I believe that no loss of human life from industrial currents of electricity occurred before 1879, though currents strong enough to have caused death were employed in lighting the operatic stage in Paris (at the first performance of Meyerbeer's *Le Prophète*) as long ago as 1849, and in lighthouses on and off the coast of England in 1857. In 1879 a stage carpenter was killed at Lyon by the alternating current of a Siemens dynamo that was giving a voltage of about 250 volts at the time. The man became insensible at once and died in twenty minutes; artificial respiration was not applied. The first death in this country took place at a theatre in Aston, outside Birmingham, in 1880, where a bandsman short-circuited a powerful electric battery, became insensible, and died in forty minutes. Since that date the annual number of deaths from electric shock has steadily increased, particularly during this century, in which the industrial employment of electricity has extended so widely, and is now quite large. In the ten years 1901-10 the Registrar-General's returns show a total of 183 such deaths in England and Wales, the population having risen from 32½ to 36 million during that period. In the three years 1901 to 1903 there were 25 such deaths; in 1908, 25; in 1909, 29; in 1910, 26. Only 2 of these 183 victims were females, because women are so much less exposed to contact with dangerous electric currents than are men. Many deaths by electricity occur annually on the Continent, though I can only bring forward a few scattered figures to prove it. In Germany, 35 were killed in 1908, 52 in 1909, 46 in 1911. In Austria, 11 were killed by electricity in 1907, 10 in 1910, 10 in 1911. In Switzerland, 21 were killed in 1905, 19 in 1906. I think it probable that about 200 persons are killed by electricity annually over the whole of Europe. As regards the United States of America, where electricity is so very extensively employed, I have not been able to find any statistical records. As long ago as 1888 Brown estimated that during the past five years some 200 people had been killed by handling live electric wires. One must remember that in America life is held very cheap, and that safeguards and protective legislation tend to be regarded as undue restrictions upon industry

and commerce. I imagine that not less than 200 persons are accidentally killed by electric currents every year in America.

As a rule, only a single person is killed by electricity in any single accident; but in an accident occurring in 1909 at Olginiate, a village in Lombardy, 10 people were killed outright by a three-phase current at 3,000 volts. One was saved by artificial respiration, and about a dozen more were severely injured (Hoest).

It is necessary before going further to explain the meaning of certain technical terms that cannot be avoided when electric currents are under discussion. Any given electric current is maintained by an electromotive force or pressure that for practical purposes is measured in volts; to give a hydraulic analogy, the pressure or voltage, or, as it is still sometimes confusingly called, tension, that drives the current through an electric lamp corresponds to the head of water, or pressure measured in pounds per square inch, that causes water to run out of a turned-on tap. The rate at which a current of electricity flows, or the quantity (measured in coulombs) flowing in unit time, is measured in amperes; to give the hydraulic analogy, an electric current of so many amperes may be compared to a stream of water or so many gallons per second. The resistance met with by a current as it flows through a circuit or any part of it is measured in ohms; electric resistance is analogous to the frictional resistance met with by water flowing through pipes or in partially choked channels. An electric current that flows steadily in one direction is called "direct" or "continuous." For technical reasons it is often found more convenient to use currents that frequently and regularly reverse, flowing first in one direction round the circuit and then round in the opposite direction, say from 50 to 150 times a second; these are called "alternate" or "alternating" currents of electricity. An alternating current that reverses the direction of its flow 100 times a second is described as an alternating current of fifty periods or cycles a second, or as having a frequency or periodicity of fifty cycles; the frequency of an alternating current is of great importance in considering its dangerousness to life. Electric energy, or the power of doing work, is measured in joules; one joule represents the energy expended in one second by one ampere in one ohm.

Post-mortem Evidence as to the Cause of Death.

The interest of men of science, of physicians and pathologists, in deaths due to industrial electric currents was first shown in France. In 1882 the celebrated French medico-legal expert and pathologist, Brouardel, made a careful *post-mortem* examination of a man killed in Paris at the Tuileries by a 250-volt alternating current, and he decided that death was fulminating, due to the electric discharge, and directly caused by arrest of the heart. Bourrot at the same time examined a second and similar case *post mortem*, and came to the conclusion that death was due to violent excitation of the vagus nerve and consequent arrest of the heart, with the result that the heart could not resume its functions, and death by asphyxia followed. In 1885 a man killed instantaneously by electric shock at the Health Exhibition in London was examined forty hours after death by Sheild and Delépine. Rigor mortis was marked; extreme fluidity of the blood was observed, even the right heart being free from clots. The authors came to the conclusion that "No doubt the vital spots at the base of the brain are in such cases markedly implicated." As the result of a *post-mortem* examination made by Pla in 1891, he concluded that death by electric shock was due to an instantaneous suppression of all the organic functions. The brain and its membranes were hyperaemic in this case; the blood was fluid, but showed no microscopical change. The victim had died twenty minutes after receiving the fatal shock. In 1892 Buchanan described the case of a man who came in contact with a 2,400-volt alternating current, and fell back insensible with one cry for help. Ten minutes later he was found to be livid, with dilated pupils and blood-stained mucus coming from the nares. Artificial respiration was performed; the man inspired slightly three times and then died, becoming quite rigid in about four minutes. The *post-mortem* examination was made thirty-one hours later; rigor mortis was still marked, the blood was liquid and tarry, the brain was congested, the spinal cord was

congested but healthy. Buchanan remarked that the cause of death was evidently asphyxia. In the same year Crossland recorded the case of a youth of 17, who was killed by a current at a pressure of 115 volts. *Post mortem* the blood was found to be "fluid-inky," but no other lesion could be discovered.

It is well to say something at this point as to the infliction in America of the death penalty on criminals by means of electricity, which had been widely discussed in the lay press and the medical papers of America and this country since 1889, and was first put into practice in the State of New York in August, 1890. Various suggestions had been made as to the strength and nature of the current to be used, and the methods and sites of its application to the body of the criminal. The upshot was that alternating currents of high electromotive force—1,200 to 1,700 volts, while Carleton recommended 3,000 volts—were used, with large electrodes fixed to the head, neck, arms, legs, and elsewhere; the current was turned on several times in each case, and for periods lasting up to 70 seconds or more. Each execution, or "electrocution" as it was first called in 1892, lasted from 3½ to 8 minutes. Enormous quantities of electricity were employed in these executions. To quote one example, an alternating current of 7 amperes was maintained for 70 seconds through the body of one criminal, at a pressure of 1,500 volts; assuming that the man weighed 10 st., here was enough energy expended to raise the temperature of his whole body through more than 5° F., quite apart from any heat generated by the prolonged contraction of the electrically-stimulated muscles. Spitzka states that within twenty minutes of an electrocution the temperature of the body rises to 120° or 129.5° F. in many cases, and that coagulation of the myosin of the muscles takes place. The whole muscular system was thrown into complete tonic rigidity, we are told, when the current was turned on, and this was maintained until it was turned off. The *post-mortem* examinations of persons thus electrocuted shewed, among other things, extensive capillary haemorrhages in the brain and in the floor of the fourth ventricle, and it was assumed that death was due to injury to the brain. No doubt these haemorrhages were caused by the rupture of small vessels following on the great rise in the blood pressure produced by the prolonged tonic spasm of the muscles; they are not a common feature after death by electric shock. But I think it is obvious that the *post-mortem* changes observed in such electrocutions as these are not of much use in explaining the mode of death by electric shock in industrial accidents, in which the voltage of the current is often much less, the quantity of current passing through the body of the victim is very much less (probably rarely approaching 7 amperes), and the duration of the contact is not often more than a few seconds. The conditions in which electrocutions have been performed and the electrical quantities involved in them are so very different from those ordinarily obtaining in death by accidental electric shocks, that as a matter of fact electrocutions have thrown no light at all on the mode in which deaths by misadventure with electric currents as they commonly occur are brought about. The objects of the responsible authorities were to produce instant insensibility, in the first place, and in the second place death, and both of these objects were attained by the method of electrocution adopted. It was generally supposed that death in electrocution was due to asphyxia or injury to the brain; although, and to my mind quite unjustifiably, it was also argued that it was the subsequent *post-mortem* examination, and not the electrocution, that was the real cause of death, a view that was upheld again and again from time to time in the public press of America until at any rate as late as the year 1905.

During the last twenty years a great many *post-mortem* examinations have been made in cases of sudden death by electric shock, but I do not think that any useful purpose would be served by going through them in detail, as they do not in general throw light on the exact way in which death has been brought about. Stress may, however, be laid on a few points commonly observed. In the first place, burns of greater or less superficial extent are generally seen at the points where the electric current has entered and left the body. They have been carefully studied by Shield and Delépine, and by Malli, and are due to the relatively great resistance offered by the skin to the

passage of the electric current, which is transformed into heat in proportion to the amount of resistance it meets and to the square of the current. If the current is at a low voltage and the contact is brief, the resulting burns may be so slight as easily to escape notice. But if contact with the electric conductor is prolonged, the burning may be very extensive and deep—in extreme cases it has even been found necessary to send for the fire brigade to extinguish the burning victim, who is kept alight by the transformation into heat of the electric energy being poured into him. In the second place, abnormal fluidity of the blood has often been found *post mortem*; in this, those cases of sudden death by electric shock resemble cases of sudden death by asphyxia. In the third place, no pathological changes are regularly found in the heart muscle, although there are good reasons for believing that in most instances death is directly due to paralysis of the heart. In the fourth place, the central nervous system often shows neither macroscopical nor microscopical changes of importance, except in the cases where relatively large quantities of electricity have passed through the body for long periods of time; when this happened, capillary haemorrhages have often been found in the brain and cord, with chromatolysis or destruction of the Nissl bodies in the nerve cells. In a word, the *post-mortem* evidence as to the cause of death by electric currents in industrial accidents is generally negative, but may suggest asphyxia in some cases, in others organic vascular and nervous lesions in the brain and cord.

Evidence from Anatomical and Electrical Considerations.

When one comes to look into a number of both fatal and non-fatal instances of accidental shock by industrial electric currents, it becomes apparent that the part of the body through which the current flows is extremely important in determining the result of the shock. Practically speaking, there is not the smallest danger of sudden death if the current enters one foot or leg and leaves it by the other or by the lower part of the trunk, however high the voltage and however great the current thus forced through the lower part of the body and the legs. But there is a danger, even with electric currents of as low a voltage as 65 volts, when the current travels through the thorax, and so has the chance to pass through the substance of the heart. The degree of danger here depends upon two factors—first, the resistance presented to the flow of electricity by the skin at the points at which the current enters and leaves the body, and, secondly, upon the voltage of the current. The resistance of the skin varies very widely in any given case, being high when the skin is greasy or dry, or when the area of contact with the electric conductor is small, and relatively low when the skin is wet or the area over which it comes into contact with the conductor is great. To give a single example illustrating my meaning, one may handle a bare wire carrying, say, an electric lighting current at a pressure of several hundred volts with complete impunity, so long as the hands by which the current enters or the feet or boots by which it leaves the body are dry, because in these circumstances the amount of current flowing through the body is too small to be dangerous. But if the hands and feet are damp or wet, the electrical resistance of the skin at the points of entry and exit of the current may be so much lowered that a relatively strong current will flow from the hands through the body to the feet; and if the proportion of this current that passes through the heart is strong enough to paralyse it, then sudden death will occur.

Hence the cardiac region in the thorax is the chief danger area of the body in cases of dangerous or fatal electric shock. Experimental evidence obtained from animals makes it certain that the central nervous system constitutes another area of danger; but for practical purposes the number of industrial accidents recorded in which the current entered by the head and left the body without traversing the region of the heart would seem to be small—at any rate, I have not been able to find any.

The direction in which an electric current flows through the body, whether from right to left or left to right, or whether from the head to the feet or the feet to the head, has no influence on the effects it produces. As a matter of convenience one always speaks of a current as

"entering" at the point where the body comes into contact with the uninsulated electric conductor carrying the current, and "leaving" at the place where it is in contact with some indifferent but conducting substance—with the earth in the case of a person who is standing—by means of which the current after passage through the body is conveyed back to the source whence it came. But it must be understood that these words "entering" and "leaving" are used without prejudice to the actual direction in which the current flows through the body in any given case.

Experimental Evidence.

It is upon the evidence obtained by the experimental electrocution of animals that most of our knowledge as to the modes of death by electric shock rests. No electrical apparatus capable of producing currents strong enough to kill animals was invented before about the middle of the eighteenth century. At that time electricity suddenly developed into a popular and spectacular science in France and Germany, just as in the middle of the nineteenth century table turning, spiritualism, and clairvoyance were popularly taken up all over England and America with the greatest energy. In neither case was much real scientific progress made by this arousal of popular interest; birds, beetles, and other living creatures were electrocuted by frictional electricity by Gordon (1745), Gralath (1746), Nollet (1749), and many others (Benjamin). It was noted that the birds exhibited ecchymoses where the electric sparks struck them, much like the ecchymoses seen on persons killed by lightning (Nollet). Priestley in 1767 killed kittens and dogs with the discharges of condensers, and tried without success to resuscitate a kitten by artificial respiration, distending the lungs by blowing with a quill into the trachea. Abildgaard (1775), using condensers and Leyden jars, tried without success to electrocute a 3-months-old foal; he succeeded in killing cocks and hens by electric discharges sent through the head, and made the important observation that fowls treated in this way and to all appearances dead could be brought back to life by electric shocks sent through the body from breast to back, but remained dead if not treated in this manner. Thus, a cock received the discharge of a Leyden jar through its head, and fell down apparently dead at once, blood coming from its nose and throat, no doubt in consequence of the rupture of some superficial vessels by the mechanical violence of the spark; but when a second Leyden jar was discharged into its breast the cock leaped up and flew away with alacrity, upsetting and breaking the Leyden jar. Abildgaard concluded that when death took place in the fowls it was due to syncope brought on by nervous shock.

Brodie (1828), in some experiments made to explain the mode in which death is produced by lightning, was led to suppose that electric shocks caused death by destroying the functions of the brain. He speaks of restoring to life the guinea-pigs apparently killed by electric discharges by means of perseveringly inflating their lungs by bellows. Brown-Séguard (1850) expressed the opinion that animals killed by electric discharges died by asphyxia, tetanus being set up and preventing respiration till death ensued. It must be remarked, however, that this explanation does not account for the many instances in which death occurs without the establishment of tetanus, but with simple failure of the heart or respiration.

Some important experiments on the electrocution of animals by sparks from the large induction coil belonging to the Polytechnic were made in 1869 by Richardson. They led him to believe that death could take place in two ways—either by failure of the respiration or by failure of the heart; in each case as a consequence of injury to the nervous centres. The heart was the last organ to be brought to rest. In the case of a pigeon anaesthetized with methylene bichloride and killed by a six-inch spark from the induction coil, and apparently killed outright, all four chambers of the heart went on beating for an hour and a quarter after death. Discussing the *post-mortem* observations he made, Richardson was finally led to a number of conclusions that are certainly erroneous. "Death," he said, is duo "in all cases where it is instantaneous to the sudden expansion of the gaseous part or atmosphere of the blood, combined in extreme degrees of

shock with a sudden conversion of animal fluid from the fluid into the gaseous condition." He had found that the vessels of the brain were distended, the arteries contracted, and that sometimes there were slight serous or haemorrhagic effusions beneath the arachnoid; "often, on lifting up the brain and medulla, there is a free escape of bubbles of gas," but he does not say whence this gas came. I cannot find that any other observer (except Corrado in a couple of instances) has observed gas in the blood vessels as the result of electrocution, either in animals or man. The large Apps induction coil Richardson used gave sparks up to 29 inches in length, and even with 29-inch sparks could produce no fatal effects unless reinforced by the use of Leyden jars; the currents he obtained would have been very small, presumably a few milliamperes at most, though the voltage would have been very great—tens or hundreds of thousands of volts; and these facts explain to some extent the inconclusive character of Richardson's results.

The fact is that electricity is a science in which beyond all others science is measurement. For all practical purposes accurate measurements of the strengths of currents, of electromotive forces and of resistances, were luxuries at the command of a few physical laboratories only until the end of the Seventies of last century. Until after the year 1880 the men of science who investigated the subject of electrocution never even thought of giving any precise figures whereby one could calculate the electrical dimensions of the currents they employed. Their statements are qualitative and not quantitative, and so are of historical rather than practical interest in any discussion about the cause of death by electricity.

One of the first experimenters to give accurate measurements of the voltages and currents he used was Grange (1884). He failed to kill guinea-pigs by continuous currents at 31 and 48 volts, and rats with currents of 62 volts; with an alternating current at 825 volts he failed to kill a dog weighing 17 lb., but some of his other attempts at electrocution were more successful. His failures were due to the want of skill with which he affixed the electrodes to the dogs, for he found the resistance of his dogs to be as much as from 50,000 to 80,000 ohms, while later experimenters have observed resistances of only a few hundred ohms when the electrodes were rationally applied to the animals. Grange found capillary haemorrhages in the central nervous systems of the animals he killed, and concluded that these haemorrhages were the cause of death. The fact that later experiments have shown that alternating currents at voltages as low as 10 or 15 volts suffice to kill dogs if electrodes are used so as to reduce the resistance of the animals to a minimum, proves what care is necessary in drawing definite deductions as to the possibilities of death by electric shocks; for here we have Grange failing to electrocute dogs with alternating currents of no less than 825 volts electromotive force.

In 1885 Mann made some interesting experiments on the effects of electricity on the action of the human heart. He applied the electrodes to the praecordia and back, and found that a slowly alternating current of from 15 to 30 milliamperes did not prejudice the heart's action. His method of experimentation was admirable, and failed to give more positive results only because the voltage he employed between the two electrodes was not large enough to drive stronger currents through the thorax, fortunately for the person on whom the experiments were made. It would be of the greatest interest to know how high a voltage can be used, and how large a fraction of an ampere can be passed with impunity through the human heart, from front to back through the thorax, with electrodes applied to the best advantage; because it is the strength of the current passing through the heart that is the main factor in determining death in the large majority of industrial accidents as they actually occur, and it is a quantity that has never yet been measured. Experiments to determine these points, however, in human beings would be far too dangerous to be justifiable—unless, indeed, some American criminal condemned to death were to offer to take on the task and were allowed to do so.

In 1885, and further in 1887, d'Arsonval made some interesting remarks on deaths caused by industrial electric currents, advancing the views as to their mode of

production that he has continued to hold faithfully ever since. These deaths, he said, were brought about in one of two ways:

- (1) By direct action, the mechanical effect or disruptive action of the electric current on the tissues; or
- (2) By indirect or reflex action on the nervous centres.

In the first case death is final; in the second it is often apparent only, so that the victim may recover if treated by artificial respiration immediately after receiving the shock. Most of the victims of industrial electric accidents had died of asphyxia, he believed.

In 1889 Donlin published some details of ten autopsies made on electrocuted criminals in America, and advanced the view that death was due to action of the electric current (conducted by the blood) upon the ganglia of the heart, causing a spasm of the heart muscle; in other cases it was produced by disorganization of the blood and interference with the circulation. I cannot find that these two theories ever had much vogue, or that the spasm of the heart muscle and disorganization of the blood have ever been observed experimentally, either before or after Donlin's elaboration of these views. An editorial in the *Lancet* (1890) brought forward the explanation that electrocuted persons died "by concussion of the brain and explosion within the closed cavity of the skull"; here, again, we have a theory of the cause of death that lacks any experimental evidence in its favour or even rational support. As a contrast may be quoted the excellent experiments made in 1890 by Tatum, upon dogs for the most part. He found no *post-mortem* lesions unless he used current densities many times in excess of those needed to produce death; weak currents might produce death by arresting respiration, strong currents by a permanent arrest of the heart without influencing respiration, while currents of intermediate strength might kill by arresting both the heart and the respiration simultaneously. Tatum appears to me to have been the first to give due prominence to the fact that death by electricity is generally due to paralysis of the heart, and depends on injury of the heart muscle rather than of the nerves of the heart. He also showed that section of the vagi and the use of atropine or curare gave no protection against the fatal result in these electrocutions—observations that are hard to explain on the theory that death by electric currents is due to nervous inhibition. Tatum also showed that a given current would be most fatal when the two electrodes were placed in the neighbourhood of the heart.

One may say that from the year 1890 onwards three main theories of the cause of death by electricity have held sway. The first was d'Arsonval's theory, that it was due to nervous inhibition of the heart and respiration. The second, as advanced by Tatum, attributed death to direct paralysis of the cardiac muscle by the passage of the electric current through it. The third, based mainly on the *post-mortem* examinations of electrocuted criminals in America, put death down to the gross lesions—haemorrhages—found in the brain and bulb of the victims, and produced by the vast quantities of electrical energy employed to procure an easy death.

In France the first theory was, naturally enough, generally adopted, and it was supported by many others besides the French (Biraud, Jenks, Hankel, Cunningham, Witz, Hedley, Durand, Verhoogen, Gardé, Jones, Därek). The second theory was supported by a number of authors, some of whom held that both were true in given instances (Witz, Gardé, Hedley (1895), Därek, Kratter, Oliver and Bolam, Cunningham, Bordier and Lecoate, Lebrun). The third met with comparatively little support outside America (MacDonald, Golet, O'Neill, Corrado), but was reiterated with some elaboration in a modified form by Jellinek (1903). But the subject has always had great attraction for the abstract philosopher, and so it is not surprising to find that the industrious production of what may not unfairly be called "freak theories" of death by electricity has continued. Thus, Shettle (1895) attributed such deaths to the fact that the electric current deprives the arterial blood of its active magnetic properties, and prevents the corpuscles from constantly inducing magneto-electric currents in the nerves. Bennett (1897) put them down to a violent, rapid, and excessive disturbance of the

normal atomic electrical equilibrium of the body, to such an extent as to cause complete and instantaneous disease and death. Coulter (1899) quotes the view that the whole volume of the blood seems to be suddenly forced to the head in the electrocution of criminals: "this alone in each and every case would explain the cause of death." I quote these views to show that the old principle of explaining *obscurum per obscurius* dies very hard.

Towards the end of the nineteenth century it became apparent that more extended experiments on animals were required to settle the mechanism of death by electric shock. In 1898 Oliver and Bolam published some investigations made upon etherized dogs and rabbits with an alternating current at 100 volts. They came to the conclusion that the deaths produced by currents of such voltages were by a primary cessation of the heart's beat as a rule, while currents at higher voltages might paralyse both heart and respiration together. Under no circumstances did these authors produce a primary failure of the respiration, and they note that it had been frequently recorded by bystanders that the persons killed by accidental shocks from industrial electric currents had breathed a few times after receiving the shock, although to all appearances dead.

Fibrillation of the Heart Muscle.

It had long been known (Ludwig and Hoffa, 1850) that one effect of electric currents on the mammalian heart might be to paralyse the ventricles by throwing them into a state of fibrillation, also known as *Herzaddirium*, fibrillary contraction or tetanulation, consisting in a fine and rapid but inco-ordinate twitching of the separate muscular bundles. Kronecker and Selmeier (1884) had produced fibrillation in the dog's heart by the mechanical stimulation—a pin-prick—of a certain point on the anterior aspect of the ventricle, also by ligature of the coronary arteries and by electrical stimulation. They attributed it to the destruction or paralysis of a nervous co-ordinating centre located in this particular part of the heart's muscle. McWilliam (1887) made further investigations into cardiac fibrillation, and denied that it was in any way a nervous phenomenon. He believed that it depended on physical or chemical changes in the substance of the heart muscle itself. The subject was very carefully examined again by Prevest in 1898, and it demands further consideration here because there is little doubt that cardiac fibrillation is the immediate cause of death in the majority of cases of death by electric shock in man. Prevest found, as McWilliam had found before him, that cardiac fibrillation was produced with much greater ease in certain varieties of animals and birds than in others: that in some the dog or pigeon, for example—it was generally fatal and irremediable, while in others it tended to cease spontaneously after a longer or shorter period, the heart beginning to beat normally again; and that in the young of any given species cardiac fibrillation was more readily recovered from than in the adult. Thus, guinea-pigs weighing 1 lb. would often recover from cardiac fibrillation spontaneously; while with heavier animals weighing 2 lb. the heart would fail to begin again to beat normally, the guinea-pig dying of asphyxia with great dilatation of the heart, though long massage of the heart might enable it to recover. As to the exact mechanism whereby cardiac fibrillation was produced, Prevest expressed himself as uncertain; he did not think it due either to stimulation of an intracardiac nervous centre or to anaemia of the muscle substance, as Kronecker at one time believed. It is explained by Bornstau as due to the different excitability of the different muscular bundles composing the heart wall and the various length of their refractory periods; all the bundles are strongly stimulated by the electric current, and so contract with their maximum frequency, but as these maxima are unequal the contractions are not synchronous. Why these small and rapid local contractions are not propagated in such a way as to make the heart beat as a whole remains unknown. They may be excited by the local ionic dissociations caused by the passage of the electric current, Professor Gotch tells me, as is also the case in the analogous Porret's phenomenon observed in the frog's sartorius muscle, and may fail to be transmitted to the adjoining bundles because, although excitability remains, the power of propagating the stimulus to contract may be lowered. Fibrillation is also to be seen in

the auricles of the heart, but does not seem to be of any great importance here.

Later Experimental Evidence.

An illuminating and most extensive series of experiments on the electrocution of animals was published by Prevost and Battelli in 1899. The great merit of these authors was that they varied the electrical conditions of their experiments far more widely than any of their predecessors, and gave measurements not only of the voltages they employed but also of the amperages of the currents they passed through the various animals; they also registered the arterial blood pressure and the respiratory movements. Perusal of the published works of the vast majority of the other writers on this subject is apt to leave one with the impression that their authors were not particularly skilled physiologists or physicians in some instances, in others that they were not electrical experts or men of science. The work of Prevost and Battelli is both sound and brilliant, and shows a degree of competence in both physiological and electrical matters that inspires great confidence in their conclusions. They employed both alternating and continuous currents, and took great pains to ensure adequate electrical contacts between the terminals of their electric apparatus and the animal under experiment. In many cases one electrode was placed in the mouth, the other in the rectum; the resistance in different dogs with this arrangement varied between 250 and 400 ohms. Electrical contact was made for a few seconds or for a fraction of a second in different cases. An alternating current at five volts was painful to dogs when passed thus between mouth and rectum, but did not affect the respiration or the action of the heart. The current at a pressure of 10 volts in two seconds caused almost certain death, the ventricles of the heart being irremediably thrown into a state of fibrillation while the auricles continued to beat normally. Respiration stopped, owing to general muscular tetanus, during the passage of the current, beginning once more when it was cut off, but soon dying away again for want of irrigation of the respiratory centre in the bulb with blood, for after the current was turned on the blood pressure fell steadily away to nothing in about 15 seconds. Using metal electrodes covered with wetted cotton, suitably shaped and applied to the shaved chest-wall, they found the resistance of three dogs from one side of the chest to the other was about 300 ohms in each case, and these dogs were killed by alternating currents at 10 to 15 volts pressure. Fibrillary contractions of the heart muscle was found to be almost invariably fatal in dogs; life could be preserved for a time by massage of the heart and artificial respiration, but death ensued when these manipulations ceased, as the heart could not be induced to begin to beat spontaneously again. In the guinea-pig of medium size, however, massage of the fibrillating heart through the chest wall would sometimes restore the animal to life, the heart beginning its normal action again: the resistance of the guinea-pigs as arranged for electrocution was from 700 to 900 ohms, and pressures of from 20 to 120 volts were found to be fatal by heart failure, as a rule. It was noted that in the case of the rabbit cardiac fibrillation tended to spontaneous recovery in most cases, and in the rat always. Hence alternating currents up to a pressure of 120 volts were not often fatal to rabbits, under the conditions of experimentation employed by Prevost and Battelli, and were never fatal to rats, as the fibrillation of the heart would cease spontaneously, and the respiration would begin again soon after the current was turned off in both these animals. But death could be procured by the use of these relatively low voltages if the contact was prolonged and the current kept on until asphyxia from prolonged arrest of the respiration occurred.

Using alternate currents at higher voltages—120 to 4,800 volts—Prevost and Battelli found that the effects produced were quite different, so far as life was concerned, and that death, when it occurred, might be caused in a different way. Thus, with the dog, alternating currents sent from the head to the legs at pressures of from 240 to 600 volts caused arrest of the heart (with ventricular fibrillation) and arrest of the respiration also, the animal inevitably dying. At higher voltages, however, 1,200 to 4,800 volts, the ventricles of the heart continued to beat vigorously, though the auricles were paralysed in diastole,

and respiration ceased; hence at these high voltages death was due to asphyxia from failure of the respiration, and not, as at low voltages, from heart failure, or, as at intermediate voltages, by failure of both heart and respiration together. The very important observation was made that a dog killed by the ventricular fibrillation caused by a current at 40 volts could be brought to life again if a current at a much higher pressure—4,800 volts in the present example, or 240 volts in other instances quoted later—was sent through its body so as to pass by way of the heart. Very similar results were obtained with rabbits; alternating currents at 240 volts killed by throwing the heart into a state of ventricular fibrillation, but at pressures from 600 to 4,800 volts the heart was not paralysed, but went on beating with rising arterial blood pressure, though respiration was brought to a standstill. Death in these conditions was due to asphyxia from failure of the respiration, and prolonged artificial respiration was needed to bring the rabbit back to life, and was not always successful. Analogous results were obtained in the experiments on guinea-pigs and rats. It was noted that, using these high voltages, phenomena were produced in all these animals indicating that the nervous system received injuries; general convulsions might be produced, or the respiratory movements might be upset for half an hour or more with loss of sensation and the reflexes, and the severity of the nervous symptoms was more or less in proportion to the voltage and the length of time for which the current was applied. No such phenomena depending on injury to the central nervous system were seen in the experiments at voltages up to 120 volts.

Prevost and Battelli also experimented in much the same way with the continuous electric currents of dynamos and of primary batteries. They found that continuous currents at pressures below 50 volts were not fatal to dogs even in five seconds, whereas with alternating currents pressures of 10 to 15 volts were fatal in two seconds. Between 50 and 550 volts the continuous current was uniformly fatal to dogs, causing irremediable ventricular fibrillation; artificial respiration was useless. No continuous current at voltages higher than 550 volts was available; but if it had been the authors thought that at some higher voltage it would have had the effect of stopping the cardiac fibrillation and restoring the normal action of the heart, just as was the case with the alternating current. In the case of guinea-pigs, the direct current was fatal by ventricular fibrillation at pressures of from 100 to 350 volts; but higher pressures, 400 to 550 volts, were not thus fatal, because although the heart fibrillated during the passage of the current, the extra shock of turning it off suddenly (the "extra-current at break," which d'Arsonval thought so important and fatal) restored its normal action to the heart. With rabbits, as with dogs, direct currents at pressures from 50 to 550 volts threw the heart into ventricular fibrillation, from which the rabbit might or might not recover spontaneously. With rats, the heart was thrown into ventricular fibrillation by currents at from 200 to 550 volts, but only for so long as the current was passing; when it was turned off the ventricles resumed their normal mode of beating, but the auricles were paralysed in diastole for perhaps two or three minutes before they set to work again.

It is clear, then, from these experiments that direct electric currents are much less dangerous, *ceteris paribus*, than alternating currents, for dogs, rabbits, guinea-pigs, and rats. The experiments also show clearly the importance of reducing as far as possible the resistance offered to the passage of the current through the animal, and of placing the electrodes on it in the most favourable position for producing a fatal result—in other words, of placing them so that the current passes as much as possible through the substance of the heart, when the minimum fatal voltage is to be determined.

A further series of experiments was made in 1899 by Prevost and Battelli to determine the mode of death in animals by electric shocks from induction coils and condensers. These shocks were mostly at voltages varying from 1,500 to 33,000 volts, and the electric energy available was up to 1,000 joules per shock. The duration of each shock was no doubt exceedingly brief—at a guess, perhaps a thousandth of a second. One may summarize their results by saying that the fatal effect of these

electrical discharges were in proportion neither to their voltage nor to the quantity of electricity (in micro-coulombs) they contained, but to their electric energy measured in joules, taking the presence of thoracic respiration as evidence of life or death. It is worth noting that no such connexion between the amount of electric energy employed and the occurrence or not of a fatal result can be worked out in the case of animals exposed to shocks from the ordinary electric currents used industrially, or in the numerous experiments on animals already described. Young animals were generally more easily killed than old, weight for weight; the direction in which the shock passed made no difference to the result. Death was generally due to asphyxia, from central inhibition of the respiration without inhibition of the heart's action. A curious *post-mortem* lesion was sometimes found, especially in young guinea-pigs—namely, a loss of the elasticity and retractility of the lungs, which rendered recovery by the performance of artificial respiration impossible. It occasionally happened in the guinea-pig that the heart was thrown into a transient state of ventricular fibrillation; the amount of electrical energy available was not large enough to kill dogs.

In 1899 Cunningham independently made some experiments on the electrocution of etherized dogs, somewhat similar to those described a few minutes ago, and, so far as they went, with similar results. Using a continuous current at 115 volts, he found great differences in the strength of current that could be passed with impunity through different dogs; thus a large Newfoundland was killed by 300 milliamperes, while a small shaggy terrier survived 700 milliamperes, and currents smaller than 200 milliamperes were never fatal. Other experimenters have found direct currents of 200 to 300 milliamperes to be fatal to dogs; very possibly the discrepancy here may have been due to the occasional use by Cunningham of larger electrodes that did not serve to concentrate the current and make a sufficiently large proportion of it pass through the heart—a supposition confirmed by the fact that the recorded resistance (77 ohms) of one of his dogs from side to side of the chest was only a quarter of the resistance commonly found in their own experiments by Prevost and Battelli and by Weiss. Such deaths he attributed to the immediate and permanent cessation of the co-ordinated contraction of the heart caused by the electric current. He then went on to investigate the effect of electric currents applied directly to the central nervous system of the etherized dogs. He found that strong currents (1.6 amperes) through the brain caused a deep inspiration, and cessation of respiration while the current flowed; the heart kept on beating and the blood pressure rose steadily to two or three times its original value, returning again to the normal when the current was cut off and respiration began once more. But if the current was kept on for as long as four or five minutes, the heart gradually stopped. He therefore argued that death by the action of electric currents on the brain and medulla was due to asphyxia, and not to heart failure. The strength of the ordinary electric currents that may be sent through the dog's head without causing rapid death is surprising; Houston found that even 6 amperes were not necessarily fatal.

A few more recent investigations remain to be mentioned. Battelli, in 1902, electrocuted dogs, rabbits, guinea-pigs, and rats with discharges from large Ruhmkorff induction coils giving sparks up to 15 and 45 cm. in length. He was able to kill the smaller animals either by arrest of the respiration, or, using a condenser as well, by throwing the heart into fibrillary contraction. With the larger animals, however, death could only be produced by asphyxia after prolonged electrification, the available current—measured in milliamperes—being too small to cause the heart muscle to fibrillate. Battelli stated that no human being had ever yet been killed by the discharge of an induction coil, and estimated that the larger of his two coils would have required a minimum time of two minutes to kill a man, when death, had the experiment been successful, would have been by asphyxia and not by heart failure.

The fact that d'Arsonval believes death by electricity to be due to inhibition, or paralysis of the central nervous system, has been mentioned already. In 1910 he recorded a further experiment that appeared to him to prove that

death by electricity, if not due to material lesions of the nervous centres and the heart, was due to Brown-Séquard's inhibition or the action of electric shock on consciousness and the psychical functions. A dog is anaesthetized with chloroform and the cerebral cortex is exposed; stimulation of the cortex with the current from a single Daniell cell (1.1 volts) is found to produce movements of the limbs. If the dog is now killed by a current at 110 volts the heart is thrown into fibrillary contractions, the respiration stops, and the cortex ceases to be excitable by the Daniell cell. At the end of a few minutes respiration begins again, and then the cortex again becomes excitable, and, lastly, in some cases the heart begins to beat spontaneously once more. This experiment d'Arsonval takes to prove that all the vital functions are affected at the same time by an electric shock, so that in his view it is superfluous to inquire whether death is due to a paralysis of the heart or not. He admits that the recovery or death of an animal from a shock that may or may not be fatal depends entirely on the question whether the cardiac fibrillation is transient or is followed by permanent loss of the ability of the heart to beat spontaneously; and as it has been found that section of the vagi has no influence on the occurrence of this cardiac fibrillation, it is, in my opinion, impossible to agree with d'Arsonval when he attributes great importance to nervous inhibition in the large majority of the fatal accidents brought about by industrial electric currents.

NOTE.—The references to the literature will be given at the end of the third lecture.

THE USE OF PHYSICAL CONSTANTS IN TOXICOLOGY.

By OLIVER C. M. DAVIS, D.Sc.,

LECTURER ON CHEMISTRY AND MATERIA MEDICA IN THE UNIVERSITY
OF BRISTOL.

In the course of toxicological examinations it is frequently necessary to identify various organic compounds, and the increasing use of synthetic remedies renders it imperative that toxicologists should have at their disposal methods by which such drugs can be recognized with the greatest possible certainty. In cases where reasonable amounts of the substance can be obtained there is usually no great difficulty, since quantitative analyses may be made of both the original substance and its derivatives.

It sometimes happens, however, that, after a compound has been separated from some food substance or excretion, the amount available for examination is exceedingly small, and becomes still smaller after it has undergone purification. In such cases, unless some definite chemical or physiological reaction can be applied, colour tests and other purely empirical methods are adopted, and consequently, although the investigator might be satisfied with the results he had obtained, such results might not carry, and very often do not carry, such weight with others.

It is, therefore, desirable to ascertain if any physical methods are available for a more satisfactory elucidation of such problems.

One constant—the melting point—stands out pre-eminently, since it can be obtained with a very small amount of material. During recent years a modification of the usual method of identifying a substance by taking its melting point has been largely used by organic chemists.* This method may be called that of "mixed melting points."

Speaking broadly, a pure organic substance that is fusible within ordinary limits will melt sharply—that is, at one particular temperature it will be a definite solid, and when the temperature is raised gradually it will assume the liquid phase within 1° C., or possibly 2° C. Now the admixture of foreign substances with the material under examination will totally upset this state of things, and instead of fusion taking place at a definite temperature characteristic of the pure substance, it will commence at an entirely different temperature. This is

* The mixed melting point method was apparently first used by Kipping and Pope (*Trans. Chem. Soc.*, 1893, 63, 558).

due to the fact that one constituent of the mixture is acting as a solvent of the other, and solution is only gradual. A series of compounds has been investigated to illustrate this point, and in each case two substances have been chosen whose melting points are fairly close together. The usual type of apparatus was employed in which the bath was sulphuric acid.

A tube containing one pure substance was attached to the left side of the thermometer, the second pure substance to the right side, and a third tube in the middle contained an intimate mixture of equal parts by weight of each substance. The temperature was gradually raised, and the three tubes closely inspected during the process by the aid of a lens. The pure substances retained their original appearance to within about 1° C. of the final fusion point, which in each case was complete within a range of 3° C. The mixture of the two substances taken commenced to soften at a much lower temperature, and fusion extended over a considerable range in each case.

It is clear from the following table that a pair of substances may have similar melting points, but a totally different one when mixed.

Table of Melting Points of Pure and Mixed Substances.

| Substance. | Melting Point. | Melting Point of Mixture. |
|-----------------------------|----------------|---------------------------|
| Antipyryn | 110°-115° | 57°-74° |
| Antifebrin | 110° 113° | |
| Anisic acid | 181°-183° | 145°-172° |
| Succinic acid | 187°-188° | |
| Aconitine | 190°-193° | 160°-175° |
| Veronal | 190 | |
| Thymol | 50° 51° | 18°-30° |
| p. Toluidine | 45° | |
| Cocaine | 96°-98° | 63°-95° |
| p. Chlor formanilide | 100°-103° | |
| Codein | 150°-152° | 75°-135° |
| p. Acet-toluide | 150°-152° | |
| Cinnamic acid | 133°-135° | 95°-115° |
| Phenacetin | 133°-135° | |
| Sulphonal | 126°-127° | 70°-90° |
| β Naphthol | 122°-123° | |
| Cocaine | 96°-98° | 65° 85° |
| Betol | 95° | |
| Strychnine | 270° | 230°-240° |
| Cinchonidine | 260° | |

During the past three years I have had on two occasions to examine specimens of urine for small quantities of abnormal constituents, and in each case succeeded in extracting about 0.1 gram of a crystalline substance closely resembling veronal.*

In both instances the compound was first carefully purified, but the amount of pure material obtained was much too small to be investigated by any known method other than that described. The agreement between the melting points of veronal, the material suspected to be this compound, and a mixture of both, left no doubt as to the identity of the drug.

It is hoped that this application of a simple physical constant may prove of great value to toxicologists.

* The veronal was extracted from the urine with ether after preliminary treatment with lead acetate, etc., according to method described by Fischer and Hoppe (*Munch. med. Woch.*, No. 28, 1909).

THE recently issued report of the Sceptre Life Association, an insurance company which caters for abstainers and non-abstainers and keeps the results attained in each section separate, again shows the effect of total abstinence on the longevity of its policy holders. In 1912, of 132 deaths expected among non-abstainers 92 occurred, whilst there were only 53 out of 139 expected deaths of total abstainers. The percentage of actual to expected deaths among the non-abstaining insured (69.70) was more than double that of the abstaining policy holders, who come out with the low percentage of 38.13. For the twenty-nine years 1884 to 1912 the percentage of actual to expected deaths has been, for non-abstainers, 79.33; for abstainers, 51.63. Seeing that at the time of acceptance each class of policy holders was examined as rigidly as the others and all the lame ducks cast out, the results recorded must be regarded as evidence that the use of alcoholic liquors shortens the duration of even picked lives.

THE INTRAMURAL SPREAD OF RECTAL CARCINOMA.

[WITH SPECIAL PLATE.]

By PERCIVAL P. COLE, M.B., Ch.B., F.R.C.S. Eng.,
 ASSISTANT SURGEON TO THE DREADNOUGHT HOSPITAL, GREENWICH;
 SURGICAL REGISTRAR TO THE CANCER HOSPITAL; SURGEON
 TO THE WEST HAM AND EASTERN GENERAL HOSPITAL.
 (From the Cancer Hospital Pathological Laboratory.)

OPERATIVE measures for the eradication of cancer must be planned according to the pathological findings. That widely divergent views are held as to the particular operative treatment applicable to cancer of the rectum and pelvic colon is sufficiently evidenced by recent papers on the subject by Harrison Cripps, Paul, Miles, and Sampson Handley. It may reasonably be assumed that corresponding differences of opinion exist as to the pathological conditions which obtain; and, indeed, such assumption is amply confirmed by the perusal of these papers, as well as by the remarks made by speakers during the discussion on rectal cancer at the Royal Society of Medicine in 1910.

A convenient classification—adopted by Miles—of the pathological factors which must be considered in planning any radical operation for cancer of the rectum is as follows: (1) The spread of the disease in the bowel wall—intramural; and (2) that which occurs in surrounding or distant tissues—extramural.

This communication is concerned with the first factor, and an attempt has been made to determine its extent and significance.

Material.

This comprises 20 cases, in 18 of which the bowel investigated was removed by operation. Two *post-mortem* cases are included because they exhibit important features. The majority of these cases were operated on by surgeons at the Cancer Hospital, but for three I am indebted to Mr. Barker of University College Hospital, and for two to Mr. Gordon Taylor of the Middlesex Hospital. The operation in 13 cases was the radical abdomino-perineal, as described by Miles. In 3 cases the malignant disease was situated above the pelvic colon. The length of bowel removed in these 16 cases was from 9 in. to 23 in. In 2 cases a local resection was practised.

Technique.

The bowel was slit up immediately after operation, stretched by nailing to a piece of board, and placed in a fixative solution consisting either of formalin in normal saline or acid mercury perchloride. After fixation a strip the whole length of the bowel was taken and cut into inches. Each inch of tissue was embedded in paraffin, sectioned, and stained with muci-carmin according to the method which I have elsewhere detailed. In some cases two strips were taken.

Nature of Growth.

The growth in every case was an adeno-carcinoma. In 18 cases the appearance presented was that of a typical carcinomatous ulcer, in 1 there was a tendency to mass formation approximating to the papilliferous form, while 1 exhibited a diffuse colloid infiltration. The last specimen was obtained *post-mortem* from a male patient, aged 18, who rapidly succumbed, and illustrates the extreme malignancy of this form of growth.

The ulcers presented the usual features. Their edges were irregular, rolled, and everted. The long axis of the ulcer was transverse in every case, showing a tendency to involve the bowel circularly rather than longitudinally. Another point noted with regard to these ulcers was the frequency with which a narrow tract of mucous membrane was found to be involved in cases where clinical examination suggested that the ulcer had completely encircled the bowel. This narrow tract of apparently normal mucous membrane was always situated in the mid-line posteriorly. Examination of other specimens, preserved in the museum of the Cancer Hospital, indicates that this condition is so common as to be almost characteristic. The favourite site of origin of cancer of the rectum would appear to be on the anterior or lateral wall. From this point the growth spreads round the bowel, a partial

indication of its progress being afforded by ulceration, which begins to occur at a very early stage.

Spread and Ulceration.

Microscopical examination throws some light on this process of ulceration.

It is assumed that carcinoma commences as a down-growth of glandular epithelium which pierces the muscularis mucosa and invades the submucous coat. The initial carcinomatous focus will be covered by unbroken epithelium, and surface ulceration may thereafter take place, as the growth spreads, by two possible methods.

The growth of carcinoma in the submucous and deeper layers of the bowel wall may undermine the glandular epithelium, cut off its blood supply, and so induce necrosis, thereby exposing the subjacent carcinoma as the base of the ulcer.

On the other hand, successive portions of mucous membrane may be undermined as the growth progresses, and the overlying mucous membrane may be directly involved by upgrowths of carcinoma into and replacing it. The latter process appears to be that which obtains, and the phenomenon is exhibited in Fig. 1.

It will be gathered that the carcinoma spreads more widely in the submucous coat than is indicated by the surface ulceration. The muscular coat is invaded to an equal, and frequently to a greater, extent.

The relative invasion of the various layers of the bowel wall in a typical case may be represented diagrammatically as in Fig. 2.

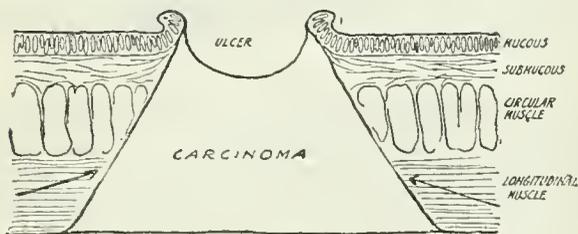

Fig. 2.

The tendency of the stroma of the growth is to progressive contraction, and the pull thereby communicated to the deeper layers of the adjacent, but uninvolved, bowel wall produces that eversion of the margins of the ulcer which is such a marked feature of these growths. Eversion of the edges of malignant ulcers in other situations may equally be a surface indication of subjacent infiltration greater in extent than the area of ulceration. Puckering of the peritoneum is another phenomenon due to the contraction of the stroma, and it is possible that the first stage of invagination may be brought about by the same means.

Invagination is frequently observed in those cases in which the greater part of the circumference of the bowel is involved and causes the growth to assume the form, when examined per rectum, of a cervix-like mass protruding downward into the lumen of the bowel. The contracting stroma of a carcinoma will exert a pull equally on the bowel above and below. The pull will, however, only be effective on the upper and more movable section, which will therefore tend to be dragged down, and this invaginating process, once commenced, will be continued and increased by peristalsis.

The tendency displayed by carcinomatous growth to encircle the bowel has been already noted. This mode of progress has been rather vaguely ascribed to the circular disposition of the vessels. The main lymphatic networks of the large bowel are: (1) The submucous; (2) the subserous; (3) an intermuscular plexus situated between the muscular layers; and two subsidiary intramuscular networks constituting (4) the plexus of the circular coat, and (5) the plexus of the longitudinal coat.

The lymph from the intramuscular networks drains for the most part into the intermuscular plexus, though communication no doubt exists between the lymph vessels of the longitudinal coat and those of the subserous plexus.

The vessels of the circular muscle coat are disposed radially, running out from the submucous coat to the intermuscular plexus like the spokes of a wheel. This arrangement is illustrated in Fig. 3, drawn from a case of

lymphosarcoma. The vessels of the longitudinal coat have generally a longitudinal direction.

Examination of sections reveals the presence of an important vascular area situated between the two muscular tunics. The vessels of this intermuscular plexus have generally a circular disposition. The importance of this plexus becomes increasingly great as the bowel is traced down until, below the peritoneal reflection, it shares with the submucous plexus the task of transferring the lymph from the bowel wall to the collecting trunks.

Deposits of carcinoma in this intermuscular lymphatic plexus are depicted in Fig. 4, and it is suggested that this plexus is largely responsible for the circular distribution of carcinomatous growths.

Collecting trunks are formed on the posterior aspect of the bowel, those from the rectum draining either into the ano-rectal glands situated within the fascia propria or into the mesocolic glands lying between the layers of the mesocolon.

It is suggestive that the area of uninvolved mucous membrane, previously noted, should occur also on the posterior aspect of the gut at the site where the collecting trunks are in process of formation.

The lymphatic distribution below the peritoneal reflection is diagrammatically represented in Fig. 5.

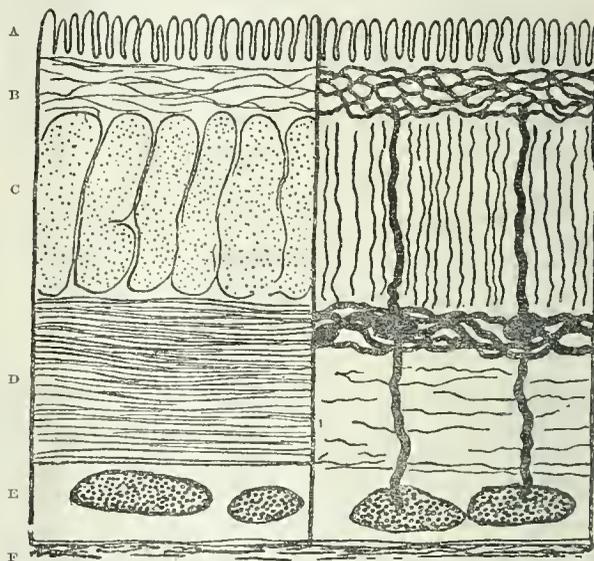

Fig. 5.—A, Mucous layer; B, submucous layer; C, circular muscle; D, longitudinal muscle; E, ano-rectal gland; F, fascia propria.

One *post-mortem* specimen included in this series is preserved in the museum of the Cancer Hospital. It exhibits a small malignant ulcer the size of a sixpence situated in the mid-line on the posterior aspect of the bowel. Microscopical examination shows that the growth has spread through the whole thickness of the bowel wall, and has freely invaded the connective tissue and glands of the mesocolon. The specimen conclusively illustrates that the size of the ulcer is no measure of the intramural invasion or extramural spread.

The observations hitherto have been concerned solely with the purely local phenomena of intramural growth. In 19 cases no evidence of permeation could be detected beyond the microscopical edge of the growth.

In the remaining case—that of the patient with rapidly growing colloid carcinoma—extensive intramural spread was noted. Every part of the growth stained brilliantly with muci-carmin, so that the condition of the various layers could be easily ascertained (Fig. 6). Sections taken from the bowel wall 14 in. above the growth exhibit much the same appearance. The spread seems to have taken place primarily by means of the subserous lymphatic plexus, involving the longitudinal muscle coat, invading the intermuscular lymphatic plexus, and thence radiating towards the lumen of the bowel. The mucous membrane, though atrophied, shows no evidence of permeation or infiltration, and, although occasional deposits are present in the submucous coat, these only occur in the lower sections.

MR. PERCIVAL P. COLE: INTRAMURAL SPREAD OF RECTAL CARCINOMA.

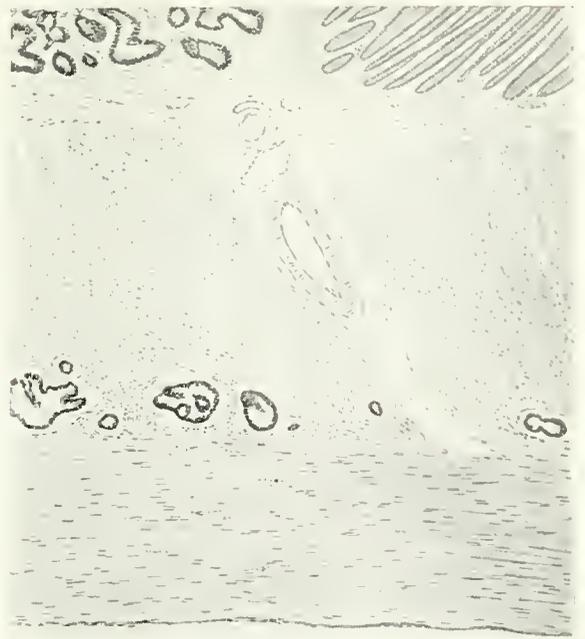

Fig. 4.—Intramural spread along the intermuscular lymphatic plexus.

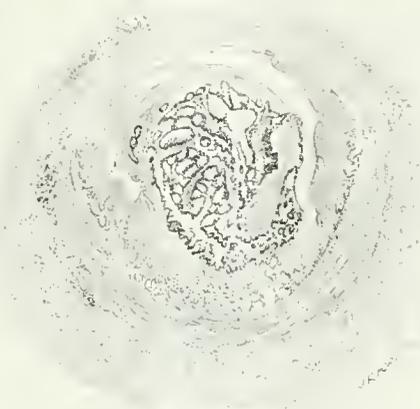

Fig. 7.—Deposit of carcinoma in the connective tissue in close proximity to the bowel wall, at a point three inches above the upper limit of the growth.

