extent and carrying thousands of tons of coal, start down stream.

Pittsburgh is stated to be the origin of more railway freight than any other point in the country. There are a large number of lines, under the control of three great companies. The most important is the Pennsylvania Railroad, whose trunk lines pass through the city, and number among their feeders the West Pennsylvania; the Allegheny Valley; the Pittsburgh, Virginia and Charleston; the Pittsburgh, Cincinnati and St. Louis; the Pittsburgh, Fort Wayne and Chicago; and the Cleveland and Pittsburgh railroads. The Pittsburgh division of the Baltimore and Ohio Railroad gives a connection with that trunk line, and by the Pittsburgh and Western, and the Pittsburgh, Cleveland and Toledo reaches the Chicago branch of the same system to the west. The Pittsburgh and Lake Erie affords the New York Central and the New York, Pennsylvania and Ohio lines an access to Pittsburgh, while its extension under the name of the Pittsburgh, MacKeesport and Youghiogheny penetrates the coal and coke district to the southeast.

In 1796, by the first accurate census on record, the population of Pittsburgh was 1,395. By 1810 it had increased to 4,968; by 1820 to 7,248; by 1830 to 12,452; by 1840 to 21,115; by 1850 to 36,601; by 1860 to 49,221; by 1870 to 86,076. In 1874 the consolidation of outlying boroughs made the population, according to the census of 1870, 121,799; and in 1890 this had increased to 238,617. These figures do not include the population of Allegheny. Including the manufacturing and residential suburbs, the total population by the census of 1880 was 274,160; and, with the large extension of manufacturing and building that has gone on since then, it was estimated in 1890 at 400,000.

The municipal governments of Pittsburgh and Allegheny are each composed of a mayor, controller, and treasurer, with city councils in two branches styled respectively select and common. These are elected by the people, and appoint other administrative officials to take charge of the police and fire departments, assessments, and public works.

The school system of each city is governed by a central board of education and ward boards, both elected by popular vote. The Pittsburgh system comprises a fine stone high school overlooking the city, and fifty-two ward schools, the approximate annual expenditure being \$550,000. In the Allegheny system there are the high school and eighteen ward schools, and an annual expenditure of about \$200,000. The principal institutions established by public taxation are the Riverside State Penitentiary, completed in 1884 in the lower part of Allegheny; the Morganza Reform School; the workhouse at Claremont, on the Allegheny river; and the Pittsburgh, Allegheny and County poorhouses.

The churches and chapels in Pittsburgh and Allegheny number 237.

Private charity has established the West Penn. Hospital with a large branch for the treatment of the insane at Dixmont, the Homeopathic Hospital, the Mercy Hospital, the Pittsburgh Infirmary, the Free Dispensary, the North Side Hospital, and St. Francis Hospital; and eighteen asylums for orphans and the aged and infirm are maintained throughout the two cities. The collegiate institutions comprise the Western University, the Western Theological Seminary (Presbyterian), the United Presbyterian Seminary, the Catholic College, the Pennsylvania Female College, and the Pittsburgh Female College.

PITTSFIELD, a borough and township of the United States, the shire town of Berkshire county, Mass., lies at a height of from 1,000 to 1,200 feet above the sea, on a plain between the Hoosacs on the east, and the Taconics on the west. As the northern terminus of the Housatonic railroad, and a junction on the Boston and Albany, and the Pittsfield and North Adams railroads, it is an important center of traffic. Most of the dwelling houses are built of wood. Among the public edifices are a court-house, in white marble; the Berkshire Athenæum, with a free library and reading-room; the Roman Catholic church of St. Joseph, in marble; the Methodist church, a spacious edifice in brick, the First Congregational church (rebuilt in 1853), for thirty years under the charge of Rev. John Todd, author of the *Student's Manual*; and the Maplewood Institute for young ladies. There is a small park with a fine soldiers' monument (1872) in the heart of the town, as well as a larger park with a race-course in the eastern suburb. Cotton and woolen goods, silk, knit goods, shoes, and tacks are among the local manufactures. The population in 1860 was 8,045; in 1870, 11,132; in 1880, 13,364; in 1890, 17,281.

PITTSSTON, a borough of Luzerne county, Pa., on the east bank of the Susquehanna, just below the confluence of the Lackawanna, 105 miles northwest of Philadelphia. It is the center of the Wyoming anthracite region, and the seat of the Pennsylvania Coal Company's operations, contains knitting mills, planing mills, terra cotta works, a stove factory, lumber yards, etc., and commands four distinct railway lines. The population was 6,760 in 1876, and 7,472 in 1880; 1890, 10,302. If West Pittston (a borough on the other side of the Susquehanna, with which Pittston communicates by two bridges) were included the total would be 15,000.

PIUS I. Hardly anything is known with certainty respecting Pius I., except that he was bishop of Rome from 158 to 167 A.D. He is said to have been born at Aquileia, and to have been the son of a certain Rufinus; it is added that he suffered martyrdom, but, although he is celebrated as a martyr in the breviary, there seems no other evidence for this assertion. A few letters extant under his name are spurious.

PIUS II. (Enea Silvio Piccolomini, commonly known

in literature as Æneas Sylvius), pope from 1458 to 1464, "whose character reflects almost every tendency of the age in which he lived," was born at Corsignano, in the Sienese territory, October 18, 1405. He died August 14, 1464, in his death as in his life a figure picturesque and significant far beyond the wont of Roman pontiffs. He was succeeded by Paul II.

PIUS III. (Francesco Todeschini), pope from September 22 to October 18, 1503, was born at Siena, May 9, 1439. He at once, on his accession to the papal see, took in hand the reform of the papal court, and arrested Cæsar Borgia; but after a brief pontificate of twenty-six days he died (October 18, 1503) of an ulcer in the leg, or, as some have alleged, of poison administered at the instigation of Pandolfo Petrucci, governor of Siena. He was succeeded by Julius II.

PIUS IV. (Giovanni Angelo Medici), pope from 1559 to 1565, was born of humble parentage at Milan, March 31, 1499. One of his strongest passions appears to have been that of building, which somewhat strained his resources in contributing to the adornment of Rome, and in carrying on the work of restoration, erection, and fortification in various parts of the ecclesiastical states. A conspiracy against him, headed by the Catholic fanatic Benedetto Accolti, was discovered and crushed in 1565. He died shortly afterward, on December 9th of that year, and was succeeded by Pius V.

PIUS V. (Michele Ghislieri), pope from 1566 to 1572, was born at Bosco in the duchy of Milan. January 17, 1504.

PIUS VI. (Giovanni Angelo Braschi), pope from 1775 to 1799, was born at Cesena, December 27, 1717. The circumstances of his election involved him in difficulties from the outset of his pontificate. General Berthier marched to Rome, entered it unopposed on February 10, 1798, and, proclaiming it a republic, demanded of the pope the renunciation of his temporal authority. Upon his refusal he was taken prisoner, and on February 20th was escorted from the Vatican to Siena, and thence from place to place—in succession to Florence, Parma, Piacenza, Turin, Grenoble, and Valence, where he died six weeks later, on the night of August 28, 1799. Pius VII. succeeded him.

PIUS VII. (Gregorio Luigi Barnaba Chiaramonti), pope from 1800 to 1823, was born at Cesena on August 14, 1742. At the death of Pius VI. the conclave met at Venice on December 1, 1799, with the result that Chiaramonti was declared his successor on March 14, 1800, and crowned on the 21st of that month. Encouraged by the intimation through Cardinal Martiniana of Napoleon's desire for the reestablishment of the Catholic religion in France, Pius appointed Caselli and Archbishop Spina to arrange a concordat with three nominees of Napoleon—Joseph Bonaparte, Cretet, and the Vendean priest Bernier. Difficulties having arisen, the aid of Consalvi was called in, and the concordat, signed at Paris on July 15th, was ratified by Pius on August 14, 1801. Its value, however, from the pontifical point of view was considerably lessened by the "Articles Organiques" appended to it by the French Government on April 8, 1802. In 1804 Napoleon opened negotiations to secure at the pope's hands his formal consecration as emperor. After some hesitation Pius was induced to perform the ceremony at Notre Dame and to extend his visit to Paris for four months. He returned to Rome on May 16, 1805, with many expressions of good will; but in the October following the French troops, in evacuating the kingdom of Naples, suddenly occupied Ancona upon the alleged necessity of protecting the Holy See. Resistance by force was out of the question, but to a requisition from

the emperor that all Sardinians, English, Russians, and Swedes should be expelled from the pontifical states, and that vessels of all nations at war with France should be excluded from his ports, Pius replied by asserting the independence and neutrality of his realm. After negotiations had dragged on for two years, in the course of which the French occupied the chief Adriatic ports, Civita Vecchia was seized and the papal troops placed under French officers. On February 2, 1808, Rome itself was occupied by General Miollis; a month later the provinces of Ancona, Macerata, Fermo, and Urbino were united to the kingdom of Italy, and diplomatic relations between Napoleon and Rome were broken off; finally, by a decree issued from Vienna on May 17, 1809, the emperor declared the papal states reunited to France by resumption of the grant of Charlemagne. Pius retaliated by a bull, drawn up by Fontana and dated June 10, 1809, excommunicating the invaders; and, to prevent insurrection, Miollis—either on his own responsibility, as Napoleon afterward asserted, or by order of the latter—employed General Radet to take possession of the pope's person. The palace on the Quirinal was broken open during the night of July 5th, and, on the persistent refusal of Pius to renounce his temporal authority, he was carried off, first to Grenoble, thence after an interval to Savona, and in June, 1812, to Fontainebleau. There he was induced, on January 25, 1813, to sign a new concordat, which was published as an imperial decree on February 12th. In conference with the cardinals, however, Pius withdrew his concessions and proposed a concordat upon a new basis. At first no attention was paid to this, and, when after the French armies were driven from Germany Napoleon endeavored to purchase a new concordat by offering to restore the papal possessions south of the Apennines, Pius refused to treat with him from any place other than Rome. The order for his departure thither reached him on January 22, 1814, and after a brief delay at Cesena he entered Rome on May 24, 1814. With his states restored to him by the congress of Vienna and freed from the Napoleonic terror, he devoted the remainder of his life to social and ecclesiastic reform in accordance with the modern spirit. His thigh having been broken by a fall in July, 1823, acute inflammation supervened, and he died on August 20th in that year. His successor was Leo XII.

PIUS VIII. (Francesco Xaviero Castiglioni), pope in 1829–30, was born at Cingoli November 20, 1761. His death took place at Rome on November 30, 1830. He was succeeded by Gregory XVI.

PIUS IX. (Giovanni Maria Mastai Ferretti), pope from 1846 to 1878, was born May 13, 1792, at Sinigaglia, near Ancona, the fourth son of Count Jerome and the Countess Catherine Vollazi of the same place.

On the death of Gregory XVI., he repaired to Rome, and on the evening of June 16, 1846, was elected to the papal chair as Pius IX., having chosen this name out of respect for his predecessor in the see of Imola, Pius VII. His election, at the final scrutiny, proved to be unanimous, the cardinals Patrizzi and De Angelis throwing all their influence in his favor. On the following morning, when it was too late, the Austrian ambassador received instructions from his government to veto the new pope's election.

Pius' first act in his new capacity was to proclaim a general amnesty for political offenses, whereby thousands of unhappy beings who had dragged out weary years in prison or in exile, ignorant, many of them, even of the offenses with which they were charged, were restored to society. With genuine catholicity of feeling he visited and relieved even the poor Jewish population in the city. He authorized the construction

of railways, organized a civil guard, and considerably modified the restrictions on the press. In order to develop further reforms he instituted a commission largely composed of laymen; and in 1847 he brought forward his scheme of a *Consulta*, or council of state, designed to assist him in the general temporal government. But, notwithstanding these concessions, the supreme power remained in the hands of ecclesiastics, and no measure passed by the council could acquire validity until it had been examined and approved in a conclave of cardinals. Hence, although both MAZZINI (*q.v.*) and Garibaldi were among his avowed supporters, the liberal party were still far from satisfied. His policy was regarded, on the one hand, with extreme dissatisfaction by Austria, and on July 17, 1847, that power sent a force of 1,500 men into Ferrara, where she was entitled by the treaty of 1815 to maintain a garrison. To this direct menace Pius replied by counter demonstrations and an indignant protest, but hostilities were ultimately averted. His policy was viewed with not less dislike at the court of Naples, but by the rest of Italy and throughout Europe he was at this time regarded as the champion of the national rights of his countrymen. Such was the posture of affairs when the revolution in Paris (February, 1848), fanned into flames the already smoldering elements of insurrection throughout Europe. The Austrians were driven out of Milan; a republic was proclaimed in Venice (see ITALY); and a "free Italy" became the general cry. At first Pius, who felt but little sympathy with the views represented by the son of Philippe Égalité, seemed disposed to head the movement.

A new ministry was formed, which, with two exceptions (Antonelli and Morichini), was composed of laymen. But at this juncture Pius began to waver. Although he had hitherto shown no sympathy with the Jesuits, he endeavored to protect them against the measures now brought forward with a view to their expulsion, and when his general, Durando, crossed the Po without his orders, and denounced the Austrians as "the enemies of the cross of Christ," he disowned, in an allocution (April 29th), all intention of participating in an offensive war for the purpose of rectifying the boundaries of Italy, and at the same time disavowed all complicity in the schemes then in agitation for creating an Italian federal republic, with himself as a nominal head. This apparent desertion of the national cause, at a time when the public mind had been roused to the highest pitch of excitement by the course of events at other centers, created an irreparable breach between Pius and the people. His new chief minister, Mamiani, who wished to see him a constitutional monarch, advocated further concessions—the handing over of the political government to the new assemblies and a responsible ministry. But after the Austrian successes in the north and Radetsky's entry into Milan (August 5th), Mamiani was dismissed, and his place was filled by Count Rossi, the French ambassador, a statesman of signal ability and intrepid character, but of conservative views. On November 15, 1848, as Rossi was alighting at the steps of the house of assembly, he was assassinated in broad daylight. It was an ominous symptom of the prevailing temper of the capital that this atrocious act elicited no expression of disapproval in the assembly, and drew forth no marks of sympathy with the victim's family. Two days later a numerous mob, largely composed of disbanded soldiers, assembled in the square of the Quirinal, and proffered fresh demands, at the same time intimating their intention, if these were not conceded, of commencing a general massacre of the inmates, excepting only the pope himself. After his secretary, Palma, had

been shot by an assassin, Pius, in order to avert further bloodshed, made the requisite concessions, and assented to the formation of a new ministry, while he himself was made a virtual prisoner. On November 24th he effected his escape, with the connivance of the French Government, to Gaeta, disguised as a dependant of Count Spaur, the Bavarian minister. Thus terminated what has been described as "the first and only attempt of a pope to govern in a liberal spirit."

The decisive defeat of the Sardinian forces at Novara by Radetsky (March 23, 1849), encouraged the papal party now to demand that Pius should be reinstated at Rome without any conditions being attached to his restoration. This demand created a divergence of opinion among the chief Catholic powers; eventually General Oudinot landed at Civita Vecchia with 10,000 French soldiers, and De Tocqueville, the French minister for foreign affairs, sought to induce Pius to resume his sovereignty on the basis of the *Statuto Fondamentale*. This he resolutely refused to do, and after the occupation of Rome by Oudinot's forces he was permitted to return (April 12, 1850), unfettered by any condition whatever.

Pius returned an altered man in relation to his state policy, in which, in fact, he was from this time guided almost entirely by Antonelli.

From the reduction of Ancona (1860), to the year 1870 Pius was maintained in Rome only by a French garrison. The emperor of the French was reluctant to appear altogether to desert the papal cause, while Cavour was unwilling, in like manner, to proceed to extremities. After the capture of Garibaldi at Aspromonte, however, Victor Emmanuel felt himself strong enough to put in a formal claim for Rome; and it was eventually arranged, by the convention on September 15, 1864, that the French should withdraw from the city before the end of 1866. This stipulation was duly observed, and on December 11, 1866, the last of the French forces quitted the capital. The engagement was, however, virtually violated by the entry, in the following year, of the Antibes legion, and for some time longer the French soldiery continued to ward off both the daring assaults of Garibaldi and the more insidious approaches of Ratazzi. In this manner, at the outbreak of the war of 1870, France had come again to be looked upon as the ally of the papacy; and the overweening claims put forward by Pius in convening a general council to proclaim the dogma of Papal Infallibility were generally interpreted as in a certain sense correlative with the aggressive designs of France on Protestant Germany. The dogma was decreed in the Vatican on July 18th, but not without strenuous opposition on the part of some of the most distinguished members of the Catholic episcopal order, who, at the same time, were staunch supporters of the temporal power (see OLD CATHOLICS). At nearly the same time the occupation by the French came definitively to an end. Their forces were withdrawn from Civita Vecchia at the outbreak of the war, when the Duc de Gramont announced that his Government relied on the convention of 1864, whereby Italy was bound not to attack the papal territory. That territory, being now, however, again exposed to the dangers of revolution, Victor Emmanuel, on receiving the tidings of the battle of Gravelotte, notified Pius that "the responsibility of maintaining order in the peninsula and the security of the Holy See" had devolved upon himself, and that his army must enter the pontifical dominions. This intimation was received by Pius with demonstrations of the liveliest indignation, but the appearance of the Sardinian troops was hailed by his own subjects with enthusiasm. On arriving outside Rome, General Cadorna summoned

the garrison to surrender, and after a short bombardment the white flag was hoisted. On the following day (September 21, 1870), the Zouaves, some 9,000 in number, after receiving, as they stood massed in the square of St. Peter's, the pontifical blessing, marched out of Rome, and the temporal power of the pope had ceased to exist.

For the rest of his days Pius IX. remained unmo-  
lestated at the Vatican, while the king resided at the Quirinal. The pontiff was virtually a prisoner; and his position, although viewed with comparative indifference in Rome, was regarded with not a little sympathy by the Catholic world at large.

Pius died February 8, 1878, and was succeeded by Cardinal Pecchi as Leo XIII.

PIZARRO, FRANCISCO, discoverer of Peru, and principal hero of its conquest, born at Truxillo in Estremadura, Spain, about the year 1471, was an illegitimate son of Gonzalo Pizarro. Of Pizarro's early years hardly anything is known. Shortly after the news of the discovery of the New World had reached Spain he was in Seville, and thence found his way across the Atlantic; there he is first heard of in 1510. On March 10, 1526, Pizarro, Almagros and Luque made compact to conquer and divide equally among themselves the great Southern empire still undiscovered, and Pizarro and Almagro, with a force of about 160 men, sailed from Panama. The force was too small to effect much at the time, and was at length recalled by the governor, but Pizarro was not to be shaken, and, though he was left for months with but thirteen followers on a small island without ship or stores, persisted in his enterprise till at length he had coasted as far as to about 9° S. latitude and obtained distinct accounts of the Peruvian empire. The governor still showing little disposition to encourage the adventurers, Pizarro resolved to apply to the sovereign in person for help, and with this object sailed from Panama for Spain in the spring of 1528, reaching Seville in early summer. After long and tedious delays, the queen, in Charles' absence, executed at Toledo on July 26, 1529 the famous *capitulation* by which Pizarro was upon certain conditions made governor and captain-general of the province of "New Castile" for the distance of 200 leagues along the newly discovered coast, and invested with all the authority and prerogatives of a viceroy. Sailing from San Lucar clandestinely (for his due complement was not yet made up) in January, 1530, Pizarro was afterward joined by his brother Hernando with the remaining vessels, and when the expedition left Panama in January of the following year it numbered three ships, 180 men, and twenty-seven horses. A footing was established on the mainland at Tumbes, whence Pizarro set out for the interior in May, 1532. San Miguel de Piura was founded a few weeks afterward, and Caxamarca entered on November 15th. The subsequent movements of Pizarro belong to the history of PERU, (*q.v.*) He died in 1541.

PLAGUE (*λοιμός, Pestis, Pestilentia*). This name has been given to any epidemic disease causing a great mortality, and in this sense was used by Galen and the ancient medical writers, but is now confined to a special disease, otherwise called Oriental, Levantine, or Bubonic Plague, which may be shortly defined as a specific febrile disease, transmissible from the sick to healthy persons, accompanied usually by buboes and sometimes by carbuncles. This definition excludes many of the celebrated pestilences recorded in history—such as the plague of Athens, described by Thucydides; that not less celebrated one which occurred in the reign of Marcus Aurelius and spread over nearly the whole of the Roman world (164–180 A.D.), which is referred to, though not fully described, by the contemporary

pen of Galen; and that of the third century (about 253), the symptoms of which are known from the allusions of St. Cyprian (*Sermo de Mortalitate*). There is a certain resemblance among all these, but they were very different from Oriental plague.

*Symptoms.*—There are two chief forms:—(1) mild plague, *pestis minor*, larval plague (Radcliffe), *peste fruste*, in which the special symptoms are accompanied by little fever or general disturbance; and (2) ordinary epidemic or severe plague, *pestis major*, in which the general disturbance is very severe. Cases which are rapidly fatal from the general disturbance without marked local symptoms have been distinguished as fulminant plague (*pestis siderans, peste foudroyante*).

1. In the minor form of the disease spontaneous swellings of the glands occur, chiefly in groins and armpits, but also in neck or other parts, which either undergo resolution or suppurate. There is a certain amount of fever; the temperature is rarely high, but has been known to be 104° Fahr. The duration of the disease is ten to twenty days usually, but may be eight weeks, for most of which time the general health is little impaired and the patient is able to go about as usual. It rarely, if ever, causes death, the only fatal case at Astrakhan in 1877 having been so through a complication.

2. As regards *pestis major*, or severe plague, the early symptoms are sometimes like those of ague (shivers, often long continued, and pains in the limbs), but combined with nervous symptoms. The patient becomes distracted, tosses about in constant fear of something he cannot describe, has a difficulty in understanding the questions put to him, and is slow in answering. He is often described as staggering like a drunken man. There is severe headache, intense thirst, and severe pain in the epigastrium. The eyes are red and turbid; the tongue swollen, dry and fissured, sometimes black, sometimes remarkably white (Colvill). This condition may pass into coma even before fever sets in. In other cases bilious vomiting is the earliest symptom. The fever which sets in may last twenty-four to thirty hours, or more. The temperature may be 100° to 107° Fahr., or even higher; but in the most rapidly fatal cases there may be little or no fever. Generally there is obstinate constipation, but sometimes diarrhoea. Besides these symptoms there are certain special ones especially characteristic of plague.

(a) Buboes or glandular swellings are observed in all except very rapidly fatal cases. They occur in 45 or 50 per cent. of the cases in the groin, in 35 per cent. in the axilla, also less frequently in the neck or other parts. These swellings may occur before the fever, simultaneously with it, or some hours after it has set in. A sudden pain like that of a stab is felt in some region of the body, which has given rise to the superstition that the unfortunate victim was wounded by the arrow of an invisible demon—a belief recorded in Constantinople in the sixth century, and said still to survive in Mohammedan countries. The buboes may suppurate, and free discharge of matter from them has in all times been held to be a favorable sign and conducive to recovery.

(b) Carbuncles were observed in about 2½ or 3 per cent. of the cases in recent epidemics in Irak. They are always an unfavorable sign.

(c) Petechiæ or hemorrhagic spots on the skin have always been regarded as signs of the worst omen. Under the name of "tokens" they were considered in the English epidemics of the sixteenth century as the infallible signs of approaching death. "They appear generally only a few hours before death" (Colvill). Hodges (1665) noticed hardness which showed the existence of hemorrhage under the skin. The skin is

sometimes so covered with petechiæ as to become of a dark livid hue after death, recalling the name Black Death (Cabiadis).

*Incubation.*—It is a very important question what time may elapse between a person receiving the poison and showing symptoms of the disease. The usual time of incubation appears to be from three to five days. In certain very malignant epidemics this period may be shortened, and, it is thought, reduced to even less than a day. In rare cases incubation may be prolonged to eight days. There are doubtful accounts of ten days' incubation. Generally a week's observation would show whether a suspected person was really affected or no. It has been thought that articles contaminated by contact with plague patients may retain the power of communicating the disease for weeks, months, or even years; but of this there is no adequate proof.

*Treatment.*—No special line of treatment has proved efficacious in checking the disease once established. Special symptoms are treated in accordance with the ordinary rules of practice, and need not here be considered. Free ventilation appears to be of the greatest service in preventing the spread of the disease, and probably in promoting recovery.

*Prevention.*—There can be no doubt whatever of the efficacy of hygienic measures in rendering a locality unsuitable for the spread of plague. Such measures include, not only personal cleanliness, but especially the removal of all foul organic matters, good drainage, and prevention of overcrowding; all such measures might be looked upon by our readers generally as matters of course, but are quite unknown in most of the homes of plague. Since there is no doubt that plague may be carried from places where it prevails epidemically, measures to prevent such importation cannot be neglected. The best known of such measures is the system of quarantine first produced about 1480. The efficiency of quarantine has been much discussed, and very strong opinions have been expressed for and against it. The subject is too large for discussion here; but it would appear that, while the system as originally applied in the Mediterranean, when traffic was comparatively slow and infrequent, and when European cities presented an extremely favorable soil for plague if introduced, was a real protection, the regulations have long ceased to correspond to the actual state of medical knowledge; and, in addition, it would be impossible to apply them to our crowded traffic. The alternative is a system of medical inspection of all arrivals in our ports, and strict isolation of ships in which plague has occurred or is suspected. Such a ship should then be treated as an infected house.

*History of the Plague.*—The first historical notice of the plague is contained in a fragment of the physician Rufus of Ephesus, who lived in the time of Trajan, preserved in the *Collections of Oribasius*.

It is not till the sixth century of our era, in the reign of Justinian, that we find bubonic plague in Europe, as a part of the great cycle of pestilence, accompanied by extraordinary natural phenomena, which lasted fifty years.

It is impossible to pass over the great cycle of epidemics in the fourteenth century known as the Black Death. Whether in all the pestilences known by this name the disease was really the same may admit of doubt, but it is clear that in some at least it was the bubonic plague.

In the fifteenth century the plague recurred frequently in nearly all parts of Europe. In the first quarter it was very destructive in Italy, in Spain (especially Barcelona and Seville), in Germany, and in England, where London was severely visited in 1400 and 1406, and again in 1428.

The sixteenth century was not more free from plague than the fifteenth. Simultaneously with a terrible pestilence which is reported to have nearly depopulated China, plague prevailed over Germany, Holland, Italy, and Spain in the first decade of the century, and revived at various times in the first half. In 1529 there was plague in Edinburgh; in London in 1537-39, and again in 1547-48; and also in the north of England, though probably not absent before.

The epidemic of 1563-64 in London and England was very severe, a thousand dying weekly in London. In Paris about this time plague was an everyday occurrence, of which some were less afraid than of a headache (Borgarucci). In 1570, 200,000 persons died in Moscow and the neighborhood, in 1572, 50,000 at Lyons; in 1568 and 1574 plague was at Edinburgh, and in 1570 at Newcastle.

In the first half of the seventeenth century plague was still prevalent in Europe, though considerably less so than in the Middle Ages. In the second half a still greater decline is observable, and by the third quarter the disease had disappeared or was disappearing from a great part of western Europe.

In 1656 one of the most destructive of all recorded epidemics in Europe raged in Naples; it is said to have carried off 300,000 persons in the space of five months. It passed to Rome, but there was much less fatal, making 14,000 victims only—a result attributed by some to the precautions and sanitary measures introduced by Cardinal Gastaldi.

*The Great Plague of London.*—The preceding enumeration will have prepared the reader to view the great plague of 1664-65 in its true relation to others, and not as an isolated phenomenon. The preceding years had been unusually free from plague, and it was not mentioned in the bills of mortality till, in the autumn of 1664 (November 2d), a few isolated cases were observed in the parishes of St. Giles and St. Martin's, Westminster, and a few occurred in the following winter, which was very severe. About May, 1665, the disease again became noticeable, and spread, but somewhat slowly. Boghurst, a contemporary doctor, notices that it crept down Holborn and took six months to travel from the western suburbs (St. Giles) to the eastern (Stepney) through the city. The mortality rapidly rose from 43 in May to 590 in June, 6,137 in July, 17,036 in August, 31,159 in September, after which it began to decline. The total number of deaths from plague in that year, according to the bills of mortality, was 68,596, in a population estimated at 460,000, out of whom two-thirds are supposed to have fled to escape the contagion. This number is likely to be rather too low than too high, since of the 6,432 deaths from spotted fever many were probably really from plague, though not declared so to avoid painful restrictions. In December there was a sudden fall in the mortality which continued through the winter; but in 1666 nearly 2,000 deaths from plague are recorded.

After 1666 there was no epidemic of plague in London or any part of England, though sporadic cases appear in bills of mortality up to 1679; and a column filled up with "o" was left till 1703, when it finally disappeared.

The last outbreak of plague on European soil was that of 1878-79 on the banks of the Volga, which caused a panic throughout Europe.

PLAICE (*Pleuronectes platessa*), a species of Flatfish, common on the coasts of northern Europe from Iceland to the Bay of Biscay. It is readily recognized by the yellow or orange-colored spots which are placed in a row along the dorsal and anal fins, and scattered over the body.

PLAINFIELD, located in Union county, N. J., is a

city in which beauty of location and other natural advantages have served to attract as residents a large number whose places of business are in New York city, Brooklyn, etc. It is situated on the Central Railroad of New Jersey, eleven miles north of New Brunswick, twelve miles west-southwest of Elizabeth, and twenty-five miles in the same direction from New York. It contains fifteen churches, two national and one savings bank, several public school buildings, a young ladies' seminary, two weekly papers, upward of 150 stores, and manufactures of carpets, clothing, cigars, oilcloth, hats, carriages, machinery, extracts, sash, tools, printing presses, etc.; also dye, electric light, and gas works. It is separated from North Plainfield by Green Brook, and in 1890 contained a population of 11,267.

PLAIN SONG, or PLAIN CHANT (*Gregorian Music*; Lat., *Cantus planus*; Ital., *Canto Gregoriano*; Fr., *Plain Chant*), a style of music, easily recognized by certain strongly-marked characteristics, some very ancient fragments of which are believed to have been in use under the Jewish dispensation from a remote period, and to have been thence transferred to the ritual of the Christian church.

PLANARIANS. The name *Planaria* was first applied by O. F. Müller in his *Prodromus Zoologie Danica* (1776) a group of worms, inhabitants of fresh and salt water, characterized so far as was then known, by a flattened leaf-like form. Ehrenberg in 1831 changed this name to *Turbellaria* on account of the cilia with which the body is furnished by means of which the worms create a whirlpool in the surrounding water. The extent of this group was subsequently more restricted, and at present the name *Turbellaria* is applied to all those (mainly free-swimming) Platyhelminths whose body is clothed externally with a ciliated epidermis, and which possess a mouth (with the exception of one division) an alimentary canal, but are without an anus. The *Turbellarians*, excluding the NEMERTINES, (*q.v.*), which until recently were classed with them, form an order of the class *Platyhelminthes*, and the old name *Planaria* is now confined to a group of the fresh-water representatives of this order.

*Size and External Characters.*—Many forms of the Turbellarians are so minute as to be hardly visible with the naked eye, while others attain to a length of several inches, and a land Planarian of no less than nine inches in length has been described by Moseley. The fresh water forms are generally small, the largest representatives of the order being marine or terrestrial. The smaller species are mostly cylindrical, or convex dorsally and flat ventrally; the anterior extremity is commonly truncated and the posterior extremity pointed. The larger aquatic forms are thinner in proportion to the increasing surface of the body, so that they come to resemble thin leaf-like lamellæ while the large land Planarians instead of increasing in superficies grow in length, so that they may be best compared to leeches. The larger aquatic forms are frequently provided with tentacles in the shape of paired finger-like processes or ear-like folds of the anterior part of the body; sometimes the tentacles are papillary outgrowths of the dorsal surface; the land Planarians are often to be distinguished by a crescent-shaped area at the fore end of the body, which is separated off from the rest. In many cases the whole dorsal surface is beset with papillæ. The aperture of the mouth varies greatly in its position; sometimes it is situated at the anterior extremity, sometimes in the middle of the ventral surface of the body, occasionally quite close to the posterior extremity; the single common or distinct male and female generative aperture are also situated

upon the ventral surface of the body, and the former in rare cases open in common with the mouth; the genital apertures always lie behind the mouth. Many Turbellarians have a sucker which serves to attach the animal to surrounding objects, or to another individual during copulation.

PLANCK, GOTTLIEB JAKOB, theologian and church historian, was born at Nürtingen in Württemberg, where his father was a notary, on November 15, 1751. His death took place on August 31, 1833.

PLANE-TREE, a forest tree of the genus *Planus*, and generally known as the buttonwood. It has also been mentioned as the Sycamore-tree (but this is disputed by some), and classed with the bread-fruit species, from its suggestive resemblance thereto. The Plane-tree proper is recognized by its broad leaves, globular fruit, and watery juice. The infant leaves are covered with a layer of down which is dissipated with its growth. When inhaled it has the effect of causing a disagreeable cough. The catkins, male and female, are globular in shape and of small dimensions. The flowers are equally diminutive, being almost imperceptible. The stamens are numerous, the seeds small, and the bark of the tree is comparatively tender. The plane is regarded with great favor as a shade-tree and grows to great size, the oriental species (*Platanus Orientalis*) for example, rising to the height of nearly 100 feet. It is a native of the east. The buttonwood of the United States (*P. Occidentalis*) is a tree of massive proportions at the base, gracefully tapering from the ground up, and attaining the height of from 70 to 100 feet. It is to be found at all points in the United States, also as far north as Montreal, Canada, and is generally to be found near the water; the banks of western rivers particularly being favored, where the tree grows rapidly and luxuriantly. The leaves are large, the foliage is heavy, the bark astringent, and the wood, when grown on dry soil, invaluable as fuel. The leaves have also been considered a specific for the poison of serpents. The California plane (*P. racemenses*) is indigenous to the Pacific coast, and is distinguished from other varieties by the singular appearance its long pendular racemens create. The wood is far better than that of the occidental plane.

PLANTAGENET. This surname, distinctive of a line of kings who ruled in England for more than three hundred years, was first adopted by Geoffrey, count of Anjou, in reference to a sprig of broom (*planta genista*) which he is said to have worn in his bonnet. He became the husband of Henry I.'s daughter Maud, and through her the progenitor of the dynasty of the Plantagenets. The Plantagenets succeeded to the throne in the person of Henry II.

Henry, the son of Geoffrey of Anjou and the empress Maud, was born at Le Mans in the year 1133, and was just twenty-one years of age when he attained the crown. Personally a man of fiery temperament and strong passions, his patience as a politician is remarkable. Bit by bit he built up a strong empire, and even kept the pretensions of the church within definite and reasonable bounds. But a single angry word undid the work of years. He was responsible for Becket's murder. He had to do penance and make his peace with the church, and to humiliate himself before Becket's grave.

His dynastic policy seemed almost an equal failure, but was productive of wide and far-reaching consequences. His ungrateful sons rebelled against him, and when he heard that even John had joined the confederacy he felt that he had nothing more to live for. His eldest son, Henry, whom he had been so anxious to make a king during his own life, sickened and died in

Covered Cup of solid gold, 6 inches high, circa 1660-70.

—Ancient Gold Phiale, found at Agrigentum, now in the British Museum. It is shown in section below. It is 5 inches in diameter.

—Silver Cup, 8½ inches high, usually attributed to Jamnitzer, but more probably by Paul Flint. Made at Nuremberg about the middle of the 16th century. (S. K. M.)

—Silver Cup, 4¾ inches high, with embossed gold band; found in a grave in the east of Seeland (Denmark). This cup dates from the earlier part of the Iron Age.

—Greek Silver Vase, 5 inches high, c. 4th century B.C.

Silver Crater, found in Ithaca. 3 3/4 inches high.

Silver Crater, 15 1/2 inches high, from Hildesheim

Sasanian Gold Bottle, about 10 inches high.

Gold Ewer, 15 inches high, from the Petrossa treasure

FIG. 14.—Silver Cup, with translucent enamels. Probably French work of the 14th century.

FIG. 15.—Silver-gilt Salt-cellar, 14 1/2 inches high. Given to New College, Oxford

—Silver Beaker, decorated with open work, filled in with translucent enamels. German or Flemish, of the 15th century. (S. K. M.)

France after flagrant acts of ingratitude and impiety. Geoffrey, to whom he had secured the duchy of Brittany, soon followed his brother; and there remained but Richard and John, besides three daughters, who were all disposed of in marriage to Continental princes. As Richard, though he came to the crown, also died without legitimate issue, the male line was continued in the two sons of John, Henry III. and Richard, king of the Romans, and the issue of the latter became extinct in the next generation.

The time of Edward III. with his great family was the climax in the fortunes of the house of Plantagenet. Nor need we pursue the family history further, as the story of its descent after the days of Edward III. will be found sufficiently treated elsewhere (see LANCASTER, HOUSE OF, and YORK, HOUSE OF).

Of the alliances of this great dynasty the most important after the days of Henry II. were those of the house of Lancaster. Henry III. married his daughter Margaret to Alexander III. of Scotland, and another daughter to the duke of Brittany. Edward I. had for his son-in-law Gilbert de Clare, earl of Gloucester, the duke of Brabant, and the earl of Holland. A daughter of Edward II. married a duke of Gueldres. But "the aspiring blood of Lancaster" spread itself over Europe by alliances with Castile and Portugal, Navarre and Denmark, Bavaria and other foreign states. It has reigned in Portugal to the present day, and it continued to reign in Spain till the end of the 17th century.

PLANTAIN (Lat. *plantago*), a name given to plants with broad palm-like leaves. This is the case with certain species of *Plantago*, *Alisma*, and *Musa*, to all of which the term is popularly applied.

PLANTAIN-EATER. See TOURAKOO.

PLANTIN, CHRISTOPHE, French publisher, born in a village near Tours (probably Saint-Avertin) in 1514, learned book-binding and book-selling at Caen, and, having married in that town, settled in 1549 as a bookbinder in Antwerp. He died in 1589.

PLANTING. See ARBORICULTURE.

PLASENCIA, a city of Spain and an episcopal see, in the north of the province of Caceres (Estremadura), is pleasantly situated on the right bank of the Xerte or Jerte, a sub-tributary of the Tagus, and at the foot of the sierras of Bejar and Vera, continuations of the Guadarrama range.

PLASTER OF PARIS. See GYPSUM.

PLATA, LA. See ARGENTINE REPUBLIC.

PLATA, RIO DE LA. See PLATE RIVER.

PLATÆA, or PLATÆÆ, a celebrated city of ancient Greece, lay at the foot of the northern slope of Mount Cithæron in Bœotia, about six and one-half miles by road south of Thebes, or a little over five geographical miles in a direct line. Its territory was separated from that of Thebes by the river Asopus. The Thebans claimed to have founded Platæa, but, however this may have been, Platæa was always at feud with its more powerful neighbor. In 519 B.C. the Platæans, being hard pressed by Thebes, applied for help to the Spartan king Cleomenes, who advised them to place themselves under the protection of Athens. They did so, and Athens and Platæa were thenceforward fast friends.

PLATE. The word *plate* (connected with the Greek flat, the late Latin *plata*=*lamina*, and the Spanish *plata*, silver) is usually employed to denote works in silver or gold which belong to any class other than those of personal ornaments or coins.

On account of the ease with which it can be worked and the pure state in which it is generally found, it is probable that gold was the first metal used by man; and it is certain that, in some countries at least, he attained

to the most marvelous skill in its manipulation at a time when the other arts were in a very elementary condition. The use of silver appears to belong to a rather later period, probably because, though a widely spread metal in almost all parts of the world, it is usually found in a less pure state than gold, and requires some skill to smelt and refine it. Though both these precious metals were largely and skillfully used by prehistoric races, they were generally employed as personal ornaments or decorations for weapons. Except in Scandinavian countries but little that can be called "plate" has been discovered in the early barrows of the prehistoric period in western Europe.

*Ancient Egypt.*—An enormous amount of the precious metals was annually brought as tribute to the Egyptian kings; according to Diodorus, who quotes the authority of Hecataeus, the yearly produce of the royal gold and silver mines amounted to 32,000,000 of minæ—that is, about \$765,000,000 of American modern money. Though this estimate is probably an exaggeration, the amount must have been very great. The gold chiefly came from the mines in the Bishári desert, about eighteen days' journey southeast of Kum Ombos. These mines were constantly worked down to the time of the Arab caliphs, but now appear to be exhausted. It is not known where the silver came from.

The chief existing specimens of Egyptian plate are five silver *phialæ* or bowls, found at the ancient Thumuis in the Delta, and now in the Bulak Museum (Nos. 482 to 486 in the catalogue). These are modeled in the form of a lotus blossom, most graceful in design, but are apparently not earlier than the fifth century B.C.

*Assyrian and Phœnician Plate.*—Among the many treasures of early art found by General Cesnola in the tombs of Cyprus none are of more interest than a large number of Phœnician silver *phialæ* or saucer-like dishes, enriched with delicate repoussé and tooled reliefs, which in their design present many characteristics of Assyrian art mingled with a more or less strong Egyptian influence. A considerable number of bowls and *phialæ* found in Assyria itself are so exactly similar to these Cyprian ones, in both shape and ornamentation, that they cannot but be classed together as the production of the same people and the same age. The British Museum possesses a fine collection of these bowls, mostly found in the palace at Nimrud.

*Etruscan Plate.*—The Etruscan races of Italy were specially renowned for their skill in working all the metals, and above all in their gold work. Large quantities of the most exquisite gold jewelry have been found in Etruscan tombs, including, in addition to smaller objects, scepters, wreaths of olive, and massive head-pieces. The Museo Kircheriano in Rome possesses a magnificent specimen of the last form of ornament; it is covered with nearly a hundred little statuettes of lions arranged in parallel rows. Little, however, that can be classed under the head of plate has yet been found. The British Museum (gold ornament room) possesses a fine specimen of early plate found at Agrigentum in Sicily.

*Hellenic Plate.*—Discoveries made of late years on the plains of Troy, at Mycenæ, and at Camirus in Rhodes have brought to light a large quantity of gold and silver plate of very remote antiquity. These early specimens of plate are all very similar in character, graceful in shape, hammered, cast, and soldered with great skill, but, with the exception of weapons and ornaments, mostly devoid of surface decoration. The most remarkable find was that which Doctor Schliemann calls "Priam's treasure," including a large number of silver vases and bowls, with fine massive double-handled cups in gold, and a very curious spherical gold bottle.

In the best times of Greek art, the chief works in gold and silver seem to have been dedicated to religious purposes, and to have been seldom used for the ostentatious pomp of private individuals. Vessels for the use of the temples, tripods in gold or silver of the richest work, and statues of the gods were the chief objects on which the precious metals were lavished.

The gold used by the Greeks probably came from Asia Minor or Egypt, while the mines of Laurium, in the mountains which form the promontory of Sunium in Attica, supplied an abundant amount of silver for many centuries.

Though a large quantity of later Græco-Roman plate still exists in various museums, the specimens of Greek silver-work of the best period are extremely rare, and most unimportant in point of size. In 1812 Doctor Lee discovered at Ithaca a very beautiful vase or cyathus  $3\frac{3}{4}$  inches high and a phiale or patera,  $9\frac{1}{2}$  inches across, both of silver, repoussé and chased, with very rich and graceful patterns of leaves and flowers—suggesting a slight tinge of Assyrian style. These are probably not later than the fifth century B. C.

*Græco-Roman and Roman Plate.*—Of what may be called Græco-Roman plate a much larger number of specimens still exist. The finest collection of these was found in 1869 at Hildesheim in Hanover, and is now in the Berlin Museum. They consist of a large number of cups, bowls, vases, dishes, and tripods, all of silver, some decorated with gilding and enriched in the most elaborate way with figure and scroll-work reliefs of the greatest beauty and finish; these, except one or two of very rude work, can hardly be later in date than the first century after Christ.

The museum at Naples contains a very large number of silver cups found in Pompeii, incrustated with figure-subjects or branches of ivy and vine in relief. In cases of this sort the cup is made double, with a smooth inner skin to hide the sinkings produced by the repoussé work in relief on the outside. Silver vessels ornamented in relief were called by the Romans *calata* or *aspera* to distinguish them from plain ones, which were called *levia*.

Among later specimens of Roman plate the most remarkable is the gold patera, nearly ten inches in diameter, found at Rennes in 1777, and now in the Paris Bibliothèque—a work of the most marvelous delicacy and high finish—almost gem-like in its minuteness of detail. Though not earlier than about 210 A. D., a slight clumsiness in the proportion of its embossed figures is the only visible sign of decadence.

The British Museum possesses good specimens of Roman silver work in its last stage of decline. These are two large caskets or toilet boxes, with silver unguent vases, oblong *lances*, pateræ, ewers, spoons, and other objects, all found in Rome in 1793.

*Plate from the Crimea.*—The finest collection of early gold and silver plate is that in the Musée de l'Ermitage at St. Petersburg, the result of many years' excavation in the tombs of the Cimmerian Bosphorus. Most of these magnificent pieces of plate, both in style of workmanship and in the character of their decoration, resemble the work of Greek artists; in some cases nothing but the costume of the figures embossed upon them shows that they were not produced in Athens.

*Oriental Plate.*—Some very curious pieces of plate in both gold and silver have been found in northern India; these appear to be of native workmanship, but the subjects with which they are embossed, and the modeling of the figures, show that they were produced under late Roman influence, or in some cases possibly even Greek influence in a highly degraded state, handed down from the time of Alexander's Indian conquests.

The gold and silver work of Russia resembles in style that of Byzantium at an early period. Shrines and other magnificent pieces of plate in the treasury of the cathedral at Moscow (see Weltmann, *Le trésor de Moscou*, 1861), though executed at the end of the fifteenth century, are exactly similar in design to Byzantine work of the eleventh or twelfth century, and even since then but little change or development of style has taken place.

*Early Medieval Plate.*—The Gothic, Gaulish, and other semi-barbarian peoples, who in the sixth century were masters of Spain, France, and parts of central Europe, produced great quantities of work in the precious metals, especially gold, often of great magnificence of design and not without some skill in workmanship. In 1837 a large number of pieces of very massive gold plate were found at Petrossa, in Roumania; much of this find was, unfortunately, broken up and melted, but a considerable portion was saved, and is now in the museum at Bucharest.

In the sixth century Byzantium was the chief center for the production of large and magnificent works in the precious metals.

During the seventh century France and other Western countries were but little behind Italy and Byzantium in their production of massive works, both secular and religious, in the precious metals. St. Éloy, the French goldsmith bishop, made a number of most splendid shrines and other sacred furniture in beaten gold—among them large shrines for the relics of St. Denis, St. Geneviève, and St. Martin, as well as gold thrones, plate, and jewelry for the French kings Clothaire II. and Dagobert I.

The existing examples of magnificent early work in the precious metals mostly belong to a somewhat later period. The chief are the gold and silver altar in Sant' Ambrogio at Milan, of the ninth century; the *Pala d'Oro*, or gold retable, in St. Mark's at Venice, begun in the tenth century; and the gold altar frontal given by the emperor Henry II. and his wife Cunigunde, at the beginning of the eleventh century, to the cathedral at Basel.

Owing to the demoralization and increase of luxury which grew in Italy with such startling rapidity during the early years of the sixteenth century, the wealth and artistic skill which in the previous centuries had been mainly devoted to religious objects were diverted into a different channel, and became for the most part absorbed in the production of magnificent pieces of plate—vases, ewers, dishes, and the like—of large size, and decorated in the most lavish way with the fanciful and over-luxuriant forms of ornament introduced by the already declining taste of the Renaissance. This demand created a new school of metal works. During the seventeenth and even the eighteenth centuries fine pieces of plate were produced in Italy, many of them still retaining some of the grace and refinement of the earlier Renaissance.

*Germany.*—From very early times Germany was specially famed for its works in the precious metals, mostly, as in other countries, for ecclesiastical use. In the fifteenth century a large quantity of secular plate was produced, of very beautiful design and the most skillful workmanship.

During the first half of the sixteenth century Augsburg and Nuremberg, long celebrated for their silver work, developed a school of artists in plate whose productions are of the most unrivaled beauty.

*Spain.*—Throughout the middle ages Spain was remarkable for its large and magnificent works in the precious metals. It is not till the sixteenth century that a really Spanish school of art was developed; and the

discovery of America with its rich stores of gold and silver gave an enormous impetus to this class of work. The "custodia," or tabernacle for the host, in many of the Spanish cathedrals, is a large and massive object, decorated in a very gorgeous though somewhat debased style. In spite of the plundering of the French, even now no country is so rich in ecclesiastical plate as Spain.

*England.*—The Celtic races of both England and Ireland appear to have possessed great wealth in gold and silver, but especially the former. It seems, however, to have been mostly used in the manufacture of personal ornaments, such as torques, fibulæ, and the like. With regard to English secular plate, though but few early examples still exist, we know from various records, such as wills and inventories, that the fourteenth century was one in which every rich lord or burgher prided himself on his fine and massive collection of silver vessels; on festive occasions this was displayed, not only on the dinner-table, but also on sideboards, arranged with tiers of steps, one above the other, so as to show off to advantage the weighty silver vases, flagons, and dishes with which it was loaded. The central object on every rich man's table was the "nef"—a large silver casket, usually (as the name suggests) in the form of a ship, and arranged to contain the host's napkin, goblet, spoon, and knife, with an assortment of spices and salt. Great sums were often spent on this large and elaborate piece of plate, *e.g.*, one made for the duke of Anjou in the fourteenth century weighed 348 marks of gold. The English silversmiths of this period were highly skilled in their art, and produced objects of great beauty in both design and workmanship. One of the finest specimens of late fourteenth century plate which still exists is a silver cup belonging to the mayor and corporation of King's Lynn. It is graceful and chalice-like in form, skillfully chased, and decorated in a very rich and elaborate way with colored translucent enamels of ladies and youths, several with hawks on their wrists. Silver salt-cellars were among the most elaborate pieces of plate produced during the fifteenth century. Several colleges at Oxford and Cambridge still possess fine specimens of these; the favorite shape was a kind of hour-glass form richly ornamented with spiral fluting or bosses.

But few existing specimens of English plate are older than the beginning of the fifteenth century. Among the few that remain the principal are two or three chalices—such as the two large gold ones found in the coffin of an archbishop of York, now used for holy communion in the cathedral, and a fine silver chalice from the church of Berwick St. James, Wilts, now in the British Museum. Both this and the York chalices are devoid of ornament, but, judging from their shape, appear to be of the twelfth or thirteenth century.

PLATE, THE RIVER, or RIO DE LA PLATA ("River of Silver"), in South America, was at first known as Rio de Solis, after Juan Diaz de Solis, who discovered it in 1515, and lost his life on its banks. The present name, a double misnomer, was bestowed by Sebastian Cabot, who, ignorant that he was on the wrong side of the continent, thought he had reached a country of mineral wealth—a mistake (perpetuated also in the designation Argentine Republic) which may be said to have received a kind of poetic justification in the fact that the distant mines of Potosí lie within the drainage area of the La Plata system. Like Rio Grande do Sul and Rio de Janeiro on the Brazilian coast, this Rio is not a river, but a vast estuary into which rivers discharge. At its narrowest it is 23 miles across, opposite Buenos Ayres 34 miles, and opposite Montevideo 63 miles. By some writers the conventional limit be-

tween estuary and ocean is drawn from Montevideo, where the water is still fresh enough to be drunk; but others go farther out and take the line 150 miles across from Maldonado to Cabo San Antonio. In the former case the length of the estuary is 125 miles. At one time it must evidently have extended 200 miles farther inland to Diamante, at the bend of the Paraná; and nature is steadily and rapidly at work prolonging the rivers proper at the expense of the estuary. At low water the average depth may be taken at 18 feet, and shoals and sandbanks are abundant, especially in the upper end. Nearly the whole expanse between Buenos Ayres and Martin Garcia Island is between 3 and 6 feet deep, and a great portion is even shallower. In the shallower portions the bottom consists of a very fine hard-grained sand, in the deeper portions of a sticky ooze. The tidal movement is so disguised by the more obvious effects of wind that Mr. Révy found people who had lived all their lives on the banks ready to deny its existence. But at Buenos Ayres the normal neap-tide is five feet three inches above ordinary low water, and the spring tides vary from six to more than ten feet. The region being one of "storms and extraordinary electric disturbance," with the pampero at one time blowing hard from the land and at another a sea-wind driving the ocean before it, the ordinary levels and currents are often violently disturbed. The general slope of the surface may even be reversed, and the main current of estuary and river run up-stream for 100 miles or more. It has been estimated that the volume of water poured into the Rio de la Plata exceeds the aggregate discharge of all the rivers of Europe put together. Nor need this be matter of surprise when the enormous extent and the character of the drainage area are taken into account.

The three great rivers of the La Plata system are the Paraná, its equal affluent the Paraguay, and the Uruguay—the second being the most important as a waterway, and the first the most interesting from its physical features.

PLATEAU, JOSEPH ANTOINE FERDINAND, was born at Brussels in 1801, and died in 1883 at Ghent, where he had been professor of physics from 1835.

PLATED WARE. The plating or coating of one metal or alloy with another is extensively practiced in metal working. In some cases the coating metal is a valuable protector from oxidation, etc., of the underlying metal; in other cases the properties and advantages of two metals—such as strength and luster—are combined in one object; and more frequently a cheap and inferior body by a superficial coating gets the appearance of a more valuable and important metal. The art of plating was originally applied to the production of imitation silver plate, whence the term "plating." The original method of silver plating consisted in attaching, by a kind of autogenous soldering, thin plates of silver to the opposite surfaces of a prepared ingot of copper alloy or of German silver. The silver plates were firmly wired to the ingot and submitted to a soldering temperature in a plating furnace, in which the surfaces became firmly united. Subsequently the ingot was rolled down to a sheet in which the relative thickness of the metals was maintained, and from such sheets "silver plated" articles were fashioned. This method of plating may be regarded as now extinct, being superseded by electro-plating, or plating by electricity. Recently, however, cooking vessels, etc., of iron, plated in an analogous manner with nickel have come into use (see NICKEL). The plating or casing of iron with brass is extensively practiced in the manufacture of stair-rods, curtain and picture rods, and "cased" tubing for upholstery purposes generally; and in the manufac-

ture of pipes for conveying water the body of lead is frequently lined with a coating of pure tin. The gilding of metals is a process analogous to plating, as are also the galvanizing of iron and the manufacture of tin and terne plates. For these see IRON.

PLATEN-HALLERMUND, AUGUST, GRAF VON, German poet, was born at Ansbach on October 24, 1796, and died at Syracuse on December 5, 1835.

PLATINUM AND THE PLATINUM METALS. The metals platinum (Pt), palladium (Pd), rhodium (Rh), iridium (Ir), ruthenium (Ru), and osmium (Os) are united into a family by a striking similarity in chemical characters and by their association in natural occurrence. A rather rare ore, called platinum ore or polyxene, is almost the only native material which is available for their extraction; it contains them all in the regular form. *Traces* of platinum are found in almost all native gold.

Platinum, though a noble metal chemically, has too modest an appearance to lend itself much to the jeweler's purposes. The Russian Government used, for a while, to strike platinum coins, but soon came to give up the practice on account of the immense fluctuations in the commercial value of the metal. Almost all the platinum produced nowadays is made into chemical utensils. Platinum, in fact, is the metal of the chemist. In industrial chemistry platinum is used chiefly for the construction of those stills for the concentration of oil of vitriol which, although a single one costs a fortune, are cheaper in the long run than glass retorts.

PLATO, the Athenian philosopher and father of idealism, was born 427 B.C., and lived to the age of eighty. His literary activity may be roughly said to have extended over the first half of the fourth century B.C. That throughout his early manhood he was the devoted friend of Socrates, that in middle life he taught those who resorted to him in the grove named Academus, near the Cephissus, and there founded the great philosophical school, that (with alleged interruptions) he continued to preside over the Academy until his death, are matters of established fact. It is said by Aristotle that he was at one time intimate with Cratylus the Heraclitean. Beyond this we have no authentic record of his outward life. That his name was at first Aristocles, and was changed to Plato because of the breadth of his shoulders or of his style or of his forehead, that he wrestled well, that he wrote poetry which he burnt on hearing Socrates, that he fought in three great battles, that he had a thin voice, that (as is told of other Greek philosophers) he traveled to Cyrene and conversed with priests in Egypt, are statements of Diogenes Laertius, which rest on more or less uncertain tradition. The express assertion—which this author attributes to Hermodorus—that after the death of Socrates Plato and other Socratics took refuge with Euclides in Megara, has a somewhat stronger claim to authenticity. But the fact cannot be regarded as certain, still less the elaborate inferences which have been drawn from it. The romantic legend of Plato's journeys to Sicily, and of his relations there with the younger Dionysius and the princely but unfortunate Dion, had attained some degree of consistency before the age of Cicero, and at an unknown but probably early time were worked up into the so-called *Epistles* of Plato, now all but universally discredited. Nor is there sufficient ground for supposing, as some have done, that an authentic tradition is perceptible behind the myth. For the details of the story the reader is referred to Grote, who believed in the genuineness of the *Epistles*. Men's thoughts had begun to be disturbed and eager when Socrates arose. The skeptical movement had confused men's notions

as to the value of ethical ideas. "If 'right' is one thing in Athens and another at Sparta, why strive to follow right rather than expediency? The laws put restraint on Nature, which is prior to them. Then why submit to law?" And the ingenuities of rhetoric had stirred much unmeaning disputation. Every case seemed capable of being argued in opposite ways. Even on the great question of the ultimate constitution of things, the conflicting theories of absolute immutability and eternal change appeared to be equally irrefragable and equally untenable.

The first result, and, as the Platonic Socrates declares, the only result he had obtained, was the consciousness of knowing nothing. But he who knows that he knows nothing is disposed to seek, and only those who seek will find. And the seeking mind attains, if not to knowledge, yet to a new standard of knowing. So long as results are contradictory, so long as negative instances are successfully applied, the searcher may make progress, but is still to seek. For the aim of inquiry is the universal.

Human life and experience the sphere of search; truth and good, regarded as identical, the end of it; universality the test of reality, conversation the method, rational thought the means—these are the chief notes of the dialectic of Socrates. Applying the native strength of his intelligence directly to the facts of life, he revealed their significance in countless ways, by unthought-of generalizations, by strange analogies, combining what men had not combined, distinguishing what they had not distinguished—but always with the single aim of rousing them to the search after eternal truth and good.

The spirit which led on toward this unseen goal was not less practical than speculative. Socrates desired not only that men might know, but that they might know and do. Utility is the watchword no less of the Socratic than of the Baconian induction. But Socrates never doubted that if men once know they will also do. His own conscious conviction of the unity of truth and good he believed to be unconsciously the basis of all men's actions. They erred, he thought, from not seeing the good, and not because they would not follow it if seen. This is expressed in the Socratic *dicta* "Vice is ignorance," "Virtue is knowledge." Men therefore must be brought to see the good and true, and that they may see it they must first be made aware that they do not see.

This lifelong work of Socrates, in which the germs of ethics, psychology, and logic were contained—after it had been sealed by the death in which he characteristically at once obeyed his countrymen and convinced them of error—was idealized, developed, dramatized—first embodied and then extended beyond its original scope—in the writings of Plato, which may be described as the literary outcome of the profound impression made by Socrates upon his greatest follower.

These writings (in pursuance of the importance given by Socrates to conversation) are all cast in the form of imaginary dialogue. But in those which are presumably the latest in order of composition this imaginative form interferes but little with the direct expression of the philosopher's own thoughts. The many-colored veil, at first inseparable from the features, is gradually worn thinner, and at last becomes almost imperceptible.