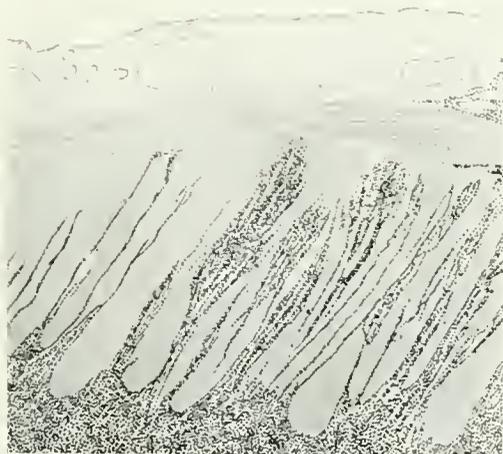

Fig. 3.—Growth is seen spreading along the radial lymphatics of the circular muscle coat.

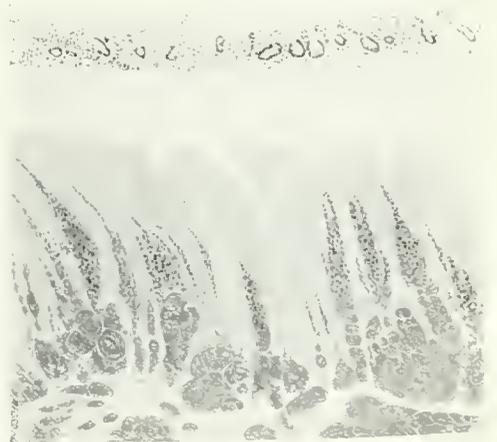

Fig. 6.—Intramural spread along the subperitoneal and intermuscular lymphatic plexuses. The growth is spreading along the radial lymphatics of the circular coat towards the submucous coat. The mucous membrane is atrophic.

MR. ARCHIBALD YOUNG: DISLOCATION OF THE METATARSUS.

Fig. 1.—Case I: Showing complete outward dislocation of metatarsus. Note prominence on inner side of foot caused by internal eminence.

Fig. 2.—Case II: Showing outward dislocation of metatarsus.

Fig. 3.—Case II. Showing slight dorsal displacement of proximal end of metatarsus.

Fig. 4.—Case III: Before reduction of dislocation. Note prominence on inner side of foot caused by proximal end of first metatarsal.

Fig. 5.—Case III. After reduction of dislocation.

It has been suggested that local recurrence after local excision is strong evidence in favour of the presence of intramural permeation, even though such be undemonstrable.

That a typical carcinomatous ulcer may be formed as a result of invasion of the bowel wall from without is demonstrated by a case in this series.

On opening the abdomen, it was noted that the pelvic colon was densely adherent to the anterior and left lateral surface of the rectum at the bottom of Douglas's pouch. Separation from the uterus was regarded as an unsafe procedure, so this organ was also removed. On examination of the 12 in. of excised bowel the presence of two growths was revealed, though only one had been diagnosed. These were located on the bowel walls at the site of adhesion. The upper growth, in the pelvic colon, was of the whipcord type, and had completely encircled and constricted the bowel wall, giving rise to the symptoms of obstruction for which the patient was admitted to hospital. The lower growth, in the rectum, presented itself as a carcinomatous ulcer involving the anterior and left lateral walls of the bowel. It is difficult to escape the conclusion that the upper was the older growth and that the lower one had arisen as a result of contact.

In Fig. 7 is depicted a carcinomatous deposit in the pericolic connective tissue 3 in. above the upper margin of a growth. If in such a case a local excision had been practised with the removal of 1 in. of normal bowel above and below the growth, this deposit must necessarily have been left in close proximity to the intestinal junction. Local recurrence in such a case is readily explained. Clinical and *post-mortem* evidence also favours the view that recurrence is an extramural phenomenon.

Finally, it may be stated that in every case in the series the growth had spread to the tissues outside the bowel wall.

DISLOCATION OF THE METATARSUS, WITH AN ACCOUNT OF THREE CASES.

[WITH SPECIAL PLATE.]

By ARCHIBALD YOUNG, B.Sc., M.B., C.M.,

CONSULTING AND VISITING SURGEON, BROADSTONE JUBILEE HOSPITAL, PORT GLASGOW; ASSISTANT SURGEON, WESTERN INFIRMARY, GLASGOW; LATE SENIOR ASSISTANT TO THE REGIUS PROFESSOR OF SURGERY, UNIVERSITY OF GLASGOW, ETC.

FREQUENCY OF THE CONDITION.

DISLOCATION at the Lisfranc (tarsal-metatarsal) joint is an unusual form of injury, but it is probably much less rare than would be suggested by a consideration of the meagre literature on the subject. The comparative dearth of references in surgical literature may be realized when the figures given by Stimson in his treatise on fractures and dislocations are quoted: "Malgaigne collected 21 cases of the various dislocations, Hitzig 29, Bayer 68, and Fischer 18 of the first metatarsal." Pansa, quoted by Nasse and Borchardt, in the *Handbuch der praktischen Chirurgie* (Bergmann, Bruns, and Mikulicz),² "was able to collect, in the year 1897, 22 complete and 23 partial dislocations."

Considering the exposure of the foot to violence, these figures are undoubtedly small, and give almost certainly a false idea of the actual frequency of such a type of injury.

DEARTH OF RECORDS.

The relative dearth of records may in part be explained by the fact that minor degrees of displacement have been overlooked. The development of radiography in recent years ought to act now as an effective preventive of this type of error. Part explanation may also be found in the fact that the existence of these dislocations might readily be overlooked when they form mere incidents in a more severe injury to the foot and ankle, perhaps calling for immediate amputation.

Indeed, another aspect of this possibility is suggested by the fact that several writers of repute have put it on record

that these dislocations, when they do occur, are usually the result of crushing force of such severity as to destroy the vitality of the soft parts to a degree which renders amputation necessary.

Thus Griffith³ says they are usually "complicated by destruction of the soft parts, and frequently require amputation"; Wharton⁴ says, "These dislocations usually result from crushing forces which destroy the vitality of the soft parts so completely that amputation is required"; and even Erichsen⁵ states, "The question of amputation will always present itself in these cases, and must be determined on general principles, by the age of the patient, and by the extent of injury to the soft parts."

It is probable that such dislocations are neither so uncommon, nor, as regards the prognosis, of so grave a nature as the records and opinions referred to above would imply.

The varieties of dislocation are as follows:

1. Dislocations of single metatarsal bones.
2. Dislocations of several metatarsal bones simultaneously.
3. Dislocations of the whole metatarsus *en bloc*.

Any of these forms may be, and the second and third usually are, complicated by other injury, such as fracture, accompanying damage to the cuneiform bones or cuboid, with or without displacement, or damage to soft parts.

In Group 1 the first metatarsal seems to be by far the most commonly dislocated. In the cases reported it was almost always displaced upwards. As already quoted, Fischer⁶ was able to collect records of 18 cases of this injury. The recorded cases of isolated dislocation of the other metatarsals are very few in number.

In Group 2 cases have been recorded of quite a number of different combinations. In groups of two at a time there are records of the first and second being displaced together; also the third and fourth, and the fourth and fifth. The direction of displacement varied in each—sometimes upwards and inwards, at other times upwards and backwards. In groups of three at a time, there are records of 2 cases of dislocation of the first, second, and third metatarsals, these being displaced together upon the dorsum; in 1 case the displacement was downwards into the sole. The second, third, and fourth have been, in one or two cases, displaced together upon the dorsum.

Of dislocations of four metatarsals at a time, 4 cases are mentioned by Stimson, all having been dislocations of the first four metatarsals. In two of these the affected bones were displaced bodily upwards. In 1 case (reported by Malgaigne) the first three were displaced downward, and the fourth upward. In one (reported by Ely⁷) the first metatarsal was displaced inwards, the others upwards and outwards. This case of Ely's, it will be seen later on, seems to have been very similar to one of the three cases which I have to report in this paper.

Group 3 comprises those cases in which all the metatarsal bones have been displaced bodily at the tarsal-metatarsal joint.

Four forms have been described, according as the displacement was upward, outward, downward, or inward. Only one example of each of the two last-mentioned forms has been reported, and one, the inward form, is not free from doubt as to its correct description. The case of downward displacement was reported by Smyly.⁸ The injury was caused by the fall of a wagon which pressed the heel forward, while the toes were fixed.

Even the upward and outward displacements have not been met with, or recognized, with any degree of frequency. Hitzig, quoted by Stimson, gives the number of cases of upward dislocation he was able to collect as 11, the most usual cause being direct violence, but in 2 cases muscular violence was the agent, the patients sustaining the injury in making violent effort "to avoid falling, after having slipped while carrying heavy bundles."⁹

This form of dislocation may be complete or incomplete, and it may be complicated by a part or the whole of one or more of the cuneiforms being displaced along with the metatarsals. Examination has shown in those cases examined *post mortem*, or where the injury was compound, just such damage—in the way of rupture of dorsal and plantar ligaments and of muscles, in the fracture or separation of cuboid and cuneiform bones, and in the fracture of one or more of the displaced metatarsals, or

their separation from each other in a lateral direction—as one might expect such an injury would readily produce or imply. The resultant clinical picture has varied a good deal in the different cases, the normal axis of tarsus and metatarsus being in some cases preserved, in others the metatarsus being displaced laterally *en bloc*, so leading to an angular deformity, in addition to the foreshortening of the foot. The proximal ends of the metatarsals bulge on the dorsum, forming a ridge corresponding roughly to the line of the joints, or proximal to this on the dorsum of the tarsus. In some of the recorded cases reduction was successfully accomplished. Even in the cases where it failed fairly good function was obtained in time. In only one of the cases was amputation done as a primary expedient.

Of the outward dislocation, Stimson states that 10 cases have been reported, by Langier and Lacombe, Tutschek, Mignot-Danton,¹⁰ Désprès,¹¹ and Bayer. It is pointed out by Stimson, as also it has been indicated by others, that in virtue of the manner in which the proximal end of the second metatarsal is locked between the first and third cuneiforms, such a lateral dislocation can hardly occur uncomplicated by fracture unless it be preceded by an upward or downward displacement. The proximal end of the second metatarsal has usually been broken, though in two cases it was the third that was fractured. In four of the ten cases quoted by Stimson reduction was effected.

PREPONDERANCE OF OUTWARD DISLOCATIONS.

The reasons for the preponderance of outward dislocation are worthy of brief reference. They are almost solely anatomical. Notice has already been taken of the fact that lateral displacement is possible only as a sequel to upward or downward displacement, or when associated with fracture. It is hardly necessary to point out further that where lateral displacement eventuates upon the vertical dislocation the latter is almost always dorsal in direction. The explanation of the preponderance of the outward displacement is not far to seek when regard is had to the anatomical relations of the cuneiform-metatarsal joint. The notch between the first and third cuneiforms into which the second metatarsal fits is not similar on its two sides. Its internal angle is about 90 degrees, while its outer is almost 120 degrees. This admits all the more readily of primary slipping of the ill-fitting metatarsal towards the outer side. Further, the inner wall, formed by the first or internal cuneiform, is fully 1 cm. in height; while the outer wall, formed by the third or external cuneiform, is at most 0.5 cm. in height, so that here again is a condition which predisposes to the outward displacement.

Associated with the dislocation of the metatarsals, as has already been said, there may be fracture of the bases of the second or third metatarsals or of both. Also, there may be any degree of damage to, or comminution of, cuneiforms, and even of the cuboid. The degree of injury to, sprain, or rupture of dorsal and plantar ligaments, also of interosseous ligaments and muscles, will vary in different cases, but must always be considerable.

CAUSES AND METHOD OF PRODUCTION OF THE INJURY.

As regards the *actual forces causing* the metatarsal dislocation, the following facts are ascertainable from the records.

Falls of different kinds have caused the injury. For example, in several recorded cases, the first metatarsal has been dislocated by a fall from a horse, the actual displacement being determined by the pressure of the stirrup. A fall from a height—the patient alighting on the anterior part of the foot—has led to the upward displacement of the whole, or part, of the metatarsus, especially when the metatarsus has been forcibly plantar-flexed. Falls of heavy weights upon the upper part of the instep, driving the tarsus violently downwards, have led to the upward displacement of individual bones or groups of bones of the metatarsus.

Theoretically, any form of violence which is applied in the direction of abduction of the anterior part of the foot, the heel (or tarsus) being fixed, or which tends to produce forcible adduction of the heel (or tarsus) while the anterior part of the foot is fixed, may produce outward dislocation of the metatarsus. Two of the cases which I have to report are examples of the second mentioned type.

Conversely, it may be surmised that, did anatomical conditions permit, or encourage, the inward dislocation, it might be produced by violence tending to produce forcible adduction of the anterior part of the foot, the heel (or tarsus) being fixed; or violent abduction of the heel (or tarsus) the front of the foot being fixed.

Forces of complex character, and applied in irregular fashion, will have to be assumed in many cases where, as for example in my third case, one metatarsal is driven in one direction and the others in the opposite direction. It is possible that the tarsus may have acted as a wedge, driving the metatarsals apart; or some direct violence of a specially localized type, applied immediately to the sole, or to the dorsal surface of the foot, may have caused the bones to be driven in opposite directions. The comparative capacities of particular ligaments for resisting special strain, and the varying force of intrinsic muscles, as applied in special circumstances, may also require to be taken into consideration.

DIAGNOSIS.

The diagnosis of metatarsal dislocations should not be, nor is it, so far as my experience enables me to judge, difficult. More especially is this the case now that we are able to command the aid of the *x* rays to supplement what can be learnt from a careful consideration of the clinical pictures which such injuries present. Certainly, so far as the complete dislocations are concerned, there are no special difficulties.

Henry Morris¹² writing, in 1883, of the dislocations upwards and downwards, says that these “are readily diagnosed by the shortening of the foot, without a corresponding elongation of the heel, and by the projection and depression on the instep.” Gould and Warren¹³ corroborate this: “When backward dislocation occurs, the foot is shortened, and a prominence, with a groove either before or behind it, is seen in the plantar and dorsal displacements. The foot is usually somewhat adducted, and the hollow of the sole is flattened.” Nasse and Borchardt¹⁴ speak of the symptoms of dorsal complete dislocation as being very characteristic (Smyly's case of plantar dislocation being the sole authentic recorded example of the other type), thus: “The whole foot seems shortened, being in the position of moderate talipes equinus, while the toes are held in the position of dorsal flexion by the tense extensor tendons. The arch of the dorsum of the foot is exaggerated; right across it there extends a tumour-like prominence, formed by the bases of the metatarsal bones.”

Smith¹⁵ called particular attention to the peculiar alteration in the form of the sole of the foot in the upward dislocation. Instead of presenting the usual concavity, this becomes convex, both in its antero-posterior and in its transverse diameters.

As regards the diagnostic features of the lateral dislocations, Morris¹² refers to the projection at the inner or the outer border of the foot; Gould and Warren¹³ point out that there is not necessarily in these any shortening of the foot, but that there is “some adduction or abduction, according as the displacement is inward or outward.” Nasse and Borchardt¹⁴ are more explicit. They say: “The lateral dislocations at the Lisfranc joint are easy to recognize. In the outward dislocation the point of the foot is mostly always adducted; on the inner edge the first cuneiform, and on the outer margin the base of the fifth metatarsal project markedly. In the inward dislocation the first metatarsal forms, on the inner margin of the foot, a definite projection; correspondingly, on the outer side there is a depression, behind which the cuboid projects.”

These descriptions are quite in keeping with the findings in the cases which have come under my observation. It is, in the normal foot, so easy to make out prominent bony landmarks at the tarsal-metatarsal region, that any considerable departure from the normal regularity ought to be readily appreciated, provided that a careful inspection and manual examination be made; especially if comparison be made with the other (the uninjured) foot, and provided that the examination is not delayed long enough for swelling of the soft parts to so mask contours as to preclude accurate recognition of bony outlines. Parenthetically, it may be said, that in such gross displacements as we have to deal with in cases of complete dislocation the swelling of the soft parts must be very considerable to

completely obliterate and conceal such gross changes of bony relations. Practically, indeed, this is not, in my opinion, a substantial difficulty.

X RAYS IN DIAGNOSIS AND IN TREATMENT.

Further, as has been already said, we have now the all-important *x*-ray aid to an accurate diagnosis, and this aid ought never to be neglected where there is no insuperable obstacle to its use. Even if the diagnosis seems quite clear enough without its use, it will almost certainly determine a more accurate appreciation of the exact physical condition, and not improbably lay bare some detail which would otherwise be overlooked. It is, besides, a very real, if not absolutely essential, aid to estimation of the completeness or incompleteness of reduction of the displacement once this has been undertaken, and it may be laid down quite definitely that, whatever its value, in an individual case, from the point of view of diagnosis, as a guide or check regarding the efficiency of reduction, it ought never to be neglected. Both at the time of reduction, and at some period subsequent to this (say two or three weeks), the efficiency of the treatment should be confirmed by *x*-ray plates, taken both in the vertical and in the horizontal planes.

REDUCTION OF DISPLACEMENT.

Reduction of these dislocations should not present any insuperable difficulties, though the records of some of the earlier reported cases would seem to suggest that reduction might prove a formidable, and even an impossible, undertaking. Indeed, there are on record at least two cases in which death occurred as the result, so it would appear, of the attempts at reduction.¹⁶

In most cases, and certainly where any difficulty is encountered, an anaesthetic should be given—ether or chloroform. Under its influence there ought not to be much difficulty in manoeuvring the displaced bones into their proper position. In the case of dislocation of single bones, traction upon the displaced bone, combined with or followed by direct pressure on the projecting or displaced end, should in most instances readily effect reduction, and much the same may be said of dislocations of several bones together. If replacement prove difficult, open operation, under simple aseptic precautions, may quite readily be resorted to, and the bone or bones can be directly levered into position, or any part which cannot be fully reduced may be resected.

As for the complete dislocations, traction on the anterior end of the foot, combined with direct pressure on the dislocated bones, will generally prove effective. For the vertical dislocations this is certainly all that is ever likely to be necessary. In the case of the lateral dislocations the tarsus is first of all fixed, then traction on the anterior part of the foot is applied in such a manner as to exaggerate the pathological position. Simultaneously with this exaggeration of the malposition lateral pressure in the direction of adduction or of abduction will complete the reduction—adduction where the dislocation is outward, abduction in the case of the inward form (which, as already stated, is probably very rare).

In the three cases which I have to report reduction proved comparatively easy. In all three, chloroform anaesthesia was employed, and the actual reduction was accomplished by a combination of traction on the anterior part of the foot, adduction and abduction movements, plantar flexion followed by dorsal flexion, and direct pressure on projecting bones. In all three cases the general correctness of the replacement was at once verified by fluorescent screen and subsequently by *x*-ray plates. As stated earlier, it is probably wise to follow this course of immediate and later *x*-ray confirmation wherever possible.

TREATMENT AFTER REDUCTION.

As regards further treatment, it may be said that, once correctly reduced, these dislocations do not tend readily to redisplacement, but it is well to provide artificial fixation, by means of a plaster-of-Paris case, for several weeks. In the case of the upward displacements a period of two or three weeks ought to be ample, but where any strain is likely to be put on the foot this period may be prolonged somewhat with advantage.

In the case of lateral dislocations fixation should be maintained for a longer period, and this for two reasons: (1) on account of the greater damage to ligaments and soft tissues; (2) on account of the frequent coexistent fracture of metatarsals or cuneiforms. A period of six to eight weeks in plaster is regarded by most writers as essential, and it is generally advised that thereafter, and for some considerable time, an artificial support should be employed for the arch of the foot—such, for example, as a Whitman's brace.

In the less frequent cases, where time, care, and perhaps expense are of less importance, all forms of fixation may perhaps be dispensed with, and provided reduction has been effectively accomplished, reliance may be placed entirely on rest for a prolonged period, combined with gentle and systematic massage.

In two of the cases which follow, fixation by plaster was employed for three weeks, and no subsequent support was found necessary or advisable. In the third, the plaster case was kept on for four weeks, and was not thereafter reapplied.

It is obvious that early massage, so long as it is gently carried out, as also early active movements of the foot so as to prevent the stiffening and immobilization of the intertarsal and tarsal-metatarsal joints—so long as such movements stop short of strain on the injury-weakened ligaments—will be the most valuable and important factors in determining ultimate complete restoration of function.

In cases which have been recorded, quite tolerable functional capacity has in time been developed, even where replacement could not be at all, or at any rate completely, effected. Thus, in one case, recorded by Cock,¹⁷ of complete upward dislocation, combined with fracture of the first cuneiform and scaphoid, reduction was not accomplished, and yet the patient was back at his work—as a railway porter—within eight months of receiving his injury.

CASE I.

R. J., aged 30, male, admitted to the Broadstone Jubilee Hospital, Port Glasgow, on November 2nd, 1909, suffering from an injury just received. A heavy bale of yarn fell upon him from some height, causing, in addition to sundry abrasions and some injury to the chest, a somewhat severe injury to his left foot. The mechanism of production of the injury to the foot seems to have been as follows: The man got just sufficient warning of the falling weight to permit him to brace himself for the shock, but insufficient to allow of his evading it. When struck by the bale he had his feet widely separated, his back and shoulders somewhat bent, and his muscles tensely strung to resist the impact. He was struck in the upper dorsal region, and it may be supposed that the impact of the force was transmitted down the trunk and both lower limbs in such a way as to exert itself in maximum intensity at the tarsal-metatarsal regions of both feet. It may also be supposed that one foot got a larger share of the violence than the other. In any case, only one foot suffered to any extent. By reason of the wide separation of the feet, and the tense state of the limb muscles, the anterior parts of the feet, and especially of the foot which suffered, may be supposed to have been fixed—jammed firmly against the ground. The downward acting force would tend, therefore, to carry the whole tarsus and heel portion of the foot inwards—as actually happened. That this had indeed happened was at once obvious on examination—even on a quite superficial examination—of the foot. The internal cuneiform could be seen and felt bulging prominently on the inner side of the foot; the fifth metatarsal could be recognized projecting abnormally on the outer side. There was considerable swelling of the soft tissues and much pain. Crepitus was felt, suggesting some comminution of bone either at proximal ends of second and third metatarsals, or of cuneiforms, or of both. Examination by fluorescent screen, and subsequently by *x*-ray plate, confirmed the diagnosis of dislocation and determined the extent of displacement as well as of the accompanying fracture.

Considering the violence necessary to produce the dislocation, the amount of actual damage to bone seems small. In the accompanying reproduction (Fig. 1) of the radiographic picture the displacement is well shown, but the exact damage to bone is not quite definite. That there is some bone fracture is obvious, but whether this has been of the proximal end of the second metatarsal or of the projecting extremity of the third cuneiform is not clear.

As the man suffered great pain the dislocation was reduced without delay under chloroform anaesthesia. The reduction was easily accomplished by traction on the anterior part of the foot, followed by plantar flexion and forcible adduction. The correctness of the reduction was at once verified by fluorescent screen and confirmed by an actual plate exposure. The corrected foot was at once fixed in a plaster-of-Paris case, with the ankle at right angles, and the foot in a position of moderate inversion.

The plaster support was retained for three weeks. The patient had no pain to speak of, once the reduction had been

accomplished, and swelling quickly subsided; so much so that the plaster case was probably not of very great value after the first few days. At the end of three weeks it was removed and massage was instituted. After a week of this the patient was allowed to get about, but was advised not to put his full weight on the foot for a week or two more. The arch of the foot was well restored, and there was not then—nor did there appear later—any tendency to recurrence of displacement. Completely satisfactory function was restored in about ten weeks. No artificial support was employed subsequent to the removal of the plaster.

CASE II.

W. P., aged 46. Admitted to the Broadstone Hospital, Port Glasgow, on February 28th, 1911. The patient, a man, was injured in a shipyard by a falling plate, which slid down the front of the right leg, and pinned the anterior part of the booted foot, so that it had to be extricated subsequently by the man's comrades. Immediately the foot was thus caught by the fallen plate as in a vice the man fell over to the right, so that the heel portion of the foot was violently adducted, the anterior part of the foot being meantime firmly fixed. Probably there was also at the same time some degree of torsion violence, applied at the tarsal-metatarsal articulation. The mechanism of production of the injury was, thus, not very dissimilar from that in Case I, though in the latter the fixation of the anterior part of the foot was not produced in the same direct way.

The resulting lesion was quite obvious on admission and was recognized as a dislocation of the metatarsus by Dr. Alex. Butler, one of the surgeons to the hospital. The anterior part of the foot was markedly abducted and somewhat everted. The internal cuneiform was prominent at the inner side, the fifth metatarsal at the outer side. The base of the first metatarsal bulged slightly on the dorsum of the foot. There was considerable tension of the skin and soft tissues. No crepitus was felt. Pain was considerable, and to relieve this temporarily the foot was fomented till the following day, when, in ordinary course, I visited the hospital. I had no hesitation in coinciding with the diagnosis made by Dr. Butler. Skiagrams were obtained, which confirmed our joint diagnosis (see Figs. 2 and 3). One was taken from above downwards, the other with the foot in profile. The former, though quite a good picture, cannot be said to give much support to the idea of there being any accompanying fracture, either of metatarsal base or of cuneiform. The latter shows the slight dorsal displacement of the proximal end of the inner metatarsals.

Under chloroform anaesthesia the dislocation was reduced. What seemed to be quite definite crepitus was felt during reduction, but the exact site of the crepitus was not clearly established, though it was thought to be at the site of the in-setting proximal end of the second metatarsal. Once the reduction was complete crepitus could not again be elicited, and, in view of the fact that no crepitus was felt before reduction, and that the skiagram gives no definite indication of fracture, the suggestion may with some justification be made that in this case the added torsion element mentioned in describing the mechanism of production of the dislocation, may have had the effect of producing first of all a dorsal displacement such as would permit of the second metatarsal slipping over or past the third cuneiform without fracture. Fig. 3 in any case makes it clear that some dorsal dislocation had occurred. In this case there was rather more difficulty encountered in accomplishing reduction than there was in Case I.

After reduction the foot was encased in plaster in slightly over-corrected and somewhat inverted position. Ten days later the patient was dismissed with his foot still in plaster.

Three weeks after the date of reduction the plaster was removed. There was slight thickening about the inner side of the tarsal-metatarsal articulation, but the position of parts was all that could be desired. The plaster was not reapplied, but firm bandaging with flannel was continued for some time and massage was instituted. The patient was encouraged also to begin carefully to use the foot actively. Function was well restored after three months.

CASE III.

T. H., aged 24, male, admitted to the Broadstone Hospital, Port Glasgow, on August 28th, 1911. Injured by falling a considerable distance in a shipyard. His right foot was seriously damaged by the fall, but this was the only injury of consequence he received. Exactly how the foot was injured neither he nor his mates could definitely say, and so the actual mechanism of production of the lesion sustained could not be established. The only statement made—for what is worth—was to the effect that the man did not alight on the injured foot. In view of the nature of the damage produced this may perhaps be open to some doubt, for, as I have already suggested in the general statement which has gone before, the resultant displacement of the metatarsals certainly somewhat suggests that the cuneiforms were impacted violently against the metatarsus, driving the first metatarsal inwards and the second, third, and fourth outwards. In any case, on admission to hospital, the nature of the injury was quite evident. I saw, and dealt with, the case on the day the injury was received. The complete inward dislocation of the proximal end of the first metatarsal was quite obvious; it could be felt, and indeed seen, projecting on the inner side of the foot. The next three metatarsals could be seen and felt projecting outwards and on the dorsal aspect of the outermost cuneiform and cuboid, the skin being stretched tightly over them. It was easily determined, on examination, that the second and third metatarsals were fractured close to

their proximal ends, and part at least of the dorsal prominence was caused by the special projection of the sharp proximal ends of the distal fragments of these bones. The small proximal fragments were, however, also dislocated upwards. There was much bruising of the tissues of the dorsum of the foot, much effusion of blood into the tissues, and at one place the skin was almost torn through. Had reduction not been at once effected it is almost certain that the skin would have given way and sloughed.

The diagnosis was confirmed by means of the x rays. Fig. 4 shows quite clearly that the facts made out by ordinary methods of physical examination conformed with actuality.

Reduction was carried out without much difficulty on the same day, chloroform anaesthesia being employed, Dr. Butler anaesthetizing, and Dr. James Walker assisting me. The displacement of the first metatarsal was first corrected, and thereafter, by a reversal of the lateral pressure and adduction, the outer bones were readily replaced.

Plaster-of-Paris support was employed for four weeks; thereafter bathing, rubbing, and regulated passive and active movements being instituted. The result was in every way satisfactory, though stiffness persisted longer than in the other two cases.

Fig. 5 shows the complete correction of the displacement: it is a reproduction of a skiagram obtained about five weeks after the injury.

The publication of this paper has been delayed with a view to the searching of the records of the large Glasgow hospitals for cases of such injury. Only one case has been found in the last ten years' records of the Western Infirmary, which was at least labelled "Dislocation of metatarsus." The index title was all that one could obtain; access could not be had to any details, so that even this one case can hardly be counted. In neither of the other two hospitals could information be got from those likely to be aware of the occurrence of such an injury; in both, the radiographic experts could call to mind no example of such a condition as I have drawn attention to in this report.

This seems to make all the more remarkable the fact that, in a comparatively small hospital such as that at Port Glasgow, we should have had in so short a time, comparatively, three examples of a relatively infrequent lesion.

CAPTAIN W. S. PATTON, I.M.S., in No. 50 of the New Series of *Scientific Memoirs of Officers of the Medical and Sanitary Department of the Government of India*, gives a description of the work done by himself in the etiology of Oriental sore in Cambay during June, 1910. His researches were chiefly concerned with the carrier of the parasite, the *Leishmania tropica*, from person to person, and he believes that he has made out a case against the bug, *A. Stenomyia* of unknown species and a *Phlebotomus*, probably *Cabu-Annandalei*, as well as ordinary house flies and lice, were all studied, but with negative results. In bugs, however (*Cimex rotundatus*), the parasites were found to flagellate in the stomach if the temperature was below 25° C., and this happened also in the nymphs. Complete development apparently did not take place in the adult bug, as flagellates were never seen in them beyond the tenth day, but in the nymphs Patton believes this does take place. In addition to these facts he brings forward epidemiological observations and clinical cases of people who were bitten by bugs and afterwards developed sores. Though all this is very interesting and suggestive, it does not absolutely prove that the bug is the regular intermediate host. It may be so in Cambay, but it seems just as clear that in other parts of the world—Bagdad, for example—it is not. It is evident that more work on the subject is required.

THE APPLICATION OF FUNGI AS STYPTICS.

BY

EDWARD KNIGHT, L.R.C.P. AND S. EDIN.,

GRAVESEND.

SEVERAL species of fungus were largely used in former times as applications for arresting hæmorrhage, both by surgeons and the common people.

Dioscorides¹ mentions agaric (*ἀγαρικός*) as a fungus springing from the trunks of rotting trees, and states that three obols of it taken with water stays spitting of blood. The fungus was so-called because it was found at Agaria, in Sarmatia. Linnaeus in his classification of plants adopted the Latin term *Agaricus* for a large genus of fungi. But in pharmacy now the name "agaric" is usually given to various corky species of *Polyporus* growing on trees—as the *P. officinalis*, chiefly found on the larch, the *P. fomentarius* on the oak and birch, and the *P. ignarius* on the willow, plum, and cherry. During the eighteenth century the agaric of oak was often laid on bleeding wounds by French surgeons. Audouillet applied pieces to the mouths of bleeding vessels after several capital amputations with good results. It was also used successfully for checking bleeding by James Ford, a Bristol surgeon. Some differences of opinion were expressed as to how it acted.

Ford took the view that its effect was more due to its soft porous texture than to any specific styptic action, and then employed in its place a fungus, very similar to it in substance, that grows abundantly on casks in wine vaults. Afterwards he wrote an account of the success of agaric and the *Fungus vinosus* in amputations. Oak agaric was so much used in surgery as to be called "surgeons' agaric." It was gathered in autumn, and, the outer rind being removed, the yellow-brown substance within was cut into slices, which were beaten with a hammer to make them soft and pliable. No precautions seem to have been taken to render them aseptic, although fungi, it is well known, are often infested with the larvae of insects.

Agaric was highly commended in 1788 by Buchan,² in his *Domestic Medicine*, as a styptic: he went so far as to say that, being easily obtainable, it ought to be kept by every family in case of accidents. As 80,000 copies of this work were sold in Great Britain during the author's lifetime and it was translated into all the principal European languages,³ it is not unlikely that his recommendation helped much to make agaric a popular remedy for bleeding with our forefathers. No work of the kind had been published before in this country. Cobbett⁴ thought it tended to make its readers hypochondriacal, and in his *Advice to Young Men* he wrote: "Read the *Domestic Medicine*, and by the time that you have done you will imagine that you have all the diseases of which it treats." But the fungus prepared as described was useful for domestic purposes in another way. After being boiled in nitre, it made good tinder when fires were lighted with flint and steel, and, being extensively manufactured on the Continent, was termed "anadon" and "German tinder." Of late years agaric has received little notice in surgical works as a dressing for large bleeding wounds, but there is mention occasionally of anadon as a plaster for stopping bleeding from small blood vessels.

A fungus that has had a far more lasting reputation as a styptic is the giant puff ball, *Lycoperdon giganteum*, formerly known as *Crepitus lupi*, which it is said the Greeks called *κράβιλον*, on account of its resemblance, when full grown, to a human skull. It is of a globular shape, and commonly found growing in pastures during the autumn. At an early stage of its growth the outer covering, or peridium, is like white kid, and the pulp inside, or capillitium, firm and fleshy, but afterwards dry, spongy, and powdery. The powder, which consists of spores, among which are many fine filaments, has been used by the peasantry for centuries to stop hæmorrhages. Recently an old countrywoman in Kent said she remembered when she was a girl and bled from the nose her mother would take her to an orchard, and, making her lie down on the grass, gather a puff-ball and apply the powder to her nose with good effect. As regards the use of the giant puff-ball in surgery, there is good evidence that it has been applied frequently to stop bleeding with

excellent results. In 1560 it was recommended as a styptic by F. Wurtz, a German surgeon. Afterwards, in 1706, Helvetius wrote in a letter⁵ concerning the fungus:

But of all hæmostatics, *Crepitus lupi*, commonly called "vesse-de-loup," a fungus of the family of Lycoperdous is the best, which stops bleeding in a surprising manner, without causing either pain or an eschar as vitriols do. The largest and most powdery of the Lycoperdous should be chosen; it is cut in slices and applied to the arteries or open veins. To remove these they are bathed with a little warm water, for it forms a kind of glue when mixed with the blood that is very adhesive.

This was written after seeing an operation for cancer during which the fungus was applied as a dressing. Adrien Helvetius⁶ was born in Holland in 1661, his father being physician to the Prince of Orange. He went to Paris to vend certain drugs, and was so successful in treating many cases of dysentery with ipecacuanha, then a drug almost unknown, that he was awarded a handsome sum by the French Government for revealing the secret of his cures. Among his patients was the Duchess of Chaulnes, and this led to his being recommended by Colbert to the Dauphin. Thus he gained much renown as a physician.

The next observation on the styptic properties of the fungus seems to be a memoir presented to the Royal Academy of Sciences at Paris by Le Fosse, who was farmer to the King of France. In this he asserts, according to a translation which appeared in the *Gentleman's Magazine* in 1755:

1stly. That by applying the powder or dust of the *Lycoperdon* or blunlist, to very considerable divided arteries in horses, the blood was stopped in a few minutes and the arteries cicatrized by this means alone without any succeeding hæmorrhage.

2dly. That about 24 hours after the application of this remedy, a membrane or rather a pellicule was observed to cover the extremity of the divided artery with a small grume, which perfectly closed the orifice.

3dly. That the pulsation of the artery was very distinctly perceived there.

4thly. That the grume was conically shaped, the base closing the orifice, and the point turning inward.

Special commissioners having been appointed by the Academy to determine the truth of these statements, Le Fosse applied the powder of the fungus to several large arteries which had been divided in a mare.

"The blood spurted," the Commissioner's report states, "with great force from four arteries; he applied the *Lycoperdon* powder to the stump, with only a cap of hog's bladder, and took off his dressing in a quarter of an hour, when three of the arteries were staunched, but the fourth bled fast; however, by applying a pinch of the powder to the bleeding artery, which he kept to it only with his finger, that also was staunched in six minutes." More of such evidence being given the report ends: "From what has been laid down it may be concluded that M. le Fosse has advanced nothing but the truth; however, we agree that the use of this powder for stopping of blood was not wholly unknown; but it is not certain that the blood of the most considerable divided arteries was ever attempted to be stopped by this remedy before." (Signed) Bernardde, Jussien, and Bonvart.⁷

Within the last fifty years some practitioners in Ireland have pointed out the value of puff-ball as an application for controlling violent and constant hæmorrhages. Sir William Whittia,⁸ for example, remarks concerning this fungus:

The writer has seen it used in formidable hæmorrhages, dusted over the bleeding surface, and plugged into deep and tortuous wounds where the open vessels could not be reached with a ligature, and the rapid and effective manner in which it arrested bleeding was most surprising. He has seen it immediately arrest copious hæmorrhages which he believes could not have been controlled by any other hæmostatic. How it acts is unknown.

The writer, in bleeding hæmorrhoids or fissures, has had great satisfaction with the remedy which he uses plugged into large hollow suppositories and inserted into the rectum. He has been able to satisfy himself that he has saved life in this way, in a case in which the shock of an operation would have been fatal. He finds it to be an excellent remedy for epistaxis, and he plugs the nostrils with the fungus, leaving it *in situ* for several days, and always finds it act most satisfactorily in stopping the bleeding.

A poor woman in Ireland who had suffered from an open cancer of the breast for a long period, and had tried almost every form of dressing without allaying her sufferings or the constant hæmorrhages, eventually sought the aid of a

country quack, who suggested the application of a puff-ball. The surgeon who attended her states:

From the day the patient commenced the use of this substance her sufferings were greatly mitigated, and she improved in health and strength. The frequent bleedings ceased, and the foul odour from the sore was greatly diminished; indeed, so admirably did the puff-ball act, that the poor woman lived in comparative comfort for seventeen years after the first appearance of the cancerous ulceration.

"Mr. Pagan of Belfast," he mentions, in giving further evidence of the value of puff-ball, told him "that when removing a large tumour from the neighbourhood of the orbit, he encountered the most violent hæmorrhage from large arteries in the bone, which of course he could not tie, and which even pegging with pieces of wool failed to control, yet a small piece of puff-ball at once restrained all bleeding."⁹

In a case of alarming hæmorrhage after miscarriage Dr. Duncan¹⁰ of Tyrone introduced half of a puff-ball into the vagina and arrested the bleeding, when ergot and plugging the vagina in another way had failed.

Two cases of profuse bleeding from the nose were treated successfully in America with pieces of puff-ball inserted as plugs in the nostrils by Dr. Hall,¹¹ who wrote:

As a hæmostatic for controlling the severer forms of epistaxis, I believe it has no equal. I have such confidence in it for this purpose that I am now never without it. I believe that no valid objections can be raised against its use on the ground that it is not sufficiently aseptic, while, on the contrary, it is to be preferred to many hæmostatics on account of its non-irritating qualities.

If we compare these observations with those made before in the eighteenth century we find them much alike in their favourable estimate of the fungus as a styptic. I have seen troublesome bleeding after the extraction of a tooth readily stopped by a bit of puff-ball thrust into the empty socket when other styptics had been applied with no good result. If the plug is swallowed accidentally it can do no harm, as the fungus is quite innocuous when eaten. Heating the puff-ball in an oven to render the dressing aseptic does not appear to impair its hæmostatic properties. One objection may be raised to its application to wounds of the face—that an ugly brownish stain is often left, but this usually soon disappears.

In times when more often than not excessive hæmorrhage was checked with burning irons, boiling oil and tar, and powerful escharotics, the application in their place of soft non-irritating fungi must have been greatly appreciated by patients who were wont to suffer much under the hands of surgeons.

AFTER-HISTORY OF GASTRO-ENTEROSTOMY FOR PEPTIC ULCER.

By ALECK W. BOURNE, M.B., B.C., F.R.C.S.,
LATE HOUSE-SURGEON, ST. MARY'S HOSPITAL, LONDON.

THE present paper is a study of the after-history of 67 cases upon which the operation of gastro-enterostomy had been performed for ulcer of the stomach or duodenum. The operations have been done by many different surgeons, and for almost every clinical type of ulcer. They were performed at St. Mary's Hospital during a period beginning in 1904 and ending in April, 1910. In the most recent cases there was an interval of at least eighteen months between the operations and the inquiry as to the present condition of the patients, while in the older cases more than five years had elapsed.

The results here reported have been based upon the patient's freedom or otherwise from those symptoms which troubled him before the operation, or which still indicate active ulceration. Thus, when a patient, having been operated upon, reports himself entirely free from pain, sickness, and vomiting of blood, while he can enjoy

ordinary food, and has perhaps gained in weight, his result is marked as "excellent" (E).

Supposing, however, that a patient states that he is little better, and that his pain, vomiting, etc., have not improved or that the improvement be only very slight, his result is recorded as "bad" (B).

It is remarkable that the great majority of all cases are easily classified into one or other of the above categories. If any improvement has taken place, it is in most cases complete. There have, however, been some in which the recovery has been only partial, and these are classified respectively as "good" and "fair" (G), (F).

Where results are recorded as excellent there is no possible doubt that this is a true description of the case, for, as a rule, the patients themselves are most enthusiastic when referring to their condition. Similarly, there has been no hesitation in stamping any case as failure when the patient is still troubled with symptoms; for, even though pain, vomiting, etc., may have been slightly reduced, if the patient is still conscious of disease in the stomach or duodenum he has not been cured by the operation.

THE MORTALITY OF THE OPERATION.

Out of 92 cases there were 7 deaths immediately following the operation (7.6 per cent.). All these deaths occurred amongst the first 39 cases; throughout the last 53 cases there was no death.

The causes of death were as follows:

- 1 general peritonitis due to perforation of the ulcer just after the operation.
- 1 general peritonitis from leakage of the anastomosis.
- 1 septic bronchopneumonia.
- 2 collapse.
- 2 causes unknown.

The death of the first case was almost unavoidable; it could, perhaps, have been prevented by invaginating the ulcer at the time of the operation, but, as the liability of the ulcer to perforate can scarcely be ascertained during the operation, invagination is rarely performed. This case was an unfortunate accident. The second case—due to leakage—was the result of faulty technique. This was one of the earliest cases of the series. Where the ordinary method of suture is employed leakage at the site of anastomosis is very rare. In one case, in 1904, Murphy's button was used; the patient died soon after the operation, from melaena. The third patient died from bronchopneumonia, quite independently of the special nature of the operation. This patient would probably have died whatever operation had been performed.

Two patients died of collapse during the first week. The collapse may have been due to the gravity and duration of a serious operation performed upon a patient probably exhausted by a succession of hæmorrhages, and a long period of semi-starvation from continued vomiting. Another cause of the collapse may have been hæmatemesis or melaena following operation. This is not an infrequent cause of death. In neither of these cases, probably, did the operation contribute to the speedy death of the patient, for in the first instance—death due to collapse from exhaustion and low vitality—the patient would have died if not operated upon; and in the second—death from hæmorrhage—the operation probably had no part in starting the bleeding.

Thus of the 5 cases of death the causes of which are known, 2 died owing to unfortunate accidents, 2 died in spite of the operation, and in 1 only was death due directly to the operation—the case in which the anastomosis leaked. So much has the technique improved during the last few years that this cause has been practically eliminated.

AFTER-HISTORY OF 68 PATIENTS.

Of the 92 cases of the series 68 have been traced; of these 3 have died in the interval (4.4 per cent.). Probably others of the 92 cases not traced have died, and this would account for the failure to trace them. From the accounts furnished by their friends, it appears that 1 died of perforation, 1 from "a recurrence of the malady" (hæmatemesis), and 1 from a cause unknown. Thus the total mortality of the operation, plus that of the unhealed ulcer after operation, is 10.9 per cent. These figures should be compared with the mortality of the disease when treated

by medical means. Apparently the statistics here collected would show that the immediate danger of gastro-enterostomy is serious (7.6 per cent.), but under present conditions it is exceedingly slight; there has, for instance, been no death in the last 53 cases, that is, since 1908.

The general results of the series can be stated in 67 cases.

Classification of Results in 67 Cases.

| Result. | No. of Cases. | Percentage. |
|---------|---------------|-------------|
| E. | 29 | 43.2 |
| B. | 26 | 38.8 |
| G. | 6 | 8.9 |
| F. | 6 | 8.9 |

Thus nearly half the cases were in no way ameliorated. Reckoning E and G together, and B and F, we have approximately 52 per cent. cured and 48 per cent. not improved. Ample proof is thus afforded that gastro-enterostomy is not indicated promiscuously for all kinds of peptic ulcer. At the same time, it is an important conclusion that the results are very sharply defined, inasmuch as 55 of the cases are either completely cured, or in no way improved, while only 12 cases are partially relieved. Supposing, on the one hand, the bulk of the cases were partly cured and only a small proportion showed a decisive result of good or bad, then the results would not be so significant, but as the effect of operation is so markedly successful in 43 per cent. and so hopelessly bad in 38 per cent. it is clear that there must be some very real difference in the etiology of the disease, or the pathology, or the exact performance of the operation which renders surgical treatment thoroughly successful or absolutely useless.

Age and Sex.

If the age of the patients and its effect on the prognosis be examined, it will be seen that, generally speaking, the older the patient the better the outlook. Thus:

Table of Ages.

| Age. | No. of Cases. | Result. | |
|--------------|---------------|------------|-------|
| | | Excellent. | Bad. |
| Below 20... | 1 | 0 | 100 % |
| 20 to 30 ... | 13 | 23 % | 77 % |
| 30 to 40 ... | 14 | 28 % | 72 % |
| 40 to 50 ... | 20 | 65 % | 35 % |
| 50 to 60 ... | 14 | 72 % | 28 % |

The age limits were 19 and 61, and the average age was 40.

From this table it would seem that the age of the patient is an important factor, but this is probably only apparent, for the type of ulcer varies with the age.

Again, the question of sex seems to influence the prognosis. Of 63 cases, there were 35 males and 28 females, and approximately one-third of the females and two-thirds of the males were cured. There were 23 males and 11 females over the age of 40; of the 23 males 20 were cured, and of the 11 females only 4 were cured.

Duration of Symptoms.

The duration of the symptoms is some indication of the chronicity of the disease; but on examining the series it has been found that no relation exists between the chronicity and the result of operation. Some of the patients had suffered for less than one year, while others had had symptoms for more than fifteen years; but the number of "cures" is distributed equally. It has been suggested that gastro-enterostomy is suitable for the chronic ulcers, and not for the acute variety; but these cases afford no evidence to support this.

Character of the Pain.

The character of the pain, however, is of great importance, for the figures show that the result of operation depends very largely upon the time after food at which

the pain occurs. This varies from immediately after a meal to one and a half hours, and, in proportion as this interval is long, so is the prognosis good. Clinically, the ulcer is frequently diagnosed as gastric or duodenal by a consideration of this feature of the pain, and it will be seen from the table below that cases of duodenal ulcer, as a rule, do much better after this operation than cases of gastric ulcer. Physiologically, duodenal and pyloric ulcers may be considered together, both forms tending to cause stenosis.

Position of the Ulcer in 64 Cases.

| Position. | No. of Cases. | Result. | |
|--------------------------|---------------|---------------------|---------------|
| | | Excellent and Good. | Bad and Fair. |
| Gastric ... | 24 | 38 % | 62 % |
| Duodenal and pyloric ... | 37 | 70 % | 30 % |
| Not stated ... | 7 | — | — |

Mode of Action of Gastro-enterostomy.

The question whether the ulcer is gastric or duodenal is of far greater importance than either age or sex. The pathological effects of the two forms of ulcer are usually quite different. The important pathological effect of duodenal and pyloric ulcer is pyloric stenosis, and it is probably in the relief of this condition that gastro-enterostomy has its greatest usefulness. The anastomotic opening provides a means of drainage, and this is probably the secret of the success of the operation in so many cases of this kind. For example, cases of pyloric carcinoma owe their relief after this operation to simple drainage. Therefore, whether the actual ulcer be healed or no, the stenosis and its attendant train of symptoms is certainly cured, and the first effect of this is to maintain the stomach at rest and relieve it of a volume of fluid continually in contact with the ulcer. Now just as drainage of any other hollow viscus, such as the bladder, promotes its recovery from a septic state, so drainage of the stomach probably has a most important bearing upon its recovery from an ulcer which is in a septic and progressive condition.

Gastric drainage may also be accomplished by means of lavage, though not so perfectly as by gastro-enterostomy, for, in the case of lavage the fermenting fluid is removed at intervals only, whereas by anastomosing the stomach with the jejunum a continuous drainage is maintained and a retention of irritating fluid never occurs. One of the cases was x-rayed after a bismuth meal, and the fluid was seen to pass very quickly out of the stomach, so that there was scarcely time to obtain good photographs.

Though the patient owes much of his distress to dilatation caused by stenosis, and its relief from this condition is easy to understand, undoubtedly a true healing of the ulcer with cicatrization is promoted in those cases where there has been frequent bleeding, for haematemesis and melacna are often completely arrested. Some claim that the healing of the ulcer is due simply and solely to the drainage effected by the operation, which prevents its constant contact with septic fluid, but, while drainage clearly relieves stenosis, some other factor is probably concerned in the healing of the ulcer.

Of the pathogenic factors associated with peptic ulcer, one of the most important is hyperchlorhydria. Of those cases in which a test meal analysis was performed, it was found that the vast majority suffered from a hyperacidity; in fact, one of the surest aids to the diagnosis of simple ulcer is the presence of this excess of acidity. Indeed, it has been shown that experimental gastric ulcer can only be produced or maintained when the acidity of the stomach is above the normal (Bolton). Hence it follows that the relief of this condition should be one of the first aims in the treatment of peptic ulcer.

The administration of sodium bicarbonate destroys the acidity; but in gastro-enterostomy we have a more efficient method, for by this operation the acid fluid is not allowed to accumulate.

The effect of the operation on hyperchlorhydria can be determined by the analysis of test meals by the usual method; and from tables of such cases, published by

Dr. W. H. Willcox, it can be seen that the total amount of acid is materially diminished.

From a study of the analysis before operation some idea can be formed of the probable success of the operation, for the results bear some relation to the amount of acidity. Thus, reckoning the total acidity in terms of hydrochloric acid, we have:

Acidity before Operation.

| Total Acidity. | Result. | |
|---|------------|------|
| | Excellent. | Bad. |
| Between 0.12 per cent. and 0.19 per cent. ... | 5 | 3 |
| Between 0.22 per cent. and 0.3 per cent. ... | 13 | 3 |

Reckoning 0.15 per cent. as the normal, we gather that those cases with a definite hyperchlorhydria from 0.2 per cent. to 0.3 per cent. show better results than those cases not associated with hyperacidity; and it is in accordance with theoretical considerations that this should be so.

At first sight it might be imagined that the diminution of acidity after gastro-enterostomy is due to regurgitation of the alkaline juice of the duodenum into the stomach. This cannot be the case to any great extent, however, for the amount of bile in test meals drawn off is, as a rule, so slight that not sufficient alkali can have regurgitated to have neutralized the excess of acid. In some cases no bile at all is found; in others, only the slightest trace, showing that the amount of regurgitation is inappreciable. But it is easy to understand how the acidity is corrected when we remember the part played by the anastomosis in the drainage of the stomach. By these means accumulation of the gastric contents is prevented, and although there may be a hypersecretion of acid, the rapid drainage into the jejunum prevents it from raising the percentage of acid in the gastric juice.

Thus does gastro-enterostomy, by drainage of the stomach, bring about the two essential conditions for the cure of ulcer—namely, rest and normal acidity. Rest is so important for recovery from disease of any other part of the body that it is only to be expected that it should be imperatively necessary for the stomach and duodenum. The degree of rest secured by this operation for the duodenum is almost absolute, for the first part of the duodenum—where the ulcer usually occurs—is thrown into a state of complete physiological inactivity. This may partly account for the better results in the case of the duodenum.

THE OPERATION AND AFTER-TREATMENT.

I.

From what has been stated above, it is clear that a cure of the disease depends upon permanence of the anastomotic opening, for as soon as the drainage becomes ineffective the former conditions recur, and fresh ulceration is likely. In some cases of cicatricial pyloric stenosis it is impossible for the opening to close, for any fistula will remain open as long as there is obstruction below. This may be an additional reason why the operation is so successful in cases of pyloric stenosis. But when the ulcer does not cause an obstruction of the pylorus, closure of the artificial opening is possible, and perhaps probable.

In only two cases has it been possible to determine the size of the opening, and in each case it was still patent.

CASE I.—J. C. Duodenal ulcer, and slight degree of hour-glass contraction of the stomach. Gastro-enterostomy had been done near the cardiac end. April, 1910: Laparotomy, stomach opened, and anastomosis admitted three fingers. The pylorus admitted one finger, and was artificially stenosed.

CASE II.—H. S. Gastric ulcer. Gastro-enterostomy in January, 1909. Readmitted August, 1910, for melæna, etc., and laparotomy was performed in December, 1910. The opening admitted three fingers, and the pylorus was artificially stenosed. Three months after the patient was quite well.