The Platonic dialogues are not merely the embodiment of the mind of Socrates and of the reflections of Plato. They are the portraiture of the highest intellectual life of Hellas in the time of Plato—a life but distantly related to military and political events, and scarcely interrupted by them. Athens appears as the center of the excitable Hellenic mind, profoundly

stirred by the arrival of great sophists, and keenly alive to the questions of Socrates, although in the pages of Plato, even more than in reality, he only "whispers with a few striplings in a corner;" for, in the Platonic grouping, the agora, which was the chief scene of action of the real Socrates, retires into the background, and he is principally seen consorting with his chosen companions, who are also friends of Plato, and with the acquaintances whom he makes through them. The scene is narrowed (for the Academy was remote from the bustle of resort, and Plato judged the Hellenic world securely from the vantage-ground of partial retirement)—but the figures are distinct and full of life. In reading the dialogues, we not only breathe the most refined intellectual atmosphere, but are also present witnesses of the urbanity, the freedom, the playfulness, the generous warmth of the "best society" in Athens. For Plato has a numerous repertory of *dramatis personæ*, who stand in various relations to his chief character—the impetuous Chærephon, Apollodorus the inseparable weak brother, old Crito the true-hearted, Phædo the beloved disciple, Simmias and Cebes who have been with Philolaus, the graceful and ingenuous Phædrus; the petulant Philebus; Theætetus of the philosophic nature, who is cut off in his prime, and the incorrigible Alcibiades; then Plato's own kinsmen—Glaucou the irrepressible in politics, in quarrel, and in love; Adimantus, solid and grave; Critias in his phase of amateur philosopher, and not as what he afterward became; Charmides, not in fiery manhood, but in his first bloom of diffident youth; and many others who appear as mere acquaintances, but have an interest of their own—the accomplished Agathon, the gay Aristophanes, Eryximachus the all-worthy physician; Meno, light of spirit; Callias, entertainer of sophists; Calicles the willful man of the world, Cephalus the aged father of Lysias, and Nicias the honored soldier. All these appear, not as some of them do on the page of history, in sanguinary contention or fierce rivalry, but as peaceful Athenians, in momentary contact with Socrates, whose electric touch now benumbs and now exhilarates, and sometimes goads to frenzy of love or anger. Still more distantly related to him, as it were standing in an outer circle, are the imposing forms of Gorgias and Protagoras, surrounded with the lesser lights of Hippias, Prodicus, and Polus. Thrasymachus, Euthydemus, Dionysodorus hang round like comic masks, adding piquancy to the design. The adversaries Anytus and Meletus are allowed to appear for a moment, but soon vanish. The older philosophers, though Socrates turned away from them, also make their entrance on the Platonic stage. Parmenides with his magnificent depth is made to converse with the imaginary Socrates, who is still quite young. A stranger from Elea plays an important part in some later dialogues, and Timæus the Pythagorean is introduced discoursing of the creation of the world. In these dialogues Socrates is mostly silent; in the *Philebus* he has lost himself in Plato; and in the twelve books of the *Laws*, where an unnamed Athenian is the chief speaker, even the Platonic Socrates finally disappears.

In evolving his philosophy from the Socratic basis, Plato works along three main lines—the ethical and political, the metaphysical or scientific, and the mystical. All three are often intimately blended, as in the close of *Rep.*, bk. vi., and even where one element is uppermost the others are not wholly suppressed.

Two great forces are persistent in Plato, the love of truth, and zeal for human improvement. In the period culminating with the *Republic*, these two motives, the speculative and the practical, are fused in one harmonious working. In the succeeding period, without ex-

cluding one another, they operate with alternate intensity. In the varied outcome of his long literary career, the metaphysical "doctrine of ideas" which has been associated with Plato's name underwent many important changes. But pervading all of these there is the same constant belief in the supremacy of reason and the identity of truth and good. From that abiding root spring forth a multitude of thoughts concerning the mind and human things—turning chiefly on the principles of psychology, education, and political reform—thoughts which although unverified, and often needing correction from experience, still constitute Plato the most fruitful of philosophical writers. While general ideas are powerful for good or ill, while abstractions are necessary to science, while mankind are apt to crave after perfection, and ideals, either in art or life, have an acknowledged value, so long the renown of Plato will continue. "All philosophic truth is Plato rightly divined; all philosophic error is Plato misunderstood"—is the verdict of one of the keenest of modern metaphysicians.

Plato's followers, however, have seldom kept the proportions of his teaching. The diverse elements of his doctrine have survived the spirit that formulated them. The Pythagorizing mysticism of the *Timæus* has been more prized than the subtle and clear thinking of the *Theætetus*. Logical inquiries have been hardened into a barren ontology. Semi-mythical statements have been construed literally, and mystic fancies perpetuated without the genuine thought which underlay them. A part (and not the essential part) of his philosophy has been treated as the whole. But the influence of Plato has extended far beyond the limits of the Platonic schools. The debt of Aristotle to his master has never yet been fully estimated. Zeno, Chrysippus, Epicurus borrowed from Plato more than they knew. The moral ideal of Plutarch and that of the Roman Stoics, which have both so deeply affected the modern world, could not have existed without him. Neopythagoreanism was really a crude Neoplatonism. And the Sceptics availed themselves of weapons either forged by Plato or borrowed by him from the Sophists. A wholly distinct line of infiltration is suggested by the mention of Philo and the Alexandrian schools, and of Clement and Origen, while Gnostic heresies and even Talmudic mysticism betray perversions of the same influence. The effect of Hellenic thought on Christian theology and on the life of Christendom is a subject for a volume, and has been pointed out in part by Prof. E. Zeller and others (comp. NEOPLATONISM). Yet when Plotinus in the third century (after hearing Ammonius), amid the revival of religious paganism, founded a new spiritualistic philosophy upon the study of Plato and Aristotle combined, this return to the fountain-head had all the effect of novelty. And for more than two centuries, from Plotinus to Proclus, the great effort to base life anew on the Platonic wisdom was continued. But it was rather the ghost than the spirit of Plato that was so "unsphered." Instead of striving to reform the world, the Neoplatonist sought after a retired and cloistered virtue. Instead of vitalizing science with fresh thought, he lost hold of all reality in the contemplation of infinite unity. He had some skill in dealing with abstractions, but laid a feeble hold upon the actual world.

"Hermes Trismegistus" and "Dionysius Areopagita" are names that mark the continuation of this influence into the Middle Ages. The pseudo-Dionysius was translated by Erigena in the ninth century.

Two more "Platonic" revivals have to be recorded—at Florence in the fifteenth and at Cambridge in the seventeenth century. Both were enthusiastic and both uncritical. The translation of the dialogues into Latin by Marsiglio Ficino was the most lasting effect of the

former movement, which was tinged with the unscientific ardor of the Renaissance. The preference still accorded to the *Timæus* is a fair indication of the tendency to bring *fumum ex fulgare* which probably marred the discussions of the Florentine Academy concerning the "chief good." The new humanism had also a sentimental cast, which was alien from Plato. Yet the effect of this spirit on art and literature was very great, and may be clearly traced not only in Italian but in English poetry.

The critical study of Plato begins from Schleiermacher, who did good work as an interpreter, and tried to arrange the dialogues in the order of composition. His attempt, which, like many efforts of constructive criticism, went far beyond possibility, was vitiated by the ground-fallacy of supposing that Plato had from the first a complete system in his mind which he partially and gradually revealed in writing. At a considerably later time Karl Friedrich Hermann, to whom all students of Plato are indebted, renewed the same endeavor on the far more plausible assumption that the dialogues faithfully reflect the growth of Plato's mind. But he also was too sanguine, and exaggerated the possibility of tracing a connection between the outward events of Plato's life and the progress of his thoughts. This great question of the order of the dialogues, which has been debated by numberless writers, is one which only admits of an approximate solution. Much confusion, however, has been obviated by the hypothesis (first hinted at by Ueberweg, and since supported by the present writer and others) that the *Sophistes* and *Politicus*, whose genuineness had been called in question by Socher, are really intermediate between the *Republic* and the *Laws*. The allocation of these dialogues, and consequently of the *Philebus*, not only on ground of metaphysical criticism, but also on philological and other evidence of a more tangible kind, supplies a point of view from which it becomes possible to trace with confidence the general outlines of Plato's literary and philosophical development. Reflecting at first in various aspects the impressions received from Socrates, he is gradually touched with an inspiration which becomes his own, and which seeks utterance in half-poetical forms. Then first the ethical and by and by the metaphysical interest becomes predominant. And for a while this last is all absorbing, as he confronts the central problems which his own thoughts have raised. But, again, the hard-won acquisitions of this dialectical movement must be fused anew with imagination and applied to life. And in a final effort to use his intellectual wealth for the subvention of human need the great spirit passed away.

PLATON, LEVSHIN, a celebrated Russian archbishop, was born at the village of Tchashnikovo, near Moscow, in 1737, and died in 1812.

PLATTNER, CARL FRIEDRICH, a famous scientific metallurgist, was born in Kleinwaltersdorf, near Freiberg in Saxony, on January 2, 1800, and died in the latter town, January 22, 1858.

PLATTSBURGH, a village and township of the United States, the shire-town of Clinton county, N. Y., and the port of entry of Champlain customs district, lies on the west side of Lake Champlain at the mouth of the Saranac. By rail it is 168 miles north of Albany and seventy-three south-southeast of Montreal (Canada). A branch line runs twenty miles southwest to Au Sable and forms a favorite route to the Adirondacks, and the Chateaugay Railroad runs thirty-four miles west by north to Lyon Mountain, where there are extensive iron mines. Plattsburgh contains county buildings and court-house, a high school, and a small public library. It has nail and wagon factories, flour-

mills, saw-mills, an iron furnace, machine shops, and a large sewing-machine manufactory. It is a garrison town of the United States army, with extensive barracks about a mile south of the village. Its population in 1890, was 7,500.

PLATTSMOUTH, capital of Cass county, Neb., one of the United States west of the Missouri River, is located on the Burlington and Missouri River Railroad at a point on the Missouri River below the mouth of the Platte, twenty-two miles south of Omaha. It is a thriving and promising city that has grown rapidly of late years, and is conspicuous for the costly improvements, including a steel railroad bridge, that have been projected and completed during the past decade. The city is provided with complete educational, commercial and transportation facilities, contains six churches, two national banks, county buildings, a fine high-school building, two newspaper offices, a large number of stores, and many private residences architecturally attractive. It also has manufactories of locomotives, coaches and freight cars, organs, engines, flour, terra-cotta, wagons, brooms, etc., is lighted by gas and electric lights, and in 1890 contained a population of 8,392.

PLATYHELMINTHES. See PLANARIANS and TAPEWORMS.

PLATYPUS. The Duck-billed Platypus (*Platypus anatinus*) was the name assigned to one of the most remarkable of known animals by Shaw.

The platypus is pretty generally distributed in situations suitable to its aquatic habits throughout the island of Tasmania and the southern and eastern portions of Australia. Slight variations in the coloring and size of different individuals have given rise to the idea that more than one species may exist; but all naturalists who have had the opportunity of investigating this question by the aid of a good series of specimens have come to the conclusion that there is but one; and no traces of any extinct allied forms have yet been discovered.

The length of the animal when full grown is from eighteen to twenty inches from the extremity of the beak to the end of the tail, the male being slightly larger than the female. The fur is short, dense, and rather soft to the touch, and composed of an extremely fine and close under-fur, and of longer hairs which project beyond this, each of which is very slender at the base, and expanded, flattened, and glossy toward the free end. The general color is deep brown, but paler on the under parts. The tail is short, broad, and depressed, and covered with coarse hairs, which in old animals generally become worn off from the under surface. The eyes are small and brown. There is no projecting pinna or ear-conch. The mouth, as is well known, bears a striking resemblance to the bill of a duck. It is covered with a naked skin, a strong fold of which projects outward around its base. The nostrils are situated near the extremity of the upper surface. There are no true teeth, but their purposes are served by horny prominences, two on each side of each jaw—those in the front narrow, longitudinal, sharp-edged ridges, and those behind broad, flattened, and molariform. The upper surface of the lateral edges of the mandible has also a number of parallel fine transverse ridges, like those on the bill of a duck. In the cheeks are tolerably capacious pouches, which appear to be used as receptacles for food.

The platypus is aquatic in its habits, passing most of its time in the water close to the margin of lakes and streams, swimming and diving with the greatest ease, and forming for the purpose of sleeping and breeding deep burrows in the banks, which generally have two orifices, one just above the water level, concealed among long grasses and leaves, and the other below the

surface. The passage at first runs obliquely upward in the bank, sometimes to a distance of as much as fifty feet, and expands at its termination into a cavity, the floor of which is lined with dried grass and leaves, and in which the eggs are laid and the young brought up. The food consists of aquatic insects, small crustaceans, and worms, which are caught under water, the sand and small stones at the bottom being turned over with their bills to find them. They appear at first to deposit what they have thus collected in their cheek pouches, and when these are filled they rise to the surface and quietly triturate their meal with the horny teeth before swallowing it. Swimming is effected chiefly by the action of the broad forepaws, the hind feet and tail taking little share in locomotion in the water. When asleep they roll themselves into a ball. In their native haunts they are extremely timid and wary, and very difficult to approach, being rarely seen out of their burrows in the daytime.

PLAUEN, a busy manufacturing town of Saxony, in the government district of Zwickau, is situated on the Elster, sixty miles to the south of Leipsic.

PLAUTUS, T. MACCIUS, was the greatest comic and dramatic genius of Rome, and still ranks among the great comic dramatists of the world. While the other creators of Roman literature, Nævius, Ennius, Lucilius, etc., are known to us only in fragments, we still possess twenty plays of Plautus. A few of them are incomplete, and in some cases they show traces of later interpolations, but they have reached us in the main as they were written by him in the end of the third and the beginning of the second century B.C. The few facts known of his life rest on the authority of Cicero, of Aulus Gellius, and of Jerome in his continuation of the Eusebian *Chronicle*. He was born in the earlier half of the third century B.C., and died at an advanced age in the year 184 B.C.

PLAYFAIR, JOHN, mathematician and physicist, was born at Benzie, Forfarshire, where his father was parish minister, on March 10, 1748, and died in 1819.

PLEADING, in law, denotes in civil procedure the statement in legal form of the grounds on which a party to an action claims the decision of the court in his favor, in criminal procedure the accusation of the prosecutor or the answer of the accused. The term "pleadings" is used for the collected whole of the statements of both parties, the term "pleading" for each separate part of the pleadings. A pleading may be the statement of either party; a "plea" is (except in Scots and ecclesiastical law) confined to the defense made by an accused person. To "plead" is to frame a pleading or plea.

All systems of law agree in making it necessary to bring the grounds of a claim or defense before the court in a more or less technical form. In Roman law the action passed through three stages (see ACTION), and the manner of pleading changed with the action. The development of the system of pleading in Roman and English law proceeded upon very similar lines. It is possible that the English system was directly based upon the Roman. Bracton (*temp.* Henry III.) uses many of the Roman technical terms. Pleading was oral as late as the reign of Henry VIII., but in the reign of Edward III. pleadings began to be drawn up in writing, perhaps at first more for the purpose of entry on the court records than of the instruction of the court. The French language was used up to 36 Edw. III. st. 1, c. 15, after which English was used for oral pleading, but Latin for enrollment. Latin was the language of written pleadings at common law until 4 Geo. II. c. 26.

In the United States two systems of pleading in civil procedure exist side by side. Up to 1848 the pleading did not materially differ from that in use in England at

the same date. But in 1848 the New York legislature made a radical change in the system, and the example of New York has been followed by more than twenty States. The New York Civil Code of 1848 established a uniform procedure called the civil action, applicable indifferently to common law and equity. The pleadings are called *complaint*, *answer* (which includes *counterclaim*), and *reply*. The *demurrer* also is still used. In some States which follow the new procedure the complaint bears the name of *petition*. In the inferior courts, such as courts of justices of the peace, the pleadings are more simple, and in many cases oral. In States which do not adopt the amended procedure, the pleading is much the same as it was in the days of Blackstone, and the old double jurisdiction of common law and equity still remains. Criminal pleading differs little from that in use in England. (See Bishop, *Laws of Criminal Procedure*.)

PLEBEIANS. See NOBILITY and ROME.

PLEDGE, or PAWN, in law, is "a bailment of personal property as a security for some debt on engagement." The term is also used to denote the property which constitutes the security. Pledge is the *pignus* of Roman law, from which most of the modern law on the subject is derived. It differs from hypothec and from the more usual kind of mortgage in that the pledge is in the possession of the pledgee; it also differs from mortgage in being confined to personal property. Pledges pawned for 10s. (\$2.50) or under, not redeemed in time become the property of the pawnbroker, pledges above that sum are redeemable until sale. The sale must be by public auction. The pawnbroker is entitled to charge as interest 25% where the loan is under 40s., (\$10), and 20% where the loan is above that amount. Special contracts may be made where the loan is above 40s. (\$10). Unlawful pawning of goods not the property of the pawner, and taking in pawn any article from a person apparently under the age of sixteen or intoxicated, or any linen or apparel or unfinished goods or materials intrusted to wash, make up, etc, are (*inter alia*) made offenses punishable by summary conviction. An annual license, costing £7, 10s. (\$37.50), must be taken out for every pawnbroker's shop.

The law of Scotland as to pledge generally agrees with that of England, as does also that of the United States. The main difference is that in Scotland and Louisiana a pledge cannot be sold unless with judicial authority. In some of the States the common law as it existed apart from the Factor's Acts is still followed; in others the factor has more or less restricted power to give a title by pledge. In some States pawnbroking is regulated by the local authorities, and not, as in most, by the general law of the State.

PLESIOSAURIANS. The remarkable extinct marine reptiles included in the group of the *Plesiosauria* (or *Sauropterygia*, as they are sometimes called) existed during the whole of the Mesozoic period, that is, from Triassic into Cretaceous times, when they appear to have died out. The best known of these reptiles, and that which gives its name to the group is the *Plesiosaurus*, a genus established by Conybeare in 1821, and including numerous species, some of which may have attained a length of as much as twenty feet. The nearly allied *Elasmosaurus* of North America, however, reached a much greater size, its remains indicating an animal about 45 feet in length. Several almost perfect skeletons of *Plesiosaurus* having at different times been found, the general proportions of the body are well known. Although the different species vary in regard to proportions, the small size of the head and extreme length of the neck are always striking points in the

skeleton of a *Plesiosaurus*, while the tail is proportionately short. The limbs, both fore and hind, are well developed and modified for swimming; the forms of the various bones making it clear that the digits of each limb were not separate, but inclosed in one covering of integument, as in the flippers of a whale or a turtle.

PLETHO. See GEMISTUS.

PLEURISY, or PLEURITIS, inflammation of the pleura or serous membrane investing the lungs and lining the interior of the thoracic cavity. It is a common form of chest complaint, and may be either acute or chronic, more frequently the former.

Pleurisy frequently arises from exposure to cold; hence it is more common in the colder weather; but besides this various other causes are connected with its occurrence. Thus it is often associated with other forms of disease within the chest, more particularly pneumonia, bronchitis, and phthisis, and also occasionally accompanies pericarditis. Again it is apt to occur as a secondary disease in certain morbid constitutional states, *e.g.*, the infectious fevers, rheumatism, gout, Bright's disease, diabetes, etc. Further, wounds or injuries of the thoracic walls are apt to set up pleurisy, and the rupture of a phthisical cavity in the lungs causing the escape of air and matter into the pleura has usually a similar effect.

The symptoms of pleurisy vary, being generally well marked, but sometimes obscure. In the case of dry pleurisy, which is on the whole the milder form, the chief symptom is a sharp pain in the side, felt especially on breathing. Fever may or may not be present. There is a slight dry cough; the breathing is quicker than natural and is shallow and of catching character. If much pain is present the body leans somewhat to the affected side, to relax the tension on the intercostal muscles and their covering, which are even tender to touch. On listening to the chest by the stethoscope the physician recognizes sooner or later "friction," a superficial rough rubbing sound, occurring only with the respiratory acts and ceasing when the breath is held. It is due to the coming together during respiration of the two pleural surfaces which are roughened by the exuded lymph. The patient may himself be aware of this rubbing sensation, and its vibration or fremitus may be felt by the hand laid upon the thoracic wall during breathing. This form of pleurisy may be limited or may extend over the greater part of one or both sides. It is a not infrequent complication of phthisis in all its stages. In general it disappears in a short time, and complete recovery takes place; or, on the other hand, extensive adhesions may form between the costal and pulmonary surfaces of the pleura, preventing uniform expansion of the lung in respiration and leading to emphysema. Although not of itself attended with danger, dry pleurisy is sometimes preliminary to more serious lung disease, and is always therefore to be regarded while it lasts with some degree of anxiety.

*Pleurisy with effusion* is usually more severe than dry pleurisy, and although it may in some cases develop insidiously, it is in general ushered in sharply by rigors and fever, like other acute inflammatory diseases. Pain is felt in the side or breast of a severe cutting character, referred usually to the neighborhood of the nipple, but it may be also at some distance from the affected part, such as through the middle of the body or in the abdominal or iliac regions. This transference of the pain occasionally misleads the medical examiner. The pain is greatest at the outset, and tends to abate as the effusion takes place. A dry cough is almost always present, which is particularly distressing, owing to the increased pain the effort excites. The breathing is painful and difficult, tending to become shorter and

shallower as the disease advances and the lung on the affected side becomes compressed. The patient at first lies most easily on the sound side, but as the effusion increases he finds his most comfortable position on his back or on the affected side. When there is very copious effusion, and, as is apt to happen, great congestion of the other lung, or disease affecting it, the patient's breathing may be so embarrassed that he cannot lie down.

The treatment of pleurisy need only be alluded to in general terms. It will necessarily depend as regards details upon the form and severity of the attack. One of the first symptoms calling for treatment is the pain. Opiates in the form of morphia or Dover's powder are useful along with the application to the chest of hot poultices or fomentations sprinkled with turpentine. In severe cases much relief to the pain and difficulty of breathing may be afforded by the application of a few leeches to the side. Cases of simple dry pleurisy usually soon yield to such treatment, aided if need be by the application of a fly-blister or of iodine to the chest. The fixing as far as possible of the one side of the thorax by means of cross straps of adhesive plaster according to the plan recommended by Doctor Roberts seems of use in many instances. In the case of pleurisy with effusion, in addition to these measures, including blistering, the internal use of saline cathartics and diuretics appears to be often of service in diminishing the amount of the fluid in the pleural cavity, as are also powerful diaphoretics such as pilocarpin. When these measures fail to reduce the effusion the question of the artificial removal of the fluid comes to be considered.

PLEURO-PNEUMONIA. See MURRAIN.

PLEVNA, or PLEVEN, the chief town of one of the provinces in the principality of Bulgaria, lies in the midst of a series of hills (whose crests rise above it for 200 to 600 feet) about 6,000 yards to the east of the river Vid (a tributary of the Danube), into which the streamlets by which it is traversed discharge. Its position at the meeting-place of roads from Widdin, Sofia, Shipka, Biela, Zimnitsa, and Nikopoli gives it a certain military importance, and in the Russian campaign of 1877 it became one of the great centers of operation. The Russians, who had been defeated in two minor attacks, on July 20th and 30th, were again repulsed with a loss of 18,000 men in an assault (September 7-13) in which they employed 75,000 infantry and 60,000 cavalry. They formally invested the town on October 24th and obliged Osman Pasha to surrender on December 10th. In 142 days the assailants had lost 40,000 men and the defenders 30,000.

PLEVEL, IGNAZ JOSEPH, though now almost forgotten, was once one of the most popular composers in Europe. He was born at Rupperthal, near Vienna, June 1, 1757. He died at Paris, November 14, 1831.

PLINY, THE NATURALIST. Caius Plinius Secundus, commonly distinguished as the elder Pliny, the author of the *Natural History*, is believed to have been born (23 A.D.) at Novum Comum (Como). Like his nephew, the elder Pliny had seen military service, having joined the campaign in Germany under L. Pomponius Secundus; like him, also, he had been a pleader in the law-courts, and a diligent student of Greek and Roman literature. Much of his literary work was done, he tells us himself, in the hours stolen from sleep. Of his many works the *Naturalis Historia* in thirty-seven books has alone been preserved, and in a nearly complete state. This voluminous treatise professes to be an encyclopædia of Roman knowledge, mainly based on the researches and speculations of the Greeks. What A. von Humboldt accomplished in our own times, in

his great work *Cosmos*, Pliny had essayed to carry out on similar principles—but, of course, without the scientific knowledge, and also without the comprehensive view of the universe which is the inheritance of the present age. Pliny, we must admit, was an industrious compiler, but he was not, like Aristotle, a man of original research.

In his first book, which contains a summary of the whole work, he names the authors, both Greek and Latin, from whom the matter of each book was derived. The list indeed is a surprising one, and of comparatively few have we any remains. His theology is "agnostic" or Epicurean; if there is any God, he says, it is vain to inquire His form and shape; He is entirely a Being of feeling and sentiment and intelligence, not of tangible existence. He believes in the "religion of humanity," according to a rather recent definition of the idea. God is what Nature is; God cannot do what Nature cannot do; He cannot kill himself, nor make mortals immortal, nor raise the dead to life, nor cause one who has lived never to have lived at all, or make twice ten anything else than twenty.

With all its faults, inevitable to the infant state of science, Pliny's work is an astounding monument of industry. It is believed to have been published about two years before his death. He wrote, besides several other treatises, a history of the wars from the first in Germany, in twenty books, and a continuation of the history of Aufidius Bassus down to his own times, in thirty-one books—now all lost.

He is said to have been a great student, an early riser, abstemious and temperate in his meals. In his later days he appears to have grown somewhat unwieldy and asthmatic, for Pliny the younger, in describing his uncle's death by suffocation from the fumes in the eruption of Vesuvius, 79 A.D., says that his breathing "propter amplitudinem corporis gravior et sonatior erat" (because of the size of his body was heavy and loud). Pliny's friendship with Vespasian may be inferred from his custom of attending the morning levée; he seems to have first known him in the German wars in the time of Claudius.

Besides his published works, the elder Pliny left, as his nephew tells us, 160 note-books of extracts (electorum commentarios clx.), written in a very small hand on both sides of the page. He acted as procurator in Spain in 71, and was recalled to Rome by the death of his brother-in-law Caius Cæcilius, who by will appointed him guardian of the younger Pliny. At the time of his death, the elder Pliny had the command of the Roman fleet at Misenum. He fell a victim to his imprudent curiosity in advancing within the range of the thickly-falling ashes during the eruption of Vesuvius in 79 A.D.

**PLINY THE YOUNGER.** Caius Cæcilius Secundus, commonly called Pliny the Younger, was the nephew and heir of the elder Pliny, the naturalist. He was born 61 A.D. at Comum (Como) on the southern shore of Lake Larius in northern Italy, near to which, on the east side, stood the spacious and beautiful family villa. He took the name of Cæcilius from his father, who had married Plinia, the elder Pliny's sister. At ten years of age he was left to the care of Virginius Rufus, a distinguished man and thrice consul.

Pliny was a man of refined taste, highly accomplished, devoted to literature, kind and indulgent to his freedmen and his slaves, gentle and considerate in all his family relations, humane and forgiving to all who had offended him. By profession an advocate, and a pupil of the famous Quintilian (ii. 14), he was a frequent and very popular pleader at the courts of the centumviri held in the Julian basilica, as well as occasionally in the senate and in public prosecutions (vi. 20).

His fame in centumviral trials, which were chiefly

connected with will cases, is attested by Martial (x. 19, 17), whose epigram he quotes in lamenting the poet's death (iii. 21). But, though himself somewhat ambitious of praise as a pleader (for he seems to have regarded Cicero as his model in everything), he sternly reprobated the arts of bribery and flattery which were commonly adopted by patrons to secure the applause of their clients. Fond as he was of eloquence, he seems to have given up legal practice from some feeling of disgust at these abuses, and to have devoted himself to the duties of the state-offices. He was appointed augur and præfect of the treasury in the temple of Saturn, and rose in due course through the offices of quæstor, prætor, and tribune of the people, finally attaining to the consulship, 100 A.D. He died in 115, leaving interesting literary remains in the form of his *Letters*.

**PLOCK (PLOTSK)**, a government of Russian Poland, on the right bank of the Vistula, having the provinces of Western and Eastern Prussia on the north, and the Polish provinces of Lomza on the east, and Warsaw on the south. Its area is 4,200 square miles. Its flat surface, 350 to 500 feet above the sea-level, gently rises toward the north, where it merges in the Baltic coast-ridge of the Prussian lake district. Only a few hills reach 600 feet above the sea, while the broad valley of the Vistula has an elevation of but 130 to 150 feet.

*History.*—After the second dismemberment of Poland in 1793, what is now the government of Plock became part of Prussia. It fell under Russian dominion after the treaty of Vienna, and, in the division of that time into five provinces, extended over the western part of the present province of Lomza, which was created in 1864 from the Ostrolenka and Pultusk districts of Plock, together with parts of the province of Augustowo.

**PLOCK**, capital of the above province, situated on the right bank of the Vistula, sixty miles to the west-northwest of Warsaw.

**PLOTINUS.** See **NEOPLATONISM**.

**PLOVER**, French *Pluvier*, Old French *Plovier*, which doubtless has its origin in the Latin *pluvia*, rain (as witness the German equivalent *Regenpfeifer*, Rain-fifer); but the connection of ideas between the words therein involved, so that the former should have become a bird's name, is doubtful. Belon (1555) says that the name *Pluvier* is bestowed "pour ce qu'on le prend mieux en temps pluvieux qu'en nulle autre saison," (because they are more easily caught in times of rain than at any other season), which is not in accordance with modern observation, for in rainy weather plovers are wilder and harder to approach than in fine. The Gray Plover is a bird of almost circumpolar range, breeding in the far north of America, Asia, and Eastern Europe, frequenting in spring and autumn the coasts of the more temperate parts of each continent, and generally retiring further southward in winter, sometimes as far as Tasmania.

**PLOW.** See **AGRICULTURE**.

**PLÜCKER, JULIUS**, mathematician and physicist, was born at Elberfeld on June 16, 1801, and died in 1868. Of the very numerous honors bestowed on Plücker by the various scientific societies of Europe it may suffice to mention here the Copley medal, awarded to him by the Royal Society two years before his death.

**PLUM (PRUNUS).** Our cultivated plums are supposed to have originated from one or other of the species *P. domestica* or *P. insititia*. The young shoots of *P. domestica* are glabrous and the fruit oblong; in *P. insititia* the young shoots are pubescent, and the fruit more or less globose. A third species, the common sloe or black-thorn, *P. spinosa*, has stout spines; its flowers expand before the leaves; and its fruit is very rough to the

taste, in which particulars it differs from the two preceding. These distinctions, however, are not maintained with much constancy. *P. domestica* is a native of Anatolia and the Caucasus, and is considered to be only naturalized in Europe. *P. insititia*, on the other hand, is wild in southern Europe, in Armenia, and along the shores of the Caspian.

PLUMBAGO, a name frequently applied to graphite in allusion to its remote resemblance to lead, whence it is popularly called "black lead."

PLUNKET, WILLIAM CONYNGHAM PLUNKET, BARON, an eminent lawyer, orator, and statesman, was born in the county of Fermanagh, Ireland, in July, 1765. After the union of Great Britain and Ireland Plunket returned to the practice of his profession, and became at once a leader of the equity bar. In 1804, in Pitt's second administration, he became solicitor-general and then attorney-general for Ireland. In 1812, having amassed a considerable fortune, he reëntered parliament as member for Trinity College, and identified himself thoroughly with the Grenville or anti-Gallican Whigs.

In 1822 Plunket was once more attorney-general for Ireland, with Lord Wellesley as lord-lieutenant.

In 1827 Plunket was made master of the rolls in England; but, owing to the professional jealousy of the bar, who not unnaturally thought him an intruder, he was obliged to abandon this office. Soon afterward he became chief justice of the common pleas in Ireland, and was then created a peer of the United Kingdom. In 1830 he was appointed lord chancellor of Ireland, and held the office, with an interval of a few months until 1841, when he finally retired from public life. During this period he made some able speeches in favor of parliamentary reform; but they were scarcely equal to his earlier efforts; and his reputation as a judge, though far from low, was not so eminent as might have been expected. He died in 1854, in his ninetieth year.

PLUSH (French *Peluche*), a textile fabric having a cut nap or pile the same as fustian or velvet.

PLUTARCH, a Greek prose writer, born at Chæronea in Bœotia, and a contemporary of Tacitus and the Plinys. The precise dates of his birth and death are unknown; but it is certain that he flourished under the Roman emperors from Nero to Trajan inclusive, so that from 50 to 100 A.D. will probably include the best years of his life. There is some probability that he outlived Trajan, who died in 117.

The celebrity of Plutarch, or at least his popularity, is mainly founded on his forty-six *Parallel Lives*. He is thought to have written this work in his later years after his return to his native town Chæronea. His knowledge of Latin and of Roman history he must have partly derived from some years' residence in Rome and other parts of Italy.

Nearly all the lives are in pairs; but the series concludes with single biographies of Artaxerxes, Aratus (of Sicyon), Galba, and Otho. In the life of Aratus, not Sosius Senecio, but one Polycrates, is addressed.

It is not to be supposed that Plutarch was content to write merely amusing or popular biographies. On the contrary, the *Lives* are works of great learning and research, and they must for this very reason, as well as from their considerable length, have taken many years in their compilation.

The voluminous and varied writings of Plutarch exclusive of the *Lives* are known under the common term of *Opera Moralia*. These consist of above sixty essays, some of them long and many of them rather difficult, some too of very doubtful genuineness. Their literary value is greatly enhanced by the large numbers of citations from lost Greek poems, especially verses from the

dramatists, among whom Euripides holds by far the first place. They evince a mind of vast and varied resources, historical as well as philosophical—the mind of an inquirer and seeker after knowledge, rather than that of an exponent or an opponent of any particular philosophical system.

PLUTO, the god of the dead in Greek mythology. His oldest son was Hades, "the Unseen;" the name Pluto was given him as the bestower of the riches of the mine, and in ordinary language it ousted the dread name of Hades, which was, however, retained in poetry. He was the son of Cronus and Rhea, and brother of Zeus and Poseidon. Having deposed Cronus, the brothers cast lots for the kingdoms of the heaven, the sea, and the infernal regions, and Pluto obtained the infernal regions, which from their ruler were afterward known as Hades. The "house of Hades" was a dark and dreadful abode deep down in the earth. How literally the god was supposed to dwell underground is shown by the method of invoking him, which was by rapping on the ground to attract his attention.

PLUTUS, ("wealth"), the Greek god of riches, whom Demeter bore to Iasion "in the fat land of Crete."

PLYMOUTH, a municipal and parliamentary borough and seaport town of Devonshire, England, is picturesquely situated on Plymouth Sound in the southwest corner of the county, at the confluence of the Tamar and Plym, forty-four miles southwest of Exeter. With the borough of Devonport and the township of East Stonehouse it forms the aggregate town known as the "Three Towns." There is railway communication by means of the Great Western and South-Western lines, and by several branch lines connected with these systems. The defenses of the town, in addition to the citadel, an obsolete fortification built by Charles II., on the site of an older fort, consist of a most elaborate chain of forts of great strength mounted with guns of the heaviest caliber, and forming a complete line of defense round the whole circumference both landward and seaward. The streets are for the most part narrow and crooked, and the houses very irregular both in style of architecture and in height. Great improvements have, however, recently taken place. The more ancient part of the town near the water-side has been much altered, and a number of model dwellings have also lately been erected. In the principal thoroughfares there are numerous handsome shops and other imposing business establishments.

Plymouth not only holds a leading position in the country as a naval station, but is the center of the growing trade of Devonshire and Cornwall, and is also becoming a holiday center and health resort. To the south of the town is the Sound, protected by the magnificent breakwater, within the limits of which and the harbors connected with it the whole British navy might find a safe anchorage. The western harbor, known as the Hamoaze, at the mouth of the river Tamar, is devoted almost exclusively to the requirements of the royal navy, as along its banks are the dockyard, the Keyham factory, the arsenal, and other government establishments (see DEVONPORT and DOCKYARDS). The eastern harbor, Cattewater with Sutton Pool, now protected by a new breakwater at Mount Batten, is the anchorage ground for merchant shipping. Commodious dock accommodation is provided at the Great Western Docks, Millbay, between Plymouth and Stonehouse, opened in 1857, and comprehending a floating basin over thirteen acres in extent with a depth of twenty-two feet at spring tides, a tidal harbor of thirty-five acres, and a graving dock. The port has an extensive trade with America, the West Indies, Mauritius, Africa, and the Baltic ports, as well as an exten-

sive coasting trade. It is the starting point for many of the emigrant ships for Australia, New Zealand, and British America. The chief exports are minerals, including copper, lead, tin, granite, and marble. There is also some trade in pilchards and other fish. The imports are chiefly agricultural produce and timber. Plymouth has few manufactures, the principal being biscuits, black-lead, candles, manures, soap, starch, sugar, lead, and the celebrated Plymouth gin. The principal industries are connected with shipbuilding and the fisheries. Population (1891), 87,307.

PLYMOUTH, a township and village of the United States, the shire-town of Plymouth county, Mass., and a port of entry on Cape Cod Bay—the village lying at the terminus of a branch of the Old Colony Railroad, thirty-seven miles south-southeast of Boston. The main interest of Plymouth is historical, and centers in the fact that it was the first settlement of the Pilgrim Fathers of New England, who landed December 21 (N.S.), 1620, on the rock now covered by a handsome granite canopy in Walker street. Leyden street, so called in memory of the Dutch town where the exiles had stopped for a season, is the oldest street in New England. The houses and general appearance of Plymouth are, however, thoroughly modern. Pilgrim Hall (which is built of granite and measures seventy feet long by forty feet wide) was erected in 1824–25 by the Pilgrim Society constituted in 1820; it contains a public library and many relics of the fathers—including Miles Standish's sword and Governor Carver's chair. The corner stone of a national monument to the Pilgrims was laid August 1, 1859, on a high hill near the railroad station; 1,500 tons of granite were used for the foundation; and a pedestal forty-five feet high is surrounded by statues twenty feet high of *Morality*, *Law*, *Education* and *Freedom*, and bears a colossal statue of *Faith*, thirty-six feet high, holding a Bible in her right hand (the largest granite statue in the world). Burying Hill was the site of the embattled church erected in 1622, and contains many ancient tombstones and the foundations of the watchtower (1643) now covered with sod. Cole's Hill is the spot where half of the *Mayflower* Pilgrims found their rest during the first winter. Five of their graves were discovered in 1855 while pipes for the town water-works were being laid, and two more (now marked with a granite slab) in 1883. The bones of the first five are deposited in a compartment of the canopy over the *Forefathers' Rock*. A town hall (1749), the county court-house, and the house of correction are the main public buildings of Plymouth. The population of the township was 4,758 in 1830, 6,024 in 1850, 6,238 in 1870, 7,093 in 1880, and 7,292 in 1890. Manufactures of sail-duck, cotton-cloth, tacks, nails, plate-iron, rolled zinc and copper rivets, hammers, etc., are carried on; the cordage factories are among the largest and most complete works of the kind in the world.

PLYMOUTH, a borough of the United States, in Luzerne county, Penn., on the Bloomsburg division of the Delaware, Lackawanna and Western Railroad, eight miles from Wyoming, is a flourishing coal-mining town, which increased its population from 2,648 in 1870 to 9,344 in 1890. At Plymouth Junction, two miles to the northeast, a branch line to Wilkesbarre connects with the Central Railroad.

PLYMOUTH BRETHERN (BRETHERN, or CHRISTIAN BRETHERN), are a sect of Christians who received the name in 1830 when the Rev. J. N. Darby induced many of the inhabitants of Plymouth to associate themselves with him for the promulgation of opinions which they held in common. Although small Christian communities existed in Ireland and elsewhere calling them-

selves *Brethren* and holding similar views, the accession to the ranks of Mr. Darby so increased their numbers and influence that he is usually reckoned the founder of Plymouthism. Darby (born in November, 1800, in London; graduated at Trinity College, Dublin, in 1819; died April 29, 1882 at Bournemouth) was a curate in the Episcopalian Church of Ireland until 1827, when he felt himself constrained to leave the Established Church; betaking himself to Dublin, he became associated with several devout people who refused all ecclesiastical fellowship, met steadily for public worship, and called themselves the Brethren.

The theological views of the Brethren do not differ greatly from those held by evangelical Protestants (for a list of divergences, see Reid, *Plymouth Brethrenism Unveiled and Refuted*); they make the baptism of infants an open question and celebrate the Lord's Supper weekly. Their distinctive doctrines are ecclesiastical. They hold that all official ministry, anything like a clergy, whether on Episcopalian, Presbyterian, or Congregational theories, is a denial of the spiritual priesthood of all believers, and a striving against the Holy Spirit. Hence it is a point of conscience to have no communion with any church which possesses a regular ministry.

PNEUMATIC DISPATCH. The transport of written dispatches through long narrow tubes by the agency of air-pressure was introduced in 1853, by Mr. Latimer Clark, between the Central and Stock Exchange stations of the Electric and International Telegraph Company in London. The stations were connected by a tube  $1\frac{1}{2}$  inches in diameter and 220 yards long. Carriers containing batches of telegrams, and fitting piston-wise in the tube, were sucked through it (in one direction only) by the production of a partial vacuum at one end. In 1858 Mr. C. F. Varley improved the system by using compressed air to force the carriers in one direction, a partial vacuum being still used to draw them in the other direction. This improvement enables single radiating lines of pipe to be used both for sending and for receiving telegrams between a central station supplied with pumping machinery and outlying stations not so supplied. In the hands of Messrs. Culley and Sabine this radial system of pneumatic dispatch has been brought to great perfection in connection with the telegraphic department of the British post-office. Another method of working, extensively used in Paris and other Continental cities, is the circuit system, in which stations are grouped on circular or loop lines, round which carriers travel in one direction only. Various forms of the system are used in America in the principal cities. In one form of circuit system—that of Messrs. Siemens—a continuous current of air is kept up in the tube, and rocking switches are provided by which carriers can be quickly introduced or removed at any one of the stations on the line without interfering with the movement of other carriers in other parts of the circuit. More usually, however, the circuit system is worked by dispatching carriers, or trains of carriers, at relatively long intervals, the pressure or vacuum which gives motive power being applied only while such trains are on the line. On long circuits means are provided at several stations for putting on pressure or vacuum, so that the action may be limited to that section of the line on which the carriers are traveling at any time.

PNEUMATICS is that department of hydrodynamics which treats of the properties of gases as distinct from liquids. Under HYDROMECHANICS will be found a general discussion of the subject as a branch of mathematical physics.

The gaseous fluid with which we have chiefly to do is our atmosphere. Though practically invisible, it ap-

peals in its properties to other of our senses, so that the evidences of its presence are manifold. Thus we feel it in its motion as wind, and observe the dynamical effects of this motion in the quiver of the leaf or the momentum of the frigate under weigh. It offers resistance to the passage of bodies through it, destroying their motion and transforming their energy—as is betrayed to our hearing in the whiz of the rifle bullet, to our sight in the flash of the meteor. In its general physical properties the air has much in common with other gases. It is advisable therefore first to establish these general properties, and then consider the characteristic features of the several gases.

Matter is conveniently studied under the two great divisions of solids and fluids. The practically obvious distinction between these may be stated in dynamical language thus:—solids can sustain a longitudinal pressure without being supported by a lateral pressure; fluids cannot.

The mutual action between any two portions of matter is called the stress between them. This stress has two aspects, according as its effect or tendency is considered with reference to the one or the other body. Thus between the earth and moon there is a stress which is an attraction. The one aspect is the force which attracts the moon to the earth; the other is the force which attracts the earth to the moon.

The stress which exists between the contiguous portions of a fluid is of the nature of a pressure. The ideal or perfect fluid is a substance in which this stress between contiguous portions is always perpendicular to the common interface. In other words there is no stress tangential to the interface at any point.

The pressures at two contiguous points in a fluid may either differ or not. If they differ, the change of pressure must be balanced by some extraneous force acting on the fluid in the direction in which the pressure increases. Any direction in which no such force acts must be a direction in which there is no change of pressure; otherwise equilibrium will be destroyed. Suppose now the resultant force at every point in a fluid at rest to be given. In directions at right angles to the force at any given point the pressure will not vary. Hence we can pass to an infinite number of contiguous points at which the pressure is the same as at the given points. By making each of these in turn the starting-point, we can pass on to another set of points, and so gradually trace out within the fluid a surface at every point of which the pressure is the same. Such a surface is called a surface of equal pressure, or briefly a level surface; and we can see from the mode of its construction that it is at every point of it perpendicular to the resultant force at that point.

It is evident that, for a fluid situated as our atmosphere is, the pressure must diminish as we ascend. The equipotential surfaces and consequently the surfaces of equal pressure and of equal density will be approximately spheres concentric with the earth. At any point there will be a definite atmospheric pressure, which is equal numerically to the weight of the superincumbent vertical column of air of unit cross section. The effect of this pressure, as exemplified in the action of the common suction-pump, seems to have been first truly recognized by Galileo, who showed that the maximum depth from which water can be pumped is equal to the height of the water column which would exert at its base a pressure equal to the atmospheric pressure. As an experimental verification, he suggested filling with water a long pipe closed at the upper end, and immersing it with its lower and open end in a reservoir of the same liquid. The liquid surface in the pipe would, if the pipe were long enough, stand at a definite height, which

would be the same for all longer lengths of pipe. The practical difficulty of constructing a long enough tube (33 feet at least) prevented the experiment being really made till many years later.

Torricelli, however, in 1642, by substituting mercury for water, produced the experiment on a manageable scale. See BAROMETER.

The transition from the gaseous to the liquid state is conveniently studied by the help of isothermal lines, which may be generally defined as curves showing the relation between two mutually dependent variables for given constant temperatures. Such variables are the pressure and volume of a mass of gas. Let the numbers representing the volumes be measured from a chosen origin along a horizontal axis, and the numbers representing the pressures similarly along a vertical axis passing through the same origin. If we consider a mass of gas at a given temperature, for any volume that can be named there will be a definite pressure corresponding, and *vice versa*. Hence the point whose coördinates are the corresponding volume and pressure is completely determined if either coördinate is given. The temperature always being kept constant, let now the volume change continuously. The pressure will also alter according to a definite law; and the point whose coördinates are at any instant the corresponding volume and pressure will trace out a curve. This curve is an isothermal curve, or simply an *isotherm*. The isotherm would be a rectangular hyperbola, whose asymptotes are the coördinate axes. For any gas not near its point of liquefaction the isotherm will not deviate greatly from the hyperbolic form.

So long as the substance is in the gaseous form, the isotherm remains approximately hyperbolic; but at the pressure at which liquefaction takes place a marked change occurs in the form of the curve.

The necessity for a very low temperature long prevented the obtaining in a liquid form of the standard gases—hydrogen, oxygen, nitrogen, etc.—which were accordingly distinguished by the name *permanent gases*. Faraday proved that these could not be liquefied at a temperature of  $-110^{\circ}$  C., even when subjected to a pressure of 27 atmospheres. Naterer likewise failed to reduce these gases to the liquid state, even at a pressure of 3,000 atmospheres. His means for reducing the temperature were not satisfactory. In 1877 Cailletet and Pictet, working independently, first successfully effected their approximate liquefaction.

In many experiments on the properties of gases it is necessary to have an efficient and rapid means for altering the density. Instruments for this purpose are called air-pumps, and their function may be either to rarefy or condense the air—usually the former.

Otto Von Guericke of Magdeburg constructed the first air-pump about the year 1652. It was simply a spherical glass vessel opening below by means of a stop-cock and narrow nozzle into the cylinder of an “exhausting syringe,” which inclined upward from the extremity of the nozzle, while at the same time the former was forced open by the pressure of the denser air in the vessel and nozzle. Thus, at every complete stroke of the piston, the air in the vessel or receiver was diminished by that fraction of itself which is expressed by the ratio of the volume of the available cylindrical space above the outward opening valve to the whole volume of receiver, nozzle, and cylinder.

The important characteristics of an efficient air-pump are as follows. The piston must work smoothly and easily. The valves must act precisely, and be when closed absolutely air-tight. The plate on which the receivers rest must be smooth and plane, so that the ground edges of the receivers may be in close contact

all round. This perfect fitting is beyond the powers of the best workmanship, so that it is necessary to press between the receiver and plate a thin layer of lard, which renders the junction air-tight. Somewhere in the duct leading from the receiver to the piston cylinders, a stop-cock must be fixed, so that it may be possible to shut off the receiver completely from these. Then a second stop-cock is required as a ready means for admitting air to the receiver, whenever the need should arise. A combination three-way stop-cock is a very usual form. And, finally, the apparatus should be provided with a pressure gauge—a mercury manometer communicating by means of a duct with the main duct and receiver.

The cooling of a gas by its own expansion may be observed in one of its effects during exhaustion in an ordinary receiver. Frequently a cloud of minute drops of water—a veritable fog—forms in the exhausted air. The reason simply is that the air has become cooled below its dew-point, or the temperature corresponding to the pressure of water vapor present.

PNEUMONIA, or inflammation of the substance of the lungs, manifests itself in several forms which differ from each other in their nature, causes, and results—viz.: (1) Acute Croupous or Lobar Pneumonia, the most common form of the disease, in which the inflammation affects a limited area, usually a lobe or lobes of the lung, and runs a rapid course; (2) Catarrhal Pneumonia, Broncho-Pneumonia, or Lobular Pneumonia, which occurs as a result of antecedent bronchitis, and is more diffuse in its distribution than the former; (3) Interstitial Pneumonia or Cirrhosis of the lung, a more chronic form of inflammation, which affects chiefly the framework or fibrous stroma of the lung and is closely allied to phthisis.

*Acute Croupous or Lobar Pneumonia.*—This is the disease commonly known as inflammation of the lungs.

The symptoms of acute pneumonia are generally well marked from the beginning. The attack is usually ushered in by a rigor (or in children a convulsion), together with vomiting and the speedy development of the febrile condition, the temperature rising to a considerable degree— $101^{\circ}$  to  $104^{\circ}$  or more. The pulse is quickened and there is a marked disturbance in the respiration, which is rapid, shallow, and difficult, the rate being usually accelerated to some two or three times its normal amount. The lips are livid, and the face has a dusky flush. Pain in the side is felt, especially should any amount of pleurisy be present, as is often the case. Cough is an early symptom. It is at first frequent and hacking, and is accompanied with a little tough colorless expectoration, which soon, however, becomes more copious and of a rusty brown color, either tenacious or frothy and liquid. Microscopically this consists mainly of epithelium, casts of the air cells, and fine bronchi, together with granular matter and blood and pus corpuscles.

The treatment of acute pneumonia, which at one time was conducted on the antiphlogistic or lowering principle, has of late years undergone a marked change; and it is now generally held that in ordinary cases very little active interference is called for, the disease tending to run its course very much as a specific fever. The employment of blood-letting once so general is now only in rare instances resorted to; but, just as in pleurisy, pain and difficulty of breathing may sometimes be relieved by the application of a few leeches to the affected side. In severe cases the cautious employment of aconite or antimony at the outset appears useful in diminishing the force of the inflammatory action. Warm applications in the form of poultices to the chest give comfort in many cases. Cough is relieved by ex-

pectorants, of which those containing carbonate of ammonia are specially useful. Any tendency to excessive fever may often be held in check by quinine. The patient should be fed with milk, soups, and other light forms of nourishment. In the latter period of the disease stimulants may be called for, but most reliance is to be placed on nutritious aliment. After the acute symptoms disappear counter irritation by iodine or a blister will often prove of service in promoting the absorption of the inflammatory products. After recovery is complete the health should for some time be watched with care.

When pneumonia is complicated with any other ailment or itself complicates some preëxisting malady, it must be dealt with on principles applicable to these conditions as they may affect the individual case.

The symptoms characterizing the onset of catarrhal pneumonia in its more acute form are the occurrence during an attack of bronchitis of a sudden and marked elevation of temperature, together with a quickened pulse and increased difficulty in breathing. The cough becomes short and painful, and there is little or no expectoration. The physical signs are not distinct, being mixed up with those of the antecedent bronchitis; but, should the pneumonia be extensive, there may be an impaired percussion note with a tubular breathing and some bronchophony.

Acute catarrhal pneumonia must be regarded as a condition of serious import. It is apt to run rapidly to a fatal termination, but on the other hand a favorable result is not infrequent if it is recognized in time to admit of efficient treatment. In the more chronic form it tends to assume the characteristics of chronic phthisis (see PHTHISIS). The treatment is essentially that for the more severe forms of bronchitis (see BRONCHITIS), where in addition to expectorants, together with ammoniacal, ethereal, and alcoholic stimulants, the maintenance of the strength by good nourishment and tonics is clearly indicated. The breathing may often be relieved by light warm applications to the chest and back. Convalescence is often prolonged, as special care will always be required in view of the tendency of the disease to develop into phthisis.

The symptoms of chronic interstitial pneumonia are very similar to those of chronic phthisis (see PHTHISIS), especially increasing difficulty of breathing, particularly on exertion, cough either dry or with expectoration, sometimes copious and fetid. In the case of coalminers the sputum is black from containing carbonaceous matter.

The physical signs are deficient expansion of the affected side—the disease being mostly confined to one lung—increasing dullness on percussion, tubular breathing, and moist sounds. As the disease progresses retraction of the side becomes manifest, and the heart and liver may be displaced. Ultimately the condition as regards both physical signs and symptoms takes the characteristics of the later stages of phthisis with colliquative symptoms, increasing emaciation, and death. Occasionally dropsy is present from the heart becoming affected in the course of the disease. The malady is usually of long duration, many cases remaining for years in a stationary condition and even undergoing temporary improvement in mild weather, but the tendency is on the whole downward.

The treatment is conducted on similar principles to those applicable in the case of phthisis. Should the malady be connected with a particular occupation, the disease might be averted or at least greatly modified by early withdrawal from such source of irritation.

PNOM-PENH, the capital of CAMBODIA.

PO, the largest river of Italy, traverses the whole length of the great plain between the Alps and the

Apennines, which was in the Miocene period an arm of the sea connecting the Adriatic with the Mediterranean by what is now the Col d'Altare or Col di Cadibona and has gradually been filled by detritus from the surrounding highlands. That its course lies much nearer the Apennines than the Alps is evidently due to the fact that the tributaries from the loftier range on the north, whether in the form of glacier or stream, have all along been much more powerful than the tributaries from the south. The total length of the river from its conventional source to the mouth of the principal channel is 417½ miles, and the area of its basin, which includes portions of Switzerland and Austria, is estimated at 26,798 square miles.

POCHARD, POCKARD, or POKER, names properly belonging to the male of a species of Duck (the female of which is known as the Dunbird) the *Anas ferina* of Linnæus, and *Fuligula* or *Æthya ferina* of later ornithologists—but names very often applied by writers in a general way to most of the group or Subfamily *Fuligulinae* commonly called Diving or Sea-Ducks.

POCOCK, EDWARD, one of the most eminent of English Oriental and Biblical scholars, was born in 1604, and died in 1691.

POCOCKE, RICHARD, distantly related to the preceding, was the son of Richard Pockocke, head master of the free school at Southampton, where he was born in the year 1704. He died in 1765.

PODIEBRAD, GEORGE OF, king of Bohemia, was the son of Herant of Podiebrad, a Bohemian nobleman, and was born April 6, 1420. On the death of Ladislaus in 1457 he was chosen king of Bohemia (March, 1458.) George died March 22, 1471, and was succeeded by Ladislaus, eldest son of Casimir IV.

PODOLIA, a government of southwestern Russia, having Volhynia on the north, Kieff and Kherson on the east and south, Bessarabia on the southwest, and Galicia (Austria) on the west, from which last it is separated by the Zbrutch, or Rodvotcha, a tributary to the Dniester. It has an area of 16,223 square miles, extending for 200 miles from northwest to southeast on the left bank of the Dniester.

PODOLSK, a district-town of Russia, in the government of Moscow, is situated twenty-three miles to the south of the capital, at the junction of the two main roads going from Moscow to the Crimea and to Warsaw, and within a mile from the Podolsk railway station.

PODOPHYLLIN, a popular remedy which is much used by those who are averse to the employment of calomel and other mercurial preparations, and hence has been called vegetable mercury. The drug, as used in medicine, is obtained from the rhizome of the American mandrake or May apple. *Podophyllum peltatum*, L., an herbaceous perennial belonging to the natural order *Berberidaceæ*, indigenous in woods in Canada and the United States. In small doses it acts as a slow and gentle laxative, especially if combined with henbane and belladonna, but in large doses it is an irritant hydragogue cathartic, the action of which persists for some time. The usual dose as a laxative and mild hepatic stimulant is about ⅙ of a grain, but the samples met with in commerce vary considerably in strength, and act with varying effect upon different individuals. Specimens having a greenish tint should be avoided, since they probably contain podophyllo-querctin, and tend to cause severe griping. In large doses it appears to lose its stimulant action on the liver. Podophyllin is official in the pharmacopœias of Great Britain, India, France, Russia, and the United States.

POE, EDGAR ALLAN, is the most interesting figure in American literature, and his life furnishes the most extraordinary instance on record of systematic misrep-

resentation on the part of a biographer. It was not quite correct to describe Poe as the son of strolling players, but his father, a man of good family, had married an actress and taken to the stage as a profession. Their son was born in Baltimore, February 19, 1809; and father and mother died in 1811 when he was a child. The orphan was adopted by his godfather, Mr. Allan, a wealthy merchant, and from his eighth till his thirteenth year (1816-1821) was placed at school in England. Thence he was transferred to an academy at Richmond, Va., and thence at the age of seventeen to the university of Virginia at Charlottesville. Mr. Allan was childless, and apparently treated his adopted son as his own child. Why Poe left the university after one session is not clearly explained, but it has been ascertained that he was not expelled, but on the contrary was honorably distinguished as a student, although it is admitted that he had contracted debts and had "an ungovernable passion for card-playing." These debts may have been sufficient cause for a quarrel with Mr. Allan. Poe disappeared for two years, setting out for Europe to join the Greeks in their fight for independence. Reappearing at Richmond in 1829, he stayed at home for a year, and then was entered as a military cadet at West Point. But all his ambitions by this time were toward literature; he neglected his duties, disobeyed orders, and was dismissed from the service of the United States. What he did for two years after is not ascertained, but in 1833 he reappeared as the successful competitor for a prize offered by a Baltimore newspaper for a prose story. From that time he subsisted by literature. Mr. Allan had married again, and died soon afterward, leaving an heir by his second wife, and "not a mill" to Poe.

During the fifteen years of his literary life Poe was connected with various newspapers and magazines in Richmond, New York, and Philadelphia, and there is unanimous testimony that, so far from being an irregular contributor, he was a model of punctuality and thoroughness, and took a pride in these homely virtues. His connection was not in any one case "severed by his irregularities." He wrote first for the *Southern Literary Messenger* in Richmond, and edited it for some time; then, in 1837, he removed to New York, and wrote criticisms and did editorial work for the *New York Quarterly Review*; then, after a year, with a prospect of more lucrative employment, he removed to Philadelphia, and for four years was the mainstay of *Graham's Magazine*. His literary work was poorly paid for, though some of his most powerful tales—*Hans Pfaal*, *Arthur Gordon Pym*, *Ligeia*, *The House of Usher*, *The Murders in the Rue Morgue*, *Marie Roget*, *The Descent into the Maelström*—were among Poe's contributions to these periodicals. His short stories were an easy prey for the newspaper pirate, and when thousands were reading them the author received nothing but the few dollars paid him by the publication in which they first appeared. *The Raven* was first published in 1845, and in a few months was being read and recited and parodied wherever the English language was spoken; but the half-starved poet, who had to live by his genius, received only ten dollars for the production. And, fertile and active as his imagination was, these short works of his, which served for the passing sensation of the newspaper reader, were far from being extempore effusions. His *Philosophy of Composition* is sometimes, indeed generally, regarded as half-serious, half a jest, in the author's peculiar way of mystification.

His wife died in 1847, and he followed her in 1849, dying under painful circumstances at Baltimore. For a critical estimate of Poe's writings the reader may be referred to Professor Nichol's *American Literature*.

There are few English writers of this century whose fame is likely to be more enduring. The feelings to which he appeals are simple but universal, and he appeals to them with a force that has never been surpassed.

POERIO, CARLO, Italian statesman, born in 1803, was descended from an old Calabrian family and was a son of Giuseppe Poerio, a distinguished lawyer of Naples. He died at Florence, April 28, 1867.

POETRY. In modern criticism the word poetry is used sometimes to denote any expression (artistic or other) of imaginative feeling, sometimes to designate one of the fine arts.

As an expression of imaginative feeling, as the movement of an energy, as one of those great primal human forces which go to the development of the race, poetry in the wide sense has played as important a part as science. In some literatures (such as that of England) poetic energy and in others (such as that of Rome) poetic art is the dominant quality. It is the same with individual writers. In classical literature Pindar may perhaps be taken as a type of the poets of energy; Virgil of the poets of art. In English poetical literature Elizabeth Barrett Browning typifies, perhaps, the poets of energy; while Keats (notwithstanding all his unquestionable inspiration) is mostly taken as a type of the poets of art. In French literature Hugo, notwithstanding all his mastery over poetic methods, represents the poets of energy.

In some writers, and these the very greatest—in Homer, Æschylus, Sophocles, Dante, Shakespeare, Milton, and perhaps Goethe—poetic energy and poetic art are seen in something like equipoise. It is of poetry as an art, however, that we have mainly to speak here; and all we have to say upon poetry as an energy is that the critic who, like Aristotle, takes this wide view of poetry—the critic who, like him, recognizes the importance of poetry in its relations to man's other expressions of spiritual force, claims a place in point of true critical sagacity above that of a critic who, like Plato, fails to recognize that importance. And assuredly no philosophy of history can be other than inadequate should it ignore the fact that poetry has had as much effect upon human destiny as that other great human energy by aid of which, from the discovery of the use of fire to that of the electric light, the useful arts have been developed.

1. *What is Poetry?*—Definitions are for the most part alike unsatisfactory and treacherous; but definitions of poetry are proverbially so.

Yet some definition, for the purpose of this essay, must be here attempted; and, using the phrase "absolute poetry" as the musical critics use the phrase "absolute music," we may, perhaps, without too great presumption submit the following:

*Absolute poetry is the concrete and artistic expression of the human mind in emotional and rhythmical language.*

2. *What position does Poetry take up in Relation to the other Arts?*—Notwithstanding the labors of Lessing and his followers, the position accorded by criticism to poetry in relation to the other arts was never so uncertain and anomalous as at the present moment. On the one hand there is a class of critics who, judging from their perpetual comparison of poems to pictures, claim her as a sort of handmaid of painting and sculpture. On the other hand the disciples of Wagner, while professing to do homage to poetry, claim her as the handmaid of music. To find her proper place is therefore the most important task the critic can undertake at this time, though it is one far beyond the scope of a paper so brief as this. With regard to the relations of poetry to painting and sculpture, however, it seems

necessary to glance for a moment at the saying of Simonides, as recorded by Plutarch, that poetry is a speaking picture and that painting is a mute poetry. It appears to have had upon modern criticism as much influence since the publication of Lessing's *Laocoon* as it had before. Perhaps it is in some measure answerable for the modern vice of excessive word-painting. Beyond this one saying, there is little or nothing in Greek literature to show that the Greeks recognized between poetry and the plastic and pictorial arts an affinity closer than that which exists between poetry and music and dancing. Understanding artistic methods more profoundly than the moderns, and far too profoundly to suppose that there is any special and peculiar affinity between an art whose medium of expression is marble and an art whose medium of expression is a growth of oral symbols, the Greeks seem to have studied poetry not so much in its relation to painting and sculpture as in its relation to music and dancing.

The true place of poetry lies between music on the one hand and prose, or loosened speech, on the other.

And now how stands poetry with regard to the plastic arts?

As compared with sculpture and painting the great infirmity of poetry, as an "imitation" of nature, is of course that the medium is always and of necessity words—even when no words could, in the dramatic situation, have been spoken. What human sounds could render the agony of Niobe, or the agony of Laocoon, as we see them in the sculptor's rendering? Not articulate speech at all; not words but wails. It is the same with hate; it is the same with love. We are not speaking merely of the unpacking of the heart in which the angry warriors of the *Iliad* indulge. Even such subtle writing as that of Æschylus and Sophocles falls below the work of the painter. Hate, though voluble perhaps, as Clytæmnestra's when hate is at that red-heat glow which the poet can render, changes in a moment whenever that redness has been fanned to hatred's own last complexion—whiteness as of iron at the melting-point—when the heart has grown far too big to be "unpacked" at all, and even the bitter epigrams of hate's own rhetoric, though brief as the terrier's snap before he fleshes his teeth, or as the short snarl of the tigress as she springs before her cubs in danger, are all too slow and sluggish for a soul to which language at its tensest has become idle play. But this is just what cannot be rendered by an art whose medium consists solely of words.

It is giving voice, not to emotion at its tensest, but to the variations of emotion, it is in expressing the countless shifting movements of the soul from passion to passion, that poetry shows in spite of all her infirmities her superiority to the plastic arts.

The faculty of developing a poetical narrative from a philosophic thought is Oriental, and on the whole foreign to the genius of the Western mind. Neither in Western drama nor in Western epic do we find, save in such rare cases as that of Vondel, anything like that power of developing a story from an idea which not only Jami but all the parable poets of Persia show.

In recent English poetry, the motive of Shelley's dramatic poem *Prometheus Unbound* is a notable illustration of what is here contended. Starting with the full intent of developing a drama from a motive—starting with a universalism, a belief that good shall be the final goal of ill—Shelley cannot finish his first 300 lines without shifting (in the curse of "Prometheus") into a Manichæism as pure as that of Manes himself:—

"Heap on thy soul, by virtue of this curse,  
Ill deeds, then be thou damned, beholding good;  
Both infinite as is the universe."

According to the central thought of the poem human nature, through the heroic protest and struggle of the human mind typified by Prometheus, can at last dethrone that supernatural terror and tyranny (Jupiter) which the human mind had itself installed. But, after its dethronement (when human nature becomes infinitely perfectible), how can the supernatural tyranny exist apart from the human mind that imagined it? How can it be as "infinite as the universe?"

POGGENDORFF, JOHANN CHRISTIAN, physicist, an editor for more than half a century of the well-known scientific journal called after him *Poggendorff's Annalen*, was born in Hamburg on December 29, 1796. He had an extraordinary memory, well-stored with scientific knowledge, both modern and historical, which served him in good stead in the critical part of his editorial duty. He had a cool and impartial judgment, with a strong preference for facts as against theory of the speculative kind at least, and was able to throw himself into the spirit of modern experimental science, represented in the early part of his editorial career by such great names as Berzelius, Faraday, Brewster, Fresnel, Regnault. He also possessed in more than German measure the German virtue of orderliness in the arrangement of knowledge and in the conduct of business. To this he added an engaging geniality of manner and much tact in dealing with men; so marked in fact was this part of his character that, notwithstanding his somewhat trying position, he never during his long life was involved in anything that could be fairly called a literary quarrel. Its editor soon made *Poggendorff's Annalen* the foremost scientific journal in Europe.

Poggendorff's literary and scientific reputation speedily brought him honorable recognition. In 1830 he was made royal professor and in 1834 Hon. Ph.D. and extraordinary professor in the university of Berlin, and in 1839 member of the Berlin Academy of Sciences. He ultimately became a member of many foreign societies, and received more than the usual share of the orders bestowed by continental nations for scientific merit. During his lifetime many offers of ordinary professorships were made to him, but he declined them all, devoting himself to his duties as editor of the *Annalen*, and to the pursuit of his scientific researches. He died at Berlin on January 24, 1877.

POGGIO, Gian Francesco Poggio Bracciolini, eminent in the annals of the revival of learning, was born in 1380 at Terranova, a village in the territory of Florence. His distinguished abilities and his dexterity as a copyist of MSS. brought him into early notice with the chief scholars of Florence.

POGY, a popular name for the fish *Clupea menhaden*, almost universally in use in the State of Maine and Massachusetts (see MENHADEN).

POINSOT, LOUIS, mathematician, was born at Paris, January 3, 1777. In 1794 he became a scholar at the Polytechnic School, which he left in 1796 to act as a civil engineer. He died at Paris, December 5, 1859. Poinsot's earliest work was his *Élémens de Statique*, in which he introduces the idea of statical couples and investigates their properties. He contributed a number of papers on pure and applied mathematics to *Liouville's Journal* and to the *Journal* of the Polytechnic School.

POINT DE GALLE. See GALLE.

POINTE À PITRE, the principal port of the island of Guadeloupe.

POISONS. An exact definition of the word "Poison" is by no means easy. There is no legal definition of what constitutes a poison, and the definitions usually proposed are apt to include either too much or too little. Generally, a poison may be defined to be a substance having an inherent deleterious property, rendering it

capable of destroying life by whatever avenue it is taken into the system; or it is a substance which when introduced into the system, or applied externally, injures health or destroys life irrespective of mechanical means or direct thermal changes. In popular language, a poison is a substance capable of destroying life when taken in small quantity; but a substance which destroys life by mechanical means as, *e.g.*, powdered glass, is not strictly speaking a poison.

The subject of toxicology forms one of the most important branches of MEDICAL JURISPRUDENCE, (*q.v.*) The medical jurist should be familiar with the nature and actions of poisons, the symptoms which they produce, the circumstances which modify their working, the pathological results of their action, and the methods of combating these.

*Action of Poisons.*—Poisons may exert a twofold action. This may be either local, or remote, or both local and remote. The local action of a poison is usually one of corrosion, inflammation, or a direct effect upon the sensory or motor nerves. The remote actions of poisons are usually of a specific character, though some writers group the remote effects of poisons under two heads, and speak of the common and the specific remote effects of a poison. The local action of a poison of the corrosive class is usually so well marked and obvious that the fact of the administration of a poison of this class is generally unmistakable. The same may be said, in a less degree, of the irritant poisons, especially the mineral irritants; but here the symptoms sometimes so closely simulate those of natural disease as to render the recognition of the administration of poison a matter of difficulty. Hence an accurate acquaintance with the remote specific effects of the various poisons is indispensable to the medical jurist. The class of poisons which has been administered or taken will thus be suggested to his mind by the observation of the symptoms; and not infrequently the specific poison taken will be suspected. It is almost universally admitted that absorption of a poison is necessary for the production of its specific remote effects, and the old notion that a poison may kill, by its action through the nervous system, without absorption, is abandoned.

*Modifying Circumstances.*—The ordinary action of a poison may be greatly modified by the largeness of the dose, by the state of aggregation, admixture, or of chemical combination of the poison, by the part or membrane to which it is applied, and by the condition of the patient. Thus, for example, opium may be a medicine or a poison according to the dose in which it is given; and a dose of the drug which may be beneficial to an adult in certain states of the system may be fatal to a child, or to an adult when suffering from some forms of disease. All barium salts, again, are poisonous, except the quite insoluble sulphate. The simple cyanides, and many double cyanides, are highly poisonous; but yellow prussiate of potash, which is a double cyanide of iron and potassium, is almost without action upon the system. The part or tissue to which a poison is applied greatly affects the activity of a poison, owing to the varying rapidity with which absorption takes place through the cutaneous, mucous and serous surfaces, and by the other tissues of the body. Curare, an arrow poison, may be swallowed in considerable quantity without appreciable result, while a minute quantity of the same substance introduced into a wound is speedily fatal. Idiosyncrasy has an important bearing in toxicology. Pork, mutton, certain kinds of fish, more especially shell fish so-called, and mushrooms have each produced all the symptoms of violent irritant poisoning, while other persons who have partaken of

the same food at the same time have experienced no ill effects. Some persons are stated, on good authority, to be capable of taking with impunity such poisons as opium, corrosive sublimate, or arsenic, in enormous doses—and this irrespective of habit, which is known to have such an influence in modifying the effects of some poisons, notably the narcotics. A tolerance of poisons is sometimes engendered by disease, so that a poison may fail to produce its customary effect. Thus, opium is tolerated in large quantities in tetanus and in delirium tremens, and mercurial compounds may in some febrile affections fail to produce the usual constitutional effects of the metal. On the other hand, diseases which impede the elimination of a poison may intensify its effects.

The *evidence* that a poison has been administered is based upon the symptoms produced, on the appearances met with in the body after death, on the analysis of articles of food and drink, of excreta and ejecta, and of the organs of the body after death, and on physiological experiments made with substances extracted from the same articles. These physiological experiments are usually made upon animals, but in some cases, as for instance when aconite has to be searched for, the physiological experiments must be made also upon the human subject. The evidence obtained from one or more of these sources, as compared with the properties or effects of various known poisons, will enable the medical jurist to form an opinion as to the administration or non-administration of a poison.

The *symptoms* exhibited by the patient during life rarely fail to afford some clue to the poison taken. Persons may, however, be found dead of whose history nothing can be learned. Here post-mortem appearances, chemical analysis, and, it may be, physiological experiments are all-important for the elucidation of the nature of the case.

Poisoning may be *acute* or *chronic*. The general conditions which should arouse a suspicion of acute poisoning are the sudden onset of serious and increasingly alarming symptoms in a person previously in good health, especially if there be pain in the region of the stomach, or, where there is complete prostration of the vital powers, a cadaveric aspect, and speedy death. In all such cases the aid of the analytical chemist must be called in either to confirm well-founded or rebut ill-founded suspicions.

The *mode of treatment* to be adopted in the case of poisoned persons varies greatly according to the nature of the poison. The first indication, when the poison has been swallowed, is to evacuate the stomach; and this may usually be done by means of the stomach-pump when the poison is not of the corrosive class; or the stomach may be gently washed out by means of a funnel and flexible siphon-tube. In many cases emetics are valuable. Antidotes and counter-poisons may then be given. The former are such substances as chalk to neutralize the mineral acids and oxalic acid; the latter have a physiological counteraction, and are such as atropine, which is a counter-poison to morphia. These may usually be administered most effectively by hypodermic injection. The stomach may to a certain degree be protected from the injurious effects of irritants by the administration of mucilaginous drinks; alkaloids may be rendered sparingly soluble by means of astringent substances containing tannin; and pain may be relieved by means of opium, unless contra-indicated by the nature of the poison. The effects of the convulsant poisons, such as strychnine, may be combated by means of the inhalation of chloroform.

The *classification* of poisons is a matter of difficulty. Various attempts have been made to classify them scien-

tifically, but with no signal success; and perhaps the best system is that which groups the various poisons according to the more obvious symptoms which they produce. Our knowledge of the more intimate action of poisons is still too imperfect to admit of any useful classification according to the manner in which they specifically affect the vital organs. Poisons may in the manner indicated be classified as (1) *Corrosives*, (2) *Irritants*, (3) *Neurotics*, and (4) *Gaseous Poisons*. The subject of poisonous food has already been treated under the heading MEDICAL JURISPRUDENCE.

POISSON, SIMÉON DENIS, a celebrated French mathematician, was born at Pithiviers in the department of Loiret, on June 21, 1781, and died in 1840.

As a teacher of mathematics Poisson is said to have been more than ordinarily successful, as might have been expected from his early promise as a répétiteur at the Polytechnic School. As a scientific worker his activity has rarely if ever been equaled. Notwithstanding his many official duties, he found time to publish more than 300 works, several of them extensive treatises, and many of them memoirs dealing with the most abstruse branches of pure and applied mathematics. There are two remarks of his, or perhaps two versions of the same remark, that explain how he accomplished so much: one, "La vie n'est bonne qu'à deux choses—à faire des mathématiques et à les professer;" (Life has but two good things—to study mathematics and be a professor); the other, "La vie c'est le travail." (Life is toil.)

POITIERS, a town of France, formerly the capital of Poitou, and now the chief town of the department of Vienne, lies 206 miles southwest of Paris on the railway to Bordeaux, at the junction of the Boivre with the Clain (a tributary of the Loire by the Vienne), and occupies the slopes and summit of a plateau which rises 130 feet above the level of the streams by which it is surrounded on three sides. King John having been defeated and made prisoner in the disastrous battle of Poitiers (fought four miles east of the town on the hillside of Nouaille, September 19, 1356), Poitou was recognized as an English possession by the treaty of Brétigny (1360). Nine years later it was recovered by Duguesclin.

POITOU, one of the old provinces of France, which also formed one of the great military governments of the kingdom, was bounded north by Brittany, Anjou, and Touraine; south by Angoumois and Aunis; east by Touraine, Berri, and Marche; and west by the ocean. It was divided into Lower Poitou, which corresponded to the modern department of La Vendée, and Upper Poitou, now split into the departments of Deux-Sèvres and Vienne.

POKER, a game at cards—probably a development of *il frusso* (played in Italy in the fifteenth century). A similar but less simple game, called *primiera*, was also played in Italy in the sixteenth century, whence under the name of *primero* it traveled to Spain. *La prime* is mentioned by Rabelais (sixteenth century;) and later the game of prime elaborated was played in France under the name of *l'ambigu* or *le meslé*. Prime was also played in England in the sixteenth century; and later a bastard kind of prime, called post and pair, was much played in the west of England. Gleek had some points of resemblance to these games. The more modern game of brag is only post and pair with variations. Poker (originally played in America) may be described as developed brag, though in some respects it "throws back" to the parent games post and pair, *l'ambigu*, and *primero*.

*Draw Poker* is played with a pack of fifty-two cards, and by any number of persons from two to six.

Before the dealer begins to deal the cards, the player

next to his left, who is called the *ante-man*, or *age*, must deposit in the pool an *ante* not exceeding one-half the limit previously agreed upon; this is called a blind.

The deal is performed by giving five cards to each player, one at a time, beginning with the player to the left of the dealer.

After the cards have been dealt the players look at their hands, and each player, in rotation, beginning with the player to the left of the *age*, determines whether he will *go in* or not. Any player who decides to go in, that is, to play for the pool, must put into the pool double the amount of the ante, except the player holding the *age*, who contributes the same amount as his original ante. This makes the blind good, and all the players interested in that hand will have contributed alike.

Those who decline to play throw their cards, face downward; upon the table in front of the next dealer.

Any player, when it is his turn, and after making the ante good, may *raise*, *i. e.*, increase the ante any amount within the limit of the game.

Another feature that may be introduced when betting upon the *original hand*, is the *straddle*. The straddle is nothing more than a double blind.

When all are in who intend to play, each player has the right to draw any number of cards he chooses, from one to five, or he can retain his cards as originally dealt to him. If a player draws cards, he must discard a like number from his hand previous to drawing, and the rejected cards must be placed face downward upon the table near the next dealer.

When all the hands are filled, the player to the left of the *age* has the first say, and he must either bet or retire from the game, forfeiting what he has already staked. The same with all the other players, in rotation, up to the *age*. When a player makes a bet, the next player must either *see him*, *i. e.*, put in the pool an equal amount, or *go better*, *i. e.*, make the previous bet good, and raise it any amount not exceeding the limit; or he must pass out.

If all the players pass up to the *age*, the latter takes the pool, and the deal ends.

The value of the hands is as follows, given in the regular order: One pair, two pair, triplets, a straight (straights are not always played; it should therefore be determined whether they are to be admitted at the commencement of the game. If, however, it has been agreed before commencing to play that straights are to be counted in the game, a straight flush outranks four cards of the same denomination, four aces, for instance), a flush, a full, fours (when straights are not played, fours beat a straight flush), a straight flush. When none of the foregoing hands are shown, the highest card wins; if these tie, the next highest in those two hands, and so on. If upon a *call* of a show of hands, it occurs that two or more parties interested in the call hold hands identical in value, and those hands are the best out, the parties thus tied must divide the pool, share and share alike.

*Whisky Poker* is a neat variation of draw poker, and is a most amusing game. Each player contributes one chip to make a pool, and the same rule governs as at "draw," except that the strongest hand you can get is a straight flush.

Five cards are dealt to each player, one at a time, and an extra hand is dealt on the table, which is called the "*widow*."

The eldest hand then examines his cards, and if, in his judgment, his hand is sufficiently strong, he passes.

The next player then has the privilege of the widow, and, for the purpose of illustration, we will suppose he takes it; he then lays his discarded hand (that which

he relinquishes for the widow) face up in the center of the table, and the next player on the left selects from it that card which suits him best in filling his hand, and so on all around the board, each player discarding one card and picking up another, until some one is satisfied, which he signifies by knocking upon the table.

When this occurs, all the players around to the satisfied party have the privilege of one more draw, when the hands are shown, and the strongest wins.

If any player knocks before the widow is taken, the widow is then turned face up, and each player from him who knocks has but one draw.

Should no one take the widow, but all pass to the dealer, he then turns the widow, and all parties have the right to draw until some one is satisfied.

*Straight Poker*, or *Bluff*, as it is sometimes called, is played with a pack of fifty-two cards. The game is governed by the same rules as draw poker, and differs from the latter game in the following particulars only:

I. The winner of the pool has the deal.

II. Each player antes before the cards are cut for the deal.

III. Any player may pass with the privilege of coming in again, provided no player *preceding* him has made a bet.

IV. No player is permitted to discard, or draw any cards.

V. When all the players pass, the eldest hand deals, and each player deposits another ante in the pool, thus making what is termed a "double-header." When a misdeal occurs, the rule is the same.

To avoid confusion, and prevent misunderstanding, instead of each player depositing an ante before the cards are cut, it is usual for one of the players (at the commencement of the game, the dealer) to put up a sum equal to an ante from each, thus: if four are playing and the ante is one chip, the dealer puts up four chips, and passes the *buck*, *i. e.*, a knife or key, to the next player at his left. When the next deal occurs, the player having the buck puts up four chips, and passes the *buck* to his next neighbor, who in turn does the same, and so it goes round as long as the game continues. Straight poker is but seldom played, having been superseded by the draw game.

*Stud Poker* is the name of a game which, in all essential particulars, is like the other poker games, and is subject to the same laws and mode of betting, passing, etc. It is played in this manner:

Five cards are dealt, one at a time—the first dealt as usual, face down, all the others face up, the highest pair, or best hand winning, as at "draw." To illustrate, suppose the dealer's four cards as exposed, are a king, four, seven, and a five, and his opponent's a queen, ten, six, and nine—the dealer's hand in sight is the better hand, and the call being made and the unknown cards turned over, the non-dealer shows an ace, and his opponent an eight; of course, the dealer loses.

POKROVSKAYA SLOLODA, or POKROVSK, also KASAKSTADT, a village of the district of Novo-uzen, in the government of Samara, Russia, on the left bank of the Volga, almost opposite Saratoff.

POLA, the principal naval harbor and arsenal of the Austrian-Hungarian monarchy, is picturesquely situated at the south extremity of the peninsula of Istria, fifty-five miles to the south of Trieste.

The foundation of Pola is usually carried back to the mythic period, and ascribed to the Colchian pursuers of Jason and the Argonauts. In all probability it was a Thracian colony, but its verifiable history begins with its capture by the Romans 178 B. C. It was destroyed by Augustus on account of its espousal of the cause of

Pompey, but was rebuilt on the intercession of his daughter Julia, and received (according to Pliny) the name of Pietas Julia. It seems to have attained its greatest prosperity about the time of the emperor Septimius Severus (193-211 A.D.), when it was an important war harbor and contained 35,000 to 50,000 inhabitants.

POLAND (the Polish *Polska*, German *Polen*, French *Pologne*) was till toward the end of the eighteenth century a large and powerful kingdom, extending, with Lithuania, which was incorporated with it, over the basins of the Warta, Vistula, Dwina, Dnieper, and upper Dniester, and having under its dominion, besides the Poles proper and the Baltic slavs, the Lithuanians, the White Russians, and the Little Russians or Ruthenians.

If Schafarik is correct in seeing the name of the Poles in the *Bulanes* of the geographer Ptolemy, we shall have this Slavonic people mentioned as early as the second century after Christ.

All that we are told of the early Slavs shows them to have been a quiet agricultural people. We find them at first living in village communities with a tribal government. Nestor says, "The Poliani lived in separate groups, and each governed his family." Gradually a class of serfs sprung up, whose origin cannot be clearly traced. Röpell in his history supposes that they were the descendants of rival tribes who had been conquered. At all events we soon find the following divisions of society among the Poles:— (1) the nobility who throughout Polish history constitute the nation properly so-called; (2) a superior class of peasants who were personally free, but bound to perform certain services (these are always called Polish *kmienci*); and (3) the peasants strictly so called, who were the property of their masters and had no rights. We shall see how there was gradually formed in Poland a proud military aristocracy, which circumscribed the power of the king by the *pacta conventa*, so that he became a mere puppet in their hands. The nobles had absolute power over the serfs, as each separate palatinate had its tribunals. In course of time the *kmienci* became mere bondsmen. The miserable condition of the latter is seen in such books as Connor's *Letters on Poland*, published at the conclusion of the seventeenth century. Connor, who was physician to John Sobieski, had good opportunities for forming an opinion. Thus the trade of the country fell wholly into the hands of foreigners and Jews.

With the reign of Mieczyslaw I. (962-992) we begin to have something firmer in our grasp. He became a suitor for the hand of Dabrowha, the daughter of the king of Bohemia. Being a Christian she refused to give her hand to a pagan, and Mieczyslaw consented to be baptized in 965. He died in 992 universally regretted, as we are told, and was succeeded by his son Boleslaw, surnamed the Great. During his reign Otho III. of Germany paid him a visit, and the Polish prince received him with such magnificence that the emperor elevated his duchy into a kingdom, probably intending that it should always remain a fief of the empire.

Toward the end of his life Boleslaw sought to aggrandize himself at the expense of Russia. He was succeeded by Mieczyslaw, his son, who abandoned himself to pleasure, and left the kingdom in a disordered state. He is said to have first divided Poland into palatinates, a term which will be explained shortly. On his death an interregnum ensued. To heal the universal wounds it was resolved to send for Kazimiérz (Casimir), the son of Mieczyslaw. Kazimiérz was succeeded by a second Boleslaw (1058-1101), of whom many curious stories are told. After the disappearance of Boleslaw, who had taken his son with him and fled, the State remained

nearly a year without a sovereign. Finally, being afraid of a Russian or Hungarian invasion, the Poles called to the throne Wladyslaw (Ladislaus), the brother of Boleslaw. The power of Poland was diminished in his reign, as many provinces were occupied by the Russians. He was succeeded by his son, Boleslaw III., to whom the Poles have affixed the surname Krzywousty, or the Wry-mouthed. On his death Boleslaw was succeeded by his brother Mieczyslaw, who was so unpopular that he was expelled from the country in 1177. The crown, therefore, according to the prophecy, devolved upon Kazimiérz, the youngest son of Boleslaw Krzywousty. During his reign many judicious laws were passed in Poland; among other improvements he abolished the evil custom of purveyance. In the reign of Boleslaw V. (1227-79) the Mongols made an incursion into Poland, but were subsequently diverted into Hungary, having gained a victory at Lignica (Liegnitz) in Silesia in 1241.

An unfortunate and uninteresting prince, Leszek the Black, succeeded, but the dignity of the house of Piast was fully restored when Przemyslaw, without condescending to solicit the title of sovereign from the hands of the pope, received the crown from his nobles and clergy at Gniezno (Gnesen). Thus did Poland again become a kingdom. This unfortunate prince, however, was afterward murdered by the margrave of Brandenburg at Rogozno (1295). The reign of Waclaw (Wenceslaus) (1300-5) was not of great importance. He united the crowns of Poland and Bohemia, but soon became unpopular on account of his preference of his Bohemian subjects. With him expired the race of the holy peasant Premysl, which had ruled Bohemia according to the ancient chronicles for nearly 600 years. The relations of the latter country to the German empire were now to become much closer. Wladyslaw Lokietek, who succeeded Waclaw, was constantly engaged in wars with the Teutonic knights.

Wladyslaw was succeeded by his son Kazimiérz (Casimir) III., justly surnamed the Great, whose reign was a golden period for Poland. Casimir was succeeded, as had been arranged, by Louis of Hungary, who held the crown for twelve years only, and of that period spent but a short time in the country. Louis showed too great a fondness for his own subjects; he had also the misfortune to be unacquainted with the Polish language. After his death his second daughter Jadwiga was elected queen, but she was to accept as husband any prince whom the diet might propose to her. As a matter of state policy she was induced to marry Jagiello, the prince of Lithuania, a man of savage manners; but Lithuania was thus annexed to Poland, with which it remained joined ever afterward—a more complete federation having taken place at Lublin in the year 1569. In 1386 they were married, and from that year we may date the commencement of the dynasty of the Jagiellos in Poland, which lasted for nearly two centuries, terminating in 1572—indeed, we may say nearly a century longer, omitting the short and brilliant period of Batory (1576-1586), for Sigismund III. was the son of Catherine daughter of Sigismund II., and Wladyslaw IV. and John Casimir were his sons; after the death of the latter the throne became entirely elective. The new sovereign was baptized by the name of Wladyslaw.

The consolidation of Lithuania with Poland was destined to be a much more tedious and protracted matter than its somewhat violent union. Great as may have been the grief of Wladyslaw at the death of Jadwiga, it did not prevent him from contracting three subsequent marriages—the third wife being Sophia, a princess of Kieff.

The younger Wladyslaw was able soon after his accession to add (by election) both Bohemia and Hungary to his dominions. At first Wladyslaw was everywhere successful, and had instilled such terror into the Turks that Amurath proposed a truce for ten years and offered to cede all his conquests except Bulgaria. The conditions, having been accepted, were ratified by mutual pledges; unfortunately Wladyslaw was induced by Cardinal Cesarini to recommence the war and violate his oaths. The sultan on hearing of this perjury at once prepared for battle at the head of a formidable army. The encounter took place at Varna, in the present principality of Bulgaria. After performing prodigies of valor, Wladyslaw was defeated and slain.

After a brief interregnum Kazimiérz, brother of the deceased king, was chosen to succeed him; he had previously been grand-duke of Lithuania. In this reign the Poles carried on successful wars with the Teutonic knights, which resulted in peace, by which western Prussia, including Pomerania and the cities Dantzic, Thorn, and others, were to belong to Kazimiérz, while eastern Prussia was left to the knights, who were, however, to hold it as a fief of the crown, and each subsequent grand master was to be the vassal of the Polish king and senate.

Kazimiérz was succeeded by his son John I., surnamed Albert, a feeble prince, most of whose wars were unsuccessful. John Albert was succeeded by his brother Alexander, an utterly insignificant king; in his reign, however, we trace the first germ of the detestable *liberum veto*, which ruined Poland. The feeble Alexander was succeeded by his brother Sigismund (in Polish, Zygmunt), another son of Kazimiérz. Sigismund was engaged in constant wars with Basil, the czar of Russia.

In this reign the order of Teutonic Knights embraced the doctrines of Luther; their dominions were already a fief of the Polish kingdom. Gradually this small principality was to absorb the Slavonic elements which surrounded it, and to rise triumphant over the ruins of Poland. The doctrines of the Reformation were now becoming widely spread over Europe, and the element of religious animosity was largely infused into this land of perpetual anarchy and tumults. Sigismund, however, was a man of remarkable ability, and under his rule the country flourished. He survived to the age of eighty-two, and his memory is still cherished with affection by the Poles. His broad heavy physiognomy may be seen accurately represented in the old editions of Kromer, who dwells much upon his merits.

He was succeeded by his son Sigismund II. (1548-72), otherwise called Sigismund Augustus, but this prince was not elected till a very stormy debate had ensued as to whether he should repudiate his wife or not. He had married, as a widower (his first wife having been Elizabeth, daughter of Ferdinand of Austria), a fair widow of the house of Radziwill one of the most illustrious of the families of Lithuania. The nobles, however, who already treated their sovereign as a chief magistrate and nothing more, and had begun to control all his movements, required at the diet of Piotrkow that the marriage should be annulled, merely on the grounds that the country would gain more by his alliance with the daughter of a foreign potentate. But Sigismund, by sowing discord in the ranks of his opponents—proposing among other things to destroy pluralities in church and state—contrived to carry his point. His wife was crowned in 1550, but died within six months after, not without suspicions of having been poisoned by her mother-in-law. In this reign, Warsaw was fixed upon as the seat of the government, since, being part of Masovia, it was, strictly speaking, neither Polish

nor Lithuanian. It afterward became the regular capital of the country. An interregnum now occurred on the failure of the line of the Jagiellos, and the throne was publicly offered for competition. Four candidates appeared—Ernest, archduke of Austria; Henry of Valois, duke of Anjou, brother of the French king; a Swedish prince; and finally Ivan the Terrible of Russia. The contest, however, really lay between the first two. The political importance of France and the astute diplomacy of Montluc, the ambassador from that country, caused the decision to be given in favor of the French candidate.

By the death of his brother Charles IX. he became heir to the French crown. Henry at once secretly fled to France, but was pursued and overtaken, and refused to return. The Poles, however, were well rid of one of the most corrupt sovereigns of a corrupt house. In 1589 the knife of the Dominican friar terminated his life, and with it the line of the Valois.

The Poles, piqued at the contempt with which their crown had been treated, assembled at Stezycy and resolved to declare the throne vacant if the king did not return by May 12, 1575. During the interregnum the Mongols made incursions into Podolia and Volhynia, and grievously devastated those countries. The appointed period having elapsed, Stephen Batory, prince of Transylvania, was elected, having previously stipulated to marry the princess Anne, sister of Sigismund Augustus. There were some difficulties, however, before he succeeded in obtaining the royal authority. The primate Ucharski nominated the emperor Maximilian king. This caused considerable opposition, and the city of Dantzic did not recognize the new sovereign till compelled. To conciliate the nobility Batory was obliged to consent to some serious diminutions of the royal prerogative. This king was a great soldier, successful against both Prussians and Russians, the latter of whom he compelled, in 1582, to evacuate Livonia, which was thus again annexed to Poland. He also did much to encourage letters.

On the death of Batory in 1586, after many quarrels among the leading families, the throne was again brought into the market. The candidates were, among others, the archduke Maximilian of Austria; Feodore Ivanovitch, the feeble Russian czar; and Sigismund, a Swedish prince, son of Catherine, sister of Sigismund Augustus. The last of the three was finally elected, although not without considerable opposition from Maximilian, who was only driven from his candidature by main force. The reign of Sigismund III. was on many grounds a disastrous one for Poland, and it was a very long one.

He was succeeded by his son Wladyslaw IV., who was elected by the diet. During his reign the usual wars took place with the ancient enemies of the republic—the Swedes, Russians, and Turks. He died at Merez in Lithuania, between Grodno and Vilna, May 20, 1648, and was succeeded by his brother John Casimir, the other candidates being the czar Alexis, father of Peter the Great, and Ragotzi, prince of Transylvania. One of the first acts of the new king was to endeavor to negotiate with Bogdan, but the negotiations were brought to an abrupt termination by the treachery of Wisniowiecki, the Polish general, who fell upon the unsuspecting Cossacks while they were deliberating about the terms of the convention. After this massacre Bogdan raised another army, but was completely defeated by John Casimir at Beresteczko in 1651. The kingdom, however, was thrown into the greatest confusion by the disputes of the nobles, and all vigorous action was paralyzed. The blood-stained annals of these wars are full of horrors; the population

in many districts was entirely extirpated; everywhere murder and plunder were rampant; and tortures too horrible to mention were inflicted upon the unhappy prisoners.

Worn out with age, and disgusted with his repeated failures, the king abdicated in 1668. In due time three candidates for the vacant throne made their appearance—the prince of Condé, the prince of Neuburg, supported by Louis XIV., and Charles of Lorraine, who was put forward by Austria. The first of these could rely upon the coöperation of the great Sobieski, who at this time begins to figure in history, but eventually none of the three was chosen. The election fell upon a native Pole—Prince Michael Korybut Wisniowiecki, of a noble family indeed, but so impoverished that he may be said to have had regal honors thrust upon him against his will, and we are even told that he was offered the crown half in derision. Michael soon became a mere puppet in the hands of his turbulent subjects. His reign, however, was rendered illustrious by the great successes of Sobieski against the Turks, although the Poles suffered the loss of the important town of Kamenets, and Michael, powerless to make head against them, concluded the treaty of Buczacz, by which he even stipulated to pay them tribute. By the great victory of Khotin in 1673, Sobieski did much to repair these losses and was about to follow up his glorious campaign when he heard of the death of Wisniowiecki at Lemberg in Galicia; so sudden was the end of Michael that some have even supposed that he was poisoned,—“by a Frenchman,” says Connor. The diet met at Warsaw; there were several candidates; and among others Charles of Lorraine and Philip of Neuburg again put forward their claims. While the nobles were still in session, Sobieski, fresh from his glorious victory, entered and proposed the prince of Condé. A stormy discussion ensued, and in the midst of it one of the nobles, Jablonowski, was heard to say, “Let a Pole rule over Poland.” The cry found a magic echo among those who were present, and the gallant Sobieski, the greatest of Polish generals, and one of the first soldiers of his time, was appointed king under the title of John III., although not without considerable opposition from Michael Pac, the general-in-chief of Lithuania, who was, however, ultimately induced to withdraw his protest.

Some years of peace followed, during which the king in vain endeavored to raise supplies for an army to reconquer the provinces which Russia had appropriated. All his plans were neutralized by the absurd practice of the *liberum veto*. In 1683 the Turks made their grand invasion which they had long been preparing. After scouring the plains of Hungary, they advanced to the very walls of Vienna. The emperor Leopold at once fled with his court, but had great difficulty to avoid falling into the hands of the Mongols. The elector of Saxony, John George, marched out of Dresden on July 22d with 12,000 men and 18 guns, and reached Krems on August 28th. The Polish king, who had been solicited by the emperor himself, and to whom all Europe looked now as its savior, left Cracow accompanied by his son, and succeeded in reaching the quarters of Prince Charles of Lorraine. He was to act in concert with a man who had been competitor with him for the Polish crown; their meeting passed off amicably, and no subsequent jealousies seem to have marred their operations. The Polish and German troops effected their junction at Krems on the Danube, near Vienna; there were about 77,000 men ready for active operations in the field. On September 12th, after mass, Sobieski descended from the city to encounter the dense masses of the Moslems in the plains below.

The assault was made simultaneously on the wings

and center of the enemy. In spite of the bravery of the Turks they were overpowered by the *élan* of the Poles. Six pashas were slain, and the vizier fled with the remnant of his army. The booty taken was immense.

The king, after this brilliant achievement, showed some inclination to be reconciled to Louis XIV., but the emperor succeeded in diverting him by holding out hopes of securing the government of Moldavia and Wallachia for his son. By the treaty of Moscow, which Sobieski concluded in 1686 with Sophia, the regent of Russia, Smolensk, Severia, Tchernigoff, and Kieff were definitely annexed to the latter country. The private life of Sobieski was embittered by family dissensions; he was very much under the influence of his wife, a woman of great beauty, but avaricious, fond of power, and revengeful. Thus the illustrious soldier had not peace in his own house, nor was he likely to meet with it in the stormy debates of the diet; and so wearisome had his position become that he several times thought of abdicating, and the Austrian party (such was the gratitude he met with) sought to effect this. He finally sank under an accumulation of disorders, and expired on June 17, 1696, at his favorite castle of Willanow. Many incidents of his death-bed have been recorded by Zaluski, the bishop of Plock, which show that the king died ill at ease, being filled with the gravest apprehensions concerning the future of his country. The family is now extinct. With him sank the glory of Poland, which was rapidly hastening to its fall.

After a time the diet met as usual to elect the new sovereign. The three chief candidates were James Sobieski, the son of the late king; the prince of Condé, a nephew of Louis XIV.; and the elector of Saxony. The elector was appointed, and, in order to qualify for the throne, abjured Protestantism. In 1699, by the peace of Carlowitz, the Turks renounced all claim over the Ukraine and Podolia, but the king was foolish enough to allow himself to be drawn into a war with the Swedes, in consequence of which Cracow was taken in 1702. Charles XII. of Sweden became master of the country, and deposed the newly elected Frederick Augustus, in whose place was chosen Stanislaw Leszczyński, palatine of Posen, a man of benevolence and learning. All the courts of Europe recognized this new king except the czar Peter, and when the latter defeated Charles at the battle of Poltava in 1709 Leszczyński was compelled to leave the country, and Augustus II., as he was styled, was restored. Stanislaw at the approach of the Russian troops retired to Lorraine, which he governed till his death at an advanced age. In this reign Poland lost Courland, which had long been one of its fiefs, but was now seized by the Russians and given by the empress Anne to her favorite Biren. The *Dissidents*, as the Protestants were called, were slowly decreasing in number, and in an *émeute* which occurred at Thorn in 1724 many were cruelly put to death. A little later, in 1733, a law was passed by which they were declared incapable of holding any office or enjoying any dignity. Augustus II. died at Warsaw in the last mentioned year. He was a contemptible king, notorious for his private vices. At the instigation of many of the Poles, Stanislaw Leszczyński, who was now residing in Lorraine, and had become the father-in-law of Louis XV., was induced to return to Poland, and was elected king at Warsaw by a large majority. This election, however, was displeasing to Austria and Russia, who resolved to resist his pretensions and to secure the election of Frederick Augustus, the son of the late king. A Russian army arrived in the neighborhood of Warsaw, and a party of the nobles opposed to the French influence proclaimed the Saxon. He accordingly swore to the *pacta conventa*, and was crowned

king at Cracow in 1734. Meanwhile the unfortunate Stanislaw fled to Dantzic, where he hoped to hold out until assistance should arrive from France. The city, however, was obliged to capitulate after a siege of five months; and Stanislaw, after many adventures and narrow escapes, reached the Prussian dominions. In 1736 a diet of pacification was held at Warsaw, which was followed by a general amnesty. The condition of the country during this reign was deplorable, although Poland was engaged in no wars. Factions rent the government, and the peasantry, crushed and suffering, betook themselves to robbery and pillage. The king was a man of low tastes, and abandoned himself to pleasure. One of his favorite amusements was shooting dogs from the windows of his palace at Warsaw, in consequence of which dogs became very scarce in the city. He was too idle to learn a word of Polish, and left everything to the management of his minister Brühl. Frederick died October 3, 1763, at Dresden, where he was buried. In 1764 Stanislaw August Poniatowski was elected king, chiefly through the machinations of the Russian empress Catherine. The new monarch was a man of refined manners and elegant mind, but weak, and a mere puppet in Muscovite hands. In 1768 a few patriots met at the little town of Bar in Podolia, and formed what was called the Confederation of Bar, their object being to free the country from foreign influence. Among the members of this confederation were the Pulawskis (Casimir and Joseph), Joachin Potocki, and Adam Krasinski, bishop of Kamenets. Their military operations extended over all Poland and Lithuania, but the Russian troops stationed round the capital prevented the junction of the confederates with the national army. Moreover the confederates, whose number amounted to about eight thousand fighting men, were badly organized. In spite of a few trifling successes they saw their efforts gradually growing weaker. Nor did a bold attempt to carry off the king result in success. Their party speedily broke up, and Casimir Pulawski, one of the leading spirits, left the country and joined the Americans in their War of Independence, in which he soon afterward perished. But the partition of the country had already been secretly agreed upon by Russia, Prussia, and Austria. The idea appears to have been first suggested by Frederick the Great.

In 1772 Prussia took the Palatinates of Malborg, Pomeria, and Warmia, Culm, except Dantzic and Thorn, and a part of Great Poland; Austria took Red Russia or Galicia, with a part of Podolia, Sandomir, and Cracow; and Russia took White Russia, with all the part beyond the Dnieper. The Poles were obliged to sanction this plundering of their country in a diet held in 1778. The only real benefit conferred on the nation by this diet was the introduction of a better system of education; the Jesuits were also suppressed, and their immense estates became national property. Although the country had been mutilated in this fashion, it yet enjoyed tranquillity for a short time, and even made some material progress. Thus some useful manufactures were introduced. In 1788 a remarkable diet was opened which lasted four years—the longest on record, for the others had only endured a few days or a few weeks at most. At this many important changes were introduced, such as the amelioration of the condition of the burghers and peasants; but it was now too late. On this occasion the *liberum veto* was decisively suppressed and the throne declared hereditary. The elector of Saxony, grandson of the wretched and incapable Augustus III., was declared the successor of Stanislaus. The Roman Catholic was to be the dominant religion, but the Dissidents were to be tolerated. The burghers were to send deputies to the diet on the same footing as the nobles.

The peasants were not yet emancipated, but their condition was improved. The new constitution was finally promulgated on May 3, 1791. The king and the two chambers took the oaths to preserve it. The country now seemed to breathe afresh, and to be established upon a new basis. But the selfishness of the Polish nobles, who had always been the evil genius of the country, overturned all the arrangements. Among the most prominent non-contents was Felix Potocki, who was anxious to restore to the nobility the privileges they had lost by the new constitution. In concert with him were Francis Xavier Branicki and Severin Rzewuski, who sought the assistance of foreign powers, and especially Russia. These enemies of their country formed, in 1792, the Confederation of Targovica, and soon afterward at their instigation Russian troops invaded Poland and Lithuania. The feeble king, Stanislaus Augustus, made no resistance; he signed the convention of Targovica, and the Russians occupied Warsaw.

In 1793 another treaty of partition was signed, by which Prussia acquired the remainder of Great and a portion of Little Poland, and the Russian boundary was advanced to the center of Lithuania and Volhynia. An insurrection now broke out under the leadership of Thaddeus Kosciuszko, which at first made head against the Prussians and Russians, who had invaded the country from all quarters; but the successes of the insurgents were stained by the murders committed by the popular party at Warsaw. Suwaroff now entered the country, and Kosciuszko was finally defeated and made prisoner at the battle of Maciejowice in 1794; there is no truth, however, in the assertion that he cried out on that occasion, "Finis Poloniae;" this he always denied till the day of his death. After storming the suburb Praga, Suwaroff took Warsaw, and the city was sacked with great cruelty. The kingdom of Poland was now at an end, and the third division took place. Austria had Cracow, with the country between the Pilica, the Vistula, and the Bug; Prussia had the capital, with the territory as far as the Niemen; and the rest went to Russia. Stanislaus resigned the crown at Grodno on April 25, 1795; he was summoned to St. Petersburg, where he is said to have endured many indignities from the emperor Paul, who never allowed him to remain seated in his presence. There he died in 1798.

Many of the Poles now entered foreign services, as, for instance, the legion which followed the fortunes of France; but the fate of these exiled patriots was often a sad one. Many perished on the burning sands of St. Domingo. Many were killed in the famous expedition to Moscow. The Poles looked anxiously to the success of Napoleon. But all that the conqueror did for them was to form the duchy of Warsaw, consisting of six departments—Posen, Kalisz, Plock, Warsaw, Lomza, and Bydgoszcz—with a population of more than 2,000,000, which he united with Saxony.

A resettlement of Poland took place by the treaty of Vienna (1814). (1) Austria was to have Galicia and the salt-mines of Wieliczka. (2) Posen was to belong to Prussia. This power was also confirmed in what it had gained at the first partition. (3) The city and district of Cracow were to form an independent republic under the guarantee of the three powers. This historical town was annexed by Austria in 1846 in defiance of all international law. (4) The remainder of ancient Poland, comprising the chief parts of the recent grand-duchy of Warsaw (embracing a tract bounded by a line drawn from Thorn to near Cracow on the west, to the Bug and Niemen in the east), reverted to Russia, and was to form a constitutional kingdom subject to the czar. This constitution, considering the circum-

stances, was a very liberal one. Poland was to be governed by responsible ministers, a senate, and a legislative chamber. There were to be a national army under the national flag and a separate budget. Polish was to be the official language; personal liberty and the freedom of the press were also guaranteed. It was obvious from the first that it would be difficult to unite a country with such a liberal constitution to another still governed by a patriarchal despotism. Zajacek was named viceroy, and the grand-duke Constantine, brother of the emperor Alexander, took the command of the army.

The rebellions of the Poles in 1830 and 1863 more properly belong to Russian history; perhaps, however, a few facts connected with them may be appropriately introduced here.

Considering the delicate position of affairs in Russian Poland, things had worked fairly well. The impulse to the Polish revolution was undoubtedly given by the French. It was begun by some students, who hoped to seize the grand-duke Constantine at his residence, Belvedere, in the vicinity of Warsaw. In the evening of November 29, 1830, they accordingly proceeded to the palace, but did not succeed in capturing the grand-duke. The city, however, rose, the troops fraternized with the people, and the chief command was intrusted to General Chlopicki, a veteran of the wars of Napoleon. Early in 1831 a large Russian army, commanded by Diebitsch, advanced to reduce them to submission. Chlopicki laid down his dictatorship, but the Poles pursued the insurrection with vigor under the command of Prince Adam Czartoryski. They were disappointed in their hopes of assistance from foreign powers. On September 8th Warsaw surrendered to Paskewitch, who had taken the command, Diebitsch having died of cholera (June 10th), and a few weeks afterward the grand-duke Constantine died at Vitebsk. On February 26, 1832, Poland was declared a Russian province.

No other outbreak occurred till 1863, but for some time previously the country had been disturbed. On November 29, 1860, on the occasion of the thirtieth anniversary of the revolution of 1830, many political manifestations took place both in the churches and streets, and portraits of Kosciuszko and Killinski, a patriot of the time of the last partition, were distributed. Some riots took place, and unfortunately several persons were killed. These proceedings were followed by concessions from the emperor Alexander, who established municipal institutions in Warsaw and the chief cities of the kingdom. The Russian czar was acting under the advice of Wielopolski, a Pole, who was appointed director of public instruction and worship. Riots, however, still continued, and in 1862 the grand-duke Constantine was named viceroy. On the night of January 15, 1863, a secret conscription was held, and the persons suspected of being most hostile to the government were dragged from their beds and enlisted as soldiers. Immediately after this the insurrection broke out, which was directed by a secret committee (Rzad), the proceedings of which were as mysterious as those of the Fehmgerichte. Soon after bands of rebels began to make their appearance in the Polish forests. There were, however, no regular battles between the Russian troops and the Poles—only guerilla fighting, in which the Poles, under the greatest disadvantages, showed splendid heroism. The secret emissaries of the revolutionary government, armed with daggers, succeeded in putting to death many Russian spies—not the least memorable case being that of the Jew Hermani, stabbed while on the staircase of the Hôtel de l'Europe at Warsaw. On the other hand the chiefs of the insurg-

ents captured were shot or hanged. Langiewicz held out for some time, but was defeated by the Russians, and succeeded in making his escape into Galicia. A reign of terror was inaugurated by General Mouravieff, and all attempts at reconciliation made by the great powers of Europe were useless. By May, 1864, the rebellion was quite suppressed, and it will be seen by the results that it cost Poland dear. The kingdom of Poland now ceased to exist; it has been parceled out into six governments. The Russian language was ordered to be used in all public documents instead of Polish, and the university of Warsaw has been Russified, all lectures now being delivered in that language.

We have not dwelt upon the terrible massacres of the Polish nobles by the peasants in Galicia in 1836, said to have been instigated by the Austrian Government. This province has been tolerably quiet since, but the Poles have to struggle with the large Ruthenian or Red-Russian population, speaking a different language, and being adherents of the Greek Church or Uniates.

In Prussian Poland, though it is but fair to add that we hear no stories of massacres, the Germanization of the province has been more complete. Posen will soon be lost as a Polish town, and many historical places have had their names obliterated for such substitutes as Bismarcksdorf and Sedan.

#### POLISH LITERATURE.

The Polish Language, according to the latest statistics, is still spoken by nearly 10,000,000 of people, distributed, according to the *Revue Slave* (Warsaw, 1878), as follows:—in Russia, 4,640,000; in Austria, 2,444,200; in Prussia, 2,405,800; in Turkey, 10,000. It belongs to the western branch of the Slavonic tongues, and exhibits the closest affinities with the Czech or Bohemian and Lusatian Wendish (see SLAVONIC LANGUAGES). Unlike the people of other Slavonic countries, the Poles are comparatively poor in popular and legendary poetry, but such compositions undoubtedly existed in early times, as may be seen by the writings of their chroniclers; thus Gallus translated into Latin a poem written on Boleslaw the Brave, and a few old Polish songs are included in Wojcicki's *Library of Ancient Writers*. A great deal of early literature written in Poland is in Latin. The earliest specimen of the Polish language is the so-called Psalter of Queen Margaret, discovered in 1826 at the convent of St. Florian. The date of the MS. appears to be the middle of the fourteenth century, in its present form it is only a copy of a much older text. The ancient Polish hymn or war song, "Piesn Boga Rodzica," was an address to the Virgin, sung by the Poles when about to fight. The oldest manuscript of this production is dated 1408, and is preserved at Cracow.

The next monument of Polish literature to which we come is the Bible of Queen Sophia or Bible of Szarospatak. It is imperfect and only contains the early books, viz., the Pentateuch, Joshua, Ruth, and Kings; there are, however, fragments of three others. It is said to have been written by Sophia, the fourth wife of Jagiello, about the year 1455.

Perhaps a few words should be said concerning the writers in Latin. Martin Gallus lived in Poland between 1110 and 1135. From his name he has been supposed by some to have been a Frenchman, and we must remember that Poland swarmed at the time with foreign ecclesiastics. The education of the country was wholly in the hands of the ecclesiastics, many of whom were foreigners. In this way we must explain the prevalence of the Latin language. Such a system would be sure to stifle all national outgrowth, and accordingly we have among the Poles none of those early monuments of the language of which other nations

boast. For instance, there are no *bilini* or legendary poems, such as are found among the Russians, although many passages in the ancient chroniclers from their poetical coloring seems to be borrowed from old songs or legends, and the first verses of some of these compositions have been preserved.

**POLAND, RUSSIAN.** After the three dismemberments of the old kingdom, the name of Poland was chiefly retained by the part of the divided territory annexed to Russia. Since the insurrection of 1863, however, the name "kingdom of Poland" has disappeared. Thenceforward this portion of the Russian empire is referred to in official documents only as the "territory of the Vistula," and later on as the "Vistula governments." Nevertheless the geographical position of Russian Poland, its ethnographical features, its religion, and its traditions differentiate it so widely from the remainder of the Russian empire that the name of Poland still survives in current use. The area of this territory is 49,157 square miles, and the population exceeds 7,300,000. See **RUSSIA**.

**POLARITY AND ENANTIOMORPHISM.** Any figure, such as a solid of revolution which has one line in it in reference to which the figure is symmetrical may be said to have an axis, and the points at which the axis cuts the surface of the figure are poles. But the term polarity when applied to material figures or substances is usually confined to cases where there are not only a definite axis and poles, but where the two poles have distinct characters which enable us to recognize them and say which is which. It is in this sense that the word is used here.

Two figures or two portions of matter are said to be *enantiomorphous* to each other when these forms are not superposable, *i.e.*, the one will not fit into a mold which fits the other, but the one is identical in form with the mirror image of the other.

*Polarity.*—As examples of polarity we may take an awn of barley or a cat's tail, in which we recognize the distinction between the two poles or ends, which we may call A and B by finding that it is easy to stroke from say A to B, but not in the opposite direction. As an example of enantiomorphism we may take our two hands, which will not fit the same mold or glove, but the one of which resembles in figure the mirror image of the other.

*Enantiomorphism.*—A figure having polarity of the first kind gives a mirror image resembling itself in form and in position; a figure having polarity of the second kind gives a mirror image resembling itself in form but not in position—the poles being inverted. A figure the axis of which has both kinds of polarity will, therefore, give a mirror image not superposable to the figure itself, because the polarity of the second kind is reversed, while that of the first kind remains unchanged. The figure and its mirror image are enantiomorphous, as well as polar. We can construct a figure which is enantiomorphous to its mirror image, but not polar. Imagine a muff so made

Fig. 1.

Fig. 2.

that in one half the fur lies the one way, and the opposite way in the other half (fig. 1, where the arrow-heads indicate the lie of the fur). In whichever way we put our hands into this muff one end will be wrong; the muff in the figure has, in fact, two right-hand ends. It has, therefore, no polarity; the two ends are exactly alike.

But there are two ways in which such a non-polar muff could be made—with two right-hand ends as in the figure, or with two left-hand ends, and these two forms are enantiomorphous. A helix or screw has similar properties (compare fig. 2 with fig. 1); if uniform it is non-polar, but is either right or left-handed. Hence the property which each of two enantiomorphous bodies possesses has been called by Sir William Thompson "helicoidal asymmetry."

**POLARIZATION OF LIGHT.** See **LIGHT**.

**POLAR REGIONS.** The polar regions extend respectively from the Arctic and Antarctic Circles, in  $66^{\circ} 32'$  N. and S., to the north and south poles, the circles being 1,408 geographical miles from the poles. The intense cold and the difficulties of ice navigation have made the discovery and examination of these regions a slow and hazardous task. Millions of square miles are still entirely unknown. In the present article the history of the progress of discovery within the north polar region will be traced, and some account of its physical geography will follow. A similar review of work in the south polar region will conclude the article.

#### NORTH POLAR REGION.

The Arctic Circle is a ring running a little south of the northern shores of America, Asia, and Europe, so that those shores form a fringe within the polar region, and are its boundary to the south, except at three openings—those of the North Atlantic, of Davis Strait, and of Behring's (more properly Bering's) Strait.

The width of the approach to this region by the Atlantic Ocean, in its narrowest part, is 660 miles, from the Norwegian Islands of Lofoten to Cape Hodgson, on the east coast of Greenland. The width of the approach by Davis Strait in the narrowest part, which is nearly on the Arctic Circle, is 165 miles; and the width of Behring's Strait is forty-five miles. Thus out of the whole ring of 8,640 miles along which the Arctic Circle passes about 900 miles is over water.

A rumor respecting Thule, an island on the Arctic Circle, first brought by **PYTHEAS** (*q.v.*), and afterward doubted, was the extent of the knowledge of the north polar regions with which the ancients can be credited. But in the ninth century some Irish monks really appear to have visited Iceland. The monk Dicuil, writing about 825, says that he had information from brethren who had been at Thule during several months, and they reported that there was no darkness at the summer solstice.

King Alfred told the story of the first polar voyages undertaken for discovery and the acquisition of knowledge, in his very free translation of **Orosius**.

The Norsemen of the Scandinavian peninsula, after colonizing Iceland, were the first to make permanent settlements on the shores of Greenland, and to extend their voyages beyond the Arctic Circle along the western coast of that vast glacier-covered land. (See **GREENLAND**.)

The last trace of communication between Greenland and Norway was in 1347. The black death broke out in Norway and the far off colony was forgotten.

Sebastian Cabot, whose own northern voyages have been spoken of in the article **CABOT**, was the chief promoter of the expedition which sailed under Sir Hugh Willoughby and Richard Chancellor, on May 20, 1553, "for the search and discovery of the northern parts of the world, to open a way and passage to our men, for travel to new and unknown kingdoms." Chancellor reached the Bay of St. Nicholas, and landed near Archangel, which was then only a castle. He undertook a journey to Moscow, made arrangements for commercial intercourse with Russia, and returned safely. His suc-

cess proved the practical utility of polar voyages. It led to a charter being granted to the Association of Merchant Adventurers, of which Cabot was named governor for life, and gave fresh impulse to arctic discovery.

In the spring of 1556 Stephen Burrough, who had served with Chancellor, sailed in a small pinnace called the *Searchthrift* and kept a careful journal of his voyage. He went to Archangel, and discovered the strait leading into the Kara Sea, between Nova Zembla and the island of Waigat. In May, 1580, the company fitted out two vessels under Arthur Pet and Charles Jackman, with orders to pass through the strait discovered by Burrough, and thence to sail eastward beyond the mouth of the river Obi. Pet discovered the strait into the Kara Sea, between Waigat and the mainland, and made a persevering effort to push eastward, returning to England in safety. Jackman, after wintering in a Norwegian port, sailed homeward but was never heard of again.

In 1558 a narrative and map were published at Venice which profoundly affected the system of polar cartography for many years afterward. The publication was the handiwork of a Venetian nobleman named Niccolò Zeno.

We now come to the voyages of Frobisher, undertaken to obtain the means for equipping an expedition for the discovery of a shorter route to India by the northwest. Aided by Michael Lok, an influential merchant and diligent student of geography, Frobisher sailed, in the spring of 1576, with two small vessels of twenty to twenty-five tons, called the *Gabriel* and *Michael*.

John Davis, who made the next attempt to discover a northwest passage, was one of the most scientific seamen of that age. He made three voyages in three successive years, aided and fitted out by William Sander-son and other merchants. Sailing from Dartmouth on June 7, 1585, he was the first to visit the west coast of Greenland subsequent to the abandonment of the Norse colonies. He called it "The Land of Desolation." He discovered Gilbert's Sound in  $64^{\circ} 10'$  (where now stands the Danish settlement of Godthaab) and then, crossing the strait which bears his name, he traced a portion of its western shore.