When, however, the stenosis is due to pyloric spasm associated with an ulcer in its vicinity, free drainage of the stomach will lead to a relaxation of the spasm, as in other parts of the body. The function of the pylorus will then be restored and the gastro-enterostomy opening will fall into disuse, as all such fistulae do, when the obstruction to the *via naturalis* is relieved. In this way the ulcer may

be healed and the patient permanently cured. But, on the other hand, the old condition of affairs may be reproduced when the anastomosis closes, and it is possible that a further ulcer will be formed, thus accounting for some of the many relapses. If this be the case, a measure perhaps indicated is artificial closure of the pylorus so as to reproduce most nearly that type of case—permanent pyloric stenosis—which does best after gastro-enterostomy. In two recurrent cases of this series this was done, but not sufficient time has yet elapsed to judge of the results.

In those cases in which the pylorus is quite patent and no obstruction exists it is difficult to see how gastro-enterostomy can be of much benefit, for one of the two important morbid conditions—retention of septic fermenting fluid—cannot exist, and the other—hyperacidity—can be little relieved by the operation, for there is already sufficient drainage through the pylorus. Such cases are those of gastric ulcer situated well away from the pylorus, with little scar contraction and atonic dilatation of the stomach. It is probable that this is the type which reacts so unfavourably to surgical treatment. Artificial closure of a healthy functional pylorus is, however, a serious measure, and one hardly likely to be of any use in such cases.

II.

In earlier days a much debated question was whether the anastomosis should be made on the anterior or posterior wall of the stomach. Latterly, however, it has been decided that what is known as posterior gastro-enterostomy is the operation of choice, and unless there be some strong contra-indication, such as the presence of adhesions, the anterior operation is never performed. Throughout this series only one or two anterior operations have been done, and then only because the posterior was not possible. We cannot, from these few cases, judge the relative merits of the two operations, but it may be accepted that the reasons set forth in favour of abandoning the anterior operation are very cogent, and that the result of the operation as practised to day must be correspondingly better.

III.

A further point of discussion has been the position of the anastomosis on the posterior wall—that is, whether it should be placed near the cardia or pyloric antrum. Unfortunately, it has been impossible to obtain the records of the exact position of the opening, and no statistical conclusions can be drawn from this series. This point, however, is probably of some importance, for the question ultimately resolves itself into this, Which position will make for the best drainage?—drainage being the aim of gastro-enterostomy. Bismuth meals show that, immediately after eating, the food occupies the fundus of the stomach for a short time, while the pyloric antrum remains comparatively empty and contracted. Later the antrum dilates, receives a portion from the cardia, and a series of churning movements commence, the semi-digested mass being finally ejected through the pylorus. As the motor activities of the two halves of the stomach differ, so do their secretory functions. The fundal cells furnish the acid, and probably the pepsin also. Drainage of the fundus will relieve it of its distension by preventing its acting as a receptacle, and the fundus will discharge its contents immediately, so that gastric digestion will scarcely take place, and no accumulation of hydrochloric acid, which is secreted by the fundal glands, will occur.

But when the anastomosis unites the pyloric antrum with the jejunum drainage will not occur immediately, but only when the antrum receives its portion of the meal from the fundus. The normal churning movements of the antrum will immediately drain the contents into the jejunum, and the fundus will consequently discharge itself into the antrum more quickly than normal. Thus the difference is chiefly in the rapidity of drainage. When the opening is near the fundus, drainage is more rapid than when near the antrum, and acid will scarcely be present.

From these considerations it is seen that the result of operations will be better in cases of hyperchlorhydria when the opening is near the fundus, whereas for pyloric stenosis the anastomosis should be made with the pyloric antrum. This question gives rise to many more reflections, which, however, cannot be considered here.

Other differences in methods of operating are the formation, or not, of a loop of jejunum, and the size of the opening. The "no loop" operation is almost invariably performed at present, and the size of the opening should err rather on the side of capacity, in order to obviate premature closing. As in the previous cases, the notes of this series do not yield sufficiently full details, and no conclusion can be drawn.

POSSIBLE CAUSES OF THE FAILURES.

1. Recurrence of the Original Ulcer, or Its Failure to Heal.

(a) Closure of the anastomosis. The causes of this have already been considered.

(b) Persistence of those conditions which either gave rise to the ulcer or prevented it from healing.

The causes of gastric and duodenal ulceration have been discussed freely of late, and some light has been thrown thereon by Dr. Bolton; but it is not yet known definitely what gives rise to the ulcer. However, there are some suspected causes, such as oral sepsis. This condition should certainly be corrected some days before operation, and the mouth be kept in good condition.

The second and most important question is that of diet. The patient, and often his doctor, regard the operation of gastro-enterostomy as the complete and final means of cure, instead of realizing that it is no more than an excellent means of helping the stomach to cure itself. He forgets that careful dieting over a long period, together with frequent administrations of alkali, are almost as necessary and important as the operation. Many cases of gastric ulcer are cured by these means alone; therefore, will it not add greatly to the chances of complete and permanent cure if operative treatment is supplemented by careful medical treatment? Gastro-enterostomy is usually employed in cases which have failed to react to medical treatment, though in nearly every case under such a régime there is improvement, relapse occurring when the patient resumes his former dietetic life. The carelessness of the patient with respect to his diet is probably the commonest cause of relapse in this series—made up of hospital patients who, unfortunately, are often unable to select their food. But where gastro-enterostomy is followed by carefully regulated medical treatment, not necessarily strict, but reasonably moderate, the best results can be obtained.

2. Formation of Jejunal or Gastro-jejunal Ulcer.

Several cases have been reported, some being discovered at the operation for perforation. With Dr. Bolton's work in view, we may attribute such ulceration to hyperchlorhydria. There may be other causes, the nature of which we do not know, but so long as we remember that an experimental ulcer can be produced only in the presence of hyperacidity, we have at least one means of prevention in the administration of alkali and judicious dieting referred to above.

3. Apparent Relapses.

In these cases the ulcers are probably healed after gastro-enterostomy, but notwithstanding, the symptoms of pain and perhaps of vomiting and haematemesis persist, or return at a varying interval.

1. *The Pain of Adhesions.*—Simple ulcers of the stomach and duodenum give rise to adhesions between these organs and the neighbouring serous surfaces. In the majority of these cases the patient suffers no pain, but when adhesion exists between the anterior wall of the stomach and the abdominal wall, pain is probably a persistent symptom, for the parietal peritoneum is known to be very sensitive. Each time the stomach moves relatively to the abdominal wall, as it does after meals, there will be a drag on these adhesions, and consequently a pull on the parietal peritoneum. In such cases the pain will be very obstinate, entirely unrelieved by simple gastric sedatives, such as sodium bicarbonate, hydrocyanic acid, etc. In those cases in which the ulcer was noted to be on the anterior wall of the stomach at operation and the patient shows no permanent improvement, adhesions may be suspected as the cause of failure.

2. *Carcinomatous Change.*—It is known that about 60 per cent. of cancers of the stomach arise on the sites of old simple ulcers. Chronic and unhealed peptic ulcers are specially liable to this form of degeneration, but it is

possible that carcinoma may originate on the scarred site of an old ulcer healed by gastro-enterostomy. If this be the case there will be a relapse of the symptoms, with the other signs usually attendant on cancer of the stomach.

GENERAL CONCLUSIONS.

Reviewing the results of this series broadly, we see that as a general rule gastro-enterostomy is excellent for men of middle age who suffer from duodenal ulcer, especially if associated with some pyloric stenosis, whereas failure generally follows operation in cases of young women suffering from gastric ulcer.

Thus, of 12 females under 35—all subjects of gastric ulcer—10 cases were complete failures, and 2 only were successful. Some of these cases were in young and anaemic women, and on opening the abdomen no ulcer was found. There were 4 cases in which no ulcer was discovered, and of these 3 did badly. Probably in these 4 cases no ulcer existed, and it is clear that operative treatment could have been of no avail.

A more exact knowledge of the symptomatology and morbid anatomy of the ulcer might enable us to predict, with even more confidence, the result of gastro-enterostomy.

SUMMARY.

1. The results of treatment by gastro-enterostomy are generally either excellent cures, or complete failures.
2. The immediate mortality of 92 cases is 7.6 per cent., but of the last 53 cases it is 0.
3. The general results are: 43 per cent. excellent; 38 per cent. bad.
4. Prognosis is much better when the patient is over 40.
5. According to sex, 69 per cent. of males are cured; 23 per cent. of females are not improved.
6. The duration of symptoms is of no assistance in forecasting the result of operation.
7. The length of time elapsing between the meal and the onset of the pain is of great importance; the longer it is the better the outlook.
8. Duodenal ulcers yield very much better results than gastric ulcers; the gastric give 38 per cent. of cures, duodenal 70 per cent. of cures.
9. Cases of pyloric stenosis yield the best results.
10. The degree of hyperchlorhydria is of importance, cases showing a total acidity of over 0.2 per cent. reacting well, cases with a normal acidity doing badly.
11. The improvement effected by the operation is probably due to the relief of dilatation, pyloric spasm, and hyperacidity by the drainage of the stomach.
12. Failures may follow the closing of the anastomosis.
13. The position of the anastomotic opening on the posterior wall of the stomach may be of great importance.
14. Failures may be due to:
 - (a) Recurrence, or failure to heal of the original ulcer.
 - (b) Formation of jejunal ulcer.
- Apparent relapses:
 - (a) Adhesions—causing pain, vomiting, etc.
 - (b) Carcinomatous degeneration.
15. Cases where an ulcer is not found at operation do badly.

In conclusion, I would like to express my thanks to Mr. J. Ernest Lane, F.R.C.S., and the other members of the surgical staff of St. Mary's Hospital, who have kindly given me permission to use their cases.

THE Illuminating Engineering Society (32, Victoria Street, London, S.W.) has done good service in following a recent American precedent and reprinting from its official organ for general circulation a pamphlet with the title *Light and Illumination: their Use and Misuse*. It gives a few simple recommendations on this subject. The reader is told concisely what kind of illumination to avoid, how to obviate the evil of glare and dazzle, how to concentrate the light where required, and how to secure its effective distribution. He is also assisted in the choice of globes, shades, and reflectors, and instructed in the part which walls and ceilings play in the lighting of home, shop, office or factory. To do all this within the compass of a threepenny pamphlet, and to do it without treading upon any commercial corns, or showing any preference for this or that illuminant, is a useful achievement. The instructions are helped out with several illustrations which show even more clearly than the text what kind of lighting is deficient and prejudicial to the sight.

A METHOD OF PERFORMING GASTRO-JEJUNOSTOMY.*

By KENNETH BLACK, F.R.C.S.ENG.,

EX-SURGICAL RESIDENT AT GUY'S AND ST. THOMAS'S HOSPITALS,
MANCHESTER ROYAL INFIRMARY, AND NOTTINGHAM
GENERAL HOSPITAL.

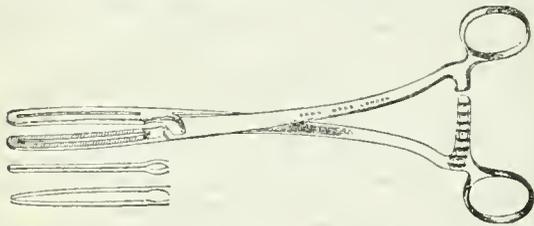

I SHALL endeavour to explain a method, slightly different from the ordinary one, of performing the operation of gastro-jejunosotomy—a method adopted in 26 consecutive operations for the following lesions:

| | Operations. |
|---|-------------|
| Gastric ulcer, with or without adhesions ... | 11 |
| Pyloric stenosis and gastric dilatation the result of simple ulceration ... | 6 |
| Gastric dilatation associated with enteroptosis ... | 1 |
| Severe haematemesis from simple ulceration ... | 1 |
| Duodenal ulcer ... | 1 |
| Carcinoma of the stomach ... | 1 |
| Carcinoma of pylorus ... | 5 |
| | 26 |

Of these operations two only had fatal results. In one case (of very advanced carcinoma of the pylorus) the patient died from exhaustion, two days after the operation; and in the other (of duodenal ulcer) the patient, who had previously undergone an operation for some pelvic disease, died, three weeks after an apparently successful gastro-jejunosotomy operation, from the effects of an abdominal abscess, the cause whereof was not ascertained, but which, it is believed, was unconnected with the gastro-jejunosotomy operation.

Method of Operating.

After the abdomen had been opened in the usual way, and the diseased area examined, the stomach, transverse colon, and great omentum were turned over on to the abdominal wall, so that the posterior wall of the stomach lay uppermost. The transverse mesocolon was then cut through and the stomach drawn through the opening

made in it. Two short-bladed forceps were then applied, one to each end of the portion of stomach selected for junction with the jejunum. This portion of stomach—that is, the portion lying between the two forceps—was not “clamped” with a forceps, but was left “free.” The omission to check, by clamping it, haemorrhage and gastric contents, was a special feature of the modified method of operating which I am attempting to describe. The edges of the cut in the transverse mesocolon were fastened, with a few stitches, to the stomach wall—an important step as a provision against the possibility of the small intestine subsequently passing through the opening and becoming strangulated.

The next step was to select a portion of the jejunum for junction with the stomach. Each end of the selected portion was grasped with a short-bladed clamp forceps of the same kind as had been previously applied to the stomach. Thus there were four clamp forceps in use, two grasping a portion of the stomach and two grasping a portion of the jejunum. By means of these two pairs of forceps the portions of stomach and jejunum which were to be connected were brought close together and held side by side. Sponge cloths were then packed round the exposed portions of stomach and jejunum.

With a Lembert suture the outer coats of the stomach and jejunum were then stitched together for a length of about 4½ in. Openings of the requisite length (3½ in. to 4 in.) were made in both the stomach and the jejunum. When the stomach was opened its larger vessels were secured and ligatured. This was a special feature of the operation, the objects being to check haemorrhage during the operation and to prevent post-operative haemorrhage.

The next step was by stitching to join the opening in

* Read before the Nottingham Medico-Chirurgical Society.

the stomach to that in the jejunum. There were four rows of stitching. The first row, already mentioned, was simply peritoneal stitching. The second row, just in front of the first row, joined one side of the opening in the stomach to the corresponding side of the opening in the jejunum; this row of stitches secured the whole thickness of the stomach wall to the jejunum. And, similarly, the third row, joining the other side of the opening in the stomach to the other side of the opening in the jejunum, extended to the whole thickness of the walls of the stomach and jejunum. This third row closed the openings in and completed the junction of the stomach and jejunum. The fourth row of stitches, similar to the first row and corresponding to it, on the other side of the openings, was simply a Lembert peritoneal continuous suture. In doing this stitching a straight non-cutting needle was used, and, with the object of facilitating the work of the operator's assistant, care was taken that all the stitching should be “towards” the operator.

The sponge cloths were then removed and the stomach turned down and replaced in the abdominal cavity, which was then closed in the usual way.

Advantages.

The essential difference between this method of operating and that usually described and practised is that in the latter, with the object of checking haemorrhage and stomach contents, the portion of the stomach selected for the opening is clamped throughout its entire length with the blades of a long-bladed forceps, whereas in the former only the two ends are grasped with forceps, and the portion of stomach lying between these two forceps is not clamped at all.

The method described by me seems to have the following advantages:

1. In the ordinary method reliance has to be placed solely on the tightness of the stitching for the prevention of post-operative haemorrhage into the stomach, which not infrequently occurs and has even proved fatal. In the method described by me, on the other hand, it is possible, when opening the stomach, readily to see and ligature the larger vessels in the stomach wall; this overcomes the risk of post-operative haemorrhage.

2. When long-bladed forceps are used it is in practice by no means easy in some cases to get the stomach “nicely” between the blades. On the other hand, the short-bladed forceps can be applied quickly and with ease. Also, when the long-bladed forceps are used, there is more danger of damaging the stomach walls unless rubber tubing is used to cover the blades.

3. When long-bladed forceps are used it is difficult in practice, owing to the thickness of the stomach walls, to clutch hold of and clamp a sufficient length of the stomach; hence the length of the opening which can be made in the stomach is limited, for obviously the opening cannot be greater than the length of stomach clamped by the forceps. But in practice, even the whole of this length, limited though it is, is not available for the opening, because the “tension” at each end of the clamped portion of the stomach is found to be so considerable as to prevent ease of stitching, and obviously the opening cannot be given a greater length than that which can be stitched up with accuracy. On the other hand, in the modified method of operating described above, an opening 3½ to 4½ in. long can be made with ease. The operation of gastro-jejunosotomy has more satisfactory results, and the risk of regurgitant vomiting is obviated if the opening is a large one.

It is easier, and takes less time, to perform gastro-jejunosotomy in the way described above than in the way more commonly adopted.

It may be urged that the modified method described by me has some drawbacks. Let us consider them.

1. The flow of blood during the operation may interfere with accuracy of stitching. This is true only to a limited extent, for bleeding from the cut is mostly checked, as already mentioned, by ligaturing the larger vessels in the stomach wall, and the oozing from the smaller vessels is dealt with by the operator's assistant, who wipes away the blood as each stitch is inserted.

2. There is a risk of the patient straining when the stomach is open and forcing out some of its contents. This also is true only to a limited extent, for the stomach

ought to be washed out thoroughly before the operation; and even if anything does trickle out during the operation, it can easily be wiped away. In practice I have never found any harm result. It is suggested that the advantages of the method described by me more than counterbalance its drawbacks.

The short-bladed forceps used were made by Messrs. Down Bros.

MEDICAL, SURGICAL, OBSTETRICAL.

SUBACUTE OSTEITIS OF THE EPIPHYSIS OF THE OS CALCIS.

RECENTLY attention has been drawn to the changes that take place at the epiphyses, as the result of an injury, which at the time may appear trivial, but which if neglected may be followed by more serious consequences. In all doubtful cases it is wise to have an x-ray examination made, since the most careful clinical examination often fails to detect an abnormality, which at once becomes revealed when the part is radiographed.

Within the last year I have had two cases, both of which occurred in boys of the age of 13 years, and in both cases the symptoms and signs were similar.

A healthy, well-developed schoolboy was brought to me with a request that I would photograph his foot, which was painful and caused him to limp.

The history was that in June, 1911, he went to London to see the Coronation, and did a great deal of walking and standing. He then noticed a pain in his heel. The pain has persisted off and on up to the present time, was worse after he had been walking, or when his heel was subjected to the slightest blow. It was particularly noticeable whilst he would be in the act of drawing off his boot. From time to time there had been slight swelling of the heel, but he had never noticed any bruising. In consequence of his disability he was unable to take his proper share in the games.

There was some tenderness over the back of the heel, with slight swelling on either side of the insertion of the tendo Achillis. Contraction of the muscles of the calf of the leg caused slight pain. There was no wasting of the muscles, and the movements at the ankle joint were unimpaired. His gait was what one would expect in this condition. To save his heel from impact with the ground he walked on the forepart of the foot, with the heel raised, and the knee slightly flexed.

Radiographic Examination.

The radiographic plates that were taken showed the following condition: The shape and structure of the bones were normal with the exception of the epiphysis of the os calcis. This was seen to be very irregularly ossified, and there was an abnormal gap between the epiphysis and the body of the os calcis. The epiphysal plate appeared to be displaced upwards and backwards, and there were calcareous deposits in the lower part of the tendo Achillis.

I take it that this condition had originated as a subacute osteitis in the neighbourhood of the epiphysis, due to strain or to excessive walking on hard pavement in one not accustomed to it, and that this osteitis had led to weakness of union between the epiphysis and body, with subsequent partial displacement.

A very similar condition affecting the tubercle of the tibia is now well recognized, being known as "Osgood Schlatter's disease of the tibial tuberosity," and it is reasonable to assume that a similar condition may be met with at the epiphysis of the os calcis, which, though to a great extent protected by its dense fibrous covering, is, from its position, liable to injury.

The treatment recommended is to supply support to the heel. This can be done by means of strapping shaped similar to a jaw bandage. The central part is placed over the heel; the ends are then carried forward round the ankle joint and crossed. The patient should also be instructed to wear a soft pad inside the boot.

WILLIAM EDMOND, F.R.C.S.

Medical Officer, Electrical Department, Salop Infirmary.

IODINE IN CORNEAL ULCER.

WITH reference to the case of corneal ulcer treated by iodine, reported in the BRITISH MEDICAL JOURNAL of January 25th, p. 169, by Fleet Surgeon C. T. Bishop, I wish to mention that for the past sixteen months I have treated all cases of ulcers and ulcerations of the cornea, irrespective of cause, that have come to my surgery, and

also those occurring in my private practice, with daily applications of tr. iodi. In all cases so treated I have had, to quote Fleet Surgeon Bishop's own words, "very striking results."

I am of opinion that this is one of the most satisfactory methods of treatment for nearly all cases of ulcer of the cornea, due attention being paid at the same time to the treatment of the cause, whether local or constitutional or both.

The method I employ is the following—namely: The eye having been previously anaesthetized with a few drops of 4 per cent. solution of cocaine, the end of an ordinary wooden applicator is sharpened to a pin's point and a little cotton-wool firmly wound round it. The point is dipped in the tincture of iodine and the surface of the ulcer gently touched with it. The conjunctival sac is next thoroughly irrigated with distilled water.

May I call Fleet Surgeon Bishop's attention to May and Worth's *Diseases of the Eye* (second edition, p. 120), where the above method of treatment is described?

INTERNAL TRAUMATIC VAGINAL HAEMORRHAGE.

THE following case of internal traumatic vaginal haemorrhage resulted in the formation of a perivaginal haematoma after a normal labour.

On January 23rd, at 10 a.m., I was called to see a multipara in labour. On examination I found a left occipito-anterior presentation, the membranes not ruptured, the os partially dilated, and an old perineal laceration. The pains were of normal strength and duration. I left the patient and returned at noon. The head was now on the perineum and was carefully conducted out of the vagina, the patient being under light chloroform anaesthesia. The placenta was expressed in due time by Credé's method, and I left the patient quite comfortable to the midwife in attendance.

At 2 p.m. a message came that the patient complained of pain, which I took to be ordinary after-pains, and sent two 1-grain opium pills with instructions. At 6 p.m. I was again called to see the patient on account of pain and faintness. At this time she seemed to be suffering considerably, was pale and cold with a quick pulse. On examination in the cross-bed position the vulva gaped widely; the mucous membrane of the post-vaginal wall was very congested and everted, presenting the appearance of an inverted placenta at the vulvar orifice; the whole posterior triangle of the anatomical perineum was very tense and bulging, and the vaginal canal practically occluded; the cervix uteri could not be reached by the finger. The fundus uteri was globular, firmly contracted, and raised above the level of the umbilicus. Rectal examination disclosed to the left and behind a tense well-defined swelling about the size of a large orange. A hypodermic injection of morphine and ergotinin was administered.

At 9 p.m. the rectal swelling had increased considerably; the pulse became faster, and the patient more collapsed, so I decided to have her removed to the Doncaster Infirmary, where I again saw her at 2 a.m. on January 24th, with Dr. Henry Clarke. At this time there was a well-marked ecchymosis extending from the anus laterally on both sides to the outer limit of the ischio-rectal fossae. Dr. Clarke, in attempting to reach the cervix uteri, caused a rush of blood from the vagina, and consequent disappearance of the vaginal obstruction and of the tumour to be felt from the rectum. Then, with careful examination under the altered circumstances, we found, high up in the vagina on the left side, a tear which, owing to the congested condition, looked like a punctured wound of sufficient size to admit the tip of the little finger. This was stitched in the usual way, and the patient has gone on well.

The foregoing notes I consider interesting and instructive. Interesting because, according to Jellett, "internal traumatic vaginal haemorrhage" sufficient in amount to require treatment is a very rare condition; there were only 10 cases in 20,000 deliveries at the Rotunda Hospital.

Again, the labour was not unduly prolonged; the child was delivered naturally—in fact, the case was normal in every respect. It is instructive in its warning not to regard all pains after labour as trifling after-pains.

Carcroft, Doncaster.

ON

MEDICAL AND SURGICAL PRACTICE IN HOSPITALS AND ASYLUMS.

TONGSHAN HOSPITAL, NORTH CHINA.

A CASE OF SUBPERIOSTEAL LIPIOMA OF THE FEMUR.

(By H. B. KENT, M.B., B.S.Lond., Medical Officer to the Kailan Mining Administration and to the Chinese Government Railways, North China.)

THE following case is of pathological interest, and shows to what extent the philosophy of a Chinaman will permit him to put up with a considerable burden for several years. The patient, a man aged 41, walked into my outpatient room, and said he came to know whether he could have removed the swelling visible in the annexed illustration. It was fixed deeply into the tissues of the thigh, being attached by a deep root extending the whole length of the fascia lata. This root is well marked by the horizontal veins seen in the picture. In one part (which may be identified in the photograph by the white area) fluctuation undoubtedly existed, but elsewhere it was, in my opinion, solid. But this solidity was not very striking, for two other European medical men thought they obtained a doubtful thrill. The man's aspect did not suggest that the growth had had any serious effect on his general health.

History.

His history was that seven years ago a swelling appeared in the front of his thigh extending the whole length of the bone.

This swelling had gradually increased in size until it reached its present dimensions. It was quite painless, and his health had been otherwise good. Five years ago a medical man attached to Indian troops (stationed here after the Boxer trouble in 1900) tapped the swelling, which was then comparatively small. The patient stated that only blood came out, so that even at this date the solidity of the tumour was questioned. Quite recently the tumour had been again tapped in Tientsin, with the same result. In view of these circumstances I advised the man to take the risk of an operation, and have the tumour removed.

Operation.

An incision was made over the summit of the swelling and gradually enlarged so that it extended the whole length of the tumour. Bleeding was fairly free from the large veins, but was easily controlled. The deep fascia was divided, and it was then plain that the tumour was deep in respect of the muscles of the thigh. It was interesting to note that the tumour had so displaced the extensor muscles that the patella was at right angles to the joint, the articular surface facing upwards and slightly forwards instead of horizontally backwards. The task of displacing the muscles to either side of the tumour was a

feels one, but was ultimately achieved with the actual division only of the sartorius muscles.

Unfortunately the patient, who had been anaesthetized with chloroform, showed signs that his heart was failing. His colour and pulse became very bad. Open ether was given by Dr. Cooper, and the patient rallied to some extent. The operation was continued as quickly as possible.

Having stripped of the muscles it was obvious that the tumour was an enormous lipoma, attached to the femur in four-fifths of its length. Its lower pole was free. The femoral vessels were displaced inwards and were much stretched.

Starting from the lower pole the tumour was with difficulty freed from its fibrous attachments. This was a long operation, and the patient's condition became very grave. Cardiac stimulants and saline infusion were given during the last part of the operation. When the whole of the tumour had been removed it was found that the whole length of the femur was laid bare, being stripped of its periosteum.

The enormously stretched muscles were rolled up longitudinally, and a few stitches put in to hold them. The skin was brought together. It was thought that if the man rallied a secondary plastic operation could be done later.

The patient was exceedingly ill. His pulse was hardly perceptible and his colour very bad. Every method of cardiac stimulation was tried, but without much beneficial result. The unfortunate man died an hour and a half after getting back to bed.

Examination of the Tumour.

The tumour was found to be a lobulated lipoma. One portion (which had been tapped previously) had undergone degeneration, and there was some fluid in this part. Beyond this small portion the tumour was quite solid. The dimensions of the tumour were:

Circumference (around the tumour and thigh), 4ft.

Length from upper to lower pole, 2 ft. 9 in.

Weight after removal, 60 lb.

REMARKS.

I see that Sir John Bland-Sutton, in his book *Tumours, Innocent and Malignant*, quotes two English cases of periosteal lipomas of the femur. Details are not given, but in civilized countries I doubt whether any one would allow a growth to become so large as that in the case now recorded before seeking surgical aid.

It was unfortunate that the patient died, but I think the cardiac muscle must have had for several years a severe strain put upon it. There were no bruits audible before operation. The bleeding at no time was excessive. We must conclude that the operation was greater than his cardiac muscle could stand. I do not believe the fact that we started with chloroform had any bearing on the ultimate result. *Post-mortem* examinations being illegal in China, no subsequent investigation as to condition of heart and other organs could be made.

In conclusion I must express my thanks to Dr. J. G. Gibb, M.D.Lond., F.R.C.S.Eng., of the Union Medical College, Peking, for his great assistance at the operation; and to Lieutenant Alexander Cooper, of the United States Army Medical Corps, for his help in giving the anaesthetic and supervising the saline infusion.

British Medical Association.

CLINICAL AND SCIENTIFIC PROCEEDINGS.

SOUTH WALES AND MONMOUTHSHIRE BRANCH.

A CLINICAL meeting of the Branch was held at the Newport and County Hospital on Thursday, February 6th, at 3 p.m. Mr. R. J. COLLIER showed: (1) A case of marked unilateral proptosis with enlarged thyroid. (2) A specimen of sarcoma of the choroid, demonstrating the tumour very clearly. Mr. GREER showed: (1) A number of radiographs taken before and after operation for recent fractures of the tibia and fibula; the patients, who had been treated with plates and screws, were in attendance. (2) An ununited fracture of the tibia and fibula in an infant, which had been produced by a bone-setter's treatment of a bow-leg; the radiographs showed a bone graft taken from the child's rib in position and the absorption of the rib and development of callus. The patient was shown. (3) A series of thyroid glands removed by hemithyroidectomy, with photomicrographs exhibiting the histological structure found in Graves's disease and other pathological conditions. Dr. J. MCGINN exhibited: (1) An apparatus for ionization, a number of patients treated, and photographs of the morbid conditions at various stages. (2) Keating-Hart's apparatus for use with a high frequency machine in fulguration. (3) Photographs and patients suffering from lupus erythematosus. The cases and exhibits were discussed and examined by the members present.

Reports of Societies.

MEDICAL SOCIETY OF LONDON.

Monday, February 21st, 1913.

Sir W. WATSON CHEYNE, President, in the Chair.

Unilateral Renal Lesions.

MR. RALPH THOMPSON read a communication based upon 13,505 autopsies, 8,218 on males, and 5,287 on females, at three London hospitals. All the autopsies were read through, no reliance being placed on indexes. The term "solitary kidney" was limited to cases where one kidney had either never developed, or had apparently undergone complete atrophy before birth. From the 13,500 *post-mortem* examinations he had collected 23 cases of solitary kidney, or 1 in 587 autopsies. Of the 23 cases, 14 were in males, 8 in females, and 1 in a case where the sex was not stated. Disease or mechanical lesion of the solitary kidney was only found in two cases. Some of the cases of supposed solitary kidney were really instances of double kidney. Dr. J. D. Rolleston recently stated that double ureter occurred in 1 per cent. of cases, but Mr. Dunn, Mr. Steward, and Mr. Rowlands stated that during an operation they had not come across a case of double ureter. Dr. H. M. Turnball found this condition in only 1 in 150 of all autopsies recorded at the London Hospital; 8 were on the left side, 7 on the right. Mr. Thompson showed an instructive specimen exhibiting aberrant vessels, and then passed to the consideration of injuries to the kidneys. He had found records of injury to the left kidney in 19, and to the right kidney in 22. There were notes of only 3 cases in which both kidneys were injured. Of ascending inflammation of the kidney he brought forward 14 cases in which that occurred in the left kidney, 12 affecting the right. In 3 the side was not stated. The total number of bilateral ascending inflammations was 135, and of unilateral 38. The next aspect dealt with was hydronephrosis and growth, and he said that the incidence of unilateral hydronephrosis was as follows: The left side only was affected in 52 cases, the right side only in 44. The number of cases of unilateral hydronephrosis occurring with an unknown cause included a much larger number of males than females. Out of the cases of hydronephrosis associated with granular kidney 3 were bilateral, and 7 on the left side, but none on the right. A series of cases were related in which there was evidence of tuberculous peritonitis and abdominal lymphadenitis, leading to pressure on the ureters. Sufficient attention had not been paid to constriction of the ureters by fibrous bands formed as a result of tuberculous peritonitis. A man complained of right renal colic, and suffered from haematuria. Catheterization showed that the function of the right kidney was very imperfect, but that of the left was unimpaired. Mr. Thompson operated, and found the right kidney septic, and a fibrous band was stretched tightly over the ureter about 2 in. below the pelvis. The band was divided, and then a well-marked stenosis of the right ureter was discovered. The kidney was excised, but the patient died six weeks later from tuberculous meningitis. The excised kidney showed no signs of malignant peritonitis. With regard to renal calculus, Mr. G. W. King had collected for the author 100 clinical records of successive cases at Guy's Hospital, which showed 57 in which the calculus was on the right side, 41 on the left; 2 were bilateral. Mr. Thompson's own collection showed 27 left, 39 right, 14 bilateral. Adding those from London Hospital gave 210 cases, of which 81 were left, 102 right, 22 bilateral; 5 not stated. Among 19 cases in children there were 11 right and 8 left. In the *Lancet*, early last year, an authority stated that *post-mortem* records taught that surgeons should be careful about undertaking nephrectomy for tuberculous disease, as the other kidney was frequently affected. Mr. Thompson's researches at three hospitals, however, revealed the following facts: (1) The unilateral cases of *post-mortem* renal tuberculosis were as 37 to 74 bilateral. (2) In the unilateral cases the right was affected in the proportion of 13 to 5 on the left. Pyelonephritis and bacilluria were admittedly more common on the right than on the left side. In regard to the reason why the right kidney should be more often affected than the left by inflammatory conditions, there seemed to be anatomical evidence that blood infection was more likely

to reach the right kidney. That infection could reach the kidney from the alimentary canal was proved by reference to certain cases of carcinoma. The points upon which the author invited discussion were: (1) That the incidence of solitary kidney was much nearer the higher percentages recorded by some observers than the lower figures by others. (2) That the incidence of double ureters was more frequent than textbooks on surgery indicated. (3) That ascending inflammation might affect only one kidney in about 20 per cent. of all cases, and was more common on the left side, owing to pelvic causes. (4) That hydronephrosis was frequently unilateral, and was more common on the left side, chiefly owing to pelvic trouble. (5) That infarcts and miliary tubercles represented blood infection, and bacilluria represented lymphatic infection. Local tuberculosis and renal calculus, as well as infarcts, miliary tubercle, and bacilluria, were more common on the right side. The explanation was apparently to be found in the anatomical conditions, namely: (1) The arrangement of the blood vessels; (2) the anatomy of the colon; (3) the normal anatomical obstruction which might be present to the flow of urine along the ureter, before it reached the limits of the bony pelvis.

MR. THOMSON WALKER considered that Mr. Ralph Thompson had given the society some very interesting and important facts concerning diseases of the kidney. Unilateral renal disease lay at the root of the treatment of a large number of diseases of the kidney. Renal tuberculosis, carcinoma of the kidney, advanced cases of stone, pyelonephrosis, and some other diseases, all called for nephrectomy, and that operation could not be undertaken as a curative measure unless the disease were unilateral. There was a pathological and a clinical aspect. Mr. Thompson had shed a much more cheerful light on the former than pathologists were accustomed to impart. The pathologist had the advantage of being able to study and report on the specimen at leisure, but he also laboured under the grave disadvantage that he looked at the disease—and that was especially so in the case of a vital organ like the kidney—from the point of view only of its final stage. Mr. Walker proposed to confine his remarks practically to tuberculosis. On that question the view of the pathologist was very pessimistic, as far as unilateral and bilateral distribution was concerned. Professor Adami said it was usual at autopsies to find both kidneys affected, but the disease was more advanced in one than in the other. But the surgeon was, said Mr. Thomson Walker, more concerned with the *ante-mortem* pathology, the prime fact of which was that it was the early stage which was the surgically important one. Mr. Thompson's *post-mortem* statistics had confirmed those of several Continental observers. But, however important and pessimistic might be the *post-mortem* figures, they could not get over the mass of clinical and surgical evidence which had now accumulated that renal tuberculosis was, in its early stage, a unilateral disease. Miliary tuberculosis did not loom surgically into the field; it was too generalized. Having recognized the disease early, then by performing nephrectomy in the early (unilateral) stage one could cure renal tuberculosis in the large majority of cases. Israel found, clinically, that unilateral cases numbered 88 per cent., Krönlein, 92 per cent. In the clinical diagnosis of renal tuberculosis very little help was derived by the ordinary physical diagnosis. Pain, for instance, might be entirely absent during the whole course of the disease; or there might be pain in one kidney only, and it was still a problem whether the fellow kidney was healthy. It might be that one kidney had been destroyed by tuberculosis without pain, and that the second had become infected and was painful. The same might be true of tenderness and enlargement of the organ. One kidney might have been destroyed by tuberculosis without having been enlarged or tender, or palpable; but when the second became involved it might be both large and tender. Mr. Walker referred to an instance where a patient's enlarged and tender kidney, unlike its fellow, still functioned; thus, its removal would have resulted in fatal uraemia. This type of complication explained many cases where anuria came on after operation for renal tuberculosis in the statistics of the older surgeons. The use of the ureteric catheter for diagnosis was dwelt upon, and sources of fallacy indicated by Mr. Walker. When

the bladder was much involved tuberculin should be given, then the vesical complication underwent improvement until at length catheterization could be carried out for the determination of the diseased kidney. In many cases that failed, and then the question of opening the bladder and catheterizing the ureters arose. That was not easy, as the bladder was extensively ulcerated and contracted, and bled very readily. Another suggestion was to put a temporary ligature on it and collect the urine from the other side, but that did not appeal to him, and he had had no experience of it. Should not one, in such a case, open the supposed healthy kidney and find whether it was tuberculous? That had been his practice in most cases of that kind. He believed that in most cases tuberculosis of the kidney commenced at the apices of the pyramids, and passed outwards to produce the cavernous type. Tubercle bacilli were sure to be in the urine, therefore he relied upon the ureteric catheter. An objection to nephrectomy was that it involved destruction of some part of the kidney—a very important matter, seeing that it would probably be the patient's only working kidney. Unilateral urinary tuberculosis was usually secondary to a lesion elsewhere, such as in the spine or in a joint; therefore if one kidney were removed by operation, what proof was there that the primary focus elsewhere would not destroy the other kidney? That could only be answered by a study of the effect of nephrectomy in those cases; but the second kidney, when it was involved, seemed in most instances to have been infected from the first, not from the distant disease area. Israel collected 1,023 records of nephrectomy for unilateral tuberculosis, with a "near mortality" (that is, up to six months) of 12.9 per cent., and a late mortality (after six months) of 10.15 per cent.; in other words, 75 per cent. of cases were looked upon as cured. Pulmonary tuberculosis accounted for 45 per cent. of the late deaths.

Urinary Secretion of Potassium Iodide.

Dr. O. KAUFFMANN read a contribution entitled, Some experiments on the urinary excretion of potassium iodide and their clinical significance. He sought to test whether, by means of the time required by the kidneys to excrete a fixed dose of potassium iodide, a measure could be found of renal efficiency in certain directions in which neither the volume and degree of concentration of the urine nor the quantity of urea formed a reliable measure. In persons whose general state was satisfactory—with no renal disease, endocarditis, or cardiac failure—iodine was found in the urine an hour and a half after the administration, and the excretion usually ceased nine to twelve hours after the giving of the dose. Subjects with Bright's disease, cardiac failure, or arterial degeneration showed a delay until the third hour, and ceased sooner than in the case of the healthy. In health or when lying in bed, whether on a pure milk diet or a mixed diet, 10 to 20 mg. of iodine appeared in the urine. In the same person the quantity of iodine excreted did not necessarily vary with the quantity of urea passed in the same time, nor with the amount of urinary water. Pyrexia was associated with a diminished excretion of iodine. The administration of iron was followed by a decrease of urinary iodine, but the exhibition of potassium citrate had the contrary effect. The power of the kidneys to excrete potassium iodide was a measure of one kind of renal efficiency which could not be gauged by either the quantity of water or the quantity of urea passed, and for which the chlorides, seeing that their mass depended essentially upon food ingestion, could not be used as a measure. In interstitial nephritis Dr. Kauffmann regarded the potassium iodide efficiency as a valuable diagnostic aid.

ROYAL SOCIETY OF MEDICINE.

CLINICAL SECTION.

Friday, February 14th, 1913.

Sir WILLIAM OSLER, President, in the Chair.

Discussion on Cervical Rib.

Dr. F. WOOD JONES opened a discussion on cervical rib from the anatomical point of view. There was an antagonism between the development of a limb plexus and the development of ribs extending over that area from

which the limb had originated. A limb bud might arise nearer to the head or nearer to the tail than normally, and its limb plexus might be of the pre-fixed or post-fixed type. With either variation costal anomalies might result. Both might proceed so far that the plexus readjusted itself with the development of the seventh cervical rib or abortion of the first thoracic rib, as the case might be; or there might be disharmony between nerve movement and rib development and brachial neuritis might be caused by abnormal pressure. This antagonism also accounted for the vascular symptoms, for the sympathetic vascular nerves ran for the most part in the lowest cord of the brachial plexus, and symptoms might be produced by cervical ribs or by first thoracic ribs, depending on the constitution of that plexus. By radiography a definite diagnosis as to the nature of the offending costal element could be made only by a count of the vertebra elements lying cephalic to the costal process. Mr. W. THORBURN said he analysed the results of twenty surgical operations which he had performed. There were no serious difficulties. A transient paralysis of the brachial plexus and suprascapular nerve were met with in three cases, and the pleura was twice wounded without after ill-effects. He had removed the first dorsal rib in error, but with perfect functional result. All the cases had improved, and complete cures were obtained in more than one half. He preferred a long vertical incision at the back of the posterior triangle of the neck with dissection forward. Mr. PERCY SARGENT had operated upon 29 cases, 26 of whom were female. Asepsis and gentleness of manipulation were essential, but it was not always necessary to remove the rib, division of the continuing band being often sufficient. In only one case was pain unrelieved. Dr. S. A. K. WILSON laid stress on the dissociation of the muscles of the hand with regard to their wasting, particularly as a means of distinguishing the condition from progressive muscular atrophy. He showed several photographs to illustrate the point. Dr. FARQUHAR BUZZARD spoke of a similar dissociation of wasting. The pain might be of any degree or distribution. He had met with many instances of acroparaesthesia. The question of occupation was important, and several had obtained relief by giving up some particular form of work. He doubted whether there were any characteristic sensory symptoms in "cervical rib." Twelve cases were shown, all in women. Of these, 10 had been operated upon, 9 with good effect; in one case the result had been unsatisfactory. Of the remaining two, one had improved without operation, and the other remained *in statu quo ante*.

SECTION OF LARYNGOLOGY.

Friday, February 7th, 1913.

Mr. T. MARK HOVELL, Vice-President, in the Chair.

Exhibition of Cases.

MR. C. W. M. HOPE exhibited two cases of Malignant disease of the larynx treated by injections of seleniol, an electrolytic colloid of selenium. A man, aged 25, had mixed cell sarcoma of the tonsil and deep glands removed at separate operations; in spite of the infiltrating character of the secondary growth seleniol had given local and general improvement. The second patient, a man aged 53, had extensive fungating growth of the larynx, causing obstruction, and a secondary growth; 3 c.cm. of seleniol had been injected three times a week into the tissues, close to the thyroid cartilage. General improvement followed; the fungating growth gave place to a clean ulcer, and the dyspnoea was relieved. Mr. DE SANTI doubted the efficacy of seleniol, but considered that operation offered the only hope. He would have advised clearing out the glands of the neck at the first operation, or shortly after; in 8 similar cases of his own recurrence had followed in three to six months. Mr. BETHAM ROBINSON pointed out that lympho-sarcomata, and some other sarcomata of the tonsil did well after operation, but the class of growth with much infiltration and little definition was hopeless. Dr. ADOLPH BRONNER asked if antimeristine had been used by any member. Dr. DOUGLAS HARMER had employed antimeristine in a case of extrinsic carcinoma of the larynx with material obtained by Dr. Schmidt in the method prescribed. After each of the ten doses the temperature was raised, the tumour increased, and

ultimately fungated. Dr. Kelson showed a case of *Pedunculated tumour attached to the inferior turbinal* of a man aged 72. Dr. P. HEMINGTON PEGLER believed it to be an instance of mucous hypertrophy. Mr. T. B. LAYTON exhibited a case of *Syphilitic stenosis of the larynx* with calcification of the fascia of the neck, previously shown by Mr. Charters Symonds and Mr. F. J. Steward in 1899. The palate was extensively scarred, and evidence of interstitial keratitis and choroiditis had appeared in the interval. There was some dyspnoea. Wassermann's reaction was positive. Mr. BETHAM ROBINSON had proposed tracheotomy. The extreme hardness round the hyoid bone was much the same as when the case was first shown, but the larynx was freer. Dr. W. HILL doubted, as on the previous occasion, the appropriateness of the word "calcification"; he considered "keloidal" as more suitable. Mr. HAROLD BARWELL indicated that an x-ray examination would clear up this point. Dr. H. J. DAVIS compared the hardness with Dupuytren's cicatricial contraction. Mr. J. F. O'MALLEY exhibited a case of *Webbing of the vocal cords* in the anterior commissure due to a shot wound, in a boy aged 11. The pellets of an "Eley 14" cartridge had ricocheted from a wall. The x-ray plate showed four pellets on the right side and one on the left. The damage was done by the one shot. Posterior to the webbing the cords moved well; the voice was hoarse. Mr. H. BARWELL recommended that nothing should be done, as the breathing space was sufficient. Mr. E. B. WAGGETT advised laryngotomy. In a case of webbed cords under Dr. WILLIAM HILL the voice was recovered after operation. Dr. FITZGERALD POWELL suggested waiting till the boy's voice changed. Dr. H. J. DAVIS would prefer laryngoscopy treatment and subsequent dilatation; he feared the voice might become worse after an operation. Dr. W. MILLIGAN preferred immediate operation, for two or three years' postponement would result in atrophy of the muscles. Dr. LAMBERT LACK considered that operation on the larynx of the child usually ended in failure. Operation might lead to stricture as well as loss of voice. He would defer operation till the boy had grown up. The CHAIRMAN was in favour of postponing interference. Dr. J. DONELAN's case of *Adhesion of the uvula to the posterior pharyngeal wall* gave rise to some discussion. Dr. DAN MCKENZIE had seen a good result after Dr. Dundas Grant had removed part of the bony palate and attached stitches passed through the soft palate to the incisor teeth; he had also experience of the method of passing rubber tubes through the nares and out through the mouth; the projecting tubes were tied together. Mr. DE SANTI related how Mr. W. G. Spencer detached the adhesion with the scissors and raspatory. The soft parts were then rolled together and transfixed with a silver wire suture, which was passed through the muco-periosteum of the hard palate. Reconstruction was very apt to follow. Mr. BETHAM ROBINSON had passed a lead plate round the separated palate. Silks passed through the plate were led out through the nostrils and mouth and tied together; the result was good. Dr. MILLIGAN did not consider any method gave really good results. Dr. FITZGERALD POWELL recommended the rubber tube method; the tube should be cleaned and replaced for a month. The CHAIRMAN had stitched preputial mucosa to the raw surface, and the case, six years later, had a good voice and excellent nasal breathing. Dr. DONELAN exhibited a new tonsillotome which could be used as a tonsillectome. Dr. WATSON WILLIAMS demonstrated an instrument in which the power was applied by the grip. Dr. H. J. DAVIS brought Sluder's own tonsil guillotines, and showed how Sluder employed them. Dr. WILLIAM HILL referred to the improvements Mr. J. F. O'Malley had made in Ballenger's instrument; personally he was impressed with the effectiveness of the reinforced Mackenzie. Dr. DAN MCKENZIE had seen severe cicatrices after the use of the blunt tonsillectome; he preferred a sharp Mackenzie guillotine. Dr. W. MILLIGAN thought the Sluder operation too forcible; he had seen the mucous membrane dissected off and the snare applied with great skill and finish. Mr. E. B. WAGGETT also approved of the snare. Dr. DUNDAS GRANT mentioned that a rectangular knife with a blunt point was useful in dissecting out the upper pole of the tonsil; this pole was readily enucleated by the guillotine. Dr. W. H. KELSON considered many tonsils were easily detachable; the present requirement was a suitable method

of dealing with the more difficult cases. The CHAIRMAN pinned his faith to the Mackenzie guillotine. With reference to Dr. H. J. DAVIS's case of cyst of the upper jaw. Mr. BETHAM ROBINSON had found elasticity on pressing the palate, and from the irregularity of the teeth deduced a dentigerous cyst. The antrum was probably small and unaffected. Dr. H. J. DAVIS reported that this side of the face was dark on transillumination; the cyst had increased in size; a similar case had developed osteo-mylitis after an out-patient operation. Mr. T. JEFFERSON FAULDER exhibited a man, aged 24, with a *Bony enlargement of the left side of the face* for three years; epiphora had been present during that time. Mr. BETHAM ROBINSON considered the condition as chronic osteitis of the character of leontiasis ossea; he advised potassium iodide. Dr. DONELAN regarded the condition as inflammatory, following rhinitis; he recommended operation. Mr. DE SANTI agreed with Mr. Betham Robinson's view, and was against operation. Dr. HEMINGTON PEGLER said the bilateral character pointed to a mild form of leontiasis. Dr. DAN MCKENZIE suggested the opening of the nasal duct into the nose above the inferior turbinal; he would show a case in which this had been done. Dr. E. A. PETERS showed a case of *Chronic pemphigus* in a man aged 49. It began after a small operation on polypi; small vesicles first appeared on the pharynx and palate, and eventually large vesicles developed on the face, wrists, and lips. A bacteriological examination showed a few contaminating staphylococci. Arsenic, rest, and small doses of opium were acting well. Dr. R. E. SCHOLFIELD related a case with similar symptoms where iodide of potassium and antipyrin had been taken previously. Dr. H. J. DAVIS had found orthioform of great service. Mr. DOUGLAS HARMER exhibited specimens illustrating a case of *Suppuration of the antrum due to Aspergillus fumigatus*. The patient, a lady, had suffered for years from hay fever, and caught a severe cold when motoring. A persistent one-sided discharge followed, with a "wet blotting-paper" cast on the pharyngeal wall. The right antrum was dull and the right nasal mucous membrane extremely swollen. The antrum was opened intra-nasally and irrigated twice a day, when membrane and gritty fragments came away with difficulty. Various applications were made, but finally sodium iodide internally and local applications of five-volume hydrogen peroxide were effective. The antrum became suddenly clear. Only three cases were mentioned in literature. The fungus was common in chronic lung cavities and the ear. Dr. H. J. DAVIS mentioned a case where the antrum was filled with polypi and small yellow bodies which exhibited a mycelium. Dr. ADOLPH BRONNER had found the fungus in cases which resembled chronic eczema of the external auditory meatus. Dr. DOUGLAS HARMER exhibited two specimens of the brine shrimp (*Artemia salina*) which had been recovered from the nose, where they caused a sensation of movement and intense irritation. The patient had been using a saline lotion prepared from patent sea salt. Dr. S. F. HARMER reported that *Artemia salina* lived in basins of concentrated sea water. The eggs present in sea-salt hatched out under favourable conditions; probably in this instance they had developed in an old solution which had been left unused. Dr. HAROLD BARWELL exhibited a boy, aged 13, with extensive *Ulceration of pharynx, larynx, and naso-pharynx*. Wassermann's reaction was positive, and so determined the nature of the ulceration. Dr. H. J. DAVIS showed (1) case of *Rodent ulcer opening into the nose*; (2) a *Suppurating dental cyst*; (3) *Lupus of the tongue, face, anterior nares, and palate*. Dr. E. A. PETERS remarked on the three clinical forms of lupus present as determined by the character of the local tissue, namely, (a) hypertrophic growth on the moist palate; (b) dry or atrophic in the dry anterior nares; (c) warty lupus on the friction surface of the tongue.

SECTION OF OBSTETRICS AND GYNAECOLOGY.

Thursday, February 6th, 1913.

Dr. AMAND ROUTH, President, in the Chair.

Red Degeneration of Uterine Fibromyomata.

A COMMUNICATION on this subject was read by Professor LORRAIN SMITH (Edinburgh) and Dr. FLETCHER SHAW (Manchester). The authors based their conclusions upon

the examination of 24 specimens, all characterized by their red colour; in other respects there were differences, and they therefore divided them into two groups, one in which thrombosis was the principal change (thrombotic group), and another in which there was no thrombosis, but a marked increase in blood vessels so numerous as to warrant this non-thrombotic group being regarded as angiomatous degeneration. The thrombotic group contained 15 out of the 24 specimens described; they were all associated with definite clinical symptoms, they were coloured a deep red, and showed no free blood on their cut surface. In a few specimens all the vessels appeared to be filled with thrombi, but in the majority only a portion of the vessels were thrombosed. Most of the specimens showed the red coloration throughout; in some it was partial, and in a few it was limited to the neighbourhood of the thrombosed vessels. The clinical symptoms included abdominal pain and tenderness of the tumour, rapid increase in size, fever and quick pulse. Micro-organisms were only found in a few cases, in all of which clinical symptoms of some severity were present. All the tumours were found to contain fat in the tissues, and, following Leith Murray, the authors believed the red coloration to be due to the haemolytic action of lipid bodies. Of the 15 specimens in this group 6 were clinically associated with pregnancy or the puerperium. The non-thrombotic group (angiomatous degeneration) included 9 specimens. These tumours were of a bright red colour and showed free blood on their cut surface. All showed the presence of large numbers of thin-walled vessels of microscopic size filled with blood, the red colour being due to the presence of these vessels. In only one specimen was much fat found, and this was of a dark red colour, as in the thrombotic group. None of the patients showed definite clinical symptoms other than haemorrhage and pressure.