In 1594 the Amsterdam merchants fitted out a vessel of 100 tons, under the command of Willem Barents. The coast of Nova Zembla was sighted on July 4th, and from that date until August 3d Barents continued perseveringly to seek a way through the ice-floes, and discovered the whole western coast as far as Cape Nassau and the Orange Islands at the northwest extremity. The second voyage in which Barents was engaged merely made an unsuccessful attempt to enter the Kara Sea. The third was more important. The voyages of Barents stand in the first rank among the polar enterprises of the sixteenth century. They led directly to the flourishing whale and seal fisheries which long enriched the Netherlands.

The English enterprises were continued by the Muscovy Company, and by associations of patriotic merchants of London; and even the East India Company sent an expedition under Captain Waymouth in 1602 to seek for a passage by the opening seen by Davis, but it had no success.

The best servant of the Muscovy Company in the work of polar discovery was Henry Hudson. His first voyage was undertaken in 1607, when he discovered the most northern known point of the east coast of Greenland in  $73^{\circ}$  north named "Hold with Hope," and examined the edge of the ice between Greenland and Spitzbergen, reaching a latitude of  $80^{\circ} 23'$  north. On his way home he discovered the island now called Jan

Mayen, which he named "Hudson's Tutches." In his second expedition, during the season of 1608, Hudson examined the edge of the ice between Spitzbergen and Nova Zembla. In his third voyage he was employed by the Dutch East India Company, and he explored the coasts of North America, discovering the Hudson river. In 1610 he discovered Hudson's Strait, and the great bay which bears and immortalizes his name (see HUDSON).

The voyages of Hudson led immediately to the Spitzbergen whale fishery. From 1609 to 1612 Jonas Poole made four voyages for the prosecution of his lucrative business, and he was followed by Fotherby, Baffin, Joseph, and Edge. These bold seamen, while in the pursuit of whales, added considerably to the knowledge of the archipelago of islands known under the name of Spitzbergen, and in 1617 Captain Edge discovered a large island to the eastward, which he named Wyche's Land.

At about the same period the kings of Denmark began to send expeditions for the rediscovery of the lost Greenland colony. In 1605 Christian IV. sent out three ships, under the Englishmen Cunningham and Hall, and a Dane named Lindenov, which reached the western coast of Greenland and had much intercourse with the Eskimo. Other expeditions followed in 1606-7.

Meanwhile the merchant adventurers of London continued to push forward the western discovery. Sir Thomas Button, in command of two ships, the *Resolution* and *Discovery*, sailed from England in May, 1612. He entered Hudson's Bay, crossed to its western shore, and wintered at the mouth of a river in  $57^{\circ} 10'$  N., which was named Nelson's river after the master of the ship, who died and was buried there. Next year Button explored the shore of Southampton Island as far as  $65^{\circ}$  N., and returned home in the autumn of 1613. An expedition under Captain Gibbons, dispatched in 1614, was a miserable failure; but in 1615 Robert Bylot as master and William Baffin as pilot and navigator in the *Discovery* examined the coasts of Hudson's Strait, and Baffin, who was the equal of Davis as a scientific seaman, made many valuable observations. In 1616 Bylot and Baffin again set out in the *Discovery*. Sailing up Davis Strait they passed that navigator's farthest point at Sanderson's Hope, and sailed round the great channel with smaller channels leading from it which has been known ever since as Baffin's Bay. Baffin named the most northern opening Smith Sound, after the first governor of the East India Company, and the munificent promoter of the voyage, Sir Thomas Smith. Wolstenholme Sound, Cape Dudley Digges, Hakluyt Island, Lancaster Sound, Jones Sound, and Cary Islands were named after other promoters and friends of the voyage.

In 1631 two expeditions were dispatched, one by the merchants of London, the others by those of Bristol. In the London ship *Charles* Luke Fox explored the western side of Hudson's Bay as far as the place called "Sir Thomas Roe's Welcome." In August he encountered Captain James and the Bristol ship *Maria* in the middle of Hudson's Bay, and went north until he reached "Northwest Fox his furthest," in  $66^{\circ} 47'$  N. He then returned home and wrote the most entertaining of all the polar narratives. Captain James was obliged to winter off Charlton Island, in the southern extreme of Baffin's Bay, and did not return until October, 1632. Another English voyager, Captain Wood, attempted, without success, to discover a northeast passage in 1676.

The sixteenth and seventeenth centuries were periods of discovery and daring enterprise, and the results gained

by the gallant seamen of those times are marvelous when we consider their insignificant resources and the small size of their vessels. Hudson's Strait and Bay, Davis Strait, and Baffin's Bay, the icy seas from Greenland to Spitzbergen, and from Spitzbergen to Nova Zembla, had all been discovered. The following century was rather a period of reaping the results of former efforts than of discovery. It saw the settlement of the Hudson's Bay Territory and of Greenland, and the development of the whale and seal fisheries.

The Hudson's Bay Company was incorporated in 1670, and Prince Rupert sent out Zachariah Gillan, who wintered at Rupert's river. At first very slow progress was made. A voyage undertaken by Mr. Knight, who had been appointed governor of the factory at Nelson river, was unfortunate, as his two ships were lost and the crews perished. This was in 1719. In 1722 John Scroggs was sent from Churchill river in search of the missing ships, but merely entered Sir Thomas Roe's Welcome and returned. His reports were believed to offer decisive proofs of the existence of a passage into the Pacific; and a naval expedition was dispatched under the command of Capt. Christopher Middleton, consisting of the *Discovery* pink and the *Furnace* bomb. Wintering in Churchill river, Middleton started, in July, 1742, and discovered Wager river and Repulse Bay. In 1746 Capt. W. Moore made another voyage in the same direction, and explored the Wager Inlet. Captain Coats, who was in the service of the company, 1727-51, wrote a useful account of the geography of Hudson's Bay. Later in the century the Hudson's Bay Company's servants made some important land journeys to discover the shores of the American polar ocean. From 1769 to 1772 Samuel Hearne descended the Coppermine river to the polar sea; and in 1789 Alexander Mackenzie discovered the mouth of the Mackenzie river.

The countrymen of Barents vied with the countrymen of Hudson in the perilous calling which annually brought fleets of ships to the Spitzbergen seas during the eighteenth century. The Dutch had their large summer station for boiling down blubber at Smeerenberg, near the northern extreme of the west coast of Spitzbergen. Captain Vlamingh, in 1664, advanced as far round the northern end of Nova Zembla as the winter quarters of Barents. In 1700 Capt. Cornelis Roule is said by Witsen to have sailed north in the longitude of Nova Zembla, and to have seen an extent of forty miles of broken land. But Theunis Ys, one of the most experienced Dutch navigators, was of opinion that no vessel had ever been north of the 82d parallel. In 1671 Frederick Martens visited the Spitzbergen group, and wrote the best account of its physical features and natural history that existed previous to the time of Scoresby. In 1707 Captains Gilies and Outsger Rep went far to the eastward along the northern shores of Greenland, and saw very high land in 80° N. which has since been known as Gilies Land. The Dutch geographical knowledge of Spitzbergen was embodied in the famous chart of the Van Keulens (father and son), 1700-1728. The Dutch whale fishery continued to flourish until the French Revolution, and formed a splendid nursery for training the seamen of the Netherlands. From 1700 to 1775 the fleet numbered 100 ships and upward. In 1719 the Dutch opened a whale fishery in Davis Strait, and continued to frequent the west coast of Greenland for upward of sixty years from that time. In the course of 6,372 Dutch whaling voyages to Davis Strait between 1719 and 1775 only thirty-eight ships were wrecked.

Since the year 1773 the objects of polar exploration, at least so far as England is concerned, have been mainly

the acquisition of knowledge in various branches of science. It was on these grounds that the Honorable Daines Barrington and the Royal Society induced the government to undertake arctic exploration once more. The result was that two vessels, the *Racehorse* and *Carcass* bombs, were commissioned, under the command of Captain Phipps. The expedition sailed from the Nore on June 2, 1773, and was stopped by the ice to the north of Hakluyt Headland, the northwestern point of Spitzbergen. They reached the Seven Islands and discovered Walden Island; but beyond this point progress was impossible. When they attained their highest latitude in 80° 48' N., north of the central part of the Spitzbergen group, the ice at the edge of the pack was twenty-four feet thick. Captain Phipps returned to England in September, 1773. Five years afterward Captain Cook received instructions to proceed northward from Kamchatka and search for a northeast or northwest passage from the Pacific to the Atlantic. In accordance with these orders Captain Cook, during his third voyage, reached Cape Prince of Wales, the western extremity of America, on August 9, 1778. His ships, the *Resolution* and *Discovery*, arrived at the edge of the ice, after passing Behring Strait, in 70° 41' N. On August 17th the farthest point seen on the American side was named Icy Cape. On the Asiatic side Cook's survey extended to Cape North. In the following year Captain Clerke, who had succeeded to the command, made another attempt, but his ship was beset in the ice, and so much damaged that further attempts were abandoned.

The wars following the French Revolution put an end to the voyages of discovery till, after the peace of 1815, north polar research found a powerful and indefatigable advocate in Sir John BARROW, (*q.v.*) Through his influence a measure for promoting polar discovery became law in 1818 (58 Geo. III c. 20), by which a reward of £20,000 (\$100,000) was offered for making the northwest passage, and of £5,000 (\$25,000) for reaching 89° N., while the commissioners of longitude were empowered to award proportionate sums to those who might achieve certain portions of such discoveries. In 1817 the icy seas were reported by Captain Scoresby and others to be remarkably open, and this circumstance enabled Barrow to obtain sanction for the dispatch of two expeditions, each consisting of two whalers—one to attempt discoveries by way of Spitzbergen and the other by Baffin's Bay. The vessels for the Spitzbergen route, the *Dorothea* and *Trent*, were commanded by Capt. David Buchan and Lieut. John Franklin, and sailed in April, 1818. Driven into the pack by a heavy swell from the south, both vessels were severely nipped, and had to return to England. The other expedition, consisting of the *Isabella* and *Alexander*, commanded by Capt. John Ross and Lieut. Edward Parry, followed in the wake of Baffin's voyage of 1616. Ross sailed from England in April, 1818. The chief merit of his voyage was that it vindicated Baffin's accuracy as a discoverer. Its practical result was that the way was shown to a very lucrative fishery in the "North Water" of Baffin's Bay, which continued to be frequented by a fleet of whalers every year. Captain Ross thought that the inlets reported by Baffin were merely bays, while the opinion of his second in command was that a wide opening to the westward existed through Lancaster Sound of Baffin.

Parry was consequently selected to command a new expedition in the following year. The vessels returned in October, 1820; and a fresh expedition in the *Fury* and *Hecla*, again under the command of Captain Parry, sailed from the Nore on May 8, 1821, and passed their first winter on the coast of the newly discovered Melville

Peninsula in  $66^{\circ} 11'$  N. The expedition returned in the autumn of 1823. Meantime Parry's friend Franklin had been employed in attempts to reach by land the northern shores of America, hitherto only touched at two points by Hearne and Mackenzie. Franklin went out in 1819, accompanied by Doctor Richardson, George Back, and Hood. They landed at York factory, and proceeded to the Great Slave Lake. In August of the following year they started for the Coppermine river, and, embarking on it, reached its mouth on July 18, 1821. From that point 550 miles of coast-line were explored, the extreme point being called Cape Turnagain. Most frightful sufferings, from starvation and cold, had to be endured during the return journey; but eventually Franklin, Richardson, and Back arrived safely at Fort Chippewyan. It was now thought desirable that an attempt should be made to connect the Cape Turnagain of Franklin with the discoveries made by Parry during his second voyage; but the first effort, under Captain Lyon in the *Griper*, was unsuccessful.

In 1824 three combined attempts were organized. While Parry again entered by Lancaster Sound and pushed down a great opening he had seen to the south named Prince Regent's Inlet, Captain Beechey was to enter Behring's Strait, and Franklin was to make a second journey to the shores of Arctic America. Parry was unfortunate, but Beechey entered Behring Strait in the *Blossom* in August, 1826, and extended our knowledge as far as Point Barrow in  $71^{\circ} 23' 30''$  N. latitude. Franklin, in 1825-26, descended the Mackenzie river to its mouth, and explored the coast for 374 miles to the westward; while Doctor Richardson discovered the shore between the mouths of the Mackenzie and Coppermine, and sighted land to the northward, named by him Wollaston Land, the dividing channel being called Union and Dolphin Strait. They returned in the autumn of 1826.

Work was also being done in the Spitzbergen and Barents Seas. From 1821 to 1824 the Russian Captain Lutke was surveying the west coast of Nova Zembla as far as Cape Nassau, and examining the ice of the adjacent sea. In May, 1823 the *Griper* sailed, under the command of Captain Clavering, to convey Captain Sabine to the polar regions in order to make pendulum observations. Clavering pushed through the ice in  $75^{\circ} 30'$  N., and succeeded in reaching the east coast of Greenland, where observations were taken on Pendulum Island. He laid down the land from  $76^{\circ}$  to  $72^{\circ}$  N.

Parry's attempt in 1827 to reach the pole from the northern coast of Spitzbergen, by means of sledge-boats, has been described under the heading PARRY. The highest latitude reached was  $82^{\circ} 45'$  N.; and the attempt showed that it is useless to leave the land and trust to the drifting pack in polar exploration.

In 1829 the Danes undertook an interesting piece of exploration on the east coast of Greenland. Captain Graah of the Danish navy rounded Cape Farewell in boats, with four Europeans and twelve Eskimo. He advanced as far as  $65^{\circ} 18'$  N. on the east coast, where he was stopped by an insurmountable barrier of ice. He wintered at Nugarlik in  $63^{\circ} 22'$  N., and returned to the settlements on the west side of Greenland in 1830.

In the year 1829 Capt. John Ross, with his nephew James, having been furnished with sufficient funds by a wealthy distiller named Felix Booth, undertook a private expedition of discovery in a small vessel called the *Victory*. Eventually they were picked up by a whaler in Barrow Strait, and brought home. Great anxiety was naturally felt at their prolonged absence, and in 1833 Sir George Back, with Dr. Richard King as a companion, set out by land in search of the missing explorers.

The tracing of the polar shores of America was completed by the Hudson's Bay Company's servants. In June, 1837, Messrs. Simpson and Dease left Chippewyan, reached the mouth of the Mackenzie, and connected that position with Point Barrow, which had been discovered by the *Blossom* in 1826. During the spring of 1847 Doctor Rae explored on foot the shores of a great gulf having seven hundred miles of coast-line. He thus connected the work of Parry, at the mouth of Fury and Hecla Strait, with the work of Ross on the coast of Boothia, proving that Boothia was part of the American continent.

While the English were thus working hard to solve some of the geographical problems relating to Arctic America, the Russians were similarly engaged in Siberia. In 1821 Lieutenant Anjou made a complete survey of the New Siberia Islands. Baron Wrangell prosecuted similar investigations from the mouth of the Kolyma between 1820 and 1823. In 1843 Middendorf was sent to explore the region which terminates in Cape Tchel-yuskin.

The success of Sir James Ross' Antarctic expedition and the completion of the northern coast-line of America by the Hudson's Bay Company's servants gave rise in 1845 to a fresh attempt to make the passage from Lancaster Sound to Behring Strait. The story of this unhappy expedition of Sir John Franklin, in the *Erebus* and *Terror*, has already been told under FRANKLIN (*q.v.*); but some geographical details may be given here.

It was not until 1848 that anxiety began to be felt about the Franklin expedition. In the spring of that year Sir James Ross was sent with two ships, the *Enterprise* and *Investigator*, by way of Lancaster Sound. He wintered at Leopold Harbor, near the northeast point of North Devon. In the spring he made a long sledge journey with Lieutenant M'Clintock along the northern and western coasts of North Somerset.

On the return of the Ross expedition without any tidings the country became thoroughly alarmed. An extensive plan of search was organized—the *Enterprise* and *Investigator* under Collinson and M'Clure proceeding by Behring Strait, while the *Assistance* and *Resolute* with two steam tenders, the *Pioneer* and *Intrepid*, sailed May 3, 1850, to renew the search by Barrow Strait, under Captain Austin. Two brigs, the *Lady Franklin* and *Sophia*, under Captain Penny, a very energetic and able whaling captain, were sent by the same route. He had with him Doctor Sutherland, a naturalist, who did much valuable scientific work.

In 1851 the *Prince Albert* schooner was sent out by Lady Franklin, under Captain Kennedy, with Lieutenant Bellot of the French navy as second. They wintered on the east coast of North Somerset, and in the spring of 1852 the gallant Frenchman, in the course of a long sledging journey, discovered Bellot Strait separating North Somerset from Boothia—this proving that the Boothia coast facing the strait was the northern extremity of the continent of America.

The *Enterprise* and *Investigator* sailed from England in January, 1850.

The Hudson's Bay Company assisted in the search for Franklin. In 1848 Sir John Richardson and Doctor Rae examined the American coast from the mouth of the Mackenzie to that of the Coppermine. In 1849 and 1850 Rae continued the search; and by a long sledge journey in the spring of 1851, and a boat voyage in the summer, he examined the shores of Wollaston and Victoria Lands, which were afterward explored by Captain Collinson in the *Enterprise*.

In 1852 the British government resolved to dispatch another expedition by Lancaster Sound. Austin's four

vessels were recommissioned, and the *North Star* was sent out as a depot ship at Beechey Island. Captain Kellett received command of the *Resolute*, with M'Clintock in the steam tender *Intrepid*. Among Kellett's officers were the best of Austin's sledge travelers, M'Clintock, Meham, and Vesey Hamilton, so that good work was sure to be done.

The traveling parties of Kellett's expedition, led by M'Clintock, Meham, and Vesey Hamilton, completed the discovery of the northern and western sides of Melville Island, and the whole outline of the large Island of Prince Patrick, still farther to the westward. M'Clintock was away from the ship with his sledge party for 105 days and traveled over 1,328 miles. Meham was away ninety-four days and traveled over 1,163 miles. Sherard Osborn, in 1853, was away ninety-seven days and traveled over 935 miles. The *Resolute* was obliged to winter in the pack in 1853-54, and in the spring of 1854 Meham made a most remarkable journey in the hope of obtaining news of Captain Collinson at the Princess Royal Islands. Leaving the ship on April 3d he was absent seventy days, out of which there were sixty-one and a half days of traveling. The distance gone over was 1,336 statute miles. The average rate of the homeward journey was twenty-three and one half miles a day, the average time of traveling each day nine hours twenty-five minutes. This journey is without a parallel in arctic records.

The catastrophe to Sir John Franklin's expedition led to 7,000 miles of coast-line being discovered, and to a vast extent of unknown country being explored, securing very considerable additions to geographical knowledge. Much attention was also given to the collection of information, and the scientific results to the various search expeditions were considerable. The catastrophe also afforded a warning which would render any similar disaster quite inexcusable. If arrangements are always carefully made for a retreat beforehand, if a depot ship is always left within reach of the advancing expedition as well as of the outer world, and if there is annual communication, with positive rules for depositing records, no such catastrophe can ever happen again.

The American nation was first led to take an interest in polar research through a very noble and generous feeling of sympathy for Franklin and his brave companions. Mr. Grinnell of New York gave practical expression to his feeling. In 1850 he equipped two vessels, the *Advance* and *Rescue*, to aid in the search, commanded by Lieutenants De Haven and Griffith, and accompanied by Doctor Kane. They reached Beechey Island on August 27, 1850 and assisted in the examination of Franklin's winter quarters, but returned without wintering. In 1853 Doctor Kane, in the little brig *Advance* of 120 tons, undertook to lead an American expedition up Smith Sound, the most northern outlet from Baffin's Bay.

On July 10, 1860, Doctor Hayes, who had served with Kane, sailed from Boston for Smith Sound, in the schooner *United States* of 130 tons and a crew of fifteen men. His object was to follow up the line of research opened by Doctor Kane. He wintered at Port Foulke, in  $78^{\circ} 17' N.$ , and about ten miles from Cape Alexander, which forms the eastern portal of Smith Sound. Doctor Hayes crossed Smith Sound in the spring with dog-sledges, but his observations are not to be depended upon, and it is very uncertain how far he advanced northward on the other side. He returned to Boston on October 23, 1861.

The story of Charles Hall of Cincinnati, who was led to become an arctic explorer through his deep interest in the search for Franklin, has been told in the article devoted to him.

The Spitzbergen seas have been explored, in recent years by Norwegian fishermen as well as by Swedish and German expeditions and by English yachtsmen.

Between 1858 and 1872 the Swedes sent seven expeditions to Spitzbergen and two to Greenland. All returned with valuable scientific results.

The gallant enterprises of other countries rekindled the zeal of England for arctic discovery; and in October, 1874, the prime minister announced that an expedition would be dispatched in the following year. Two powerful screw steamers, the *Alert* and *Discovery*, were selected for the service, and Captain Nares was selected as leader. The expedition returned to England in October, 1876. The *Alert* reached the highest northern latitude ever attained by any ship, and wintered farther north than any ship had ever wintered before. The results of the expedition were the discovery of 300 miles of new coast-line, the examination of this part of the frozen polar ocean, a series of meteorological, magnetic, and tidal observations at two points farther north than any such observations had ever been taken before, and large geological and natural history collections.

In the same year, 1875, Sir Allen Young undertook a voyage in his steam yacht the *Pandora* to attempt to force his way down Peel Sound to the magnetic pole, and if possible to make the northwest passage by rounding the eastern shore of King William Island. The *Pandora* entered Peel Sound on August 29, 1875, and proceeded down it much further than any vessel had gone before since it was passed by Franklin's two ships in 1846. Sir Allen reached a latitude of  $72^{\circ} 14' N.$

In 1879 an enterprise was undertaken in the United States, with the object of throwing further light on the sad history of the retreat of the officers and men of Sir John Franklin's expedition, by examining the west coast of King William Island in the summer, when the snow is off the ground. The party consisted of Lieutenant Schwatka, of the United States Army, and three others. Wintering near the entrance of Chesterfield Inlet, in Hudson's Bay, they set out overland for the estuary of the Great Fish River, assisted by Eskimo and dogs, on April 1, 1879. They only took one month's provisions, their main reliance being upon the game afforded by the region to be traversed. The party obtained, during the journeys out and home, no less than 522 reindeer. After collecting various stories from the Eskimo at Montreal Island and at an inlet west of Cape Richardson, Schwatka crossed over to Cape Herschel, on King William Island, in June. He examined the western shore of the island with the greatest care for relics of Sir John Franklin's parties, as far as Cape Felix, the northern extremity. The return journey was commenced in November by ascending the Great Fish River for some distance, and then marching over the intervening region to Hudson's Bay. The cold of the winter months in this country is intense, the thermometer falling as low as  $-70^{\circ}$ , so that the return journey was most remarkable, and reflects the highest credit on Lieutenant Schwatka and his companions. As regards the search little was left to be done after M'Clintock, but some graves were found, as well as a medal belonging to Lieutenant Irving, of H.M.S. *Terror*, and some bones believed to be his, which were brought home and interred at Edinburgh.

Mr. Gordon Bennett, the proprietor of the *New York Herald*, having resolved to dispatch an expedition of discovery at his own expense by way of Behring Strait, the *Pandora* was purchased from Sir Allen Young, and rechristened the *Jeannette*. Lieutenant De Long of the United States navy was appointed to com-

mand, and it was made a national undertaking by special Act of Congress, the vessel being placed under martial law and officered from the navy. The *Jeanette* sailed from San Francisco on July 8, 1879, and was last seen steaming toward Wrangell Land on September 3d. This land had been seen by Captain Kellett, in U.S.S. *Herald* on August 17, 1879, but no one had landed on it, and it was shown on the charts by a long dotted line. The *Jeannette* was provisioned for three years, but as no tidings had been received of her up to 1881, two steamers were sent up Behring Strait in search. One of these, the *Rodgers*, under Lieutenant Berry, anchored in a good harbor on the south coast of Wrangell Land, in  $70^{\circ} 57' N.$  on August 26, 1881. The land was explored by the officers of the *Rodgers* and found to be an island of about seventy miles long by twenty-eight, with a ridge of hills traversing it east and west, the seventy-first parallel running along its southern shore. Lieutenant Berry then proceeded to examine the ice to the northward, and attained a higher latitude by twenty-one miles than had ever been reached before on the Behring Strait meridian, namely,  $73^{\circ} 44' N.$  Sir R. Collinson, in 1850, had reached  $73^{\circ} 23'$ . No news was obtained of the *Jeannette*, but soon afterward melancholy tidings arrived from Siberia. After having been beset in heavy pack ice for twenty-two months, the *Jeannette* was crushed and sunk on June 12, 1881, in  $77^{\circ} 15' N.$  latitude and  $155^{\circ} E.$  longitude. The officers and men dragged their boats over the ice to an island which was named Bennett Island, where they landed on July 29th. They reached one of the New Siberia Islands on September 10th, and on the 12th they set out for the mouth of the Lena. But in the same evening the three boats were separated in a gale of wind. A boat's crew with Mr. Melville, the engineer, reached Irkutsk, and Mr. Melville set out in search of Lieutenant De Long and his party, who had also landed. The other boat was lost. Eventually Melville discovered the dead bodies of De Long and two of his crew on March 13, 1883. They had perished from exhaustion and want of food. The *Rodgers* was burnt in its winter quarters, and one of the officers, Mr. Gilder, made a hazardous journey homeward through northeast Siberia.

On September 18, 1875, Lieutenant Weyprecht, one of the discoverers of Franz-Josef Land, read a thoughtful and carefully prepared paper before a large meeting of German naturalists at Gratz on the scientific results to be obtained from polar research and the best means of securing them. He urged the importance of establishing a number of stations within or near the Arctic Circle, in order to record complete series of synchronous meteorological and magnetic observations. Lieutenant Weyprecht did not live to see his suggestions carried into execution, but they bore fruit in due time. The various nations of Europe were represented at an international polar conference at Hamburg in 1879, and at another at St. Petersburg in 1882; and it was decided that each nation should establish one or more stations where synchronous observations should be taken from August, 1882. This useful project was matured and executed. The stations were at the following localities round the Arctic Circle:—

Norwegians...	<i>Bosekop</i> , Alten Fjord, Norway,	M. Aksel S. Steen
Swedes.....	<i>Ice Fjord</i> , Spitzbergen,	Mr. Ekholm.
Dutch.....	<i>Dickson Harbor</i> , mouth of Yenisei, Siberia,	Dr. Smaller.
Russians...	{ <i>Sagastyr Island</i> , mouth of Lena, Siberia,	Lieut. Jurgens.
	{ <i>Moller Bay</i> , Nova Zembla,	Lieut. Andreief.
	{ <i>Point Barrow</i> , N. America,	Lieut. Ray, U.S.A.
Americans..	{ <i>Lady Franklin Bay</i> , $81^{\circ} 44' N.$ ,	Lieut. Greely, U.S.A.

English.....	<i>Great Slave Lake</i> , Dominion of Canada,	Lieut. Dawson.
Germans.....	<i>Cumberland Bay</i> , west side of Davis Strait,	Dr. Giese.
Danes.....	<i>Godthaab</i> , Greenland,	A. Paulsen.
Austrians....	<i>Jan Mayen</i> , North Atlantic, $71^{\circ} N.$ ,	Lieut. Wohlgenuth.

The whole scheme was successfully accomplished with the exception of the part assigned to the Dutch at Dickson Harbor. They started in the *Varna* but were beset in the Kara Sea and obliged to winter there. The *Varna* was lost, and the crew took refuge on board Lieutenant Hovgaard's vessel, which was also forced to winter in the pack during 1882-83.

The American stations commenced work in 1882. Lieutenant Greely's party consisted of two other lieutenants, of twenty sergeants and privates of the United States army, and of Doctor Pavy, an enthusiastic explorer who had been educated in France, and had passed the previous winter among the Eskimo of Greenland. On August 11, 1881, the steamer *Proteus* conveyed Lieutenant Greely and his party to Lady Franklin Bay during an exceptionally favorable season; a house was built at the *Discovery's* winter-quarters, and they were left with two years' provisions. The regular series of observations was at once commenced, and two winters were passed without accident. Traveling parties were also sent out in the summer, dogs having been obtained at Disco. Lieutenant Lockwood made a journey along the north coast of Greenland, and reached a small island in  $83^{\circ} 24' N.$  and  $44^{\circ} 5' W.$  Doctor Pavy, with one companion, went a short distance beyond the winter-quarters of the *Alert* and two trips were made into the interior of Grinnell Land. The coast on the western side was reached, and a large lake was discovered near Discovery Harbor. The chief value of the work of Lieutenant Greely's party consisted in the synchronous observations taken during 1882. As no succor arrived in the summer of 1883—though relieving vessels were dispatched both in 1882 and in 1883—Lieutenant Greely started from Lady Franklin Bay with his men on August 9th, expecting to find a vessel in Smith Sound. On October 21st they were obliged to encamp at Cape Sabine, on the western shore of Smith Sound, and build a hut for wintering. A few depots were found, which had been left by Sir George Nares and Lieutenant Beebe, but all was exhausted before the spring. Then came a time of indescribable misery and acute suffering. The poor fellows began to die of actual starvation; and, when the relieving steamers *Thetis* and *Bear* reached Cape Sabine, Lieutenant Greely and six suffering companions were found just alive. If the simple and necessary precaution had been taken of stationing a depot ship in a good harbor at the entrance of Smith Sound, in annual communication with Greely on one side and with America on the other, there would have been no disaster. If precautions proved to be necessary by experience are taken, there is no undue risk or danger in polar enterprise.

#### SOUTH POLAR REGION.

The south polar region, unlike the northern region, is almost covered by the ocean, the only extensive land being far to the south. It was of course entirely unknown to the ancients and to the early navigators of modern Europe, although a theory prevailed among geographers that a great continent existed round the south pole; the "Terra Australis Incognita." Lope Garcia de Castro, the governor of Peru, sent his nephew Alvaro Mendaña in search of it, who sailed from Callao in 1567. Another expedition under Pedro Fernandez de Quiros left Callao in 1605, and discovered

land in April, 1606, which he called Australia del Espiritu Santo, now known to be one of the New Hebrides group. These were the first regular expeditions in search of the supposed southern continent.

The first ship that ever approached the Antarctic Circle was one of a fleet which sailed from Rotterdam under the command of Jacob Mahu as admiral, in June, 1598. She was called the *Good News*, a yacht of 150 tons, with Dirk Gerritz as her captain. She was separated from the rest of the fleet in Magellan's Strait in 1599, and was carried by tempestuous weather far to the south, discovering higher land in 64° S. This appears to have been the land afterward named the South Shetlands. Gerritz and his crew were eventually captured by the Spaniards at Valparaiso. In 1671 La-Roche discovered South Georgia, a solitary island in the South Atlantic, but north even of the latitude of Cape Horn. Where so little is known, and where there is so little land, the discoveries within a few hundred miles of the Antarctic Circle come to be spoken of as south polar.

Captain Cook, in January, 1773, sailed southward from the Cape of Good Hope in the *Resolution*, with the *Adventurer* in company, and, after passing much ice, crossed the Antarctic Circle on the 17th, in longitude 39° 35' E. In the same afternoon they sighted thirty-eight icebergs to the southward besides much loose ice; and in 67° 15' their progress was stopped. Cook did not think it prudent to persevere in getting farther south, and bore up for New Zealand.

Auckland Island was discovered by Captain Bristow in 1806, and Campbell Island by Hazleburgh in 1810, both south of New Zealand, but far to the north of the Antarctic Circle. In 1818 Mr. William Smith of Blyth rediscovered the land known as South Shetland. His work was confirmed by Mr. Bransfield, the master of H.M.S. *Andromache*, flag-ship on the west coast of South America, who further discovered another portion named Bransfield Land. Further coast-line was cited by the French expedition under Dumont d'Urville in 1838, who named it Prince de Joinville and Louis Philippe Land.

The South Orkneys were discovered by Capt. George Powell, in the ship *Dove*, on October 6, 1821. Mr. Weddell, R.N., with the sailing vessels *Jane* and *Beaufoy*, penetrated as far south as 74° 15' S. on February 20, 1823.

POLE, REGINALD, generally known as Cardinal Pole, was born at Stourton Castle, Staffordshire, March 3, 1500. Henry VIII. was eager to keep him at court, but Pole appears to have held aloof from politics until the question of the king's divorce drew him from his retirement. He was probably from the first opposed to Henry's policy, but we find him, nevertheless, in 1530, at Paris, charged with the duty of obtaining the decision of the Sorbonne on the question at issue. That decision given, he returned to England, but refused to approve the king's divorce, or the other measures connected with it. The king, anxious to gain his adhesion, offered him the archbishopric of York, vacant by the death of Wolsey in 1531. After some hesitation, he refused the offer and left the country.

Late in 1536 he was made cardinal, and early next year he was sent as papal legate with the object of uniting Charles V. and Francis I. in an attack upon England, which was to coincide with a rising of the Romanists in that country. In 1549 he was a candidate for the papacy on the death of Paul III., and at one moment was on the point of being elected, but in the end was unsuccessful, and retired to Maguazzano, on the Lake of Garda. The pope at once on the accession of Mary appointed him legate, and entered into negotiations with the

queen. A marriage between her and Pole was at one moment contemplated, but the state of public feeling in England rendered his return impossible, and he was kept waiting for a year in Flanders and Germany. The reaction at length produced a parliament favorable to Rome, and enabled him to return (November, 1554). Pole became Mary's chief adviser, and, with her, must bear the blame of the persecution which followed on the reunion with Rome. On Cranmer's death (March, 1556) he became archbishop of Canterbury, but soon afterward (May, 1557) fell into disgrace with the pope, Paul IV., who was his personal enemy. On the outbreak of war with France, Paul, the political ally of that country, canceled Pole's legatine powers and even charged him with heresy. No remonstrances on the part of Mary and Pole himself could induce the pope to retract this sentence, and Pole died (November 18, 1558) at enmity with the power in whose support he had spent his life.

POLECAT. This name is applied to one of the English members of the large Family *Mustelidæ*, which contains besides the Martens, Weasels, Otters, and Badgers. The polecat ranges over the greater part of Europe and America. It is not found in the extreme south. In fine weather it lives either in the open air, in holes, fox-earths, rabbit-warrens, under rocks, or in wood-stacks; while in winter it seeks the protection of deserted buildings, barns, or stables. During the day it sleeps in its hiding place, sallying forth at night to plunder dovecots and hen-houses. It climbs but little, and shows far less activity than the marten. It feeds ordinarily on small mammals. The polecat is very tenacious of life and will bear many severe wounds before succumbing; it is also said to receive with impunity the bite of the adder. Its fetid smell has become proverbial.

The Siberian Polecat (*Putorius evermanni*), is very like the European in size, color, and proportions, but with head and back both nearly or quite white, and skull more heavily built and sharply constricted behind the orbits, at least in fully adult individuals. It inhabits the greater part of southwestern Siberia, extending from Tibet into the steppes of southeastern European Russia.

The Black-footed or American polecat (*Putorius nigripes*), a native of the central plateau of the United States, and extending southward into Texas. It is very closely allied to the last species, but has nevertheless been made the type of a special sub-genus named *Cynomyonax*, or "King of the Prairie Marmots," a name which expresses its habit of living in the burrows of, and feeding upon, the curious prairie marmots (*Cynomys*) of the United States. An excellent account of this species may be found in Dr. Elliott Coues' *Furbearing Animals of North America*.

The Mottled Polecat (*Putorius sarmaticus*), a rare and peculiar species occurring in southern Russia and southwestern Asia, extending from eastern Poland to Afghanistan.

POLEVOY. See RUSSIAN LITERATURE.

POLICE. The branch of criminal justice which comprises a methodical system for the prevention and detection of crime is commonly known by the name of "Police." With the system having these objects is combined the execution of many duties not strictly involved in the popular definition of crime, but materially affecting the security and convenience of the public. Bentham, more comprehensively, says that police is in general a system of precaution either for the prevention of crime or of calamities. It is destined to prevent evils and provide benefits.

In this view the definition and use of the word

"Police," as meaning the regulation and government of the city and country in relation to the inhabitants, are not sufficiently close. When Blackstone says that by the public police and economy he means "the due regulation and domestic order of the kingdom, whereby the individuals of the State, like members of a well governed family, are bound to conform their general behavior to the rules of propriety, good neighborhood, and good manners, and to be decent, industrious, and inoffensive in their respective stations," the definition is capable of an interpretation at once too wide and too narrow for the present purpose. It is vain to look for an accurate description of police, as a system, in writers of a period when the thing sought for had no existence. The system is of recent growth, and it is necessarily more associated with personal instruments for the attainment of objects than with the objects to be attained. An observation of Gibbon, referring to the *ædiles* and *quæstors* of the Roman empire, that officers of the police or revenue easily adapt themselves to any form of government, correctly presents the idea of distinctive personal elements. A system of police administration includes neither the making of the law nor the law itself. Officers of police are neither legislators nor (in the usual sense) magistrates. They are the instruments by which conformity to the rules of the commonwealth is obtained.

Apart from the repression of crime as generally understood, it is plain that, at least in crowded cities, a power ought to exist for the suppression of noise and disorder, the regulation of locomotion and traffic, the correction of indecency, and the prevention of a numerous class of annoyances and impositions which can only be restrained by cognizance being taken of them at the instant. To these may be added a number of petty disputes the immediate settlement of which tends materially to the public peace. Over such subjects as these it is obviously for the general advantage that the police should have a summary control. Any apprehension of danger to liberty can only be founded on its abuse and not upon its proper exercise.

Employment of persons in these various duties, as well as in the prevention and detection of graver matters of crime, constitutes division of state labor. Therefore, while it is perfectly correct to speak of the various legislative and other measures for good order as "matters of police," the organization and management of the police forces constitute a distinct subject.

The essential features of the established police system, alike in Great Britain and in foreign states, in cities and towns as in countries, and village communities comprise the following matters:—

I. A body of persons in relation to the state enforcing obedience to the criminal law, the prevention and detection of crime, and the preservation of order, over a defined area, generally divided and subdivided for the purpose of description and immediate government of the force, but having one jurisdiction throughout.

II. The division of that force into classes of various rank, comprising, in general, in ascending order, constables, sergeants, inspectors, and superintendents (or their equivalents)—the constables being the most numerous and themselves divided into classes.

III. General control of the entire body by heads, whether styled commissioners or chiefs, having power to make regulations for the government of the force, subject in turn to the control of state authorities.

IV. Patrol day and night of the streets, roads, and public places—the "beats" and "tours of duty" of constables being prescribed by regulations, and actual performance and compliance being secured by the sergeants and inspectors.

V. The payment of the force, including establishment charges, out of public funds provided for the purpose.

The police force of the British empire, metropolitan, municipal, and rural together, is about 210,000. Of this total, 51,000 are in the United Kingdom and 147,000 in India, the remainder being in the colonies and dependencies. If to this total be added the number of village police in India who are legally recognized, whose number is not less than 350,000, the grand total of the police for the empire is 560,000. Thus we have for the whole empire an average of one policeman to every 571 of the people and to every 16 square miles (Sir Richard Temple).

The different States of the Union have a system of police closely resembling that of England, and founded similarly on acts of the legislature combined with common law applicable to peace officers. Congress as well as the States separately may establish police regulations, and it is to be observed that the criminal law of England has been reproduced in various shapes in nearly all the States. The source of revenue for the maintenance of the police is taxation of real and personal property. Every State and every city in a State has its separate special administration. For the purposes of this article New York must suffice. The regulations of the police of Brooklyn, Philadelphia, and other cities present the same general features.

The police department of the city of New York consists of a "board of police" composed of four "commissioners" (appointed by the mayor with the consent of the board of aldermen) and the "police force" and officers appointed by the board. The board, consisting of the commissioners, is the head of the police department, and governs and controls its business; it is invested with and exercises all the powers conferred by law upon the police department, makes appointments, and by rules and regulations through a superintendent prescribes the general discipline of the department. The orders cannot, however, conflict with the constitution of the United States nor with the constitution or laws of the State of New York.

The police force of the city comprises officers ranking as follows: Superintendent of the whole force; four inspectors (the whole area of the city being divided into four inspection districts, subdivided into precincts, with an inspector to each), sergeants, and roundsmen who are visiting officers—the body of the force being termed "patrol men," with "overmen" at stations and prisons.

The force (clothed in uniform) is divided into as many companies as there are precincts, and such other companies and "squads" as the board may order. The superintendent is the chief executive officer of the force, subject to the orders, rules, and regulations of the board, and it is his duty to enforce in the city all the laws of the State and ordinances of the city, and the rules and regulations of the police board. The superintendent promulgates written or printed orders to the officers and members of the police force not inconsistent with law or the rules and regulations of the board. It is the duty of the police force at all times of the day and night within the city and county of New York, and they are accordingly empowered, to especially preserve the public peace; prevent crime; detect and arrest offenders; suppress riots and insurrections; protect the rights of persons and of property; guard the public health; preserve order at every primary and public election; remove nuisances existing in public streets, roads, places, and highways; repress and restrain disorderly houses and houses of ill-fame; arrest all street beggars and mendicants; provide a proper police attendance at every fire in order that the firemen, fire-engines, and property exposed may be suitably assisted or protected;

assist, advise, and protect immigrants, strangers, and travelers in public streets, or at steamboat and ship landings or railroad stations; enforce any law relating to the suppression and punishment of crime, or to the observance of Sunday, or regarding pawnbrokers, or mock auctions, or emigration, or elections, or gambling, or intemperance, or lotteries, or lottery policies, or vagrants, or disorderly persons, or the public health, or any ordinance or resolution of common councils, within the said district, applicable to police, health, or criminal procedure.

Special regulations are made on these and other kindred subjects, such as the regulation of traffic, preventing obstructions, the visitation of places of amusement, public houses and drinking places, observation of servants in charge of houses, and of suspicious persons, lost children, processions, balls and parties, elections, etc., and the attendance of an adequate number of police at every assembly of citizens.

The detective force, called the "detective squad," consists of a captain and other members assigned by the board to detective duty. This portion of the force has an office, as other portions of the police force, and is under the direct orders of the superintendent, to whom reports are made, and who in turn reports to the board. There is also a "special service squad" under the officer commanding the detective force.

There is a sanitary code, and a "sanitary police company" is set apart from the police force by the board of police, performing duties assigned by the board. The captain of the sanitary company assigns policemen to act as school officers. There are harbor police, a police steamboat and steam-boiler inspection squad to enforce the statute law on the subject, an "ordinance police squad" to enforce ordinances of the corporation, and a "property office."

Members of the force are subject to rules; at the discretion of the board, on written application, they are permitted to receive rewards or presents for services rendered by them in the discharge of duties which are both "meritorious and extraordinary," but for such only.

Admission to the force, examination, instruction, drill, and discipline are provided for by special regulations. The right of every member of the police force to entertain political or partisan opinions, and to express the same freely when such expression shall not concern the immediate discharge of his official duties, as well as the right of the elective franchise, is deemed sacred and inviolable; but no member of the force is permitted to be a delegate or representative to, or member of, or to take part in any political or partisan convention, whose purpose is the nomination of a candidate or candidates to any political office. Upon the days of election for public offices held under the laws of the State, he must do all within his power to preserve the peace, protect the integrity of the ballot box, enforce the rights of lawful voters, and prevent illegal and fraudulent voting. As an adjunct to the police in most American cities may be mentioned the patrol wagons (in which a number of police can be hurriedly transported to any given point), and the ambulances for the removal of the victims of accident or sudden disease.

POLIGNAC, an ancient French family, which had its seat in the Cevennes near Puy-en-Velay (Haute-Loire). Cardinal MELCHOIR DE POLIGNAC (1661-1742) was a younger son of Armand XVI., marquis de Polignac, and at an early age achieved distinction as a diplomatist. In 1726 he received the archbishopric of Auch, and he died in Paris in 1742. Count JULES DE POLIGNAC (ob. 1817), grand-nephew of the preceding, was created duke by Louis XVI., in 1780, and in 1782

was made postmaster-general. His position and influence at court were largely due to his wife, the bosom friend of Marie Antoinette. The duchess died shortly after the queen, but her husband, who had received an estate from Catherine II., in the Ukraine, survived till 1817. Of their three sons the second, Prince JULES DE POLIGNAC (1780-1847), held various offices after the restoration of the Bourbons, received from the pope his title of "prince" in 1820, and in 1823 was made ambassador to the court of St. James. On the revolution of July, 1830, he fled for his life, but after wandering for some time among the wilds of Normandy, was arrested at Granville. His trial before the chamber of peers resulted in his condemnation to perpetual imprisonment (at Ham), but he was benefited by the amnesty of 1836, when the sentence was commuted to one of exile. During his captivity he wrote *Considérations politiques* (1832). He afterward spent some years in England, but finally was permitted to reënter France on condition that he did not take up his abode in Paris. He died at St. Germain on March 29, 1847.

POLILLO. See PHILIPPINE ISLANDS.

POLITIAN. Angelo Ambrogini, known in literary annals as ANGELO POLIZIANO or POLITIANUS, from his birth-place, was born at Montepulciano, in Tuscany, in the year 1454.

Poliziano was great as a scholar, as a professor, as a critic, and as a Latin poet at an age when the classics were still studied with the passion of assimilative curiosity, and not with the scientific industry of a later period. He died half broken-hearted by the loss of his friend and patron, Lorenzo de' Medici, in 1494, at the age of forty, just before the wave of foreign invasion which was gathering in France swept over Italy.

POLITICAL CONVENTIONS are conventions composed of delegates from any of the several political organizations of the United States, for the purpose of formulating a platform of political principles, and nominating as candidates for office those whose political affiliations and rules of conduct are in harmony with the views of such party. Delegates are chosen by popular vote, and representation is based upon the number of voters in the precinct, county, district, or State whence such delegates are elected. This fact is determined by the central committee, which has been previously selected, and upon the discretion of which the party relies for the disposition of business connected with the conduct of a campaign, and for the success of the campaign itself. These committees, in brief, exercise a political trust committed to their care, and are held responsible for its faithful discharge. The ethics of a convention, so to speak, demand concert of action, the settlement of internal differences, the cordial and substantial support of the nominees, and the employment of all honorable means for the promotion of harmony in the party to the end that failure shall not be the sequel. The convention is presided over by a chairman selected from among the delegates in attendance, who appoints the various committees, decides all points of parliamentary law raised during the proceedings, promulgates the result of ballots ordered as the same are reached, and generally exercises a supervision over the entire deliberations. He is assisted in his administration by a secretary, sergeant-at-arms, and other officers; and at the final conclusion of the proceedings affixes his signature to the same, in testimony to their correctness. He is not debarred from calling a delegate to preside and participating in the convention debates, nor from submitting such opinions, motions or amendments as may in his opinion promote the expedition of business or the attainment of purposes under consideration.

Delegates, in addition to the forming of a platform

and the nomination of candidates, also participate in the selection of campaign committees, local, county, State and National, who, as already stated, have charge of the campaign, the apportionment of future representation and the calling of future conventions. Upon the completion of the business for the transaction of which the convention assembled, an adjournment follows, and if there is necessity for further deliberation, owing to circumstances arising subsequent to adjournment, the executive committee convenes and decides where to re-call the convention, or pass upon the matter in executive session.

**POLITICAL ECONOMY.** The present condition of the study of political economy seems to prescribe, as most suitable for these pages, a treatment of the subject different from that adopted in relation to other departments of knowledge.

The history of economic inquiry is most naturally divided into the three great periods of (1) the ancient, (2) the mediæval, and (3) the modern worlds.

#### ANCIENT TIMES.

*The Oriental Theocracies.*—The earliest surviving expressions of thought on economic subjects have come down to us from the Oriental theocracies.

*Greek and Roman Antiquity.*—The practical economic enterprises of Greek and Roman antiquity could not, even independently of any special adverse influences, have competed in magnitude of scale or variety of resource with those of modern times. The unadvanced condition of physical science prevented a large application of the less obvious natural powers to production, or the extensive use of machinery, which has acquired such an immense development as a factor in modern industry. The imperfection of geographical knowledge and of the means of communication and transport were impediments to the growth of foreign commerce. These obstacles arose necessarily out of the mere immaturity of the industrial life of the periods in question. Now the historical vocation of the ancient civilization was to be accomplished, not through industry, but through war, which was in the end to create a condition of things admitting of its own elimination and of the foundation of a regime based on pacific activity.

*The Greeks.*—This office was, however, reserved for Rome, as the final result of her system of conquest; the military activity of Greece, though continuous, was incoherent and sterile, except in the defense against Persia, and did not issue in the accomplishment of any such social mission.

In the *Works and Days* of Hesiod, we find an order of thinking in the economic sphere very similar to that of the theocracies. With a recognition of the divine disposing power, and traditional rules of sacerdotal origin, is combined practical sagacity embodied in precept or proverbial saying. But the development of abstract thought, beginning from the time of Thales, soon gives to Greek culture its characteristic form, and marks a new epoch in the intellectual history of mankind.

The movement was now begun, destined to mold the whole future of humanity, which, gradually sapping the old hereditary structure of theological convictions, tended to the substitution of rational theories in every department of speculation.

In the Greek thinking on such questions, as on all sociological subjects, the following general features are observable:

1. The individual is conceived as subordinated to the state, through which alone his nature can be developed and completed, and to the maintenance and service of which all his efforts must be directed. The great aim of all political thought is the formation of good citizens;

every social question is studied primarily from the ethical and educational point of view. The citizen is not regarded as a producer, but only as a possessor, of material wealth; and this wealth is not esteemed for its own sake or for the enjoyments it procures, but for the higher moral and public aims to which it may be made subservient.

2. The state, therefore, claims and exercises a controlling and regulating authority over every sphere of social life, including the economic, in order to bring individual action into harmony with the good of the whole.

3. With these fundamental notions is combined a tendency to attribute to institutions and to legislation an unlimited efficacy, as if society had no spontaneous tendencies, but would obey any external impulse, if impressed upon it with sufficient force and continuity.

Every eminent social speculator had his ideal state, which approximated to or diverged from the actual or possible, according to the degree in which a sense of reality and a positive habit of thinking characterized the author.

The most celebrated of these ideal systems is that of Plato. In it the Greek idea of the subordination of the individual to the state appears in its most extreme form. In that class of the citizens of this republic who represent the highest type of life, community of property and of wives is established, as the most effective means of suppressing the sense of private interest, and consecrating the individual entirely to the public service.

*The Romans.*—Notwithstanding the eminently practical, realistic, and utilitarian character of the Romans, there was no energetic exercise of their powers in the economic field; they developed no large and many-sided system of production and exchange. Their historic mission was military and political, and the national energies were mainly devoted to the public service at home and in the field. To agriculture, indeed, much attention was given from the earliest times, and on it was founded the existence of the hardy population which won the first steps in the march to universal dominion. But in the course of their history the cultivation of the soil by a native yeomanry gave place to the introduction on a great scale of slave laborers, acquired by their foreign conquests; and for the small properties of the earlier period were substituted the vast estates—the *latifundia*—which, in the judgment of Pliny, were the ruin of Italy. The industrial arts and commerce (the latter, at least when not conducted on a great scale) they regarded as ignoble pursuits, unworthy of free citizens; and this feeling of contempt was not merely a prejudice of narrow and uninstructed minds, but was shared by Cicero and others among the most liberal spirits of the nation. As might be expected from the want of speculative originality among the Romans, there is little evidence of serious theoretic inquiry on economic subjects. Their ideas on these as on other social questions were for the most part borrowed from the Greek thinkers. Such traces of economic thought as do occur are to be found in (1) the philosophers, (2) the writers *de re rustica*, and (3) the jurists. It must, however, be admitted that many of the passages in these authors referred to by those who assert the claim of the Romans to a more prominent place in the history of the science often contain only obvious truths or vague generalities.

In the philosophers, whom Cicero, Seneca, and the elder Pliny sufficiently represent (the last indeed being rather a learned encyclopædist or polyhistor than a philosopher), we find a general consciousness of the decay of industry, the relaxation of morals, and the growing spirit of self-indulgence among their contem-

poraries, who are represented as deeply tainted with the imported vices of the conquered nations.

Looking back on the history of ancient economic speculation, we see that, as might be anticipated *a priori*, the results attained in the field by the Greek and Roman writers were very scanty.

#### MIDDLE AGES.

The Middle Ages (400-1300 A.D.) form a period of great significance in the economic, as in the general, history of Europe. They represent a vast transition, in which the germs of a new world were deposited, but in which little was fully elaborated. There is scarcely anything in the later movement of European society which we do not find there, though as yet, for the most part, crude and undeveloped.

No large or varied economic activity was possible under the ascendancy of feudalism. That organization, as has been abundantly shown by philosophical historians, was indispensable for the preservation of order and for public defense, and contributed important elements to general civilization. But, while recognizing it as opportune and relatively beneficent, we must not expect from it advantages inconsistent with its essential nature and historical office. The class which predominated in it was not sympathetic with industry, and held the handicrafts in contempt, except those subservient to war or rural sports. The whole practical life of the society was founded on territorial property; the wealth of the lord consisted in the produce of his lands and the dues paid to him in kind; this wealth was spent in supporting a body of retainers whose services were repaid by their maintenance. There could be little room for manufactures, and less for commerce; and agriculture was carried on with a view to the wants of the family, or at most of the immediate neighborhood, not to those of a wider market. The economy of the period was therefore simple, and, in the absence of special motors from without, unprogressive.

In the latter portion of the Middle Ages several circumstances came into action which greatly modified these conditions. The crusades undoubtedly produced a powerful economic effect by transferring in many cases the possessions of the feudal chiefs to the industrious classes, while by bringing different nations and races into contact, by enlarging the horizon and widening the conceptions of the populations, as well as by affording a special stimulus to navigation, they tended to give a new activity to international trade. The independence of the towns and the rising importance of the burgher class supplied a counterpoise to the power of the land aristocracy; and the strength of these new social elements was increased by the corporate constitution given to the urban industries, the police of the towns being also founded on the trade guilds, as that of the country districts was on the feudal relations. The increasing demand of the towns for the products of agriculture gave to the prosecution of that art a more extended and speculative character; and this again led to improved methods of transport and communication. But the range of commercial enterprise continued everywhere narrow, except in some favored centers, such as the Italian republics, in which, however, the growth of the normal habits of industrial life was impeded or perverted by military ambition, which was not, in the case of those communities, checked as it was elsewhere by the pressure of an aristocratic class.

The enfranchisement of the working classes was the most important practical outcome of the Middle Ages. The first step in this movement was the transformation of slavery, properly so called, into serfdom. The latter is, by its nature, a transitory condition. The serf was

bound to the soil, had fixed domestic relations, and participated in the religious life of society; and the tendency of all his circumstances, as well as of the opinions and sentiments of the time, was in the direction of liberation. This issue was, indeed, not so speedily reached by the rural as by the urban workman. Already in the second phase serfdom is abolished in the cities and towns, while agricultural serfdom does not disappear before the third. The latter revolution is attributed by Adam Smith to the operation of selfish interests, that of the proprietor on the one hand, who discovered the superior productiveness of cultivation by free tenants, and that of the sovereign on the other, who, jealous of the great lords, encouraged the encroachments of the villeins on their authority. But that the church deserves a share of the merit seems beyond doubt—moral impulses, as often happens, conspiring with political and economic motives. The serfs were treated best on the ecclesiastical estates, and the members of the priesthood, both by their doctrine and by their situation since the Northern conquests, were constituted patrons and guardians of the oppressed or subject classes.

Out of the liberation of the serfs rose the first lineaments of the hierarchical constitution of modern industry in the separation between the entrepreneurs and the workers. The personal enfranchisement of the latter, stimulating activity and developing initiative, led to accumulations, which were further promoted by the establishment of order and good government by the civic corporations which grew out of the enfranchisement. Thus an active capital class came into existence. It appeared first in commerce, the inhabitants of the trading cities importing expensive luxuries from foreign countries, or the improved manufactures of richer communities, for which the great proprietors gladly exchanged the raw produce of their lands. In performing the office of carriers, too, between different countries, these cities had an increasing field for commercial enterprise. At a later period, as Adam Smith has shown, commerce promoted the growth of manufactures, which were either produced for foreign sale, or made from foreign materials, or imitated from the work of foreign artificers. But the first important development of handicrafts in modern Europe belongs to the fourteenth and fifteenth centuries, and the rise of manufacturing entrepreneurs is not conspicuous within the Middle Ages properly so called. Agriculture, of course, lags behind; though the feudal lords tend to transform themselves into directors of agricultural enterprise, their habits and prejudices retard such a movement, and the advance of rural industry proceeds slowly. It does, however, proceed, partly from the stimulation arising from the desire to procure the finer objects of manufacture imported from abroad or produced by increased skill at home, partly by the expenditure on the land of capital amassed in the prosecution of urban industries.

Some of the trade corporations in the cities appear to have been of great antiquity; but it was in the thirteenth century that they rose to importance by being legally recognized and regulated.

#### MODERN TIMES.

The close of the Middle ages, as Comte has shown, must be placed at the end, not of the fifteenth, but of the thirteenth century. The modern period, which then began, is filled by a development exhibiting three successive phases, and issuing in the state of things which characterizes our own epoch. During the fourteenth and fifteenth centuries the Catholic-feudal system was breaking down by the mutual conflicts of its own official members, while the constituent elements of

a new order were rising beneath it. On the practical side the antagonists matched against each other were the crown and the feudal chiefs; and these rival powers sought to strengthen themselves by forming alliances with the towns and the industrial forces they represented. The movements of this phase can scarcely be said to find an echo in any contemporary economic literature. In the second phase of the modern period, which opens with the beginning of the sixteenth century, the spontaneous collapse of the mediæval structure is followed by a series of systematic assaults which still further disorganize it. During this phase the central temporal power, which has made a great advance in stability and resources, lays hold of the rising elements of manufactures and commerce, and seeks, while satisfying the popular enthusiasm for their promotion, to use them for political ends, and make them subserve its own strength and splendor by furnishing the treasure necessary for military success. With this practical effort and the social tendencies on which it rests the mercantile school of political economy, which then obtains a spontaneous ascendancy, is in close relation. While partially succeeding in the policy we have indicated, the European Governments yet on the whole necessarily fail, their origin and nature disqualifying them for the task of guiding the industrial movement; and the discredit of the spiritual power, with which most of them are confederate, further weakens and undermines them. In the last phase, which coincides approximately with the eighteenth century, the tendency to a completely new system, both temporal and spiritual, becomes decisively pronounced, first in the philosophy and general literature of the period, and then in the great French explosion. The universal critical doctrine, which had been announced by the Protestantism of the previous phase, and systematized in England toward the close of that phase, is propagated and popularized, especially by French writers. The spirit of individualism inherent in the doctrine was eminently adapted to the wants of the time, and the general favor with which the dogmas of the social contract and *laissez faire* were received indicated a just sentiment of the conditions proper to the contemporary situation of European societies.

#### FIRST MODERN PHASE.

The first phase was marked, on the one hand, by the spontaneous decomposition of the mediæval system, and, on the other, by the rise of several important elements of the new order. The spiritual power became less apt as well as less able to fulfil its moral office, and the social movement was more and more left to the irregular impulses of individual energy, often enlisted in the service of ambition and cupidity. Strong governments were formed, which served to maintain material order amid the growing intellectual and moral disorder. The universal admission of the commons as an element in the political system showed the growing strength of the industrial forces, as did also in another way the insurrections of the working classes. The decisive prevalence of peaceful activity was indicated by the rise of the institution of paid armies—at first temporary, afterward permanent—which prevented the interruption or distraction of labor by devoting a determinate minority of the population to martial operations and exercises. Manufactures became increasingly important; and in this branch of industry the distinction between the entrepreneur and the workers was first firmly established, while fixed relations between these were made possible by the restriction of military training and service to a special profession. Navigation was facilitated by the use of the mariner's compass. The art of printing

showed how the intellectual movement and the industrial development were destined to be brought into relation with each other and to work toward common ends. Public credit rose in Florence, Venice, and Genoa, long before Holland and England attained any great financial importance. Just at the close of the phase, the discovery of America and of the new route to the East, while revolutionizing the course of trade, prepared the way for the establishment of colonies, which contributed powerfully to the growing preponderance of industrial life, and pointed to its ultimate universality. It is doubtless due to the equivocal nature of the stage, standing between the mediæval and the fully characterized modern period, that on the theoretic side we find nothing corresponding to this marvelous practical ferment and expansion. The general political doctrine of Aquinas was retained, with merely subordinate modifications. The only special economic question which seems to have received particular attention was that of the nature and functions of money, the importance of which began to be felt as payments in service or in kind were discontinued, and regular systems of taxation began to be introduced.

#### SECOND MODERN PHASE—MERCANTILE SYSTEM.

Throughout the first modern phase the rise of the new social forces had been essentially spontaneous; in the second they became the object of systematic encouragement on the part of governments, which, now that the financial methods of the Middle Ages no longer sufficed, could not further their military and political ends by any other means than increased taxation, implying augmented wealth of the community. Industry thus became a permanent interest of European governments, and even tended to become the principal object of their policy. In natural harmony with this state of facts, the mercantile system arose and grew, attaining its highest development about the middle of the seventeenth century.

The mercantile doctrine, stated in its most extreme form, makes wealth and money identical, and regards it, therefore, as the great object of a community so to conduct its dealings with other nations as to attract to itself the largest possible share of the precious metals. Each country must seek to export the utmost possible quantity of its own manufactures, and to import as little as possible of those of other countries, receiving the difference of the two values in gold and silver. This difference is called the balance of trade, and the balance is favorable when more money is received than is paid. Governments must resort to all available expedients—prohibition of, or high duties on, the importation of foreign wares, bounties on the export of home manufactures, restrictions on the export of the precious metals—for the purpose of securing such a balance.

But this statement of the doctrine, though current in the text books, does not represent correctly the views of all who must be classed as belonging to the mercantile school. Many of the members of that school were much too clear-sighted to entertain the belief, which the modern student feels difficulty in supposing any class of thinkers to have professed, that wealth consists exclusively of gold and silver. The mercantilists may be best described, as Roscher has remarked, not by any definite economic theorem which they held in common, but by a set of theoretic tendencies, commonly found in combination, though severally prevailing in different degrees in different minds. These tendencies may be enumerated as follows:—(1) toward overestimating the importance of possessing a large amount of the precious metals; (2) toward an undue exaltation (*a*) of foreign trade over domestic, and (*b*) of the industry which

works up materials over that which provides them; (3) toward attaching too high a value to a dense population as an element of national strength; and (4) toward invoking the action of the state in furthering artificially the attainment of the several ends thus proposed as desirable.

We must not expect from the writers of this stage any exposition of political economy as a whole; the publications which appeared were for the most part evoked by special exigencies, and related to particular questions, usually of a practical kind, which arose out of the great movements of the time. They were in fact of the nature of counsels to the governments of states, pointing out how best they might develop the productive powers at their disposal and increase the resources of their respective countries. They are conceived (as List claims for them) strictly in the spirit of *national* economy, and cosmopolitanism is essentially foreign to them. On these monographs the mercantile theory sometimes had little influence, the problems discussed not involving its tenets. But it must in most cases be taken to be the scheme of fundamental doctrine (so far as it was ever entitled to such a description) which in the last resort underlies the writer's conclusions.

While the mercantile system represented the prevalent form of economic thought in the seventeenth century, and was alone dominant in the reign of practical statesmanship, there was growing up, side by side with it, a body of opinion, different and indeed hostile in character, which was destined ultimately to drive it from the field. The new ideas were first developed in England, though it was in France that in the following century they took hold of the public mind, and became a power in politics. That they should first show themselves here, and afterward be extended, applied, and propagated throughout Europe by French writers, belongs to the order of things according to which the general negative doctrine in morals and politics, undoubtedly of English origin, found its chief home in France, and was thence diffused in widening circles through the civilized world. In England this movement of economic thought took the shape mainly of individual criticism of the prevalent doctrines, founded on a truer analysis of facts and conceptions; in France it was penetrated with a powerful social sentiment, furnished the creed of a party, and inspired a protest against institutions and an urgent demand for practical reform.

#### THIRD MODERN PHASE—SYSTEM OF NATURAL LIBERTY.

Both in England and France the ruling powers had already begun to be alarmed by the subversive tendencies which appeared inherent in the modern movement, and took up in consequence an attitude of resistance. Reaction became triumphant in France during the latter half of the reign of Louis XIV. under the disastrous influence of Madame de Maintenon. In England, after the transaction of 1688, by which the government was consolidated on the double basis of aristocratic power and official orthodoxy, the state policy became not so much retrograde as stationary, industrial conquest being put forward to satisfy the middle class and wean it from the pursuit of a social renovation. In both countries there was for some time a noticeable check in the intellectual development, and Roscher and others have observed that, in economic studies particularly, the first three decades of the eighteenth century were a period of general stagnation, eclectic for the most part taking the place of originality. The movement was, however, soon to be resumed, but with an altered and more formidable character. The negative

doctrine, which had risen and taken a definite form in England, was diffused and popularized in France, where it became evident, even before the decisive explosion, that the only possible issue lay in a radical social transformation. The political schools of Voltaire and Rousseau in different ways led up to a violent crisis, while taking little thought of the conditions of a system which could replace the old; but the more complete and organic school, of which Diderot is the best representative, looked through freedom to reorganization. Its constructive aim is shown by the design of the *Encyclopédie*—a project, however, which could have only a temporary success, because no real synthesis was forthcoming, and this joint production of minds often divergent could possess no more than external unity. It was with this great school that the physiocrats were specially connected; and, in common with its other members, while pushing toward an entire change of the existing system, they yet would gladly have avoided political demolishing through the exercise of a royal dictatorship, or contemplated it only as the necessary condition of a new and better order of things. But, though marked off by such tendencies from the purely revolutionary sects, their method and fundamental ideas were negative, resting, as they did, essentially on the basis of the *jus nature*.

The more liberal, as well as more rational, principles put forward by the English thinkers of the new type began, early in the eighteenth century, to find an echo in France, where the clearer and more vigorous intellects were prepared for their reception by a sense of the great evils which exaggerated mercantilism, serving as instrument of political ambition, had produced in that country. The impoverished condition of the agricultural population, the oppressive weight and unequal imposition of taxation, and the unsound state of the public finances had produced a general feeling of disquiet, and led several distinguished writers to protest strongly against the policy of Colbert and to demand a complete reform.

The heads of the physiocratic school were François Quesnay (1694-1774) and Jean Claude Marie Vincent, sieur de Gournay (1712-1759).

The general political doctrine is as follows. Society is composed of a number of individuals all having the same natural rights. If all do not possess (as some members of the negative school maintained) equal capacities, each can at least best understand his own interest, and is led by nature to follow it. The social union is really a contract between these individuals, the object of which is the limitation of the natural freedom of each, just so far as it is inconsistent with the rights of the others. Government, though necessary, is a necessary evil; and the governing power appointed by consent should be limited to the amount of interference absolutely required to secure the fulfilment of the contract. In the economic sphere, this implies the right of the individual to such natural enjoyments as he can acquire by his labor. That labor, therefore, should be undisturbed and unfettered; and its fruits should be guaranteed to the possessor; in other words, property should be sacred. Each citizen must be allowed to make the most of his labor; and therefore freedom of exchange should be insured, and competition in the market should be unrestricted, no monopolies or privileges being permitted to exist.

The physiocratic school never obtained much direct popular influence, even in its native country, though it strongly attracted many of the more gifted and earnest minds.

In Italy, as in the other European nations, there was little activity in the economic field during the first

half of the eighteenth century. It was then, however, that a really remarkable man appeared, the archdeacon Salustio Antonio Bandini (1677-1760), author of the *Discorso sulla Maremma Siense*, written in 1737, but not published till 1775. The object of the work was to raise the Maremma from the wretched condition into which it had fallen through the decay of agriculture. This decay he showed to be, at least in part, the result of the wretched fiscal system which was in force; and his books led to important reforms in Tuscany, where his name is held in high honor. Not only by Pecchio and other Italian writers, but by Roscher also, he is alleged to have anticipated some leading doctrines of the physiocrats, but this claim is disputed. There was a remarkable renaissance of economic studies in Italy during the latter half of the century, partly due to French influence, and partly, it would appear, to improved government in the northern states.

The same breath of a new era which was in the air elsewhere in Europe made itself felt also in Spain.

In both Italy and Spain, as is well observed by Comte, the impulse toward social change took principally the direction of economic reform, because the pressure exercised by governments prevented so large a measure of free speculation in the fields of philosophy and general politics as was possible in France. In Italy, it may be added, the traditions of the great industrial past of the northern cities of that country also tended to fix attention chiefly on the economic side of public policy and legislation.

We have seen that in Italy and England political economy had its beginnings in the study of practical questions relating chiefly to money or to foreign commerce. In Germany it arose (as Roscher has shown) out of the so-called cameralistic sciences. From the end of the Middle Ages there existed in most German countries a council, known as the Kammer (Lat. *camera*), which was occupied with the management of the public domain and the guardianship of regal rights. The emperor Maximilian found this institution existing in Burgundy, and established, in imitation of it, aulic councils at Innsbruck and Vienna in 1498 and 1501. Not only finance and taxation, but questions also of economic policy, came to be intrusted to these bodies. A special preparation became necessary for their members, and chairs of cameralistic science were founded in universities for the teaching of the appropriate body of doctrine. One side of the instruction thus given borrowed its materials from the sciences of external nature, dealing, as it did, with forestry, mining, general technology, and the like; the other related to the conditions of national prosperity as depending on human relations and institutions; and out of the latter German political economy was at first developed.

In no country had mercantilist views a stronger hold than in Germany, though in none, in the period we are now considering, did the system of the balance of trade receive a less extensive practical application. All the leading German economists of the seventeenth century—Bornitz, Besold, Klock, Becher, Horneck, Seckendorf, and Schröder—stand on the common basis of the mercantile doctrine. And the same may be said of the writers of the first half of the eighteenth century in general.

The stagnation in economic inquiry which showed itself in England in the early part of the eighteenth century was not broken by any notable manifestation before 1735, when Bishop Berkeley put forward in his *Querist*, with much force and point, views opposed to those of the mercantile school on the nature of national wealth and the functions of money, though not without

an admixture of grave error. But soon a more decisive advance was made. While in France the physiocrats were working after their own fashion toward the construction of a definitive system of political economy, a Scottish thinker of the first order was elucidating, in a series of short but pregnant essays, some of the fundamental conceptions of the science. What had been written on these questions in the English language before his time had remained almost altogether within the limits of the directly practical sphere. With Locke, indeed, the general system of the modern critical philosophy had come into relation with economic inquiry, but only in a partial and indeterminate way. But in Hume the most advanced form of this philosophy was represented, and his appearance in the field of economics decisively marks the tendency of the latter order of speculation to place itself in connection with the largest and deepest thought on human nature and general human history. Most of the essays here referred to first appeared in 1752, in a volume entitled *Political Discourses*, and the number was completed in the collection of *Essays and Treatises on Several Subjects*, published in the following year. The most important of them are those on Commerce, on Money, on Interest, and on the Balance of Trade. Yet these should not be separated from the rest, for notwithstanding the unconnected form of these little treatises, there runs through them a profound unity of thought, so that they indeed compose in a certain sense an economic system. They exhibit in full measure Hume's wonderful acuteness and subtlety, which indeed sometimes dispose him to paradox, in combination with the breadth, the absence of prejudice and the social sympathies which so eminently distinguish him, and they offer, besides, the charm of his easy and natural style and his rare power of lucid exposition.

The characteristics of Hume which are most important in the history of economic investigation are (1) his practice of bringing economic facts into connection with all the weighty interests of social and political life, and (2) his tendency to introduce the historical spirit into the study of those facts. He admirably illustrates the mutual action of the several branches of industry, and the influences of progress in the arts of production and in commerce on general civilization, exhibits the striking contrasts of the ancient and modern system of life (see especially the essay *On the Populousness of Ancient Nations*), and considers almost every phenomenon which comes under discussion in its relations to the contemporary stage of social development. It cannot be doubted that Hume exercised a most important influence on Adam Smith, who in the *Wealth of Nations* calls him "by far the most illustrious philosopher and historian of the present age," and who esteemed his character so highly that, after a friendship of many years had been terminated by Hume's decease, he declared him to have "approached as nearly to the idea of a perfectly wise and virtuous man as perhaps the nature of human frailty will permit."

Coming now to the great name of Adam Smith (1723-1790), it is of the highest importance that we should rightly understand his position and justly estimate his claims. It is plainly contrary to fact to represent him, as some have done, as the creator of political economy. The subject of social wealth had always in some degree, and increasingly in recent times, engaged the attention of philosophic minds. The study had even indisputably assumed a systematic character, and, from being an assemblage of fragmentary disquisitions on particular questions of national interest, had taken the form, notably in Turgot's *Réflexions*, of an organized body of doctrine. The truth is that Smith took up the science

when it was already considerably advanced; and it was this very circumstance which enabled him, by the production of a classical treatise, to render most of his predecessors obsolete. But, while all the economic labors of the preceding centuries prepared the way for him, they did not anticipate his work. His appearance at an earlier stage, or without those previous labors, would be inconceivable; but he built, on the foundation which had been laid by others, much of his own that was precious and enduring.

There has been much discussion on the question—What is the scientific method followed by Smith in his great work? By some it is considered to have been purely deductive, a view which Buckle has perhaps carried to the greatest extreme.

That Smith does, however, largely employ the deductive method is certain; and that method is quite legitimate when the premises from which the deduction sets out are known universal facts of human nature and properties of external objects. Whether this mode of proceeding will carry us far may indeed well be doubted; but its soundness cannot be disputed.

Smith's earliest critics were Bentham and Lauderdale, who, though in general agreement with him, differed on special points. Jeremy Bentham was author of a short treatise entitled *A Manual of Political Economy* (1843), and various economic monographs, the most celebrated of which was his *Defense of Usury* (1787). This contained (Letter xiii.) an elaborate criticism of a passage in the *Wealth of Nations*, already cited, in which Smith had approved a legal maximum rate of interest fixed but a very little above the lowest market rate, as tending to throw the capital of the country into the hands of sober persons, as opposed to "prodigals and projectors." Smith is said to have admitted that Bentham had made out his case. He certainly argues it with great ability; and the true doctrine no doubt is that, in a developed industrial society, it is expedient to let the rate be fixed by contract between the lender and the borrower, the law interfering only in case of fraud.

Lord Lauderdale, in his *Inquiry into the Nature and Origin of Public Wealth* (1804), a book still worth reading, pointed out certain real weaknesses in Smith's account of value and the measure of value, and of the productivity of labor, and threw additional light on several subjects, such as the true mode of estimating the national income, and the reaction of the distribution of wealth on its production.

Alongside of evils of the new industrial system just then arising, socialism appeared as the alike inevitable and indispensable expression of the protest of the working classes and the aspiration after a better order of things; and what we now call "the social question," that inexorable problem of modern life, rose into the place which it has ever since maintained. This question was first effectually brought before the English mind by Thomas Robert Malthus (1766–1834), not, however, under the impulse of revolutionary sympathies, but in the interests of a conservative policy.

The first edition of the work which achieved this result appeared anonymously in 1798 under the title—*An Essay on the Principle of Population, as it affects the future improvement of Society, with remarks on the speculations of Mr. Godwin, M. Condorcet, and other writers*. This book arose out of certain private controversies of its author with his father Daniel Malthus, who had been a friend of Rousseau, and was an ardent believer in the doctrine of human progress as preached by Condorcet and other French thinkers and by their English disciples. The most distinguished of the latter was William Godwin, whose *Enquiry concerning Political Justice* had been published in 1793. The

views put forward in that work had been restated by its author in the *Enquirer* (1797), and it was on the essay in this volume entitled *Avarice and Profusion* that the discussion between the father and the son arose, "the general question of the future improvement of society" being thus raised between them—the elder Malthus defending the doctrines of Godwin, and the younger assailing them. The latter "sat down with an intention of merely stating his thoughts on paper in a clearer manner than he thought he could do in conversation," and the *Essay* on population was the result.

The project of a formal and detailed treatise on population was an afterthought of Malthus. The essay in which he had studied a hypothetic future led him to examine the effects of the principle he had put forward on the past and present state of society; and he undertook an historical examination of these effects, and sought to draw such inferences in relation to the actual state of things as experience seemed to warrant. The consequence of this was such a change in the nature and composition of the essay as made it, in his own language, "a new work." The book, so altered, appeared in 1803 under the title—*An Essay on the Principle of Population, or a View of its Past and Present Effects on Human Happiness; with an Enquiry into our prospects respecting the future removal or mitigation of the evils which it occasions*.

Malthus had undoubtedly the great merit of having called public attention in a striking and impressive way to a subject which had neither theoretically nor practically been sufficiently considered. But he and his followers appear to have greatly exaggerated both the magnitude and the urgency of the dangers to which they pointed. In their conceptions a single social imperfection assumed such portentous dimensions that it seemed to overcloud the whole heaven and threaten the world with ruin. This doubtless arose from his having at first omitted altogether from his view of the question the great counteracting agency of moral restraint.

David Ricardo (1772–1823) is essentially of the school of Smith, whose doctrines he in the main accepts, while he seeks to develop them, and to correct them in certain particulars. But his mode of treatment is very different from Smith's. The latter aims at keeping close to the realities of life as he finds them—at representing the conditions and relations of men and things as they are; and, as Hume remarked on first reading his great work, his principles are everywhere exemplified and illustrated with curious facts. Quite unlike this is the way in which Ricardo proceeds. He moves in a world of abstractions. He sets out from more or less arbitrary assumptions, reasons deductively from these, and announces his conclusions as true, without allowing for the partial unreality of the conditions assumed or confronting his results with experience. When he seeks to illustrate his doctrines, it is from hypothetical cases—his favorite device being that of imagining two contracting savages, and considering how they would be likely to act. He does not explain—probably he had not systematically examined, perhaps was not competent to examine—the appropriate method of political economy; and the theoretic defense of his mode of proceeding was left to be elaborated by J. S. Mill and Cairnes.

The most complete exposition of his system is to be found in his *Principles of Political Economy and Taxation* (1817). This work is not a complete treatise on the science, but a rather loosely connected series of disquisitions on value and price, rent, wages and profits, taxes, trade, money and banking.

On the whole what seems to us true of Ricardo is this, that, while he had remarkable powers, they were

not the powers best fitted for sociological research. Nature intended him rather for a mathematician of the second order than for a social philosopher.

After Malthus and Ricardo, the first of whom had fixed public attention irresistibly on certain aspects of society, and the second had led economic research into new, if questionable, paths, came a number of minor writers who were mainly their expositors and commentators, and whom, accordingly, the Germans, with allusion to Greek mythical history, designate as the Epigoni. By them the doctrines of Smith and his earliest successors were thrown into more systematic shape, limited and guarded so as to be less open to criticism, couched in a more accurate terminology, modified in subordinate particulars, or applied to the solution of the practical questions of their day.

The most systematic and thorough-going contemporary critic of the Ricardian system was Richard Jones (1790–1855), professor at Haileybury. Jones has received scant justice at the hands of his successors. J. S. Mill, while using his work, gave his merits but faint recognition. Even Roscher says that he did not thoroughly understand Ricardo, without giving any proof of that assertion, while he is silent as to the fact that much of what has been preached by the German historical school is found distinctly indicated in Jones' writings.

In 1844 J. S. Mill published five *Essays on some Unsettled Questions of Political Economy*, which had been written as early as 1829 and 1830, but had, with the exception of the fifth, remained in manuscript. In these essays is contained any dogmatic contribution which he can be regarded as having made to the science. The subject of the first is the laws of interchange between nations.

In 1848 Mill published his *Principles of Political Economy, with some of their Applications to Social Philosophy*. This title, though, as we shall see, open to criticism, indicated on the part of the author a less narrow and formal conception of the field of the science than had been common among his predecessors. He aimed, in fact, at producing a work which might replace in ordinary use the *Wealth of Nations*, which in his opinion was "in many parts obsolete and in all imperfect." Adam Smith had invariably associated the general principles of the subject with their applications, and in treating those applications had perpetually appealed to other and often far larger considerations than pure political economy affords. And in the same spirit Mill desired, while incorporating all the results arrived at in the special science by Smith's successors, to exhibit purely economic phenomena in relation to the most advanced conceptions of his own time in the general philosophy of society, as Smith had done in reference to the philosophy of his century. This design he certainly failed to realize.

The question of economic method was also taken up by the ablest of his disciples, John Elliott Cairnes (1824–75), who devoted a volume to the subject (*Logical Method of Political Economy*, 1857; 2d ed., 1875). Professor Walker has lately spoken of the method advocated by Cairnes as different from that put forward by Mill, and has even represented the former as similar to, if not identical with, that of the German historical school. But this is certainly an error.

Cairnes' most important economic publication was his last, entitled *Some Leading Principles of Political Economy Newly Expounded* (1874). In this work, which does not profess to be a complete treatise on the science, he criticises and emends the statements which preceding writers had given of some of its principal doctrines, and treats elaborately of the limitations with which

they are to be understood, and the exceptions to them which may be produced by special circumstances. Whilst marked by great ability, it affords evidence of what has been justly observed as a weakness in Cairnes' mental constitution—his "deficiency in intellectual sympathy," and consequent frequent inability to see more than one side of a truth.

All the later European economic schools presuppose—in part adopting, in part criticising—the work of the English economists from Smith to Ricardo and the Epigoni. The German school has had in a greater degree than any other a movement of its own—following, at least in its more recent period, an original method, and tending to special and characteristic conclusions. The French school, on the other hand—if we omit the socialists, who do not here come under consideration—has in the main reproduced the doctrines of the leading English thinkers—stopping short, however, in general, of the extremes of Ricardo and his disciples. In the field of exposition the French are unrivaled; and in political economy they have produced a series of more or less remarkable systematic treatises, text books, and compendiums, at the head of which stands the celebrated work of J. B. Say. But the number of seminal minds which have appeared in French economic literature—of writers who have contributed important truths, introduced improvements of method, or presented the phenomena under new lights—has not been large. Sismondi, Dunoyer, and Bastiat will deserve our attention, as being the most important of those who occupy independent positions (whether permanently tenable or not), if we pass over for the present the great philosophical renovation of Auguste Comte, which comprehended actually or potentially all the branches of sociological inquiry. Before estimating the labors of Bastiat, we shall find it desirable to examine the views of Carey, the most renowned of American economists, with which the latest teachings of the ingenious and eloquent Frenchmen are, up to a certain point, in remarkable agreement. Cournot, too, must find a place among the French writers of this period, as the chief representative of the conception of a mathematical method in political economy.

Of Jean Baptiste Say (1767–1832) Ricardo says—"He was the first, or among the first, of Continental writers who justly appreciated and applied the principles of Smith, and has done more than all other Continental writers taken together to recommend that enlightened and beneficial system to the nations of Europe." His *Traité d'Économie Politique* (1803) was essentially founded on Smith's work, but he aimed at arranging the materials in a more logical and instructive order.

Jean Charles L. Simonde de Sismondi (1773–1842), author of the *Histoire des Républiques Italiennes du moyen âge*, represents in the economic field a protest, founded mainly on humanitarian sentiment, against the dominant doctrines. He wrote first a treatise, *De la Richesse Commerciale* (1803), in which he followed strictly the principles of Adam Smith. But he afterward came to regard these principles as insufficient and requiring modification. He contributed an article on political economy to the *Edinburgh Encyclopædia*, in which his new views were partially indicated. They were fully developed in his principal economic work, *Nouveaux Principes d'Économie Politique ou de la Richesse dans ses rapports avec la Population* (1819; 2d ed., 1827).

The personal union in Sismondi of three nationalities, the Italian, the French, and the Swiss, and his comprehensive historical studies, gave him a special largeness of view; and he was filled with a noble sympathy for the suffering members of society. He stands nearer to

socialism than any other French economist proper, but it is only in sentiment, not in opinion, that he approximates to it.

In no French economic writer is greater force or general solidity of thought to be found than in Charles Dunoyer (1786–1862), author of *La Liberté du Travail* (1845; the substance of the first volume had appeared under a different title in 1825), honorably known for his integrity and independence under the régime of the Restoration.

At this point it will be convenient to turn aside and notice the doctrines of the American economist Carey. Not much had been done before him in the science by citizens of the United States. Benjamin Franklin, otherwise of world-wide fame, was author of a number of tracts, in most of which he merely enforces practical lessons of industry and thrift, but in some throws out interesting theoretic ideas. Thus, fifty years before Smith, he suggested (as Petty, however, had already done) human labor as the true measure of value (*Modest Inquiry into the Nature and Necessity of a Paper Currency*, 1721), and in his *Observations Concerning the Increase of Mankind* (1751) he expresses views akin to those of Malthus. Alexander Hamilton, secretary of the treasury, in 1791 presented in his official capacity to the House of Representatives of the United States a report on the measures by which home manufactures could be promoted. In this document he gives a critical account of the theory of the subject, represents Smith's system of free trade as possible in practice only if adopted by all nations simultaneously, ascribes to manufactures a greater productiveness than to agriculture, and seeks to refute the objections against the development of the former in America, founded on the want of capital, the high rate of wages, and the low price of land. The conclusion at which he arrives is, that for the creation of American manufactures a system of moderate protective duties was necessary, and he proceeds to describe the particular features of such a system. There is some reason to believe that the German economist List, was influenced by Hamilton's work, having, during his exile from his native country, resided in the United States, where he doubtless became acquainted with Hamilton's writings.

Henry Charles Carey (1793–1879), son of an American citizen who had emigrated from Ireland, represents a reaction against the dispiriting character which the Smithian doctrines had assumed in the hands of Malthus and Ricardo. His aim was, while adhering to the individualistic economy, to place it on a higher and surer basis, and fortify it against the assaults of socialism, to which some of the Ricardian tenets had exposed it. The most comprehensive as well as mature exposition of his views is contained in his *Principles of Social Science* (1859). Inspired with the optimistic sentiment natural to a young and rising nation with abundant undeveloped resources and an unbounded outlook toward the future, he seeks to show that there exists, independently of human wills, a natural system of economic laws, which is essentially beneficent, and of which the increasing prosperity of the whole community, and especially of the working classes, is the spontaneous result—capable of being defeated only by the ignorance or perversity of man resisting or impeding its action. He rejects the Malthusian doctrine of population, maintaining that numbers regulate themselves sufficiently in every well governed society, and that their pressure on subsistence characterizes the lower, not the more advanced, stages of civilization. He rightly denies the universal truth, for all stages of cultivation, of the law of diminishing returns from land. His fundamental theoretic position relates to the antithesis of wealth and value.

Frédéric Bastiat (1801–1850), though not a profound thinker, was a brilliant and popular writer on economic questions. Though he always had an inclination for such studies, he was first impelled to the active propagation of his views by his earnest sympathy with the English anti-corn law agitation. Naturally of an ardent temperament, he threw himself with zeal into the free-trade controversy, through which he hoped to influence French economic policy, and published in 1845 a history of the struggle under the title of *Cobden et la Ligue*. In 1845–48 appeared his *Sophismes Économiques* (Eng. trans. by P. J. Stirling, 1873), in which he exhibited his best qualities of mind.

Bastiat is weak on the philosophical side; he is filled with the ideas of theological teleology, and is led by these ideas to form *a priori* opinions of what existing facts and laws must necessarily be. And the *jus nature*, which, like metaphysical ideas generally, has its root in theology, is as much a postulate with him as with the physiocrats.

Augustin Cournot (1801–1877), appears to have been the first (the German, H. H. Gossen, praised by Jevons, wrote in 1854), who, with a competent knowledge of both subjects, endeavored to apply mathematics to the treatment of economic questions. His treatise entitled *Recherches sur les Principes Mathématiques de la Théorie des Richesses* was published in 1838. He mentions in it only one previous enterprise of the same kind (though there had in fact been others)—that, namely, of Nicolas François Canard, whose book, published in 1802, was crowned by the Institute, though “its principles were radically false as well as erroneously applied.” Notwithstanding Cournot's just reputation as a writer on mathematics, the *Recherches* made little impression.

The first Italian translation of the *Wealth of Nations* appeared in 1780. The most distinguished Italian economist of the period here dealt with was, however, no disciple of Smith. This was Melchiorre Gioja, author, besides statistical and other writings, of a voluminous work entitled *Nuovo Prospetto delle Scienze Economiche* (6 vols., 1815–17; the work was never completed), intended to be an encyclopædia of all that had been taught by theorists, enacted by governments, or effected by populations in the field of public and private economy. We can but very briefly notice Bomagnosi (d. 1835), who, by his contributions to periodical literature, and by his personal teaching, greatly influenced the course of economic thought in Italy; Antonio Scialoja (*Principii d'Economia Sociale*, 1840; and *Carestia e Governo*, 1853), an able advocate of free trade (d. 1877); Luigi Cibrario, well known as the author of *Economia Politica del medio evo* (1839; 5th ed. 1861; French trans. by Barneaud, 1859), which is in fact a view of the whole social system of that period; Girolamo Boccardo (b. 1829; *Trattato Teorico-pratico di Economia politica*, 1853); the brilliant controversialist Francesco Ferrara, professor at Turin from 1849 to 1858 (in whose school most of the present Italian teachers of the science were, directly or indirectly, educated), a partisan of the *laissez faire* doctrine in its most extreme form, and an advocate of the peculiar opinions of Carey and Bastiat on the subject of rent; and, lastly, the Neapolitan minister Ludovico Bianchini (*Principii della Scienza del Ben Vivere Sociale*, 1845 and 1855), who is remarkable as having followed in some degree an historical direction, and asserted the principle of relativity, and who also dwelt on the relations of economics to morals, by a due attention to which the Italian economists have, indeed, in general been honorably distinguished.

The *Wealth of Nations* was translated into Spanish

by Ortiz in 1794. It may perhaps have influenced Gaspar de Jovellanos, who in 1795 presented to the council of Castile and printed in the same year his celebrated *Informe de la Sociedad Economica de Madrid en expediente de Ley Agraria*, which was a powerful plea for reform, especially in taxation and the laws affecting agriculture, including those relating to the systems of entail and mortmain. An English version of this memoir is given in the translation (1809) of Laborde's *Spain*. vol. iv.

Roscher observes that Smith did not at first produce much impression in Germany. He does not appear to have been known to Frederick the Great; he certainly exercised no influence on him. Nor did Joseph II. take notice of his work. And of the minor German princes, Karl Friedrich of Baden, as a physiocrat, would not be accessible to his doctrines. It was otherwise in the generation whose principal activity belongs to the first decade of the nineteenth century. The Prussian statesmen who were grouped round Stein had been formed as economists by Smith, as had also Gentz, intellectually the most important man of the Metternich régime in Austria.

The highest form of the Smithian doctrine in Germany is represented by four distinguished names:—Karl Heinrich Rau (1792–1870), Friedrich Nebenius (1784–1857), Friedrich Benedict Wilhelm Hermann (1795–1868), and Johann Heinrich von Thünen (1783–1850.)

#### THE HISTORICAL SCHOOL.

The negative movement which filled the eighteenth century had for its watchword on the economic side the liberation of industrial effort from both feudal survivals and governmental fetters. But in all the aspects of that movement, the economic as well as the rest, the process of demolition was historically only the necessary preliminary condition of a total renovation, toward which western Europe was energetically tending, though with but an indistinct conception of its precise nature. The disorganization of the body of opinion which underlay the old system outran the progress toward the establishment of new principles adequate to form a guidance in the future. The critical philosophy which had wrought the disorganization could only repeat its formulas of absolute liberty, but was powerless for reconstruction. And hence there was seen throughout the West, after the French explosion, the remarkable spectacle of a continuous oscillation between the tendency to recur to outworn ideas and a vague impulse toward a new order in social thought and life, this impulse often taking an anarchical character.

From this state of oscillation, which has given to our century its equivocal and transitional aspect, the only possible issue was in the foundation of a scientific social doctrine which should supply a basis for the gradual convergence of opinion on human questions. The foundation of such a doctrine is the immortal service for which the world is indebted to Auguste Comte.

The leading features of sociology, as he conceived it, are the following: (1) it is essentially *one* science, in which all the elements of a social state are studied in their relations and mutual actions; (2) it includes a dynamical as well as a statical theory of society; (3) it thus eliminates the absolute, substituting for an imagined fixity the conception of ordered change; (4) its principal method, though others are not excluded, is that of historical comparison; (5) it is pervaded by moral ideas, by notions of social duty, as opposed to the individual rights which were derived as corollaries

from the *jus naturæ*; and (6) in its spirit and practical consequences it tends to the realization of all the great ends which compose "the popular cause"; yet (7) it aims at this through peaceful means, replacing revolution by evolution.

Omitting preparatory indications and undeveloped germs of doctrine, we must trace the origin of the school to Wilhelm Roscher.

Among the earlier writers of the school is Bruno Hildebrand, who, in 1848, published the first volume of a work, which, though he lived for many years after, he never continued, entitled *Die National-ökonomie der Geyenwart und Zukunft*. In 1853 appeared the work of Karl Knies, entitled *Die Politische Oekonomie vom Standpunkte der geschichtlichen Methode*.

The historical method has exhibited its essential features more fully in the hands of the younger generation of scientific economists in Germany, among whom may be reckoned Lujo Prentano, Adolf Held, Erwin Nasse, Gustav Schmoller, H. Rösler, Albert Schäffle, Hans von Scheel, Gustav Schönberg, and Adolf Wagner.

It is to be regretted that very little is known in America of the writings of the recent Italian economists. Luigi Cossa's *Guida*, which was translated at the suggestion of Jevons, has given us some notion of the character and importance of their labors. In America some notoriety has attached to the economic movement advocated by Henry George, a serious disturbance occurring in the Catholic Church on account of the advocacy of his opinions by a priest. (See HENRY GEORGE, vol. X.)

In France the historical school has not made so strong an impression—partly, no doubt, because the extreme doctrines of the Ricardian system never obtained much hold there. In England too, the dualism which exists on the Continent has been established; and there is reason to expect that here more speedily and decisively than in France or Italy the historical school will displace its antagonist. It is certainly in England next after Germany that the preaching of the new views has been most vigorously and effectively begun.

POLK, JAMES KNOX, eleventh president of the United States was of Scoto-Irish descent, his ancestors, whose name was Pollok, having emigrated from Ireland in the eighteenth century. He was the eldest of ten children, and was born November 2, 1795, in Mecklenburg county, N. C., from which his father, who was a farmer, removed in 1806 to the valley of the Duck river, Tennessee. At an early age he was placed in a merchant's office, but as he showed a disinclination for business his father at last permitted him to begin preparatory studies for the university. In 1815 he entered the university of North Carolina, where in 1818 he graduated with the highest honors. Called to the bar in 1820, he speedily made for himself a high reputation, and in 1823 he entered the State legislature. In August, 1825, he was chosen to represent his district in Congress, to which he was reelected every succeeding two years until 1839. As a strong supporter of Democratic opinions he identified himself with every important discussion, and, though he was not a brilliant speaker, his solid abilities, extraordinary energy, and indomitable will soon gave him a place in the front rank of politicians. In 1835 he was chosen speaker of the House of Representatives, to which he was reelected in 1837, and in 1839 he was elected governor of Tennessee. In 1844 he was the Democratic candidate for the presidency, and was chosen over Clay by a majority of sixty-five electoral votes. The election in great measure turned on the annexation of Texas, which was effected before his in-

auguration. One of the earliest questions with which his administration had to deal was the boundary of Oregon, which, although he had previously declared the title of the United States to Oregon to be "clear and undisputed," was finally fixed at the parallel of 49° instead of 54° 40.' Following the annexation of Texas came the Mexican war, resulting in the treaty of Guadalupe Hidalgo, February 2, 1848, by which New Mexico and California were ceded to the United States. Other important measures of his administration were the admission of Iowa and Wisconsin to the Union, the adoption of a low tariff in 1846, the organization of the department of the interior, and the adoption of the method of collecting government revenues by specie without the aid of the banks. Polk retired from office March 4, 1849, and died in Nashville, June 15th of the same year.

POLLACK (*Gadus pollachius*), a species of cod-fish, abundant on rocky coasts of northern Europe, and extending as far south as the western parts of the Mediterranean, where, however, it is much scarcer and does not attain to the same size as in its real northern home. In Scotland and some parts of Ireland it is called *Lythe*. It is distinguished from other species of the genus *Gadus* by its long pointed snout, which is twice as long as the eye, with projecting lower jaw, and without a barbel at the chin. The three dorsal fins are composed of respectively twelve, eighteen or twenty, and from seventeen to nineteen rays, and the two anal fins of thirty-one and nineteen or twenty. A black spot above the base of the pectoral fin is another distinguishing mark.

POLLAN (*Coregonus pollan*), a species of the Salmonoid genus *Coregonus* which has been found in the large and deep loughs of Ireland only.

POLLIO, CAIUS ASINIUS, a Roman orator, poet, and historian, who played a conspicuous part in the troubled history of his time, was born in 76 B.C., and died in his villa at Tusculum in 4 A.D.

PÖLLNITZ, KARL LUDWIG, FREIHERR VON, known as a writer of memoirs, was born on February 25, 1692. He was repeatedly converted to Catholicism and re-converted to the Reformed faith; but he died a Catholic on June 23, 1775.

POLLOK, ROBERT, was the author of *The Course of Time*, a poem that has passed through many editions, and is still a favorite in serious households in Scotland. He was born in 1798 at Moorhouse, in the parish of Eaglesham in Renfrewshire, took his degree at Glasgow, and died in 1827.

POLLOKSHAWS, a burgh of barony in Renfrewshire, Scotland, situated near the White Cart, on the Glasgow and Kilmarnock Railway, two and one-half miles south-by-west of Glasgow, of which it is now reckoned a suburb, connected by tramway. The staple industries are cotton-spinning, hand and power-loom weaving of silk and cotton fabrics, dyeing, bleaching, and calico-printing. There are also paper works, potteries, and large engineering works. Population in 1871, 8,921; in 1881, 9,363; and estimated 11,500 in 1890.

POLLUX. See CASTOR AND POLLUX.

POLLUX, JULIUS, of Naucratis in Egypt, a Greek sophist of the second century. He taught at Athens, where, according to Philostratus, he was appointed to the professorship by the emperor Commodus on account of his melodious voice. He died at the age of fifty-eight, leaving a son behind him.

POLO. This game, which is a species of "hockey on horseback," is of Eastern origin, and seems to have been a favorite pastime in Persia, Tartary, and the frontiers of India from prehistoric times.

The English name of the game is perhaps derived from "pulu," which is the Tibetan for a ball, and the

pastime itself reached India from Persia through Afghanistan. It speedily gained favor with the officers of British cavalry regiments quartered in India, and was introduced into the United Kingdom in 1871, and into the United States about the same time.

POLO, MARCO, the Venetian, the most famous perhaps of all travelers.

Venetian genealogies and traditions of uncertain value trace the Polo family to Sebennico in Dalmatia, and before the end of the eleventh century names of its members are found in the Great Council of the Republic.

Andrea Polo, of S. Felice, was the father of three sons, Marco, Nicolo and Maffeo, of whom the second was the father of the subject of this article.

In 1260 we find Nicolo and Maffeo at Constantinople. In the year named the two brothers went on a speculation to the Crimea, whence a succession of chances and openings carried them to the court of Barka Khan at Sarai, and further north, and eventually across the steppes to Bokhara. Here they fell in with certain envoys who had been on a mission from the Great Khan Kublai to his brother Hulagu in Persia, and by them were persuaded to make the journey to Cathay in their company. It was the first time that the khan, a man of full energy and intelligence, had fallen in with European gentlemen. He was delighted with the Venetian brothers, listened eagerly to all that they had to tell of the Latin world, and decided to send them back as his envoys to the pope, with letters requesting the dispatch of a large body of educated men to instruct his people in Christianity and in the liberal arts.

The brothers arrived at Acre in April, 1269. They learned that Clement IV. had died the year before, and no new pope had yet been chosen. So they went home to Venice, where they found that Nicolo's wife was dead, but had left a son Marco, now a fine lad of fifteen. The papal interregnum was the longest that had been known, at least since the dark ages. After the Polos had spent two years at home there was still no pope; and the brothers resolved on starting again for the East, taking young Mark with them.

The second start from Acre must have taken place about November, 1271; and from a careful consideration of the indications and succession of chapters in Marco Polo's book, it would seem that the party proceeded from Ayas to Sivas, and then by Mardin, Mosul, and Bagdad to Hormuz at the mouth of the Persian Gulf (see ORMUS), with the purpose of going on to China by sea; but that, some obstacle having interfered which compelled them to abandon this plan, they returned northward through Persia.

The Venetians, in their further journey, were met and welcomed by the Great Khan's people, and at last reached his presence at Shangtu, in the spring of 1275. Kublai received them with great cordiality, and took kindly to young Mark, by this time about twenty-one years of age. The "young bachelor," as the book calls him, applied himself diligently to the acquisition of divers languages and written characters chiefly in use among the multifarious nationalities included in the khan's court and administration; and Kublai, seeing that he was both clever and discreet, soon began to employ him in the public service.

His first public mission was one which carried him through the provinces of Shansi, Shensi, and Szechuen, and the wild country on the coast of Tibet, to the remote province of Yunnan, called by the Mongols *Karajang*, and into northern Burmah (Mien), a country which twenty years ago was an almost *terra incognita*. Marco rose rapidly in favor, and was often again employed on distant missions, as well as in domestic administration;

but we are able to gather but few details of his employment.

Some years pass ere we hear more of Marco Polo; and it is then in a militant capacity.

Jealousies, always too characteristic of Italian communities, were in the case of Venice and Genoa sharpened by direct commercial rivalry. In 1298 the Genoese made preparations to strike a blow at their rivals on their own ground, and a powerful fleet of galleys, under Lamba Doria as admiral, made straight for the Adriatic. Venice, on hearing of the Genoese armament, hastily equipped a fleet still more numerous, and placed it under the command of Andrea Dandolo. The crew of a Venetian galley at this time amounted, all told, to 250 men, under a *comito* or master, but besides this officer each galley carried a *sopracomito* or gentleman commander, who was usually a noble. On one of the galleys of Dandolo's fleet went Marco Polo in this last capacity.

The hostile fleets met before the island of Curzola on September 6th, and engaged next morning. The battle ended in a complete victory to Genoa. Sixty-six Venetian galleys were burnt in the Bay of Curzola, and eighteen were carried to Genoa, with 7,000 prisoners, one of whom was Marco Polo. The captivity of less than a year's duration was memorable as being the means of bringing about the record of his remarkable experiences in the east. Up to this time he had doubtless often related his stories of Cathay among his friends; and from these stories indeed, and the frequent employment in them of a numerical expression unfamiliar in those days, he had acquired the nickname of *Marco Millioni*. Yet it would seem that he had committed nothing to writing, but, in the prison of Genoa, Marco Polo fell in with a certain person of writing propensities, Rusticiano or Rustichello of Pisa, who was also a captive of the Genoese. He it was, apparently, who persuaded Marco Polo to defer no longer the committal to paper of his wonderful experiences. In any case it was he who wrote down these experiences at Marco's dictation; and he is the man therefore to whom we owe the existence of this record, and possibly the preservation even of the traveler's name and memory.

We learn but little of Marco Polo's personal or family history after this captivity. On January 9, 1324, the traveller, now in his seventieth year, and sinking day by day under bodily infirmity, sent for a neighboring priest and notary to make his testament. We do not know the exact time of his death, but it fell almost certainly within the year 1324, for we know from a scanty series of documents, commencing in June, 1325, that he had at the latter date been some time dead. He was buried in accordance with his will, in the church of St. Lorenzo, where the family burying-place was marked by a sarcophagus, erected by his filial care for his father Nicolo, which existed till near the end of the sixteenth century. On the renewal of the church in 1592 this seems to have been cast aside and lost.

The copious archives of Venice have yielded up a few traces of our traveler. Besides his own will just alluded to, there are in the library the wills of his uncle Marco and of his younger brother Maffeo; a few legal documents connected with the house property in St. John Chrysostom, and other papers of similar character; and two or three entries in the record of the *Maggior Consiglio*. We have mentioned the sobriquet of Marco Millioni which he got from his young townsmen. It is alleged that long after the traveler's death there was always in the Venetian masques one individual who assumed the character of Marco Millioni, and told Munchausen-like stories to divert the vulgar. Such, if this be true, was the honor of our great man in his own country.

No genuine portrait of Marco Polo exists. There is a medallion portrait on the wall of the Sala dello Scudo in the ducal palace, which has become a kind of type; but it is a work of imagination no older than 1761. The oldest professed portrait is one in the gallery of Monsignor Badia at Rome. The Europeans at Canton have attached the name of Marco Polo to a figure in a Buddhist temple there containing a gallery of "Arhans" or Buddhist saints, and popularly known as the "temple of the five hundred gods." There is a copy of this at Venice, which the Venetian municipality obtained on the occasion of the Geographical Congress there in 1881. But the whole notion was a groundless fancy.

POLOTSK, a district town of the government of Vitebsk, at the confluence of the Polota with the Dwina (Düna), five miles from the Smolensk and Riga Railway, is one of the oldest towns in Russia. The town is now of trifling importance, and the population, 12,200 in 1880, has since decreased. Upward of two-thirds of the inhabitants are Jews; the remainder have belonged mostly to the Greek Church since 1839.

POLTAVA, a government of southwestern Russia, bounded by Tchernigoff on the north, Kharkoff on the east, Ekaterinoslaff and Kherson on the south, and Kieff on the west, and having an area of 19,265 square miles.

POLTAVA, capital of the above government, stands on the right bank of the Vorskla, eighty-eight miles by rail to the south-southwest of Kharkoff. There are two lyceums for boys and girls, a "realschule," a military school for cadets, a theological seminary, and two girls' colleges, besides Russian, German, and Jewish primary schools. The manufactures are insignificant; the principal are tobacco works (\$135,000), and a tannery (\$70,000). In 1889 the population was 41,050.

POLYÆNUS, a Macedonian, lived at Rome as a rhetorician and pleader in the second century. When the Parthian war (162-165 A.D.) broke out, Polyænus, too old to share in the campaign, dedicated to the emperors Marcus Antoninus and Lucius Verus a work, still extant, called *Strategica* or *Strategemata*, an historical collection of stratagems and maxims of strategy written in Greek and strung together in the form of anecdotes. His works on Macedonia, on Thebes, and on tactics (if indeed this be not identical with the *Strategica*) are lost.

POLYANTHUS. See PRIMROSE.

POLYBIUS, the historian, was a native of Megalopolis in Arcadia, the youngest of Greek cities, but one which played an honorable part in the last days of Greek freedom as a staunch member of the Achæan league. He died at the age of eighty-two. We may therefore follow the majority of authorities in placing his birth between 214 and 204 B.C. Little is known of his early life. As the son of Lycortas he was naturally brought into close contact with the leading men of the Achæan league. With the foremost of them, Philopœmen, he seems to have been on intimate terms, and after Philopœmen's tragic death in Messenia (182), he was intrusted with the honorable duty of conveying home the urn in which his ashes had been deposited. The next year (181), witnessed his first entry into political life. The next twelve years of his life are a blank, but in 169 he reappears as a trusted adviser of the Achæans at a difficult crisis in the history of the league. In 171 war had broken out between Rome and the Macedonian king Perseus. The final defeat of Perseus was rapidly followed by the arrival in Achaia of Roman commissioners charged with the duty of securely establishing Roman interests there. As a result of their proceedings 1,000 of the principal Achæans were arrested and carried off

to Italy. Polybius was among the number, but, while his companions were condemned to a tedious incarceration in the country towns of Italy, he obtained permission to reside in Rome.

In 151, after seventeen years of banishment, the few surviving exiles were allowed to return to Greece. But the stay of Polybius in Achaia was brief. For when, in 147, Scipio himself took the command in Africa, Polybius hastened to join him, and was an eye-witness of the siege and destruction of Carthage. He returned in 146 to find Corinth in ruins, the fairest cities of Achaia at the mercy of the Roman soldiery, and the famous Achæan league shattered to pieces. All the influence he possessed was freely spent in endeavoring to shield his countrymen from the worst consequences of their rashness. The excesses of the soldiery were checked, and at his special intercession the statues of Aratus and Philopœmen were preserved. An even more difficult task was that intruded to him by the Roman authorities themselves, of persuading the Achæans to acquiesce in the new régime imposed upon them by their conquerors, and of setting the new machinery in working order. With this work, which he accomplished so as to earn the heartfelt gratitude of his countrymen, his public career seems to have closed.

**POLYCARP.** The importance of Polycarp, bishop of Smyrna, for the earliest period of church history arises from his historical position. He was on the one hand a disciple of John and other apostles and disciples of Jesus; on the other hand he was the teacher of Irenæus, the first of the catholic fathers. The chief facts to be gathered about the life of Polycarp are these. He must have been born before the year 69, for on the day of his death he declared that he had served the Lord for eighty-six years. He became a Christian in his earliest youth, and was an associate of the apostle John and other disciples of Jesus who had come from Palestine to Asia Minor. What he heard from them he kept in lifelong remembrance, and in his manhood and old age he used to gather the young people round him, and repeat to them what he had learned from those who had seen Christ in the flesh. Among these youthful hearers was Irenæus, who has recorded much of what he thus learned.

In early life Polycarp became the head of the Church of Smyrna, where he was held in the highest respect. The congregation looked up to him as an apostolic and prophetic teacher, and consequently as combining in himself all the spiritual gifts which God had conferred on Christendom. How great his reputation was is best shown by the fury of the heathen and the Jews in his martyrdom. But his reputation extended far beyond the limits of his own diocese. His letter to the church at Philippi shows us how fully his apostolic spirit, his wisdom and justice, must have been recognized even in Macedonia. It is one of the interesting incidents in the church history of the second century that Polycarp, in the year before his death, when he was above ninety years of age undertook the journey to Rome in order to visit the bishop Anicetus. On his return to Smyrna he enjoyed only about six months of uninterrupted activity. Then, on the occasion of the festive games, there arose, as in so many other instances, an outburst of popular feeling against the Christians, in which Polycarp was to die a martyr's death. The proconsul was anxious to save him, and tried to induce him to recant, but he remained steadfast. He was delivered up to the populace, and his body was burned. By his death Polycarp shielded his congregation from further persecution.

**POLYCLETUS.** Two Greek sculptors bore this name. For the most part the younger Polycletus con-

finied himself to statues of athletes who had won prizes at Olympia. In recent excavations there two bases of statues by him have been found, but no remains of his work. We may assign him to about the date 371 B.C.

**POLYCRATES,** a celebrated Greek tyrant of Samos, was the son of Æaces. After distinguishing himself by his liberality toward his poorer fellow-citizens he took advantage of a festival to Hera in order to make himself master of Samos, (537 or 536 B.C.) Allied with Amasis, king of Egypt, he prospered greatly, so that his fame went forth through all Greece and Ionia. He had 100 ships and 1,000 bowmen. He made war indiscriminately on friend and foe, declaring with grim humor that he gratified his friends more by returning to them their own than by not taking it at all. His great public works were executed, according to Aristotle, for the purpose of employing his subjects and diverting their thoughts from the recovery of their freedom. The splendor of his palace is attested by the design which many centuries later the emperor Caligula formed of rebuilding it. Polycrates was also a patron of letters; he collected a library and lived on terms of intimate friendship with the poet Anacreon, whose verses were full of references to his patron. When the Persians under King Cambyses were preparing to invade Egypt, Polycrates, anxious to conciliate the growing power of Persia, sent forty ships to their help, (525 B.C.) But the squadron had hardly reached the island of Carpathus when the crew mutinied and turned the ships' heads back to Samos. Not very long afterward Oroëtes, the Persian satrap of Sardes, by working on the avarice and ambition of Polycrates, lured him to Magnesia and put him to a shameful death, (522 B.C.)

**POLYGLOT.** A polyglot is a book which contains side by side versions of the same text in several different languages; and the most important polyglots are editions of the Bible, or its parts, in which the Hebrew and Greek originals are exhibited along with the great historical versions, which are of value for the history of the text and its interpretation.

**POLYGNOTUS,** a Greek painter of whom very little is known. He was born at Thasus, and son of the painter Aglaophon. His works included paintings at Athens, Delphi, etc. He died about 476 B.C.

**POLYHISTOR, CORNELIUS ALEXANDER,** a Milesian and disciple of Crates, who through the fortune of war became the slave and afterward the freedman of Cornelius Lentulus. He received the Roman citizenship from Sulla, and wrote books on historical and geographical subjects, of which more than a hundred and fifty fragments have been collected. The most interesting refer to the history of the Jews, for which Alexander drew on historical and poetical works of Jewish and Samaritan Hellenists. The date of his death is uncertain.

**POLYNESIA.** Polynesia has been used to denote all the intertropical islands of the Pacific Ocean eastward of the Philippine Islands to the north and the New Hebrides to the south of the equator. The New Hebrides and other islands west of that group were included under the term Australasia. Of late years these islands (sometimes also including Fiji) have been known as Melanesia, while the western islands of the North Pacific have been known as Micronesia. Thus Polynesia has been restricted to the central and eastern islands inhabited by the brown or Sawaiori race, becoming an ethnographic rather than a geographical term. Articles dealing with the western islands north and south of the equator will be found under MICRONESIA and MELANESIA. The western boundary of this region runs from the great barrier reef of Australia eastward of New Guinea and the Philippine Islands.

All the intertropical islands of the Pacific eastward of this imaginary line are included, and also a few others which extend outside the tropic of Capricorn to nearly 30° S. latitude. Any other divisions for geographical purposes, except those of groups of islands, appear to be unnatural and uncalled for. For ethnographical purposes special terms are used for the three different classes of people found in this wide area.

If we exclude NEW CALEDONIA (*q.v.*), which is of older formation than the rest, all the islands of Polynesia are either of volcanic or of coral formation. The volcanic islands, with the exception of the Hawaiian archipelago, are all south of the equator. Within the volcanic region there are a few coral islands, but these are all more or less elevated. The soil in the volcanic islands is generally very fertile. The climate is hot and moist in most of them; consequently the vegetation is wonderfully rich. The islands are densely clothed with luxuriant verdure from the sea-beach to the summits of the mountains. In addition to several species of palms, beautiful ferns, dracænas, crotons, and other elegant foliage plants abound. Pines are found on some of the western islands. For flowers none of them will compare with the hedgerows and meadows of England. There are, it is true, many beautiful and sweet-scented flowers, but they are not usually found in great profusion.

Fruits are abundant. Some of the indigenous kinds are good, and many of the best productions of other tropical countries have been introduced and flourish. Oranges are plentiful in many islands; also pine-apples, guavas, custard apples, and bananas. The mango has been introduced into some islands, and flourishes well. Most of these fruits have been introduced by missionaries. One of the fruits most abundantly used, both in a ripe state and cooked when unripe as a vegetable, is the Chinese banana, *Musa Cavendishii*.

The natives live chiefly upon vegetable food. In most of the volcanic islands the taro is the most important food-producer. Next to this comes the yam. Probably next in importance to this are the plantains and bananas, then the bread-fruit and arrow-root. The bread-fruit is more or less plentiful in most of the volcanic islands, and during one season of the year the natives very largely subsist upon it. It is not, however, by any means so nutritious as the taro or the yam. Although the raw cocoa-nut is not eaten to any considerable extent by the natives of volcanic islands, this must not be omitted in an enumeration of the principal articles of their food supply, for it enters into the composition of most of their made dishes in the form of expressed juice or oil; the soft, half-grown kernel is used as a kind of dessert, and the liquid from it, when the kernel is only half developed, is one of their principal beverages. The *Ava*, or *Kava*, a narcotic drink largely used, is made from the root of a pepper. In some islands the cocoa-nut is the chief article of commerce. The fully-grown kernel is cut into slices, dried in the sun, and sold as "cobra," from which much of the palm oil of commerce is expressed. On many islands cotton is largely grown, and on a few, especially in the Hawaiian archipelago, sugar cultivation has made considerable progress. Many other vegetable products might be utilized if there were a demand for them. The candle-nut is abundant everywhere near the coast. Coffee has not been grown to any considerable extent. Wild ginger and wild nutmegs are abundant on some of the islands. In some places indigo has been introduced, and has spread so much as to become a nuisance. But the probability is that, on these hot, moist, and fertile islands, cocoa-nuts, cotton, or sugar will always be the most profitable crops to cultivate for exportation.

The indigenous fauna of Polynesia is poor in mammals but rich in birds. Some say pigs are indigenous, but they were doubtless introduced by early navigators. Horses and cattle have been introduced. They degenerate very rapidly, unless they are continually improved by newly-imported stock. Sheep and goats are introduced into some islands, but sheep do not usually thrive. Dogs are plentiful. Pigeons and doves, especially the fruit-eating pigeons and doves, are abundant. The *Carpophaga* furnish a very important article of food in some of the islands. Some of the species of *Ptilonopus* are exceedingly beautiful. Certain non-venomous snakes are found in many of the islands. Insect life is abundant, and some of the butterflies are very beautiful.

The lagoons formed by the coral reefs around the islands invariably abound in fish, many of them most gorgeous in their coloring—vying in this respect with the parrots of Australia. Fish form a very important part of the food supply.

One of the most wonderful creatures in the marine fauna of Polynesia is the palolo (*Palola viridis*), an annelid which appears upon the surface of the ocean, near the edge of the coral reef, at certain seasons of the year. The palolo are from nine to eighteen inches long, and about one-eighth of an inch thick. They are eaten by the natives, and are esteemed a great delicacy. They live in the interstices of the coral reef, and are confined to a few localities.

The atolls differ in almost every respect from the islands of volcanic origin. Little that is said of one class would be true of the other. These coral islands are all low, generally not more than ten or twelve feet above the high-water mark. They are simply sand-banks formed by the accumulation of debris washed onto the reefs during strong winds.

The vegetation of the atolls is extremely poor, not more than about fifty species of plants being found in Tokelau, Ellice and Gilbert groups, in all of which groups collections have been made. The cocoa-nut is abundant on most of these islands. Indeed, that, with fish and the fruit of the screw-pine (*Pandanus*), constitutes the main food supply on some atolls.

The fauna of the atolls consists mainly of a few birds, some lizards and insects. Fish abound about the reefs, and most of the natives are deep-sea fishermen. In the Ellice Islands the people domesticate frigate birds.

There are comparatively few of the elevated coral islands in Polynesia, but they are so distinct from both the atolls and the volcanic islands that they need a separate description. They all lie within or near the lines marking off the volcanic ridge upon the map. South of the volcanic ridge there are many coral reefs forming shoals. The elevated coral islands doubtless were once such reefs. Lying within the area of volcanic action, they have participated in the upward movement, and have been raised from shoals to become islands. Some have evidently been lifted by successive stages and apparently by sudden movements. None of the islands can be compared with the volcanic islands for fertility, all having a less rich soil and being much drier; still they are fairly fertile. They suffer sometimes from drought, but are much less seriously affected in this way than the atolls.

The flora of the elevated coral islands is less rich than that of the volcanic islands, but much richer than that of the atolls.

The climate of the islands varies considerably. Some, especially the elevated coral islands, are very healthy for tropical regions. Speaking generally, the average reading of the thermometer over a large extent of Polynesia is about 80° Fahr. It very seldom sinks lower than 60°, and, owing to the small size of most of the islands, and

the prevalence of trade-winds during the greater portion of the year, the heat is always moderated and rarely becomes intense.

A great portion of southern Polynesia is subject to destructive cyclones. The tract over which they pass may be said to be, generally, that of the volcanic chain indicated by the lines on the map, although the northern edge of this region is not so subject to cyclones as the southern portion. The hurricane season is from December to April. Some islands are visited by a more or less destructive cyclone nearly every year; Samoa lies on the upper edge of the tract, and gets one, on an average, about every seven or eight years. The cyclones are always accompanied by considerable electric disturbances, especially when they are passing away. Apart from the fever, ague, and dysentery, there is comparatively little disease in any portion of Polynesia. The principal purely native diseases are such as affect the skin. A form of elephantiasis prevails more or less on all the damp mountainous islands. Many Europeans are subject to it, especially those who are much exposed to the sun by day and the dews by night.