The Cause of Internal Rotation of the Fetal Head.

Dr. JAMES YOUNG (Edinburgh) read a paper on internal rotation, and illustrated it by models and by an epidiascope demonstration. The author formulated the view that a firm cylindrical body, closely fitting a curved cylindrical canal, when forced along that canal continually changes its position; the lower end, in contact with the posterior wall of the canal, is carried continually forward as the body descends. The application of this view to the descent of the head in occipito-anterior and occipito-posterior positions was discussed and illustrated by the original models constructed by the author.

SECTION OF OTOLOGY.

Friday, February 21st, 1913.

Dr. DUNDAS GRANT, President, in the Chair.

The Temporal Bones.

Mr. ARTHUR CHEATLE gave a detailed description of both temporal bones from 120 persons, showing that in 82 there was symmetry and in 38 asymmetry. The diploitic or infantile type was present in 44, on both sides in 24, and one side in 20.

Otitic Abscess of Pterygoid Region.

Dr. DAN MCKENZIE showed and described a case where an abscess of this type was drained through the external auditory meatus, the patient recovering. The abscesses followed suppurative labyrinthitis with facial paralysis, developing in the course of suppuration of the middle ear of eighteen years' duration, attributed to scarlet fever. The discharge had increased during the last two weeks, and facial paralysis suddenly occurred five days before admission; there had never been any vertigo, nausea, or vomiting. Dr. McKenzie performed the radical mastoid operation and labyrinthotomy. The bone disease was found chiefly in the region of the Fallopian aqueduct. A fistula had developed in connexion with the external semicircular canal, and was enlarged; inferior vestibulotomy was performed through the wall of the promontory. The patient, however, did not make good progress; pain was complained of in the ear and the corresponding side of the head, and the discharge did not cease. Lumbar puncture was performed later on, 20 c.cm. of clear fluid being drawn off. The headache then subsided. Marked oedema of the left side of the face, chiefly of the temple and zygomatic

region, left cheek and orbit, developed. The patient could not masticate his food on account of the pain caused by movements of the lower jaw, which was found to be fixed in a half-open position. All attempts to open the mouth wider or to close it caused much suffering. Dr. McKenzie therefore opened up again and evacuated a pterygoid abscess. Intermittent fever continued for a week after the operation, then the temperature fell to normal. Facial paralysis, however, remained. As a complication of purulent otitis, otitic pterygoid abscess was rare, as only fifteen instances had been recorded.

Deafness after Epidemic Cerebro-spinal Meningitis.

Dr. H. J. DAVIS showed this case; the patient was a boy, aged 6, and the deafness was progressive and bilateral. The child was in danger of becoming a deaf-mute, and Dr. Davis commented on the more systematic and adequate way in which these cases were taken in hand and educated in America and on the Continent as compared with this country.

EDINBURGH OBSTETRICAL SOCIETY.

Wednesday, February 12th, 1913.

Dr. HAIG FERGUSON, President, in the Chair.

Uterine Haemorrhage of Ovarian Origin.

Dr. JAMES YOUNG described two cases of this type. The first patient was 40 years old, and a 7-para. Menstruation had always been copious, but was regular till the last three years. During that space of time it appeared fortnightly, frequently lasting ten days, and it was associated with ovarian pain. Curettage revealed glandular endometritis, but proved of no benefit. Ultimately supra-vaginal hysterectomy was performed, and the right ovary was removed. The endometrium showed glandular hyperplasia, as before. The ovary contained a corpus luteum with a large blood space. The luteal cells were ploughed up by haemorrhage, and the surrounding ovarian stroma was oedematous and haemorrhagic. The second patient was 28 years old, a unipara. Menstruation had been regular till May, 1912, when it lasted three weeks and was attended with severe abdominal pain. A pelvic tumour developed and was removed; it was then found to be an enlarged ovary containing a luteal haematoma. Microscopically it showed similarity to the other case. The haemorrhage corresponded to a prolonged period and was associated with excessive bleeding in the ovary, the region where the menstruation-producing substance was elaborated. Hence the haemorrhage must have been due to an excessive ovarian activity, probably frequent as a cause of menorrhagia and metrorrhagia where there was no definite uterine tumour, etc. The glandular endometritis found in these cases on curettage corresponded to an excess of the glandular hyperplasia present in the menstrual mucosa.

Eclampsia with Symmetrical Necrosis of Renal Cortex and Suppression of Urine.

Professor ROBERT JARDINE and Dr. A. M. KENNEDY (Glasgow) described three cases clinically suggesting eclampsia, in which similar pathological changes involved the kidneys. In the first a 9-gravida aged 34 had concealed accidental haemorrhage in the seventh month of pregnancy. There was absolute anuria for four and a half days. The patient was delivered three hours after admission and died four days later. There were no fits. The second patient was a 2-gravida aged 38, who was delivered of twins the day after admission. The urine, on admission, was loaded with albumen. There was anuria for two and a half days ending in death, preceded by one convulsion. The third patient was a 1-gravida aged 23, four and a half months pregnant, admitted comatose after several fits. The urine was loaded with albumen, and she died after one and a half to two days' suppression. Dr. Kennedy found in all these cases symmetrical necrosis of the kidney cortex, more or less limited to the outer two-thirds and varying in degree with the duration of the suppression. In the two older cases the necrosis was more or less uniform and was separated from the living inner third by a haemorrhagic zone. The cortical vessels were thrombosed in the necrotic zone only. In the earliest case the necrosis was in patches, which were surrounded by intense congestion. There was little thrombosis, and it was limited to the capillaries.

The questions arose, Was the thrombosis primary and the cell degeneration secondary, or was this latter change primary? or, finally, were both due to the same cause? Dr. Kennedy believed that the kidney necrosis was similar to the focal liver necrosis present in eclampsia, and that it was the primary factor. Professor Teacher had previously described two similar cases with Professor Jardine, and believed, on the other hand, that the condition was due to spasm of the smaller renal arteries. This explanation was based upon the presence of Raynaud's disease in the one instance, upon the symmetrical nature of the necrosis, and upon the thrombosis being frequently in the arteries just beyond the arterial arches. In the five cases, however, Raynaud's condition was present in one only, and the symmetrical necrosis was quite consistent with a general toxæmia. From this, and the starting of the thrombosis in the capillaries in the earliest case, the authors believed that the necrosis was primary. In the liver also it might be present without thrombosis. The authors, in conclusion, ascribed the necrotic change to the eclamptic toxin, whatever this might be.

LIVERPOOL MEDICAL INSTITUTION.

Thursday, February 14th, 1913.

Mr. R. W. MURRAY in the Chair.

The fifth pathological meeting of the session was devoted to the consideration of tuberculous disease.

Specimens.

The following specimens were shown and described:—
Mr. NEWBOLT and Dr. S. W. McLELLAN: (1) Tuberculous sac of hernia. (2) Tuberculous mastitis. Mr. ARMOUR and Dr. S. W. McLELLAN: Alveolar sarcoma of Billroth, tumour of the face. Mr. THELWALL THOMAS and Dr. REES: (1) Tuberculous breast. (2) Tuberculous synovitis. Mr. MONSARRAT: Tuberculous adenitis of the mesentery. Dr. NATHAN RAW: (1) Healed tuberculosis of apex, with thickened pleura. (2) Tuberculosis of the appendix. (3) Tuberculosis in a fish. (4) Pure cultures of human, bovine, and avian bacilli. (5) Suprarenal glands and kidneys showing tuberculous infection. (6) Uteri and Fallopian tubes with acute tuberculous disease. Mr. F. JEANS and Mr. THURSTAN HOLLAND: Large calcified tuberculous gland from omentum. Dr. STOPFORD TAYLOR and Dr. R. W. MACKENNA: Wax casts of tuberculous affections of the skin. Professor ERNEST GLYNN: Tuberculosis in a fish. Dr. BUSHBY showed a card specimen. Dr. BLAIR BELL: Tuberculous salpingitis (two cases). Dr. BARENDT, Mr. MONSARRAT, Mr. THURSTAN HOLLAND, and Professor ERNEST GLYNN discussed the specimens.

Pathology and Bacteriology of Tuberculosis.

Dr. NATHAN RAW, in a paper on this subject, discussed the variations in type of the tubercle bacillus and their cultural appearances. The methods of entry of the organism and the manner of extension were next described. Dr. Raw quoted the work of Dr. J. Fraser in support of his own view, that bone and joint tuberculous affections in children were due to the bovine bacillus. The effect of vaccination on the cow was mentioned; it had been shown that the animal might have large quantities of the tubercle bacillus in the milk for long afterwards. Mr. JEANS thought that the virulence of the bacilli varied in different districts. Dr. LOGAN discussed the frequency of tuberculosis in children and in people late in life. He thought the disease was frequently mistaken for chronic bronchitis in the old. Mr. ADAIR DIGHTON thought that infection of the tonsils and cervical glands was caused by infection from the sputum. Professor ERNEST GLYNN was surprised at Dr. Raw's opinion that acute miliary tuberculosis, tuberculosis of lymph glands (other than mesenteric), of bones and joints and of the meninges was usually caused by bacilli of bovine type. This opinion was diametrically opposed to the published observations of the Royal Commission and to the still larger number of observations by other investigators, collected by Park and Krumweide. Professor Ernest Glynn asked Dr. Raw to state the reasons and to detail the experiments which made him advance such an opinion. Dr. Raw placed all cases of pulmonary tuberculosis, with or without secondary enteritis and laryngitis, in a "human ward" for treatment with bovine tuberculin, and all other

cases in a "bovine ward" for treatment with human tuberculin. If the figures of the Royal Commission or Park and Krumweide were to be relied upon, by far the larger proportion of Dr. Raw's cases were in the wrong ward. Dr. MURRAY BIGH asked if Dr. Nathan Raw would state if he could distinguish the two kinds of bacilli microscopically. Dr. CRACE-CALVERT also spoke. In his reply, Dr. NATHAN RAW said he had arrived at his conclusions by clinical observation. But he said his experimental work had shown that the lesions specified in children were of the bovine type, and were caused through milk. In answer to Dr. Bigh, Dr. Raw stated that he knew of no certain means of distinguishing between the two organisms microscopically.

MANCHESTER MEDICAL SOCIETY.

Wednesdays, February 5th and 19th, 1913.

Dr. J. J. COX in the Chair.

Treatment of Syphilis by Neo-salvarsan with Wassermann Control.

Mr. SAVATARD said that since Mr. McDonagh's paper on "A Rational Method of Treating Syphilis" was read last July he had treated some 25 cases and given about 100 injections with excellent results. In 5 cases he had administered the drug intramuscularly, but all the patients had suffered pain afterwards. The remainder had all been treated intravenously. The greatest care had been taken in the preparation of the patient and of the apparatus. McDonagh's syringe was used. The neo-salvarsan was dissolved in freshly redistilled water (heated to 100° C. and then cooled to 25° C.). The dosage varied from 0.6 gram to 0.9 gram. All the cases thus treated had, apart from their syphilitic affection, been otherwise healthy. No bad symptoms had resulted and in no instance had there been any rise of temperature. The injections had been given in some cases weekly, in others fortnightly, and in others every three weeks. When a cure was aimed at, the injections were continued till the Wassermann reaction was negative both before and after the last injection. To produce this result in "secondary" cases at least seven injections had been found necessary. Mercury had been administered afterwards. The earlier the treatment the sooner was the cure effected. Among the "secondary" cases previously untreated were macular, papular, pustular and framboesiform syphilides. A case of syphilitic leucoderma in a man was also mentioned in which a single injection had effected a symptomatic cure. The "tertiary" cases shown had previously resisted prolonged treatment with mercury and potassium iodide, and among these were patients with extensive lesions of the buccal cavity and a malignant syphilide. The speaker commended the use of the provocative injection in cases of latent syphilis.

Dr. ARNOLD RENSRAW dealt with the pathological aspect of the question. The evolution of the Wassermann reaction was traced from the time when Pfeiffer demonstrated the phenomenon of bacteriolysis. Discussing the nature of the "antibodies" which cause a positive reaction, the speaker considered that they could not be true antibodies, similar, say, to those present in streptococcal infections, since, so far as he knew, no spirochaetes had been demonstrated as being ingested by leucocytes. Subsequently he had maintained that a positive Wassermann reaction was an expression of the amount of liberated endotoxin obtained by the destruction of spirochaetes and its subsequent action upon the cells. Whether that reaction was due to the actual disorganization of the cells, brought about in some special chemical manner (possibly a catalytic reaction) by the particular endotoxin set free by the dead spirochaetes, had yet to be determined. Dr. Renshaw then discussed McDonagh's review of the life-cycle of the organism of syphilis, and observed in conclusion that stomatitis cases usually gave a very strongly positive reaction; and, where a mouth lesion of any magnitude was present with only a slightly positive reaction, it should be suspected that the disease had had some other infective process—for example, tuberculosis—superadded, or that the condition had progressed to the stage of carcinoma.

X Rays in Pulmonary Tuberculosis.

In a memoir on the early diagnosis of pulmonary tuberculosis in young children, with especial reference to the value of x rays, Dr. LAPAGE drew attention to the

frequency of pulmonary tuberculosis in children, and to the evidence which showed that the disease was so often at the roots of the lungs. He described the conditions which gave most difficulty in diagnosis: (1) Active open disease at the roots; (2) active disease limited to the bronchial glands; (3) healed disease in the lungs, with some super-added condition, causing general symptoms resembling those of tuberculosis. Having noted the fact that with ordinary clinical methods it was often impossible to make a definite diagnosis, owing to the absence of physical signs, the value of the *x* rays in clinching a diagnosis based on suspicious symptoms only was demonstrated. The results of the examination of 150 cases, mostly chosen for suspicious clinical conditions, was given in tabular form. The table showed the relation between the clinical and the *x*-ray examination as made independently by clinician and radiographer. Dr. Lapage upheld the great value of the *x* rays in these early cases as a supplement to the clinical examination, and pointed out the importance of establishing the normal screen picture of the thorax.

Dr. W. J. S. BYTHELL first dealt with the nature of the evidence afforded by an *x*-ray examination, directing attention specially to the importance of thoroughly examining the appearance of the roots of the lungs. In his opinion the normal streaky markings visible in all lungs might be increased by bronchitis, and he regarded shadows due to enlargement of the bronchial glands or to pulmonary consolidation as the only reliable signs of tuberculous infection. As the result of the 300 or 400 examinations he had made he concluded that the majority of children living in large towns present evidences of this tuberculous infection after the age of 6 to 8 years. In most cases the glands were able to overcome the bacilli, but should they cease and break down the infection extended directly to the adjacent lung tissue and led to a tuberculous broncho-pneumonia, originating at the hilus of the lung. In any case, he was strongly of opinion that pulmonary tuberculosis in children commenced in the vast majority of cases, if not invariably, at the root of the lung. In the earliest stages of this root disease definite indication of the lesion might often be discovered by means of the rays when there were no physical signs to be detected.

GLASGOW OBSTETRICAL AND GYNAECOLOGICAL SOCIETY.

A MEETING of this society was held on January 29th, the President, Dr. LINDSAY, in the chair. The following specimens were exhibited:—Dr. BALFOUR MARSHALL: (1) *Intramural uterine fibroid*; (2) *Uterus with fibroids*, the tumours had burrowed into both broad ligaments; (3) *Fibroid from left broad ligament*; (4) *Ovarian cystoma*; (5) *Fibroid with double salpingo-oöphoritis*; (6) *Bilateral salpingo-oöphoritis*; (7) *Parovarian cyst with torsion of pedicle*. Dr. MUNRO KERR: (1) *Specimen of Extrauterine pregnancy*, showing process of tubal abortion; (2) *Bilateral malignant ovarian tumour*; (3) *Adenocarcinoma of uterus*. Dr. A. W. RUSSELL: (1) *Multilocular ovarian cyst of left ovary*—the right ovary had been removed for a similar condition eight months previously; (2) *Oedematous fibroma of ovary*—the tumour had been present two years without pain. Dr. W. D. MACFARLANE: (1) *Melanotic carcinoma of vulva*—excision of growth and glands had been carried out; (2) *Double ovarian dermoids* (Dr. Ritchie's case); (3) *Multiple fibroids in pregnant uterus*. Dr. SHANNON: (1) *Ovarian cyst*; (2) *Cancer of right ovary*, with peritonitis. Dr. McILROY: *A Bilobed placenta* with velamentous attachment of cord and area of infarction. Dr. BALFOUR MARSHALL recorded a case of *Maldevelopment* showing a dystopic (pelvic) left kidney, absence of vagina, and presence of Müller's ducts, the right in part represented by a cornuate small uterus. Both ovaries and a right Fallopian tube were present. The menstrual molimen had not been experienced, and the patient sought medical advice on account of amenorrhoea and a swelling in the pelvis. The tumour, exposed by incision, lay in the left side of the pelvis; the left iliac artery passed above the upper pole of the kidney and the pelvic colon covered it; the rectum lay close to the inner border. Large renal vessels were seen passing under the sigmoid mesocolon. The kidney was immovable, and covered by vascular

peritoneum. The ureter was short. The ovaries lay along the edge of the *psaos* muscle, half an inch from the deep abdominal ring. The genito-inguinal ligament was seen passing from the anterior pole of the left ovary into the inguinal canal. A crescentic band ran across the pelvis evidently representing Müller's duct, and on the right side a thickened, spindle-shaped swelling $1\frac{1}{2}$ in. long was present; it was a rudimentary uterine horn. The right Fallopian tube bore its fimbriated extremity, which projected normally into the peritoneal cavity. A well-marked *fimbria ovarica* was present. Dr. Marshall then read a paper on *Artificial vagina*, and reviewed various operative procedures for correcting atresia vaginae without subsequent contraction. In some cases the uterus was present; thus the atresia was not necessarily developmental, being not rarely due to inflammatory processes in early infancy; and atresia in adults sometimes followed traumatism at childbirth. In others there was true congenital atresia with absence of the uterus. Pregnancy might follow the formation of an artificial vagina. Operators differed as to the justifiability of operations undertaken to give a coitional vagina when the uterus was absent. Simple splitting of the recto-vesical septum was so fatal that several leading French surgeons in the last century advised against its performance. Plastic operations dated from Heppner, 1872, (a) transplanting of skin flaps or epithelial growths; (b) transplantation of vaginal flaps taken from cases operated on for prolapse; (c) implantation of pieces of peritoneum; (d) implanting bowel mucosa. Martin advocated suture of uterine cervix to vulvar orifice after opening of the septum. In the combined abdomino-vaginal operation of Pfannenstiel the cervix was freed by laparotomy after partly opening of the recto-vesical septum from below. The abdomen was then closed, and the cervix pulled down and attached to the vulvar orifice or mucosa of vaginal rudiment. More recently an artificial vagina had been made out of a segment of resected bowel. Suequireff first recorded in 1904 three cases operated on by his method of transplanting the rectum. The method is objectionable because a sacral anus is left. Baldwin transplanted a segment of ileum. Twelve cases of this method have been reported, and four of Mori's, which differs from Baldwin's in that a single stretch of bowel is implanted instead of a double loop. Dr. MUNRO KERR, in discussion, spoke of a case of atresia where he had operated after Baldwin's method. Dr. ALEX. MACLENNAN read a paper on a method of *Radical removal of the carcinomatous uterus*. Preliminary enurettage was done three days before the main operation, when the bifurcation of the iliac artery was identified, the peritoneum in that region incised, and the ovarian and anterior divisions of the internal iliac arteries tied. The ureter was traced into the pelvis, and if it passed into diseased tissue was divided and implanted into the bladder. The peritoneum was incised parallel with the ureter and across the front of the uterus to the opposite side. Then the broad ligaments were separated, and the lateral aspect of the pelvis cleared. The peritoneum behind the broad ligaments was stripped from Douglas's pouch, and the pelvic contents were detached by a digging process and pressed downwards. The uterus was then separated from the bladder and vagina, and the whole mass packed into the pelvis. The loose peritoneum and sigmoid were stitched so as to shut off the peritoneal cavity. The patient was then placed in the lithotomy position and the parts removed from below. The cavity was packed with gauze, which was afterwards gradually removed. The paper was discussed by Dr. BALFOUR MARSHALL and Mr. DUFF.

In commenting on February 15th on the *Pharmacopoeia* prepared for the use of medical men belonging to the Leicester Public Medical Service, we observed that as the prescriptions were excellent and the compounds inexpensive, it would not be surprising to find the volume adopted in other districts as well as in that for which it was produced. As will be seen by an announcement in our advertisement columns, the book, which is of convenient size for the pocket, has been placed on sale, and specimens can be obtained, price 1s., from the Leicester Public Medical Service, East Bond Street, Leicester. Special terms will be made for quantities, and a special title-page and lettering on the cover will be arranged for orders of 50 and upwards.

Rebuelus.

GLYCOSURIA AND ALLIED CONDITIONS.

DR. CAMMIDGE is well known for his contributions to the chemistry of the urine, and his book on *Glycosuria and Allied Conditions*¹ is based upon the material submitted to him during the last fourteen or fifteen years. He approaches the subject from the chemical side, and, indeed, claims that it is "essentially a chemical problem." If we hesitate to accept this statement, it is not because we deny the importance of the chemical side of the problem, but because the physiological questions involved are at least as essential, while both chemistry and physiology are only aids to the solution of an obscure clinical problem. If the disease were better understood and its relations to chemistry and physiology definitely settled, a modicum of either would suffice, but, as the surroundings are dark, we grope for light in every direction and accept each scrap of chemical or physiological information in the hope that it may prove of use. The writer on diabetes is obliged to bear this burden, although much of it will doubtless prove to be irrelevant, but at the present time he cannot tell what part may be safely discarded or in what direction to look for the true light.

Out of the 400 and odd pages of which this book is composed, considerably more than half is devoted to the description of the chemistry and physiology of glycosuria. The author finds fault with clinicians for not studying the other carbohydrates which are at times present in the urine, and for using the term "glycosuria" to include all carbohydrates. The answer to the first charge is that these conditions are so rare that the opportunity is wanting. One who has been engaged, like the author of this book, in examining urines containing unusual carbohydrates sent to him from all parts of the country, may get the false impression that these cases are less rare than they really are, even in the practice of hospital and consulting physicians who give special attention to diabetes. The second charge can hardly be true, for no one knowingly speaks of pentosuria as glycosuria, although it is quite possible that any one who was not on the look-out for its occurrence might miss it. As to laevulosuria it is doubtful whether laevulose occurs in the urine by itself, although it is not uncommon in association with dextrose, and any physician who is sufficiently familiar with the problem to be able to detect this would not be likely to fall into the error of terminology involved by speaking of it as glycosuria. As a routine qualitative test for sugar the author prefers Benedict's modification of Fehling's solution, and gives a formula for its preparation.

The first three chapters are devoted to the chemistry of sugars and other reducing substances and of the acetone bodies; the fourth chapter to experimental glycosuria; the fifth to alimentary, transitory, and intermittent glycosurias. It is quite probable that temporary or intermittent glycosuria is due to inhibition of the glycogen-forming function of the liver, and it may be in this way that a dose of alcohol causes glycosuria in persons who are not actually diabetic. We doubt whether the opinions of Loeb on hereditary diabetes are well founded, especially when he asserts that the hereditary form is seldom met with in youth, nor do we believe that it can be usefully differentiated as a separate form of the disease.

In Chapters VI, VII, VIII, and IX the author deals with persistent glycosuria or diabetes, and describes its symptoms, diagnosis, pathology, and treatment. He states clearly and concisely the various and conflicting theories that are now current, and inclines to the view which von Noorden has of late adopted. It would be unfair to expect Dr. Cammidge to do more than this, and we recognize fully the ability with which he has placed before his readers a faithful exposition of the various problems as they appear at the time of writing; the numerous additions made to this literature render the picture as shifting as that of a kaleidoscope, and the more carefully a writer follows the most recent investigations the more likely he is to find that his picture needs constant alteration. Chapter IX deals with the dietetic treatment of diabetes,

and contains tables which are carefully worked out so as to show the weight of each particular article of food and its contents in protein, fat, carbohydrates, and caloric value. Why margarine takes the place of butter is not explained in the text; if it is because margarine is less likely to form oxybutyric acid, this rather theoretical objection should not be allowed to deprive diabetics of this article of diet where there is no evidence of acidosis.

In connexion with the diagnosis of pancreatic diabetes, the author refers to his "pancreatic reaction," and gives a modification of his original plan, which he recommends as preferable to that he originally described. It has the further advantage of being quantitative, but for his description the reader must be referred to the work itself. He mentions adrenalectomy as a means of recognizing an affection of the pancreas, but quotes no personal experience to add to that of those who appear to have found it a more or less reliable test.

In the description of von Noorden's oatmeal cure he conveys the impression that von Noorden would keep a patient upon this diet for several weeks with only intervening days of green vegetables. Von Noorden's own practice as described in his most recent book is that after a course of one or two days of vegetarian diet or a single day's fast, he gives two days of oatmeal diet, then one or two days of vegetarian diet, after which the patient returns for some days to a mixed restricted diet suitable to his case, and this alternation may be repeated as often as seems desirable. On page 304 Dr. Cammidge makes the statement that "more than a hundred years ago Prout pointed out the great advantage of limiting the quantity of food in diabetes"; but Prout only took his degree in 1811, and the first mention of the desirability of limiting the quantity of food is in the second edition of his book published in 1825. On page 320 he refers to the danger of diabetic patients being allowed to take an unlimited quantity of saccharine; as no serious ill effects from the ordinary use of this substance have been observed in the thirty years during which it has been widely in use the warning is hardly needed. A more serious mistake is the recommendation to push codeine. We have seen the opium habit developed in not a few cases of diabetes by the unwise pushing of opiates without the smallest benefit to the disease and to the incurable ruin of the patient. When a case of diabetes comes under treatment it may be proper to prescribe a nightly dose of opium for a few nights; but when the glycosuria has been controlled it is better to stop it, as it increases constipation and checks secretion without causing further reduction of sugar excretion. In the doses which Dr. Pavy recommended codeine it is only a placebo, while in larger doses it is an expensive substitute for morphine.

THE MAYBRICK CASE.

THE most recent addition to the series of "Notable English Trials" comes from the versatile pen of Mr. H. B. IRVING, author and actor too. It deals with the ever-green story of the *Trial of Mrs. Maybrick*² at Liverpool in 1889 for the murder of her husband by arsenical poisoning. In his introduction Mr. Irving gives a masterly summing-up of the case and the events subsequent; next follows a table of important dates in the history of the case, a list of counsel, all of whom attained eminence in their profession; then we have a full and detailed report of the speeches, evidence, and summing-up, which occupied together seven days, after which the jury, having deliberated some thirty-five minutes, returned a verdict of "Guilty," and Mr. Justice Stephen, without comment, sentenced the prisoner to death. The verdict was received by the public at large with considerable astonishment. The *Times* of the following day wrote: "It is useless to disguise the fact that the public are not thoroughly convinced of the prisoner's guilt. It has been noticed by them that the doctors differed beyond all hope of agreement as to the cause of death." Petitions for reprieve poured into the Home Office from all parts of the country, the signatures

¹ *Glycosuria and Allied Conditions*. By P. J. Cammidge, M.D. London: Edward Arnold. 1913. (Med. 8vo, pp. 470. 16s. net.)

² *Trial of Mrs. Maybrick*. Edited by H. B. Irving, M.A. Oxon., author of *The Life of Judge Jeffreys*, *French Criminals of the Nineteenth Century*, etc. Edinburgh and London: William Hodge and Company. 1913. (Demy 8vo, pp. 410, with 5 illustrations. 5s.)

amounting to nearly half a million, including a petition from the medical men of Liverpool, where the trial had been held. These gentlemen based their protest on the ground that the symptoms of arsenical poisoning during life and after death were insufficient, that only the discovery of arsenic in the viscera suggested such a cause of death, and that the quantity of arsenic found in the viscera was less than in any previous case. The *Lancet* published a long article, highly unfavourable to Mrs. Maybrick. The *BRITISH MEDICAL JOURNAL* was hardly less unfavourable; it published letters from seven professors of medical jurisprudence in different parts of the country; of these, four supported and three dissented from the verdict. The gallows had already been erected in Walton Jail, within hearing of Mrs. Maybrick, when on August 22nd the Home Secretary's decision was announced and the punishment commuted to penal servitude for life, "inasmuch as, although the evidence leads clearly to the conclusion that the prisoner administered and attempted to administer arsenic to her husband with intent to murder, yet it does not wholly exclude a reasonable doubt whether his death was *in fact* caused by the administration of arsenic."

Mrs. Maybrick, having served fifteen years' imprisonment, was released in January, 1904, and left England. The vital question of this trial was whether or no arsenic was the cause of death. A number of competent medical authorities who gave evidence all agreed that the cause of death was gastro-enteritis. Those called for the prosecution declared that the symptoms definitely indicated arsenic as the irritant poison which had set up gastro-enteritis; the witnesses for the defence were equally confident that the inflammation of the stomach might have been caused by sausages, cheese, lobster, or some irritant substance other than arsenic. The learned judge in his summing-up of the evidence on this point told the jury:

These parts may be passed over as really more fit for medical jurisprudence than for a jury actually engaged upon the administration of criminal law; you probably are men engaged in different ranks of life, and I should think it probable that a very small number of you have any other knowledge of medicine than that which we all pick up in the course of our lives and in the course of our general experience. This would be a kind of guide, and you must infallibly rely upon it to a greater or less extent.

The jury, advised to rely infallibly upon the knowledge they "had picked up in the course of their general experience" of the causes of gastro-enteritis and the symptoms of arsenical poisoning, was composed of three plumbers, one painter, two farmers, a wood-turner, a provision dealer, a grocer, a baker, an ironmonger, and a milliner. The judge, in expressing great diffidence in his own powers of digestion of the medical evidence, added:

I would not for the world say anything disrespectful of a science to which we all owe so very much; but it is a science based more or less upon conjecture, and good sense and good fortune in making guesses. A celebrated physician in olden times said that he spent his time in putting drugs of which he knows little into a body of which he knows less. This is one of those pointed sayings which are convenient, but there is a degree of truth at the bottom of it. Persons who are employed for the time being in the tremendous functions confided to us ought to be very modest in their conclusions. That modesty cuts, on an occasion like this, all ways. It cuts to a certain extent against the prosecution, and it cuts against the defence, and it diminishes and lowers the degree of assurance with which we receive medical evidence of all kinds.

It was unfortunate that the court should have displayed so much modesty about the only essential issue of the trial, for unless the jury were satisfied beyond a doubt that the cause of death was arsenical poisoning the charge of murder must absolutely fail.

But other features of the case indicating motive and opportunity for the commission of the crime were handled with less modesty. Maybrick, 24 years older than his wife, was at 50 years of age a confirmed hypochondriac with an unhealthy appetite for drugs, chiefly of a stimulating nature. On May 8th Mrs. Maybrick wrote a fatal letter to a man, Brierley, with whom she had relations. Mr. Irving gives a facsimile of this letter, which was intercepted by a servant; it contained this passage:

Since my return I have been nursing M. day and night. *He is sick unto death.* The doctors held a consultation yesterday, and now all depends upon how long his strength will hold out. But, my darling, relieve your mind from all fear of discovery now or in the future. He has been delirious since Sunday.

The learned judge said, "Now that was not true, as she knew, having been with him all the time, and so far from being sick unto death, for some days after that the doctor expected a favourable result." On May 9th a nurse swore that she saw Mrs. Maybrick dealing surreptitiously with a bottle of meat-juice which was afterwards found to contain arsenic. On May 11th Maybrick died; two days later the *post-mortem* examination was made, and traces of arsenic were found in his viscera.

The house was searched at the time of the death and there was found in various bottles and other articles, including a handkerchief and the pocket of a dressing gown belonging to Mrs. Maybrick, sufficient arsenic to poison many people, assuming 2 grains to be a fatal dose. We have not space to give the evidence in fuller detail. Sir Charles Russell, afterwards Lord Chief Justice of England, who defended Mrs. Maybrick, spared no pains during the rest of his life in repeated efforts to secure her release, declaring that though the means of poisoning her husband were undoubtedly within reach of Mrs. Maybrick, there was no direct evidence of her having administered arsenic to him, that the symptoms were agreed by all to be those of gastro-enteritis, but that while some witnesses attributed the disease to arsenical poisoning, there was a strong body of evidence to the contrary. And at this we must leave a case of deep interest, with a recommendation to read Mr. Irving's excellent work, one of the most interesting features of which is a letter, which we never remember to have seen before, written to her mother by Mrs. Maybrick on June 23th, whilst in prison awaiting her trial:

I sincerely hope my solicitors will arrange for my trial to take place in London. This, of course, could be arranged upon the application of the prisoner for a writ of *certiorari*. I shall receive an impartial verdict there, which I cannot expect from a jury in Liverpool, whose minds have come to a moral conviction *en attendant*, which must influence their decision to a certain extent. The tittle-tattle of servants, the public, friends and enemies, and from a thousand by-currents, besides their personal feeling for Jim, must leave their traces and prejudice their minds no matter what the defence is.

Her advisers, however, decided it was the stronger and wiser course to face a trial in Liverpool.

To the many theories that have been advanced with regard to the Maybrick case may the writer of these notes add one of his own—namely, that if the prisoner had had her own way and gone for trial to London she would have enjoyed a far better chance? This view is confirmed by some conclusions embodied in a document drafted on her behalf in 1892: (1) That the judge in summing-up placed himself in a position where his mind was open to the influence of public discussion and prejudice, to which was probably attributable the evident change in his attitude between the first and second days; and he also assumed facts against the prisoner which were not proved; (2) that the jury were allowed to separate and frequent places of public resort and entertainment during such day. This latter was, of course, grossly improper, and could not have happened in London. But there was no Court of Criminal Appeal in those days; neither was the witness-box open to the accused as to-day. According to the verdict of the Lancashire jury of 1889, Mrs. Maybrick is fortunate in having lived so long. According to the commentator of to-day, she is unfortunate in having lived too soon. That is to say, before the creation of the Court of Criminal Appeal.

CLINICAL DIAGNOSIS.

Clinical Diagnosis by Dr. J. C. TODD, is a laboratory manual which can be thoroughly recommended. It keeps pretty well to the conventional lines, but it is a distinct improvement on many of its predecessors of similar scope, not only in its illustrations, which for the most part are excellent, and its up-to-dateness, but also in its general

² *Clinical Diagnosis: A Manual of Laboratory Methods*. By James Campbell Todd, Ph.B., M.D. Second edition. Philadelphia and London: W. B. Saunders Company, 1912. (4p. 469; with 12 coloured plates. 10s. 6d. net.)

lucid method of treatment. It deals with all the examinations which the clinician may have to undertake in the course of his work, and it includes special chapters on animal parasites, vaccines, and bacteriological methods. The book is of convenient size, and it is printed in a manner which invites perusal and ensures ease of reference.

The little book on *Systematic Case-taking*,⁴ by Dr. H. L. McKisack of Belfast, adds another to the rather numerous list of similar manuals. As it makes no pretensions to be comprehensive, there may be good reason for omissions and for the summary fashion in which certain subjects are discussed, since it is intended as a guide to students in case-taking, and elaborate discussion of methods of diagnosis which practitioners would demand do not come within its scope. The book has the merits of being well written, and of describing clearly that which the author desires to lay before his readers, but it continues the terminology of the physical signs in the chest which has confused many generations of students. Thus, on p. 49 the tympanic note is said to be of a drum-like character, and on the next page emphysema is described as giving rise to a form of resonance which is also "drum-like." The descriptions of vocal resonance and pectoriloquy are not quite clear. Unless these sounds are defined and the student is referred to something with which he can always refresh his ear there is danger that he will never really know what is meant by the terms; where words used are not English it would be well to explain them, otherwise students may continue to use words all their lives which they do not understand. In the section on the sputum the usual classification of the naked-eye appearances might have been given. In describing inflation of the stomach, the quantities of tartaric acid and sodium bicarbonate to be used should surely be stated, and in saying that splashing sounds are evidence of dilatation of the stomach the author should point out what means there are, if any, of distinguishing between splashing sounds produced in the stomach from those produced in the adjacent bowel. The radiography of the stomach is too important to be dismissed in less than two lines, while in the description of Ewald's test breakfast "a couple of slices of bread with one or two cupfuls of tea" is not an adequate statement, and is likely to lead to inaccurate results. Further, when the test for lactic acid is spoken of it should be stated that this acid may be present in bread, and that for this test the meal should consist of gruel. Should not the student be taught to look for traces of blood in the faeces by chemical examination, and, on the other hand, to look for blood in the urine with the microscope and not by chemical tests? The taking of alcohol might have been mentioned as one of the causes of the temporary appearance of sugar in the urine. The modification of Dorennus's urometer is by Heintz, not by "Hind." The volume concludes with a table for the differentiation of painful throat affections and brief descriptions of methods of staining micro-organisms, of Widal's and Wassermann's reactions, of the estimation of free hydrochloric acid and total acidity of stomach contents, of the mode of employing the diazo reaction and Russo's methylene blue reaction, a very short and hardly adequate account of electrical examination occupying little more than a page. There are tables of states of unconsciousness, of the various forms of paralysis, and of the clinical tests for tuberculosis. It will be seen, therefore, that it is a comprehensive manual for students.

ELECTRO-THERAPEUTICS AND RADIOLOGY.

DR. MARTIN'S work on *Practical Electro-therapeutics and X-ray Therapy*⁵ differs little in intention and arrangement from a number of others issued on both sides of the Atlantic during recent years. It is, however, an interesting compendium from an American pen, and is not too heavily freighted with snippets from other people's

observations. The well-illustrated section on the x-ray in fractures, dislocations, and bone diseases should be of considerable value as a means of reference. There is also a chapter on forensic radiography, and here the author tells a story from his experience. He was called as an x-ray expert in a suit for damage, when the learned counsel, having gathered apparently from an examination of cameras that lenses have a wide range, launched the abrupt and it settles the question imperative, "Now tell the court with what kind of lens you made these pictures!" And this happened "only a short time ago."

Any one who sets out, at the present day, to write a textbook of x-ray diagnosis and treatment, undertakes a very formidable task. Bones and joints alone would fill a full-sized textbook, and the same is true of diseases of the chest, and equally true of alimentary disorders. Large books have been written on genito-urinary radiography, and still larger books on x-ray therapeutics. X-ray apparatus and technique offer material for an entire book. Messrs. BYNELL and BARCLAY'S book⁶ deals with all these topics in a space of 140 pages. The authors state specifically that their book is not intended to be a complete textbook of the subject, but rather a general outline, their object being to enable medical men to learn enough about the subject to render them capable of selecting from their patients such cases as are suitable for x-ray diagnosis or treatment. The authors point out that most books on radiography are written for the x-ray specialist, and contain much technical detail that is of no interest to the medical practitioner. In the present book such details are placed in a short introductory chapter and a short appendix. In each chapter a selection of subjects has been made for discussion, and a further selection for illustration. Naturally many subjects appear to have received too scant notice, but the text, as far as it goes, is full of practical common sense, and the authors have done wisely in confining their descriptions to conditions they have actually seen. The illustrations, also, are taken from their own cases, and are excellently reproduced in the form of full-page plates on art paper.

At this late day in electro-therapeutics it seems scarcely possible for a practical summary of the whole subject, including x-rays and heat and light radiations, to be brought within the limits of rather less than 70,000 words. Yet a concise pen on the other side of the Channel has accomplished as much, and in Dr. G. GEIGER'S compendium of medical electricity⁷ the ordinary worker who follows French will find, if not all that he requires to know, at least a useful guide for workroom and hospital reference. A novel feature which we do not remember to have seen attempted in the many similar works coming from the British and American press in recent years is a table of radiographic exposures, calculated for twenty or thirty different parts of the body under the various conditions of instrumentation. The length of exposure depends upon so many factors that it must have been difficult to present it in tabular form, and, having done so, the advantage remains a little questionable. At the end of the book indications are given for the x-ray and other treatment of a number of conditions, which are arranged alphabetically, but it is one of several drawbacks of the kind in a foreign manual that the x-ray quantities are expressed in units which are not very familiar to the British radiologist.

NOTES ON BOOKS.

WHEN Cowper wrote his well known lines in praise of "the cups that cheer but not inebriate," he had probably little or no knowledge of the complicated process by means of which his favourite beverage had been brought from its home in an Eastern tea-garden to his fireside at Olney. Even at the present day there are doubtless many tea

drinkers who are in much the same plight, and to them, as well as to the children for whom it is primarily intended, Miss EDITH A. BROWNE'S attractive little book on *Tea* (which forms the third volume of the excellent "Peeps at Industries" series),⁸ should prove a source both of interest and instruction. Miss Browne is well fitted to play the part of guide to her readers in their tour through the tea-producing countries of the world. Her book, she tells us, is "the result of experience, observation, information, and pictures harvested on the spot"; and whilst her mastery of the subject shows itself in almost every page, she never allows her knowledge to become unduly obtrusive. The history of tea, that "sober, sage, and venerable liquid," from the plantation to the tea table, is told in simple yet graphic language; and the author has contrived to invest the most prosaic details of the tea trade with something of the glamour of the East. The book is rendered doubly interesting by the many excellent photographs which serve as illustrations to the text.

A directory that contains full particulars of the members of any given profession must always be a useful addition to the library of a member of that profession; but nowhere is the need for such a book of reference felt more keenly than in the educational world. Hitherto the *Schoolmasters' Yearbook* has provided all necessary information with regard to the male members of the teaching profession; and now the repeated applications of women teachers to be included in the *Yearbook* have resulted in the compilation of a companion volume called *The Directory of Women Teachers*.⁹ This directory has been arranged on the same lines as the *Yearbook*, and contains, in addition to the names, addresses, and short biographies of women engaged in the higher and in secondary education, a list of the secondary schools, training colleges, universities, and other kinds of educational establishments for girls in every part of the kingdom, together with a quantity of miscellaneous information likely to be of use to those engaged in tuition. The arrangement of this unwieldy mass of material leaves nothing to be desired; each entry is clear and concise, and great care has been taken to avoid overlapping or repetition. The annual publication of a similar volume should be of the greatest service, not only to the teachers themselves, but to parents who are in need of advice and guidance as to where and how to bring up their daughters.

In a paper on alcoholism and degeneracy¹⁰ contributed to the first International Eugenics Congress MM. MAGNAN and FILLASSIER have collected some interesting statistics dealing with the experience of the City of Paris and the Department of the Seine in respect of insane persons admitted to asylums. The figures illustrate the frequent association of alcoholism with stigmata of degeneracy, and the authors direct attention to the burden on society which this large army of incompetents represents. From 1887 to 1911 there were 89,728 admissions: of these, 27,315 were alcoholics. Naturally figures of this sort do not throw much light upon the questions as to whether alcohol is a *vera causa* of insanity or whether alcoholism is merely a stigma of degeneracy, but they are additional evidence of the magnitude of a problem which has yet to be faced in its entirety by statesmen of all countries.

We have received a copy of the *Minutes of the General Medical Council and of its Various Committees for the Year 1912*,¹¹ being the forty-ninth volume of the series. Rather less than one-half of the volume, which contains 461 pages, is occupied by the minutes of the Council itself: the rest contains the minutes of the Executive Committee and of the Branch Councils, and twelve reports of committees to which matters were referred by the Council. The *General Index to the General Medical Council*,¹² vols. xl to xlix, which has also been received, contains 153 octavo pages. The issue annually of a revised edition of an index to the minutes of the Council greatly facilitates reference to matters dealt with by that body in previous years.

MEDICAL AND SURGICAL APPLIANCES.

A Simple Ether Can.

DR. W. J. MCCARDIE (Birmingham) writes: The free use of ether by the open method and the fear of the result of breakage of a glass bottle have caused me to have made a simple metal can of large capacity (11 oz.). It is made of thin metal, which quickly takes up heat from the

hand, is inexpensive and unbreakable. It has no neck, and therefore there is no waste of neck space, which is a drawback to glass bottles. The nozzle is simple in form and covered with two screw caps. Being ether-tight the can may be carried in any position in the surgeon's bag. Any form of dropper can be easily fitted. The can has been made for me by Messrs. Mayer and Meltzer.

THE MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.

The quarterly meeting of the Association was held at the Darent Industrial Colony, Dartford, on February 20th, under the presidency of Dr. J. G. SOUTAR.

Mental Deficients.

During the morning members inspected the various centres of activity in the Colony, including the female and male workshops and wards for adult imbeciles, for the feeble-minded section, and for imbeciles under 16 years of age—three separate classifications of cases. At the luncheon which followed, the PRESIDENT thanked, on behalf of the Association, Mr. Helby, the Chairman of the Council Committee, and Dr. Rotherham, Medical Superintendent, for the interesting evidences of good training so abundant in the institution, and surprising even to those who knew something of such work. He thought that if members of the Cabinet, and others in the House, could visit the institution, the Mental Deficiency Bill would rapidly be passed through all its stages, since it would be realized that it would confer upon thousands of neglected persons the boon received by the inmates of Darent Colony. Dr. ROTHERHAM, in a brief reply to the President's remarks, praised highly the capacity and efforts of the instructional staff, who were all skilled in their work before they took up the posts. Mr. HELBY said that the success of the institution was due to the continuous and harmonious efforts of the medical and instruction staff, and quoted the following passage from the last report of the Commissioners in Lunacy, issued a few weeks ago:

We cannot conclude without expressing our pleasure and satisfaction with all we saw and learnt during our visit of inspection, and we desire to record our impression that the work of the institution is being carried out on well-planned lines, and with much skill and thoughtfulness in organization, and that the object in view, namely, the adequate training and occupation of the imbecile class, is being attained in a most satisfactory and gratifying manner.

Criminal Lunatics.

The meeting passed the following resolution on the subject of the detention of criminal lunatics in county and borough asylums, and appointed a deputation on the subject:

That the Parliamentary Committee consider it is most undesirable that criminal lunatics be sent to county and borough asylums, and recommend to the Council that the Association be asked to express this opinion to the Home Secretary.

Assistant Medical Officers in Asylums.

Dr. J. BEVERIDGE SPENCE, in a paper on this subject, referred to the recent discussion in the BRITISH MEDICAL JOURNAL, and said that he had been for some time of the opinion that something should be done to improve the position of these officers; he had been in full accord with the work of a committee of the Medico-Psychological Association, which had issued an interim report, advocating a more advanced education for applicants for these posts. On the question of the facilities to continue the study of

psychological science at some centre—leave being granted for that purpose—the money factor had to be considered. It would, perhaps, be really necessary to increase the rate of remuneration in order to attract to the speciality the right kind of man, especially now that in other branches of the profession young men were advertised for at salaries of £400 and £500, with greater individual liberties than those known to assistant medical officers of asylums. In order to collect information on the subject he had sent out forms to the superintendents of 94 asylums, and he gratefully acknowledged the courteous response of 92 of those gentlemen. Of these 17 asylums had only one assistant medical officer. The average minimum salary of the senior assistant medical officer was £224, and the average maximum £309, exclusive of emoluments: the lowest was £150 rising to £200, and the highest £330 with a maximum of £430. The salaries of medical officers junior to the first seemed to vary from an average minimum of £160 to an average maximum of £208, the highest being £185 rising to £330, and the lowest £130 rising to £150. The emoluments he found difficult to tabulate. In nearly every instance the medical superintendents approved of their senior assistant being married. Only eight regarded the idea unfavourably, while a few thought permission might be granted if accommodation were provided. There seemed, however, to be a feeling against this permission being granted to the second assistant. There were now married assistant medical officers in twenty-three asylums, while in sixty-three institutions these officers were not married. Dr. Spence then proceeded to consider the question of accommodation for married assistant medical officers under three heads: (1) Those who had rooms in the asylum main building; (2) those occupying a house on the asylum estate; (3) those who rented a house outside the asylum grounds. He made a comparison of the conditions and salaries of assistant medical officers of asylums with those of somewhat similar officers in prisons, to the advantage of the latter. He counselled the association to continue its efforts to better the lot of the former, and said that personally he was in favour of an advance in the average salaries of assistant medical officers of asylums.

Industrial Training at Darenth.

Dr. F. O. SPENSLEY, Senior Assistant Medical Officer (Darenth), said that forty years ago, at Hampstead Asylum, under the Metropolitan Asylums Board, an attempt was made to give the patients under 16 years of age some instruction in music, singing, and simple work in schools. So successful was this that the Board suggested the building of a schoolroom and shoemakers' and tailors' shops. In 1874 the Board purchased a site for the separate treatment of imbecile children; meantime it used the London Orphan Asylum at Clapton for the purpose, and Dr. Fletcher Beach was its first medical superintendent. In 1876 Darenth Training School was built. In the first year the patients' labour realized £66 5s. 7d. In order that the training might not be thrown away, it was decided to build, adjacent to the schools, two blocks for 120 males and 120 females, adults, the Local Government Board insisting, however, on the elimination of the hopelessly "incurable," a term which the subcommittee altered to "unimprovable." Subsequently these two wards grew into the adult asylum, with 1,052 beds. The author traced the growth of the institution to its present dimensions and many-sided activity, including mat-making, brush-making by wire-drawing, pan work, envelope and paper bag making, tin-smith work, carpentry, book-binding, and printing. Patients of both sexes were drilled, to the obvious improvement of their physique and deportment; 835 out of the total of 1,064 adult imbeciles were now undergoing industrial training. At present a wide and clearly-marked line was drawn between the inhabitants of the pavilions and those of the remainder of the institution. They were admitted classified as feeble-minded, and were to be kept quite apart from the certified patients. It would, he submitted, be difficult to find a better illustration of the impossibility of determining an arbitrary line of demarcation between an imbecile and a feeble-minded person. Among the so-called feeble-minded in the institution were many patients whose mental state was far below that of many of the certified imbeciles. He

sketched a different classification, and described the methods pursued to encourage each patient to do his best, and therefore improve as far as possible. Last year the industries realized £12,367, an increase of £8,000 in five years.

Dr. SHUTTLEWORTH, in discussing the paper, alluded to the transfer from Darenth to Rochester House, Ealing, of "improvable" cases in 1900 to 1904 for the purposes of industrial training. He agreed that there was very little difference between the high-grade imbecile and the ordinary feeble-minded person.

The discussion was continued by Drs. POWELL, LANGDON-DOWN, CORNER, and FLETCHER BEACH (the first superintendent of the institution), and Dr. SPENSLEY replied.

ONE HUNDRED YEARS AGO.

THE KNOWLEDGE OF TROPICAL DISEASES IN 1813.

THE first quarterly part of the *Edinburgh Medical and Surgical Journal* for 1813 would nowadays probably be described as a "tropical diseases number"; for out of twelve original communications which it contained five were written by medical men abroad, and dealt with maladies met with in India and the Leeward Islands. It may not be uninteresting—it may even be profitable—to spend a few minutes in the consideration of what was known about these diseases a hundred years ago as revealed in the accredited medical journals of the time.

The first article was by Mr. George Playfair, who is described as Assistant-Surgeon, Bengal; its subject was the good effect of treatment by a combination of ipecacuan and laudanum in dysentery; and it came in the form of a letter from Calcutta, bearing the date April 11th, 1812. The first paragraph is more of the nature of a covering letter, and would hardly be printed as part of the paper by the editor of to-day. Here it is:

Should the following trivial remarks, on a very simple method of curing dysentery, have anything new, interesting, or useful, you may make what use of them you please; and should you consider them of any importance, you may give the result publicly through the medium of your journal.

This mode of commencement is not unfamiliar to the editors of to-day, whatever it may have been in 1813.

Mr. Playfair deserves praise for the prompt and brief manner in which he states the chief conclusion of his article; it is that ipecacuan given in doses from 30 to 60 grains, with an equal proportion of laudanum acts well in cases of dysentery. Further, he is to be commended for the frank way in which he disclaims all originality: "I recollected to have seen in, I think, a Medical Review, that ipecacuan and opium had been tried in large doses with effect." He tells how he tried the plan of combining the two drugs in one large dose when he was surgeon of an Indian in the years 1803-4, and was losing a number of his dysentery patients; after giving the ipecacuan and laudanum (from half a drachm to a drachm of the former and from thirty to sixty drachms of the latter), he confined the man for some hours to a horizontal position to counteract the tendency to vomiting; but even if the first dose was brought up the second was commonly retained. He narrates four illustrative cases, stating, as was common in those days, the names of his patients—namely, D. Morison, W. Troy, Garragin, and Dawson; and he says he could have given other instances. The good effect was immediate, seldom was more than one dose required to cure, but the treatment had to be employed at the beginning of the attack, for if the disease had become chronic the stomach was too irritable to retain the medicine. One of the patients was a seaman, and the others were privates "of his Majesty's 65th regiment." He gave in one case some rhubarb, calomel, and magnesia, in addition to the laudanum and ipecacuan, but not until the dysentery had stopped. "I claim not," he writes, "the honour of having been the inventor of this simple formula"; but he evidently believes it has only to be made widely known in order to save many lives.

Events have shown that Mr. Playfair was not deceived in the reliance he placed on this combination of ipecacuan and laudanum, for throughout the course of the nineteenth century medical men in various parts of the world continued to report well of these drugs in dysentery. There were groups of cases in which failure had to be recorded,

but on the whole the verdict has been favourable. Mr. Playfair wrote his article in 1812, and he was in Calcutta when he did so. It is, therefore, something of a coincidence that in 1912 Major Leonard Rogers, Professor of Pathology in Calcutta, should have been writing in praise of ipecacuanha in dysentery. His papers, published in this JOURNAL¹ have done much to justify a belief not only in the good effects of ipecacuanha in dysentery, but also in its specific action on the amoebae which are recognized as the cause of amoebic dysentery and hepatitis. Professor Rogers encountered the same difficulty which met Mr. Playfair in giving ipecacuanha, namely, the tendency the stomach showed to reject the large doses which were necessary to produce a curative effect; but he has surmounted it in a different way, namely, by giving a soluble salt of emetine (the principal alkaloid of ipecacuanha) by hypodermic injection. Further, he has found that emetine so given serves as a means of distinguishing between amoebic dysentery and bacillary dysentery, and the other non-amoebic causes of blood and mucus in the stools. If given in sufficient doses it does good in the amoebic form, whilst it has no effect on the other diseases. Perhaps this may serve to explain some of the failures of ipecacuanha in dysentery which have from time to time been reported. Such modifications have a hundred years effected in the use of ipecacuanha in dysentery.

Mr. Playfair's article is followed by one on "Cases of Hydrophobia, treated, one of them successfully, by Mr. F. Tynon, Assistant Surgeon, H.M. 22nd Light Dragoons; with Observations by Dr. A. Berry, of the Madras Establishment, Proceedings of the Medical Board, and Resolutions of the Honourable Governor in Council, in reference thereto." This article, or rather this little sheaf of papers—for which, writes the editor in a footnote, "we are indebted to Mr. James Kellie, Assistant Surgeon at Bangalore, and to Dr. Shoolbred, Surgeon to the Presidency at Calcutta"—is in its turn succeeded by one by Dr. John Shoolbred himself on a "Case of Hydrophobia successfully treated." The successful treatment in these cases was bleeding. In Mr. Tynon's first patient the bleeding was only to 15 oz., and it produced no good effect, but in the second the bleeding was at once carried out, until "scarcely a pulsation was to be felt in either arm," and the result was recovery. Dr. Andrew Berry, in his observations on the case, regarded it as a real cure of hydrophobia, and he laid stress on the necessity for the abstraction of a large amount of blood. He noted that Dr. Fothergill, as far back as 1774, had published a case in which the patient had been bled; but only to the extent of 6 oz.; it was insufficient to produce a cure. The Medical Board, in commenting on these cases, strongly pressed the importance of bleeding early in hydrophobia, and to such an extent as to produce fainting; and Dr. Shoolbred, in connexion with his successful case, also emphasized the necessity of opening the vein by a large orifice, of allowing the blood to flow quickly, and up to fainting ("ad animi deliquium"). The Medical Board pointed out that a previous successful case had been reported by Drs. Burton and Rush of Philadelphia in 1805. This was doubtless the case recorded by R. Burton in the *Medical Repository* of New York (vol. viii, p. 15, 1805). Dr. Shoolbred's patient was a native, named Ameir, a "Muselman Bhestie (water-carrier)," and there seems to have been no doubt that he was suffering from rabies. A most graphic account is given of his symptoms; indeed, Dr. Shoolbred's paper is admirable both in its descriptions and in its survey of the knowledge then current regarding hydrophobia. He is rather hard put to it to explain why previous cases in which massive bleedings had been performed had yet proved fatal. There was, for instance, the patient who was bled by Dr. Rutherford of Edinburgh to the extent of 66 oz., but who nevertheless died; the untoward issue is ascribed by Dr. Shoolbred to the fact that the 66 oz. had been taken away gradually—not a very convincing explanation, one thinks.

The use of bleeding in hydrophobia is now only of historical interest, for Pasteur's method of prevention by inoculation in the incubation period has replaced all other plans; and a disease which, when established, is incurable can now in the great majority of instances be prevented,

if dealt with promptly. Still, Mr. Tynon's observation made no little stir at the time. Mr. Baumpfield, writing on bleeding in hydrophobia in the *Medical and Physical Journal* for December, 1812, had heard of the Indian case, curiously enough through a short summary in the pages of the *Kilkenny Chronicle*, but did not know the authority on which it stood; and, in Germany, Vogelsang referred in 1815 to Tynon's method of treatment.² In that year (1815) Albers and Bellingham each reported an unsuccessful case, the one in the *Edinburgh Medical and Surgical Journal* and the other in the *London Medical and Physical Journal*; thereafter the subject was allowed to drop, although Edmonston was still writing about it in 1816.³ Yet Dr. Shoolbred's paper is worthy of being read in 1913, if only for its realistic description of an attack of hydrophobia.

A few words must suffice for the remaining two papers on tropical diseases in this old journal. They both dealt with yellow fever, or, as it was then sometimes called, tropical or Caribbean fever, and especially with the depletory method of treating it—namely, by means of bleeding, free purgation, and the cold affusion; and they both referred back to earlier contributions on the same disease in the preceding volume of this journal. They are interesting instances of the way in which naval surgeons and physicians were at that time building up a knowledge of tropical medicine. They remind us also that British ships were cruising much in West Indian waters in these years (1812-13), for this country was at war with America, and had also to keep watch against French privateers in the Caribbean Sea. The papers were written from Guadeloupe (not finally ceded to France till 1816) and from the Leeward Island station.

The study of tropical diseases was obviously in its infancy in 1813; but there were indications that British medical men in India and in the West Indies were beginning to turn their attention to it, being forced to it indeed by the mortality from such maladies which was making itself felt in the troops stationed abroad and among the sailors manning the Indiamen and the fighting frigates of the time. There were no schools of tropical medicine in those days such as are to be seen now; but there was already a clear indication of the necessity which was to be laid upon Great Britain of the later nineteenth and of the earlier twentieth centuries to send forth of the best of her medical sons to discover the cause of Malta fever, to unravel the problem of sleeping sickness, and to learn to stay many another scourge existing in these tropical countries over which she has been placed as ruler, and for which she has already paid a price in blood.

ROYAL MEDICAL BENEVOLENT FUND.

At the February meeting of the Committee twenty-three cases were considered and grants amounting to £222 voted to twenty of the applicants. The following are abstracts of the cases relieved:

1. Widow, aged 63, of M.R.C.S. No income, and supplements slight assistance from children by taking boarders. Relieved twice, £22. Voted £12.
2. Widow, aged 43, of M.R.C.S. Three children, aged 13 to 7, and practically dependent on her earnings by letting lodgings. Relieved three times, £34. Voted £10.
3. M.D. Edin., aged 52. Met with a severe bicycle accident a year ago, and has since been incapacitated and dependent on a widowed sister who can ill afford to help. Voted £12.
4. Widow, aged 56, of L.R.C.P., L.R.C.S.I. Unprovided for at husband's recent death, and hopes to support herself by receiving boarders. Children only able to give very slight help. Voted £10.
5. Daughter, aged 51, of L.R.C.P.I. Has always been in feeble health, and is now incapacitated by a chronic complaint for which she has been promised admission to a hospital. Voted £5 now and £5 on leaving the hospital.
6. Daughter, aged 67, of late M.D. Edin. Used to have a small income, but was obliged to mortgage the property from which it was derived, and now receives nothing owing to foreclosure by the mortgagee. Voted £12.
7. Daughter, aged 65, of late M.R.C.S. Was comfortably provided for by her father, but lost everything through the dishonesty of her trustee, and is now dependent on a small pension from another society. Relieved twice, £36. Voted £12.

¹ BRITISH MEDICAL JOURNAL, June 22nd, 1912, p. 1424, August 24th, 1912, p. 405; September 28th, 1912, p. 828.

² *Journ. d' pract. Meilk.*, xli, p. 8, 1815.

³ *Lond. Med. Reposit.*, v, p. 466, 1816.

8. Daughter, aged 62, of late M.R.C.S. Has had a school for several years, but now, owing to competition, finds it very difficult to meet her expenses, and is obliged to maintain two mentally afflicted sisters. Relieved once, £10. Voted £12.

9. Deserted wife, aged 46. Since husband's disappearance a few years ago has supported herself in different ways, but is now in difficulties, which she quite hopes will be temporary. Relieved once, £10. Voted £10.

10. Widow, aged 70, of M.R.C.S. Since husband's death thirty years ago has kept a lodging-house, but now, owing to failing sight and chronic rheumatism, finds it very difficult to do the necessary work. Only income a few shillings a week from savings which have been invested. Relieved once, £12. Voted £5, and to be advised to apply for an old age pension.

11. Daughters, aged 60 and 55, of late M.R.C.S. Entirely dependent on letting lodgings, and both in feeble health. Relieved eight times, £95. Voted £12.

12. Daughter, aged 66, of late M.R.C.S. Was fairly provided for at father's death, but made most unfortunate investments which now yield only about 5s. a week. Relieved twice, £35. Voted £12.

13. Daughter, aged 44, of late F.R.C.S. No income, and health so indifferent that it is impossible to keep any post even when obtained. Relieved fourteen times, £117. Voted £12.

14. Widow, aged 63, of M.R.C.S. Quite unprovided for at husband's death several years ago, and owing to a deformity has never been able to obtain regular work. Slight help from children. Relieved nine times, £106. Voted £12.

15. Daughter, aged 61, of late M.R.C.S. Has suffered for many years from a chronic complaint, and been obliged to spend her capital both for treatment and maintenance. Relieved twice, £24. Voted £12.

16. Daughter, aged 56, of late M.R.C.S. Health too feeble for anything but light work, and has to help support two sisters, who are unfitted for any occupation. Relieved four times, £72. Voted £18.

17. Widow, aged 64, of M.D.Lond. After husband's death, about ten years ago, started a boarding house at a seaside place but lost all her capital, and is now unable to obtain suitable employment. Relieved twice, £24. Voted £12.

18. Widow, aged 57, of L.R.C.P.Edin. Slight help from children and lets lodgings. Relieved three times, £32. Voted £2 and case to be reconsidered.

19. Widow, aged 44, of M.B., C.M.Glasg. Quite unprovided for at husband's death a year ago, after a long illness, and obliged to endeavour to keep a home together because of her three youngest children, aged 10 to 4; slight help from elder children. Relieved once, £12. Voted £20.

20. Daughter, aged 35, of L.S.A. Has been offered a situation abroad, but requires a little help for unavoidable expenses. Relieved once, £10. Voted £5.

Contributions may be sent to the honorary treasurer, Dr. Samuel West, 15, Wimpole Street, W.

SCIENCE NOTES.

The large number of investigations that have been made into the etiology of canine distemper and the diversity of organisms found by the different investigators are proof of the fact that until quite recently, at any rate, the real causal agent has not been definitely determined. Apart from the veterinary and economic aspect of distemper, it offers the bacteriologist an opportunity of studying a contagious disease of the respiratory tract. The list of investigators since the time of Pasteur includes the names of many medical men. It is highly probable that the question of the specific organism is on the road to settlement. Dr. J. P. McGowan, in 1910, was the first to describe a particular coccobacillus found in pure culture in the trachea and lungs of dogs which succumbed to typical distemper in the laboratories of the Royal College of Physicians of Edinburgh. The contagion spread to other laboratory animals not usually considered susceptible to the disease. He also obtained the same organism from kennels in various parts of Scotland where distemper was raging. The finding of this organism in pure culture in the trachea of dogs dying of distemper was corroborated by Dr. Leitch, of Dundee. In 1901 Dr. Monckton Copeman had described before the Royal Society a somewhat similar, but not identical, organism. Dr. McGowan claimed to have produced typical distemper by introducing into the nostrils of dogs cultures of his bacillus. Quite independently, Ferry, working in the laboratories of Messrs. Parke, Davis and Co. in Detroit, obtained an organism identical with McGowan's, to which he gave the name *Bacillus bronchicentis*. The scrupulous precautions he took against natural conveyance of the disease to the animals under experiment added greatly to the strength of his conclusions. Two workers in the Department of Experimental Pathology of Cornell University—Torrey and

Rabe—have gone into the whole subject very carefully and fully, without preconceived notions or predilection for any particular microbe, and their results, which are given at length in the *Journal of Medical Research* (January, 1913), prove apparently beyond a doubt that the organism described by McGowan is the specific cause of canine distemper.

Goldberger (*Folia Serologica*, 1911), in an investigation on the haemolytic action of various acids and the protective or antihæmolytic properties of different serums in combination with them, found that, in comparison with normal serum, the power of cancer serum to protect red corpuscles against the action of oleic and lactic acids was very high. He tested the serum in various other diseases, such as gastric ulcer, tuberculous pneumonia, nephritis, cardiac disease, and exophthalmic goitre, but in none was the antihæmolytic power above that of normal serum. The importance of these observations, and especially the possibilities thereby opened up for serological diagnosis, inevitably led to a critical repetition of the experiments by others. Sweek and Fleischer, as the result of an investigation of the serum of 12 normal and 18 cancer cases, have found that in no case was there marked increase in the inhibitory power of the serum of cancerous patients, and that the method can be of no diagnostic value, as the antihæmolytic property of the serum in normal individuals varies within very wide limits.

The second of the Galton Laboratory Lectures on National Eugenics was delivered at University College, London, on February 18th, when Professor Karl Pearson discussed the heredity of albinism and piebaldism in man. With regard to albinism, he laid stress on the fact that it could not be defined as a definite property. Although the condition, with pink eyes, white hair, and white skin, was perfectly well known, pure albinism was comparatively rare, and in the circumstances it was hardly possible to follow the Mendelians and describe albinism as a unit character. He argued that if the Mendelian theory was to be applied it would be necessary to assume that both parents had latent albinism to account for the offspring being albinos, so that in every instance in which the child of a normal person and an albino exhibited albinism the normal parent must have contained latent albinism, but this was inconsistent with the fact that albinism was very rare in England, only one family in 25,000 being so affected. Consideration of the occurrence of albinism in the coloured races suggested that this phenomenon was a considerable step towards the evolution of a white from a coloured people. It was, he thought, possible that in the course of evolution the white man had been evolved from the coloured, and that if the pedigrees of those present could be traced far enough back a dark-skinned progenitor would eventually be discovered. Professor Pearson went on to observe that the Mendelian regarded piebaldism as distinct from albinism. He cited cases, however, in which piebaldism in certain families had, in the course of generations, developed into albinism. The cases of albinism and piebaldism were too complex to be reduced to any theory of units. The character of piebaldism, for instance, varied from individual to individual and from family to family. He knew of no theory to account for the facts, nor was the time ripe for such a theory. There was a danger in collecting facts in the light of a certain theory, and much of the work of to-day would have to be done over again. The Mendelian school was trying to force the facts into Mendelism, but men, like dogs and mice, still refused to fit into Mendelian categories.

The skull of the new type of fossil man (*Eoanthropus dawsoni*) discovered at Pittdown, in the valley of the Sussex Ouse, an account of which was published in the *Journal* of December 21st (p. 1719) and December 28th (p. 1763), has been presented to the British Museum by the discoverer, Mr. Charles Dawson, F.S.A., F.G.S., and Mr. G. M. Maryon-Wilson, the owner of the gravel pit where it was found. Mr. Dawson gave a short description of the skull, the associated objects, and the restoration to the meeting of the trustees on February 22nd. The specimens will shortly be placed in the large hall of the Natural History Museum at South Kensington.

SATURDAY, MARCH 1ST, 1913.

INSURED PERSONS MAKING THEIR OWN ARRANGEMENTS.

THE Memorandum 143/L.C. issued by the Commissioners to assist Insurance Committees in dealing with applications from insured persons who wish to make their own arrangements is printed in the SUPPLEMENT (page 212), and should be read by every practitioner interested in the working of the Insurance Act. While it makes the intentions of the Commissioners quite clear, it does not appear to settle the vexed questions that have arisen around Section 15 (3) of the Act, questions, indeed, which probably can only be settled by an action in the courts.

The Insurance Act by this Section authorizes an Insurance Committee to allow *any* other persons (that is, other than those excluded by an income limit from participation in the panel arrangements) to make their own arrangements for medical treatment, and, subject to regulations, to contribute from its funds towards the cost of that treatment sums not exceeding in the aggregate the amounts which the Committee would otherwise have expended in providing medical treatment for such persons. By Regulation 14 (7) the Committee may allow *any* insured persons, whether individually or collectively, to make their own arrangements. There is nothing here about "exceptional circumstances," simply a plain statement that an Insurance Committee may if it thinks fit allow *any* insured persons to make their own arrangements. Alarmed by the use which has been made of this proviso by practitioners who do not wish to go on the panel, and by insured persons who prefer to have the services of such practitioners—a much larger number in each case than apparently was ever contemplated by the Commissioners—it has been found convenient to read into the Act ideas which may have been in the minds of the framers, but which we certainly cannot find stated in that document.

The Memorandum states (par. 2) that the Act "does not contemplate" arrangements under Section 15 (3) as an alternative to the normal panel system, but only as a provision to meet the "exceptional cases" for which special arrangements are more suitable than the arrangements made by the Insurance Committee. It is probable that nobody at the time this section was drafted foresaw the possibility of an extensive use being made of it in the way of "contracting out," but we must take the plain words of the Act, and these seem to give an Insurance Committee power to allow any persons it pleases to make their own arrangements. It is very doubtful, to say the least of it, whether the Commissioners have the right to suggest restrictions which will have the effect of practically nullifying a privilege granted to insured persons by Parliament.

The Memorandum contains in its third paragraph a reminder that an Insurance Committee must consider each case on its merits. This is rather an unkind cut, for it is well known that many of the Committees have been rejecting applications in a wholesale manner, and we know of no reason why they should

have taken this line except that they had good cause for the belief that such was the wish of the Commissioners. However, we may now expect that each case will receive due consideration, in order to ascertain whether it falls into one of the classes which the Commissioners agree may well be allowed to make their own arrangements—namely, those whose occupation compels them to travel about; those, such as nurses and members of hospital and asylum staffs, who have special advantages in the way of medical treatment, and those who wish to have a particular system of treatment not undertaken by doctors on the panel. The justice and convenience of allowing the two former classes to make their own arrangements is obvious. The last class is probably intended to include Christian Scientists and others with heterodox ideas as to medical treatment.

When we come to the case of those persons who desire to make their own arrangements because they wish to employ some doctor who is not on the panel, one thing is made quite clear—namely, that no arrangement will be allowed, so far as the Commissioners can prevent it, which would give any advantage to the doctor off the panel as compared with the panel doctor. The doctor off the panel must satisfy the Committee that the treatment given by him is equal to that provided by the panel doctor; he must keep and furnish the same records and certificates; he must give if required domiciliary attendance for such of his patients as are recommended for sanatorium benefit; and he must agree to give reasonable facilities in order that the Committee or the Commissioners shall be satisfied that the above conditions are fulfilled. He must also state the quarterly sum he proposes to charge the insured person or the scale of fees on which his charges will be calculated, and if these fees exceed those fixed by the Committee, the insured person will have to pay the excess. If a doctor is prepared to attend any substantial number of insured persons he is told that his proper course is to go on the panel, and in view of the restrictions placed upon him by the present circular, it is difficult to perceive any advantage to be gained by such a practitioner refusing to do so, even if his patients are allowed to make their own arrangements. If he wishes only to take a limited number he may be allowed to go on the panel for that number provided that the doctors on the panel agree to the arrangement. It would appear that the Commissioners are within the four corners of the Act in making these stipulations, which will certainly deter many practitioners from accepting insured persons, as such, as patients. Under Clause 15 (3) the Committee may contribute towards the expenses of those allowed to make their own arrangements, but only subject to the Regulations. Regulation 14 (8) lays on the Committee the duty of satisfying itself that the arrangements made are satisfactory, "that is to say, such as to secure treatment . . . not inferior in nature, quality, or extent to that provided under the arrangements made by the Committee and to comply in other respects with any conditions which by reason of any scheme for the distribution of Parliamentary grant must be complied with in the case of treatment provided otherwise."

As we have said, it is probable that some of the questions involved in the much-discussed Clause 15 (3) will have to be settled by a court of law, but it seems clear, first, that the Insurance Committee, and the Committee alone, can decide whether a person is or is not to be allowed to "make his own arrangements"; secondly, that the Commissioners have no warrant in

the Act or Regulations for laying down elaborate statements as to "exceptional cases"; thirdly, that the intention of the Act would be fulfilled if the Committee allowed all persons who desired it to make their own arrangements so long as it is made clear to them that they could only expect a specified contribution towards their doctors' bills, and would be responsible themselves for the payment of any difference; and, fourthly, that the Commissioners are within their powers in demanding that certain stipulations shall be complied with by those practitioners attending insured persons allowed to make their own arrangements and in respect of whom a contribution is made by the Insurance Committee. On the other hand, the elaborate safeguards to secure that the treatment obtained by those who "contract out" is satisfactory are unnecessary so far as the patient is concerned; he may well be assumed to know whether he is properly treated. If the person chiefly concerned is satisfied, the Insurance Committee need trouble itself no further. If he is not satisfied, he may be relied upon to seek the services of some other doctor, probably this time on the panel, especially as he is liable for any difference between the amount allowed him and his doctor's bill, and cannot in any case make anything out of the transaction.

There is another side to this question which must not be overlooked by the profession. We understand that in Wales bodies of insured persons have already asked to be allowed to make their own arrangements collectively under Clause 15 (3) of the Act with a view of employing one or more whole-time doctors or of obtaining concessions with regard to dependants. Similar action may be taken by other bodies of insured persons. Such attempts to place doctors under a form of lay control to which the strongest objection has always been taken by the profession will be resisted to the utmost. It is not only repugnant to the medical profession, but is against the best interests of the public, who will be far better served by a system of free choice of doctor and the fair competition involved in such a system.

It is evident that the question of the restrictions which should be put on the right to "contract out" is one which needs serious consideration from all points of view.

THE NEW MYSTICISM.

THE headmaster of Eton has recently made known his opinion¹ of an addition to the already numerous methods of spiritual healing with which America, that land of many inventions, has endowed a suffering world. This is the New Mysticism, and its prophet would appear to be a Miss Curtis, of whom we have to confess we have never heard, although there seems something familiar in the doctrine of "the disassimilation of old ideas by the understanding of the purpose of the hypogastric plexus," a structure which appears to have a curious attraction for the modern mystic, and may perhaps have been the real objective of the fakir who spent fifty years in the contemplation of his own navel. We are told that the essence of the teaching is silence, which is supposed to be employed in meditation, and many will start with a certain prejudice in favour of a system which sets out to still the tongue of the valedictorian and neurasthenic. Mr. Lyttelton tells

us that "its votaries can point not only to many lives relieved of terrible bodily ailments, but to many souls uplifted and mental horizons enlarged. . . . It would not," he continues, "be too much to say that its power of healing character is quite as remarkable as that of healing bodily tissues." We are, indeed, quite prepared to believe that it is greater. Mr. Lyttelton appears to have accepted the statements, doubtless made in all good faith on behalf of the New Mysticism, without question, although he is obviously puzzled by a good deal of the teaching, for he says that when "the healing power is sincerely exercised and preached with conviction human beings will put up with the most singular and chaotic exposition of principles that can be imagined." The new doctrine seems to have in it something of Christian Science and something of orthodox Christianity. The theological or philosophical part of the doctrine, to quote Mr. Lyttelton again, appears to seek "to find a new set of phrases in which to designate our relation with the infinite," and he seems to accept the opinion that the subconscious mind, as distinct from self-consciousness, is the source of our true communion with the infinite. This is a favourite doctrine just now with writers of various kinds, from novelists to philosophers, or those who so dub themselves. But is there a tittle of support for it in philosophy? The history of mankind is all the other way.

We gather that the teaching of the New Mysticism as regards healing resembles that of Christian Science, and Mr. Lyttelton anticipates that the same shafts of ridicule and scorn which have often been shot at the elder of the two creeds will be sharpened afresh. "In particular," he writes, "it will be asked if 'these people' think they can mend a broken leg. A large number of critics seem willing to allow that all kinds of spiritual healing of 'nervous disorders' or mental trouble are reasonable and possible. Others, perhaps not so many, are prepared to admit that tissues actually change in quality and to some extent in position, when spiritual influences are brought to bear on them. A few would concede the possibility of a dislocated joint being cured, but, if any claim to heal a broken joint is advanced or even hinted at, the whole movement is suspected of fraud, and the supposition gains ground that nothing happens beyond what is now well recognized as 'suggestion.'" This is the kind of passage that, coming from a man of high education like Mr. Lyttelton, makes us almost despair that sound notions as to the nature of disease and injury can ever be made to penetrate the public mind. No one has ever asked if any one thinks he can mend a broken leg unless it were some one grossly ignorant of the subject. The surgeon does not mend the broken leg; he only puts it in the posture and the conditions which enable nature to mend it in the best position and to the greatest advantage of its future usefulness. If Mr. Lyttelton wishes to see what sort of job nature by her own efforts wrongly persisted in can make of a broken bone, he should pay a visit to the museum of the Seamen's Hospital, where he will see fragments welded together in every conceivable kind of malposition. Nature has done her work quite efficiently so far as the strength of the mend goes, but owing to the want of surgical direction some very undesirable results have been produced. Then, again, it is quaint to think of people who see nothing very wonderful in a dislocation replacing itself, but who are doubtful as to the repair of a broken joint. Here again Mr. Lyttelton, and we may add the New Mystics, might

¹ *Contemporary Review*, January.

be enlightened by the study of a few x-ray photographs of dislocated joints. When Mr. Lyttelton tells us that a faith healer who, he says, has undoubtedly performed some very striking cures, has by prayer nearly achieved the adjustment of a badly dislocated hip-joint, the bone being much nearer to being settled in the socket than it was, one can only wonder why a faith that has done so much has failed to reduce the dislocation entirely. A profane person might hint a doubt as to the diagnosis.

Mr. Lyttelton, for whom we have the highest respect, would seem to be imperfectly equipped for the discussion of questions of healing: he makes the assumption that the successful management of a broken bone is a question of mere mechanics, and rather scoffs at theists who ascribe omnipotence to God, and then "confidently and scornfully draw the line limiting His beneficent power to certain phenomena which they think they can safely classify as 'nervous.'" He asks why those who see no difficulty in allowing an action by the Deity—or by suggestion—through the mind on nerves should laugh at the theory that bones may be acted on in similar ways. He takes physicians to task for drawing the line at what they conceive to be nervous complaints as the limit of the power of suggestion. We agree that "it is a question of evidence how far suggestion has been operative in the past"; and it is just this evidence that we have called for again and again from Christian Scientists and other mind healers, and which up to the present we have failed to get. "But who," asks Mr. Lyttelton, "in such a mysterious region can say that suggestion may not be more powerful in the future?" All healers," he goes on to say, "postulate a certain condition of receptivity or of co-operative energy of faith in the patient's mind. But supposing that condition is greatly effected by the condition of other minds in the locality or house or family—and what is more probable?—a healer is quite justified in asserting that his success would be far greater if some knowledge of the power of mind over matter were distributed over a wider area." "To the secularist or sceptic, who cannot help admitting the evidence as to suggestion," he says, "it may be urged that the good done by suggestion might be enormously extended if it were not for the cynical refusal of thousands of educated people to credit it with any power whatever except when they are forced to admit the evidence; thus making an atmosphere in which suggestion becomes increasingly inoperative." This, if it means anything, means that these cynical people can by mere negation or doubt counteract the beneficent influence of a force or faculty inherent in the sick person. We seem to have come very near Mrs. Eddy's malicious animal magnetism. It is not desirable that the number of suggestionable people should be largely increased, for suggestion can be applied, and is applied, in many other spheres than medicine, and the number of subjects suitable for its operation would only increase the number of false prophets in politics, religion, commerce, and, in fact, in every department of human life. Miss Curtis, quoted by Mr. Lyttelton, dealing with pain, says: "An essential feature of this way of healing—essential, that is, to its success—is that the healer must hold his imagination as already accomplished. . . . Another way of psychological healing is by denial and affirmation. The condition which has been brought about by unintelligent belief, that is, by habitually receiving the negative interpretation of the senses, has to be denied as untrue to Principle, untrue to the *Substantial*

nature of the patient, and the right state of mind, with all its motor consequences for the body, has to be steadily affirmed in its place." Again, Miss Curtis says: "It is best not to deny facts, conditions, and effects in the objective plane. It is waste of time to deny the illness—that can look after itself: deny its root, its subjective and psychical correspondence. Do not deny the headache . . . but get at the mental state which brought about the headache and root that out by affirming the quality of Principle which knows no such thing." This may, perhaps, do for some headaches in neurotic people, but how about a stomach-ache in a child brought about by eating too much Christmas pudding? How are we to get at the mental state which brought this about? and root it out by affirming the quality of Principle which knows no such thing? We are to get at it by the repetition of some word or words, such as Wisdom, Eternal Love, Truth. If, for instance, we want to give up the habit of afternoon tea, but have not the strength of will to break it at once, we are, while lifting the cup to the lips, to repeat the word Wisdom. Hence we are to learn that if the mind is fixed steadily on "Eternal Principle," the diseased tissues can take care of themselves. This is rather a wide conclusion, and the works of these apostles of new healing cults lead to the conviction that they have never seen real, everyday disease. They have to deal largely with *malades imaginaires*, and their method of treatment may not unjustly be described as cure by the scientific use of the patient's imagination.

The new mysticism seems in Mr. Lyttelton's exposition, with its rhapsodies about the subconscious mind and the hypogastric plexus, to be not only nebulous, as he admits, but grossly materialistic; and while we have, of course, no wish to enter on a discussion of rival creeds, we think a level-headed man would of the two prefer the old-fashioned Christianity, which with its appeal to the higher faculties of mind and spirit, has the qualities of being intelligible to the average man, woman, and child, and fairly adapted to the needs of our poor human life.

STREET PERILS AND AMBULANCE PROVISION.

A BELATED return of the Board of Trade for 1911 shows that the number of accidents in the streets of London is larger than ever, and that the percentage of accidents is increasing in a higher ratio than is the population.

In the last year for which precise figures are available, 20,587 accidents were returned in streets within the City and the area of the Metropolitan Police: 435 terminated fatally. This alarming increase in street accidents in London is attributed to increasing congestion of traffic, and to the indiscriminate mingling of vehicles proceeding at various and varying speeds. The motor omnibus appears to be responsible for more fatalities than the trams, and to the increased use of mechanically propelled vehicles may be largely attributed the enormous rise in the total accidents during recent years. The other day, in a police-court case, the prosecuting counsel, speaking on behalf of the City Commissioner, commented on the large proportion of cases in which those who had been prosecuted for reckless driving had been acquitted by juries, and emphasized the difficulty in which the police were often placed in

their endeavours to protect the public and punish the offenders.

Another aspect of this question, and one to which we have repeatedly directed attention, is that of the lack of adequate provision for dealing promptly with, and with the avoidance of needless suffering to, the victims of these daily accidents in London streets. A jury recently investigated the death of a man in St. Bartholomew's Hospital who had been conveyed from Islington in a wheel-litter, the journey occupying thirty-five minutes. A rider was attached to the verdict urging the London County Council to adopt a more up-to-date ambulance system in the area under its jurisdiction, and similar to that which works so well within the City of London. In the enlightening debate to which this occurrence gave rise in the Council, on February 18th, the apologetists for the present state of neglect vouchsafed the information that "before many years were over," and when fresh parliamentary powers had been obtained, and after a conference with the various ambulance agencies in London had taken place, an efficient service might be brought into existence!

The real truth is that the London County Council has for three years, thanks to the Metropolitan Ambulance Act, 1909, had all the powers necessary for running a service in the County of London similar to, and as efficient as, the City's ambulance service. Indeed, the so-called City scheme was elaborated by the London County Council itself in 1902. The report made to the Council by their General Purposes Committee in November, 1912, was the quintessence of futility and procrastination. It revived a discredited scheme which was propounded before the Home Office Committee in 1907; whereby the one-horse cabs possessed by boards of guardians, together with Asylums Board ambulances, etc., should be utilized for street accidents, without any organizing authority or uniform system. That scheme was admittedly impossible then because, as the Local Government Board had pointed out, it was altogether illegal. Since then Parliament, instead of removing the statutory bar to the adoption of any such scheme, has definitely committed the duty of providing ambulances for street accidents and other casualties in public places to the County Council. The spokesmen of the Government, alike in the Lords and the Commons, regarded it as hopeless and impossible to entrust such municipal powers to the Poor Law authorities.

Our contemporary the *Hospital* has recently published, opportunely but unkindly, the pledges given by county councillors, when elected in 1910, to put in force the powers conferred by the Ambulance Act of 1909. If those pledges had been redeemed, we should have seen the county ambulance service performing its beneficent work to-day as efficiently as the City service. We earnestly plead for the prompt prevention of needless suffering occasioned by the present gravely defective means of transport of the injured.

Liverpool was a pioneer city in making improved arrangements for dealing with street accidents, and in providing rapid ambulances. The influence of its example has been felt on the other side of the Atlantic, where most of the great American cities have highly organized and efficient services, either hospital or municipal; but, as has been said, the London County Council has not far to go for a model, since one exists immediately over its borders—in fact, topographically, in the midst of the area for which it is responsible.

COUNTY COUNCILS AND THE TREATMENT OF TUBERCULOSIS.

At the annual meeting of the County Councils Association on February 25th, Mr. Henry Hobhouse, Chairman of the Insurance Act Committee, asked the meeting to consider whether it could recommend county councils to proceed with the provision of institutes for (1) insured persons, (2) for their dependants, and (3) for the rest of the community requiring institutional treatment. He urged that it would be undesirable for the county councils to surrender so important a branch of health administration to the district councils or the Insurance Committees, and expressed the opinion that a council might, without adding a serious burden to the rates, undertake the institutional treatment of insured persons if the Insurance Committee would transfer the 8d. a head or other residue of the money provided for sanatorium benefit. He recognized that public opinion would almost certainly demand the inclusion of dependants, but thought the question of treating other non-insured persons was less pressing, although their treatment must be contemplated in any scheme which was to have the approval by the Local Government Board, and that Board would probably insist on the necessary number of beds being provided. He concluded by urging that the buildings erected for the purpose should be inexpensive. The subject was fully discussed, and eventually the following resolution was adopted: "That this association recommends the county councils to undertake the duty of providing institutional treatment for insured persons suffering from tuberculosis, and for such of their dependants as the funds of the Insurance Committees by arrangement will allow; but that, inasmuch as the association has not been successful in its efforts to obtain a guarantee of the contribution from the Exchequer towards the annual cost to complete the schemes which was asked for, it is not, as an association, prepared to express any opinion with regard to the establishment of such schemes, and considers that each county council should decide upon its own course of action in the matter."

FUTURE STAGES OF THE TUBERCULOSIS CAMPAIGN.

THE Lady Priestley Memorial Lecture, delivered by Professor Metchnikoff in November last, has been translated by Sir Ray Lankester, and published by the National Health Society at the price of a shilling. It may fairly be regarded as the standard account of present knowledge and as the most enlightened indication for future research that is now available for reference. Much has been established, but more remains to be proved, which is yet only in the stage of probability. No point in the whole lecture is more striking than the evidence that is brought forward to show that races of mankind hitherto uninfected are especially susceptible when exposed to the poison, while Europeans, living in the same country and under similar conditions, exhibit little or no tendency to acquire the disease. It must be assumed that they have somehow acquired immunity owing to the unsuspected presence within them of tubercle in some other form. But this lessened susceptibility requires further investigation and study. The apparent immunity conferred by antecedent scrofula has often been noted as a clinical phenomenon, but it has not always been accepted as a factor in prognosis. Many a sufferer from tuberculous glands in the neck has been erroneously regarded as "consumptive," and has been allowed to rest under the ban of an unnecessarily gloomy prognosis. Experiment, so far as it has gone at present, would seem to prove that the organism producing the so-called scrofulous lesion is an attenuated form of the tubercle bacillus, and that many degrees of attenuation may be naturally produced. More light is needed to

distinguish between the virulent and the non-virulent types, the one causing active disease and the other conferring comparative immunity. Is it the bovine form which plays the latter part? The old tradition, still persisting in some country districts, that the air of the cowhouse is good for the consumptive, may have a germ of truth in it. The evidence afforded by the cutaneous reaction devised by von Pirquet tends to prove that a very large proportion of the individuals forming civilized communities are already the hosts of some form of tubercle, and that in very many cases no other indication of its presence is forthcoming during life. Hence the justifiable conclusion that natural vaccination is a factor of vast importance, not only in respect of tuberculosis, but also as against other infectious diseases which are at all times prevalent in the community, but only affect isolated individuals. The further study of the whole subject and its particular application to tuberculosis will doubtless be greatly stimulated, both in the laboratories and in the course of practice, by the indications which Professor Metchnikoff has laid down.

CHEST HOSPITALS AND TUBERCULOSIS SCHEMES.

It has been announced that the Committee of the Mount Vernon Hospital for Consumption and Diseases of the Chest will recommend the governors, at a meeting to be held on March 12th, to sell the hospital at Hampstead, and to devote the funds to the maintenance and extension of the Northwood Sanatorium. The institution consists of a chest hospital at Hampstead, a sanatorium for consumption at Northwood, Middlesex, and an out-patient department and offices in Fitzroy Square. Soon after the National Insurance Bill was introduced the committee became apprehensive that if passed into law the bill would have the effect of seriously affecting the income of the charity derived from voluntary subscriptions, and that if this anticipation were fulfilled it might become necessary to accept money from the State for the hospital treatment of insured persons, with the inevitable consequence of State control, resulting eventually in the absorption of the hospital by the State. The Committee considered that such a result would be deplorable in respect of the building at Hampstead, and that in respect of the country branch at Northwood it would be directly contrary to the wishes of the donor, who had contributed nearly a quarter of a million for its establishment. A subcommittee reported in November, 1911, that it was unanimously of opinion that the Insurance Act would seriously affect the financial welfare of the hospital. It advised that the future work of the institution lay in the direction of using it for the benefit of patients able to pay 30s. a week for treatment in the sanatorium, and did not consider that it would be possible to retain a free hospital at Hampstead while converting the sanatorium at Northwood into a paying institution. It recommended that the Hampstead property should be sold, and that from the proceeds of this sale and from invested funds the Northwood institution should be enlarged. In this way it was thought that 200 or 250 beds could be maintained, and accommodation provided in the one building for an equal or greater number of patients than are now treated in the two hospitals. The medical staff, in December, 1911, drew up a memorandum giving reasons against this proposal. It pointed out that the Mount Vernon Hospital had been founded fifty years ago for the treatment of persons suffering from all kinds of diseases of the chest, including, in addition to consumption, bronchitis, pleurisy, asthma, and diseases of the heart, and that the establishment at Northwood was a sanatorium designed for early cases of phthisis. They expressed the opinion that it would be impracticable to conduct a chest hospital in the proper sense of the term at Northwood, and that the sale of the Hampstead buildings would

almost completely sacrifice the educational value of the hospital, which had been recognized by the University of London as one of the institutions at which candidates for its higher degrees in medicine and surgery might pursue their studies. As an alternative, the medical staff suggested the separation of the two institutions, allowing each to continue under distinct management, Northwood as a sanatorium and Hampstead with the buildings in Fitzroy Square as a chest hospital. Later on the medical staff were informed that the committee of management proposed to ask the governors to approve of such modifications in trusts and by-laws as might be necessary to constitute the establishments at Hampstead and Northwood separate institutions. The medical staff consented to this proposal on certain conditions, the chief of which was that the essential constitution of the Mount Vernon Hospital should remain the same as at present—namely, a hospital for consumption and other diseases of the chest. This plan was approved by the governors at their meeting in March, 1912, and there seems to have been no reason to suppose that it would not be carried into effect until, at a meeting of the committee of management on February 19th, the chairman proposed a resolution to ask the governors at the meeting on March 12th next to instruct the committee of management to sell the Hampstead hospital. At a conference between the medical staff and the committee of management held shortly before this meeting the former had expressed their continued opposition to the sale of the Hampstead hospital. The resolution proposed by the chairman was, however, carried at the committee of management, and it will apparently be submitted to the meeting of governors. The proposal raises certain general questions of importance. As it stands, it would involve the diversion of funds originally provided for a hospital for diseases of the chest of all kinds to the extension and maintenance of a sanatorium for paying patients suffering from consumption. The matter is no doubt complicated by the fact that the State has undertaken to provide treatment, domiciliary, dispensary, and institutional, for insured persons, and proposes to extend the system to the dependants of insured persons, and finally to the whole community. It does not seem probable that the county councils, the bodies to be made financially responsible, will be ready or willing to undertake the treatment of all tuberculous persons unless Parliament makes a special grant, which at present seems improbable. Meanwhile, provision is required for two classes of persons—the poorer uninsured and the middle class of limited means. The policy of restricting the advantages of Northwood sanatorium to persons able to pay 30s. a week is therefore open to criticism. But a more serious objection attaches to the proposal to close the hospital for diseases of the chest at Hampstead. It was not founded for the reception of consumptives alone, and has, we believe, always treated other diseases of the lungs, and also diseases of the heart. Very important additions to our knowledge of the nature and treatment of diseases of the heart have recently been made, some of the most important by members of the staff of the Mount Vernon Hospital. The hospital at Hampstead offers special opportunities for still further advances in methods of diagnosis and treatment, and it may well be hoped that the governors will continue to afford this by maintaining the hospital in its present state of efficiency.

A NEW PHASE OF THE OPIUM QUESTION.

SINCE the commencement of the new year fresh light has come from various sources in regard to the present position of what is known as "the opium question." In a recent debate in the House of Commons it was stated, on behalf of the Government, that a great improvement was taking

place in China in regard to opium smoking and the cultivation of the poppy. The chaos in the outlying provinces which had followed the overthrow of the Manchu dynasty was giving place to energetic suppression of the opium vice by the Republican Government and the uprooting of the poppy. Measures of Draconian severity, ill suited to humanitarian reforms as we conduct them in the West, appear to have been invoked as evidence of the sincerity of the Young China party. Moreover, the Under Secretary for Foreign Affairs stated that "Great Britain was under no obligation to force any definite or indefinite amount of Indian opium into China. The opium trade must have been known by the persons engaged in it to be highly speculative, and they could not expect that this or any other country should secure for them good and profitable bargains." He added, however, that he could make no promise that the Government would release China from her treaty obligations in regard to growing and importing opium. The weak spot in our arrangements with China, made in 1907 and renewed in 1911, is that while we undertake not to send Indian opium into any province which has ceased to produce it, we claim, somewhat paradoxically, that so long as provinces in China continue to grow the poppy themselves so long shall we require them to import opium from India. This policy appears to offend the growing sense of China's autonomy and independence, while the native farmers fail to see why their country should not, at considerable profit to themselves, "support home industries." Again, there has been recently published as a parliamentary paper [Ct. 6605] the "Instructions" which were issued to the British plenipotentiaries at The Hague Opium Conference, held last winter. We now learn that the British Government forbade their delegates to enter into any discussion at the Conference in regard to the arrangements made by His Majesty's Government with China, or as to restudying the treaty obligations regulating the Indo-Chinese opium traffic. It, nevertheless, attached especial importance to the Conference "thoroughly and completely dealing with the restriction of the manufacture, sale, and distribution of morphine and cocaine." We daily read of the spread of the morphine and cocaine habit, and we are glad to see the stress laid upon this aspect of the question, even though it appears from the reports of the Conference that the German Government prevented the articles of the Convention being drawn as strictly as they otherwise might have been in this regard. We cannot help feeling, however, that sooner or later the British Government will have to review their opium agreements with China, and cease to press the obnoxious drug, raised under Government monopoly in India, upon China, whether China grows the poppy herself or not. While this is a matter mainly affecting the two countries concerned there is no reason why the International Convention of 1912 should not be forthwith ratified and put in force. In addition to the twelve Powers which participated in the Conference, eighteen others have since signed the Convention, three have declined to do so, and a few others have not as yet replied. We understand that it is the intention of the Netherlands Government, in accordance with the provisions of the Convention, shortly to invite the Powers which are ready to act to send representatives to The Hague in order that, without further delay, ratification of the Convention and legislation in accordance with its articles may be put in hand, and an international control of opium and the allied drugs be thereby established. In such international action Great Britain would find her hands strengthened and her advice more readily accepted if even at some sacrifice, she could announce to the world that the Indo-Chinese traffic, twice denounced unanimously by the House of Commons to be morally indefensible, were no more.

INTRAMURAL SPREAD OF CANCER OF THE RECTUM.

THERE has been very considerable difference of opinion amongst surgeons regarding the paths of spread of cancer starting in the rectum. The opinions held are not merely academic, since in practice the extent of the operations undertaken for its eradication must be governed by them. It is contended by Harrison Cripps, for example, that the spread in the rectal wall is of no great extent, and that extramural dissemination is a late phenomenon. Sampson Handley made a rather startling contribution to the discussion by demonstrating by means of mucicarmine staining what he considered to be cancer cells in the mucous lymphatics of the rectum for several inches above and below the margins of the malignant growth. So far no adequate support or criticism of these appearances has been brought forward; the observation seemed to be accepted with the reservation that it was a rarity, or the exclusive selection of mucin-secreting cells by mucicarmine was doubted. Miles, in planning his extensive operation for cancer of the rectum, was guided largely by the sites of recurrence following more restricted measures, and, though not definitely disputing the spread of cancer along lymphatics in the rectal wall, laid most stress on its rapid conveyance to the extrarectal glands. The practical outcome is that, in conformity with the ideas of very restricted intramural spread, surgeons of one type remove the growth together with comparatively little free edge on either side of it, and content themselves with a restoration of the bowel by end-to-end anastomosis wherever possible; another type, impressed with the idea of extensive intramural dissemination, would remove a considerable portion of bowel; whilst the third type, in accordance with the observations on rapid extramural involvement, will remove the tissues containing the lymphatic glands and vessels as the primary danger zones—an operative procedure that entails removing also that part of the bowel with which these lymphatic glands and tracts are in intimate relation. In order to get at the real facts of the case too much dependence must not be placed on opinions derived from clinical observations merely nor on *post-mortem* material where the picture is blurred by the advanced changes and the secondary inflammatory processes that ensue thereon. It is only in the case of fairly early conditions, where a large amount of bowel with its surroundings has been removed, that the pathologist can trace the spread of the disease. Mr. Percival Cole has been fortunate in such material. In his paper on intramural spread of rectal carcinoma, published at page 431, he has confined himself to one part of the problem; but we may surmise that the same material can to some extent yield further information regarding extramural dissemination, which he regards as being of greater importance. He concludes, after a thorough histological examination of twenty cases, that the mucous and submucous spread of rectal cancer is very restricted and need not be seriously considered from a practical point of view. The cancer cells spread by the lymphatic vessels radially through the circular muscular coat to deeper plexuses, where they may travel for some distance beyond the superficial extent of the growth. Conveyance of cells in the rectal wall is more extensive in these deep plexuses than in the submucous coat. In one case of colloid cancer with extensive intramural dissemination he was able to demonstrate the fact that the submucous coat was involved secondarily by upgrowths of cells from the deep plexus by way of the radial intramuscular channels. This observation throws doubt on the continuity of the channels of the submucous plexus, and it may quite well be that this plexus is merely the interlacing arborescence of the radial offshoots from the deep plexus. No support is given to Handley's theory of mucous and submucous permeation, and it is thought

improbable that the discrete, well-formed cells which that been observer described—cells which have no histological resemblance to the columnar cells of the rectal epithelium—were disseminated cancer cells. Mr. Cole's conclusion is that intramural spread is of comparatively little clinical importance, and that the finding of post-operative recurrences apparently in the bowel wall is explicable by contact transference or retrograde infiltration of the bowel wall from extramural involvement.

THE STERILIZATION OF DRINKING WATER BY ULTRA-VIOLET RADIATION.

It is generally known that ultra-violet radiation has bactericidal properties, and already it is being applied industrially to the sterilization of urban drinking supplies. Since it was brought forward in its experimental stage at the Competitive Exhibition of Sterilizing Apparatus held at Marseilles in 1910, the system has been adopted by some French towns and has been introduced into India. The results up to date were given by M. de Reeklinghausen at a recent meeting of the Société de Médecine Publique et de Génie Sanitaire.¹ In one important respect the procedure has been modified since the first experiments. Formerly the quartz mercury-vapour lamp, which is the source of the ultra-violet radiation, was completely immersed in the water. Such a method may seem very simple and efficacious, but it has been found that the chilling effect of immersion in running water makes it impossible to maintain the very high temperature necessary if the lamp is to emit a large proportion of ultra-violet radiation. In recent installations the lamp has been placed in close proximity to the water, but is allowed to burn entirely in air; it is stated that a lamp working at 660 watts, burning in air, emits almost ten times as much ultra-violet radiation as a lamp of even slightly greater energy immersed in water. Apparatus has been constructed, therefore, which provides that the water, while passing as close as possible to the lamp, shall be separated from it by an air-space. Another necessary condition is that the water, in the course of its passage round the lamp, shall be violently agitated by means of bafflers, so that the bactericidal radiations may be more effective. It is on these principles that the first apparatus of large capacity has been constructed and installed at Marseilles, in series with the Puech and Chabal system of roughing filters and pre-filters. One form or other of previous filtration, preferably something simple and rapid, is evidently necessary, especially in dealing with the water of rivers, if the best results are to be obtained; it does not greatly reduce the microbial contents of the water, but it gets rid of suspended matter. If this be not done, the bactericidal radiations cannot penetrate properly, for the unfiltered particles form a kind of screen, and under this cover whole colonies of micro-organisms may escape. Another urban installation, capable of sterilizing 500 cubic metres (110,000 gallons) in twenty-four hours, has been at work for the past two years at Marommeles-Rouen, and bacteriological examinations have shown the constancy of its action, even after the lamps have been burning for several thousands of hours. Some of the water at Maromme is bottled, and in spite of this extra risk of contamination its sterility has been maintained. Another waterworks on this principle has been constructed at Isle-sur-Sorgues, near Avignon, and an installation of 600 cubic metres capacity has been set up in India. A similar but quite small apparatus for hospital and domestic use is also described by de Reeklinghausen. This is constructed to sterilize 600 litres (more than 130 gallons) an hour, providing that the water has previously been freed from matter in suspension. No description of this apparatus is given, but from a diagram reproduced with the paper it appears that the prefiltered

water is admitted by an automatic valve carried to the sterilizing apparatus, and made to circulate on three sides of the lamp casing. It is then sent into the reservoir as sterilized drinking supply. One apparatus of this kind, sent out to a regiment in Africa, is reported to be working satisfactorily. In the case of water which is strongly coloured a more powerful sterilizing installation is necessary. De Reeklinghausen states that he and his colleagues have constructed for this purpose special lamps of 3 ampères 500 volts, and that with these the output of ultra-violet is greatly increased. They have also made an apparatus with two of these lamps as a single unit. Together their consumption is 3 kilowatts, and the luminous capacity of the tubes of mercury vapour, which are placed end to end, is about 16,000 candles. The ultra-violet radiation with these 500-volt lamps is estimated to be eleven times greater than that obtainable with the 220-volt lamps hitherto used, although the former necessitate only about double the electrical expenditure. This two-power apparatus, with a capacity to sterilize from 1,600 to 2,000 cubic metres a day, has been used for the water of rivers which, though already filtered, was markedly yellow in colour. Before the passage through the apparatus the microbial content of the water averaged something like 200 bacteria per cubic centimetre; this was reduced to 2.5 after irradiation. The colon bacillus, which was frequently found in the water before its subjection to the sterilizing agent, was eliminated altogether. There remains the question of the cost of sterilization. M. Louis Marnier,² in a paper which is chiefly concerned with the engineering side of the alternative and older system of sterilization by ozone, has compared the two procedures in this respect. According to his figures, the total consumption of electrical energy in the sterilization of 1,000 cubic metres (220,000 gallons) per hour by the ultra-violet method is 69 kilowatt hours, a kilowatt hour being the Board of Trade unit. This includes the energy required for prefiltration and for regulating the water supply, and is based upon experiments with lamps which were not immersed in the water. In order to obtain the same result with immersed lamps, more than 200 kilowatt hours would be necessary. To these figures has to be added the cost of replacing the lamps, for it has been stated that some lamps have lost their bactericidal properties in less than 2,000 hours. This is probably an over-estimate, and later experiments appear to show that the lamps will last very much longer than this before requiring renewal—perhaps five times as long. The other method, that of sterilization by ozone, involves a somewhat large expenditure on plant, and M. Marnier's figures, worked out for several ozone-sterilizing systems, show the cost to be generally greater than that of the mercury-vapour lamp. With the ozone method, also, the water requires some form of preliminary purification, if not the more or less thorough filtration which is necessary in the other case. There are, however, fewer supplementary expenses with ozone, and, taking this into account, the ultimate difference in cost may not be considerable. This is an advantage, as it clears the way for tests based solely on comparative efficiency. Ozone, which for sterilizing purposes is used in concentrations of at least one gram per cubic metre of air, has the drawback of imparting a disagreeable taste, which disappears only after the water has been standing for some time.

SPIROCHAETES IN THE BRAIN IN GENERAL PARALYSIS.

A PAPER published in the *Journal of Experimental Medicine* (February, 1913) makes the striking announcement that Dr. H. Noguchi has succeeded in demonstrating the *Treponema (spirochaeta) pallidum* in the brain of 12 out of 70 cases of general paralysis observed in the

¹ *Revue d'Hygiène*, December, 1912.