There are in Polynesia people who belong to both the dark and the light sections of the Indo-Pacific races. At present the dark are found only in the western islands as far as Fiji. The whole of eastern Polynesia is inhabited by a light brown people to whom the name Sawaióri is here given. They extend out of Polynesia to New Zealand. The third kind of people, called Tarapon, inhabit the northern portion of western Polynesia, the islands generally known as Micronesia.

Papuans is the name used by the Malays of the Indian Archipelago for the black, frizzly-haired people found in the Aru Islands and New Guinea. That the inhabitants of the western portion of Polynesia ought to be classed with these Papuans there can be no doubt. The older name is therefore adopted here to include the whole, rather than the newer and less distinctive name Melanesian, which has been applied to only a part of the race. For further details the reader is referred to the articles MELANESIA, NEW GUINEA, etc. In speaking of the affinities of the Papuans with other peoples much caution is required; but there is some reason for thinking they may be remotely classified, together with all the other black people of the southern hemisphere, with the tribes of South America. (See NEGRO.)

The Sawaioris or brown people who occupy the islands of eastern Polynesia are generally regarded as having affinities with the Malays of the Indian Archipelago, and are sometimes spoken of as a branch of the Malay race, or family. They cannot, however, with any accuracy be so described. The Malays, as they now exist, are a comparatively modern people, who have become what they are by the mixture of several elements not found in the more primitive race. The Sawaioris and the Tarapons of Polynesia, the Malagasy (Hovas) of Madagascar, and the Malays are allied races, but no one of them can be regarded as the parent of the rest. The parent race has disappeared; but the Sawaióri, as the earliest offshoot from it, and one which, owing to the conditions under which it has lived, has remained almost free from admixture of blood, may be taken as most nearly representing what the parent was.

The Sawaioris are, physically, a very fine race. On some islands they average five feet ten inches in height. They are well developed in proportion to their height. Their color is a brown, lighter or darker generally according to the amount of their exposure to the sun—being darker on some of the atolls, where the people spend much time in fishing, and among fishermen on the volcanic islands, and lighter among women, chiefs, and others less exposed than the bulk of the people.

Their hair is black and straight; but in individual examples it is sometimes wavy, or shows a tendency to curl. They have very little beard. Their features are generally fairly regular; eyes invariably black, and in some persons oblique; jaws not projecting, except in a few instances; lips of medium thickness; noses generally short but rather wide at the bases. The foreheads are fairly high, but rather narrow.

The terms for family among this race are used in two senses—(1) of a household, and (2) of all blood relations on both the male and the female side, including the wife or the husband, as the case may be, brought in by marriage—also those who have been adopted by members of the clan.

Property belonging to a clan is held in common. Each clan usually possesses land, and over this no one member has an exclusive right, but all have an equal right to use it. The chief or recognized head of the clan or section alone can properly dispose of it or assign its use for a time to an outsider; and even he is expected to obtain the consent of the heads of families before he alienates the property. Changes have been made in many islands in this respect; but there can be little reason to doubt that the joint ownership of property in clans was common among the entire race in former times.

The amusements of these people are numerous; throwing the javelin, throwing at a mark with slings, and archery are practiced. Some resort to cock-fighting. There are fishing matches; and at a particular season large companies used to resort to pigeon-catching. In their houses they have a number of games. Betting is very often carried on in connection with these. Much time is spent, especially after the evening meal, in asking riddles, in rhyming, etc. The recital of songs and myths is also a source of great amusement; and on special occasions there is dancing. The night dances were generally accompanied by much indecency and immorality, and for that reason were discountenanced on the introduction of Christianity.

In most of their manufactures they are in advance of the Papuans. They are clever workers in wood, and canoe and house building have become legitimate occupations. In religion they invariably believe in the existence of the spirit of man after death. Their amusements are numerous, some boisterous and even savage.

The Tarapon people have many points of resemblance to the Sawaioris, but, as a rule they are of smaller stature and less robust. They have straight black hair, which is more lank than that of the Sawaioris. The Tarapons, however, differ considerably from one another, and are evidently a mixed race. The natives of the Caroline Islands are larger than the Gilbert Islanders. They are also much lighter in color; they are more yellow, whereas the Gilbert Islanders are darker, than the Sawaioris. In many respects the Tarapons bear a much closer resemblance to the people of some portion of the Indian Archipelago than do the Sawaioris.

The traditions of the Gilbert Islanders tell us that their islands were peopled from the west and also from the east. So far as we have materials for examination, craniometry confirms other evidence, and indicates that the Tarapon people are more mixed than either of the other Polynesian races.

All the Tarapon people are navigators, but, owing to the fact that upon their atolls they have little good timber, most of their canoes are inferior to those of the Sawaioris. Their houses are also inferior. Their arms are fairly well made. In the Gilbert Islands they manufacture elaborate armor, to cover the entire body, from the fiber of the cocoa-nut husk in the Caroline

Islands very fine mats are made; and a hand-loom is used, with which a coarse cloth is made.

There is a general notion abroad that in all the islands of Polynesia the native races are rapidly decreasing; and this supposed fact is sometimes attributed to the missionaries. The alleged diminution, however, is a general conclusion from particular premises, and facts drawn from wider observations do not confirm it. (1) The estimates of population made by the first European or American visitors to Polynesia were far too high. In nearly all islands the people live almost entirely upon the coast; hence it was an error to reckon the inland portions as having a population proportionate to the number of people seen upon the coast. Then, when the visits of foreign ships were a novelty, the people from other districts would crowd to the place where the ships anchored to see them. (2) Those who have resided in Polynesia, and who have made observations on the subject, know that previous to the introduction of Christianity there had been a great decrease in the population of most of the islands. There are numerous evidences that they were formerly much more thickly peopled. On the island of Niue the increase is more than 3 per cent. per annum. The rapid decline of population in Hawaii is entirely exceptional.

**POLYP.** In its Greek and Latin forms the word *polypus*, was first used as descriptive of the CUTTLE-FISH, (*q.v.*) In speaking of the *Acalephæ* Aristotle says, "They hold their prey as the polypus does with its feelers," and there is no doubt that in this and other passages he referred to the octopus. The word was also, though less generally, applied to the woodlouse (*Onistus*)—the reason for both usages being equally evident. Though the former meaning persists in the word *poulpe*, yet by the beginning of the eighteenth century it seems to have been forgotten, and the word was by analogy transferred to a group of animals then beginning to attract much attention. Béaumur and Bernard de Jussieu were the first to fix the usage of the word polyp as applicable to hydroids, corals, and *polyzoa*. In following up the discoveries of Marsigli and Peysonelle in regard to the little coral organisms, Jussieu used the name of polyp definitely to describe those Sertularians, Alcyonians, sea-mats, etc., which were then (1742) known as animals.

Frembley, Ellis, Lamoureaux, Lamarack and others defined the meaning of the term similarly. (See HYDROZOA CORALS.)

**POLYPTERUS**, a genus of Ganoid fishes common in many rivers of tropical Africa, and known on the Nile by the name of *abū bishīr*.

**POLYPUS**, a term in surgery, signifying a tumor which is attached by a narrow neck to the walls of a cavity lined with mucous membrane. The most common variety is a polypus of the nose of a simple character and easily removed. Polypi are also met with in the ear, larynx, uterus, vagina, and rectum. See SURGERY.

**POLYSPERCHON**, one of Alexander's generals, and the successor of Antipater as regent of Macedonia in 318 B.C. He was driven from the kingdom by Cassander in 316. For the leading incidents of his brief term of office see PHOCION; compare also MACEDONIA.

**POLYTECHNIC SCHOOLS** are factors in the educational system which have successfully obtained in the United States of late years, though they were founded abroad, the first being established at Paris in 1794. The latter, however, was changed into a military school by Napoleon, and as such has since been conducted. They are designed to subserve a specific purpose, in affording facilities for an education in, and a practical application of the sciences, particular reference being had to physics, mathematics, and chemistry.

At the date of their establishment in the United States the means therefor, as also for their maintenance, were secured through the liberality and enterprise of private persons, and it was not until 1862 that the government by the donation of lands, created a fund for the promotion of the system. Meanwhile the Rensselaer Institute, founded at Troy, N. Y., in 1824, the first of the kind in America, and the Franklin Institute, founded at Philadelphia the same year, were doing excellent work. Not only had they established reputations for efficiency, invaluable and extended, but their plan had been incorporated in the curriculum of Eastern colleges, and adopted in 1848 by the Mechanics Institute at Cincinnati, Ohio. Prior to this time the Central School of Arts and Manufactures of Paris and the School of Design of Great Britain came into operation and in 1856 the school system of the latter country was further enhanced by the addition of a department of science and art.

Soon after the action of Congress in 1862 many of the States took hold of the subject and equipped schools with apparatus, text-books, etc., designed to promote the acquisition of a scientific and mechanical education. Some of these are now in a flourishing condition, but the schools founded by congressional appropriation have not entirely realized the expectations indulged in that connection. The claim is made that education in various branches is not up to the standard, that in equipment they are lacking, and that the instruction is less practical than the requirements of the service contemplate.

Supplementary to the usual course in the schools of many of the States, a system of scientific education less advanced, however, has been established and manual training schools are now maintained in nearly all the leading cities of the country. The system originated in the Imperial Training School of Moscow, Russia, about 1868, and its work was first exhibited in America upon the occasion of the Centennial Exposition at Philadelphia in 1876. Since that date it has become part of the course at Girard College in that city and of the common schools in Boston, Washington, Baltimore, San Francisco, and elsewhere, and of the workingmen's school and kindergarten, established in New York by Felix Adler, assisted by the society of Ethical Culture. The system finds favor with leading thinkers and educators and will grow in importance in the future.

**POLYXENA**, in Greek legend, a daughter of Priam, last king of Troy, and Hecuba.

**POLYZOA** is the name applied by J. Vaughan Thompson in 1830 to a group of minute polyp-like organisms which were subsequently (1834) termed "Bryozoa" by Ehrenberg. The forms included in this group were stated by Thompson to be "in a general way the whole of the Flustranceæ, in many of which I have clearly ascertained the animals to be Polyzoæ," they having been previously considered by zoölogists to be allied to the Hydra-like polyps. These organisms had previously been known by the hard corneous "cells" or chambers which are formed by the animals on the surface of their bodies, and build up, in consequence of the formation of dense colonies by budding, complex aggregates known as "sea mats" and "sea mosses." Thompson expressly stated the opinion that the organization of the animals detected by him led to the conclusion that "they must be considered as a new type of the Mollusca Acephala."

Subsequently (1844) Henri Milne-Edwards pointed out the relationship of Thompson's Polyzoa to the Brachiopoda, and, adopting the latter's views as to their Molluscan affinities, proposed to unite these two classes with the Tunicata in a group to be called "Mollusco-

idea." Recent researches have entirely separated the Tunicata from this association, and have demonstrated that they belong to the great phylum of Vertebrata. On the other hand, the association of the Polyzoa with the Brachiopoda appear at present to be confirmed, though the relationship of these two classes to the Mollusca has been shown to rest on mistaken identification of parts; see, however, Harmer.

The Polyzoa appear to be related to the Sipunculoid Gephyræan worms (*Gephyræa inermia*) more nearly than to any other class of the animal kingdom. The study and interpretation of the facts of their ontogeny (growth from the egg) presents such extreme difficulty that in the present state of our knowledge it is necessary to regard them *ad interim* as forming with the Brachiopoda and Sipunculoids an isolated group, to which the name "Podaxonia" may be applied, pending the decision of their affinities by the increase of our knowledge of the embryology of important members of the group.

POMBAL, SEBASTIAN JOSEPH DE CARVALHO E MELLO, MARQUIS DE, the greatest statesman Portugal has produced in modern times, was the son of Emmanuel de Carvalho, and was born at Soure, near Pombal, on May 13, 1699. He was educated at the university of Coimbra, was then for a short time in the army, and received his first public appointment, and was sent as minister to London in 1739, and was promoted to the embassy at Vienna by King John V. in 1745, and recalled in 1750 to become minister for foreign affairs. He soon began to show his strength; in 1751 he checked the Inquisition, by allowing no executions without the royal permission; he improved the navy, the police, and the finances, and freed the Indians of the Brazils from slavery. The Count d'Oeyras, as he was now made, then devoted himself to internal administration. On September 3, 1769, an attempt on the king's life was frustrated by the count, who was in 1770 made marquis of Pombal. He remained in power till the death of the king in 1777, but the new sovereign, Queen Maria, at once accepted his resignation, and persecuted him till his death in 1782.

POMEGRANATE forms a tree of small stature, or a bush with opposite, shining leaves, from the axils of some of which proceed the brilliant scarlet flowers. These are raised on a short stalk, and consist of a thick fleshy cylindrical or bell-shaped calyx tube, with five to seven short lobes at the top. From the throat of the calyx proceed five to seven roundish, crumpled, scarlet or crimson petals, and below them very numerous slender stamens. The pistil consists of two rows of carpels placed one above another, both rows embedded in, and partially inseparable from, the inner surface of the calyx tube. The fruit, which usually attains the size of a large orange, consists of a hard leathery rind, which is the enlarged calyx tube, inclosing a quantity of pulp derived from the coats of the numerous seeds. This pulp, filled as it is with refreshing acid juice, constitutes the chief value of the tree.

The tree is without doubt wild in Afghanistan, north-western India, and the districts south and southwest of the Caspian, but it has been so long cultivated that it is difficult to say whether it is really native in Palestine and the Mediterranean region. It has been cited as wild in northern Africa, but this appears to be a mistake. On a review of the whole evidence, botanical, literary, and linguistic, Alphonse de Candolle (*Origine des Plantes Cultivées*) pronounces against its African origin, and decides in favor of its source in Persia and the neighboring countries.

POMERANIA (Germ. *Pommern*) is a maritime province of Prussia, bounded on the north by the Baltic, on the west by Mecklenburg, on the south by Branden-

burg, and on the east by West Prussia. Its area is 11,620 square miles. The province is officially divided into the three districts of Stralsund, Stettin, and Cöslin; but more historical interest attaches to the names of Vorpommern and Hinterpommern, or Hither and Farther Pomerania, applied to the territory to the west and to the east of the Oder respectively. The interior of the province is thickly sprinkled with lakes, the combined area of which is equal to about one-twentieth of its entire surface. The soil of Pomerania is for the most part thin and sandy, especially to the east of the Oder. About 55 per cent. of the surface is under tillage, while 19 per cent. consists of meadow and pasture, and 20 per cent. is covered by forests. The principal crops are potatoes, rye, and oats, but wheat, barley, tobacco, and beetroot for sugar are also cultivated. Large flocks of sheep are kept both for their flesh and wool, and geese and goose-feathers form lucrative articles of export. With the exception of its inexhaustible layers of peat or soft coal, the mineral wealth of Pomerania is insignificant. Its industrial activity is also of no great importance. Commerce, however, is relatively much more flourishing. Stettin is one of the chief seaports of Prussia, and Stralsund, Greifswald, and Colberg also possess a foreign trade, the exports consisting mainly of grain, timber, and fish.

In 1880 Pomerania contained 1,540,034 inhabitants, all of whom were Protestants except 23,877 Roman Catholics and 13,886 Jews. The Slavonic element in the population is now represented only by a few thousand Poles and a handful of the ancient Cassubians on the east border. Pomerania is the most sparsely populated province in Prussia, the ratio being 132 inhabitants per square mile. About 67 per cent. of the population belong to the rural districts, while the remainder live in communities of 2,000 and upward. There are only nine towns with more than 10,000 inhabitants, at the head of which stands Stettin with 91,000.

POMEROY, a city of the United States, in Meigs county, Ohio, lies on the right bank of the Ohio about half-way between Pittsburgh and Cincinnati. It is the terminus of the Ohio River division of the Columbus, Hocking Valley and Toledo Railway, and has extensive coal-mines dating from 1833, salt works (14,000,000 bushels per annum), and bromine factories. Incorporated as a village in 1841 and as a city in 1868, Pomeroy had 5,824 inhabitants in 1870 and 5,560 in 1890.

POMFRET, JOHN, who was born in 1667 and died in 1703, holds a certain place in English letters as the author of a short poem, *The Choice*, which embodies in easy and happy Drydenic diction the refined Epicureanism of the eighteenth century, and was consequently widely popular throughout that century.

POMONA, the old Roman goddess of tree-fruits (*poma*).

POMPADOUR, JEANNE ANTOINETTE POISSON LE NORMANT D'ÉTIOLLES, MARQUISE DE, the most famous of all the mistresses of Louis XV., was born in Paris on December 29, 1721, and was baptized as the legitimate daughter of François Poisson, an officer in the household of the duke of Orleans, and his wife Madeleine de la Motte. In 1741 she was married to a nephew of her protector and guardian, Le Normant d'Étiolles, who was passionately in love with her, and soon became a queen of fashion. She first met Louis XV. at a ball given by the city to the dauphin in 1744, and he was immediately subjugated. She at once gave up her husband, and in 1745 was established at Versailles as "maîtresse en titre." Louis XV. bought her the estate of Pompadour, from which she took her title of Marquise, and the command of the political situation

passed entirely into her hands. The continuous policy of France since the days of Richelieu had been to weaken the house of Austria by alliances in Germany; but Madame de Pompadour changed this hereditary policy because Frederick the Great wrote scandalous verses on her; and because Maria Theresa wrote her a friendly letter she entered into an alliance with Austria. This alliance brought on the Seven Years' War with all its disasters, the battle of Rosbach and the loss of Canada. She even ingratiated herself with the queen, after the example of Madame de Maintenon, and was made a lady-in-waiting; but the end was soon to come. "Ma vie est un combat," she said, and so it was with business and pleasure; she gradually grew weaker and weaker, and when told that death was at hand she dressed herself in full court costume, and met it bravely on April 15, 1764, at the age of forty-three.

POMPEII, an ancient town of Campania, situated on the shore of the Bay of Naples, almost immediately at the foot of Mount Vesuvius. To its proximity to that volcano it owes its celebrity—the peculiar circumstances of its destruction by the great volcanic outburst of Vesuvius and of its rediscovery in modern times, having converted that which would otherwise have been known only as an obscure country town into a place of world-wide fame, as one of the most interesting relics preserved to us from antiquity.

An earthquake, which affected all the neighboring towns, occurred 63 A.D., venting its force especially upon Pompeii, a large part of which, including most of the public buildings, was either destroyed or so seriously damaged as to require to be rebuilt rather than repaired (Tacit., *Ann.*, xv. 21; Seneca, *Q. N.*, vi. 1). The actual amount of the injuries sustained, which is intimated in general terms by Tacitus and Seneca, is more accurately known to us from the existing remains; for the inhabitants were still actively engaged in repairing and restoring the ruined edifices when the whole city was overwhelmed by a much more appalling catastrophe. In 79 A.D. the neighboring mountain of Vesuvius, the volcanic forces of which had been slumbering for unknown ages, suddenly burst into a violent eruption, which, while it carried devastation all around the beautiful gulf, buried the two cities of Herculaneum and Pompeii under dense beds of cinders and ashes.

So completely was the unfortunate city buried under this overwhelming mass that its very site was forgotten, and even the celebrated topographer Cluverius in the seventeenth century was unable to fix it with certainty. It was not till 1755 that systematic excavations on the site were begun, and, though they were thenceforth carried on more or less continuously during the whole of that century, it was not till the beginning of the present century that they assumed a regular character; and the work, which had received a vigorous stimulus during the period of the French Government (1807-1814), was prosecuted, though in a less methodical and systematic manner, under the succeeding rule of the Bourbon kings (1815-1861). Of later years the process has been carried on, under the enlightened direction of Signior Fiorelli, in a much more careful and scientific manner than before, and the results have been in many respects of the highest interest.

The town was situated on a rising ground of small elevation, separated by a distance of less than a mile from the foot of the actual rise of the outer cone of Vesuvius.

The area occupied was of an irregular oval form, and about two miles in circumference. It was surrounded by a wall, which is still preserved around more than two-thirds of its extent.

The general plan of the town is very regular, the

streets being generally straight, and crossing one another at right angles or nearly so; uniformly paved with large polygonal blocks of hard basaltic lava, fitted very closely together, though now in many cases marked with deep ruts from the passage of vehicles in ancient times, and calculated much more for foot passengers than for any extensive traffic of wheeled carriages.

The forum was unquestionably at Pompeii, as at Rome itself, and in all other Italian cities, the focus and center of all the life and movement of the city, and was at once the resort of the lounge and the gathering place of men of business. Hence it was surrounded on all sides by public buildings or edifices of a commanding character, and surrounded on three sides by a portico. It is, however, certain from the existing remains that both this portico and the adjacent buildings had suffered severely from the earthquake of 63. The north end of the forum, where alone the portico is wanting, is occupied in great part by a building, the most imposing in the whole city, which is now generally known as the Temple of Jupiter. On the east side of the forum were four edifices; the first is generally known, though without doubt erroneously, as the Pantheon, or Temple of the twelve gods. Next to this comes a building generally regarded as the curia or senaculum—the meeting-place of the local senate, or town council. Beyond this comes another temple of small dimensions, commonly called the Temple of Mercury; and beyond this again, bounded on the south by a street known as the Street of the Silversmiths, is a large and spacious edifice, erected by a priestess named Eumachia. The south end of the forum is occupied by three small buildings of very similar form and arrangement, which are supposed to have served as courts of law; while the greater part of the west side is occupied by two large buildings—a basilica, which is the largest edifice in Pompeii, and a temple, which is commonly called the Temple of Venus, but without any evidence; the most recent authorities regard it, on somewhat better grounds, as dedicated to Apollo.

Besides the temples which surround the forum, the remains of four others have been discovered, three of which are situated in the immediate neighborhood of the theaters. Among the most conspicuous buildings are the theaters, of which there were two, placed, as was usual in Greek towns, in close juxtaposition with one another. The largest of these, which was partly excavated in the side of the hill, was a building of considerable magnificence, being in great part cased with marble, and furnished with seats of the same material, which have, however, been almost wholly removed. Its internal construction and arrangements resemble those of the Roman theaters in general, though with some peculiarities that show Greek influence, and we learn from an inscription that it was erected in Roman times by two members of the same family, M. Holconius Rufus and M. Holconius Celer, both of whom held important municipal offices at Pompeii during the reign of Augustus. The smaller theater, which was erected, as we learn from an inscription, by two magistrates specially appointed for the purpose by the decurions of the city, was of older date than the large one, and appears to have been constructed about the same time as the amphitheater, soon after the establishment of the Roman colony under Sulla. The smaller theater is computed to have been capable of containing fifteen hundred spectators, while the larger could accommodate five thousand persons. Adjoining the theaters is a large rectangular inclosure, surrounded by a portico, the purpose of which has been the subject of considerable controversy, but it is now generally admitted to have been the quarters or barracks of the gladiators, who were

permanently maintained in the city with a view to the shows in the amphitheater.

Adjoining the amphitheater was found a large open space, nearly square in form, which has been supposed to be a forum boarium or cattle market, but, no buildings of interest being discovered around it, the excavation was filled up again, and this part of the city has not been since examined. Among the more important public buildings of Pompeii were the thermæ, or public baths, an institution that always held a prominent position in every Roman or Græco-Roman town. Three different establishments of this character have been discovered, of which the first, excavated in 1824, was for a long time the only one known.

Great as is the interest attached to the various public buildings of Pompeii, and valuable as is the light that they have in some instances thrown upon similar edifices in other ruined cities, far more curious and interesting is the insight afforded us by the numerous private houses and shops into the ordinary life and habits of the population of an ancient town. In this respect Pompeii stands alone, among all antiquarian discoveries—the difficulties of exploration at Herculaneum having greatly checked all further investigations on that equally promising site. But here again it is impossible in an article like the present to do more than briefly advert to the general results of the excavations (compare ARCHITECTURE). The excavations systematically conducted for many years past have presented us with examples of houses of every description, from the humble dwelling-place of the artisan or proletarian, with only three or four small rooms, to the stately mansions of Sallust and Pansa—the last of which is the most regular as well as the most extensive of all.

Of the numerous works of art discovered in the course of the excavations the statues and large works of sculpture, whether in marble or bronze, are inferior to those found at Herculaneum, but some of the bronze statuettes are of exquisite workmanship, while the profusion of ornamental works and objects in bronze, and the elegance of their design, as well as the finished beauty of their execution, are such as to excite the utmost admiration—more especially when it is considered that these are the casual results of the examination of a second-rate provincial town. The same impression is produced in a still higher degree by the paintings with which the walls of the private houses, as well as those of the temples and other public buildings, are adorned, and which are not merely of a decorative character, but in many instances present us with elaborate compositions of figures, historical and mythological scenes, as well as representations of the ordinary life and manners of the people, which are full of interest to us, though often of inferior artistic execution. An illustration of the character of the Pompeian wall-paintings is given in the article MURAL DECORATION.

The architecture of Pompeii must be regarded as presenting in general a transitional character from the pure Greek style to that of the Roman empire. All the three orders of Greek architecture—the Doric, Ionic, and Corinthian—are found freely employed in the various edifices of the city, but rarely in strict accordance with the rules of art in their proportions and details; while the private houses naturally exhibit still more deviation and irregularity. The architecture of Pompeii suffers also from the inferior quality of the materials generally employed. No good building stone was at hand; and the public as well as private edifices were constructed either of volcanic tuff, or brick, or the irregular masonry known to the Romans as *opus incertum*. In the private houses, even, the columns are mostly of brick, covered merely with a coat of stucco.

In a few instances only do we find them making use of a kind of travertine, found in the valley of the Sarno, which, though inferior to the similar material so largely employed at Rome, was better adapted than the ordinary tuff for purposes where great solidity was required. The portion of the portico surrounding the forum which was in the process of rebuilding at the time when the city was destroyed was constructed of this material, while the earlier portions, as well as the principal temples that adjoined it, were composed in the ordinary manner of volcanic tuff.

Outside the gate leading to Herculaneum is found a house of a different character from all the others, which from its extent and arrangement was undoubtedly a suburban villa, belonging to a person of considerable fortune. It is called—as usual without any authority—the villa of Arrius Diomedes. The remains of a still more extensive suburban house which were discovered in 1764, and to which the name was given, without the slightest foundation, of the villa of Cicero, are no longer visible, having been covered up again with earth.

In the vaulted corridors of the first villa were discovered no less than seventeen skeletons of the unfortunate inhabitants, who had evidently fled thither for protection. Almost all the skeletons and remains of bodies found in the city were discovered in similar situations, in cellars or underground apartments—those who had sought refuge in flight having apparently for the most part escaped from destruction, or having perished under circumstances where their bodies were easily recovered by the survivors.

The road leading from the gate of Herculaneum toward that city is bordered on both sides for a considerable extent by rows of tombs, as was the case with all the great roads leading into Rome, and indeed in all large Roman towns. Without of course approximating to the stately structures that adorned the Via Appia or Latina, these tombs are in many instances monuments of considerable pretension, and of a highly ornamental character, and naturally present in the highest degree the peculiar advantage common to all that remains of Pompeii, in their perfect preservation.

No manuscripts have been discovered in Pompeii. Inscriptions have naturally been found in considerable numbers, and we are indebted to them for much information concerning the municipal arrangements of the town, as well as the construction of various edifices and other public works. The most interesting of these are such as are written in the Oscan dialect, which appears to have continued in official use down to the time when the Roman colony was introduced by Sulla. From that time the Latin language was certainly the only one officially employed, though Oscan may still have been spoken by a portion at least of the population. Still more curious, and almost peculiar to Pompeii, are the numerous writings scratched or rudely painted upon the walls, which have in some instances a semi-public character, such as recommendations of candidates for municipal offices, but more frequently are the mere expression of individual impulse and feeling, not uncommonly conveyed in rude and imperfect verses. In one house also a whole box was found filled with written tablets—diptychs and triptychs—containing the record of the accounts of a banker named L. Cæcilius Jucundus.

POMPEY is the common English form of the Roman name Pompeius.

I. CNEIUS POMPEIUS MAGNUS, the great triumvir, whose name we always associate with Cæsar and Crassus, was born in 106 B.C. and fought by his father's side when a stripling of seventeen in the Social or Italian War on the side of Sulla against the party of Marius

and Cinna. He followed up his successes in Italy by defeating the Marians in Sicily and Africa, and on his return to Rome in 81, though he was still merely an "eques" and not legally qualified to celebrate a triumph, he was allowed by general consent to enjoy this great distinction, while Sulla greeted him with the surname of Magnus, a title he always retained and handed down to his sons. After this he defeated Sertorius in Spain, suppressed in Italy the slave insurrection aroused by Spartacus in 71, and during the same year was elected to the consulship and entered Rome in triumph. In 66 the whole of the Roman empire in the East was put under his control, and in 61, after defeating Pontius, annexing Syria and Palestine, capturing Jerusalem, Asia, and the East, Pompey, in his forty-fifth year, returned to Rome to celebrate the most magnificent triumph ever witnessed there and to be hailed as the conqueror of Spain, Africa, and Asia.

The remainder of Pompey's life is inextricably interwoven with that of Cæsar. He was married to Cæsar's daughter Julia, and as yet the relations between the two had been friendly. With the death of Pompey's wife Julia, in 54, came strained relations between him and Cæsar, and soon afterward he drew closer to what we may call the old conservative party in the senate and aristocracy. The end was now near, and Pompey blundered into a false political position and an open quarrel with Cæsar. Pompey's cause, with that of the senate and aristocracy, was finally ruined by his defeat in 48 in the neighborhood of the Thessalian city Pharsalus. That same year he fled with the hope of finding a safe refuge in Egypt, but was treacherously murdered as he was stepping on the shore by one of his old centurions. He had just completed his fifty-eighth year.

II. SEXTUS POMPEIUS MAGNUS, the younger son of Pompey the Great, born 75 B.C., continued after his father's death to prolong the struggle against the new rulers of the Roman empire. In 43 he was proscribed along with the murderers of Cæsar, and he put himself at the head of a fleet, by means of which he made himself master of Sicily, and thence ravaged the coasts of Italy. Rome was threatened with a famine, as the corn supplies from Egypt and Africa were cut off by his ships, and it was thought prudent to negotiate a peace with him, which was to leave him in possession of Sicily, Sardinia, and Achaia, provided he would allow Italy to be freely supplied with corn. But Sextus renewed the war and gained some considerable successes at sea. However, in 36 his fleet was defeated and destroyed by Agrippa off the north coast of Sicily, and in the following year he was murdered at Mitylene by an officer of Antony.

PONCE DE LEON, LUIS, See LEON, LUIS PONCE DE.

PONCELET, JEAN VICTOR, mathematician, was born at Metz, July 1, 1788. From 1808 to 1810 he attended the Polytechnic School, and afterward, till 1812, the Practical School at Metz. From 1815 to 1825 he was occupied with military engineering at Metz; and from 1825 to 1835 he was professor of mechanics at the Practical School there. In 1834 he became a member of the Academy; from 1838 to 1848 he was professor to the faculty of sciences at Paris, and from 1848 to 1850 commandant of the Polytechnic School, where he effected a reform in the course of study. He died December 22, 1867.

POND, JOHN, astronomer-royal, was born about 1767 in London.

During an administration of nearly twenty-five years, Pond effected a reform of practical astronomy in England comparable to that effected by Bessel in Germany.

He died at Blackheath, September 7, 1836, and was buried beside Halley in the churchyard of Lee. The Copley medal was conferred upon him in 1823, and the Lalande prize in 1817 by the Paris Academy, of which he was a corresponding member. He published eight folio volumes of *Greenwich Observations*, translated Laplace's *Système du Monde* (in 2 vols. 8vo, 1809), and contributed thirty-one papers to scientific collections. His catalogue of 1,112 stars (1833) was of great value.

PONDICHERRI, chief settlement of the French possessions in the East Indies, situated on the Coromandel coast, in  $11^{\circ} 56'$  N. latitude and  $79^{\circ} 53'$  E. longitude; it is eighty-six miles south of Madras, and is connected with the South Indian Railway system. The territory consists of three districts—Pondicherry, Villianur, and Bahur—comprising an area of 112 square miles, with a population in 1881 of 139,210; in 1890, estimated at 145,000.

PONEVYEZH, a district town of Russia, in the government of Kovno, situated on the upper course of the Neveja river, and connected by rail with Libau on the northwest and with Düna (eighty miles distant) on the east. Its population (8,070 in 1865) had in 1881 reached 15,030, of whom nearly one-half were Jews, and to nearly 20,000 in 1890.

PONIATOWSKI, a family of Poland, the earliest member of which to acquire high distinction was STANISLAUS CIOLEK, regarding whose descent there are conflicting accounts. In any case he was born in 1677 and had sufficient influence and ability to insure his rapid promotion in the army of Charles XII., and as major-general at the battle of Poltava in 1709 was able by his self-command in facilitating the passage of the Dnieper to save the retreating army. In 1711 he was sent on a special embassy to Constantinople, when he succeeded in obtaining from the sultan a promise to send an army to aid Charles in the war with Russia; but the promise was never carried out. After the death of Charles he gave his adhesion to Augustus II., by whom he was in 1724 made grand treasurer of Lithuania, and in 1731 palatine of Mazovia. On the death of Augustus II. he sought to effect the promotion of Stanislaus Leszczyński to the throne, but ultimately he gave in his submission to Augustus III., and after holding under him several high offices was in 1752 appointed castellan of Cracow. He died in 1762, leaving by his marriage with Constance Princess Czartoryski four sons, the best known of whom was the second, STANISLAUS AUGUSTUS, king of Poland, born January 17, 1732. Sent by Augustus III. to the court of Russia, he won the favor of the grand-duchess Catherine, who succeeded to the throne by the assassination of her husband, July 9, 1762. Through her influence he was, September 7, 1764, chosen king of Poland. For an account of his despicable and disastrous rule see POLAND. After signing his abdication, November 25, 1795, he took up his residence at St. Petersburg, where he enjoyed a pension of 200,000 ducats paid jointly by Austria, Russia, and Prussia. He died unmarried, February 12, 1798. Of the other sons of Stanislaus Poniatowski, Casimir (born in 1721 and died in 1800), the eldest, was grand chamberlain of Poland and commander of the royal guard. Andrew (born in 1735 and died in 1773), became an Austrian field-marshal; and Michael (born in 1736 and died in 1794), was ultimately promoted primate of Poland. JOSEPH ANTON (1762-1813), prince and marshal of France, son of Andrew Poniatowski was born at Warsaw, May 7, 1762. At the age of sixteen he entered the service of Austria. After the resolution of the diet to reorganize the Polish army he was recalled and obtained the rank

of major-general. On the outbreak of hostilities with Russia in 1792 he was made commander of the army defending central Poland, but on the outbreak of the insurrection in 1794, he enrolled himself as a volunteer under Kosciuszko, although Kosciuszko had previously held inferior military rank to his own. In command of a division he had charge of the defense of the northern side of Warsaw, and after its capitulation he went to Vienna. In Napoleon's campaigns he held the command of the Polish army corps, distinguishing himself at Smolensk, Borodino, and Leipsic, where he took 1,000 prisoners, and in token of his brilliant exploit was created by Napoleon a marshal of France the same evening. He was employed in covering the retreat from Leipsic, and when the enemy obtained possession of the suburbs he endeavored to join the main army by plunging into the Elster, but was fired upon and, enfeebled by wounds, was drowned, October 19, 1813. JOSEPH (1816-1873), grandson of Casimir mentioned above, was born February 4, 1816, at Rome. Entering the Tuscan service, he went in 1849 as minister of Tuscany to London. In 1850 he took up his residence in Paris, and becoming a naturalized citizen was in 1854 chosen a member of the French senate. In 1870 he removed to London, where he supported himself by teaching music. He was the composer of several operas. He died July 3, 1873.

PONS, JEAN LOUIS, French astronomer, born at Peyre (Haut-Dauphiné), December 24, 1761, received a place at the Marseilles observatory in 1789, and in 1819 became the director of the new observatory at Marlia near Lucca, which he left in 1825 for the observatory of the museum at Florence. He died October 14, 1831.

PONSARD, FRANÇOIS, French dramatist, was born at Vienne in Dauphiné on June 1, 1814. He was bred a lawyer, and his first performance in literature was a translation of *Manfred* (1837). But the first important, and indeed the most important, event of his life was the representation of his play *Lucrèce* at the Théâtre Français on April 1, 1843. It so happened that the tastes and capacities of the most popular actress of the day, Rachel, suited his style of drama, and this contributed greatly to his own popularity. He followed up *Lucrèce* with *Agnès de Méranie* (1846), *Charlotte Corday* (1850), and others. Ponsard accepted the empire, though with no very great enthusiasm, and received the post of librarian to the senate, which, however, he soon resigned, fighting a bloodless duel with a journalist on the subject. *L'Honneur et L'Argent*, one of his most successful plays, was acted in 1853, and he became an Academician in 1855. For some years he did little, but in 1866 he obtained great success with *Le Lion Amoureux*. He died a year later at Paris in July, 1867, soon after his nomination to the commandership of the Legion of Honor.

PONTANUS, JOVIANUS, a famous Italian humanist and poet, was born in 1426 at Cerreto in the duchy of Spoleto, where his father was murdered in one of the frequent civil brawls which then disturbed the peace of Italian towns. His mother escaped with the boy to Perugia, and it was here that Pontano received his first instruction in languages and literature. Failing to recover his patrimony, he abandoned Umbria, and at the age of twenty-two established himself at Naples, which continued to be his chief place of residence during a long and prosperous career. He died in 1503 at Naples, where a remarkable group of terra-cotta figures, life-sized and painted, still adorns his tomb in the church of Monte Oliveto. He is there represented together with his patron Alphonso and his friend San-nazzaro in adoration before the dead Christ.

PONTECORVO, a city of Italy in the province of

Caserta, on the left bank of the Garigliano, with a population of 5,172 in 1889 (commune 10,191), answers to the ancient Fregellæ, a Volscian city, colonized in 323 B.C. by the Romans, who thus occasioned the Second Samnite War. The principality of Pontecorvo (about forty square miles in extent), which Napoleon bestowed on Bernadotte in 1806, was in 1810 incorporated with the French empire.

PONTEFRACT, or POMFRET, a market town and municipal and parliamentary borough in the West Riding of Yorkshire, England, finely situated on an eminence near the junction of the Calder and Aire, and on three railway lines, thirteen miles southeast of Leeds, and fourteen northwest of Doncaster. The streets are wide and regular, and there are many good houses and shops. There are extensive gardens and nurseries in the neighborhood, and licorice is largely grown for the manufacture of the celebrated Pomfret cakes. The town possesses iron foundries, sack and matting manufactories, tanneries, breweries, corn mills, and brick and terra-cotta works. The population of the municipal borough (extended in 1875) in 1871 was 6,432, in 1881 it was 8,798, and in 1890 estimated at 10,000. The increase is mainly due to the fact that Pontefract is now a military center.

PONTEVEDRA, a maritime province of Spain, is bounded on the north by Coruña, on the east by Lugo and Orense, on the south by Portugal (Entre Douro e Minho), and on the west by the Atlantic, and has an area of 1,739 square miles. The general character of the province is hilly, with a deeply indented coast; its products are those common to all GALICIA (*q.v.*), of which historical province it formed a part. The population in 1890 is nearly 500,000 and has many municipalities with a population over 10,000.

PONTEVEDRA, capital of the above province, and an episcopal see, is a picturesque old granite-built town, pleasantly situated at the head of the Ria de Pontevedra, where the Lerez is spanned by the old Roman bridge (whence the name—*pons vetus*). The inhabitants engage in agriculture, sardine fishing, and the manufacture of cloth and hats. The population of the municipality in 1890 was 20,857.

PONTIAC, the capital of Oakland county, Mich., one of the Upper Lake States of the United States, is located on Clinton river and is the distributing point for a rich and populous agricultural and lumber territory. It is distant from Detroit twenty-six miles in a northwesterly direction; thirty-seven miles southeast of Flint, and thirty-four miles northeast of Ann Arbor, on the Detroit and Milwaukee railroad, by which, and tributary railway lines, easy communication with other portions of the country is obtainable. The city was incorporated in 1861, and its growth has been steady and permanent. It is the location of the Eastern Michigan Asylum for the insane, erected in 1877, at a cost of \$500,000, also for the Reform School, founded by the State in 1871. It contains a court-house, jail, etc., two high-schools, one of which cost \$70,000, and a number of school buildings, eight churches, three banks, printing offices at which are issued two or more weekly papers, a military academy, four hotels and many stores. In addition to these, there are a number of foundry and machine shops, lumber, planing and grist mills, and other industrial establishments in operation, together with electric-light works, refining, marble, granite and knitting works. The landscape in the immediate vicinity is dotted with many small and beautiful lakes, and is otherwise attractive. The population in 1870 was 4,867, in 1880, 4,509 and 6,243 in 1890.

PONTIANAK. See BORNEO.

PONTIFEX. The principal college of priests in

ancient Rome consisted of the *pontifices*, the *rex sacrorum*, and the *flamines*, under the headship of the *pontifex maximus*. The *rex sacrorum* was the functionary who under the republic succeeded to the sacrificial duties which in old time had been performed by the king; the *flamines* were sacrificial priests of particular gods, the most important being the *flamen Dialis*, or priest of Jupiter, whose wife, the *flaminica Dialis*, was priestess of Juno. The *pontifices* on the other hand were not assigned to the service of particular gods, but performed general functions of the state religion; and their head, the *pontifex maximus*, was the highest religious authority in the state. The functions of *pontifex maximus* were too weighty to be discharged by a subject in a monarchical government, and from Augustus to Gratian (382 A.D.) this supreme priesthood was held by the emperors in person. The supreme pontiff was in the religion of the state what the father was in the religion of the family. His dwelling was in the *regia* close to the altar of Vesta, the sacred hearth of the state; and the most sacred objects of national worship, the *penates publici* and the mysterious palladia of Roman sovereignty, were his special care. The pontiffs supplied technical guidance and help in those religious functions in which the senate or magistrates had the first part; while the charge of the calendar with its complicated intercalation and system of feast days gave them an important influence on the affairs of civil life, also having the weighty function of declaring and interpreting the laws of religion, which involved such important social matters as marriage and testamentary dispositions; but this function was declaratory and not magisterial. The number of *pontifices* was gradually enlarged, first to nine and then, under Sulla, to fifteen, and the emperors exercised the right of adding supernumeraries at will.

PONTINE MARSHES. See LATIUM.

PONTOISE, a commercial town of France, at the head of an arrondissement of the department Seine-et-Oise, eighteen miles by rail northwest of Paris, picturesquely situated on the right bank of the Oise where it is joined by the Viosne, and at the intersection of the railway from Paris to Dieppe by Gisors with that of the valley of the Oise. The traffic on the main river is large, and the tributary drives numerous mills. Grain and flour are the principal staples of the trade of Pontoise; the population in 1881 was 6,675, and estimated in 1890 at 7,500.

PONTOON. pontoons are vessels employed to support the roadway of floating bridges. They may be either open or closed, heavy and only movable when floated, or light enough to be taken out of the water and transported overland, as when required to form part of the equipment of an army in the field. From time immemorial floating bridges of vessels bearing a roadway of beams and planks have been employed to facilitate the passage of rivers and arms of the sea. Xerxes crossed the Hellespont on a double bridge, one line supported on three hundred and sixty, the other on three hundred and fourteen vessels, anchored head and stern with their keels in the direction of the current. Darius threw similar bridges across the Bosphorus and the Danube in his war against the Scythians, and the Greeks employed a bridge of boats to cross the river Tigris in their retreat from Persia. Floating bridges have been repeatedly constructed over rivers in Europe and Asia, not merely temporarily for the passage of an army, but permanently for the requirements of the country; and to this day many of the great rivers in India are crossed, on the lines of the principal roads, by floating bridges, which are for the most part supported on boats such as are employed for ordinary traffic on the river.

But light vessels which can be taken out of the water and lifted onto carriages are required for transport with an army in the field. Alexander the Great occasionally carried with his army vessels divided into portions, which were put together on reaching the banks of a river, as in crossing the Hydaspes. Cyrus crossed the Euphrates on stuffed skins. In the fourth century the emperor Julian crossed the Tigris, Euphrates, and other rivers by bridges of boats made of skins stretched over osier frames. In the seventeenth century the Germans employed timber frames covered with leather as pontoons, and the Dutch similar frames covered with tin; and the practice of carrying about skins to be inflated and employed for the passage of troops across a river, still exists in the East, and has been introduced into America in a modified form, india-rubber being substituted for skins.

Pontoons have been made of a variety of forms and of almost every conceivable description of material available for the purpose of combining the two essential qualities of transportability over land and power of support in water. Numerous expedients for lightening the equipment have been suggested, in America more particularly.

In modern warfare great attention has been paid to the pontoon service. The French bridge of this description is made of wood. It is of adequate length, width and depth, and each boat exceeds 1,400 pounds in weight. The Russians employ frames covered with canvas, while the Austrians use floats of wood. During the Mexican war the subject was first suggested in the United States, but hostilities closed before the suggestion could be practically adopted. When the Civil War broke out, the subject was revived, and every known design was canvassed and tested. Among those which the necessities of the situation gave birth to were the blanket pontoon bridges, improvised in part out of the soldiers' blankets. The boats were a simple, substantial frame of wood, light of weight, and easily handled. They were arranged so as to form floats, over which the blankets were folded and tied by cords; and when a sufficient number had been lashed together were found capable of sustaining a considerable weight. The system was designed by General Haupt; and upon testing the frame or crib it was ascertained that 687 pounds would sink it but one foot. With a proper equipment of boats, and a competent force, a company could cross streams without the delay incident to such occasions, say within less than half an hour from the time of reaching the banks of the same.

PONTOPPIDAN, ERIK, a learned Danish author, was born at Aarhus on August 24, 1698, and studied divinity at the university of Copenhagen. In 1738 he was made professor extraordinarius of theology at Copenhagen, and in 1747 bishop of Bergen, Norway, where he died on December 20, 1764.

PONTORMO, JACOPO DA, whose family name was CARUCCI, a painter of the Florentine school, born at Pontormo in 1494, son of a painter of ordinary ability, was apprenticed to Leonardo da Vinci, and afterward took lessons from Pier di Cosimo. The most extensive series of works which he ever undertook was a set of frescoes in the church of S. Lorenzo, Florence, from the Creation of Man to the Deluge, closing with the Last Judgment. He died of dropsy on January 2, 1557, and was buried below his work in the Servi.

PONTUS was the name given in ancient times to an extensive tract of country in the northeast of Asia Minor, bordering on Armenia and Colchis. It was not, like most of the divisions of Asia, a national appellation, but a purely territorial one, derived from its proximity to the Euxine, often called simply Pontus by the Greeks.

Originally it formed part of the extensive region of Cappadocia, which in early ages extended from the borders of Cilicia to the Euxine; but afterward it came to be divided into two satrapies or governments, of which the northernmost came to be distinguished as "Cappadocia on the Pontus," and thence simply as "Pontus." The term, it is probable, did not come into general use until after the time of Alexander the Great.

The sea-coast, like the rest of the south shore of the Euxine, was from an early period studded with Greek colonies, most of them of Milesian origin, though in many cases deriving their settlement directly from Sinope, itself a colony of Miletus. Next to that city, between the mouth of the Halys and that of the Iris, stood Amisus, originally a colony direct from Miletus, but which subsequently received a body of Athenian settlers. It was one of the most flourishing of the Greek colonies on this coast, and is still a considerable town under the name of Samsun. Proceeding eastward from thence, we find Side, called in later times Polemonium; Cotyora, a colony of Sinope, where Xenophon embarked with the 10,000 Greeks; Cerasus, afterward named Pharnacia; and Trapezus, also a colony of Sinope, which was a flourishing and important town in the days of Xenophon, but did not attain till a later period to the paramount position which it occupied under the Roman and Byzantine empire, and which it still retains under the name of TREBIZOND.

But, besides these Greek settlements, there were in the interior of Pontus several cities of considerable importance. The principal of these were Amasia, on the river Iris, the birth-place of Strabo, which was made the capital of his kingdom by Mithradates the Great; Comana, higher up the valley of the same river, which, like the place of the same name in Cappadocia, was consecrated to a native goddess named Ma; Zela, nearer the frontier of Galatia, which was in like manner consecrated to a goddess named Anaitis; and Cabira, in the valley of the Lycus, afterward called Neocæsarea, a name still retained in the abbreviated form of the modern Niksar. Several smaller towns are mentioned by Strabo as giving name to the surrounding districts, of which he has left us the names of not less than fifteen; but these obscure appellations of local divisions are in themselves of little interest, and for the most part not mentioned by any other writer.

PONTUS DE TYARD, one of the famous Pleiade who helped to reform French literature in the sixteenth century, was the highest in rank and the most affluent in fortune of the seven. He was indeed in some sort an anticipator of Ronsard and Du Bellay. He was seigneur of Bissy in Burgundy, was born at the seigniorial house in or about 1521, and died at a great age at Bragny on the Saône, another seat of his, on September 25, 1605. He was thus the last survivor as well as one of the eldest of the group.

PONTYPOOL, a town and urban sanitary district of Monmouthshire, England, situated on an acclivity above the river Avon Lwyd, on the Monmouthshire Canal, and on the Great-Western and Monmouthshire Railways, eight miles north of Newport. The town possesses large forges and iron-mills for the manufacture of iron-work and tin-plate. The population of the urban sanitary district (area 800 acres) in 1871 was 4,834, in 1881 it was 5,244, and in 1890 (estimated) 7,000.

PONTYPRIDD, sometimes also called Newbridge, a market town of Glamorganshire, Wales, situated on the Taff at its junction with the Rhondda, and on the Glamorganshire Canal, twelve miles north-northwest from Cardiff and twelve south from Merthyr-Tydfil. It receives its name from a remarkable bridge of one arch

spanning the Taff, erected by William Edwards, a self-taught mason. The bridge is a perfect segment of a circle, the chord being 140 feet, and the height at low water 36 feet. Near the town is a far-famed rocking stone nine and a half tons in weight, surrounded by so-called Druidical remains. In the beginning of the century Pontypridd was an insignificant village, and it owes its progress chiefly to the coal and iron in the neighborhood. It possesses anchor, chain, and cable works, chemical works, and iron and brass foundries. The population in 1881 was 12,317, and in 1890 upward of 13,000.

PONZA, the principal island of a small volcanic group, the Pontian, Pontine, or Pontinian Islands, which lie twenty miles off the Circeian promontory (Monte Circello), the northern end of the Gulf of Gaeta, on the west coast of Italy. Ponza is five miles long and very irregular in outline; its soil is fertile, and in 1881 it had 3,828 inhabitants.

POOLE, a market town, municipal borough, county in itself, and seaport of Dorsetshire, on the south coast of England, is picturesquely situated on a peninsula between Holes Bay and Poole Harbor, 30 miles east from Dorchester and 120 southwest of London. There is a large general trade with the British colonies and the United States, and an important coasting trade, especially in grain to London, and Purbeck clay to the Staffordshire potteries. In 1883 the number of vessels that entered the harbor was 933 of 81,003 tons, the number that cleared 874 of 77,948 tons. Some ship-building is carried on, and there are manufactures of cordage, netting, and sail-cloth. The town also possesses large potteries, decorative tile works, iron-foundries, engineering works, agricultural implement works, and flour-mills. The area of the borough is 5,111 acres, with a population in 1871 of 10,129, and in 1881 of 12,310, and in 1889 estimated at about 14,000.

POOLE, MATTHEW, author of a learned though now almost wholly antiquated *Synopsis Criticorum Biblicorum*, was born at York in 1624, and died at Amsterdam in 1679.

POOLE, PAUL FALCONER, an eminent English painter, was born at Bristol in 1806. He exhibited his first work in the Royal Academy at the age of twenty-five, the subject being the *Well*—a scene in Naples. There was an interval of seven years before he again exhibited his *Farewell, Farewell*, in 1837, which was followed by the *Emigrant's Departure*, *Hermann and Dorothea*, and *By the Waters of Babylon*. This last picture attracted much attention from the fine poetic imagination which it displayed. In 1843 his position was made secure by his *Solomon Eagle*, and by his success in the Cartoon Exhibition, in which he received from the Fine Art Commissioners a prize of \$1,500. After his exhibition of the *Surrender of Syon House* he was elected an Associate of the Royal Academy in 1846, and was made an Academician in 1861. He died in 1879, in his house at Hampstead, in his seventy-third year.

POONA, a district in the Deccan, Bombay, has an area of 5,347 square miles, and is bounded on the north by the districts of Nasik and Ahmednagar, on the east by those of Ahmednagar and Sholapur, on the south by the Nira river, separating it from Satara and Phaltan, and on the west by the Bhor state and Sahyadri Hills. Toward the west the country is extremely undulating. To the east it opens out into plains; but a considerable area is now being put under forest. Poona is watered by many streams, which, rising in the Sahyadra range, flow eastward until they join the Bhima, a river which intersects the district from north to south. The Great Indian Peninsula Railway runs through it,

and affords an outlet for its produce through the Bhor Ghat to Bombay. The Khadakvasla Canal, about ten miles southwest of Poona, which it supplies with water, is one of its most important works. The climate is dry and invigorating; the average annual rainfall is about thirty inches.

The population of the district in 1881 was 900,621 (455,101 males and 445,520 females), of whom 834,843 were Hindus, 42,036 Mohammedans, 1,574 Parsis, 10,880 Jains, 9,500 Christians, and 1,788 of other religions. The only towns with a population exceeding 10,000 are POONA (*q. v.*), Poona cantonment (30,129), and Junnar (10,373).

POONA, the chief town of the above district, is situated in a treeless plain about 2,000 feet above the sea, and overlooked by the Ghats, which rise 1,000 feet above the plain.

**POOR LAWS.** Without embarking on an inquiry as to the causes of pauperism or the primary right of any persons to have their wants, however pressing, met by the state, it is sufficient to say that in Great Britain "there is no man so indigent or wretched but he may demand a supply sufficient for all the necessaries of life from the more opulent part of the community, by means of the several statutes enacted for the relief of the poor" (Blackstone). Moreover, apart from statute, by the common law of England the poor were sustainable "by parsons, rectors of the church, and the parishioners, so that none of them die for default of sustenance."

This has reference to the fact that in early days the poor of England were supported by monks, donations of land having been made the latter, conditioned upon their contributing to the support of the poor and aged. The reciprocal relation thus established continued until the reign of Henry VIII., when the monasteries were abolished, their property given to the nobles and a vast landed interest vested in a class of people who were not charged with responsibilities incident to the support of the poor and aged. The effect of this action on the part of the crown was to greatly increase the amount of vagabondage and the number of indigent, for whose relief it was necessary to make provision, which finally became so onerous as to call for immediate and defined regulation. Such was had, and in many instances the statutes specially directed against vagrancy provided for a system of compulsory labor. During the reign of Edward VI. further legislation intended to restrain vagrancy was adopted providing for the return to their own country of foreign mendicants, and authorizing any person to take children carried about by the impotent and lame, and bring them up to honest labor till such child, if a woman, attained the age of fifteen, or was married, and if a man child until eighteen, if the master so long lived. In Elizabeth's reign legislation took a more vigorous turn and penalties were provided for persons above fourteen being rogues, vagabonds, or sturdy beggars, embracing imprisonment, whipping, burning the gristle of the right ear through with a hot-iron, etc.

In 1597 considerable progress was made toward establishing a system of poor-laws, providing for the appointment of overseers of the poor from among the church-wardens of every parish in the kingdom, who with four substantial householders should attend to the care of children of parents or persons unable to support them, also of those having no means of maintenance. Competent sums for these purposes and for the procurement of a stock of flax, hemp, wool, etc., to set the poor to work were derived by a weekly tax levied upon the inhabitants of the parish according to the ability of those against whom the levy was made: the pay-

ment of which was enforced by warrants of distress. This legislation, however, was not altogether attended with favorable results, and subsequent efforts during the reigns of James I., Charles II., etc., were directed to remedying the existing evil, additional provisions being enacted. Finally, the accumulated evils of the working of the poor laws led to the passage of *Gilbert's Act* in the reign of George III. which did away with many of the evils arising from previous enactments. During the same reign so burdensome became the poor-rate, that a system of out-door relief was adopted. Still the poor-rate continued to increase until 1818, when it began to diminish. To abolish the evils which investigation of the system developed, alterations were proposed in the laws and found expression in the Poor Law Amendment Act of 1834. The objects of the act were to raise the bulk of the community from the idleness into which the maladministration of the laws for their relief had thrown them, also to arrest the progress and ultimately diminish the amount of pressure on the owners of lands and houses.

Its effect was to reduce the amount of money expended in the relief of the poor but the act had to contend with obstacles and both Houses of Parliament were inundated with petitions against the system; but by 1837 it was generally accepted—and has since obtained—notwithstanding, that from the date of its adoption, the indoor relief provided for in the amendment has been the source of a constant struggle between the pauper class and the administrators of the law. The poor are now sent to the workhouses, which are supported by the poor-rate, a tax levied and expended by the overseers of the poor, and district asylums are in some places provided for the destitute not charged with any offense under the Vagrant Act. A child found begging may be sent to a certified industrial school, and while a school is being found justices may order detention for a week in the poor-house. The number of paupers now in receipt of relief in England and Wales approaches 800,000 and the annual cost approximates \$50,000,000.

The second report of the commissioners showed that of 110 unions which had been in operation more than a year, the saving in 43 of the largest was 46 per cent.; in 24 of the smallest unions the rate of saving was not more than 29 per cent.; and in 26 unions of intermediate size a saving of 42 per cent. was effected. Even in many parishes not then included in a union the wide promulgation of the principles of the amending act gave an impulse to improvement in the administration of the poor laws, which was attended by a marked reduction in the expenditure.

The criminal liability of parents and others *in loco parentis* to provide sustenance has been considered. The purely civil liability for necessaries under implied contracts is of course outside the scope of this article, but there is an express liability created by the poor laws. The liability of the father and grandfather and the mother and grandmother, and the children of poor persons under the statute of Elizabeth has been set out in an earlier part of this article. The statute extends only to natural relations.

As to poor laws in other countries, the articles devoted to those countries must be referred to. It is to be observed that legal provision is made for paupers in every part of the United States. The poor-law system which obtains in the different States in its general features is similar to that which prevails in England so far as regards the mode of raising the fund (*viz.*, by way of rate) and the class of people to whom relief is afforded. Each district (commonly a town, county, or city) provides for its own poor. In some of the States paupers

having no legal settlement are relieved by the State Government (1834). The prevalence of slavery in the Southern States until its abolition modified the system of relief. The searching inquiry into the administration of the poor laws in 1832-34 was not confined to the United Kingdom or to the States of America. Returns were obtained through the foreign ministers, and the result as to Europe is thus comprehensively stated by Nassau Senior in 1835:—"A legal claim to relief exists in Norway, Sweden, Russia, Denmark, Mecklenburg, Prussia, Würtemberg, Bavaria, and the canton of Bern, but does not exist in the Hanseatic towns, Holland, Belgium, France, Portugal, the Sardinian states, Frankfort, Venice, Greece, or Turkey." In the north of Europe the great peculiarity of the system is stated to be "the custom of affording relief by quartering the paupers on the landholders in the country and on householders in the towns." Senior arrived at the conclusion that, in those portions of the Continent in which the English principle of acknowledging in every person a right to be supported by the public existed, the compulsory relief had not, except perhaps in the canton of Bern, produced evils resembling in either intensity or extent those then experienced in the United Kingdom, and that in the majority of the nations that had adopted it the existing system appeared to work well. The poor laws of Russia, however, if they could be called poor laws, were merely parts of her system of slavery. The absence of poor laws in France, and the charitable establishments, many of them under state management, are noticed in the article FRANCE. Senior arrived at the conclusion that the comprehensive and discriminate system of public relief established in France in relation to these institutions was not so complete as in Belgium. For the poor there see BELGIUM, where benevolent and charitable institutions and hospitals, charity workshops and depots of mendicity or workhouses, and the *bureaux de bienfaisance* are noticed. The power of expulsion *pour vagabondage* exercised as a matter of daily routine in France operates as a restraint on vagancy, although having a wider range than the English vagrancy laws. The majority of the indigent who received public relief in France are foreigners.