² *Ibid.*, January, 1913.

pathological department of the Central Islip State Hospital, New York. His results have been confirmed by Dr. J. W. Moore, who is associated with him in the composition of the paper, as well as by Dr. Flexner, the Director of the Rockefeller Institute for Medical Research, where the microscopical investigations have been carried on. It is proposed to continue the inquiry, in order to ascertain whether by an improved technique *T. pallidum* may not be demonstrated in a higher percentage of cases. Noguchi and Moore point out that Ranke and others have demonstrated the spirochaete in the pia and sheaths of the vessels in the brain in congenital syphilis, and that Dunlap, working in the New York State Psychiatric Institute, had shown the organism in a case of cerebral syphilis. Noguchi and Moore state that in the 12 cases in which they found the organism in the brain the *post-mortem* appearances were definitely those of general paralysis. Ten of the patients were men and 2 were women; 7 were of the cerebral type, and 5 of the tabetic. In 7 cases the date of onset could be satisfactorily ascertained; the longest duration of life was thirty months, and the shortest five months; the average was seventeen months. The majority were therefore much below the average duration, which has been estimated by various authors as from twenty-four to thirty-two months. The ages of the patients varied from 33 to 60 years, the average being 44. The authors consider the question whether their cases may not have been cerebral syphilis in the narrower sense. In reply to this they state that the clinical course showed a diffuse progressive deterioration which agreed with the diagnosis of general paralysis, and that there were no cranial symptoms or other focal manifestations. They consider that the diagnosis must finally depend upon the *post-mortem* appearances, which they hold to be conclusive. The specimens in most of the cases were taken from the first right frontal gyrus, in some from the left hemisphere or gyrus rectus, and were stained by the Levaditi silver method modified to produce an elective stain for *T. pallidum*. The spirochaetes were found in all layers of the cortex with the exception of the outer, or neuroglia layer. A few were found sub-cortically; none were found in the pia. In all instances they seemed to have wandered into the nerve tissue; they were not found in the sheaths of the vessels, and seldom in close proximity to the larger vessels. There seemed to be no ratio between the number of spirochaetes and the severity of the paresis, though in the case in which they were most numerous the parietic changes were very marked. The relatively short duration of the disease in the cases in which the organism was found leads them to suggest that it may be easier to find it in those which run a fairly rapid course.

THE INDIA OFFICE MEDICAL BOARD.

SIR ARTHUR BRANFOT, K.C.I.E., President of the India Office Medical Board, hands over charge of that office to the second member, Sir Richard Havelock Charles, G.C.V.O., on February 28th. Lieutenant-Colonel John Anderson, C.I.E., late Civil Surgeon of Lucknow, joins the Board as junior member. In its present form this Board has existed for nearly half a century, but in a somewhat different shape for nearly a century longer. In 1773 the Court of Directors appointed a board in London to examine candidates for their service. The names of the members do not seem to have survived. The *Gentleman's Magazine* for July, 1793, records the death in London, at the age of 77, of George Marlen, of Limehouse, for many years examining surgeon of the East India Company. Drs. Lorimer and Hunter were appointed in his place. Dr. Lorimer seems to have died soon afterwards. John Hunter served alone till his death on January 29th, 1809. Though completely overshadowed by his much greater

contemporary and namesake, Hunter was a man of some note in his day. In early life (1781-3) he had served in the Army Medical Department in the West Indies. Hunter's successor was William Dick, who had served in the Bengal Medical Service from 1781 to 1802, most of that time as Superintendent and owner of the Calcutta Lunatic Asylum. Dick resigned in 1818, and died in Scotland on January 16th, 1821. In 1815 William Frederick Chambers was appointed Assistant to Dick, and succeeded him in 1818. Chambers was Physician to St. George's Hospital. He resigned in 1835, under the pressure of excess of work, as one of the leading consulting physicians in London. In 1836 he was appointed Physician-in-Ordinary to the King, William IV; he was appointed in the same capacity to Queen Victoria on her accession in 1837, and in the same year received the Knighthood of Hanover. He died at Lynnington, aged 69, on December 17th, 1855. Chambers was succeeded by another ex-army medical officer, John Robert Hume, who had served in the Peninsula, and settled in practice in London after peace was declared in 1815. He was Physician to the Duke of Wellington, and a Commissioner in Lunacy. He resigned in 1845, and died in London on March 1st, 1857. On Hume's retirement two of the most distinguished officers on the retired list of the I.M.S., Sir James Annesley and Dr. (afterwards Sir) James Ranald Martin, were candidates for the appointment. The Chairman of the Court, by a small majority, carried the appointment of Dr. John Scott, his own medical attendant, a medical man practising at Barnes, who had served in early life as surgeon of the Indiaman *Farquharson*. Scott saw out the company; he held office till his death, from angina, on January 18th, 1859. On Scott's death Sir James Ranald Martin was appointed "Physician to the Secretary of State for India in Council." The Medical Board was established on October 31st, 1864, Martin being given the rank of Inspector-General as its President. He resigned on November 17th, 1874, and died ten days later. Martin was succeeded by Sir Joseph Fayrer, who had been junior member of the Board for the two preceding years. Fayrer held office for just twenty years, vacating on January 12th, 1895. Sir William Hooper succeeded Fayrer, and was in turn succeeded towards the end of 1903 by Sir Arthur Branfoot. The Board, as constituted in 1864, consisted of three members, the third being an officer of the A.M.D. This third member was dropped in 1873. The place of second member was usually filled by an I.M.S. officer on furlough, up to about 1889, since that time by one on the retired list. Many of the most distinguished officers of the I.M.S. have, from time to time, filled the post of second member. The first was J. W. Mudge (1864-6); others are W. Thom, S. B. Partridge, J. Ewart, H. Cayley, K. McLeod, E. F. Drake-Brockman, A. Crombie, and A. J. Willcocks. The A.M.D. officers who successively acted as third member were D. R. Mackinnon, W. K. Swettenham, and T. G. FitzGerald.

THE Paris Academy of Medicine, at a recent meeting, elected Dr. A. Carrel, of the Rockefeller Institute for Medical Research in New York, formerly of Lyons, and M. Arnozan, Professor of Clinical Medicine, to be corresponding members.

THE Morison Lectures before the Royal College of Physicians of Edinburgh will be given by Dr. G. M. Robertson, physician-superintendent of the Royal Asylum, Morningside, and lecturer on mental diseases in the University of Edinburgh, on March 10th, 12th, and 14th at 5 p.m. on each day. The lectures will discuss recent observations relating to general paralysis of the insane. The first lecture will deal with the new reactions and signs, the second with early diagnosis, and the third with etiology, prophylaxis, and treatment.

Scotland.

FROM OUR SPECIAL CORRESPONDENTS.]

ROYAL EDINBURGH ASYLUM.

The Hundredth Annual Report.

THE hundredth annual report (that for the year 1912) was read by Dr. George M. Robertson, the Physician Superintendent, at the statutory annual meeting on February 24th, 1913, when the Right Hon. the Lord Provost was in the chair.

GENERAL STATISTICS.

On January 1st there were 753 patients on the register, on December 31st the number was 784. The total number of inmates had been stationary for the previous four years, and as low as 743 at the end of the year 1907. The admissions in 1912 numbered 222, the discharges 129, and the deaths 62. The admissions were 43 more than in the previous year. Both Craig House and the West House shared in this increase, and the number of admissions to the former has only once been exceeded during the last ten years.

MELANCHOLIA.

Of the forms of insanity admitted, melancholia, as usual, was the most prevalent, and accounted for a quarter of the admissions. Its symptoms resembled and were a caricature of those of natural anxiety or despondency, the direct result of depressing causes, such as loss of friends or reverses of fortune. It differed from natural melancholy in not being a reaction to any external cause affecting the feelings, but the result of internal disorder of the brain. Mania and melancholia—or morbid elation and depression—were alternative manifestations of the same disease process, and were often associated.

ALCOHOLIC INSANITY.

Among the exciting causes of insanity, alcoholic excess, as in former years, headed the list, but the proportion of alcoholic insanity was less than usual, being only 11.2 per cent. of the total. During 1908, 1909, and 1910 the proportion of alcoholic insanity among women appeared to be steadily increasing. During the last two years the figures showed a decrease, but as the major amount of this insanity was preventable the doctrine of temperance still required to be preached.

GENERAL PARALYSIS.

The number of patients admitted with general paralysis of the insane was 24, of whom only one was a woman; the diagnosis in every case was confirmed by the Wassermann reaction and the other laboratory tests. As there were 107 admissions of men, 21.5 per cent., or over 1 in 5, of the male cases suffered from this disease. The average admission-rate for the last five years was over 19 per cent., as compared with 16.4 per cent. for the whole of England, and it must be remembered that nearly a third of the cases were not sent to institutions. A great deal of attention was directed annually to alcoholic insanity, which amounted to only 17.6 per cent. of the admissions, and was therefore less frequent in the male sex in the district than was general paralysis. While alcoholic insanity was usually recovered from on the removal of the cause, the cure of general paralysis had baffled all efforts, and the disease was fatal in two or three years' time. Of the 31 men who died during 1912 the cause in 14, or 45 per cent., was general paralysis; the average rate for the last five years was 40 per cent. Dr. Robertson concluded this part of his report with the following observations:

These statistics reveal a state of affairs that calls urgently for public attention, and only because the subject has certain aspects that require delicate handling has reference to it been avoided in the past. I, however, feel it a duty incumbent on me to do so now, not only from my position, which enables me to see the extent of the evil, but also because the incidence of this disease in this area is probably not exceeded elsewhere in Scotland. It is also a disease which there is good reason for believing is now within the power of medical science to avert, if it is not able to cure it. Large numbers of soldiers used in the past to fall victims to it, but medical treatment in the Army has become so thorough and scientific that, after

twelve or fifteen years, this profession will probably cease to supply its proportion of cases. Can something of the same kind not be done for men in the civil population? They would no doubt require to be educated to a sense of their dangers, and the value of early treatment, by short addresses or printed warnings in their workshops. The insurance or some other public authority would require to make provision for treatment, which would not be difficult or expensive owing to the short time now required, and the medical profession should be given the power of exercising more pressure than at present for insisting upon treatment till a cure be obtained. If these measures were successful, in fifteen years not only general paralysis, but a host of serious maladies, would decrease enormously in number. The old policy of merely ignoring the existence of these ills is now inexcusable and something must be done.

DISCHARGES.

Fifty-eight patients were discharged as recovered and 71 as unrecovered. The recovery-rate during 1912 was 26 per cent. of the total number of admissions. The lowness of the rate was partly accounted for by the large number of senile cases, no fewer than 18 being over 70 years of age. The average age of the admissions during the last four years was 43 years, whereas in 1912 it rose to 45.

DEATHS.

The total number of deaths was 62 (8.2 per cent. of the average number resident). This was the lowest death-rate recorded for over twenty years with the exception of 1910; the general health of the population has been very satisfactory. Sixteen of the deaths were due to general paralysis, and 16 were of persons over 70 years of age; these two groups thus accounted for 32 out of a total of 62 deaths. Among the deaths were those of two nonagenarians who had both been many years in the institution.

TUBERCULOSIS.

There were only 6 deaths (5 women) due to pulmonary phthisis; 3 of the cases were diagnosed on admission and 1 died within a fortnight. Of the other 3, 1 was known to have been affected for five years; a second was probably infected by her father, and the third was a female drunkard; alcoholism, by lowering the bodily health and weakening the powers of defence, was an important factor in the development of phthisis. The statistics showed a very satisfactory state of affairs as regards this disease, which was so prevalent at one time.

ARTIFICIAL OR TUBE FEEDING.

Under this head, Dr. Robertson's report contained the following passages:

New Attitude of Public.

It is a new experience for us to find the proper treatment of our patients hampered by political questions, as we do now, with regard to the artificial feeding of patients who refuse their food. During the course of the last eighteen months I have on several occasions found the friends of patients, as a result of what had appeared in the press on the subject, manifestly offering resistance to this most necessary and humane procedure, and they have had to be won over by persuasion and argument. I have met relatives prepared to allow the patient to starve, and probably die, rather than to be fed, although this feeding might not be necessary for a few days. I have known of cases where the patients were not fed, and have died.

Asylum Physicians Perplexed and Astonished.

It has been a source of perplexity and astonishment to all engaged in the treatment of the insane to learn that artificial feeding by means of a tube should be regarded as torture or dangerous. It is true it is unpleasant, and causes a tendency to retch, with transient sensations of choking, and on the first two or three occasions it may be accompanied by feelings of alarm, but it is certainly not painful in the ordinary sense. With regard to danger, it cannot be said to be entirely free from it, but neither can, for that matter, the everyday act of swallowing food in the weak. If the operation is done with the exercise of ordinary care and skill upon a person not suffering from an alarming degree of weakness, there is no practical danger. I have probably performed the operation, as

an assistant medical officer chiefly, over 2,000 times, and I have never seen evil results in any of those cases, but the reverse. Patients have been fed in mental hospitals in this way, for years at a time without ill health, but special attention has to be paid to the ingredients of the food in these prolonged cases. It must include, beside the staple articles of milk and eggs, the juice of vegetables and of fruit such as oranges, and it is usual, too, to add, if desirable, stimulants and medicines.

Why do Suffragettes Suffer?

During 1912 more than a fourth (66 out of 240) of the suffrage prisoners in England were liberated for reasons of ill health, which, with few exceptions, was due, wholly or in part, to their refusal to take food. I concluded at one time that the process of artificial feeding must have been resorted to in these cases much too late, when the strength had already failed from want of nourishment, for I find this is the mistake the inexperienced most commonly fall into in treating the insane, and I warn my students of this danger.

Is Feeding Adopted Too Late?

We are all more inclined to defer feeding too long than to begin too soon, but it is safer to err the other way. I now understand that what differentiates "the hunger-striker" from the insane person who refuses food, and is an important factor in the injury to health she occasionally sustains, is the purposeful and violent way she resists and struggles until utterly exhausted. After she is fed, she voluntarily ejects the meal. The patient, on the other hand, is frequently confused and even apathetic, and may be a mere passive resister, or else is intelligent enough to realize that whatever he may do, he will be fed in the end. He is also aware that no unnecessary inconvenience or indignity will be offered to him in the process to which he quickly becomes accustomed. It is probably not so much the feeding as the struggling that injures "the hunger-striker," and if she struggled to the same extent on an empty stomach in having her face washed, or her clothes put on, the consequences might be similar.

Persuasion and Tact.

No patient is ever fed without being first offered his food in the ordinary way, and until every form of persuasion has been tried in vain. He is sometimes left alone in a room with his food, or it is offered to him by some one he is friendly with, or he is coaxed by a member of the opposite sex. Lately one of our intelligent patients as a protest actually went on hunger strike in the most approved manner. As he was in good health he was allowed to starve himself for a couple of days, then the nurse of the ward arranged with the attendant, under whose constant personal supervision he was, to turn his back on him for a moment. She induced another patient to seize this opportunity of slipping a slice of bread, as if surreptitiously, under the bed-clothes of the hunger-striker. This pantomime was repeated daily, and he sustained himself on this simple menu for several days longer, till it dawned upon him, from the indifference of the officials, that they knew more about his secret supplies than he had imagined. Realizing at length that he had been circumvented, he began to eat his meals. A gentleman at Craig House last December, obeying the commands of imaginary voices, also refused his food, and had to be fed for nearly a week. On the morning of the 25th he was still obdurate; but at dinner time a slice of roast turkey, a glass of champagne, and the sight of every one else enjoying Christmas fare, supplied just the stimulus that was needed, and he himself set to with right good will, and he has continued to take his food ever since. Human nature is much the same in a mental hospital as out of it, and he who understands it best makes the most successful physician or nurse. It is hoped that these simple statements and illustrations will enable all reasonable people to see in its true light what I have already called a most necessary and a humane procedure under certain conditions, and how we meet difficulties as they arise.

PELLAGRA.

Dr. Robertson related the following case, which he said did not actually take place last year, but reflected credit on the accuracy of the medical work:

A young woman from Shetland was admitted to the West House, suffering from delusions and indefinite bodily symptoms, which were suggestive of general paralysis of the insane. Because of the incomplete picture she presented of this disease, the case was very minutely studied in every way, but its exact nature remained an unsolved problem. In this state of doubt we invited a specialist in skin diseases to report upon the symmetrical brownish-red inflammation of the back of the hands and face resembling sunburn that she suffered from. Dr. Low had the good fortune to have previously seen some casts illustrating pellagra, and he was of opinion that the eruption on this woman's hands resembled it. All the other symptoms were confirmatory of this opinion, and on reviewing the case in the light of this suggestion there was no doubt whatever that it was a typical one of pellagrous insanity, from which the patient died.

This case was the only example of undoubted pellagra then known to have occurred in this country during a period of forty-five years. Only one other undoubted case had been reported; this was described in 1866 by the late Dr. Howden, of the Montrose Royal Asylum. Since, however, Dr. Dods Brown and Dr. Cranston Low published a record of this case and attracted attention to the disease, other cases had been found.

THE CENTENARY OF THE OPENING.

The institution was opened for the reception of patients on July 9th, 1813. The proposal for its establishment was originally made twenty-one years previously by the President of the Royal College of Physicians, and its object was to provide for the care by members of the Royal Colleges of Physicians and Surgeons of insane persons who were still in a recoverable state. The rich were to be charged, and the poor were to be maintained gratuitously. The Lord Provost of the city and others holding high official positions agreed, at the suggestion of the Royal College of Physicians, to form themselves into a body of trustees to carry this scheme into operation, and regulations for the management of the institution were subsequently adopted after they had been submitted to every member of the College of Physicians and Surgeons for suggestions. The institution was thus launched under the most favourable auspices, both medical and lay, and from the beginning it aimed at being national in character.

THE MEDICAL STAFF.

The University of Edinburgh last year created a Diploma of Psychiatry open to graduates, and facilities were therefore given to the assistant physicians in the institution to attend the necessary courses of instruction; Dr. Dods Brown was one of the first to obtain this diploma, the possession of which Dr. Robertson expected would in course of time be essential for all applicants for the medical posts. In connexion with this diploma a post-graduate clinical lecture was given every Thursday forenoon at the West House. This was conducted by Dr. Robertson with the assistance of the medical officers, Dr. Donald Ross and Dr. Maxwell Ross. The well-equipped laboratory also, under the immediate charge of Dr. Muirhead, was a stimulus to scientific study, as well as of great practical assistance in the clinical examinations and treatment of patients. In addition to this routine clinical work, original researches were carried on. One of these, done conjointly by Dr. Henderson and Dr. Muirhead, on the different forms of cells found in the cerebro spinal fluid in disease, would have obtained on its merits the bronze medal granted by the Medicò-Psychological Association but for a technicality.

Dr. D. K. Henderson resigned his appointment here on being appointed chief of the Psychiatric Clinic (Phipps Institute) of Johns Hopkins Hospital, Baltimore, and was succeeded by Dr. Maxwell Ross, who had just served a term as Resident Physician in that hospital and in the Royal Edinburgh Infirmary.

Various points connected with the nursing staff were referred to—the Insurance Act, one day of rest in seven, the training of nurses, the hospital features of the Scottish asylums, and certain pension anomalies in Scotland.

DINNER OF THE ROYAL MEDICAL SOCIETY.

The annual dinner of the Royal Medical Society of Edinburgh took place on February 11th, in the hall of the society in Melbourne Place. The guest of the evening was Mr. W. Arbuthnot Lane, F.R.C.S., of London, and there was a distinguished company, including the

Moderator of the General Assembly of the Church of Scotland, the President of the Royal College of Surgeons, the Master of the Merchant Company, the President of the Royal College of Physicians, the Deans of the Faculties of Divinity, Arts, and Law, the superintendent of the Royal Infirmary, and the President of the Royal Faculty of Physicians and Surgeons of Glasgow. The Senior President of the Society (Dr. Murray Lyon) was in the chair, and in proposing the health of "The Guest" spoke of Mr. Arbutnot Lane's many and varied contributions to literature. Mr. Lane replied, and in proposing "The Royal Medical Society," said that the society was as good as it was old; he then touched upon medical education, saying that no men got a better medical education than they in Great Britain, but they must not stop there, they must go on. He had been visiting America, and he thought the Americans were leaving us behind, simply because they put their money into what they called travel, and went and saw the best men operate and practise.

INDIAN MEDICAL SERVICE DINNER.

We are requested to intimate that the Edinburgh Indian Medical Service dinner will be held in the United Service Club there on Friday, May 30th. Sir Alexander Christison, Bart., will preside. Any further information can be obtained from Colonel James Arnott, I.M.S. (ret.), 8, Rothesay Place, Edinburgh.

EDINBURGH NEW TOWN DISPENSARY.

At the annual meeting of the managers and subscribers of the New Town Dispensary—the N.T.D. as it has been called for many years—which was held on February 19th, it was shown that there was an increase in the number of patients over the number in previous years, and that the subscriptions had been rather smaller. Sympathetic reference was made to the death of Dr. George A. Gibson, who had been consulting physician for the past two years. In reply to a question as to the effect of the Insurance Act upon the attendance of patients, it was stated that in the first month there had been a diminution in the ordinary attendances of about 30 per cent., whilst the applications for attendance at confinement had increased in about the same proportion.

HYGIENE OF THE ABATTOIR.

The hygiene of the abattoir is not yet all that it might be, and it is admitted that the methods of slaughtering are far from perfect. The poleaxe, for instance, in the hands of a weak or nervous person may be the cause of much needless suffering. There was therefore a good deal of interest taken in the demonstration given at the Gorgie abattoir on February 20th, when the Royal Society for the Prevention of Cruelty to Animals invited members of the Town Council of Edinburgh and of the Meat Trade Association to witness the use of the compressed-air killer and the captive bolt pistol in slaughtering. The experiments were made on oxen, sheep, and pigs; and, whilst the new means of killing the animals were at any rate as speedy as the knife in the case of the sheep and pigs, they could hardly (from the tests made) be regarded as so satisfactory as the poleaxe in the case of the bullocks: in fact, in two out of four bullocks experimented upon the poleaxe was needed to kill after the animals had been shot.

Ireland.

[FROM OUR SPECIAL CORRESPONDENTS.]

PREVENTION OF INFANTILE MORTALITY.

The report presented to the annual meeting of the Dublin Committee for the Prevention of Infantile Mortality stated that 200 ladies were working as voluntary health visitors, under the auspices of the committee, and that during the year 22,500 visits had been paid by those visitors to mothers and their children. As there were no paid officials, all the money subscribed was spent on the poor. The Chairman said that the majority of the lady members of the society did not belong to what was known as the leisured class. They were workers who had only a few leisure hours in the evening, which they might justly claim for themselves, but which they gave up to save the lives of children.

TREATMENT OF TUBERCULOSIS.

At a special meeting of the Sligo County Council it was decided to adopt Part I of the sanatorium benefits under the Insurance Act, and to appoint a tuberculosis officer at a salary of £450 a year, with an additional allowance of £50 a year travelling expenses. Several members were against taking advantage of the beds offered by the Women's National Health Association, and it was decided to postpone further consideration of this part of the scheme, the secretary being instructed to obtain particulars from the Galway County Council as to the beds available under their scheme.

At a special meeting of the Queen's County County Council a letter was received from the Local Government Board approving of the site of the late sanatorium, which was burnt, in the grounds of the Queen's County Infirmary, as the site for a new sanatorium to be erected for the treatment of tuberculosis in the county, provided the council proceeded without delay to appoint an architect and instruct him to prepare plans and specifications for a tuberculosis dispensary and sanatorium suitable for the requirements of the county.

SOUTH CHARITABLE INFIRMARY AND COUNTY HOSPITAL, CORK.

The annual report of the South Infirmary states that 594 patients were treated in the medical wards during the year 1912, being 16 more than in the year 1911. A large number of these cases were of a very serious character, and hence entailed considerable care and responsibility in both the medical and nursing staffs. Into the surgical wards 769 cases were admitted, being an increase of 82 over 1911. The majority of these being serious cases of surgical disease or accident, necessitated the large number of 423 major operations, an increase of nearly 100 operations over the previous year. The daily average of intern patients was 83.9, being an increase of 3.7 over the previous year. In the extern departments there were 3,759 cases (an increase of 78), and a total number of attendances of 14,186. The new extern medical department, it is considered, has been of great service to the hospital. The dental department has steadily increased in its usefulness, and further developments are looked forward to in that department. Reference was made in the Treasurer's report to the arrangements to be made for the reception of patients under the Insurance Act. The City and County Insurance Committees had applied for terms for the treatment of surgical tuberculous cases, and it had been decided to fix the rate weekly at 17s. 6d. a patient, including maintenance and surgical treatment, but this has not been acted upon yet, owing to the desire of the Cork Medical Committee to deal directly with the Insurance Commissioners. Pending a settlement of terms, patients are receiving the surgical benefit of the infirmary as heretofore.

A HOUSING SCHEME.

The Council of the Urban District of Pembroke, near Dublin, has applied for a loan of £66,950, under the Housing of the Working Classes Acts, for the purpose of erecting working-class lodging-houses. At an inquiry now being held into the matter by the Local Government Board, Dr. Denham, who up to last year was M.O.H. for the district, said in his evidence that he had condemned 220 houses, and that many of these were over 200 years old and very insanitary. Another witness stated that 22 persons were occupying a four-roomed house, and another corner house accommodated 38 persons. Seven, eight, nine, and even ten families occupied houses with small, low, dirty rooms, unfit for more than two or three people. Dr. Cremen, the present M.O.H., stated that some houses were most insanitary, and consumption as a consequence was prevalent. In one house there were three persons suffering from consumption, including the father, and with three healthy members occupied one room day and night; the only window was small, with a northern aspect, and the result was that there was no ventilation and no sunshine. In another house in the same locality the mother was dying from consumption, and there were six children who had to occupy the same room. Dr. Burke, M.O.H. Donnybrook No. 2 District, mentioned one locality where, out of eighteen houses, all but one were beyond repair. Closing orders had been refused, for there were no other places for them to

occupy. From this and other evidence given it would appear that there is an urgent need for the erection of the proposed new cottages, and that there would be no difficulty in finding tenants even at somewhat higher rents than are paid at present.

OUTBREAK OF TYPHOID FEVER IN NEWRY.

For the last fortnight there has been a serious epidemic of typhoid fever in Newry, and several cases have been admitted to the infirmary, some of which have had a fatal termination. The urban council has therefore decided to appoint Professor Wilson of Belfast to inquire into the cause of this outbreak and to inspect the sources of the town water supply at Camlough Lake, including the surroundings of the lake, as well as the pipe line to the town.

England and Wales.

[FROM OUR SPECIAL CORRESPONDENTS.]

MANCHESTER AND DISTRICT.

TREATMENT OF TUBERCULOSIS IN MANCHESTER.

THE scheme of the Manchester Sanitary Committee for the treatment and prevention of tuberculosis, which has already been described in the JOURNAL, was laid before the City Council on February 19th for final consideration. The deputy chairman of the Sanitary Committee showed how the scheme was really an attempt to co-ordinate existing agencies and institutions. Fever cases were to be transferred from Baguley to Monsall, the former institution being reserved entirely for cases of tuberculosis, and when the extensions proposed were carried out there would be accommodation at Bagniey for 300 beds. These would be mainly for advanced cases, though early cases might also be accommodated. The provision for early cases would be mainly at the Crossley Sanatorium, where 62 beds would be available, and at the Abergale Sanatorium, where 50 beds were provided. There would thus be a total of 412 beds available for early and advanced cases. It was estimated that the net charge on the rates would be about £4,300 a year, but against this cost to the city should be set the saving to the Poor Law authorities which was estimated at £15,574 a year. Several members of the council urged that the root of the evil was the poverty of the people and their inability to provide themselves with good habitations and healthful surroundings, and the chairman of the Education Committee hoped that the Government would do more to arrest consumption in children of school age. The scheme was then adopted finally by the council.

LONDON.

COUNTY COUNCIL ELECTION.

WE have received the following letter with reference to the general County Council election in London, which takes place on Thursday next, March 6th:

Sir,—The London Medical Committee are anxious to assist in securing the return of certain candidates in each constituency at the approaching London County Council election. The present position of the profession is partly due to the slight value attached to the votes of medical men, which, even if unanimous, would seldom affect the result of an election. If, however, the profession enter with enthusiasm into the campaign outlined below, it would be difficult to over-estimate the services it can render. The value of its support or opposition would become proportionally enhanced, and its power of determining the conditions of service laid down under any amending Act increased.

It is suggested that every day during the contest, in such spare time as they may have, medical men should attend one of the Local Committee Rooms opened by candidates in the different districts of each constituency where their services will be gladly accepted, and on the day of the poll lend, if possible, a motor car, or other private conveyance, and that they should induce relatives, friends, and patients to give their services, and lend cars or carriages.

The ultimate object is to secure (1) improved conditions of service, and (2) medical control; the first to

render it possible, and the second to render it imperative, that every man shall do his duty to the State, his patient, and himself. It should appeal to all who have been compelled to go on the panel, and who have at heart the welfare of the poor and the honour of the profession.

Yours faithfully,
M. MACNAUGHTON-JONES, jun.
521, Finchley Road, N.W.

BUDAPEST.

Politics and Antialcoholism.—Actan for Household Use.—The "Single Child."—The Geographical Distribution of Lithiasis.

No propaganda has ever helped the case of antialcoholism in Hungary in such a measure as the present political conditions. Nominally the General Votes Bill did not meet in its present form with the approval of the Social Democratic party. They therefore resolved to respond with a general strike, but the working class could not be easily driven into a strike, as their condition is at present terribly hard, owing to scarcity of money and general trade depression. The leaders, therefore, had to find out another way of embarrassing the Government. The word went round, "Drink no alcohol. Let us weaken the Treasury, and through it the Government, by curtailing the income from spirits." A litre of pure spirit is sold here for about two crowns, or 1s. 10d., but of which one crown goes to the tax office. Against 16,597 grammar schools, only 12,336 of which are maintained by the State, there are 66,200 brandy shops in the country. The working class spends 18 per cent. of its earnings on spirits; but without doubt it has listened to its apostles and drinks considerably less spirits than formerly. Thus, whatever may be the motives of the Social Democratic leaders, the result of their tactics will be beneficial to the people by moderating the consumption of alcohol.

A Budapest druggist has found out a method by which formic acid can be distilled and refined so as to fit it for household use, in a greatly diluted form. The lay papers have expressed surprise, pointing out the poisonous nature of formic acid. The Royal Public Analyst, however, explained last week that the formic acid which is contained in the actan, acts as acetic acid. If the latter is not detrimental, then actan is not so; indeed, he declares actan is used for household purposes much more greatly diluted than acetic acid, so that its poisonous effect is less. The same opinion was declared also by Professor Kéty.

The Hungarian Child Study Society has started a widespread movement for collecting data relating to the "single child" system. The collecting had mainly been done by Dr. László Nógrády, who lectured on this subject on February 10th. Until recently it had been thought that the system was a purely economical question. People did not want to distribute the lands between several children, but it had grown into a custom independent of land questions. It was quite clear that the "single-child" family did not get richer; on the contrary, it grew poorer. The "single-child" generation did not like to work; it tended to become idle and self-indulgent. Then, if landed proprietors, their farms were worked by others, to whom heavy wages must be paid with ruinous results. The single farmers already understood that the "single" system meant their ruin, and still they did not endeavour to reform because it had become a custom and the people were very conservative. The man who would alter this state by begetting several children was despised and cast out from his class. The other reason for the "single" system was female vanity. Women thought that they would remain young for a longer time and enjoy life. The spread of the system was aided by the assistance of midwives and quacks, and, unfortunately, of doctors as well. The spread of the system was further promoted by unconscientious agents who sold preventives, and by offensive advertisements in the press. The only child was spoilt by his parents, and too often enters early into a career of dissipation, the result being rapid physical and mental deterioration. Such a system must ultimately ruin the whole people.

Dr. Paul Steiner, Lecturer to the Kolozsvár University, seeks for statistics of vesical calculi in adults in different parts of the country. He has forwarded circulars to every practitioner asking them to report all cases under their observation. Similar statistical researches were made three years ago by Professor Bókay Tanos, paediatrist, who found that inhabitants of the more remote parts of the country—namely, the districts lying between the rivers Danube and Theiss—are more often attacked with vesical calculi than those in other parts of the country.

Correspondence.

IMMEDIATE OPERATION IN APPENDICITIS.

SIR.—We must all agree with what Dr. J. W. Hunt says in his interesting letter (p. 414), where he touches on a point of very great importance to general practitioners in suburbs which have for the past ten or fifteen years been deteriorating in the financial ability of their residents to pay large operating fees. It is true that some of the "coming" men are reluctant to accept, largely, no doubt, from a praiseworthy regard for the dignity of their position, smaller fees than the men who have "arrived"; but I have personally received from both classes so much consideration, which I hope I have not abused, that it is only common gratitude to say that I have never found any difficulty in obtaining the very best surgical assistance at nominal fees, or even at no fee at all, when circumstances justified such generosity. Dr. Hunt is confessedly in a similarly fortunate position, as those of us who hold him in affectionate respect can well believe. Others no doubt have had the same happy experience of capable surgeons, and immediate operation need not be foregone for want of asking a favour. After all, it is just possible that "what is lost on the swings is made up on the roundabouts."—I am, etc.,

London, N., Feb. 24th.

WILLIAM WHITELEW.

SIR.—The unanimity in the surgical discussion on Mr. Edmund Owen's eloquent address speaks for itself. All are agreed that immediate operation is the only course "as soon as the diagnosis of an inflamed appendix has been made." Early diagnosis is the indispensable means to that desirable result. It did not come in for special consideration, but it remains the essentially debatable question, upon which it might be worth while holding a debate for the benefit and the participation of the larger section of medical practice. Two practical suggestions were impressed upon us: one of them, with an emphasis which it is not for me to challenge, "to avoid calling in a physician"; the other, with which there could not possibly be any disagreement, "to immediately call in one or two of our surgeons," for they are the best judges. We are proud of them, not only for the excellence of their technique so admirably taught at our schools, but for their diagnostic insight acquired by personal experience. That that feeling should not be reciprocated is an argument in favour of further study on the part of our physicians, as they are likely to be still wanted for a while in a teaching capacity in connexion with so eminently medical a department as that of the abdominal ailments. The variety of our "suspicious" symptoms is such as to justify a practical rule "to watch for appendicitis always, and to examine for it as a clinical routine," just as we test all our cases for any latent renal trouble. That duty should not be delegated, but specially cultivated by practitioners and physicians, lest our diagnostic skill should decay from too exclusive a reliance upon the surgeon's brilliant diagnosis at first sight, or upon his exploratory incision. Our individual efficiency would gain much, and some progress might eventually be made in the art of diagnosis, and in the thoroughness of clinical investigation in any direction open for improvement. This would also be the best means of promoting earliness of surgical examination and treatment, as the beginnings of appendicitis occur almost invariably within the medical sphere of observation.

The number of "suspected" cases being much larger than of those to be identified by the current methods, it is inevitable, as Mr. Edmund Owen does not hesitate to

admit, that the immediate attendance of the surgeon should sometimes fail to bring the actual diagnosis, and that delay should have to be incurred for further indications. In any cases of that sort that delay might be saved if by more searching methods positive evidence were obtainable of the existence of some local trouble in the region of the appendix. The neglect of any genuine facilities available for that purpose could not be readily justified. On the other hand, immediate attendance will always bring due regard for the possibility that any vague initial symptoms might be due to appendicitis, and a suggestion that a surgical exploration is the only safeguard against the unknown risks. It is apparent, then, that the rule "to operate immediately for appendicitis" has a strong tendency to become a rule "to operate immediately for suspected appendicitis." It might be well to face that new situation squarely, and to give to the subject of "suspected appendicitis, its diagnosis and its operative indications," the exhaustive consideration which it deserves. Nothing but good could result from focussing the inquiry upon the point of genuine difficulty. The surgeon's plea for immediate action could then be established upon its most legitimate and inclusive basis.—I am, etc.,

London, W., Feb. 24th.

WILLIAM EWART.

SIR.—I have just completed twenty years' experience in operating upon appendicitis, and am, like Dr. Binnie and many others in America, and Sir George Beatson, more especially, in this country, not in the present—perhaps passing—fashion.

I have not lost a single case where, in my judgement, it was necessary to try and get the patient out of his attack of appendicitis into a state of quiescence, or, to use a local phrase, which well expresses my meaning, "drydock him for repairs."

It seems to me that the policy "Look and see" is one to be deprecated, because it will inevitably lead to further carelessness in the correlation of the value of symptoms of the disease and of the general condition of the patient.

We are all agreed that definite appendicitis is a surgical disease for several hours after its onset, but later on, except where evidence of pus is present, it is, I think, a condition which requires the greatest vigilance, the strictest observance of proper non-surgical treatment, to bring it into a state whereby the offending appendix can be removed with no risk except that of the anaesthetic.—I am, etc.,

Cardiff, Feb. 25th.

J. LYNN THOMAS, C.B., F.R.C.S.

OPERATIONS ON CHILDREN IN THE OUT-PATIENT DEPARTMENT.

SIR.—After a large experience of out-patient work in a children's hospital, I thoroughly endorse the views held by Mr. Nicoll on the above subject, as expressed in the BRITISH MEDICAL JOURNAL of February 22nd, and at the Belfast meeting of the British Medical Association in 1909. I happened to be one of the secretaries of the Section of Diseases of Children at that meeting, and I ventured to doubt the expediency of operating on hernia in the out-patient department, chiefly on the ground of one's position in case of any accident. So convinced was I, however, by Mr. Nicoll's results that I immediately began to add hernia and hydrocele to the list of my out-patient operations, and my colleagues followed the same course. Since then we have enormously extended our scope, and personally I have no hesitation in operating on hare-lip, some cases of cleft palate, knock-knee and bow-leg in children about 4 or 5 years of age, enlarged tonsils, which I often enucleate entirely, adenoids, naevi, tuberculous joints in the upper extremity, glands, tumours and cysts in the neck, and many other conditions requiring surgical interference. A few weeks ago I removed in the out-patient theatre an occipital meningocele in an infant a few days old with an entirely successful result. In this way numbers of children are relieved who could not otherwise have been properly treated on account of shortness of beds and lack of funds. The results have borne very favourable comparison with those obtained in the wards, and the utility of the hospital has been very greatly increased.

If a child can be carried to hospital, and if the operation wound can be so sealed or covered as to avoid accidental

contamination, I see no reason why most of the operations necessary in children should not be performed in the out-patient department. This practice also avoids the necessity of weaning children who are thriving at the breast and whose mothers may be loth to part with them at such an early age.

The results of this practice at the Belfast Hospital for Sick Children have been so successful that our Board of Management has recently provided us with a well-equipped up-to-date theatre in the out-patient department, and at the recent annual meeting of the hospital referred in very flattering terms to the work carried out in this department. Finally, the surgeon in charge of out-patients, instead of being a glorified house-surgeon or a finger-post to the wards, has now opportunities for practice and research hitherto denied him.—I am, etc.,

ANDREW FULLERTON, B.Ch., F.R.C.S.I.

Belfast, Feb. 23rd.

THE VARIETIES OF TUBERCULINS IN THE TREATMENT OF TUBERCULOSIS.

SIR,—I read with great interest Dr. Nathan Raw's article on the above subject in the *JOURNAL* of February 1st, page 212. On January 30th I read, before the Ulster Branch of the British Medical Association, a paper on Tuberculosis in General Practice, and in it I emphasized the fact that pulmonary tuberculosis did best when treated with bovine tuberculin, and that so-called surgical tuberculosis (though I objected to this term) did best on human tuberculin.

I reported two cases of an instructive nature on this point:

1. A case of laryngeal tuberculosis with very slight lung involvement which was so sensitive to human tuberculin that I had to desist. I then tried bovine tuberculin with the happiest results.

2. A case of erythema indurata that did well on human tuberculin, but when bovine tuberculin was tried, though in smaller doses, reacted in a marked and disastrous manner.

My experience, though only in general practice, and in a much more limited way, bears out what Dr. Raw says, and it is only for this reason that I record it now.—I am, etc.,

Lisburn, co. Antrim, Feb. 2nd.

J. L. RENTOUL, M.B.

THE NEGLECT OF VACCINATION.

SIR,—Dr. Killick Millard, the Medical Officer of Health for Leicester, has criticized me very strongly (page 416) because I have ventured to express an opinion that the unvaccinated state of this country constitutes a highly dangerous condition. I recognize as well as Dr. Millard does the fact that by immediate isolation the health authorities of any given area have in late years been able to suppress small outbreaks of small-pox, but experience has shown that there are limits to this power of control, and that there is a very grave danger of an outbreak running over the border of a sanitary cordon into an unvaccinated population. Dr. Millard suggests that I am biased, but I appeal to your readers, who are capable of judging, whether an unbiased opinion on such a point is likely to come from Leicester.

I appeal to an outside authority of undoubted position, Dr. Martin Kirchner, one of the medical staff of the Ministry of the Interior of the Prussian Government, who, in an official report in 1911, said:

Although in England compulsory vaccination exists, the duty of vaccination is in reality abolished. The consequence will be, and we may live to see it, that in England, if once a serious outbreak is imported, an epidemic will be created which the English people will remember for a long time (*Schutzpockenimpfung und Impfgesetz*, Berlin, 1911.)

The complacency of Dr. Millard is not shared by all medical officers of health, though they are not always in a position to obtrude their views.

Dr. Millard proceeds to ask if I "have ever considered that infantile vaccination only protects during the period of infancy and childhood, and that this period is the least exposed to the danger of small-pox infection." I am, of course, quite aware of this, but I ask in return if Dr. Millard is aware of the elementary fact that small-pox is extremely fatal in infancy, and if he is aware of the

danger which an infantile population still runs. For in the recent outbreak in Sussex out of twenty-one cases there were five under 10 years old, of which three died (all unvaccinated). This shows what will happen if an epidemic gets out of hand.

Dr. Millard asks further if I am aware that our present system of infantile vaccination, which is not followed by revaccination, has one serious drawback in causing slight atypical forms of small-pox which are easily overlooked, and so frequently leads to serious outbreaks of the disease. I reply that it is better to have a population which presents mild cases of small-pox, if the disease occurs, than severe ones; the resulting mortality is infinitely lower, and the possible damage to the patient's eyes is avoided. I am tempted to wonder how Dr. Millard's antivaccinist supporters in Leicester will receive his admission that infantile vaccination does lead to a "slight atypical form" of small-pox.

Dr. Millard concludes with some "friendly advice" (which appears to me in extremely bad taste) to the effect that as the occupation of the public vaccinator is a dying industry I should "go on the panel" or enter the public health service. I beg to assure Dr. Millard that I am in no grave need of either branch of practice for a livelihood, that public vaccination has never been anything but a small item in my work, and it would not concern me at all if I abandoned the emoluments; further, that I do undertake work under the Insurance Act to the small extent to which I care to do so, and as I was in active practice before Dr. Millard was even a medical student I can hardly expect to enter the public health service at my time of life.—I am, etc.,

ARTHUR MAUDE,

President, Association of Public Vaccinators.

Westerham, Feb. 22nd.

THE CONSTITUTION OF THE ASSOCIATION.

SIR,—I should like to support Dr. Napier Jones in his contention that something must be done to prevent such waste of time and money as we have incurred in recent meetings of the Representative Body. Of late these meetings have resolved themselves into a hopeless endeavour to cope with a chaotic mass of resolutions and amendments, ending in a despairing surrender to the inevitable when about half the work has been somehow scrambled through. The *reductio ad absurdum* was, as Dr. Napier Jones indicates, reached at the Special Meeting of January last, the first day of which was entirely wasted. I do not think many of us have any delusions as to the quarter in which responsibility belongs for this fiasco; certainly the holding up of the meeting and the staving-off of the real issue were a masterly performance in their way. Perhaps I feel somewhat strongly on this matter, inasmuch as, when the final adjournment came, several resolutions entrusted to me by my Division were the very next items on the agenda. But of what use to invite Divisions to send up resolutions, when 50 per cent. of them will receive no attention? It is a waste of time and money for us to go to London as mere voting machines.

The remedy proposed by Dr. Napier Jones is that all the main issues should be clearly formulated by the Council, and discussion limited to these. For myself, I think it a good suggestion, if only the Council can be empowered and induced to carry it out. Many of us in the past have, however, noticed a regrettable timidity and ambiguity in the framing of such resolutions as the Council has formulated for submission to the Divisions.

Then, again, there is the difficulty that Dr. Napier Jones's proposal involves an increase in the power and authority of the Council. I say the difficulty—not the objection—because of the notorious fact that the Divisions and even the Representative Body are jealous of any such increase of the Council's present powers. Recent events have not tended to allay this mistrust; they have produced in many minds the conviction that the Council may be captured by any resolute faction and exploited for its partisan ends.

The fact remains that to rely upon Divisional and individual initiative for the supply of the subject-matter of debate has proved a failure; the main issues are flooded in a mass of irrelevant proposals, counter proposals, amendments, and riders, with the result that we have seen. The agenda committees have done their best to evolve order

out of chaos, but no committee can render it possible to adjudicate within a couple of days upon a subject matter whose adequate debate would occupy a busy month. Something, then, must, it seems, be done; and it not what Dr. Napier Jones advises, what is the alternative?—I am, etc..

CHARLES J. WHITEY,
Representative, Bath Division.

Bath, February 22nd.

SIR.—Humiliating though the defeat of the profession has been, degrading though our servitude is, there is yet some hope of retrieving our position and regaining our freedom if only we dare to look facts squarely in the face and learn from them our lesson.

It is easy to be personal: cheap to bandy about such epithets as "traitors" and "blacklegs." It is far more difficult to bring ourselves to acknowledge that the true cause of defeat lies with ourselves: that we have been living in a fool's paradise; that we have been so utterly and incomprehensibly foolish as to pit our own obsolete weapons, our undisciplined forces, and our slender purses against the modern machinery, the perfect organization, and the inexhaustible funds of the British Government. Yet this is the fact, and the sooner we acknowledge it the better it will be for us and for the future of our profession, for the continuation of the present conditions, even for a short period, means inevitably the future damnation of the profession.

Enthusiasm; pledges and undertakings, whose binding strength is ethical, not legal; a voluntary defence fund, depending upon the popularity of the policy or of the *personnel* of its trustees, and upon the power and pertinacity with which it is advocated. These have been our chief weapons. These weapons have failed us at the crucial moment. They were, indeed, the best that could be devised, fighting, as we were, under the aegis of the British Medical Association.

The Association is a learned society, with the legal powers of a learned society, and none other. It has not the power to impose upon its members a legally binding pledge, nor to inflict a compulsory levy, nor to use its funds for the protection of its members. Our only other power was that strong ethical force which has grown up round the Association, and upon which too much reliance was placed, for that force was strong enough to make the given word a binding pledge right up to the eve of battle, but weak enough to melt away when faced with ruin and starvation. Failure was inevitable from the beginning. Failure is still inevitable if we again attempt to organize on similar lines.

To re-establish ourselves we must reconstitute ourselves. The lines of reconstitution must be such that the organization will be legally able to enforce a pledge, to impose and recover a levy, and to administer its own funds for the protection of its members.

At the meeting at the Caxton Hall twelve months ago, convened by the Medical Federation, Sir Victor Horsley took exception to my statement that the only course open to the Association, in order to attain the necessary powers, was to amalgamate or closely co-operate with the Medical Federation or some similar body. He expressed the opinion that, in addition to the course we proposed, there were two others—one by means of the new company, the other by converting the Association into a trade union.

At the annual meeting in Liverpool the new company movement was acknowledged to be a failure, and the trade union idea received its quietus when, in response to a singularly enthusiastic demand for trades unionism, we were told by the legal expert that it would be impossible to convert the Association into a trade union and at the same time preserve the entity of the Association. It would thus seem that it is practically impossible to convert the Association into an efficient organization for the protection of its members.

The third course, proposed by Bristol two years ago, is for the Association closely to ally itself to and co-operate with, even to the extent of taking over and governing, some outside organization possessing the necessary powers. This course still remains open, and, in my opinion, is the only possible means of saving the Association.

With regard to the precise form of organization required

for the purpose much might be said as to the relative claims of a trade union and a limited company. The actual strength, however, of a trade union is but little greater than that already possessed by the Association in so far as pledges are concerned, for a member can resign his membership whenever he chooses, being kept loyal by his comradeship and by "peaceful picketing." The latter being an impossible weapon with us, we should again have to rely upon the weapon which has already failed us—the ethical unity of our members. On the other hand, a limited company with strong constitutional powers can impose a legally binding pledge and a compulsory levy, being able to enforce both by means of its power to sue in a court of law. A limited company has, therefore, far stronger powers of the kind we require than a trade union. It has many times been argued that, so far as the medical profession is concerned, a legal bond will not prove more binding than ethical and moral bonds; that the members of the profession who will break the latter will also break the former. Other trades have found it necessary to bind the members together with legal bonds, and have found them efficient. At all events we have proved the ethical and moral bonds alone to be utterly inefficient, and it is our duty to make the next attempt on other and, as many think, on stronger lines.

I am not in any way specially pleading on behalf of the Medical Federation. All I wish to emphasize is that the Association is *per se* powerless to protect us and our interests, and that it must perforce ally itself to some organization with stronger legal powers if it wishes to carry out any successful campaign in the future.

I, personally, am so convinced of the futility of the Association organizing any great campaign while relying on its present constitution alone that I shall decline to take part in any such campaign, either general or local. For me to do so would be dishonest, for I know it to be merely the building up again of the ruins of a house whose foundations are upon the sand.—I am, etc.,

Bristol, Feb. 21st.

H. F. DEVIS.

SIR.—At the present time, when there would appear to be a strong element in favour of making the British Medical Association a trade union, the letter in your issue of February 22nd by Dr. Arthur J. Brock is most opportune. Medical men by training and inclination are as a body unfitted for commercial pursuits, and though it cannot be denied that the British Medical Association, by its recent incursion into such regions, has gained a shilling or two a year for each insured person for those of its members who have become insurance doctors, it has on the whole been a miserable failure. By all means let all who wish for protection join together for this purpose, but every member of the Association must wish it to retain the high position it has held as a body for the advancement of medical science and healing, and this can only be by retaining in its ranks those members of the profession who have made this their only object; and can it be thought for a moment that these men will continue members of an Association that is hopelessly trying to mix up science and trade unionism in one body? If the Association persists in its present policy, it is foredoomed to failure; but by returning to its legitimate position of a scientific body, it can regain the respect, not only of its members, but also of the public. There is doubtless a considerable number of members of the British Medical Association at the present time who wish for a trade union, and if a society is formed independent of the Association, with picked officials at its head, there will be a far better chance of gaining such protection as these members consider they need in the future practice of their profession.—I am, etc.,

Fulbourn, Feb. 22nd.

F. L. NICHOLS.

SHIP SURGEONS.

SIR.—There is at present a movement on foot to raise the scale of pay of ship's officers all round. It is well known that up to the present the remuneration of the ship's officer has been very poor, but as it is, not even so poor as that of the ship's surgeon, who also ranks as an officer, though non-executive. A meeting of the Ship Owners' Association was held in Liverpool on February 24th, and it was decided to help on the consideration of an increase in the officers' salary. Surely now is the time

for a master stroke from the medical profession as regards its sea-going members. Why not make a representation to the Ship Owners' Association that an increase in salary for ship surgeons is essential, and also that a minimum wage must be established. If some effort is not made now we shall find that ship's officers will get their desires fulfilled, and that at the same time the silent medical officer will remain on his miserable pittance, and a large bulk of our profession will still continually be afloat on the meagrest possible remuneration. Some response to a call for union, and some opinions from those who know the life of the ship's surgeon, would be certainly a step in the right direction.—I am, etc.,

Manchester, Feb. 25th.

SHIP'S SURGEON.

Obituary.

SIR THOMAS FREDERICK CHAVASSE, M.D.,
C.M.EDIN., F.R.C.S.LD., F.R.C.S.ENG. (HON. CAUSA).
CONSULTING SURGEON, BIRMINGHAM GENERAL HOSPITAL.

We announced briefly last week the death of Sir Thomas Chavasse, which occurred at Linthurst Hill, Barnt Green, Worcestershire, on February 17th. after an illness following an accident in the hunting field. He was the sixth son of Thomas Chavasse, F.R.C.S.Eng., a successful family practitioner of Birmingham, and was born at Wyld Green House, Wyld Green, where his father resided during the latter part of his life. Mr. Pye Chavasse, the author of *Advice to a Mother* and other well known books, was his father's cousin, and Mr. Sam. Chavasse, another cousin, was also in good medical practice in Birmingham, so that the medical and social family connexions were very strong.

The early part of Chavasse's medical education was obtained in the Birmingham Medical School, but in 1873 he went to Edinburgh, where he graduated M.B. and C.M. in 1876 (M.D. 1878), afterwards holding the post of resident surgeon to the late Professor Spence in the Royal Infirmary. After his term of office in the infirmary he visited Berlin and Vienna, but was called home in the autumn of 1877 to become a candidate for one of two newly created assistant surgeoncies at the General Hospital. The other candidates were Mr. W. G. Archer (who retired from practice after a few years and died young), and Mr. Bennett May, afterwards the well-known surgeon to the Queen's Hospital and Professor of Surgery in the University of Birmingham. The result of the contest was the election of Archer and Chavasse, but, as the holders of the office had to be Fellows of one of the Royal Colleges of Surgeons or to obtain the Fellowship within a year, an objection was lodged against Chavasse's election on the ground that as he was only 23 years of age he could not comply with the law. This objection was over-ruled as being anticipatory, and the College of Surgeons of Edinburgh suspended its by-law and elected him a Fellow (there was no examination then) in spite of his age.

At that time there were five surgeons to the General Hospital, but the new laws had reduced the senior posts to four, so that two vacancies were required before an assistant surgeon could be promoted, and their prospects seemed dim; yet in 1880 Mr. Goodall became ill and resigned, and the following year Mr. Baker, the senior surgeon, retired. In the contest that followed Chavasse was again successful, becoming full surgeon to the hospital in December, 1881, when he was only 27; by the retirement in due course of Mr. Oliver Pemberton and the premature deaths of Mr. Bartlett and Mr. Jolly, he found himself senior surgeon to the hospital in 1894, a position he retained until his resignation early last year. In 1899 he was elected F.R.C.S.Eng. (*honoris causa*), and in 1905 he received the honour of knighthood.

At the Birmingham meeting of the British Medical Association in 1911 he presided over the Section of Surgery; he was an ex-President of the Birmingham Branch of the Midland Medical Society and the Medical Benevolent Society.

He leaves a widow, a son who is studying medicine, and three daughters of whom the eldest is married to a son of Sir John C. Holder, Bart.

Sir Thomas Chavasse was a skilful surgeon, and a popular and kind-hearted man who will be much missed. When he resigned the hospital he gave up practice, and looked forward to many years of quiet enjoyment of his leisure. "hunting four days a week," as he said when asked what he should do with himself. An excellent portrait painted by Mr. Nowell, subscribed for by the staff and governors, hangs in the board room of the General Hospital, and will preserve his memory in that institution.

A COLLEAGUE writes: Sir Thomas Chavasse had by his early training prepared himself for the practice of surgery. An initiation into the methods of Lister and a firm belief in their efficiency enabled him to keep abreast of the rapid advances that were taking place about the time of his appointment to the full staff. Study in Vienna and Berlin widened his outlook and stimulated him to increased efforts. He was a progressive surgeon, always ready to give a fair trial to new methods, though reserving to himself the right to reject them if they did not answer the purpose for which they were advocated. His clinical instinct enabled him to come quickly to a conclusion as to the nature of a case, and, having made up his mind what line of treatment to adopt, he acted boldly, and was prepared to deal with any difficulties that arose. His influence was that of a strong man whose opinion was founded on wide experience, sound judgement, and a knowledge of men and affairs. A close association with him in the wards of the hospital for many years has been a great privilege, for, apart from his charming personality, there was always the consciousness of being able to obtain his counsel and advice under all circumstances which presented difficulties, either from a surgical or an administrative point of view.

SURGEON-GENERAL GEORGE BIDIE, C.I.E.,
INDIAN MEDICAL SERVICE (RETIRED).

SURGEON-GENERAL GEORGE BIDIE, Madras Medical Service, retired, died at Bridge of Allan, Scotland, on February 19th. He was born on April 3rd, 1830, the son of W. Bidie, of Buckies, Banffshire; was educated at Edinburgh and Aberdeen, and took the M.D. degree, Marischal College, Aberdeen, and the L.R.C.S. Edin. in 1853. He entered the I.M.S. as Assistant Surgeon on February 20th, 1856, became Surgeon on February 20th, 1868, Surgeon-Major on July 1st, 1875, Brigade Surgeon on February 28th, 1883, Deputy Surgeon-General on October 11th, 1884, and Surgeon-General on October 9th, 1886. He retired on May 29th, 1890. In 1882 he was decorated with the Order of the Crown of Italy, was made a C.I.E. on January 1st, 1883, received a Good Service Pension on February 10th, 1889, and was appointed Honorary Surgeon to the Queen on February 16th, 1898. He had thus served as Honorary Surgeon to three sovereigns, Queen Victoria, King Edward VII, and King George V; his last service in this capacity being when he attended on His Majesty's Staff at the review held at Windsor Castle in June, 1912.

Soon after entering the service, he served with the Haidarabad contingent in the Mutiny in 1857-58, receiving the medal. In 1859 he was posted as Civil Surgeon of Guntur. In 1867-68 he was placed on special duty in the coffee districts of Mysore and Coorg, and reported on the ravages of the borer insect on coffee plants. From 1870 to 1872 he was Secretary to the Surgeon-General, and held that post again from 1880 to 1885. From 1872 to 1884 he was Superintendent of the Madras Museum, served on the Cinchona Commission in 1873, and became a Fellow of Madras University in 1879. In 1885 he became Sanitary Commissioner of the Madras Presidency, and in 1886 Surgeon-General with the Government of Madras. After his retirement, he acted as delegate from Madras at the International Congress on Hygiene and Demography in 1891. He was the author of numerous works, chiefly on natural history, economic products, and coinage, all subjects connected with his work as Superintendent of the Museum.

In 1854 he married Isabella, daughter of the late Alexander Wiseman, of Banchoory, Aberdeenshire. One of his sons, Lieutenant-Colonel George Bidie, has followed in his father's footsteps in the Madras Medical Service.

ERNEST MAYNARD PAIN, B.A., M.B.,
CH.M. SYDNEY.

NEWS has been received by the Church Missionary Society of the circumstances of the death of Dr. E. Maynard Pain, which took place at Old Cairo on February 12th, and was then reported by telegram. It appears that Dr. Pain had been attending cases of cerebro-spinal meningitis which had been admitted to the mission hospital. One of the patients is said to have coughed in his face, and within thirty hours he was taken gravely ill and died after an illness of only about twenty-four hours, though all that was possible was done to save his life.

This event, occurring within twelve months of the deaths of Drs. Pennell and Barnett on the North-West Frontier of India from septic poisoning, is a reminder of the risks to which medical practitioners are exposed who are working in lands where disease is met with in a specially virulent form, and particularly medical missionaries who for various reasons must face difficulties of an unusual kind. This is not the first time that Dr. Pain has been attacked by serious illness as a result of his professional responsibilities, but he never flinched from the path of duty.

Dr. Pain was the first medical graduate from Australia to join the ranks of the medical missionaries of the Church Missionary Society, which he did in the year 1902. He was born on July 23rd, 1873, at Cobbitty, New South Wales, and was the son of the Bishop of Gippsland. He was educated at Sydney Grammar School and University, and had a successful career as a student. Before going abroad he held the posts of resident medical officer, and later on of medical superintendent of the Prince Alfred Hospital, where he gained useful experience. He was, therefore, a most valuable addition to the medical staff of the mission hospital at Old Cairo, and he proved to be a capable surgeon. He was greatly respected, not only by his missionary colleagues but by the authorities of the Cairo Medical School, for which he was an examiner.

He was an enthusiastic missionary, and helped in no small measure to bring the Old Cairo Hospital to the remarkable standard of efficiency to which it has attained.

Such men are an honour to the profession to which they belong. In entering upon the calling of a medical missionary they have closed the door against those positions of eminence and worldly prosperity which might have been open to them. Yet as we think of their lives we realize that they have chosen in many ways the better part, and not only is the world the better, but the profession is the richer for the memory of a noble life. May it lead others "to follow in their train."

Dr. Pain was twice married, and leaves a widow and children.

THE announcement of the death on February 15th, after a short and sudden illness, of Dr. CAMPBELL BOYD will have been received with regret by a large circle of friends. Genial and kindly, generous and sympathetic, he was much loved and esteemed, and his death during his term of office as President of the Chelsea Clinical Society will be much felt by its members. He was a son of the surveyor for the county of Wicklow, who bore the same name. He was born 55 years ago, and received his medical education at the Carmichael College, Dublin, and Charing Cross Hospital Medical School; he obtained the diplomas of L.R.C.P.I. in 1883 and L.R.C.S.I. in 1885. He settled first in practice at Denmark Hill; after some years he removed to Surbiton, and later on settled in Chelsea. He was a member of the Obstetrical and Gynaecological Section of the Royal Society of Medicine, and of the British Medical Association. He was an active member of the Irish Medical Schools' and Graduates' Association, was a member of its Council for some years, and for the last few years filled the post of metropolitan secretary of that association. He joined the Chelsea Clinical Society in 1906; two years later he was elected a member of its council, and in 1910 became vice-president, an office which he retained until elected president in October last. At council and other official meetings his high sense of duty made him a frequent attendant, and he was always ready to give of his best to help on this society, in which he took so keen an interest. Dr. Boyd contributed to this JOURNAL a note upon a six-fingered family, and also on strophanthus as a cardiac tonic in acute heart failure. He was interested in engraving, and

had a good collection of mezzotints. He has left a widow, to whom the sad calamity has come as a crushing blow, in which she will have the sympathy of all who knew her husband.

DR. PHILIP HAIR, who died after a short illness on February 9th, had been in failing health for some time, but had continued his ordinary work until about a fortnight before his death, and even had seen two old patients on February 8th. He was the son of the late Mr. James Hair of Carlisle. He became a student at the University of Edinburgh, where he had a distinguished career, and obtained the degrees of M.B. and C.M. in 1866; in 1868 he graduated M.D. and received the gold medal for his thesis on the muscular fibres of the alligator, subsequently published in the *Journal of Anatomy and Physiology*. For a short time he remained in Edinburgh as assistant demonstrator of anatomy to Professor Goodsir and Professor (now Sir) William Turner. He afterwards spent some months in attending the hospitals in Paris and acquired fluency in French. When, some ten or twelve years ago, Dr. Blanc and Dr. Forrestier of Aix-les-Bains attended a meeting of the local medical profession Dr. Hair gratified all present by returning the thanks of the meeting to them in a very eloquent speech in their own language. After his visit to Paris Dr. Hair returned to his native city, and was elected surgeon to the Carlisle Dispensary in 1873. In 1898 he became one of the physicians to the dispensary, an appointment which he held up to the time of his death; in fact, he took a great interest in the work of that institution throughout the forty years he worked in Carlisle. Dr. Hair, who was 71 years of age, is survived by his wife and daughter.

The Services.

MUTINY VETERANS.

The Indian Medical Service.

THE article in the BRITISH MEDICAL JOURNAL of February 8th (p. 312) on the introduction into the *Monthly Army List* of the letters **C** and **M** to distinguish officers on the active and retired lists who served in the Crimea and the Indian Mutiny respectively, stated that the names of thirty-six medical officers (including one quartermaster) had been so distinguished, and that among them were the names of thirteen officers of the Indian Medical Service who served in the Mutiny, and one of them in the Crimea also. The actual number of survivors is, however, considerably larger.

The *Indian Army List* of January, 1913, gives the names of at least twelve other officers on the retired list of the Indian Medical Service who served in the Mutiny, one of them also in the Crimea. The war services of these officers were once recorded in the *Army List*, but have now dropped out. Three—Beaman, Harris, and McLeod—were Madras men; the other nine belonged to the Bengal Service.

Their names and war services are as follows:

- Beaman, A. H. Mutiny, in N.W. Province.
- Caldwell, W. S. Mutiny, with Rohilkand Field Force.
- Carter, F. Mutiny, with Punjab Movable Column, medal.
- Christison, Sir Alexander. Mutiny, action of Sasia, near Agra, July 5th, 1857; and Central India, medal with clasp. Also Burma, 1852-53, medal, and clasp for Pegu.
- De Renzy, Sir Annesley. Mutiny, siege of Lucknow, medal. Also Burma, 1852-54, medal with clasp; and Naga Hills, 1879-80, medal, and C.B. (K.C.B., June 26th, 1902.)
- Grant, N. J. Mutiny, dangerously wounded at Rohni, June, 1857.
- Harris, W. H. Crimea, siege and fall of Sebastopol, attack on Rehan, and battle of Tebernaya, medal with clasp, and Turkish medal. Mutiny, capture of Lucknow, medal.
- Hayes, W. H. Mutiny, Kol rising, wounded near Chaibasa, January 14th, 1858.
- McLeod, A. C. Mutiny.
- MacTier, W. P. Mutiny, siege of Delhi, twice mentioned in dispatches, medal with clasp. Also Sutlej campaign, 1845-6, actions of Mudki, Aliwal, and Sobraon, medal with two clasps; and Punjab campaign, 1848-9, actions of Ramnagar, Sadullapur, and Chilianwala, medal with clasp.
- Paske, C. T. Mutiny, operations near Azamgarh, medal. Also Burma, 1853, medal; and Bhutan, 1865-6, clasp.
- Sutherland, P. W. Mutiny, with Murray's Jat Horse, medal.

At least twenty-two other officers of the Indian Medical Service are still living who were in the service at the time of the Mutiny, but do not appear to have seen active service in the campaigns.

We understand that corrections will be made in future lists, and that communications have already been addressed by certain officers to the Military Secretary at the India Office, and to the Secretary at the War Office.

Vixere fortes ante Agamemnona—other wars, as fiercely contested and perhaps as important as the Crimean war and the Mutiny, had been fought in India in the previous decade; the Sutlej campaign or the first Sikh war of 1845-46, and the Punjab campaign or second Sikh war of 1848-49. Two officers of the Indian Medical Service who served in both these wars still survive. Surgeon-Major Mactier's war services are given above. The other is Surgeon-Major Henry Benjamin Hinton, who was born on March 7th, 1815, three months before the battle of Waterloo, and entered the Bengal Service on January 14th, 1839, over seventy-four years ago. He retired on March 7th, 1868. His war services comprise: Gwalior, 1843-44; Sutlej, 1845-46; actions at Badiwal, Alival, and Sobraon, medal with clasp; Punjab, 1848-49; and China, 1858-60. Though serving in India at the time, he does not appear to hold the Mutiny medal. If he is still alive—he was certainly living in December, 1912—he is now within one week of completing his century.

Does any officer still survive who took part in the first Afghan war, 1839-1842? Hinton was serving in India at the time, but his regiment, the 65th Bengal Infantry, did not take part in the campaign, but was then stationed at Dinapur and in Arakan.

THE TERRITORIAL FORCE.

FIRST LONDON DIVISION.

MAJOR-GENERAL W. FRY, C.V.O., C.B., Commanding the First London Division (T.F.), will this day (Saturday, March 1st) open the new headquarters of the Royal Army Medical Corps of this division which are situated at the Duke of York's Headquarters, Chelsea, S.W. The proceedings will be terminated with a smoking concert for which an excellent programme has been arranged. The chair will be taken by Colonel F. Harper, A.D.M.S., 1st London Division.

ROYAL NAVY MEDICAL SERVICE.

THE GILBERT BLANE MEDAL.

THE Gold Medal founded by the late Sir Gilbert Blane, Bart., to be given biennially, has been awarded by the Director-General of the Medical Department of the Navy and the Presidents of the Royal College of Physicians and the Royal College of Surgeons to Fleet Surgeon Richard C. Munday for his *Journal of H.M.S. Hyacinth* for the year 1910, and to Fleet Surgeon Edward Sutton for his *Journal of H.M.S. Highflyer*, February 21st to December 31st, 1911.

Universities and Colleges.

UNIVERSITY OF CAMBRIDGE.

THE following degrees have been conferred:

M.D.—R. P. Cockin, R. M. Ranking.
M.B., B.C.—F. S. Adams, R. S. Kennedy.
* Admitted by proxy.

UNIVERSITY OF BRISTOL.

THE following candidates have been approved at the examinations indicated:

FINAL M.B., Ch.B.—Kathleen M. Cole, B. C. E. Sell, A. G. Hieber.
D.P.H.—W. Bainbridge, W. Tomeroy, Saoe Nan Don Tiway.
Part II, *Completing Examination*: A. H. Finch. Part I: P. Moxey.

UNIVERSITY OF EDINBURGH.

UNIVERSITY COURT.

Appointments.

At a meeting of the University Court on Monday, February 18th, among other appointments made were those of Mr. R. Chapman Davie, M.A., B.Sc., as Lecturer on Botany, and of Dr. W. G. Sym, as Lecturer on Diseases of the Eye; of Mr. David G. Hogarth, M.A., Fellow of Magdalen College, Oxford, and Keeper of the Ashmolean Museum, as Munro Lecturer on Anthropology and Pre-historic Archaeology for 1914; of Dr. Alexander Lawder (Edinburgh), as additional Examiner in Chemistry, and of Dr. N. T. Brewis, as additional Examiner in Gynaecology. The draft ordinance by the University Court (foundation of the Moncrieff Arnott Chair of Clinical Medicine) was submitted and finally approved.

Medical News.

SIR RICHARD DOUGLAS POWELL, Bart., K.C.V.O., will deliver two Emeritus Lectures on the climatic treatment of pulmonary diseases on Fridays, March 7th and 14th, at 3 p.m., in the Middlesex Hospital Medical School.

SIR RICKMAN J. GODLEE, President of the Royal College of Surgeons, will on Thursday, March 13th, at 9 p.m., give the Foundation Oration before the University College Union Society on "Lister and his Work."

A DISCUSSION on the Milk and Dairies Bill will be opened by Dr. Herbert Jones, M.O.H. Hereford Combined Districts, at a meeting of the Royal Sanitary Institute, 90, Buckingham Palace Road, S.W., at 7.30 p.m. on March 11th.

AT a meeting of the Institute of Chemistry to be held at King's College, London, on March 12th, a lecture on the function and scope of the chemist in a pharmaceutical works will be delivered by Mr. Charles H. Hill, B.Sc., F.I.C.

SOME time ago it was announced that the Radium Development Syndicate would probably undertake the management of the baths of Bath. It is now stated that should negotiations to this end come to nothing, the Corporation will itself carry out a development scheme.

THE fourth lecture to be given by Dr. James Kerr Love under the auspices of the National Bureau for Promoting the General Welfare of the Deaf will be delivered at the Royal Sanitary Institute, 90, Buckingham Palace Road, S.W., on Tuesday, March 4th, at 6 p.m. The subject will be true hereditary deafness.

A COURSE in advanced clinical ophthalmology will be given at the clinique of Professor de Lapersonne at the Hôtel-Dieu, Paris, commencing on April 1st. It will continue for two months, and foreign doctors will be admitted to it. The fee for the course, which will include a special series of demonstrations on refraction by Professor Weiss, is 100 francs.

THE late Lord Ilkeston by his will left a sum of £800 to the University of Durham upon trust, to apply the income in memory of his late daughter by the foundation of a Winifred Foster scholarship for a woman student who requires help to maintain herself at the university. The net personalty was proved at £18,784, and he left certain American property to his son and successor in the title.

IN the article on "The Metropolitan Water Board as a Health Authority" published on February 15th, reference was made to the epidemics of typhoid fever at Maidstone, Lincoln, and Swanage. We have received a letter from a correspondent contending that it was unfair to mention Swanage alongside of Maidstone and Lincoln, inasmuch as at the last-named place there were only 23 cases all told, counting those that developed elsewhere, among a population with visitors of 6,000 persons. All the causes of the trouble in Swanage have now been put right.

MR. WILFRED TROTTER's two Hunterian lectures on the principles and technique of the operative treatment of malignant disease of the mouth and pharynx will be delivered at the Royal College of Surgeons on Monday and Wednesday next at 5 p.m. on each day; the first lecture will discuss principles and the second technique. The Aris and Gale lecture by Dr. Charles G. Seligmann, lecturer on ethnology in the University of London, will be given on March 7th, at 5 p.m.; the subject is the Hamitic element in the population of the Anglo-Egyptian Sudan. There are two great branches of the Hamites, the northern and the eastern; the lecture will deal only with the latter, and the mixed peoples to which they have given rise.

LIEUTENANT NINNIS, of the Royal Fusiliers, a member of Dr. Mawson's Antarctic Expedition, who lost his life by falling into a crevasse while sledging, was the son of Inspector-General Ninnis, R.N.(ret.), who was himself a member of the British expedition of 1875-6, under Sir George Nares. The expedition under the direction of Mr. Douglas Mawson, D.Sc., Lecturer in Geology in the University of Adelaide, was organized in Australasia, and the fund to defray its cost was for the most part raised there. Inspector-General Ninnis, it may be interesting to recall, was naturalist to the expedition which surveyed the northern territory of South Australia in 1864-5. Lieutenant Ninnis was an officer of high promise, and much sympathy will be felt with his father.

Letters, Notes, and Answers.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the BRITISH MEDICAL JOURNAL unless the contrary be stated.

COMMUNICATIONS respecting Editorial matters should be addressed to the Editor, 429, Strand, London, W.C.; those concerning business matters, advertisements, non-delivery of the JOURNAL, etc., should be addressed to the Office, 429, Strand, London, W.C.

MANUSCRIPTS FORWARDED TO THE OFFICE OF THIS JOURNAL CANNOT UNDER ANY CIRCUMSTANCES BE RETURNED.

CORRESPONDENTS not answered are requested to look at the Notices to Correspondents of the following week.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Office, 429, Strand, W.C., on receipt of proof.

TELEGRAPHIC ADDRESS.—The telegraphic address of the EDITOR of the BRITISH MEDICAL JOURNAL is *Anthology, Westrand, London*. The telegraphic address of the BRITISH MEDICAL JOURNAL is *Articulate, Westrand, London*.

TELEPHONE (National):—
2631, Gerrard, EDITOR, BRITISH MEDICAL JOURNAL.
2630, Gerrard, BRITISH MEDICAL ASSOCIATION.
2634, Gerrard, MEDICAL SECRETARY.

Queries, answers, and communications relating to subjects to which special departments of the BRITISH MEDICAL JOURNAL are devoted will be found under their respective headings.

QUERIES.

C. asks what cynic described poetry as a "disorder of the intestines."

W. W. N. would be glad of details and results of the method of skin-grafting by blistering and then grafting on the layer of epidermis raised by blister.

ANSWERS.

THALASSA, who wishes to begin the study of ecclesiastical architecture, will find *English Gothic Architecture*, by P. H. Ditchfield, M.A., F.S.A. (London: J. M. Dent and Sons, Is.), a good elementary book in which technical terms are explained. A standard work is Parker's *Concise Glossary of Gothic Architecture* (Oxford: Parker and Co., 5s.) Mr. T. Francis Bumpus has written two books on *The Cathedrals of England and Wales* (in three volumes, 6s. each), and *The Cathedrals of Northern France* (6s.) respectively (London: T. Werner Laurie). The study of Gothic architecture is, perhaps, best begun in Northern France, passing from the ruins of Jumièges to Chartres. Within the bounds of London our correspondent may study Westminster Abbey and Southwark Cathedral, and by looking at St. Paul's and the other Wren churches, and the new Roman Catholic Cathedral at Westminster will be able to grasp something of the two main tendencies in architecture designed to subserve the needs of the rites of the Christian churches.

TABES.

PORTCULLIS writes that "Fairlands" would probably find the treatment of the urethra suggested by Dr. L. N. Denslow in *A Surgical Treatment of Locomotor Ataxia* (London, Baillière, Tindall, and Cox, 1912) would meet his patient's case. The volume was reviewed in the BRITISH MEDICAL JOURNAL of February 15th, 1913, p. 348.

SPHYGMOMANOMETERS.

A. J.—We believe that beyond the estimation of the systolic pressure little advance has been made in the solution of the problem of variations in blood pressure, and instruments praised for some peculiarity are not generally of more value than the ordinary types.

CHEWING GUM.

DR. A. W. GILCHRIST (Nice) writes: Is it not rather in America, where the practice is so general, that Dr. Kerr should seek the information he refers to in your issue of February 22nd? I would be surprised if he succeeded in obtaining evidence of much harm arising from the indulgence in question. Indeed, I have often asked myself, in admiring the finely developed contour and firmness of the American jaw, and the superiority in general of their teeth as compared with those of our own people, whether the process of constant mastication involved in the use of gum (a kind of rumination, in fact) is not of marked developmental advantage.

LETTERS, NOTES, ETC.

PUBLIC-HOUSE REFORM.

UNDER this suggestive title, the People's Refreshment House Association has issued an attractive booklet (*Public House Reform*. The People's Refreshment House Association, Limited, Westminster. Pp. 55 + iv; 27 plates and map. Price 6d.) giving an account of its work. The object of the association is to change public-houses from being mere drinking dens to places where food and non-alcoholic refreshments are to be as easily obtained as drink. It aims to make each landlord a licensed victualler in the true sense of the word—a purveyor of victuals. The managers of the houses controlled by the association have a substantial interest in the sale of food and non-intoxicants, but none in the sale of intoxicants. It is, therefore, to the manager's interest to push the sale of food, and hence the houses are real refreshment houses. Each house has a tea-room distinct from the rooms where alcoholic drinks are sold, and many have tea-gardens. The association controls 115 public-houses in all parts of the country, and those illustrated suggest the inviting comfort of the picturesque country inn. The spread of temperance has created a demand for non-alcoholic refreshment. The tea shops which dot the streets of our cities testify to this need, whilst the cycle and the motor car have accentuated the want upon the country highways. And if extreme teetotallers cannot say with Chaucer, in the lines quoted by the association,

In everything I wot there lies measure:

For, though a man forbid all drunkenness,

He biddeth not that every creature

Be drinkless altogether, as I guess,

moderate men will watch with interest this growing effort to grapple with intemperance by giving to the word refreshments its original common-sense meaning, and not restricting it to liquors consumed under conditions which make excess dangerously easy.

RHEUMATOID ARTHRITIS.

DR. W. J. MIDELTON (Bournemouth) writes: I was much interested in Dr. F. G. Thomson's article on rheumatoid arthritis which appeared in the BRITISH MEDICAL JOURNAL of February 15th, 1913. Several years ago Dr. Jones Llewellyn kindly talked at length with me, calling my attention to many symptoms common to certain cases of arthritis, Graves's disease, tetany, myxoedema, etc.; also to the long train of symptoms showing definite impairment of the nervous system in rheumatoid arthritis. As the result of observation of a large number of cases, I find I can cordially support him. However deficient, in the minds of some, the evidence may be that infection plays a large part in most of the cases, I personally find, the more I think of infection and impairment of the nervous system, the more successful I am in relieving or curing rheumatoid arthritis and chronic arthritis generally. There is one point that seems very generally overlooked by authors on this subject—namely, lingering infection. I hold that the measles, scarlatina, etc., of childhood may linger in the system and contribute to a development of arthritis many years after. I find that persistent treatment by means of continuous counter-irritation, for years if necessary, will keep patients improving instead of going from bad to worse.

WAS NAPOLEON EMBALMED?

DR. R. HENSLÖWE WELLINGTON (Temple, E.C.) writes: Members of the Association must have been deeply interested in all that has appeared lately in the columns of our JOURNAL concerning Napoleon and the autopsy upon his body. I have watched for some mention as to whether it was embalmed or not. On p. 1444, June 22nd, 1912, of the JOURNAL is an article on "The Remains of Napoleon," in which it says that "owing to the lack of necessary materials it had been impossible to embalm the body after death," but that at the exhumation of the body in 1840 "the remains were found in an almost perfect state of preservation," and that Dr. Max Billard, who is quoted, attributes the preservation to hermetic closure of the (four) coffins in which they were enclosed preventing the access of micro-organisms. Against this Rose, in his *Life of Napoleon*, vol. ii, p. 572, says, "After being embalmed the body was laid out in state." He is not the only biographer who says this. It would therefore be interesting to know which or who is correct, and as to whether saponification took place.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

| | £ | s. | d. |
|-----------------------|-----|-----|-----|
| Eight lines and under | ... | ... | ... |
| Each additional line | ... | ... | ... |
| A whole column | ... | ... | ... |
| A page | ... | ... | ... |

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Wednesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *postes restant* letters addressed either in initials or numbers.

An Address

ON

RECENT ADVANCES IN THE DIAGNOSIS, PROGNOSIS, AND TREATMENT OF HEART DISEASE: THE POLYGRAPH.

GIVEN AT THE OPENING MEETING OF THE SESSION OF THE
TORONTO ACADEMY OF MEDICINE.

BY

FREDERICK W. PRICE, M.D., M.R.C.P.,

LECTURER IN DISEASES OF THE HEART AT THE MEDICAL GRADUATES'
COLLEGE AND POLYCLINIC; PHYSICIAN TO THE GREAT
NORTHERN AND MOUNT VERNON HOSPITALS.

MR. PRESIDENT AND GENTLEMEN,—Will you allow me, in the first place, to thank you most warmly for the privilege of addressing you this evening on a subject at which I have been working, in association with Dr. James Mackenzie, for the last few years, and which, in my view, is of the greatest practical importance to the clinician?

Complaint is sometimes made of the slowness of the advance of knowledge which is being made in medicine, and it is sometimes asserted that in recent years, taken as a whole, the advance of medicine has not kept pace with that of surgery. While not fully accepting this view, it must be admitted that there is something to be said in its favour. And, if it be true, it seems to me that the cause lies in the fact that the physician, instead of adopting the methods of exact analysis, is too often satisfied with the most general inquiries and observations in his investigations of the many problems which confront him. In my opinion, what is lacking is an endeavour to bring practical medicine more nearly to the higher state of cultivation which has been reached by experimental science. Perhaps this is more particularly true in regard to the realm of therapeutics. Let me give you a small example of this. It has been believed for generations, both among experimental pharmacologists and practical therapeutists, that the internal administration of aconite directly diminishes the pulse-rate. You will find this belief expressed in the textbooks; but, if you search for real evidence upon which the belief rests, you will be disappointed. A year or two ago I conducted an investigation in regard to this matter. The cases chosen were 3 cases of mitral disease, 1 case of aortic and mitral disease, 1 case of malignant endocarditis with a high temperature, 4 cases of pulmonary tuberculosis, and 7 cases of scarlet fever. All the patients were kept in bed. The pulse was counted nine times a day, at exactly the same times each day, for some days before the administration of the drug, for some days during its administration, and for some days after its administration. First of all, samples of tincture of aconite obtained from several firms of chemists were employed. On being tested at the University College Pharmacological Laboratory each of these samples was found to be quite inert. Afterwards specimens of aconitina prepared in the laboratory were used, commencing with very small and gradually increasing to full doses. On comparing the records of the times when the patients were taking the drug with those when they were not taking it, in no case was there any reduction in the pulse-rate.

Now if it be true that the scientific method of investigation has not been sufficiently adopted in medicine as a whole, it is refreshing to turn to a branch of medicine in which its adoption has been rewarded with results which are nothing short of brilliant, and of tremendous practical importance. The work which has been done in recent years in the domain of heart disease has gone far to solve many of the most fundamental problems which have perplexed clinicians for generations. I venture to put forward the opinion that in few, if any, of the branches of medicine or surgery has there been in recent years a greater advance than has taken place in the realm of knowledge of cardiac disorders. This progress is essentially of such a practical nature and of such great value in regard to the diagnosis, prognosis, and treatment of heart affections, that it is the duty of every practitioner to be acquainted with its nature and scope, and this evening I

want to lay before you some of the main points in the advance, dealing with the subject only from a practical point of view, with the hope that what I have to say will be of use to you in your daily practice.

Let me first of all try and show you how great was the need for new light on this subject. I think I cannot do better than touch upon two problems which have notoriously been sources of difficulty and perplexity to the clinician. The first is the question of cardiac irregularity in patients who may or may not exhibit evidences of valvular disease; the second is the extraordinary difference in the results of the administration of digitalis and its allies in persons who are suffering from identically the same lesions, and complaining of precisely the same symptoms.

Let us take the first question—namely, that of cardiac irregularity. A common experience of the practitioner is this: A patient comes to him complaining of some symptom or other, and in the process of physical examination he finds that there is a very definite irregularity of the pulse. There may or may not be evidences of valvular disease. What significance is he to attach to this irregularity? He is probably aware that cardiac irregularity may signify serious impairment or disease of the heart on the one hand, or, on the other hand, it may be of little or no importance. Indeed, on the one hand, it may be the only sign detected by the ordinary methods of examining the heart in cases in which there is serious involvement of the cardiac mechanism, while, on the other hand, certain irregularities are quite compatible with healthy hearts.

Now the second question—that of digitalis. As long as the drug has been in use for cardiac affections it has been known that the results of its administration are astonishingly various. Suppose you take three patients with precisely the same degree of cardiac failure and exactly identical lesions, and employ the same dosage of digitalis in each case. In one, perhaps, the results are extraordinarily good, the drug seems to act like a charm; in the second the results, though beneficial, are only moderate or slight; while in the third absolutely no good result at all can be detected. What is the cause of this variability? Is the drug capricious in its action or uncertain in its strength? It has been thought so. Or is it due to some particular preparation being active while another preparation is inert? This has been thought by some; and for this reason special preparations have been prepared and advertised as being more uniformly certain in their action. I hope to show you this evening that both opinions are wrong. My object is to try and answer these two questions, to try and clear up these two difficulties. And it is of vital importance to you in your general practice that these two problems should be solved.

Now, the enormous advance within recent years in our knowledge of cardiac disorders has been almost entirely due to the introduction of what are called graphic methods in examining the mechanism of the heart. For by these methods we can analyse the heart's action in a way which was never possible before. By means of an instrument called the clinical polygraph we can take a simultaneous tracing on the same recording surface of the radial artery on the one hand and of the jugular vein on the other. You can readily understand what an advance this is on the older method of merely taking a tracing of the radial artery. For the arterial pulse and apex beat afford information regarding the movements and condition of the left side of the heart alone, and only during the time that the aortic valves are open. The venous pulse, on the other hand, affords information regarding the movements and condition of the right side of the heart. It gives far more valuable information of what is actually going on inside the chambers of the heart than does the arterial pulse. Therefore, by taking simultaneous tracings of both arterial and venous pulses, we can get information regarding the movements and conditions of both sides of the heart, and it is by comparing these that we are able to obtain a precise and an accurate opinion of the cardiac mechanism.

Now, if a tracing of the jugular pulse taken from a normal individual be studied, in each cardiac cycle three main waves are seen. They indicate a rise of pressure in the vein. The first wave in point of time is due to the contraction of the auricle, and is called the "a" wave. The second wave coincides with the

commencement of the contraction of the ventricle, and is synchronous with the carotid beat at the same level of the neck, and is called the "a" wave. The third wave occurs towards the end of ventricular systole, and is called the "v" wave.

Now, under normal circumstances the stimulus for contraction of the heart arises at the remains of the sinus venosus. From this point the stimulus passes through the auricle to the auriculo-ventricular node and along the auriculo-ventricular bundle to the ventricle. The stimulus is conveyed from fibre to fibre by means of a function of the heart muscle which is called "conductivity." We can estimate the degree of conductivity. It can be done in the following way: As I have indicated, the beginning of the wave *a* corresponds with the commencement of auricular contraction. The beginning of the wave *c* practically corresponds with the commencement of the contraction of the ventricle.

You might say that there is an interval of time between the opening of the aortic valves and the carotid pulse. That is true. But the time is so short it is only about

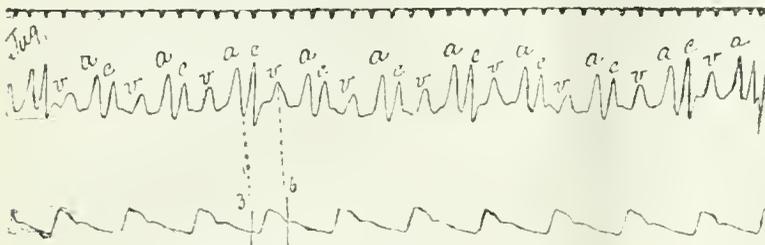

Fig. 1.—Normal or auricular form of venous pulse.

one-fiftieth of a second) that it need not be taken into account. Therefore the time distance between the beginning of the wave *a* and the commencement of the wave *c* is a measure of the function of conductivity of the heart. It is called the *a-c* interval. In normally acting hearts this interval is almost constant. It does not measure more than one-fifth of a second. If it does, we know that there is a delay in the conduction of the stimulus, and this means that the function of conductivity is depressed. We call it depressed conductivity. This probably indicates some affection of the auriculo-ventricular bundle.

Let me repeat. A normal venous pulse shows three principal waves and in the following order—*a*, *c*, and *v*, and the *a-c* interval is not more than one-fifth of a second. When in a venous pulse the *a* wave is present the form of pulse is called the *auricular form of venous pulse*. The presence of the *a* wave tells us that the auricle is contracting normally. Under what circumstances do we get the auricular form of venous pulse? It is present in two classes—(1) in all normal individuals, and (2) in a large proportion of cases of heart disease. Please remember that it is present in a considerable percentage of cases of heart disease. When in a venous curve there is no sign of the presence of the wave *a* the type of pulse is called the *ventricular form of venous pulse*, in contradistinction to the auricular form

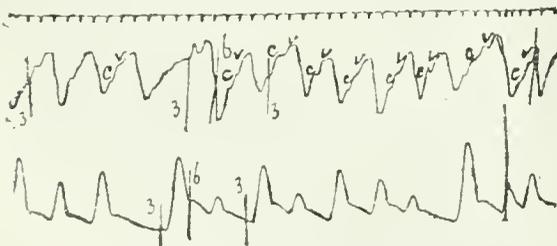

Fig. 2.—Ventricular form of venous pulse.

of pulse. By the ventricular form of venous pulse we simply mean that there is an absence of an *a* wave. What does the ventricular form of venous pulse indicate? It signifies that the auricle is not contracting in a normal manner. Under what conditions do we get it? We never

meet with it in normal individuals, but it is met with in many cases of heart disease. Therefore, if we take all cases of heart disease, whether mitral, aortic, or myocardial, and whether cardiac failure is present or not, we can divide them into two groups—(1) those cases in which the auricular form of venous pulse is present, and (2) those cases in which the ventricular form of venous pulse is present.

And now let us see how these facts are related to the subject in which we are interested this evening; and, keeping to the same order, we will take, first, the question of cardiac irregularity. I have already dwelt upon the confusion in regard to its significance. This confusion was perfectly natural, because it was found that some cases of irregularity lived to the normal span of life, and did not develop symptoms of cardiac failure; while others died from cardiac failure, perhaps soon or perhaps only after the lapse of some years. The point is, there were no means of determining the significance of the irregularity in any given case, because there were no means of differentiating the types of irregularity, or what any particular variety signified. Now this is all changed. We are able to classify the vast majority of cases of irregularity into types, and we know what each type signifies, and therefore we have rational and certain grounds for making a diagnosis and prognosis, and, as I shall show you later, in regard to treatment also. So that when a patient comes to us we can with confidence form a tolerably accurate opinion regarding his case.

Now all cases of irregularity, apart from comparatively rare exceptions, fall into one of five groups. I will enumerate them. They are: (1) What is called sinus irregularity, (2) irregularity due to what are called extra-systoles, (3) irregularity due to depressed conductivity, (4) irregularity due to the pulsus alternans, and (5) what may be called complete irregularity.

Sinus irregularity is characterized by a variation in the length of the diastolic period of the different cardiac

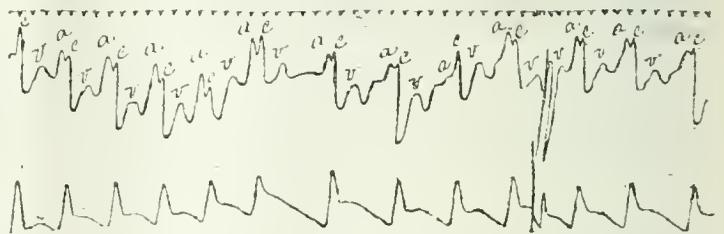

Fig. 3.—Sinus irregularity.

cycles, the systolic period remaining constant. The irregularity diminishes or disappears with increase of pulse-rate, while it is apt to increase or return with a slowing of the heart.

There is frequently a definite relationship to respiration; the irregularity is found best during slow respiration, and may only be present on deep breathing. We may be pretty sure that an irregularity is of the sinus type when there is a definite relationship to respiration. On auscultation, the interval between the first and second sound is constant, while the varying difference in the diastolic period can be made out. A certain diagnosis can be made by taking a polygraphic tracing, and usually a tracing of the radial artery is sufficient. In the case of the latter it will be found that there is no irregularity in regard to the size of the pulse waves, but the intervals between the beats vary, although there are comparatively few sizes of intervals.

Sinus irregularity is much more frequent in the young, but it may occur at all ages. It may occur during the administration of digitalis. The act of swallowing may produce it.

If any subjective symptoms are present, they are almost always merely incidental. What is the significance of this type of irregularity? Suppose that in a given case of irregularity of the heart we can be quite sure that the irregularity is of this type, what prognosis may we give?

The answer is, that the irregularity can be entirely disregarded; it is of no practical importance. No treatment is required.

Extra-systoles.—The second form of irregularity is due to what are called extra-systoles or premature contractions. By an extra-systole is meant a premature contraction of the auricle, or of the ventricle, or of both auricle and ventricle together, while the fundamental or sinus rhythm is maintained.

It is of very great importance to be able to recognize the presence of extra-systoles, because they constitute one of the most frequent causes of irregularity of the pulse, and they may be accompanied by subjective phenomena which cause the patient much distress and alarm.

When extra-systoles are present, the normal rhythm of the heart is interrupted either frequently or occasionally by a premature beat. The pause which follows the premature contraction is abnormally long. This is called the compensatory pause. When this prolonged diastole and the preceding shortened diastole together equal in time two normal cardiac cycles, then the compensatory pause is said to be complete. Since during the prolonged pause the ventricle has had an unusually long

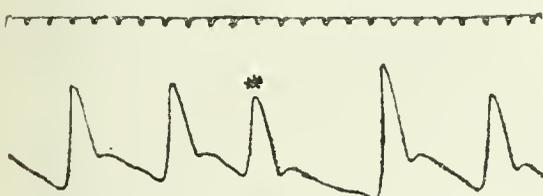

Fig. 4.—Extra-systole marked *. Large amplitude of pulse following extra-systole seen.

period in which to recuperate, the beat of the heart immediately following a compensatory pause often has a greater amplitude than the others. When a premature contraction is interpolated between two normal beats, the form of the extra-systoles is called "interpolated."

On auscultation, in the vast majority of cases two sounds are heard synchronous with each extra-systole. When the premature contraction is so feeble as to fail to open the aortic valves only one sound is heard. Very rarely the extra-systole is so feeble as not to produce any cardiac sounds at all. Auscultatory phenomena are important, because, as I shall show you later, they serve to distinguish extra-systoles from some grades of heart-block.

If an extra-systole occurs regularly after each normal beat, so that every normal beat is followed by a single

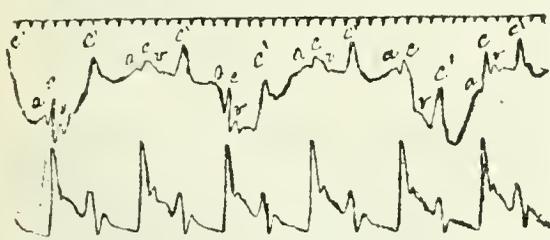

Fig. 5.—Extra-systole recurring regularly after each normal beat. Simulates pulsus alternans.

extra-systole and compensatory pause, then the pulse beats occur in pairs. The condition is pulsus bigeminus. I may as well mention here that another cause of the

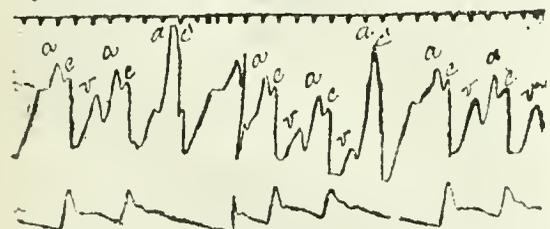

Fig. 6.—Extra-systole so feeble that no wave is palpable at wrist.

pulse beats occurring in pairs is when a patient with auricular fibrillation is getting too large a dose of digitalis. An extra-systole may be so feeble that no wave is felt

at the wrist, so that there is simply a long pause. This gives rise to what is called a "dropped beat" or an "intermittent" pulse. (Fig. 6.) The commonest cause of an intermittent pulse is an extra-systole which fails to reach the wrist. The next most common cause is partial heart-block, to which I shall refer later, and I shall tell you how to distinguish between the two conditions.

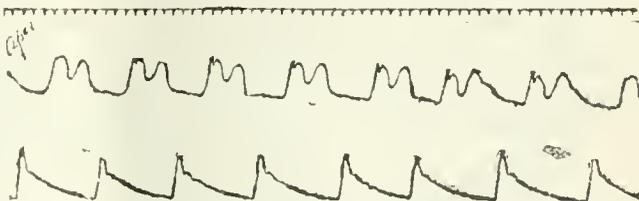

Fig. 7.—A tracing of the apex beat and radial pulse. Shows extra-systole occurring after each normal beat which fails to reach the wrist.

If an extra-systole occurs after each normal beat, and the extra-systole fails to reach the wrist on each occasion, there is halving of the rate of the arterial pulse. (Fig. 7.) This also is apt to be mistaken for partial heart-block, but, as I shall show you later, a differential diagnosis can readily be made.

Extra-systoles may be met with at any age, but they are much more frequent in the middle-aged and elderly than in the young. Indeed, in the elderly they are quite common. They are commoner in men than in women. They are more common in people who are the subjects of heart disease than in those who are not, and are more frequent in cases of cardio-sclerosis than in cases of valvular disease. But it should be remembered that there is a large group of cases in whom extra-systoles are present without any other cardiac abnormality. They may be present in people with a history of rheumatic infection, in excessive tobacco smoking, digestive disturbances, supernormal blood pressure, neurasthenia, and as a result of administration of certain poisons, especially digitalis, aconitine, muscarine, physostigmine, and adrenalin. In a considerable proportion of cases they occur without association with any of these conditions.

An individual with extra-systoles may be quite unconscious of their presence. On the other hand, he may experience sensations, and these may cause worry and anxiety, particularly if they occur after the patient has retired to bed. It is for this reason that it is very important that the nature of the complaint should be recognized. The patient may experience a sensation of fluttering in the chest when a premature beat occurs, or he may be conscious of the long pause and complain that "the heart stops," or the contraction of the heart following the pause may be accompanied by the consciousness of a thud or shock to the chest wall in the region of the heart. This thud may be followed by a feeling of exhaustion. The patient may complain of a sensation of gripping in the throat. Rarely, during a prolonged pause, faintness, sweating, and actual syncope may take place, and the anxiety of the patient may be profound. Even Adams-Stokes syndrome may be simulated.

What is the prognosis of extra-systoles? Unfortunately the public have come to attach a serious significance to them. This is absolutely without foundation. When extra-systoles are considered by themselves—that is, without reference to the conditions with which they may be associated—there is no evidence for supposing that extra-systoles can be taken as an indication of an impaired heart or add to the gravity of an already diseased heart. It is of the utmost importance that you should understand this. You may with absolute confidence reassure your patient.

In regard to treatment, your first duty is to remove any alarm in the mind of the patient. Any associated condition, such as dyspepsia or supernormal blood pressure, should be treated. Some hold the opinion that small doses of digitalis are of value for the irregularity itself. I have used the drug in many cases, and have never seen beneficial results to follow. The bromides are sometimes of value in masking or modifying the symptoms, especially in nervous subjects.

The third form of irregularity is that which may occur when the function of conductivity is depressed. I have

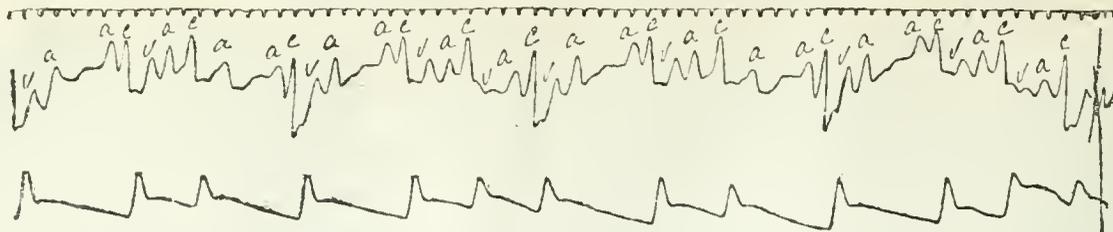

Fig. 8.—Occasional dropped beats due to partial heart-block.

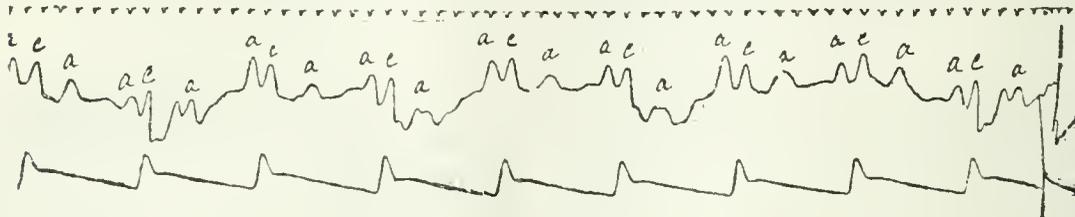

Fig. 9.—2:1 heart-block.

shown you that the stimulus passes from auricle to ventricle along the auriculo-ventricular bundle by means of a property called conductivity, and that the stimulus travels at a certain rate. The facility with which impulses pass along this tract may be impaired. There are three grades of impairment: (1) The stimulus from auricle to ventricle is merely delayed—that is, there is merely a prolongation of the interval which separates the commencements of contraction of the auricle and contraction of the ventricle. (2) The stimulus does not at times cross over: in other words, the ventricle does not at times respond to the stimulus from the auricle (this is called "partial heart-block"). And (3) no impulses at all reach the ventricle from the auricle, so that the auricles and ventricles beat quite independently of each other, the ventricles at an approximate rate of 30 per minute (this is called "complete heart-block").

In regard to the first grade, unfortunately it is only recognized with certainty by means of the polygraph.

In the third grade of heart-block, the auricles and ventricles beat quite independently of each other. As you know, the normal auricular rate is between 70 and 80 per minute. The normal ventricular rate is about 30 per minute; that is why the pulse is slow in complete heart-block. (Fig. 10.)

It is not my intention to go fully into the recognition of the various grades of heart-block. It can readily be understood that this is easily possible by the employment of the polygraph, since this instrument affords separate records of the upper and lower chambers of the heart. It is pretty safe to diagnose complete heart-block when the pulse is 36 or under.

In the severe grades of partial heart-block, and in complete heart-block, owing to the excessive slowing of the ventricular rate causing temporary anaemia of the brain, there may be attacks of faintness, giddiness, or temporary loss of consciousness. Adams-Stokes syndrome may be present.

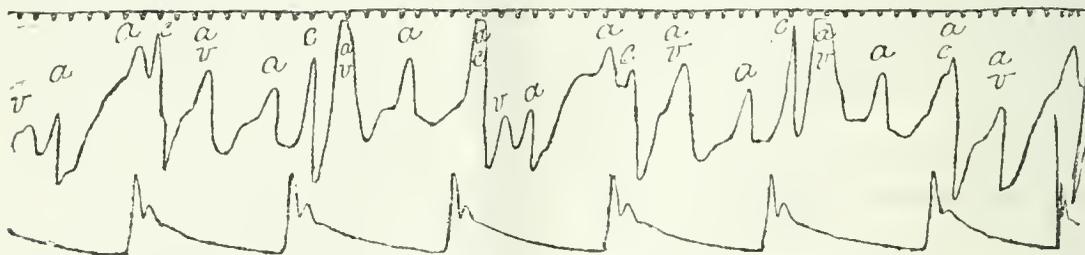

Fig. 10.—Complete heart-block.

The *a-c* interval is more than a fifth of a second. There may be considerable variations in the *a-c* intervals, and this causes irregularity of the pulse. In regard to this grade of depressed conductivity, it is important to remember that as a rule digitalis is contraindicated.

In the second grade of heart-block "dropped beats" occur. These may only be occasional, or they may be more frequent: each third or fourth impulse may fail to reach the ventricle; or every other impulse may fail to reach the ventricle, which gives rise to halving of the ventricular rate, the condition being spoken of as a 2:1 rhythm; or only each third or fourth auricular impulse may be transmitted to the ventricle, and we have 3:1 or 4:1 heart-block. In some cases of heart-block certain ratios may alternate. (Figs. 8 and 9.)

How may we distinguish between dropped beats which are due to extra-systoles failing to reach the wrist and dropped beats which are due to partial heart-block? Of course, we can do so readily by means of the polygraph. But in the great majority of cases there is a much easier way than this. All that it is necessary to do is to auscultate. In the case of extra-systoles which are not palpable at the wrist, heart sounds are heard during the pause, because the ventricle did contract; but in the case of partial heart-block no heart sounds are heard during the pause, because the ventricle failed to contract.

I shall not deal fully with the etiology and prognosis of the various grades of heart-block, as they are dealt with pretty fully in the textbooks. The only point I should like to mention is that heart-block of mild degree, giving rise to "dropped beats," sometimes occurs during the course of infective diseases, and is then frequently the only sign of myocardial damage. When present it increases the gravity of the primary disease. As a rule, however, it is temporary.

The fourth form of irregularity is that which is due to the presence of pulsus alternans. By pulsus alternans is meant a condition of the pulse in which the rhythm is perfectly regular, but each alternate beat is large and each alternate beat is small. The condition may be continuous, or it may only be observed by something which increases the pulse-rate—as, for example, exercise—or only during a few cycles immediately following an extra-systole. (Figs. 11 and 12.)

It is very unfortunate, but undoubtedly true, that in the vast majority of cases it is necessary to take a tracing of the radial artery in order to recognize it. Very rarely in cases in which it affects the pulse continuously it is perceptible by the finger. As the sign is of very great importance, we should always be on the look-out for it. On very rare occasions the small beats of pulsus alternans entirely disappear, and the pulse-rate is halved.

What is the significance of pulsus alternans? Well, its mere presence, that is apart from whether it is associated with other signs or not, is of very great importance. It is an indication of very great exhaustion of the heart

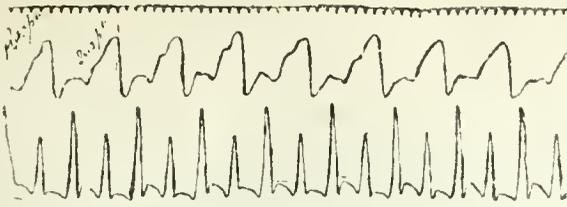

Fig. 11.—Continuous pulsus alternans.