The beneficent, including eleemosynary, institutions of united Italy are treated of under that head in ITALY.

The "pauper colonies" of Holland, established in the first quarter of the present century (the first idea of which seems to have been derived from a colony of Chinese in Java), attracted public attention in England and Europe generally about the time the provision for the poor and the administration of the poor laws were under consideration, immediately before their reform in 1834. The object of the institutions in Holland was to remove those persons who were a burden to society to the poorest waste lands, where under judicious regulations they were enabled to the number of many thousands to provide for their own subsistence.

POPAYAN, a city of the republic of Colombia, capital of the state of Cauca, is situated in 2° 26' N. latitude and 76° 49' W. longitude, at a height of 5,948 feet (E. André, 1876), on the banks of one of the head streams of the Cauca in the great plain in the heart of the cordilleras.

POPE is the name given in England to a small freshwater perch (*Acerina cernua*), also called RUFFE, which is generally distributed in the rivers of central Europe and common in most fresh waters of England. In general structure, shape, and habits the pope resembles much the common perch, but rarely exceeds a length of seven inches, and differs in its coloration,

which is olive-brown with irregular darker spots on the body and numerous blackish dots on the dorsal and caudal fins. It is most destructive to the fry of other fish, but in many parts of the country is esteemed as food.

POPE, ALEXANDER, the most famous poet of his century, was born in London, England, on May 22, 1688, but his father's retirement to Binfield took place soon after his birth. The delicate child's book education was desultory and irregular. His father's religion excluded him from the public schools, if there was no other impediment to his being sent there. Before he was twelve he got a smattering of Latin and Greek from various masters, from a priest in Hampshire, from a schoolmaster at Twyford near Winchester, from another in Marylebone, from a third at Hyde Park Corner, and finally from another priest at home.

Nothing of Pope's was printed till 1709, when he was twenty-one. But before he was introduced to Walsh, which was in 1705, he had already written the first draft of his "Pastorals," a subject on which Walsh was an authority, having written the preface to Dryden's translation of Virgil's *Eclogues*. Trumbull's influence was earlier and more extensive. For him may fairly be claimed the credit of having been Pope's schoolmaster in poetry. It was he who turned Pope's attention to the French critics, out of the study of whom grew the *Essay on Criticism*; he suggested the subject of *Windsor Forest*, and he started the idea of translating Homer. When Trumbull first saw the precocious boy, he was hard at work on his great epic.

Precocious Pope was, but he was also industrious; and he spent some eight or nine years in arduous and enthusiastic discipline, reading, studying, experimenting, taking the advice of some and laughing in his sleeve at the advice of others, "poetry his only business," he said, "and idleness his only pleasure," before anything of his appeared in print. His first publication was his "Pastorals." Tonson the bookseller had heard these pastorals highly spoken of, and he sent a polite note to Pope asking that he might have them for one of his miscellanies. They appeared accordingly in May, 1709, at the end of a volume containing contributions from Philips, Sheffield, Garth, and Rowe, besides Pope's version of Chaucer's *Merchant's Tale*.

Pope's next publication was the *Essay on Criticism*. The youthful author said with delicious loftiness that he did not expect the sale to be quick because "not one gentleman in sixty, even of liberal education, could understand it." But he misjudged his audience. The town was fairly dazzled by it—such learning, such comprehensiveness of judgment, such felicity of expression, was indeed a marvel in one so young.

The *Rape of the Lock* in its first form appeared in 1712 in *Linton's Miscellany*; the "machinery" of sylphs and gnomes was an afterthought, and the poem was republished as we now have it early in 1714. This was his first poem written on an inspiration from real life, from nature and not from books. A gentleman had in a frolic surreptitiously cut off a lock of a young lady's hair, and the liberty had been resented; Pope heard the story from his friend Caryll, who suggested that it might be a subject for a mock-heroic poem like Boileau's *Lutrin*. Pope caught at the hint; the mock-heroic treatment of the petty frivolities of fashionable life just suited his freakish sprightliness of wit, and his studies of the grand epic at the time put him in excellent vein. The *Rape of the Lock* is almost universally admitted to be his masterpiece. English critics from his own time to the present have competed in lauding its airiness, its ingenuity, its exquisite finish.

In the interval between the first and the enlarged edition of the *Rape of the Lock*, Pope gave the finish-

ing touches to his *Windsor Forest*, and published it in March, 1713, with a flattering dedication to the secretary of war and an opportune allusion to the peace of Utrecht. This was a nearer approach to taking a political side than Pope had yet made. His principle had been to keep clear of politics, and not to attach himself to any of the sets into which literary men were divided by party. Although inclined to the Jacobite party by his religion, he was on friendly terms with the Whig coterie, so friendly indeed as to offend some of his co-religionists. When Pope showed a leaning to the Tories in *Windsor Forest*, the coterie, so far from helping him, made insidious war on him—not open war, but underhand war. Within a few weeks of the publication of the poem, and when it was the talk of the town, there began to appear in the *Guardian* a series of articles on "Pastorals." But the sting of the articles did not lie in the truth of the oblique criticisms. "The pastorals of Mr. Philips," published four years before, were again trotted out. Here was a true pastoral poet, the eldest born of Spenser, the worthy successor of Theocritus and Virgil!

Pope took an amusing revenge, which turned the laugh against his assailants. He sent Steele an anonymous paper in continuation of the articles in the *Guardian* on pastoral poetry, reviewing the poems of Mr. Pope by the light of the principles laid down. Ostensibly Pope was censured for breaking the rules, and Philips praised for conforming to them, quotations being given from both. The quotations were sufficient to dispose of the pretensions of poor Philips, and Pope did not choose his own worst passages, accusing himself of actually deviating sometimes into poetry. Although the *Guardian's* principles were also brought into ridicule by burlesque exemplifications of them after the manner of Gay's *Shepherd's Week*, Steele, misled by the opening sentences, was at first unwilling to print what appeared to be a direct attack on Pope and asked Pope's consent to the publication, which was graciously granted.

The relations between Pope and his Whig friends were further strained by one or two little incidents about the same time, and the estrangement was completed in connection with Pope's translation of Homer. This enterprise was definitively undertaken in 1713, and was Pope's chief employment for twelve years. The new pieces in the miscellanies published in 1717, his *Elegy on an Unfortunate Lady* and his *Eleoisa to Abelard*, were probably written some years before their publication. The *Iliad* was delivered to the subscribers in installments in 1715, 1717, 1718, and 1720. For the translation of the *Odyssey* he took Fenton and Broome as coadjutors, who between them translated twelve out of the twenty-four books. It was completed in 1725. The profitableness of the work was Pope's chief temptation to undertake it. He cleared more than \$40,000 by the two translations, after deducting all payments to coadjutors—a much larger sum than had ever been received by an English author before. Pope, with his economical habits, was rendered independent by it, and enabled to live nearer London.

The year 1725 may be taken as the beginning of the third period of Pope's career, when he made his fame as a moralist and a satirist. In point of sheer literary power the works then composed are his greatest, but the subjects chosen belong essentially to the lower levels of poetry.

The *Dunciad* (1728) was the first work of the new period.

The *Essay on Man* (1732-34) was intimately connected with passing controversies. It belongs to the same intellectual movement with Butler's *Analogy*—the

effort of the eighteenth century to put religion on a rational basis. But Pope was not a thinker like Butler. The subject was suggested to him by Bolingbroke, who is said also to have furnished most of the arguments. Pope's contribution to the controversy consisted in brilliant epigram and illustration. In this didactic work, as in his *Essay on Criticism*, he put together on a sufficiently simple plan a series of happy sayings, separately elaborated, picking up the thoughts as he found them in miscellaneous reading and conversation, and trying only to fit them with perfect expression.

Pope died on May 30, 1744, and was buried in the church of Twickenham.

POPEDOM. Both the ecclesiastical and the temporal authority formerly exercised and still claimed by the popes of Rome profess to be of divine appointment, appealing in the first place to the language of the New Testament, and in the next to the tradition of the church, handed down as it is asserted, in unbroken continuity from apostolic times to the present age. According to the theory thus put forth, Peter the apostle was indicated by Christ Himself as superior to the rest of the twelve in faith and spiritual discernment, and as the one of the number whom it was his design to invest with special preëminence. In like manner, the church itself which Peter was afterward to found and to preside over was predestined to a like superiority among other churches, while his personal superiority was to be vested in perpetuity in his successors. In conformity with this divine design Peter, accompanied by Paul, went to Rome after Christ's death, and founded there a church over which he presided as its bishop for twenty-five years—from the first year of the reign of Claudius, 41 A.D. to 67 A.D.—eventually suffering martyrdom in the same year and on the same day as St. Paul, in the persecution under Nero. And, if we accept the records preserved in the Roman Church, we shall believe that St. Peter's successors, so long as Christianity was the object of state persecution, continued heroically to encounter the same glorious fate, the distinction of martyrdom being assigned in the Roman calendar to all but two of the bishops of Rome from Linus to Eusebius.

The question whether or no St. Peter was designed for preëminence among the apostles resolves itself, it is evident, into one of New Testament criticism; but from the time of Origen, who visited Rome early in the third century, when the theory first began to be put forward, there has always been a certain section in the church who have distinctly repudiated the affirmative assumption. Next, as regards the evidence for St. Peter's presence in Rome and lengthened labors there, as the head of a Christian congregation, it is maintained by the great majority of Protestant scholars that there is no proof that he was ever in Rome at all.

On the other hand, it is urged that, as no known tradition assigns the martyrdom of Peter to any other place than Rome, every allusion to that event is implicitly an argument for his visit to the capital; and, generally speaking, it may be said that the most recent and authoritative research seems to point to the conclusion that he both visited Rome and taught there, but that his labors were carried on in a spirit of rivalry, not to say antagonism, to those of Paul, being bestowed exclusively on a Judaizing church, while those of his fellow-apostle were devoted to the Gentile community.

We hear very little of the Christian church during the first two centuries of its existence in Rome, though Hegesippus, who made a list of the bishops of the see, places Peter and Paul at the head. The evidence obtainable, however, shows conclusively that in the second and third centuries the church of Rome began

to put forth unprecedented claims to superiority among churches, and that later we find the bishop of Rome assuming the more extended authority of a metropolitan and the authority of a patriarch.

But no external event exercised a more potent influence on the early history of the Roman Church than the removal of the seat of imperial power to Constantinople (330). For more than a century from that event it was not a little doubtful whether the patriarch of "Nova Roma" might not succeed in asserting an authority to which even the Western pontiff might be compelled to defer. It became accordingly an object of primary importance with the latter to dissociate as far as possible in the mind of Christendom the notion of an ecclesiastical supremacy derived, like that of Constantinople, mainly from the political importance of the capital from the conception of that supremacy which he himself claimed as the representative of the inalienable authority and privileges conferred on St. Peter and his successors. For such a policy an additional motive was created by the predilection shown by Constantine for his new capital and the conviction which he is said to have entertained that the days of ancient Rome were numbered. From that time it was the key-note to the utterances of the Roman primate that his supremacy, as tradition from apostolic times, could never depart from him and his successors, and that, as representing the authority of the two chief apostles, it had claims upon the obedience and reverence of the whole Christian church such as no other *apostolica sedes* could produce. To the ultimate assertion of these pretensions the long and fierce struggle carried on between the followers of Arius and the supporters of orthodoxy materially contributed. The appeal to the arbitration of Rome preferred both by Athanasius and by the Arian party, placed JULIUS I. (337-352) in the proud position of the recognized protector of the orthodox faith. In the year 339 Athanasius himself visited the Western capital and resided there for three years. His presence and exhortation confirmed the Roman pontiff still further in his policy; and from this time we perceive the see of Rome assuming, more distinctly than before, the right to define doctrine and the function of maintaining the true standard of faith amid the numerous heresies that were then troubling the whole church. While Constantinople was conspicuous by its attachment to Arianism, Rome appeared as the champion of the orthodox belief.

During the bishopric of LIBERIUS (352-366) we meet with the first instance of a schism in the Roman Church, and, in the person of Felix, with the first representative of that maintenance of a rival claim to the see which in later history assumed such importance in connection with the antipopes.

At the council of Nicæa (325), one of the canons enacted (the sixth) had already assigned to the three sees, or patriarchates, of Rome, Alexandria, and Antioch, their honorary rank in the order of their enumeration. In the year 381 the council of Constantinople was convened; it was an assembly in which the Western Church took no share, and its notable third canon was accordingly enacted without opposition. By this it was declared that the bishop of Constantinople, or Nova Roma, was entitled, although the representative of a non-apostolic see, to the next place after Rome, and consequently to precedence of the older and apostolic sees of Alexandria and Antioch.

With the division of the empire in the year 395 the question of the Roman precedence of Constantinople was left for a time in abeyance; but in the West the authority of the bishop of Rome became more and more firmly established. In the following century the

general conditions under which he was called upon to act became so materially modified as to constitute a new period in the history of our subject. The characters of the men who filled the papal chair during this century, most of them of exemplary life, some of commanding genius, would alone suffice to constitute it a memorable era.

The successor of Boniface was CÆLESTINUS I. (422-432). The evidence afforded by the events of his pontificate is somewhat conflicting in character. On the one hand, we find the churches of Africa putting forward their latest recorded protest against the Roman pretensions, adducing the sixth canon of the council of Nicæa in support of their protest; on the other hand, the success with which Cælestinus intervened in Illyricum, and again in connection with the sees of Narbonne and Vienne, proves that the papal jurisdiction was being accepted with increasing deference in other parts of the empire.

Barbaric invasion, although resulting in the overthrow of many of the institutions of civilization, and in widespread suffering and social deterioration, served but to enhance the influence and importance of the Roman see. The apparent fulfillment of prophecy, pagan as well as Christian, when the city was taken and sacked by Alaric (410) seemed to complete the effacement of the temporal power in Rome. Neither the Western emperors nor the Gothic conquerors held their court in the ancient capital, where the pope was now at once the most important and conspicuous authority. In the African provinces, the demoralization occasioned by the fierce controversies and dissensions concerning Pelagianism and Donatism compelled the Catholic communities to exchange their former attitude of haughty independence for one of suppliant appeal, and to solicit the intervention and counsel which they had before rejected. Such was the aspect of affairs in the west when LEO THE GREAT (440-461)—by some regarded as the true founder of the mediæval popedom—succeeded to the primacy.

During the Gothic rule in Italy (493-553), its representatives manifested the utmost tolerance in relation to religious questions, and showed little disposition to impose any restraints on the policy of the popes, although each monarch, by virtue of his title of "king of the Romans," claimed the right to veto any election to the papal chair.

The substitution of the rule of the Greek emperors for that of the Gothic monarchs was inimical in almost every respect to the independence and reputation of the popedom. For a short interval before Justinian landed in Italy, AGAPETUS (535-536), appearing as the emissary of Theodotus to the Eastern court, assumed a bearing which inspired the emperor himself with respect. But, after Belisarius entered Rome and the city had been reduced to subjection, the pontiff was seen to be the mere vassal of the emperor, and not only of the emperor but of the courtesan on the imperial throne. The deposition of SILVERIUS (536-540), and his mysterious fate at Pandataria, together with the elevation of VIGILIUS (540-555), the nominee of the abandoned Theodora and her pliant slave, completed the degradation of the Roman see. So sinister, indeed, had become the relations between the Roman bishop and the Eastern court that PELAGIUS I. (555-560) is said to have besought Narses to send him to prison rather than to Constantinople.

In the year 568 the Lombards invaded Italy. Like the Goths they became converts to Arianism; but they were also far less civilized, and looked with little respect on Roman institutions and Roman habits of thought, while their arrogance, faithlessness, and cruelty gained for them the special detestation of the Roman see. From the time of Constantine the Great the church had

possessed the right of acquiring landed property by bequests from individuals, and the Roman see had thus become greatly enriched. Some of its possessions lay far beyond the confines of Italy.

Under GREGORY I. (590-604), commonly known as "the Great," this territorial wealth became largely augmented; and, although, amid the universal demoralization and widespread misery of his age, he professed to discern the unmistakable signs of the approaching end of the world, the efficient administration of the estates of the church was an object of his unceasing solicitude. Through his influence with Theudelinda, the wife of Agilulf, the Lombard monarch, he not only succeeded in averting another siege of Rome, but he also managed to bring about the establishment of amicable relations between the Lombards and the Roman population. With the Byzantine court he did his best to maintain a friendly intercourse, although in his zeal on behalf of monasticism he withdrew his *apocrisiarius* from Constantinople, when the emperor Maurice forbade his soldiers to assume the monastic life. The personal qualities and virtues of Gregory are thrown into stronger relief by the comparative insignificance of his successors in the seventh century, whose tenure of office was, for the most part, singularly brief and inglorious.

But while menaced and dishonored in Italy, the papal power was making important advances in the west. In England the resistance offered by the representatives of the British Church was soon overcome, and from the time of the council of Whitby (664) the teachings and traditions of Gregory, as enforced by Augustine, Theodorus, Wilfrid, and others, found ready acceptance. The humanizing influences which these representatives of the Roman culture diffused around them exercised a potent spell over the minds and wills of the English population. Monasteries were founded; cathedrals rose, each with its school of instruction for the young, and its charity for the needy; and a spirit of filial though far from slavish devotion to Rome was everywhere created. In Frankland, however, the Merovingian kings and the populations of Neustria and Austrasia exhibited a different spirit, and the civil power showed no disposition to welcome foreign interference even in connection with ecclesiastical institutions.

While bonds of union were being created in the West, theological differences were exercising a very different though not less important influence in the East. All the dioceses within the empire where the Roman pontiff had hitherto claimed obedience—Calabria, Sicily, and Illyricum—were absolved from their ecclesiastical allegiance, and the revenues from their rich "patrimones," which had before flowed into the papal treasury, were confiscated. Under these circumstances a compact with the Lombards, who had by this time become converts from Arianism to the Catholic faith, would have seemed the obvious policy on the part of Rome, had not the political aims of the former stood in the way. In his extremity, therefore, the Roman pontiff turned to the Frank, untainted by the heresy of Arianism, and already, as the result of the teaching of Boniface, disposed to assent to any claims of the papacy which did not involve the diminution of his own prerogatives or the restoration of alienated revenues. In the year 752 Pepin le Bref assumed the dignity and title of "king of the Franks." In the following year, during the pontificate of STEPHEN III. (753-757) Aistulf, the king of the Lombards, invaded the duchy of Rome with the avowed purpose of adding the capital itself to his dominions. He seized Ravenna and the exarchate; and Stephen, finding remonstrance and entreaty alike unavailing, fled for protection to the Frankish territory and was received by King Pepin with every mark of sympathy and pro-

found respect. Within a short time after, Pepin invaded the Lombard domain and wrested from its monarch an extensive territory, embracing Ravenna and the Pentapolis; and at a council held at Cuiercy, in the same year (754), he handed over this territory to Stephen, "to be held and enjoyed by the pontiffs of the apostolic see forever." Such appears to be the real origin of that "donatio," or gift of territory (referred back, by the invention of after times, to the age of Constantine the Great), which constituted the pope a temporal ruler over what were subsequently known as the "States of the Church."

It will thus be seen that, toward the close of the eighth century, the germs of the chief papal claims were already in existence, and only needed for their full development those favoring conditions which, with the lapse of time, were certain to occur, and for which, from its peculiar character as an institution, the popedom itself was so well able to watch and wait.

While the Western primate was growing in dignity, wealth and influence, those ecclesiastical potentates who had once claimed an equal or coördinate rank, with the sole exception of the patriarch of Constantinople, altogether ceased to exist. The Saracen conquests in Syria and Egypt had involved the loss of Jerusalem to Christendom (637), and this had been speedily followed by the extinction of the churches of Antioch and Jerusalem. The patriarch of Constantinople represented, accordingly, the only spiritual power which could compare with that of Rome; but while *he* continued to be the submissive vassal of the Byzantine court, that court was compelled to see the once no less submissive pontiff of Rome changed into a successful invader of its Italian possessions and into a determined repudiator of its articles of faith. In the year 800 Charles the Great received at the hands of Leo III., in Rome, the imperial crown, and the titles of "emperor" and "Augustus." The assumption by Charles of the imperial dignity and the consequent rise of the "Holy Roman Empire" were events on the importance of which it is unnecessary here to dwell. By the theory thus established, a temporal supremacy or "condominium" was created corresponding to the spiritual supremacy of the popedom, and the Roman emperor claimed from all other rulers in Christendom an allegiance corresponding to that which the Roman pontiff claimed from all other ecclesiastical potentates. The imperial authority and papal authority were thus complementary the one to the other. The emperor claimed to confirm the papal elections; the pope claimed to confer the imperial crown upon the emperor. During the three centuries that followed upon the creation of the Holy Roman Empire—from the year 800, that is to say, down to the Concordat of Worms (1122)—it was chiefly the former contingency that seemed the more probable. During the pontificate of NICHOLAS I. (858-867), however, the papacy again made a perceptible advance. Nicholas intervened with signal effect in the disputed succession to the Eastern patriarchate, and asserted more distinctly than it had ever been asserted before the theory of the Roman supremacy. He dared, also, to forbid the divorce of Lothair (the powerful monarch of the vast territory which stretched from the German Ocean to the Mediterranean) from his wife Theutberga, thereby establishing an important precedent for papal interference in questions of private morality. And, finally, in his arduous struggle with Hincmar, metropolitan of Rheims, he gained an important victory over the powerful prelates on the Rhine in the question of appeal. It must, however, be admitted that this last advantage was gained only by the use of forged documents—the pseudo-Isodorian decretals.

This collection embodied a complete series of letters

purporting to have been written by the popes of Rome from the time of Clemens Romanus down to that with which the collection by Dionysius Exiguus commences, thus filling up the entire blank, and affording among other data ample precedent for appeals to Rome of the kind against which Hincmar had protested. When some doubt was raised as to the genuineness of the collection, Nicholas did not scruple to assure Hincmar that the originals had been lying from time immemorial in the Roman archives. These false decretals have been described as the source to which we may trace that great revolution in the relations of church and state which now gradually supervened. The pontificate of HADRIAN II. (867-872) is especially notable for the application which he sought to make of some of the principles which they laid down. When Lothair, king of Lotharingia, died without heirs, Hadrian claimed the right to bestow the crown on the emperor Louis. Christian Europe, however, was not as yet prepared to accept this bold extension of the papal prerogatives. The kingdom was seized by Charles the Bald, and Hadrian was reminded in a manifesto drawn up by the bishops of Germany that he could not at once be "universal pope and universal king." But the weakness of Charles' claim was undeniable, and we accordingly find him, five years later, consenting to receive the imperial crown at the hands of John VIII. (872-882), not as his heritage, but as a gift from the pope. During the dark and stormy period that intervened between the death of Charles the Bald and the coronation of Otto the Great at Rome (962), the Carolingian empire broke up, and the results that followed were disastrous both for the popedom and for the empire. The Saracens occupied southern Italy; the Normans poured in successive waves over Frankland; the ravages of the Magyars were yet wider spread and not less terrible. Alike in the civil and the ecclesiastical world the elements of strife and insubordination were let loose; and, while the feudal lords defied the authority of their king, and the power of the French monarch sank to the lowest ebb, the bishops in like manner forsook their allegiance to the Roman pontiff. The archbishops of Ravenna and Milan appeared indeed as his rivals, and the political influence which they commanded more than equaled his: the tenth century has been designated "the noon-day of episcopal independence." The history of the curia at this period is marked by the deepest moral degradation and the most revolting scenes. The papal jurisdiction was limited almost entirely to the capital itself, and even the succession of the pontiffs themselves is with difficulty to be traced. The office, indeed, was sometimes disposed of by the influence of immoral women. The pontificate of STEPHEN VI. (or VII., 896-897) is remembered only for the inhuman manner in which he treated the lifeless corpse of his predecessor Formosus; that of SERGIUS III. (904-911) for the virtual reign of Theodora and her daughter, the two most notorious courtesans of the age; STEPHEN IX. (939-942) was disfigured for life by the brutal treatment which he received at the hands of the Roman mob.

With the restoration of law and order the ancient regard for the popedom regained its hold on the minds of men. Under the guidance of the celebrated Gerbert, the youthful enthusiasm of Otto III. aimed at making Rome once more the center of political dominion and the seat of the imperial power. Hugh Capet, too, professed himself the "defender of the church." The French monarchs were glad, however, to purchase the support of the papacy to aid them in their struggle with the rebellious chieftains by whom the very existence of their authority was menaced, and, until the action of the papal legates again roused the spirit of national resist-

ance, the Capetian dynasty was loyal to the Roman see. That it was so was in no small measure due to the virtues and abilities of GREGORY V. (996-999), the kinsman of Otto III., a young man of considerable attainments, austere morality, and great energy of purpose, who succeeded to the papal chair at the age of twenty-four. He was succeeded by Gerbert, Pope SILVESTER II. (999-1003), from whom Otto III. derived, as already stated, his ideas of Italian and papal regeneration.

With the disappearance of these two eminent men the popedom relapsed into its former degradation. The feudal nobility regained their ascendancy, and the popes became as completely the instruments of their will as they had once been of that of the Eastern emperor. A leading faction among this nobility was that of the counts of Tusculum, and for nearly half a century the popedom was a mere apanage in their family. As if to mark their contempt for the office, they carried the election of Theophylact, the son of Count Alberic, a lad scarcely twelve years of age, to the office. BENEDICT IX. (1033-1045), such was the title given him, soon threw off even the external decencies of his office, and his pontificate was disgraced by every conceivable excess. As he grew to manhood his rule, in conjunction with that of his brother, who was appointed the patrician or prefect of the city, resembled that of two captains of banditti. The scandal attaching to his administration culminated when it was known that, in order to win the hand of a lady for whom he had conceived a passion, he had sold the pontifical office itself to another member of the Tusculan house, John, the arch-presbyter, who took the name of GREGORY VI. (1045-46). Prior, however, to his purchase of the pontifical office, the citizens of Rome, weary of the tyranny and extortions of Benedict, had assembled of their own accord and elected another pope, John, bishop of Sabina, who took the name of SILVESTER III. (rival pope, 1044-46). In the meantime BENEDICT had been brought back to Rome by his powerful kinsmen, and now reclaimed the sacred office. For a brief period, therefore, there were to be seen three rival popes, each denouncing the others' pretensions and combating them by armed force. The degeneracy of the church at this period would seem to have been in some degree compensated by the reform of the monasteries, and from the great abbey of Cluny in Burgundy there now proceeded a line of German popes, who in a great measure restored the dignity and reputation of their office. But their tenure of office was singularly brief. Clement II. died before the close of the year of his election. DAMASUS II., his successor, held the office only twenty-three days. LEO IX., who succeeded, held it for the exceptionally lengthened period of more than five years (1049-54). This pontiff, although a kinsman and nominee of the emperor, refused to ascend the throne until his election had been ratified by the voice of the clergy and the people, and his administration of the office presented the greatest possible contrast to that of a Benedict IX. or a Sergius III. In more than one respect it constitutes a crisis in the history of the popedom. But, although his own career terminated ignominiously, the services rendered by Leo to the cause of Roman Catholicism were great and permanent; and of his different measures none contributed more effectually to the stability of his see than the formation of the College of Cardinals. According to Anselm of Lucca, it was during the pontificate of Leo, at the synod of Rheims above referred to, that the title of "apostolic bishop" (*Apostolicus*) was first declared to belong to the pope of Rome exclusively. The short pontificate of NICHOLAS II. (1059-61) is memorable chiefly for the fundamental change then introduced in the method of electing to the papal office.

The manner in which it struck at the imperial influence was soon made apparent in the choice of Nicholas' successor, the line of German popes being broken through by the election of Anselm, bishop of Lucca, who ascended the pontifical throne as ALEXANDER II. (1061-73) without having received the sanction of the emperor.

The first crusade, which may be looked upon as generated by Gregory's example and a reflex of the policy which led him to sanction the expedition of William of Normandy against England, materially favored papal pretensions. It was proclaimed as a religious war, and it was as a mode of penance that the Norman and Latin warriors were enjoined to gratify their ruling passions of plunder and adventure. It was impossible that the excommunicated emperor Henry IV. should place himself at the head of such an enterprise, and it was accordingly by URBAN II. (1088-99) that the direction was assumed, and it was under his auspices that the first crusade was proclaimed at Clermont. As the movement gathered force, the prestige of the popedom was still further enhanced by the fact that the warriors who had before appeared in the field under the banners of the empire now did so as loyal sons of the church. The new orders of chivalry—the Knights of St. John, the Templars, the Teutonic Order—each bound by religious vows, received their commissions from the pontiff, were invested by him with the sword and the cross, and acknowledged no allegiance to the emperor.

Another movement at this period, which gave effective aid in the diffusion of the papal influence and authority, was the rise of the new religious orders—the Camaldules (*c.* 1012), the Cluniacs (*c.* 1048), the Carthusians (*c.* 1084), and the Cistercians (1098).

On the death of Urban, Cardinal Rainerius, a native of Tuscany, and a man of considerable learning and capacity, succeeded as PASCHAL II. (1099-1118). During the earlier years of his pontificate he is unfavorably distinguished by the manner in which he sanctioned, if he did not instigate, the cruel and unnatural revolt of the young prince Henry (afterward the emperor Henry V.) against his father. The later years of Paschal's rule seem mainly a record of the nemesis which overtook a policy dictated by the most heartless and selfish ambition. The short rule of CALIXTUS II. (1119-24), disgraced although it was by the savage revenge which he perpetrated on his rival the antipope Gregory VIII., was characterized by wise and resolute administration. But the chief event in the pontificate of Calixtus, and one which may be looked upon as inaugurating a new era in the history of our subject, was the Concordat of Worms in the year 1122.

During the pontificate of INNOCENT II. (1130-43) the importance of the new relations established with France is to be seen in the all-commanding influence of BERNARD OF CLAIRVAUX, the unswerving supporter of the papal claims, round whose career indeed the life of the Western Church for half a century may be said mainly to revolve.

Passing by the comparatively unimportant careers of the five popes whose names stand between those of Alexander and INNOCENT III. (1198-1216), we find ourselves at the stage which marks the culmination of the papal power. It was now that the papal power may be said to have effectually impressed its theory of sacerdotal government upon Europe; that the canon law, wherein that theory was elaborated, began to be taught in the universities which rose throughout Europe—Bologna, Padua, Paris, Orleans, Oxford, and Cambridge; that ecclesiastical discipline everywhere modeled itself on the practice of Rome; that the mendicant orders, especially those of St. Dominic and St.

Francis of Assisi, with their irregular enthusiasm, skillfully converted by Innocent into a widely-diffused, untiring, and devoted propaganda, aroused a new spirit alike in the universities and among the illiterate laity, and became a powerful instrument wherewith to coerce to obedience the episcopal order and the whole body of the secular clergy.

The chief interest attaching to the pontificates of HONORIUS III. (1216-27), GREGORY IX. (1227-41), and INNOCENT IV. (1243-54) arises from their connection with the policy and career of Frederick II. (emperor 1210-50). To the whole traditions of the popedom Frederick was especially obnoxious, menacing on the one hand its standard of doctrine by his reputed skepticism, and its newly acquired possessions on the other by his schemes for the revival of imperial supremacy in Italy. In the sequel his designs were baffled by the ability and resolution of Gregory and Innocent; and at the general council of Lyons (1245) Frederick was deposed from both his imperial and his kingly dignities, and his subjects declared to be absolved from their fidelity.

The policy of GREGORY X. (1271-76), a man of ability and moderation, deserves the praise of having apparently aimed at the general good of Christendom, so far, at least, as not incompatible with the overweening pretensions which he continued to uphold. After him came Celestine (1294) and Boniface (1294-1303). In the year 1305 CLEMENT V. (1305-14), an Aquitanian by birth, was elected after long contention to the pontificate. He was invested with the tiara at Lyons, and subsequently (1309) transferred his court from Rome to Avignon where, for a period of nearly seventy years, derisively styled the "Babylonian captivity," pope after pope held his court. When JOHN XXII. (1316-34) sought to interfere in a double election to the empire, the diet at Frankfort denounced his whole policy in terms that startled Europe by their boldness. Other causes contributed effectually to lower the papacy in the estimation of Europe. Clement V. concurred in the infamous devices by which Philip procured the suppression of the Order of the Templars. The traffic in benefices was now again developing into a gigantic scandal and abuse. Annates and Peter's pence were exacted with an insatiable rapacity. The wealth thus acquired was partly devoted toward extending the territorial possessions of the see; and Avignon and the county of Venaissin, purchased in 1348 from the crown of Provence, remained papal until the French Revolution. In Germany the deep discontent to which it gave rise formed an important contributing element in the cause which brought about the Reformation. In France the luxury and gross immorality of the court at Avignon, described in graphic and scathing language by Petrarch, are assigned by other contemporary writers as conducing largely to the corruption of morals throughout the realm.

The outbreak of the great schism struck no less deeply at those sentiments of veneration and deference which had been wont to gather round the Pontiff's chair. For a period of thirty-eight years, Christian Europe was scandalized by the contentions of two rival popes, the one holding his court at Rome, the other at Geneva, each hurling anathemas, excommunication, and the foulest accusations at the other. The potentates of Europe, in declaring themselves "in the obedience," as it was termed, of one or the other pontiff, were swayed almost entirely by political considerations, in which jealousy of France was the predominant sentiment. Italy, Germany, Bohemia, England, Flanders, Hungary, and Poland, all declared themselves in the obedience of the pope at Rome; Scotland, Savoy, Lorraine, declared themselves, along with France, in that

of the pope at Avignon. The Spanish kingdoms, which at first stood aloof, ultimately also decided, though from somewhat different motives, in favor of the latter pontiff. At last, at the commencement of the fifteenth century, an endeavor was made to prevail on both the reigning popes—Gregory XII. at Rome, Benedict XIII. at Avignon—to renounce their claims, with a view to the restoration of church union. The proposal was met by both popes with persistent and unscrupulous evasion. France, indignant at the subterfuges of Benedict, withdrew her support, and he accordingly retired to Perpignan. The cardinals attached to either court met together at Leghorn, and agreed to summon a general council, to meet at Pisa on March 25, 1409. The council enunciated the dogma of its own supremacy; it deposed the rival popes; it constituted the two separate bodies of cardinals a single conclave, and by this conclave a new pope, ALEXANDER V. (1409–10) was elected. Schemes of general ecclesiastical reform were discussed; and then after a four months' session the assembly adjourned, to resume, at an interval of three years, its yet more memorable deliberations at Constance. In the intervening time, Alexander V. died, not without strong suspicion of his having been removed by poison through the machinations of his successor, the notorious Balthasar Cossa, who assumed the title of JOHN XXIII. (1410–15), and took up his residence in Rome. It is with this pontiff that the gross abuse of indulgences is said to have first arisen. In the year 1416 the council of Constance met, amid the most sanguine expectations on the part of religious Europe, but it achieved practically nothing in the direction of church reform. It deposed John XXIII., for MARTIN V. (1417–31), burned John Huss, one of the first to assert the rights of the individual conscience in opposition to the prevailing hierarchical system; crushed the party of reform in the university of Paris, and banished their great leader. The council of Basel (1431–49), although it reënnunciated the principle of the superiority of a general council over the pope, found, when it sought to proceed to the more practical reforms, that it had assumed a task beyond its powers. Under the pretext of bringing about a reconciliation with the Eastern Church, and inviting its delegates to the deliberations of the council, EUGENIUS IV. (1431–47) proposed to transfer the place of meeting from Basel to some Italian city. The council, well knowing that such a measure would be fatal to its independence, refused its assent; Eugenius retaliated by dissolving the council; the council, by suspending the pope. Thereupon Eugenius summoned another council at Ferrara, which was afterward removed to Florence. The council of Basel, as a last resource, arrogated to itself the papal functions, and then proceeded to elect Amadeus, duke of Savoy, pope, with the title of FELIX V.

Although supported at first by the electors of Germany, it was, in the sequel, completely circumvented by the machinations of the able but unscrupulous Æneas Sylvius; and Pope Eugenius, at his death, seemed almost to have regained the allegiance of Christendom. Under NICHOLAS V. (1437–55), the work of reunion was brought to a completion. The council of Basel dissolved itself; and Felix V., laying aside his empty title and dignity, retired into Savoy, and was shortly after promoted to the rank of cardinal by Nicholas himself. The popedom was not destined ever again to witness the phenomenon of a rival pontiff; and no council since the council of Basel has ever ventured to assert its authority as superior to that of the Roman chair. The history of the popedom from this point (c. 1517) to the commencement of the council of Trent

(1545) will be found in the article on the REFORMATION.

The distinctive features of the doctrinal belief formulated by the council of Trent were mainly the outcome of Jesuit influences (see JESUITS); and, enforced as these tenets were by the terrorism of the Inquisition, the freedom of thought which during the revival of learning had passed comparatively unchallenged within the pale of the church was now effectually extinguished. But it must at the same time be admitted that, concurrently with this tendency to greater rigidity of doctrine, Roman Catholicism became characterized by far greater earnestness of religious teaching, displayed a remarkable activity in the cultivation of theological learning, and abolished, or sought to abolish, many glaring abuses. In this amendment, however, Rome had at first but small share. The Reformation movement within the church took its rise in Spain; and the purely political feeling which now constituted so considerable an element in the papal policy led each pontiff to regard with no little jealousy the overweening aggrandizement of the Spanish monarchy. Political considerations, in fact, sometimes prevailed over theological sympathies.

While with respect to the acceptance of doctrine, the losses of the sixteenth century were materially retrieved, the popedom was sinking rapidly in political importance. Its influence in the Italian peninsula dwindled to within the limits of the States of the Church; and the dynastic succession in Naples and Sicily, in Parma and Piacenza, underwent a total change without the curia or the pontifical interests being in any way consulted. The results of the War of the Spanish Succession disappointed in every way the hopes of Clement XI.; and his chagrin, when he found himself compelled to recognize the pretensions of the archduke Charles to the Spanish crown, was intense. The manner in which the conclusion of the war demonstrated the growing power of England was again a sinister omen for the permanence of the papal system. The conviction had long been growing up in the chief cities of the Continent that wherever the representatives of Jesuitism obtained a footing the cause of public order and domestic peace was placed in jeopardy. And, while, in distant lands, the vaunted successes of the Jesuit missionaries too often represented the diffusion of a merely nominal Christianity, their activity as traders was a constant source of irritation to the mercantile communities. The dissensions fomented by their agency at the Bourbon courts continued, however, to increase; and in 1769 the representatives of the chief Catholic powers at the Roman court received instructions to present each a formal demand that the Jesuit order should be secularized and abolished. Clement, who had vainly appealed to the empress Maria Theresa for the exertion of her influence, died suddenly of apoplexy on the day preceding that on which a consistory was to have been held for the purpose of giving effect to the demands of the powers. It was expressly with the view that he should carry out the task which his predecessor had sought to evade that Cardinal Ganganelli, CLEMENT XIV. (1769–74), was raised to the pontifical chair, chiefly through the Bourbon interest. At length he issued the brief *Dominus et Redemptor Noster*, for the suppression of the order, which he declared to have merited its ruin by "its restlessness of spirit and audacity of action." That the suppression of the Jesuit order had been attended with no little danger to the interests of the Roman see was clearly shown by the progress which liberal opinions now began to make in Germany.

On the accession of Joseph II., in 1780, to the throne of Austria, a new era commenced throughout the empire. Half the monasteries and friaries were suppressed. The bulls *Unigenitus* and *In Cena Domini*

were declared null and void within the limits of the empire. Toleration was extended to Protestant sects and to members of the Greek Church; and the introduction of papal dispensations within the Austrian dominions was declared unlawful, unless it could be shown that they were obtained without payment. A few years later the outbreak of the French Revolution seemed to portend for the popedom a like fate to that which had overtaken the Jesuit order. The demeanor of the National Assembly toward Pius himself had not been disrespectful; but the outrages on religious sentiment and decency itself perpetrated by the Convention drove the alarmed pontiff into the arms of Austria, with whom and the several reigning Italian princes he hastily concluded an offensive league. In the Italian campaign he met accordingly with no mercy at the hands of the Directory, and of Bonaparte acting as their representative. In 1797, first of all at Bologna and subsequently at Tolentino, the most vigorous conditions were imposed. Shortly after the peace of Tolentino (February, 1797) Pius was seized with an illness which seemed likely, at his advanced time of life, to prove fatal; and Napoleon, in anticipation of his death, gave instructions that no successor to the office should be elected, and that the papal government should be abolished. The sequel, however, having disappointed these expectations, the French ambassador in Rome proceeded through his agents to foment an insurrection—a design for which the demoralized condition of the capital afforded unusual facilities. The outbreak that ensued was immediately made the pretext for abolishing the existing rule, and in its place the Roman republic was proclaimed (February 15, 1798).

It was under the protection of a schismatic power—that of the emperor of Russia—that, after a lapse of eight months, PIUS VII. (1800–23) was elected pope at Venice. Pius VII., who, as Cardinal Chiaramonte, had at one time affected to approve of democratic principles, succeeded in gaining the good will of Bonaparte, and his accession was shortly followed by the concordat of 1801. Catholicism was reestablished as the state religion of France; but the confiscated property of the church was not restored, while the pretended reintroduction of the papal authority was deprived of all real validity by appending to the concordat certain “articles organiques” which effectually debarred the pontiff from the exercise of any real jurisdiction within the realm. In the concordat made with the Italian republic in 1803 the canon law was revived as the code whereby all questions not provided for in new articles were to be decided. Notwithstanding that he warmly resented the manner in which he had been duped, Pius was ultimately prevailed upon by the consummate address of Talleyrand to crown Napoleon as emperor in Paris. The immediate result of this imprudent act, as regarded the popedom, was the assertion of imperial rights in Rome itself on the part of the new emperor, and a demand that the pontiff should henceforth make common cause with him against the enemies of France. On his refusal Pius was made a prisoner, and the temporal sovereignty of the Roman see declared to be at an end. At Fontainebleau, in 1813, a new concordat was wrung from the infirm and aged pontiff (whose position and treatment strongly recalled those of his predecessor), and he was compelled to surrender almost the last remnants of his authority in France, and to disown all claim to rank as a temporal ruler. Pius VII. survived, however, not only to witness the overthrow of his oppressor, but to regain with the Restoration both his spiritual and temporal prerogatives. His policy, however, was thenceforth altogether reactionary. On the one hand he suppressed the circulation of the Scriptures in the vernacu-

lar, on the other, by a bull of August 7, 1814, he recalled the Jesuits, who since their dispersion in Latin Christendom had transferred the scene of their labors to Prussia and Russia. In other respects Pius' administration of his office was exemplary, and the same may be said of that of his successors, LEO XII. (1823–29), PIUS VIII. (1829–30), and GREGORY XVI. (1831–46.) The adversities arising out of the Revolution had proved a salutary discipline. Nepotism ceased to disgrace the papal court. Ecclesiasticism itself assumed another tone; its morality was pure; its zeal in the performance of its duties conspicuous. In France there arose a new school, known as the *Parti Prêtre*, the school of Chateaubriand, Lamennais, and Montalembert, which rejected the ancient Gallican claims and principles, and everywhere inculcated loyalty and submission to Rome as the first duty of the Catholic. In Germany neither the enlightened and strenuous efforts of Wessenberg nor the statesmanlike policy of Metternich could produce concerted action among the several states, which were accordingly eventually reduced to the necessity of each making separate terms with the curia on an independent basis. The result, in nearly all cases, was that, in reconstructing its ecclesiastical organization, and endeavoring at the same time to establish a certain *modus vivendi* in its diplomatic relations with Rome, each state was compelled to make concessions which largely favored the reestablishment of ultramontane institutions. The signal failure of Wessenberg, in his administration of the see of Constance, to reintroduce the principles advocated by “Febronius,” may be cited as one of the most notable instances of the defeat of liberal principles. In the Netherlands and in Silesia similar reactionary movements took place. In England the Catholic Emancipation Act (1829), although conceived in a spirit of conciliation, proved, in the embittered relations then existing with Ireland, of little avail, and in reality only imparted fresh strength to the machinations of the ultramontane party. The main facts in the history of the popedom from this period will be found under the head of PIUS IX. (1846–77), and Leo XIII. (1878).

POPLAR (*Populus*), the name of a small group of arborescent amentaceous plants, belonging to the order *Salicaceæ*. The catkins of the poplars differ from those of the nearly allied willows in the presence of a rudimentary perianth, of obliquely cup-shaped form, within the toothed bracteal scales; the male flowers contain from eight to thirty stamens; the fertile bear a one-celled (nearly divided) ovary, surmounted by the deeply cleft stigmas; the two-valved capsule contains several seeds, each furnished with a long tuft of silky or cotton-like hairs. The leaves are broader than in most willows, and are generally either deltoid or ovate in shape, often cordate at the base, and frequently with slender petioles vertically flattened. Many of the species attain a large size, and all are of very rapid growth. The poplars are almost entirely confined to the north temperate zone, but a few approach or even pass its northern limit, and they are widely distributed within that area; they show, like the willows, a partiality for moist ground, and often line the river-sides in otherwise treeless districts. The number of species cannot be very accurately defined—several, usually regarded as distinct, being probably merely variable forms of the same type. All yield a soft, easily-worked timber, which, though very perishable when exposed to weather, possesses sufficient durability when kept dry to give the trees a certain economic value.

POPLIN, or TABINET, is a mixed textile fabric consisting of a silk warp with a weft of worsted yarn.

POPOCATEPETL (Aztec *popocani*, “smoking,” *tepetl*, “mountain”), a burning mountain in Mexico,

in  $18^{\circ} 59' 47''$  N. latitude and  $98^{\circ} 33' 1''$  W. longitude, which along with the neighboring and somewhat lower summit of Ixtaccihuatl (Aztec "White Woman") forms the southeastern limit of the great valley in which the capital is built. As it lies in the province of Puebla, and is the great feature in the view from that city, it is also called the Puebla Volcano. With the single exception of Mount Elias in Alaska, Popocatepetl appears to be the highest peak in North America, rising as it does in a regular snow-covered cone to an altitude of 17,853 feet. There have been only two or three moderate eruptions during the last 300 years, though smoke continually issues from the crater, and from time to time vast showers of cinders and stones are shot up.

POPPÆA SABINA. See NERO.

POPPY OIL is obtained by pressure from the minute seeds of the garden or opium poppy, *Papaver somniferum*. The white-seeded and black-seeded varieties are both used for oil-pressing; but, when the production of oil is the principal object of the culture, the black seed is usually preferred. Poppy oil is a valuable and much used medium for artistic oil painting.

POPULATION. Population *statically* considered, may be defined as "the totality of human beings existing within a given area at a given moment of time." The totality just mentioned is ascertained in modern times and by civilized nations by the statistical operation known as the CENSUS, (*q.v.*) It is usual to obtain by means of a census a good deal of information beyond the bare fact of the number of persons whose existence is, for the purpose of the census, taken cognizance of. Part of this information is obtained for purposes connected with the administration of the state, such as that contained in replies to questions as to the religion, profession, etc., of the individuals numbered. But these facts, though highly important, are not facts of population strictly speaking. There are two very important characteristics common to all considerable populations—namely, the approximate constancy of the distribution of the population as regards sex and age. A census which did not distinguish between the number of male and the number of female persons composing the population of which it takes cognizance would be seriously defective. Inquiries as to the height and the girth round the chest of individuals are usually made in countries where military service is compulsory, and the degree of prevalence of bodily defects, such as blindness and deafness, is also noted for similar reasons; but such inquiries are the work of specialists, official and other, and in any case are not included in the information obtained from a census. The age of each individual is, however, easily obtained in the course of the operations of the census.

The total population of the world is, to a large extent, an estimate, inasmuch as in some countries a proper census has never been taken, while in many the interval that has elapsed since the last operation is so long as to reduce it to the level of serving as a basis for a calculation in which estimates play a large part.

The obstacles which make it difficult to attain even an approximate statement of the population of the world prevent us from obtaining any accurate knowledge whatever as to the sexual constitution of that population. We have, however, tolerably accurate information on this subject for most of the countries of Europe, for the United States, and for Canada. From the figures available it is evident that no general proposition can be laid down on the subject of the normal proportion of females to males, except that in so-called "old" countries there is usually a slight excess of the former.

The census of England and Wales for 1881 gave 1,055 females to 1,000 males.

The 1880 census of the United States gives the proportion of females to males at 96.54 per cent., which is rather smaller than that shown in 1870 (97.2 per cent.); but immigration is still a potent factor in the growth of the population of this country.

With regard to the causes of the excess of females, as in most other social phenomena, our knowledge is very small at present. The reason for the broad distinction between Europe and North America is pretty obvious. New countries are continually receiving many male and fewer female immigrants. Probably also, life being very rough in the more unsettled portions of such countries, the rate of mortality among females is a little higher than in places where women can receive more protection from hardship. On the other hand, even in Europe, men run many risks to which women are not exposed. The subject is a very interesting one, but cannot be adequately treated except at much greater length than is possible here, and we must refer our readers to special works for further information.

The characteristics of a population from the point of view of age, which German writers term "Altersaufbau," can only be treated very generally.

This "age scale" shows us the proportion in which persons of various categories of age are found combined to form populations. The general characteristics of the groups are tolerably obvious. It must be remembered that after thirty years the periods are decennial. The difference between the age scale of Europe and that of North America is considerable. In the latter, owing mainly to the fact that emigrants are usually young, a much larger proportion of the population than in Europe are under thirty years of age. On the other hand the age scale of France presents a feature of an opposite kind, namely, a deficiency of persons under fifteen years of age, and an excess of those over forty, as compared with the average of Europe. This conformation of the age scale may be compared with that of Hungary, where the number of children is larger and the number of persons over forty less than the average. It is probable that the smaller number of children in the one case and the larger in the other directly lead respectively to a smaller infant mortality in France than in Hungary.

Careful inquiries into age scales are of very recent origin, the data required for evaluating those relating to earlier periods being absent. Moreover, erroneous statements as to their age are made by a much larger number of persons than might be supposed, sometimes from carelessness or ignorance, but also intentionally. The tendency of women over twenty-five to understate their age, combined with overstatements of age by girls and young women under twenty, always tends to make the twenty to twenty-five section of the age scale unduly large. We must regard even the age scales now in existence as merely first approximations, for it is evident that observations obtained from several censuses must be reduced and combined before we can feel certain that accidental causes of error have been eliminated. This is all the more necessary as the age scale of any given population cannot be regarded as fixed, any more than the magnitude of the population itself, both being liable to modifications arising out of the varying dynamical conditions existing at different periods. And this brings us to the second portion of our inquiry, in which we shall indicate in the most general way the nature of the proximate causes which underlie the phenomena of population considered as a fact existing at a particular moment of time.

Population, *dynamically* considered, is the result of two pairs of opposing forces, whose combined action may, for convenience, be theoretically conceived of as balancing

each other, but which never do so balance as a matter of fact. A comparison of two successive censuses invariably shows some "movement of population." In nearly all civilized countries the movement shown is one of growth when the body of population examined is large. The population of a village or a small town may, quite conceivably, show a reduction in number for the period between two censuses, but this can hardly be the case with a large town, and still less with a nation, unless as the consequence of some great calamity such as an earthquake or a pestilence or a change in the climatic or economic conditions of the country inhabited. A great war, of course, produces a certain retardation of the rate of increase.

The causes of the movement of population are internal and external. The internal arise out of the numerical relation between the births and deaths of a given period, there being an increase when there are more births than deaths, a decrease in the contrary case. Haushofer expresses this by a formula which is sometimes convenient: "There is an increase where intervals between successive births are smaller than those between successive deaths." The external are immigration and emigration. The intensity of these two forces operating on population depends on a variety of causes, into which we do not propose to enter. Generally speaking, it may be said that "new" countries, where the density of population is small, attract immigrants from countries in which the density of population is great. The density of population is expressed by the figure denoting the number of inhabitants per square mile (or square kilometer) of the territory they occupy. For a discussion of the various political, social and economic causes which determine density of population, we must refer our readers to the works of Haushofer and Bloek.

During the earlier half of the century the rate of increase in the United States ranged from  $2\frac{3}{4}$  to 3 per cent. per annum in the successive decades from census to census. The increase in the population of the United States has hitherto depended so much on immigration that at present inquiries into the normal birth and death rates of the country are very difficult, except in the eastern States. Of the total population, 50,442,066, as shown in the census of 1880, no less than 6,619,943, or over 13 per cent., were foreigners. The fact that the proportion of women to men is unusually low, serves to remind us that normal phenomena of population must not as yet be looked for in the American Union.

The birth-rate of a population is the proportion borne by the number of births in a year to the number of the population. It might seem that it is easy to obtain this rate, but as a matter of fact it is practically impossible to do so. It is not difficult to ascertain, with sufficient accuracy, the number of births; the difficulty is to ascertain what is the number of the population, for that number is never the same for two days together.

The birth-rate in different countries is influenced by various circumstances into which it is not possible to enter at length. The most important circumstance is the proportion borne by the number of women of child-bearing age to the whole population. There are other circumstances which must be kept in mind in comparing the birth-rates of different countries, such as the character of the age scale as a whole, and the density of population, besides climatic and other physical characteristics of the environment of the populations examined. The birth-rate is high in new countries, where there is always a larger proportion of young men than in old states, and where the proportion of women of

child-bearing age is also large. The latter circumstance is, we may point out, quite consistent with the statement already made, that in new countries the proportion of women to men is smaller than in old ones. For an unusually large proportion of the total number of women in new countries are young.

FORBEAGLE, the name of a shark (*Lamna cornubica*), mentioned in the works of older British authors as "Beaumaris Shark."

PORCELAIN. See POTTERY.

PORCUPINE. This word, derived from the French *porc-épic*, or "spiny pig," is applied to the members of the *Hystriidae*, a family of rodents whose most prominent peculiarity is their covering of long stout spines, which form a highly efficient protection against enemies, and which are better developed in this family than in any other mammal. Zoologically the porcupines are allied to the cavies, chinchillas, agoutis, etc., and with them form the great section *Hystriomorpha* or porcupine-like rodents.

The old world porcupines or *Hystriina* range over the south of Europe, the whole of Africa, India, and the Malay Archipelago as far eastward as Borneo. They are all stout heavily-built animals, with blunt rounded heads, fleshy mobile snouts, and coats of thick cylindrical or flattened spines, which form the whole covering of their body, and are not intermingled with ordinary hairs. Their habits are strictly terrestrial.

The New-World porcupines, the *Synetherina*, have rooted molars, complete collar-bones, uncleft upper lips, tuberculated soles, no trace of a pollex, and four mammae only. Their spines are to a great extent mixed with long soft hairs; they are less strictly nocturnal in their habits; and, with one exception, they live entirely in trees, having in correspondence with this long and powerful prehensile tails. They consist of three genera, of which the first is formed by the common Canadian porcupine (*Erethizon dorsatus*), a stout heavy-built animal, with long hairs almost or quite hiding its spines, four anterior and five posterior toes, and a short stumpy tail. It is a native of the greater part of Canada and the United States, wherever there is any remnant of the original forest left. *Synetheres*, the second genus, contains some eight or ten species, known as tree porcupines, and found throughout the tropical parts of South America, one of them extending northward into Mexico.

PORDENONE, IL, whose correct name was GIOVANNI ANTONIO LICINIO, or LICINO, was an eminent painter of the Venetian school. He was commonly named Il Pordenone from having been born in 1481 at Corticelli, a village near Pordenone—a city of Italy, in the province of Udine (Friuli).

As a painter, Licinio was a scholar of Pellegrino da S. Daniele, but the leading influence which governed his style was that of Giorgione; the popular story that he was a fellow-pupil with Titian under Giovanni Bellini is incorrect. He died in 1539.

PORIFERA. See SPONGES.

PORISM. The subject of porisms is perplexed by the multitude of different views which have been held by famous geometers as to what a porism really was and is.

The treatise which has given rise to the controversies on this subject is the *Porisms* of Euclid, the author of the *Elements*. For as much as we know of this lost treatise we are indebted to the *Collection* of Pappus of Alexandria, who mentions it along with other geometrical treatises, and gives a number of lemmas necessary for understanding it. Pappus states that the porisms of Euclid are neither theorems nor problems, but are in some sort intermediate, so that they may be presented either as theorems or as problems; and they were re-

garded accordingly by many geometers, who looked merely at the form of the enunciation, as being actually theorems or problems, though the definitions given by the older writers showed that they better understood the distinction between the three classes of propositions.

Pappus gives a complete enunciation of a porism derived from Euclid, and an extension of it to a more general case. This porism, expressed in modern language, asserts that *Given four straight lines of which three turn about the points in which they meet the fourth, if two of the points of intersection of these lines lie each on a fixed straight line, the remaining point of intersection will also lie on another straight line; or, If the sides of a triangle are made to turn each about one of the three fixed points in a straight line, and if two of the vertices are made to move on two fixed straight lines, taken arbitrarily, the third vertex describes a third straight line.*

The *Porisms* of Euclid are not the only representatives of this class of propositions. We know of a treatise of Diophantus which was entitled *Porisms*. But it is uncertain whether these lost *Porisms* formed part of the *Arithmetics* or were an independent treatise.

POROS, or PORO ("The Ford"), an island off the east coast of the Morea, separated at its western extremity by only a narrow channel from the mainland at Trœzen, and consisting of a mass of limestone rock and of a mass of trachyte connected by a slight sandy isthmus. Population, 6,000.

PORPHYRY, a name originally applied to a reddish or purple rock found in Upper Egypt, principally at Jebel Dokhan, and much used by the ancients as a decorative stone. This porphyry, the *porfido rosso antico* of Italian antiquaries, consists of a dark crimson or chocolate-colored felsitic base, with disseminated crystals of white feldspar, probably oligoclase. It was a favorite material with Roman sculptors under the lower empire, and notwithstanding its excessive hardness was worked into large sarcophagi and other objects, ornamented in some cases in elaborate relief. This porphyry was also ingeniously used for the lower part of the busts of Roman emperors, the head being executed in another material, while the porphyry was used for the drapery, the color of the stone suggesting that of the imperial purple. The antique red porphyry is often confounded with the *rosso antico*, which being merely a red marble, is a much softer stone.

PORPHYRY, a philosopher and pupil of Plotinus, was born in the year 205 A. D. in Egypt and died in Lower Italy in 270 A. D. He wrote on NEO-PLATONISM (*q. v.*).

PORPOISE (sometimes spelled PORPUS and PORPESSE). "Porpoise" is commonly used by sailors to designate all the smaller cetaceans, especially those numerous species which naturalists call "dolphins;" but in scientific language it is restricted to a particular form constituting the genus *Phocæna* of Cuvier, of which the Common Porpoise of the British seas *Phocæna communis*, Cuvier (*Delphinus phocæna*, Linnaeus), is the type.

The common porpoise, when full grown, attains a length of five feet or a little more.

The porpoise is sociable and gregarious in its habits, being usually seen in small herds, and frequents coasts, bays, and estuaries rather than the open ocean. It is the commonest cetacean in the seas around the British Isles, and not infrequently ascends the river Thames, having been seen as high up as Richmond; it has also been observed in the Seine at Neuilly, near Paris. It frequents the Scandinavian coasts, entering the Baltic in the summer; and it is found as far north as Baffin's

Bay, and as far west as the coasts of the United States. Southward its range is more limited than that of the common dolphin, as, though very common on the Atlantic coasts of France, it is not known to enter the Mediterranean.

PORPORA, NICCOLA (or NICCOLO) ANTONIO, operatic composer and teacher of singing, was born in Naples on August 19, 1686, and died in 1767.

PORSENA or PORSENNIA, king of Clusium. See ETRURIA and ROME.

PORSON, RICHARD, in some respects the greatest of modern Greek scholars, was born on Christmas Day, 1759, at East Ruston, near North Walsham, in Norfolk, England, and died in 1808. In 1792 the Greek professorship at Cambridge became vacant by the resignation of Mr. Cooke. To this Porson was elected without opposition, and he continued to hold it till his death. He was a voluminous author, and his works are standards of their class.

PORTA, BACCIO DELLA. See BACCIO DELLA PORTA.

PORTA, GIAMBATTISTA DELLA, natural philosopher, was born of a noble and ancient family at Naples about the year 1543, and died in 1615.

PORTADOWN, a market-town of Armagh, Ireland, is situated on the river Bann, and on the Great Northern Railway, twenty-five miles west-southwest of Belfast and ten north-northeast of Armagh. The Bann, which is connected with the Newry Canal and falls into Lough Neagh about five miles north of the town, is navigable for vessels of ninety tons burden. Population (1890), 8,000.

PORTAGE CITY, the county seat of Columbia county, Wis., is situated on the Wisconsin river at the head of navigation and on the ship canal which connects the Wisconsin and Fox rivers. It is located on the Wisconsin Central, and is the junction of the several branches of the Chicago, Milwaukee and St. Paul railroads, which cross the State from this point in several directions. It is the center of a rich agricultural country, also in close proximity to some of the most romantic scenery to be found in Wisconsin. The city was called Winnebago Portage in early days, and the communication by steamboat with Green Bay, established about that period, has since been maintained. Portage contains a court house and county buildings, nine churches, complete school facilities, two banks, three papers, two elevators, and, besides the Portage iron works, has manufactories of sash and blinds, furniture, clothing and other industrial enterprises. It is 104 miles east-northeast of La Crosse, 47 miles west-northwest of Watertown, and 30 miles north of Madison, and has at present (1890) a population of 5,130.

PORTALIS, JEAN ÉTIENNE MARIE, French jurist and the principal author of the *Code Civil*, which as the *Code Napoléon* has been declared the greatest monument of the reign of the emperor, came of a bourgeois family, and was born at Bausset in Provence on April 1, 1745. Bonaparte knew his value, and made him a conseiller d'état in 1800, and then charged him, with Tronchet, Biggot de Prémeneu, and Jacques de Malville, to draw up the *Code Civil*. Of this commission he was the most industrious member, and many of the most important titles, notably those on marriage and heirship, are his work. In 1801 he was placed in charge of the department of cultes, or public worship, and in that capacity had the chief share in drawing up the provisions of the Concordat. In 1803 he became a member of the Institute, in 1804 minister of public worship, and in 1805 a knight grand cross of the Legion of Honor. He soon after became totally blind; and after undergoing an unsuccessful operation he died at Paris on August 23, 1807.

**PORT AU PRINCE** (originally L'HÔPITAL, and for brief periods PORT HENRI and PORT RÉPUBLICAIN), the capital of the republic of Hayti (western portion of the island HAYTI, *q.v.*), lies in 18° 34' N. latitude and 72° 20' W. longitude at the apex of the vast triangular bay which strikes inland for about 100 miles between the two great peninsulas of the west coast, and has its upper recesses protected by the beautiful island of Gonaives (thirty miles long by two broad). The city is admirably situated on ground that soon begins to rise rapidly toward the hills; and it was originally laid out by the French on a regular plan with streets of good width running north and south and intersected by others at right angles. Everything has been allowed to fall into disorder and disrepair, and to this its public buildings—a state-house, a national bank, a hospital, a lyceum, a custom-house, etc.—form no exception. The national palace remains as the flames of revolution left it in 1869, and the president lives in an ordinary house. The principal church is an “overgrown wooden shed.” Every few years whole quarters of the town are burned down, but the people go on building the same slight wooden houses, with only here and there a more substantial warehouse in brick. The state of the streets is deplorable in the extreme, and, in spite of the old French aqueduct, the water-supply is defective; while the harbor is rapidly being filled by fetid deposits. From June to September the heat is excessive, reaching 95° to 99° in the shade. The population, mostly negroes and mulattoes, is estimated at 20,000. Port au Prince was first laid out by M. de la Cuza in 1749. In 1751 and again in 1770 it was destroyed by earthquakes. During the late revolution the city was the scene of some of the operations of the opposing factions.

**PORT ELIZABETH**, a seaport town of Cape Colony, at the head of an electoral division of the southeastern province, lies in 33° 55' S. latitude on Algoa Bay, about seven miles south of the mouth of the Zwartkop river. Population (1890), 15,000.

**PORTER, JANE**, a novelist whose life and reputation are closely linked with those of her sister ANNA MARIA PORTER (1780–1832) and her brother Sir ROBERT KER PORTER (1775–1842) was born in 1776. The ability of Anna Maria Porter was the first to manifest itself in the premature publication of her *Artless Tales* (1793–95), these being followed by a long series of works. Jane Porter, whose intellectual power, though slower in development and in expression, was of a stronger nature than that of her sister, had in the meantime gained an immediate and wide popularity by her first work, *Thaddeus of Warsaw* (1803), which was translated into several languages and procured her election as canoness of the Teutonic order of St. Joachim. Seven years later her *Scottish Chiefs* anticipated in some measure the works of Sir Walter Scott in the field of national romance, though it is wanting in the higher qualities of the historic novel.

While his sisters had been winning esteem in literature, Robert Kerr Porter had in his own way been scarcely less successful. After two years of study at the Royal Academy he had gained reputation as a painter of altar-pieces and battle scenes of imposing magnitude. He went to Russia as historical painter to the emperor in 1804, accompanied Sir John Moore's expedition in 1808, married the princess Mary de Sherbatoff in 1811, was created knight commander of the order of Hanover in 1832, and became British consul at Venezuela. Accounts of his wanderings are to be found in his *Travelling Sketches in Russia and Sweden* (1808), *Letters from Portugal and Spain* (1809), *Narrative of the late Campaign in Russia* (1813), and *Travels in Georgia, Persia, Armenia, Ancient Babylonia, etc., during the years 1817–20* (1821–22). After

leaving Venezuela he again visited St. Petersburg, but died there suddenly on May 4, 1842. Jane Porter, who had joined him in Russia, then returned to England and took up her residence with her eldest brother at Bristol, where she died May 24, 1850.

**PORT GLASGOW**, a seaport, market-town, burgh of barony, and parliamentary burgh of Renfrewshire, Scotland, is situated on the south side of the Clyde, two and one-half miles east of Greenock and twenty west of Glasgow. Population (1890), 12,000.

**PORT HOPE**, a town and port of entry of Canada, in Durham county, Ontario, on the north shore of Lake Ontario, lies sixty-three miles northeast of Toronto by the Grand Trunk Railway (which is there met by the Midland branch of the Grand Trunk Railway), and is connected with Charlotte, the port of Rochester, N. Y., by a daily steamboat service. The town is picturesquely situated on the side and foot of hills overlooking the lake; and Smith's Creek, by which it is traversed, supplies abundant water-power. Flour, plaster, woolen goods, leather, beer, carriages, agricultural implements, and steam-engines and boilers are among the products of the local industries, and trade is carried on in lumber, grain, and flour. The population in 1890 was 6,000.

**PORT HURON**, a city and port of entry of the United States, county seat of St. Clair county, Mich., lies fifty-eight miles by rail northeast of Detroit, at the southern extremity of Lake Huron and on the west bank of the St. Clair river, which is there joined by the Black river. Port Huron is a point of great importance in the railway system, being the terminus of the Chicago and Grand Trunk and the Port Huron and North-Western Railways (lines to East Saginaw, Sand Beach, Almont, and Port Austin), and connected by ferry to Sarnia with the Great Western of Canada and the Grand Trunk Railways. It is also the terminus and a stopping-place of several lines of lake steamers. It has a large lumber trade, ship-yards, dry docks, saw-mills, flour-mills, planing-mills. The population was 5,973 in 1870, 8,883 in 1880, and 13,543 in 1890. Commenced in 1819, Port Huron was incorporated as a village in 1835, and as a city in 1857.

**PORTICI**, a town of Italy five miles south of Naples, on the shores of the bay and at the foot of Vesuvius, a little to the north of the site of Herculaneum. Population (1889), 11,000.

**PORT JERVIS**, a large village of the United States, in Deerpark township, Orange county, N. Y., situated at the intersection of the boundaries of New Jersey, New York, and Pennsylvania, at the junction of the Neversink with the Delaware. It is the terminus of the eastern division of the New York, Lake Erie and Western Railroad, and it has extensive repair-shops. The beauty of the surrounding scenery attracts summer visitors. Port Jervis was named after John B. Jervis, engineer of the Delaware and Hudson Canal, which connects the Pennsylvanian coal-fields with the tidal waters of the Hudson. In 1875 the Erie Railway bridge, the Barrett bridge, and many buildings were carried away by an icegorge. The population of the village was 6,377 in 1870, and 9,327 in 1890 (township, 11,420).

**PORTLAND**, a city and port of entry of the United States, capital of Cumberland county, Me., lies on Casco Bay, in 43° 39' N. latitude and 70° 13' W. longitude. By rail it is 108 miles north-northeast of Boston and 297 southeast of Montreal. The peninsula on which it is mainly built runs out for about 3 miles, has a breadth of about  $\frac{3}{4}$  mile, and rises in the west to 175 feet in Bramhall's Hill and in the east to 161 in Munjoy's Hill, which is crowned by an observatory. As

seen from the harbor, the whole city has a pleasant and picturesque appearance, and the streets are in many parts so umbrageous with trees that Portland has obtained the sobriquet of the *Forest City*. A large number of the houses are built of brick. Congress street, the principal thoroughfare, runs along the whole ridge of the peninsula, from the western promenade, which looks down over the suburbs from Bramhall's Hill to the eastern promenade, which commands the bay; it passes Lincoln Park (two and one-half acres) and the eastern cemetery, which contains the graves of Commodore Preble and Captains Burroughs and Blythe, of Revolutionary fame. On Bramhall's Hill is the reservoir (12,000,000 gallons) of the water company, which was established in 1867 to supply the city from Lake Sebago, whose beautiful expanse (fourteen miles long by eleven wide) was the favorite haunt of Nathaniel Hawthorne's boyhood. The more conspicuous buildings of Portland are the city hall (1859), with a front in olive-colored freestone, 150 feet long; the post-office (1872), constructed of Vermont white marble in the mediæval Italian style; the custom-house (1872), in granite, with rich marble ornamentation in the interior; the marine hospital (1855), a large brick erection; the Maine general hospital, 1868; the Roman Catholic cathedral; the Roman Catholic episcopal palace; and several fine churches. The Portland Society of Natural History, established in 1843 and incorporated in 1850, though it has twice lost its property by fire (1854 and 1866), has again acquired very valuable collections. The Portland institute and public library, dating from 1867, had 33,000 volumes in 1890. A medical school was founded in 1858. Portland is in the main a commercial city, with an extensive transit trade, drawing largely from Canada and the Far West. Connected with Boston by rail in 1842, and with Montreal in 1853, it has now become a terminus of six different railroads; and, since the gauge of the Grand Trunk Railroad was altered, it can import direct from San Francisco. As the harbor (which lies along the south side of the city) is seldom closed by ice, it has been long used as the winter port for the great ocean steamers between Great Britain (Liverpool and Glasgow) and Canada, which in summer ascend the St. Lawrence to Montreal and Quebec. At low water vessels drawing twenty-two feet and at high water vessels drawing thirty feet can come up to the wharves with safety in any season; and there is secure anchorage within a mile of the shore. The dry dock is one of the deepest in the United States.

	Imports.	Exports.
Average 1876-80.....	\$9,368,044	\$11,044,389
1881.....	11,078,612	12,476,389
1882.....	11,748,183	11,955,787
1883.....	10,235,991	13,847,574

Among the staple imports are wood, coal, potatoes (from Europe), salt, sugar and molasses, fish, earthenware, and textile manufactures; and among the staple exports to foreign countries fresh and preserved provisions of all kinds, grain, hay, cattle, wood, copper ore, tallow, shoes, potash, cotton, lumber (mainly to South America), and ice. Fish-curing (cod, mackerel, and sardines), preserving meat, Indian corn, and other kinds of provisions, boot and shoe-making, furniture-making, carriage-building, machinery-making, engine-building, and sugar-refining are all prosecuted on a considerable scale for the size of the town; and a large number of minor industries are also represented. In 1880 the capital invested in manufacturing was \$4,659,375, the value of the annual production \$9,569,523, and

the amount of wages paid \$1,547,375. Portland is divided into seven wards, and is governed by a mayor, a board of aldermen, and a common council. It is the seat of the sessions of the United States Courts for the District of Maine. The population of the city, in 1890, was 36,425. Its financial condition may be seen from the following figures:

Bonded debt, \$1,466,500; total debt, \$3,087,500; total valuation of property, \$34,072,405; tax rate, \$20.20 per \$1,000.

School population, 11,989; number of school buildings, 18; 1 high-school, 7 grammar schools, 15 primary schools, 1 school for deaf; 161 teachers; total enrollment, 6,211; cost of maintenance of schools, \$101,482.18 yearly.

Police force consists of 39 men, at a yearly cost of \$37,700.

Fire department apparatus consists of 5 steamers and hose, 3 hook and ladder companies, 2 fire-boats, 1 hose company, 15 horses, and is maintained at a cost of \$37,150.

Public library contains 33,000 books, and 150,000 pamphlets.

The city charities are the almshouse, Greely Hospital, insane hospital, out-door relief, reform school, and city farm; expenditure yearly, \$23,700.

The city has water-works, and is lighted by gas and electric light.

The name of Portland, as applied to this city, dates only from 1786; the Indians knew the place as Machigonne. The first European settlers (1632) called it Casco Neck, and after it passed to Massachusetts, in 1658, it was denominated Falmouth. During the rest of the seventeenth century and the early days of the eighteenth hostilities on the part of the French and the Indians prevented the growth of the town, which, by 1764, however, had increased to about 2,000 inhabitants. In 1775 it was bombarded by four British vessels, under Captain Mowatt, but it was rebuilt in 1783, and formally incorporated in 1786. A city charter was obtained in 1832. The great fire of 1866 swept over a third of the city, and caused a loss of from \$6,000,000 to \$10,000,000. Portland is the birthplace of Henry W. Longfellow, N. P. Willis, Sara P. Parton ("Fanny Fern"), Erastus and James Brooks, Commodore Preble, John Neal, and Neal Dow.

PORTLAND, a city of the United States, the second in importance and population on the Pacific coast, is also a port of entry and the capital of Multnomah county, Ore. It is located on the west bank of the Willamette river, twelve miles from its mouth, 100 miles from the ocean, 640 miles north of San Francisco, and 55 miles east of Salem. It is at the headwaters of ship navigation, the northern terminus of the Oregon and California railroad, the Pacific Coast terminus of the Union Pacific, and the headquarters of the Portland and Willamette Valley road, a narrow gauge system with upward of 200 miles in the Willamette Valley. Portland being also the center of interior water-transportation in the northwest, possesses facilities enabling shippers and travelers to reach every portion of the country for miles in nearly every direction. Up to the year 1883, the growth of the city was slow. From that year until 1886 the population was doubled. In 1887 the increase was 8,000; in 1888 over 10,000; in 1889, 15,000; and in 1890 the increase was estimated at 25,000. It has upward of seventy miles of paved streets, forty miles of sewer, forty miles of street-car lines, is lighted by gas and electricity, maintains a system of water supply, with a capacity of 9,000,000 gallons daily, supports an educational system embracing high-school, grammar school, intermediate and primary departments,

a fire and police force adequate to the needs of the service, and banking, commercial, and manufacturing facilities equal to the largest requirements. It contains a courthouse and the usual complement of county buildings, a customhouse, one high-school, five grammar schools, a number of graded schools, fourteen churches, fourteen banks, with a paid-up capital and surplus of \$8,868,750, over 100 jobbing houses with a total capital of \$65,000,000, and stores and smaller enterprises in proportion. The lines of manufacture embrace foundries and machine-shops, engine and boilerworks, flour, lumber, and planing-mills, breweries, carriage, leather, clothing, brush, furniture factories, etc., which gave employment in 1889 to 7,268 men, and turned out stock valued at more than \$20,000,000, based on actual returns. There are four daily and thirteen weekly papers published in the city, in addition to three periodicals issued monthly. The population in 1890 was 46,385.

PORTLAND, ISLE OF, a small island or peninsula of England, in the English Channel, four and one-half miles south of Weymouth, Dorsetshire, connected with the mainland by a long narrow ridge of shingle called the Chesil Bank. Population (1889), 12,000.

PORTLAND, WILLIAM BENTINCK, FIRST EARL OF, was descended from an ancient and noble family of Guelderland, and became page of honor to William, prince of Orange, from which he was advanced to be gentleman of the bedchamber. On April 9, 1689, he was created Baron Cirencester, Viscount Woodstock, and earl of Portland. With the rank of lieutenant-general he distinguished himself in command of the Dutch cavalry at the battle of the Boyne in 1690, and he was also present at the battle of Landen in 1693, and at the siege of Namur in 1695. Along with marshal de Boufflers he prepared the terms of the peace of Ryswick in 1697, and shortly afterward was appointed ambassador-extraordinary to Paris. For receiving grants of land in Ireland, and for his share in the partition treaty, he was impeached by parliament, but the prosecution did not succeed. He died November 23, 1709, and was buried in Westminster Abbey.

PORTLAND, WILLIAM HENRY CAVENDISH BENTINCK, THIRD DUKE OF, prime minister of England, was the grandson of Henry, second earl and first duke of Portland, who was son of William, first earl. He was born April 14, 1738, and was educated at Oxford university, where he graduated M.A. in 1757. He held the premiership from April 5, 1783, until the defeat of the bill for "the just and efficient government of British India" caused his dismissal from office on December 17th. In 1792 he succeeded the earl of Guildford as chancellor of the university of Oxford. Under Pitt he was, from 1794 to 1801, secretary of state for the home department, after which he was, from 1801 to 1805, president of the council. In 1807 he was appointed a second time first lord of the treasury. Ill-health caused him to resign in September, 1809, and he died October 30th following.

PORTLAND CEMENT. See BUILDING.

PORTLAND VASE. A magnificent work of art, now in the National Gallery of London.

PORT LOUIS. See MAURITIUS.

PORT LYTTTELTON, a municipal borough of New Zealand, formerly called Port Cooper and Port Victoria, lies on the northwest side of Banks Peninsula, on the east coast of South Island. Population 10,000.

PORT MAHON, or MAHON, a city and seaport in the Mediterranean, on the east coast of the Spanish island of Minorca (see BALEARIC ISLANDS), lies on a height near the head of an inlet of the sea three and one-half miles long by from 400 to 1,200 yards wide.

which, though of less importance than formerly, is still an admirable harbor of refuge. Population, 18,000.

PORTO ALEGRE, a city and seaport of Brazil, the capital of the province of Rio Grande do Sul, lies in  $30^{\circ} 2'$  S. latitude and  $51^{\circ} 12'$  W. longitude at the northern extremity of the Lagõa dos Patos (Duck Lagoon), where it receives the waters of the Jacuhi, Sino, Cahi, and Gravatahi, whose confluence opposite the city is sometimes distinguished by the name of Lagõa Viamão. Like the other towns on this lagoon, Rio Grande do Sul and Peletos, Porto Alegre is the seat of a very considerable trade, but it is impossible to say precisely what share belongs to each of the three. (See RIO GRANDE DO SUL.) The population is about 25,000.

PORTO BELLO (Span., *Puerto Bello*), a town in the republic of Colombia and state of Panamá, situated on the coast of the Caribbean Sea, about twenty-three miles east of Colon in  $9^{\circ} 32'$  N. latitude and  $78^{\circ} 38'$  W. longitude. As the name (bestowed by Columbus in 1502) implies, it possesses a fine natural harbor, the bay between Drake's Point in the north and Buenaventura Island in the south being easy of entrance and having a depth of eight to sixteen fathoms. Founded in 1584, the city rapidly grew in importance, becoming the great depot for the gold and silver from Peru, which were brought across the isthmus from Panamá, and here conveyed on board the royal galleons. From the last years of the previous century the town has steadily declined till at present it is almost entirely extinct.

PORTOBELLO, a municipal burgh of Scotland, in the county of Midlothian, lies on slightly sloping ground on the south shore of the Firth of Forth, three miles by rail east of Edinburgh. Population (1890) 7,500.

PORT OF SPAIN. See TRINIDAD.

PORTO MAURIZIO, a city of Italy, chief town of a province and center of a maritime district, lies on the coast of the Ligurian Sea, forty-six miles by rail east of Nice, and seventy miles west of Genoa, and consists of a picturesque old town situated on the heights, and a modern town of villas on the lower slopes. Population, 7,000.

PORTO RICO (Span., *Puerto Rico*), one of the Spanish West India Islands, lies seventy miles east of Hayti, between  $17^{\circ} 50'$  and  $18^{\circ} 30'$  N. latitude and  $65^{\circ} 35'$  and  $67^{\circ} 10'$  W. longitude. It forms an irregular parallelogram, 108 miles long and 37 broad, and has an area of 3,530 square miles, or rather less than that of Jamaica. From east to west it is traversed by a range of hills so situated that the streams flowing northward are much longer than those flowing south. The highest district, however, and the highest peak—El Yunque (3,600 feet)—are situated in the Sierra de Loquillo, near the northeast corner. As the hills intercept the northeast trade-winds with their rain-clouds, there is sometimes almost a superabundance of moisture in the northern lowlands, while in the south severe droughts occur, and the land demands artificial irrigation, as yet carried out with too little coöperation and system. The island is, however, exceptionally well watered, 1,300 streams being enumerated, of which forty-seven are considerable rivers; and its general appearance is very beautiful. Forests still cover all the higher parts of the hills, and differ from those of the other West Indian Islands, mainly in the comparative absence of epiphytes. Among the noteworthy trees, Baron Eggers (see *Nature*, December 6, 1883,) mentions the *Coccoloba macrophylla*, or "ortegon" of the natives, which forms extensive woods in some places, chiefly near the coast, and is conspicuous by its immense yard-long purple spikes; a beautiful *Talauma*, with white, odorous flowers, and yielding a timber called "sabino"; an unknown tree with purple flowers like those of *Scavola Plumieri*;

a large *Heliconia*; and several tree-ferns (*Cyathea Serra*, and an *Alsophila*). Besides the two staples—sugar and coffee—tobacco, cotton, rice, maize, *Caladium esculentum*, yams, and plantains, as well as oranges, coconuts, and other tropical fruits, are commonly cultivated. The rice, which is the principal food of the laborers, is a mountain variety grown without flooding. On the lowland pastures, covered mainly with *Hymenachne striatum*, large herds of excellent cattle are reared to supply butcher-meat for St. Thomas, the French islands, etc. In general, Porto Rico may be described as extremely fertile; and its exports more than double in value those of Jamaica. The great want of the island is still roads and bridges, though the government has done good work in this department in recent years; the journey across the hills can only be performed on horseback, and even along the coast-route wheeled traffic is at times interrupted. Gold, iron, copper, coal, and salt are all found in Porto Rico, but the last alone is worked.

The total population of Porto Rico was not more than 319,000 in 1830; by 1860 it reached 583,308; and by 1888, 813,937. The chief towns are St. John's the capital, Mayaguery (population 27,000), and Ponce (population 140,000).

PORT ROYAL, a town and naval station of Jamaica, occupies the outer end of a narrow strip of land called the "Palisades," which, projecting westward for about nine miles, forms the natural breakwater of the noble bay on which Kingston, the present capital of the island, is built. As a town Port Royal (though in the seventeenth century it was reputed the finest in the West Indies) is now a wretched place of 1,205 inhabitants (1881), with narrow and extremely dirty streets, and contains no buildings of note except a hospital (200 patients) and the spacious admiralty house, which is surrounded by beautiful gardens; but as a naval station it is still of very considerable importance, has well-equipped machine-shops, and is defended by a number of forts and batteries partly of quite modern erection.

PORT ROYAL, a celebrated Cistercian abbey, occupied a low and marshy site in the thickly-wooded valley of the Yvette, at what is known as Les Hameaux near Marly, about eight miles to the southwest of Versailles. It was founded in 1204 by Mathilde de Garlande, wife of Matthieu de Montmorenci-Marli, during his absence on the fourth crusade, and in its early years it received a variety of papal privileges, including (1223) that of affording a retreat to lay persons who desired to withdraw from the world for a season without binding themselves by permanent vows.

PORT SAID, a town and seaport of Lower Egypt, which owes its existence to the Suez Canal (1859-69), and was named after Sa'id Pasha, patron of the enterprise. It lies on the west side of the canal, on the low, narrow, treeless, and desolate strip of land which separates the Mediterranean from Lake Menzaleh; the supply of fresh water brought from the sweet-water canal at Ismailia by a conduit is barely sufficient for the wants of the town, which is regularly laid out, and has some streets of substantial houses. The population rose to 17,000 in 1890.

PORT ST. MARY. See PUERTO DE SANTA MARIA.

PORT TOWNSEND is an enterprising and growing town in the recently admitted State created out of Washington territory. It is available located on Puget Sound, seventy-four miles north of Olympia, forty-four miles northwest of Seattle, and within a short distance of the straits of Juan de Fuca. Within the past three years, or since the completion of the railway lines in the northwest, Port Townsend has grown rapidly in

prominence, and promises to become at an early day a city conspicuous as a trade center and shipping point. It contains several churches, school-houses, and banks, a large number of stores and manufacturing enterprises, the latter including machine shops, sash factories, wagon works, saw and grist mills, foundries, etc., and half a dozen hotels. The population, 593 in 1870, increased to 1,000 in 1880, and to 4,498 in 1890.

PORTSMOUTH, a municipal and parliamentary borough, seaport, and naval station of Hampshire, England, consists of an aggregate of towns situated in the southwestern corner of Portsea Island, opposite the Isle of Wight, eighteen miles south-by-east of Southampton and seventy-four southwest of London by the London and South-Western Railway. The original town is not now nearly so populous as the suburbs comprised in the general name of Portsea (including Portsea proper) on the north and west, Landport on the north, and Southsea on the east. Portsmouth proper is the barrack and garrison town; at Portsea is situated the great naval dockyard; Landport is occupied chiefly by the houses of artisans; and Southsea, as possessing facilities for bathing, is resided in by the wealthier classes. Population (1891) 159,255.

The port of Portsmouth extends eastward nine miles to Emsworth, and westward five miles to Hill Head at the entrance to Southampton Water. About three miles to the south of the harbor is the well-known anchorage of Spithead, protected by the Isle of Wight. The harbor, one of the best in the kingdom, stretches four miles inward to the northwest of the town with an entrance 220 yards in breadth, permitting access to vessels of the largest tonnage at low tide. There is an anchorage within the basin at low tide of 380 acres, and a portion of the harbor is permanently occupied by dismantled vessels and the reserved fleet of the navy. There is a graving-dock built by the corporation, with eighteen feet of water on the blocks, and a patent slip. Extending along the eastern shore are the ordnance gun wharf between Portsmouth and Portsea and to the north of it the great naval Government dockyard, which has lately been much enlarged. At Gosport are the royal Clarence victualing yard and the Haslar hospital. Portsmouth has a considerable trade in coal, timber, fruits, and agricultural produce.

PORTSMOUTH, a city and port of entry of the United States, one of the two county towns of Rockingham county, N. H., and alternately with Concord the seat of the sessions of the United States courts for the district of New Hampshire, lies on a peninsula on the right bank of the Piscataqua, three miles from its mouth, in 43° 4' N. latitude and 70° 45' W. longitude. By rail it is fifty-seven miles north-northeast of Boston. Quiet and old-fashioned beyond most of the New England cities, with shaded streets and many quaint antique houses, survivals from colonial times, Portsmouth is a favorite summer resort. Notwithstanding the excellence of its harbor—which is from thirty-five to seventy-five feet deep, safe, free from ice at all seasons, and capable of containing 2,000 vessels—it has very little foreign trade. There are cotton mills (Kearsarge), breweries, boot and shoe factories, and some other industrial establishments in the city; and shipbuilding, which is the principal industry, has long been extensively prosecuted. The United States navy yard, though situated on Continental or Navy Island, on the north side of the river, in the township of Kittery (Maine), is generally known as Portsmouth yard. It contains a fine Balance dry dock, 350 feet by 105. Among the more conspicuous buildings in Portsmouth are the old church of St. John, the athenæum (23,000 volumes), and the custom-house. There is a

public library of 12,000 volumes. At Little Harbor, two miles distant, is Governor Wentworth's mansion, dating from 1750. The entrance to the harbor is defended by earthworks at Jaffrey's Point and Gerrish's Island. The population was 9,738 in 1850, 9,211 in 1870, and 9,827 in 1890.

PORTSMOUTH, a city of the United States, capital of Scioto county, Ohio, lies at the confluence of the Scioto with the Ohio, and is the southern terminus of the Ohio and Erie Canal, and of a branch line of the Cincinnati, Washington, and Baltimore Railroad (Hamden to Portsmouth, fifty-six miles), as well as an important station on the Scioto Valley Railway. As the entrepôt for the rich mineral regions of southern Ohio and northeastern Kentucky, and for the productive valley of the Scioto, Portsmouth has a large and growing trade both by rail and by river; and it also contains iron-furnaces, rolling-mills, shoe-factories, hub and spoke factories, etc. Among the public buildings are an opera-house and a masonic temple. The charitable institutions include a hospital, a children's home, and a home for destitute aged women. The city has also two libraries, water-works, and tramways. The population was 6,268 in 1860, 10,592 in 1870, and 12,394 in 1890. Portsmouth was laid out in 1803, and the charter of the city dates from 1814.

PORTSMOUTH, a city of the United States, capital of Norfolk county, Va., lies on the west bank of Elizabeth river, opposite Norfolk. It is the eastern terminus of the Seaboard and Roanoke Railway (part of a great passenger route between Boston and New Orleans), has one of the best harbors on the Atlantic coast, is the seat of the United States Gosport navy yard (with a dry dock built of granite at a cost of \$974,536, and a large naval hospital), and exports cotton, lumber, pig-iron, and early vegetables. The population was 9,496 in 1860, 11,390 in 1880, and 13,268 in 1890. Portsmouth was founded in 1752. On April 20, 1861, the navy yard—then employing 1,000 men—was destroyed by fire, the loss being estimated at several million dollars.

PORTUGAL. *Geography and Statistics.*—The kingdom of Portugal, which is geographically a province of the Iberian Peninsula on its west coast, is bounded on the north by the Spanish province of Galicia, on the east by the Spanish provinces of Leon, Estremadura, and Andalusia, and on the south and west by the Atlantic Ocean. It lies between 36° 56' and 42° 10' north latitude and 6° 15' and 9° 30' west longitude. It is 362 miles in length by 140 in breadth, and contained by the latest (1878) computation 34,419½ square miles. Its coast-line is nearly 500 miles in length, and only one province, Tras-os-Montes, is not washed by the sea.

The mountain-systems of Portugal can only be adequately treated under SPAIN, as they are in every instance continuous to the west or southwest of the great Spanish ranges.

The river system of Portugal is also merely a portion of that of Spain.

The climate of Portugal is particularly equable and temperate, and its salubrious qualities were recognized by the doctors of the eighteenth century, who used to send many patients to winter there; and, though Portugal has been superseded as a winter resort by the Riviera and Algiers, there are signs that it may again become a European health-resort of the first importance.

The geology, flora, and fauna of Portugal are essentially the same as those of Spain, and will be studied under SPAIN.

*Population.*—The population of Portugal, according

to the census of January 1, 1878, was 4,160,315, and in 1881 it was calculated to be 4,306,554, or 125 persons to the square mile.

The ethnological composition of the population is most mixed: in the two northern provinces the population is essentially Galician, but farther south the mixture becomes obvious; not only did the conquering Portuguese largely intermarry with the Arabs, but in the places where they exterminated them they replaced them by colonies of crusaders of all nations, chiefly French, English, Dutch, and Frisian, who have left their mark on the features and character of the nation, and they also largely intermarried with the Jews. No Jews were so wealthy or so cultivated as those of Portugal, who, though for many centuries keeping strictly apart from the Christians, yet after their forced conversion or expulsion by King Emmanuel largely intermarried, especially with the people of Lisbon. Farther south an African physiognomy appears, derived from the thousands of negro slaves imported to till the Alentejo and Algarves, from the days of Dom Henry till the decline of the Portuguese power.

*Commerce.*—The commerce of Portugal has not rapidly, though it has steadily, increased during the last thirty years; the chief countries with which it trades are, in order of value, England and her colonies, Brazil, the United States, France, and Spain, but it is hardly fair to mention commerce with Spain, because the large amount of smuggling which takes place makes it impossible to estimate the real amount of trade between the two countries.

*Agriculture.*—The state of agriculture in Portugal is still deplorable; the wealth and energy of the country have been thrown into the wine trade, and the production and cultivation of cereals have been so much neglected that, in spite of its being eminently adapted for such cultivation, nearly all its cereals are imported from the United States, to the annual value of over \$5,000,000. The wine production, on which Portugal has so long depended, was the work of the Methuen treaty of 1703, for it was not until after that treaty that the barren rocks of the Alto Douro were covered with vines. But now, though the returns show slight alteration, there must soon be a great change. The phylloxera has utterly destroyed thousands of vineyards in Entre Minho e Douro and in Beiria.

*Manufactures.*—Nothing proves more decidedly the agricultural character of the Portuguese than the repeated failures to establish manufactures among them. This has often been ascribed to the provision respecting the importation of English goods in the Methuen treaty; but not all the efforts of Pombal or of the modern protectionist cabinets have been able to establish any important manufactures.

*Finance.*—The revenue of Portugal has for many years ceased to balance its expenditure, and the deficit has had to be met by borrowing, but it is only fair to remark that vigorous attempts have been made to reduce the expenditure of recent years. The national debt is now more than \$200 per head of population, or about \$870,000,000.

*Government.*—The government of Portugal is an hereditary and constitutional monarchy, exercised under the charter of 1826, as modified in 1852 and 1878, under which the king is charged with the executive and shares the power of making laws with two chambers. His civil list amounts to \$700,000 a year, and he is advised in all matters of administration and assisted in nominating peers by a council of state appointed for life, but depends for advice in legislative and executive matters on a cabinet of seven members selected from the chambers by a premier, summoned by the king. The

House of Peers consists of 150 members nominated by the king for life, and contains many of the most eminent professors and authors, as well as men of wealth, and additions may be made to its number by the king on the advice of the premier, with the consent of the council of state. All the members of the house of Peers do not possess titles, nor do all titled persons belong to the house of Peers; legislation and the titular and hereditary aristocracy are kept quite apart. The House of Deputies consists of 173 members, elected directly by all male citizens of twenty-five years of age, either paying in direct taxes \$1.10 a year, or deriving an annual income of \$5.50 from real estate, while all graduates, priests, officers, and certified teachers have votes without further qualification. The president of the chamber is selected by the king out of five elected candidates, and the deputies are paid. The Azores and Madeira elect members to the house at Lisbon. For administrative purposes Portugal is divided into seventeen districts, for judicial purposes into twenty-six districts or "comarcas," with appeal courts at Lisbon and Oporto, and a supreme court at Lisbon, and for military purposes into four divisions. The Roman Catholic is the state religion, but others are tolerated, and the power of the priests has been greatly checked by the wholesale suppression of monasteries in 1834. The church in Portugal is governed by a patriarch at Lisbon, two archbishops at Braga and Evora, and fourteen bishops, of whom the most important is the bishop of Oporto. For purposes of local government the districts are under the rule of civil governors, who have much the same powers as prefects in France, while in the 292 "concelhos," or administrative councils, there are elected councillors, and in the 3,960 "freguezias" or parishes the villagers elect a magistrate, who has the same powers as an English justice of the peace.

*Army and Navy.*—Under a decree dated May 19, 1884, the Portuguese army has been reorganized. The effective war strength is to be maintained at not less than 120,000 men. The term of service is for twelve years, of which three are to be with the colors, five in the first reserve, and four in the second reserve. The force is divided into thirty-six regiments of infantry, ten regiments of cavalry, four regiments, one brigade, and four companies of artillery, and one regiment of engineers. In 1889 its effective strength in time of peace was 33,231 men with 1,643 officers.

*Public Instruction.*—The public instruction of Portugal is regulated by the law of 1844, which enacted that all children should be bound to attend a primary school, if there was one within a mile, from the age of seven to fifteen, under penalty to the parents of a fine and deprivation of civil rights. Under this law there were in Portugal, in 1874, 2,649 primary schools with 122,004 pupils of both sexes. Secondary education is not neglected, and under the same law of 1844 seventeen lycées have been established in the seventeen continental districts, and from them it is possible for a pupil to enter either the university of Coimbra, which during the present century has recovered some of its ancient luster, or the special schools. These special schools are very ably conducted, and modern Portuguese policy gives, as we have seen, a higher status to teachers and professors of all grades than they obtain in most other countries.

*Public Works.*—On January 1, 1889, there were 1,245 miles of railway open (1,000) and in course of construction (245), also fifty miles of tramways were open, and 2,900 miles of telegraph were in operation, and every recent loan has been raised for the purpose of extending these important public works.

The history of Portugal really begins with the gift of the fief of the Terra Portucalensis or the county of Porto Cale to Count Henry of Burgundy in 1094. In common with the rest of the Peninsula, it was overrun by the Vandals, Alans, and Visigoths, and eventually conquered by the Arabs in the eighth century.

For two centuries Portugal remained subject to the Omayyad caliphs, and under their wise rule the old Roman colonizæ and municipia, such as Lisbon, Lamego, Viseu, and Oporto, maintained their Roman self-government and increased in wealth and importance. In 1055 Ferdinand the Great, king of Leon, Castile, and Galicia, invaded Beira; in 1057 he took Lamego and Viseu, and in 1064 Coimbra; and his son Garcia, who succeeded him as king of Galicia in 1065, maintained Nuno Mendes, count of Oporto, and Sesnando, a renegade Arab wazir, count of Coimbra, as feudal vassals of his court. In 1073 Alphonso VI., the second son of Ferdinand the Great, united once more his father's three kingdoms, and for a time rivaled his father's successes, until a fresh outburst of Mohammedan fanaticism ended in the rise of the Almoravide dynasty, and the defeat of the Christian king at Zalaca in 1086 by Yúsuf ibn Teshufin. To resist this revival of the Mohammedan power, Alphonso VI. summoned the chivalry of Christendom to his aid, and among the knights who came to his assistance were the Counts Raymond and Henry of Burgundy. In the days of his success Alphonso had compelled Motawakkil of Badajoz to cede to him both Lisbon and Santarem, but the fortune of war had changed, and Sir, the general of the Almoravide caliph Yúsuf, retook both cities. Alphonso felt the need of a valiant warrior on his Galician frontier, and in 1094 he combined the fiefs of Coimbra and Oporto into one great county and conferred it upon Henry of Burgundy with the hand of his illegitimate daughter Theresa, while to Raymond he gave Galicia and his legitimate daughter and heiress Urraca.

Count Henry of Burgundy, the first count of Portugal, was the second son of Henry, third son of Robert, first duke of Burgundy, and was in every way a typical knight of his country, a brave restless warrior, and a crusader; but when once firmly established in his county he thought much more about his chances of succeeding his father-in-law as king than of trying to carve a kingdom for himself out of the dominions of the Mohammedan caliphs. When, therefore, Alphonso VI. died in 1109 and left his thrones to his daughter Urraca, and nothing to Henry, the Burgundian at once invaded Leon. For five years the Christian princes, Henry of Burgundy, Alphonso Raimundes (the son of Count Raymond), Alphonso of Aragon, and Queen Urraca, fought together, while Sir was consolidating the Almoravide power, until Count Henry died suddenly at Astorga in 1112, leaving his wife Theresa to rule the county of Portugal during the minority of his infant son, Affonso Henriques.

Theresa, who ruled at Guimarãens during her son's minority, was a beautiful and accomplished woman, who devoted all her energies to building up Affonso's dominions into an independent state, and under her rule, while the Christian states of Spain were torn by civil wars, the Portuguese nobles were prevented from interfering, and began to recognize Portugal as their country, and to cease from calling themselves Galicians. Her regency was a stormy one in spite of all her efforts to maintain peace.

Affonso Henriques, who at the age of seventeen assumed the government, was one of the heroes of the Middle Ages; he succeeded to the rule of the county of Portugal when it was still regarded as a fief of Galicia, and after nearly sixty years' incessant fighting he

bequeathed to his son a powerful little kingdom, whose independence was unquestioned, and whose fame was spread abroad throughout Christendom by the reports of the victories of its first king over the Mohammedans. This triumph worthily closed the reign of the great crusader king, Affonso Henriques, who died on December 6, 1185.

The fame of Dom Sancho I., "the Povoador" or "City-builder," rests more on his internal administration than on his early exploits as a soldier.

The reign of Affonso II. "the Fat" is chiefly important in the constitutional history of Portugal, and for one memorable feat of arms, the recapture of Alcácer do Sal.

He was succeeded by Sancho II. who was only thirteen, and, as might have been expected during a minority, the turbulent nobility and intriguing bishops tried to undo the late king's labors to consolidate the royal power. He was deposed by the pope and was succeeded by his brother Affonso, who had led the revolt against him.

With such a commencement it might have been expected that the reign of Affonso III. would have been a period of civil war and internal dissension, or at least of complete submission to the church and the feudal nobility, but, on the contrary, it was from a constitutional point of view the most important of all the early reigns, and also that in which Portugal concluded its warfare with the Mohammedans and attained to its European limits. After a prosperous and successful reign Nemesis came upon Affonso in the rebellion of his eldest son Diniz in 1277; which continued until 1279, in which year the king died.

The period of war and of territorial extension in the Peninsula was now over, and the period of civilization was to dawn. Territorially and constitutionally Portugal was now an established kingdom; it remained for it to become civilized and thoroughly homogeneous before the great heroic period of exploration and Asiatic conquest should begin. No better man for such work than the new king, Dom Diniz, could have been found. At the end of this reign war broke out between the king and the heir-apparent, and a pitched battle was only prevented in 1323 by Queen Isabel riding between the armies and making a peace between her husband and her son which lasted until the death of the great peacemonarch, the Ré Lavrador, in 1325.

Affonso IV. pursued his father's policy of making family alliances with the kings of Aragon and Castile, and in 1328 married his daughter, Donna Maria, to Alphonso XI. of Castile, who neglected her, and for her sake Affonso IV. declared war against Castile. Peace was made through the intervention of St. Isabel in 1340, when Dom Pedro, son of Affonso, married Constance Manuel, daughter of the duke of Penafiel, and Affonso IV. himself promised to bring a strong Portuguese army to the help of Alphonso XI. against the emir of Morocco, Abú Hamen, who had crossed the straits to assist the sultan of Granada. The united Christian armies won a decisive victory at the river Salado, in which Affonso especially distinguished himself, and earned the title of "the Brave;" from that time he remained at peace with Castile, and further strengthened his position in Spain in 1347 by marrying his daughter, Donna Leonora, to Pedro IV. of Aragon. The later years of the reign of Affonso IV. were stained by the tragedy of Donna Ines de Castro.

The first act of Dom Pedro on ascending the throne in 1357 was to punish the murderers of Ines; and further, to show his love for her, he had her dead body disinterred and crowned, and afterward solemnly buried with the kings and queens of Portugal in the convent of

Alcobaça. The spirit of stern, revengeful justice which had marked the commencement of his reign continued to show itself in all matters of administration; he punished priest and noble with equal severity, and the people gave him the title of "Pedro the Severe."

The accession in 1367 of Ferdinand, the only son of Pedro by Constance, marks a crisis in the history of the Portuguese monarchy. On April 6, 1385 a cortes assembled at Coimbra, and declared the crown of Portugal to be elective, choosing, at the instance of the chancellor, Dom John to be king of Portugal. Portuguese discoveries made illustrious the closing years of the reign of King John, who died in 1433. He was succeeded by his son Edward.

Contrary to expectation, the reign of King Edward (so called after Edward III. of England) proved, in spite of his own great qualities, but short, and was marked by one signal disaster. He died in 1438.

The new king, Affonso V., was a minor, and his reign began with a struggle for the regency between his mother, Donna Leonora, and his uncle, Dom Pedro, duke of Coimbra. He was a weak, romantic king, and died in 1481.

His successor, John II., was a monarch of a very different type: though he had proved himself a brave and valiant soldier at the battle of Toro, he pursued the old policy of the house of Aviz, that of peace and family alliances with Castile and of commercial intimacy with England. A great sorrow darkened the later years of John II. in the death of his only son Alfonso, who in 1490 had married Isabella, eldest daughter of Ferdinand and Isabella of Spain; and he himself died in the flower of his age in 1495.

The reign of Emmanuel "the Fortunate" is the heroic period of Portuguese history. The reign of John III., who succeeded Emmanuel in 1521, is one of rapid decline. It was in India that the decline of the Portuguese was most perceptible. Nuno da Cunha, son of the discoverer Tristan da Cunha, governed the Indian settlements worthily till 1536, and then corruption undermined all prosperity until the arrival of Dom João de Castro in 1545. He was a Portuguese hero of the noblest type; and for three years the friend of St. Francis Xavier revived the glories of Albuquerque by winning the battle of Diu, and then died in the missionary's arms. Everything went afterward from bad to worse, till even observers like the Dutchman Cleynaerts saw that, in spite of all its wealth and seeming prosperity, the kingdom of Portugal was rotten at the core and could not last. King John III., satisfied with peace and the establishment of the Inquisition in his kingdom, did nothing to check the decline; and he endeavored to secure his aims by the marriage of his only surviving son John to his niece Joanna, a daughter of Charles V., but he had the misfortune to outlive his son, who died in 1554. When he himself died in 1557 he left the crown to his grandson, a child of three years old, the ill-fated Dom Sebastian.

Nothing could be more disastrous for Portugal than the succession of a minor at this juncture. The young king was smitten with the crusading fever, and himself was slain and his army cut to pieces at Alcácer Quibir. The sad news was brought to Lisbon by the admiral of the fleet, Dom Diogo de Sousa, and the cardinal Henry was proclaimed king of Portugal as King Henry I.

Hardly had the new king been crowned when intrigues began about his successor. He could not live long; but he determined not to examine the question himself, and so summoned a cortes at Lisbon at once to decide it. Philip II. of Spain was declared king at his death, and the kingdom was in organic union with Spain for sixty years.

At last a blow was struck against this supremacy of Spain in the revolution of 1640 and the elevation of the house of Braganza to the throne of Portugal. The whole of Portugal at once rose and expelled the Spaniards, and on January 19th a full cortes met at Lisbon, which recognized King John as king of Portugal, and his son Theodosius as heir-apparent. John IV. died in 1656.

As the prince of Brazil, Dom Theodosio, the eldest son of the late king, had predeceased him, his second son Affonso, a boy of thirteen, succeeded to the throne as Affonso VI. under the regency of his mother. He was dethroned by his brother, who also took from him his queen:

As long as Affonso VI. lived, Dom Pedro's power was not thoroughly established, but in 1683 he was proclaimed king as Pedro II. His reign was marked by good internal administration, the breaking out of the War of the Spanish Succession, and the Methuen treaty. He died at Alcantara on December 9, 1706.

The long reign of John V., who assumed the royal state at once from the regent Catherine, resembles the reign of John III.

Joseph, who succeeded his father in 1750, had the merit of perceiving the preëminent powers of Sebastião de Carvalho, who governed Portugal throughout this reign, and who, under his title of the Marquis of Pombal (see POMBAL), ranks among the very greatest of eighteenth century statesmen. Joseph died on February 20, 1777, leaving four daughters, of whom the eldest, Donna Maria Francisca, had married the king's brother, Dom Pedro.

The accession of Donna Maria was the signal for the overthrow of the great marquis and the reversal of his policy. The new queen was a weak woman. Her brain failed in 1788, and Dom John found it necessary to take the management of affairs into his own hands, though he was not actually declared regent until 1799. About the time that Dom John became regent the wish to check the spread of the principles of the French Revolution, which were as much feared in Portugal as in all other Continental states, led to the great activity of Dom Diogo Ignacio de Pina Manique, the intendant-general of police. He eagerly hunted down all Portuguese gentlemen suspected of encouraging French principles or of being freemasons, expelled all Frenchmen from the kingdom, and kept a jealous eye on the American consul, Edward Church, and a merchant named Jacome Ratton, whom he declared to be at the head of a republican conspiracy. Moreover, the Portuguese ministers not only combated the dreaded French principles at home, they also believed it a holy duty to join in the general war against France, and therefore a corps of 5,000 men was sent into the eastern Pyrenees to serve under General John Forbes Skelater, and four ships under the marquis of Niza joined the English fleet in the Mediterranean. The Spanish Government, then under the influence of Godoy, the Prince of the Peace, did not hesitate to desert Portugal and make a separate peace with the French republic at Basel in July, 1795. In 1800 Lucien Bonaparte was sent to Madrid with instructions from his brother to insist on the abandonment of the English alliance, on the opening of Portuguese ports to France and the closing of them to England. The Portuguese ministers rejected these terms, and immediately Leclerc's corps entered Spain. The campaign lasted but a few days. Olivenza and Campo Mayor fell into the hands of the Spaniards, who also won bloodless victories at Arronches and Flor da Rosa. Peace was made at Badajoz with Spain, by which Portugal ceded Olivenza, and at Paris with France, by which it consented to the extension of

French Guiana to the Amazons, and promised a large indemnity. Napoleon Bonaparte was anything but satisfied with the treaty of Badajoz, and received Lucien on his return with but little favor, for his aim was utterly to destroy Portugal as a nation; and it was with a full intention to excite her to war that he sent one of the roughest and least educated of his generals, Lannes, as ambassador to Lisbon. At length, in 1807, having beaten Austria, Prussia, and Russia, Napoleon again turned his thoughts to his project for the annihilation of Portugal, which had become more than ever a thorn in his side since it refused to cooperate in his continental schemes for ruining England. With amazing rapidity Junot accomplished the march, and the Portuguese hardly knew that war was imminent until on November 27th Colonel Lecor rushed into Lisbon with the news that the French were in possession of Abrantes. This alarming intelligence unnerved the regent, who listened to the strongly-worded advice of Sir Sidney Smith, commander of the English ships in the Tagus, to abandon his kingdom for the Brazils, and leave the English to defend Portugal; and on November 27th Dom John, after naming a council of regency, went on board the English fleet with his whole family, including the queen Maria I. The English ships had hardly left the Tagus when a small force of wearied French soldiers, who were all that remained from the terrible fatigues of the march, entered Lisbon on November 30th.

Shortly after the conclusion of the war, in 1816, the mad queen Maria I. died, and the regent succeeded to the throne as King John VI. The English Government earnestly pressed him to return to Lisbon, where dissensions in the regency and the universal discontent urgently summoned him. He accordingly left the Brazils to the government of his elder son Pedro, and set out for Portugal, where in 1822, at the earnest request of that son, he solemnly swore to obey the new constitution. He was at once met by the opposition of the queen and his younger son Dom Miguel, who refused to recognize the constitution; in consequence they were expelled from Lisbon. This event, with the invasion of Spain by the French to put down the rebellion of 1823, encouraged Francisco da Silveira, count of Amarante, to raise a pronunciamento in Tras-os-Montes; but the king at Lisbon declared, amid loud applause, that the constitution of 1822 was abrogated and his own absolutism restored, and he appointed the count of Palmella, the head of the English or constitutional party, to be his minister. But the absolutist party did not aim at a new form of constitutional government; they were desirous to reinstate the old absolutism. The queen and Dom Miguel headed a new plot; the king's friend, the marquis of Loulé, was assassinated; Palmella was imprisoned and the king himself shut up in his palace. The united action of the foreign ministers who had remained in Lisbon freed the king; the new insurrection was suppressed; Palmella was again appointed minister; and the king, with the two chief conspirators, the queen and Dom Miguel, left Portugal once more for the Brazils. In the following year (1826) John VI. died, leaving by his will his daughter, the infanta Isabel Maria, as regent, to the great disappointment of Dom Miguel, who had returned to Portugal with the expectation of receiving it as his inheritance, while his brother Dom Pedro ruled in Brazil.

The next twenty-five years are the darkest in the whole history of Portugal and the most complicated to analyze, for the establishment of parliamentary government was no easy task; it is almost impossible to follow the rapid changes which succeeded each other, and quite impossible to understand the varying motives of the different

statesmen and generals. On ascending the united thrones Dom Pedro IV. proceeded to draw up a charter containing the bases of a moderate parliamentary government and sent it over to Portugal by the English minister, Sir Charles Stuart, and then abdicated the crown of Portugal in favor of his daughter, Donna Maria da Gloria, a child only seven years old, on condition that she married his brother Dom Miguel, who was to recognize the new constitution. The charter was received with joy by the parliamentary party, and Palmella became prime minister; but in 1827 the king foolishly appointed Dom Miguel to be regent in Portugal. This ambitious prince was exceedingly popular with the old nobility, the army, and the poor; and, having declared himself absolute king, he drove the whole constitutional or chartist party—Palmella, Saldanha, Villa Flor, Sampaio, and their adherents—into exile. They fled to England, where the young queen then was, but, although they found popular opinion strongly in their favor, they found also that the duke of Wellington and his Tory ministry highly approved of Dom Miguel's behavior, and that they persisted in confounding the moderate and the radical parties, and in believing that Palmella was a democrat. Meanwhile the reign of Dom Miguel had become a reign of terror, and a new movement was begun by the conjoined chartist and radical parties, who respectively advocated the charter of 1826 and the constitution of 1822, but who sank their differences to oppose Dom Miguel. The island of Terceira (Azores) had never submitted to this prince, and there in 1829 the marquis of Palmella, the count of Villa Flor, and José Antonio Guerreiro declared themselves regents for the young queen; and on August 11, 1830, they defeated in Praia Bay the fleet sent against them by Dom Miguel. The struggle continued till May, 1834, when Dom Miguel capitulated and Queen Maria ascended the throne which she held till November, 1853. Queen Maria da Gloria died on November 15, 1853, and her husband, the king-consort, Dom Ferdinand II., assumed the regency until his eldest son Dom Pedro V. came of age.

Pedro died of cholera in 1861, and was succeeded by Dom Luis, under whom the kingdom prospered greatly. Luis died in 1889, and was succeeded by Dom Carlos, the present king.

PORUS, the name of the Indian king who withstood Alexander the Great on the banks of the Hydaspes (Jhelum). He was afterward confirmed in his kingdom by the conqueror, and still held the position of a Macedonian satrap when assassinated some time between 321 and 315 B.C.

POSEIDON, the ancient Greek god of the sea and of water generally, was fabled to be the son of Cronus and Rhea, and brother of Zeus and Pluto. In modern Greece St. Nicholas has taken the place of Poseidon as patron of sailors. But the Zachynthians have a special sea-god, half man, half fish, who dwells under the sea, rides on dolphins or in a car drawn by dolphins, and wields a trident. He seems to combine the attributes of Poseidon and Nereus. For the Roman sea-god, see NEPTUNE.

POSEN, a province in the east of Prussia, with an area (11,180 square miles) nearly equal to that of Belgium, is bounded on the north by the province of Prussia, on the east by Russian Poland, on the south by Silesia, and on the west by Brandenburg. It belongs physically to the great north German plain, and consists of a low plateau intersected by the beds of the Netze, the Warthe, and the Obra. Pop. 1,715,618.

POSEN (Polish, *Poznań*), capital of the above province, the seat of a Roman Catholic archbishop, and the headquarters of a corps of the German army, is situ-

ated at the confluence of the Cybina and Warthe, 150 miles to the east of Berlin and 90 miles to the north of Breslau. Population, 68,315.

POSIDONIUS, a distinguished Stoic philosopher, the most learned man of his time (c. 130–50 B. C.) and perhaps of all the school; by birth a Syrian from Apamea, a pupil of Panætius, he spent after his teacher's death many years in travel and scientific researches in Spain (particularly at Gades), Africa, Italy, Gaul, Liguria, Sicily, and on the eastern shores of the Adriatic.

POSITIVISM, or POSITIVE PHILOSOPHY. See COMTE.

POSSESSION is a legal term derived from Roman law. The Roman conception of possession has been generally adopted, but the Roman deductions from the conception have not been universally followed. The subject of possession, in itself a difficult one, has become more difficult owing to the various senses in which the term has been interpreted. Thus it has been said to be either a right or a fact conferring a right, or both together.

It has been already stated that there is both a physical and a mental element in the conception of possession. This does not necessarily mean that corporal contact is in all cases requisite, or that the intention to hold the thing possessed as one's own may not be abandoned for a time. The control may be potential as well as actual. An estate may be possessed without the possessor going upon the land at all, and the possession of goods may be given by delivering the key of the warehouse in which they are stored. In international law the possession of part as giving the right to the whole has been of great importance.

In both Roman and English law the possessory tended to supersede the proprietary remedies from their greater convenience—that is to say, the plaintiff based his claim or the defendant his right upon possession rather than property. The English possessory action may have been directly suggested by the interdict.

POSTOFFICE. The germ of the modern postal systems of the world is to be looked for, obviously, in the earliest organized establishment of a staff of government couriers. When, or under what precise circumstances, such an establishment was first made available by a state for the carriage of the letters of private persons there is no satisfactory evidence to show. That there must have been, even in early times, a connection, more or less authorized, between the transmission of public and of private correspondence is highly probable. Even financial reasons would soon dictate a formal permission to government couriers to carry letters for individuals. In the postal system of Spain and the German empire there is express record of such a permission in the month of April, 1544; and within fifteen or sixteen years that permission had grown into a legalized and regulated monopoly, whence the counts of Taxis drew part of their profits as postmasters-general. For the purposes of this article, however, it is enough to note that in Great Britain existing private letters of the fifteenth century—some, perhaps, of the fourteenth—bear indorsements which show that they were conveyed by relays of men and horses maintained under the control of the government, and primarily intended for its special service. In several continental states the universities had inland postal establishments of a rudimentary sort at an early date. The university of Paris, for example, organized a postal service almost at the beginning of the thirteenth century, and it lasted in a measure until the year 1719. As early as the middle of the thirteenth century entries occur in the wardrobe accounts of the kings of England of payments to

royal messengers for the conveyance of letters to various parts of the country. In the supervision of these royal messengers lies the germ of the office of postmaster-general. The first English postmaster of whom a distinct account can be given is Sir Brian Tuke, who is described (1533) in the records as "Magister Nunciorum, Cursorum, sive Postarum," "both in England and in other parts of the king's dominions beyond the seas."

The accession of James I. to the English throne, by necessitating a more frequent communication between London and Scotland, led to improvements in the postal service.

In 1607 the king granted to James Stanhope, first Lord Stanhope of Harrington, and to his son Charles Stanhope, afterward second Lord Stanhope, jointly and to the survivor of them, the postmastership of England under the title of "Master of the Posts and Messengers," with a fee of 100 marks a year, together with all "avails and profits" belonging to the office. In 1619 a separate office of "postmaster-general of England for foreign parts" was created, by new letters patent, in favor of Matthew de Quester and Matthew de Quester the younger, and in 1626 by an order in council liberty was granted to all companies of merchants, including the Merchants Adventurers, to send their letters and dispatches by messengers of their own choosing. A year afterward this liberty was revoked, except for the Company of Merchants Adventurers. Lord Stanhope, however, continued to carry letters abroad by his agents, and obtained a warrant prohibiting De Quester from interfering.

The English postoffice system continued upon conditions similar to those stated for many years. Measures of partial but valuable reform were improvised and adopted from time to time, which improved the service and paved the way for the complete and comprehensive system which such service has since become in all portions of the world. Among those instituted was that of John Hill, who undertook the conveyance of letters, packages, etc., from York to London at half the rates previously charged, the establishment of the penny post of London by Robert Murray, and William Dockevra who located sorting and distributing offices, made collections and distributions at regular intervals, and otherwise furnished a precedent for the system now in vogue. At this period the postal service of Scotland, though distinct from that of England, was similar in its operations, while that of the colonies was even more rudimentary. In fact it may be said that the postal communication of the British empire and her dependencies was of the most primitive character, inconspicuous, uncertain, and poorly conducted. Reforms, however, continued to be made, and in the reign of Queen Anne the various systems were consolidated into one establishment, which as to organization remained the great charter of the postoffice until the date of the important reforms of 1838-50, mainly introduced by the energy, skill, and characteristic pertinacity of Sir Rowland Hill.