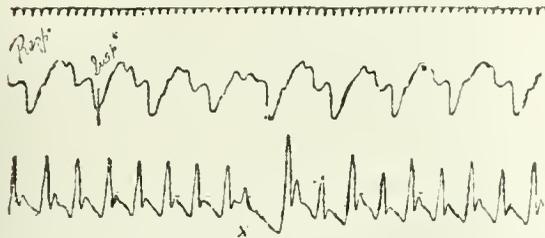

Fig. 12.—Pulsus alternans following extra-systole, etc.

muscle. When the alternans lasts only for a few cycles, the exhaustion may be only temporary. But even in these cases the prognosis must be very guarded. When the condition is continuous, in other words when it persists for many cycles, death usually follows within a few months, or at most in a few years, and sudden death is not uncommon.

In regard to treatment, absolute and prolonged rest, both physical and mental, is urgently needed.

The last form of irregularity to which I want to draw your attention can be described in one word; the irregularity is *complete*. It is an irregularly irregular pulse.

Rarely or never do two beats of the same character or length follow each other. The irregularity is more pronounced when the pulse is fast. With the slower rates we may have to adopt careful measurements of the tracings, as the variations in the length of pause are only small. The pauses between the beats show no relationship to each other, and there is seldom any relation between the strength of a beat and the length of the pause which preceded it—that is, a strong beat may succeed a short pause, and a weak beat may follow a long pause. The pulse is generally more rapid than normal; it may be very rapid. Many beats of the ventricle may not reach the wrist, especially when the ventricle is beating rapidly. Therefore, the ventricular rate should be counted at the

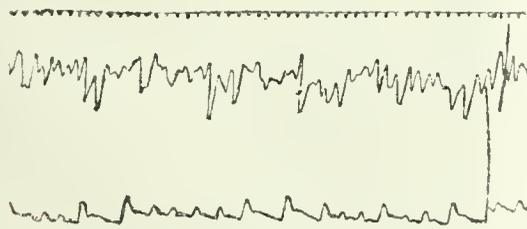

Fig. 13.—Complete irregularity of auricular fibrillation with a fast pulse.

Fig. 14.—Complete irregularity of auricular fibrillation with slow pulse.

apex, either by palpation or auscultation. All the beats may be of small amplitude, but most commonly there is an irregular intermingling of large and small beats.

What may we infer when this type of irregularity is present? We may infer that fibrillation of the auricle is

present. Now, gentlemen, the discovery of auricular fibrillation is one of the greatest discoveries in regard to heart affections which has ever been made. It is of tremendous practical importance that the condition should be recognized in regard to the diagnosis, prognosis, and treatment of cardiac disorders. It is a specific clinical condition, and fortunately its recognition is unattended with much difficulty, and can be made with certainty.

What is meant by auricular fibrillation? By it is meant a condition in which co-ordinate contraction in the auricle is replaced by inco-ordinate contraction. Instead of contracting in an orderly and simultaneous manner during systole, the individual fibres contract rapidly and independently of each other. The result is that systole, either partial or complete, of the chamber as a whole never takes place.

What is the effect of auricular fibrillation on the heart? Instead of the ventricle receiving stimuli from the auricle at regular intervals, it receives them at completely irregular intervals, and thus the ventricle is embarrassed in its work. Also, the impulses which escape are numerous, and if the conducting tissues are able to transmit them, the ventricular rate rises. Thus an irregular, and in the vast majority of cases a far too frequent, pulse is produced; the pulse rate may be as high as 140 or even 180 beats per minute. Very rarely the pulse is very slow. Such a profound change in the action of the ventricle as a rule produces a marked effect on the heart's efficiency.

When auricular fibrillation has once set in, in the majority of cases it persists for the patient's life. But, instead of this, it may appear for a few hours and afterwards never appear, or it may occur at infrequent intervals for weeks or months and then disappear. Many cases of paroxysmal tachycardia are due to auricular fibrillation, and may last for a few seconds, hours, days, weeks, or months. The tendency to occurrence increases, however, until finally the condition becomes permanent. The onset of auricular fibrillation is sudden. As a rule the onset of the symptoms is gradual, but it may be very rapid and cause the patient to become very ill within a few hours. Similarly, if the condition is intermittent, its cessation may be accompanied by an equally rapid and marked improvement in the patient's condition.

What are the symptoms of auricular fibrillation? They are the same as those of cardiac failure from other causes, such as exhaustion, shortness of breath, cyanosis, and dropsy. Patients may also complain of fluttering in the chest and neck or of irregular action of the heart. Apparently, however, they never suffer from angina pectoris. Occasionally there is an absence of symptoms of cardiac failure in auricular fibrillation, and, needless to say, they may be present in heart disease without auricular fibrillation. When the ventricular rate is over 90 per minute as a rule there are symptoms of cardiac failure.

Under what conditions may auricular fibrillation occur? It is found to arise under a variety of conditions. The majority of cases fall within two groups: (1) Those with a history of rheumatism, and (2) patients suffering from cardio-sclerosis. Those with a history of rheumatism frequently have valvular disease, more often mitral than aortic disease, and especially mitral stenosis. The condition has been seen in pneumonia, diphtheria, infective endocarditis, and in people dying of exhausting diseases, such as cancer. Digitalis may induce it in predisposed cases. In other words, auricular fibrillation may be present in any organic disease of the heart (mitral,

aortic, and myocardial). On the other hand, any organic disease may be present without auricular fibrillation. Therefore, we can divide all organic disease of the heart into two great groups: (1) Those cases with auricular fibrillation, and (2) those cases without it.

Are we able to recognize auricular fibrillation? Yes, with certainty and fairly easily, by the following: (1) The pulse is completely irregular. When the pulse is slow, as, for example, when the patient is under the influence of digitalis, it may be necessary to take a tracing of the

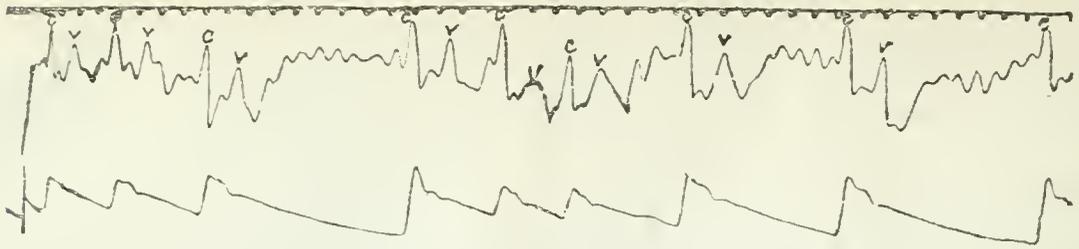

Fig. 15.—Multiple undulations in the venous curve with auricular fibrillation.

radial artery. (2) In mitral stenosis, and if a presystolic bruit, *due to auricular systole*, was present, it disappears with the onset of auricular fibrillation. If a diastolic bruit was present, it persists. A word of warning is necessary here. A murmur filling the whole space between the second and first sounds may be present in cases of rapid heart action, and the latter part of the murmur is not infrequently mistaken for a presystolic murmur due to the systole of the auricle. This mistake need not and should not arise. The murmur is not crescendo in type. On auscultating during one of the long pauses, or when the heart's rate becomes slow, a silence will be detected between the termination of the murmur and the first sound. (3) In a tracing of the jugular vein there is an absence of the normal *a* wave; in other words, there is the ventricular form of venous pulse. The normal *a* wave cannot be present because the auricle does not contract. Instead of the *a* wave, there may be multiple undulations. (Fig. 15.)

In regard to the prognosis of auricular fibrillation, the condition is indicative of some myocardial affection, and, furthermore, it is a specific clinical entity which necessarily has a profound influence on the action of the heart. The prognosis depends upon whether the heart is able to carry on its work under the new rhythm, and this, in turn, depends upon the integrity of the heart muscle. If this be good, for years there may be little or no indication of cardiac failure. In the great majority of cases, however, this is not the case, so that a considerable degree of cardiac failure results. This is especially the case when the pulse is very rapid and there is considerable dilatation of the organ. A persistent pulse-rate of 120 or over is serious. Two points of great importance in trying to form a prognosis of auricular fibrillation are (1) how far is the patient able to modify his life so as to bring it within the limit of the heart's strength, and (2) how does the heart respond to treatment? The latter point will be dealt with more fully later on.

We have now come to the end of what I have to say in regard to the subject of irregularity of the heart. I hope I have shown you that any given case must, apart from rare exceptions, fall into one of five groups, according to its type, and as we know what each type signifies we have certain and rational grounds in regard to diagnosis and prognosis, and, as I shall show you in a few minutes, we have information in regard to treatment also.

And now let us pass on to the problem of digitalis. Why is there such an extraordinary difference in the results of administration of the drug or of its allies in persons who are suffering from identically the same lesion and complaining of precisely the same symptoms? Put briefly, the answer is that the response to digitalis differs according to the condition of the heart and character of the rhythm: those cases of cardiac failure which show wonderfully good results are, in the vast majority of instances, cases of auricular fibrillation. Let me go into the matter in some detail. For the last few years I have been associated with Dr. James Mackenzie and Professor Cushman in conducting at the Mount Vernon Hospital a series of investigations dealing with the action of digitalis, and some of its allies, on the human heart.

Our plan of investigation has been as follows: With the exception of those cases where the symptoms required immediate treatment, all the patients were first given a course of rest before any drug was administered. The rule was not to commence with any drug until the pulse-rate, which had diminished as the result of rest and other causes, had remained stationary for at least some days. This allowed us to study the effect of rest, and it prevented

any drug being credited with results which were in reality due to adventitious circumstances.

Each case was daily observed, examined, analysed, and recorded with scrupulous care, attention being paid to the minutest detail. Graphic records were taken by means of the ink polygraph, and sometimes tracings were taken continuously for long periods, even up to an hour or two.

In regard to dosage, our practice has been to give, as a rule, 1 drachm of the tincture per day; or, if the case was urgent, as much as $1\frac{1}{2}$ drachms, or even 2 drachms a day. These doses were continued until some definite reaction was obtained; usually a reaction was obtained within a week, sometimes in a few days. Rarely was any distinct change to be seen before the fourth day of treatment. The drug was then stopped. If afterwards the heart relapsed to its former condition—which happened in a considerable proportion of cases, and usually in about a week—we endeavoured to find the dose which maintained the improved condition without producing any toxic symptoms. After a thorough trial with digitalis, we often tried strophanthus, squills, or one of the other drugs, and then, perhaps, went back to digitalis. We were thus able to find out the relative usefulness of these drugs, and to estimate the comparative dosage.

The first series of cases examined were 21 cases of mitral disease, 11 cases of aortic and mitral disease (in some of these the only evidence of mitral disease was the presence of a mitral systolic murmur), 1 case with aortic systolic murmur, 3 cases of cardio-sclerosis without evidence of valvular disease, 1 case of paroxysmal tachycardia, 1 case of tachycardia of obscure form, 1 case of complete heart-block, 1 case of emphysema with a mitral systolic bruit, and 3 cases of pulmonary tuberculosis with pyrexia. Of the mitral cases, 10 were cases of auricular fibrillation, while 11 were not. Of the aortic and mitral cases, 3 were cases of auricular fibrillation, and 8 were not. The aortic systolic case was not a case of auricular fibrillation. The 3 cases of cardio-sclerosis were cases of auricular fibrillation. Thus, of the 36 cases of valvular disease or cardio-sclerosis, 16 were cases of auricular fibrillation, and 20 were not. The case of emphysema and the 3 cases of pulmonary tuberculosis were not cases of auricular fibrillation.

Carefully analysing the results of these cases, the following facts were elicited: Of the cases of auricular fibrillation, all excepting 2 showed a marked slowing of the pulse and great improvement in the general condition. The two exceptions were one case in which there was pyrexia present, and another case, a man of 67 years of age, in which, while there were no evidences of valvular disease, there were indications of advanced cardio-sclerosis. The best results were obtained in those cases with a rheumatic history. In regard to the cases without auricular fibrillation, in 2 cases auricular fibrillation developed during the administration of the drug, and these cases responded to digitalis in the same manner as did most of the other cases of auricular fibrillation. Apart from these rare exceptions, in no case was there a marked slowing of the pulse or marked improvement in the general condition; in a few there was a moderate or slight degree of improvement; while in most the administration of digitalis or of its allies appeared to have no beneficial effect at all. Where improvement did take place it was comparatively slow, and it was often difficult to be sure how far the improvement was due to the rest in bed and other measures adopted and how far it could be ascribed to the drug. In general the improvement in these cases was accompanied by no definite decrease in the pulse-rate, but in a few auriculo-ventricular block or very marked slowing of both auricle and ventricle

occurred. The slowing in most cases arose from inhibitory action, but in a few cases it arose from direct action on the muscle.

In regard to dosage: as a rule improvement could be started after a time by small doses of 5 minims of the tincture three times a day, but they always required a much longer period to do so than large doses, which produced their full effects rapidly; and sometimes the small doses produced no effect in cases which responded well to the full doses. The inference is, therefore, that it is better to commence with full doses and to go on with these doses until the patient is completely under the influence of the drug, and then, if required, to continue the administration, but to diminish the dose until it is discovered what dose will keep the patient in the best condition. The indications for stopping the drug were the following: (1) Nausea or vomiting, (2) severe headache, (3) diarrhoea, (4) an unduly slow pulse, (5) coupling of the beats in cases of auricular fibrillation, and (6) partial heart-block in cases without auricular fibrillation. With the cessation of the drug, the stomach symptoms passed away.

In cases of auricular fibrillation there was a majority of cases who relapsed to the former condition in about a week after the drug was stopped. Renewed treatment restored the improvement. After a more prolonged course a relapse was often much less severe, and ultimately the improvement could be maintained with comparatively small quantities or with larger amounts taken at intervals of several days. The maintenance of the improvement was one of the most difficult matters to understand. Only great perseverance in each case enabled us to discover what particular dose kept the patient in the best condition. We found a great difference in the amount required. In one case it was as small as 1 drachm per week, while in another it was as large as 45 minims per day. As I have said, we endeavoured to find the dose which maintained the improved condition without producing any toxic symptoms, and in this respect patients were usually able to say what quantity acted best. Having discovered the best dose to maintain the improvement, patients were discharged, and were usually able to resume work while taking the drug. I should like very briefly to describe to you one case of auricular fibrillation to illustrate the kind of experience we had:

A gardener, aged 24, admitted to the Mount Vernon Hospital February 8th, 1910, complaining of weakness, palpitation, and shortness of breath.

History.—Two attacks of rheumatic fever at 12 years of age, and a subsequent attack at 18. Has been indisposed off and on ever since last attack, suffering from giddiness and shortness of breath. During the last year has been unable to work on account of shortness of breath, palpitation, pain in præcordia, swelling of abdomen, and swelling of legs. Has been in St. George's Hospital during the last four months.

State on Admission.—Orthopnoea. Pulse completely irregular, and the rate varies much from time to time, being at one time 117 and at another 88 per minute. There is a large area of cardiac pulsation in the third, fourth, fifth, and sixth interspaces. Transverse diameter of heart 7½ in. At the apex a loud systolic and a soft, short, diastolic bruit audible. The liver is felt pulsating for several inches below the costal margin. Oedema of the legs and hydrothorax are present.

Progress of the Case.—The patient was treated only by rest for ten days, and made a slight improvement, though he at once became worse when he walked a few yards. On February 19th he was put on to 15 minims of tincture of digitalis four times a day. Under the influence of the drug the pulse became slower in a few days, and the patient's condition rapidly improved. After eleven days there was a good deal of nausea, and the drug was stopped. The pulse had come down from 99 to 40. It remained under 50 for six days, when it began to rise and the dyspnoea and palpitation returned. As these phenomena continued, on April 4th digitalis was recommenced. The symptoms steadily improved, and the pulse-rate steadily came down, so that by April 11th, that is after he had taken 10 drachms, the pulse was 44. The drug was then stopped because of vomiting. We then tried him on smaller doses, and after much perseverance we found that his condition was best when he was taking about 100 minims per week. He was discharged on May 29th, feeling well, and has continued at his work, which involves severe physical exertion, ever since.

In cases without auricular fibrillation, in which there had been improvement, the improvement was usually obtained without continuing the drug. This would suggest that rest may have been a more important factor than the drug.

Comparing the different drugs, strophanthus and squills are still supposed to differ somewhat from digitalis in

their effects. We found no essential variation in the action of the three drugs on the heart. It required nearly twice the dose of tinctures of strophanthus and of squills as of tincture of digitalis, but the former two showed considerable variation in regard to dosage. In some cases they seemed to have less tendency to cause headache and gastric disturbances than digitalis, but this was not constant. On the other hand, they appeared to have a greater tendency to produce diarrhoea. In no case in which digitalis failed did any of the other members of that group of drugs succeed. On the whole, digitalis appeared to be more certain in its effects than either strophanthus or squills, but some patients seemed to tolerate the last two more easily than digitalis. Therefore they should be regarded as substitutes for digitalis. As I have already stated, aconite had no effect upon the pulse-rate. In no case in which the tincture of digitalis failed did any of the other preparations of that drug succeed. Samples of tincture of digitalis supplied by firms of chemists of repute proved wonderfully constant in strength.

It was found that the active principles of digitalis, strophanthus, and squills readily underwent decomposition when the tincture was diluted with water, and this was especially so in the case of strophanthus. For this reason the tinctures should be dispensed as such or diluted only with alcoholic preparations, with directions to the patients to take them in water, if necessary.

In a paper which I read at the annual meeting of the British Medical Association at Liverpool, and which was published in the BRITISH MEDICAL JOURNAL in September, 1912, I showed from investigations that, judged by the methods in use for observing the blood pressure clinically, the internal administration of digitalis does not raise the blood pressure in man by constricting the peripheral vessels. If that be so, there is no risk in administering the drug in cases of degeneration of the walls of the blood vessels or of supernormal blood pressure.

How does digitalis act in cases of auricular fibrillation? It was supposed that the slowing was inhibitory in origin. This has been found not to be so, for it remains after large doses of atropine. It must arise, therefore, from some direct action on the muscle of the heart. As the auricle continues to fibrillate as before, it may be presumed that the digitalis acts either in the bundle of His or in the ventricle itself. Either fewer impulses reach the ventricle from lessened conductivity in the auriculo-ventricular bundle or the ventricle becomes more refractory; in either case the ventricular rate is reduced.

Now, the practical points which I want you to carry away with you in regard to these and other cases which we have investigated, and from the investigations of other workers, are: Digitalis should not be administered as a mere rule of thumb in all cases of cardiac failure. In any given case, whether there is mitral disease, aortic disease, or disease of the myocardium, you should determine by the means which I have explained to you whether auricular fibrillation is present or not. If fibrillation is present, and it is accompanied by a very rapid pulse, you know that, whatever the lesion, in most cases, and especially in those patients with a history of rheumatism or chorea, you have a therapeutic agency of wonderful potency, and that it is possible to establish and maintain control of the heart-rate. The administration of the drug is followed by a rapid fall in the pulse-rate and a concomitant improvement in the general symptoms. Certainly two exceptions are: (1) Cases of cardio-sclerosis in which the degenerative change is so widespread that little healthy muscle remains; (2) cases in which there is pyrexia. When pyrexia is present, apparently the response to digitalis is as a rule very slight, if at all, whether auricular fibrillation is present or not. It is well to begin with a drachm of the tincture per day, or in urgent cases with even 1½ or 2 drachms per day, and continue until there is nausea or vomiting, diarrhoea, headache, an unduly slow pulse, or what is called "coupling of the beats." Coupling of the beats is a danger signal. We should either stop the drug for a few days or diminish the dose. Usually a reaction is obtained within a week, sometimes in a few days. Then the drug should be stopped until the symptoms have passed away. As a rule the patient relapses. The indication then is to find out what dose suits him best—that is, the dose sufficient to control the heart without producing toxic symptoms. It may require

weeks or even months of careful observation to find this optimum, and much perseverance will generally be required. In this respect help may frequently be obtained from the patient himself, who is often able to say what quantity suits him best; in other words, his own sensations are often a good guide. Having discovered this dose, in the great majority of cases it will be necessary for the patient to continue taking the drug for the remainder of his life. Apparently the cumulative action is not nearly of such serious account as has been supposed. Still the pulse ought to be watched day by day. By this mode of treatment you will save many lives and also bring comparative comfort to people who would otherwise be the subjects of much misery. When auricular fibrillation is not accompanied by a rapid pulse, no marked result follows the administration of digitalis; the result is scarcely greater than in cases without auricular fibrillation. The improvement is slow, and it is often difficult to be certain how far the improvement may be due to the rest in bed and other measures adopted, or to the drug.

If the case is not one of auricular fibrillation you will know that—apart from those exceptional cases in which auricular fibrillation occurs during a course of administration of the drug—as a rule, though, I am glad to say, not in all cases, the beneficial results will be only moderate or slight, or none at all. If improvement does occur, it can usually be maintained without continuing the drug. And, lastly, in regard to the administration of digitalis, it is possible to do harm in cases of diminished conduction.

Apparently, no preparations of the digitalis series of drugs are superior to the tincture of digitalis for ordinary treatment. Strophanthus and squills should be regarded as substitutes for digitalis. They may be tried when a patient is found to be peculiarly intolerant to digitalis.

In regard to the so-called alleged active principles of digitalis, it cannot be too strongly insisted that there is no pharmacological or clinical evidence that they are either pure substances or that different samples of them are uniform in potency. And therefore there is no reason to believe that they are more reliable than, and possibly they are not so reliable as, different samples of the tincture.

In the most acute cases of cardiac failure, when it may be desirable to elicit a more rapid effect than is possible by the administration of tincture of digitalis or one of its allies by the mouth, strophanthin may be administered intravenously, either two or three doses of $\frac{1}{2}$ gr of a grain at an interval of two hours, or a single dose of $\frac{1}{10}$ of a grain. Marked improvement sometimes follows in from four to eight hours. The action is in every way similar to that obtained by tincture of digitalis by the mouth, except that the same result follows in from four to eight hours instead of in about a week. Whenever necessary, we can continue the administration of tincture of digitalis by the mouth.

I have come to the end of the time at my disposal. My remarks have, on account of time, necessarily been incomplete. But I have tried to solve in some measure the problem of the significance of cardiac irregularity and the problem of the difference in the results following the administration of digitalis.

Many problems still remain to be attacked and solved. But, in conclusion, I venture to reassert the belief that the introduction of graphic methods in the study of heart disorders has been attended with brilliant results, and will compare favourably with any in medicine or surgery which have been introduced in recent years for the benefit of suffering humanity.

MR. P. H. ADAMS, B.M., F.R.C.S., has been elected to the Margaret Ogilvie Readership in Ophthalmology at the University of Oxford.

THE Metropolitan Asylums Board has arranged, for the benefit of candidates for the Diploma in Public Health, a three months' course of lectures and demonstrations in hospital administration—at the Eastern Hospital, Homerton, by Dr. E. W. Goodall, at 2.30 p.m. on Tuesdays and Fridays, beginning April 4th; at the North-Western Hospital, Hampstead, by Dr. J. MacCombie, at 5 p.m. on Mondays and Thursdays, beginning April 7th; and at the Grove Hospital, Tooting, by Dr. J. Beggs, at 5 p.m. on Wednesdays and Fridays, beginning on April 25th. The fee for the course is three guineas.

An Address

ON

CERTAIN PHYSICAL SIGNS OF MYOCARDIAL INVOLVEMENT.

DELIVERED AT THE OPENING OF THE NORTH-EAST
LONDON POST-GRADUATE COLLEGE,

BY

THOMAS LEWIS, M.D., D.Sc., M.R.C.P.,

LECTURER IN CARDIAC PATHOLOGY; ASSISTANT PHYSICIAN,
UNIVERSITY COLLEGE HOSPITAL.

LADIES AND GENTLEMEN,—In my address to you to-day I am going to speak chiefly of acute and subacute affections of the heart. This, as you are well aware, is a wide subject, and involves many problems of complexity, and some which will long remain unsolved.

But in one direction the veil of obscurity is rising a little, and it is to the new facts which have been laid bare and their possible significance that I wish to direct your attention at the present time. I have no doubt that it has been repeatedly impressed upon your minds that, in acute and subacute affections of the heart, the damage is not limited to the membranes which cover the organ both within and without. It is needless to remind you that the myocardium also suffers. Yet in practice our attention tends to direct itself especially to that organ or that portion of an organ which is responsible for evident physical signs. Our conception of a given patient's condition is profoundly affected by the appearance of a pericardial friction rub or endocardial murmur. It is but natural, perhaps, under the circumstances, that our thoughts should focus upon pericardium or heart valve, as the case may be. We are impressed by what we hear through the stethoscope, and our diagnosis, "acute pericarditis" or "acute endocarditis," clearly reveals the trend of these thoughts. It is imperative that the myocardium should not be lost sight of; this warning has been repeatedly uttered. The valve and the pericardial sac are relatively but trivial appendages; the simple loss of one or other, though it may increase the burden of work to be borne by the organ as a whole, is not irremediable. Neither valve nor sac is indispensable; efficient or tolerably efficient work can be undertaken and continued for long, if not normal, periods of time by a heart deprived of one of these structures. That fact is taught quite clearly by clinical experience.

The myocardium is the vital part of the heart; its condition should be now, and in the future inevitably will be, the first consideration in all patients in whom the working power of the heart is to be estimated or aided.

The importance of the myocardium, be it in acute or chronic heart affections, is paramount, whenever we regard our patient from the purely cardiac standpoint. And when I speak of the myocardium, I am thinking not only of the contractile tissue of the ventricle, but also of that of the auricles.

These preliminary remarks bring me to my main topic. It is of great importance that any physical sign which speaks of events which are happening in the muscle of the heart should receive the closest scrutiny, and that we should endeavour to ascertain its exact significance. Certain of these signs it is my purpose to discuss.

The greater part of the myocardium may be termed *silent*, in precisely the same sense that certain of the areas of the brain are so termed. Conspicuous lesions of the ventricular wall may be present and give rise to neither sign nor symptom. Large areas of muscle may be degenerate, and the symptoms and signs may be few and obscure. But as there are certain tracts in the central nervous system which, when affected, produce manifest disturbances, so, as recent work has shown us, there are tracts in the heart which display their injuries in a conspicuous manner. The auriculo-ventricular bundle, as you are aware, is a fine neuro-muscular strand which connects to the musculature of the auricle; in its downward course it divides into two main branches, the right and left divisions of the bundle, each of which is connected to the ventricle by an intricate arborization. This system

formed by the main bundle, the two main divisions and their terminal arborizations, is concerned in maintaining the co-ordinate beating of the cardiac chambers. When the auricle contracts an impulse travels through the main conducting tract, passes into its two chief divisions, and is distributed in the two ventricles. The impulse awakens a ventricular response. The impulse occupies time in passing from auricle to ventricle, and, as an indication of the time taken, we use the interval which elapses between the onsets of contraction of these two chambers (*As-I's* interval). The *As-I's* interval, as it is termed, thus becomes an index of the functional integrity of the tract as a whole. It may be estimated clinically with considerable exactitude, for we have means of recording the contraction in auricle and ventricle. The two methods of obtaining an index are the polygraphic and the electro-cardiographic. The *As-I's* interval as expressed by these two methods varies normally within certain limits. In polygraphic curves the *a-c* interval (representing, *a* the contraction of the auricle, and *c* the impulse in the arteries of the neck) varies from one-tenth to one-fifth of a second. In electro-cardiographic curves the *P-R* interval (representing, *P* the first auricular electric effect, *R* the first ventricular electric effect) varies from 0.12 to, at the most, 0.20 second. Increase in the *As-I's* interval or a failure of the ventricle to respond to the auricular impulse tells us clinically of deficient action of the auriculo-ventricular tract. These phenomena are spoken of collectively as "heart-block."

Now, chronic heart-block has received much study, and is at the present time one of the most fully understood subjects of modern medicine. Acute and subacute heart-block, though much more frequent, has received far less attention. My remarks will be confined to these last types, and I shall illustrate them freely by brief reports of actual cases.

Acute and Subacute Heart-block in Rheumatic Cases.

We may commence by studying infections of rheumatic origin, for they are of the greatest importance and throw considerable light upon the pathology of chronic rheumatic heart disease. I will cite a characteristic case.

A young girl, who had enjoyed fair health, was admitted under my care at the City of London Hospital, giving a history of palpitation, shortness of breath, and pain in the chest and knees of five weeks' duration. She was very seriously ill, having evident signs of pericarditis and cardiac embarrassment accompanied by commencing signs of oedema of the lungs.

I need not detail the physical signs, but, as a *post-mortem* examination subsequently proved, she was suffering from inflammatory lesions of the pericardium and of all the valves, with the exception of the pulmonary, and that these lesions were clearly of rheumatic origin. Four days after admission irregularity of the heart was observed, and this was proved to be due to heart-block (prolonged *a-c* interval and dropped beats); the heart-block continued until death supervened a fortnight later. A microscopic examination of the heart, undertaken by Dr. Butterfield, revealed perivascular inflammatory lesions of rheumatic type in the myocardium, which, while diffusely scattered in auricle and ventricle, were conspicuous in the region of the central fibrous body, where they had invaded the auriculo-ventricular bundle.

This case, which has been fully described, with the curves,³ may be taken as our starting point. It represents one of the most severe forms of acute rheumatic heart disease, invading all the layers of that organ and quickly terminating the life of the patient.

It serves as an extreme type of the cases which I shall present to your notice. The appearance of heart-block at an early period of observation was the most emphatic sign which we obtained of myocardial involvement. I do not say it was the only sign, for in this particular instance we should have been led to suspect it from the profoundness of the symptoms, the prostration, the extreme breathlessness and restlessness of our patient. But it is an important case, because we had the rare opportunity of correlating our physical findings, including the graphic records, with a very complete examination of the heart.

A case, which was not dissimilar in many respects, has been reported by Gerhardt.⁷ It was a case of acute rheumatic heart affection in which all layers of the organ were involved. But there was this important difference: whereas our case died of the rheumatic affection, Gerhardt's case succumbed, while recovering, from a superadded infection—namely, typhoid. In Gerhardt's

case perivascular inflammatory lesions were also found, but while the ventricular muscle did not escape, the bundle showed the chief inflammatory lesion. In this case, too, heart-block was the most positive sign of the myocardial mischief.

My purpose in citing these two cases will be clear. It is to impress the simple fact that the development of heart-block during the course of an acute rheumatic illness is an evidence of myocardial involvement, not necessarily limited to the auriculo-ventricular bundle, but almost certainly spreading to a greater or lesser extent beyond it. The sensitive tract, when implicated, is responsible for signs which, relative to the extent of the lesion, are far more conspicuous than those yielded by implication of the general mass of the ventricular muscle; and I am obliged to cite examples of severe trouble because they alone come to autopsy. The majority of the rheumatic illnesses end in recovery, and this is one of the chief difficulties in studying them. We have largely to judge of the events which have occurred in milder attacks from our findings in those which are severe.

I have notes of another patient, a lad of 14 years, who, having suffered on three occasions from rheumatic fever, was admitted to hospital with frank signs of acute pericarditis. He was for the time being very seriously ill. A large effusion developed which subsided but slowly. Within a few days of admission heart-block was noticed (prolonged *a-c* interval and dropped beats), and this was maintained for a number of days (Fig. 1). Eventually,

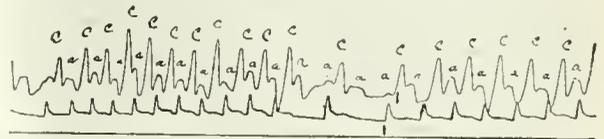

Fig. 1.—Polygraphic curves taken from a boy suffering from pericarditis of rheumatic origin. It shows partial heart-block; prolongation of the *a-c* interval and two dropped beats are present.

and as he recovered, the irregularity disappeared, and the *a-c* interval became normal. His heart permanently crippled, he left hospital.

We should stop to ponder the extent of the damage which the myocardium suffers in these severe cases which recover. That it is implicated is certain, that there is partial recovery is equally certain, but that a permanent legacy remains few can doubt.

We have not the opportunities of following the development of a chronic rheumatic heart fully through all its stages in one case. We can but sample our cases here and there, following the disease as a whole in different patients and piecing the history together. Ever and anon a patient succumbs; it may be at an early, it may be at a later period in the history of the affection. We seek what we can find in his remains, but often the morbid process has advanced too far for our needs.

We know the chronic malady to be slow in its completion. Is its progression uniform or does it come in successive and well-defined stages? I believe that we must accept the last view, from the evidence which we possess, and that, while we must recognize that the steps are neither equal in extent nor uniform in their incidence, it is by oft-repeated damage that those incurable rheumatic heart diseases are produced, the unfortunate sufferers from which swell the ranks of our out-patient departments and wards.

We must look for the steps, and the observation of transient heart-block will, I believe, often help us to discover them. This brings us to considerations which I am anxious to emphasize, for the cases already described are those in which none could overlook the signs of infection of the heart. In a very large percentage of the cases of gross heart affection, which from their nature and antecedents may be classed as rheumatic heart disease, no history of grave illness can be obtained. How many young girls come to us with advanced mitral stenosis and degenerate heart muscle and relate the story of a single and mild attack of chorea or rheumatic fever! Yet mitral stenosis does not develop during an attack of either; the advanced lesion is one which has evidently taken a long while in the making. So also has the degenerate muscle

which so often accompanies the valve lesion. The process occurs insidiously, and it is often most difficult to trace its cause.

Now heart-block is not an uncommon accompaniment of acute or subacute rheumatism, and, as in the cases of Cowan, McLeod and Paterson³ and of Magnus Alsleben,⁴ it may be practically the only sign of invasion of the heart. It is generally transient; it is mild in degree, consisting often of a simple prolongation of the *A*s-I's interval. Such simple prolongation of the interval will only become manifest when sought deliberately; it is probably a relatively common event in rheumatic cases, being as a rule overlooked.

But it is seen not only during the actual course of the joint invasion, but also from time to time in rheumatic subjects, apart from such disturbance. I may instance a patient who illustrates this contention.

A young woman of 21 was admitted to hospital for an operation in relief of exophthalmic goitre. The eyes had been prominent for two years; palpitation and the enlarged thyroid had appeared six months previous to admission. She was a rheumatic subject, having had an illness, in which several joints were painful and swollen, at the age of 16, and having suffered from frequent attacks of joint pain in the interval. Her heart exhibited the excited action common in her disease: the ventricular rate was 135 per minute on admission; a little enlargement to the left and a systolic murmur were noted. The greater part of the thyroid was removed at the operation, and the progress of the patient was uninterrupted for the space of six days; on the seventh day the heart became slow (40 to 50 per minute), and occasionally irregular, and this proved to be the result of partial heart-block. There was no fever at the time or subsequently. The further course is important. On the first day of the appearance of the irregularly nearly every second auricular impulse failed to reach the ventricle; on the second day the alternate impulses failed to yield response in the majority of instances (Fig. 2); on the third day the failure of response was much less frequent; on the fourth day the failure of response was not seen, but the *A*s-I's interval, as portrayed in

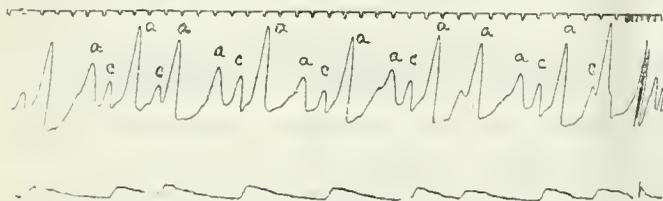

Fig. 2.

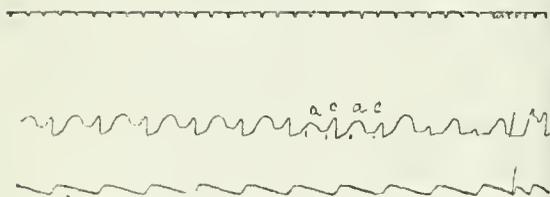

Fig. 3.

Figs. 2 and 3—Polygraphic curves from a case of exophthalmic goitre. The first curve was taken near the beginning and the second curve near the end of a transient attack of partial heart-block. The patient was a rheumatic subject. Fig. 2 shows very frequent dropped beats. Fig. 3 shows simple prolongation of the *a-c* interval.

both polygraphic curves and electro cardiograms, was unduly prolonged (*a-c* and *P-R* intervals from 0.28 to 0.30 second). On the seventh day the interval was still prolonged (Fig. 3), but on the eighth day the prolongation had vanished, and was not again seen, though the patient was repeatedly re-examined.

The events which were passing in this heart can be readily interpreted; we can imagine the origin of an inflammatory process, situated in the myocardium and involving the junctional fibres; an exudation of leucocytes attended by engorgement of the vessels and tumefaction; later its subsidence, the absorption of the fluids, and the

relief of the bundle tension. But what we cannot estimate in this patient is the degree of permanent damage left in the bundle and in the muscle of the heart. That in this or similar cases there is permanent damage most, I think, will agree; and what I suggest to you is that it is precisely in attacks such as these that the foundation of gross rheumatic heart disease is laid. I am inclined to regard an attack of this sort as one of a number of steps which, if they succeed each other, lead to permanent crippling of the heart as a working organ. In the patient in question the step would be an early one, and would not necessarily be repeated. I use it as an illustration from this standpoint, and also because had the attack occurred while the patient was at home it would almost certainly have escaped detection; it occurred without symptoms, and its course was afebrile. How often the susceptible experience such attacks is, of course, unknown at the present time; observation of them is often accidental, and their study demands very numerous fruitless examinations. They are certainly far more common than we have had reason to suppose. I might instance a very similar attack, also afebrile, in a girl of 13 years, who had rheumatic fever a year before I saw her. She sought advice for pains in the neck. The heart was normal in size, but there were early signs of mitral stenosis. The heart-block (Fig. 4) lasted for approximately four weeks, and then subsided entirely.

We may pass to later chapters in the same story. If chronic myocardial disease comes in the manner suggested we may expect to see evidences of the same process in cases in which the heart mischief is already far advanced. These cases are under more constant supervision, and our observations are consequently more numerous. I may cite the essential features of two illustrative cases.

A man of 47 years was admitted to hospital with signs of cardiac failure. He had been the subject of rheumatic fever at the age of 30, and was laid up with pleurisy at the age of 40. For twelve months prior to admission he had noticed shortness of breath and palpitation, following exertion and meals especially. For six weeks there had been pain and swelling in the upper abdomen, and the breathlessness had increased; a little dropsy had been present in the legs for a fortnight. Upon examination he was found to be breathless and cyanosed. The heart's impulse was diffuse; the limits of dullness were increased, lying $1\frac{1}{2}$ and 5 inches to right and left of the mid-sternal line. A faint systolic murmur was audible at the apex. The remaining sounds were natural. The pulse was rather feeble, but it beat regularly at 96 per minute. The liver edge was readily felt two fingerbreadths below the costal margin; the legs pitted considerably with pressure, and so also did the sacrum. The urine contained albumen.

During his stay in hospital he developed a febrile attack of approximately five days' duration, the temperature varying, rising in the evenings to 100° or 101.5° , and falling halfway, or actually to normal, in the early hours of the mornings. With the appearance of the fever, heart-block presented itself in the form of "dropped beats" and prolongation of the *A*s-I's interval. The heart-block was maintained over the febrile period, though it gradually diminished in degree. When the temperature resumed and maintained its normal level, the heart-block subsided and was not again noted (see chart and Figs. 5 and 6). During the attack the remaining physical signs of the heart remained unchanged. The patient left hospital with but little improvement in general condition.

The next case is of interest from several points of view.

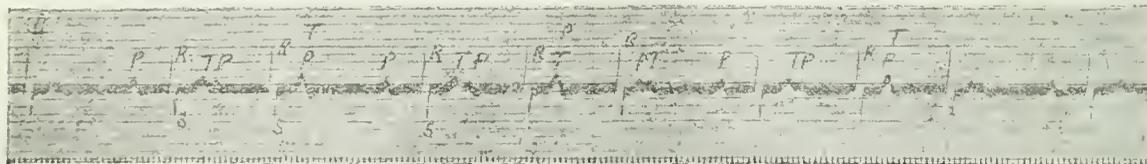

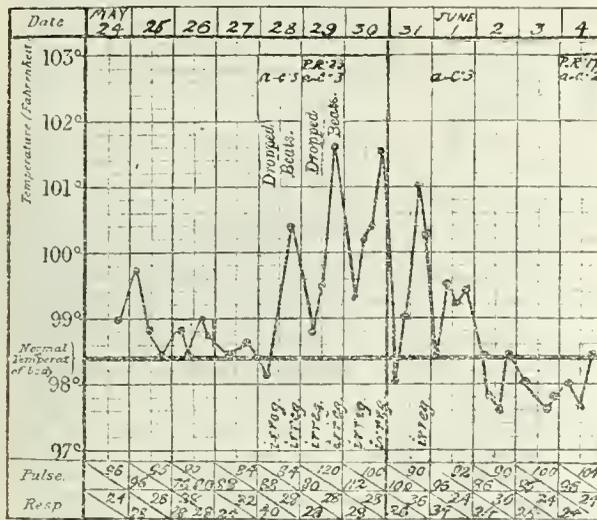

Fig. 4.—An electro-cardiogram from a young girl who had early mitral stenosis of rheumatic origin. Prolongation of the *P-R* interval and frequent dropped beats are seen. The heart-block was temporary.

In the first place the heart-block consisted of a simple and temporary prolongation of the *As-I's* interval; there were no "dropped beats." In the second place, there were other signs of myocardial involvement.

A chart showing a transient attack of fever in a patient suffering from cardiac failure. The chart shows also the days upon which the heart-block was found, and the relation of this disturbance to the febrile attack.

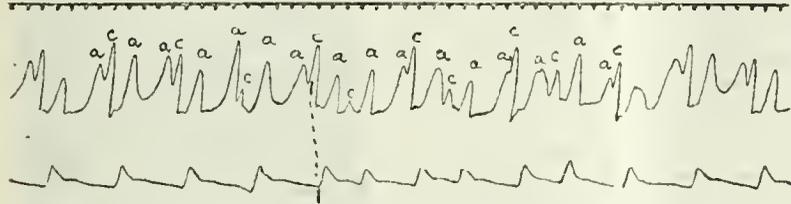

Fig. 5.—A polygraphic curve taken from a case of cardiac failure of rheumatic origin during a febrile attack. It shows frequent dropped beats.

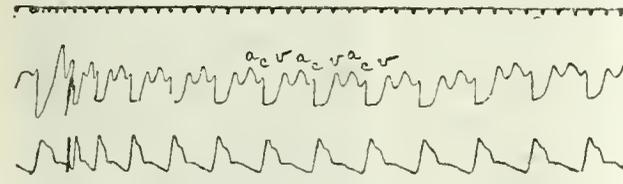

Fig. 6.—A curve showing the recovery. The pulse is now regular, and the a-c interval is 1/2 second in duration.

A girl of 13 years was admitted to hospital on July 31st, 1911, complaining of breathlessness on exertion, anaemia, and palpitation, which had been noticed since an attack of rheumatic fever a year before. She had obvious signs of mitral stenosis but there was not much cardiac enlargement. The limits of cardiac dullness lay 1 and 4 1/2 inches to right and left of the mid-sternal line. There were no signs of venous or liver engorgement and no dropsy, but the temperature was raised to 101. During the next three days the fever subsided. For twelve days it remained normal, and during this period the *As-I's* interval was found to be normal on three occasions (Fig. 7). Then for a period of five weeks the temperature fluctuated, rising frequently to 99°, 100°, or 101, sometimes falling to the base line and resting there for a few days, or at the longest a week. Coincidentally the pulse-rate rose, and the child was restive and more breathless. The heart increased in size, until at the end of the febrile period the limits of dullness lay 1 1/2 and 7 inches to right and left of the mid-line. Early in the attack the *As-I's* interval became slightly but distinctly prolonged (Fig. 8). The course was towards recovery; heart-block was present for a fortnight after the fall of temperature, but eventually cleared up entirely; the cardiac dullness decreased a little in area, but the original area was not regained. The remaining physical signs were not materially affected. The child showed no improvement in general health from first to last, but left the hospital rather worse than better for her stay.

Thus although the heart-block may be transient, as is customarily the case in these patients where its onset is observed, yet the myocardium may, as this case fully illustrates, suffer permanent injury.

It may be asked why the heart-block is so often transient;

it is usually temporary because the injury in the acute or subacute stage exceeds that of the period of recovery which follows; the inflammatory products are absorbed. That damage to the bundle should be permanently manifested

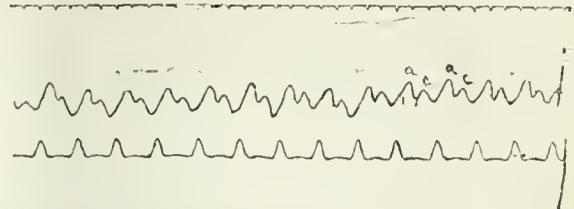

Fig. 7.

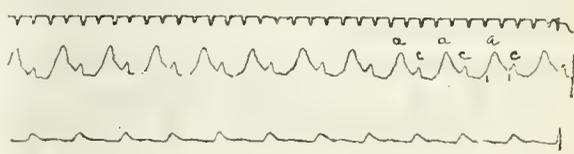

Fig. 8.

Figs. 7 and 8.—Two polygraphic curves from a child who suffered from rheumatic heart disease, including mitral stenosis. Fig. 7 was taken before and Fig. 8 during a period of pyrexia. Fig. 7 shows a normal a-c interval. Fig. 8 shows prolongation of this interval. There was subsequent recovery from the heart-block.

in some instances naturally suggests itself. I can call to mind no case in which the onset of heart-block has been witnessed and in which it has remained, but that the bundle is frequently and permanently damaged by rheumatism is fully evidenced by the now well-known fact that permanent increase of the *As-I's* interval or higher grades of block are by no means infrequent in chronic rheumatic heart disease.

I will leave the case for my contention that heart-block is a valuable sign of myocardial invasion in rheumatic heart disease at this point. I could cite or quote more instances of a similar nature to those which I have related briefly to you, but little could be gained by so doing at present. We require more necropsies than we have at present in confirmation of our clinical conclusions. We require, especially, autopsies in cases from which graphic records have been taken. The field of work is not unpromising, and in this connexion I may quote the words of a pure pathologist who has given special attention to the microscopic lesions of rheumatic heart disease. Aschoff¹ writes: "We do find not infrequently, especially in cases of rheumatic myocarditis, actual destruction of the smaller and larger branches of the conducting system, the already described specific rheumatic nodular structures having a special tendency to develop beneath the endocardium and occasionally right in the connective tissue sheaths of the system."

Heart-block in other Acute Infections.

Amongst the first cases of clinical heart-block which were recorded is the instance reported by Mackenzie.¹⁰ It occurred as a sequel to a severe febrile attack of influenza origin. Wenckebach¹¹ has recorded a similar case; the heart-block was noted during the stage of recovery. In rheumatic infections it appears coincidentally with the pyrexia, where this is present, as we have seen. Heart-block has also been recorded in pneumonia; in Magnus-Aksleben's case¹² it first appeared while the temperature was falling. I have seen a similar case.

The patient was a carman, aged 27, and the pneumonia was severe. The temperature on admission was 104; the pulse 160. Respirations were very frequent (55 per minute). The lower lobe of the right lung was involved primarily, and the patient was cyanosed and delirious. On the eighth day there were signs of fresh consolidation in the left lung, and the crisis did not come till the tenth day. The delirium continued for three days

* When the patient is going to die the heart-block remains; I have a good deal of evidence which suggests that many of the patients who enter hospital for what is termed "broken compensation" are in reality suffering from a now, and perhaps fatal, invasion of the myocardium.

after the crisis. Heart-block (frequent dropped beats and a long *a-v* interval) appeared two days after the crisis, and persisted, though subsiding gradually, for ten days (Fig. 9). In this case and in Magnus-Alsleben's, both of which recovered, the question of the myocardial infection was complicated, because the patients were upon small doses of digitalis; but

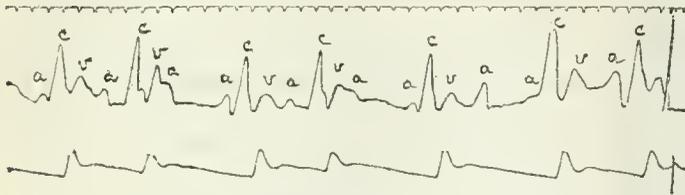

Fig. 9.—A curve showing frequent dropped beats. It was taken from a patient admitted for acute pneumonia, and represents the mechanism of the heart shortly after the crisis.

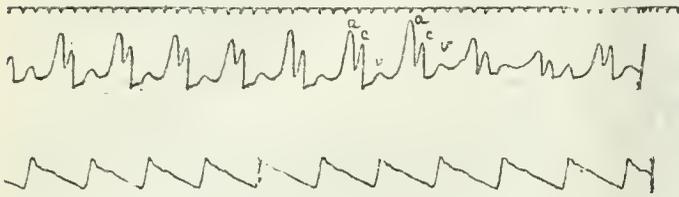

Fig. 10.—From the same case a fortnight later. At this time the heart-block had disappeared. The patient was upon the same doses of digitalis when the two curves were taken.

that the heart-block in my own case was not attributable to this source seemed clear, as the drug (digitalin *m. v.*, t.d.s.) was withdrawn on the day when the block appeared, and its re-administration as soon as the heart-block subsided failed to reimpose it (Fig. 10).

I have also seen heart-block (dropped beats and long *a-s-l's* interval) of a few days' duration as the sole sign of myocardial involvement in a case of infection of the bladder by a coliform organism (Fig. 11); and a case in which there was a mixed invasion of the endocardium by pneumococci and coli has been reported by Cowan, Fleming and Kennedy.¹ The last-mentioned case came to autopsy; while the muscle of the ventricle showed both recent interstitial change and patchy degeneration of the fibres, the heart-block which had been present was accounted for by an inflammatory lesion of the bundle.

A significant instance of acute heart-block as a sign of myocardial disease is found in diphtheria. Three cases (Magnus-Alsleben,¹¹ Fleming and Kennedy,⁶ and Dunn⁵) of the disordered mechanism have been reported in diphtheria; in each the illness terminated the life of the patient. In a fourth but less certain instance (Price and Mackenzie¹²) the issue was the same. The microscopic examination was undertaken in three cases. In Magnus-Alsleben's case the bundle showed parenchymatous degeneration, and is alone described. In Fleming and Kennedy's case a conspicuous inflammatory invasion of the auricular and ventricular muscle which involved the bundle was seen. In Price and Mackenzie's case the lymphatic infiltration of the myocardium was extreme and the bundle itself was free of it.

While heart-block is necessarily, first and foremost, a sign of bundle involvement, it does not signify that demonstrable lesions are always to be found, though in the majority of cases they can be; to us as clinicians the demonstration of functional disability is of equal if not

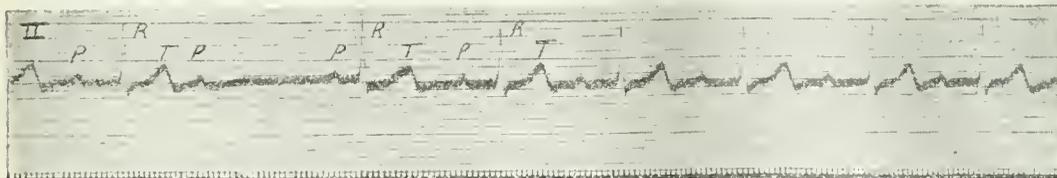

Fig. 11.—An electro-cardiogram from a boy who was admitted to hospital for subacute cystitis, due to a coliform organism. Prolongation of the *P-R* interval and a single dropped beat are seen. The heart-block was transient.

greater import. But, as I have attempted to show, we are justified in utilizing it as a sign upon a broader basis in acute infections. The bundle belongs to the myocardium, and an invasion of the bundle, especially when, as is usual, it happens through vascular channels, can hardly occur

without the exposure of the remaining muscle. It may be that under some circumstances the last-named is less susceptible, but the fact remains that the damage is rarely confined to the special tissues. In a measure, therefore, they serve as a gauge for the rest of the myocardium.³ Heart-block in acute conditions may not be an infallible sign of general myocardial disease; few signs are infallible, but it is certain that it often speaks of invasion when other signs are absent.

Damage of a Bundle Branch as a Temporary Phenomenon.

I have described to you a number of cases, rheumatic and otherwise, in which heart-block appeared as a transient physical sign, and have sought to convince you of its value as an evidence of myocardial invasion. Now, heart-block is the result of functional deficiency of the auriculo-ventricular junctional system where it exists as a single strand of tissue. You will remember that before this system connects to the ventricle it breaks into two main branches. Functional impairment, though complete, in one of these branches, does not hinder the passage of the auricular impulse to the ventricle, for it is able to pass along the other. Damage to a bundle branch does not originate heart-block. Nevertheless, a lesion of this character, though it does not disturb the rate or regularity of the ventricular

beating, can be detected by modern means. The branches of the bundle can no longer be classed with what I have termed the silent mass of myocardium. The physical sign has been but recently described, and it is electro-cardiographic. A lesion of a bundle branch produces conspicuous distortion of the electric curves, distortion of a definite and known type which can be recognized clinically. The physical sign has been repeatedly found in human hearts since its discovery, but in all the cases in which it has been recognized (my own series includes 15 cases) it has been a permanent feature of the curves. I may briefly describe a case which has recently come under my observation, and in which it was transient:

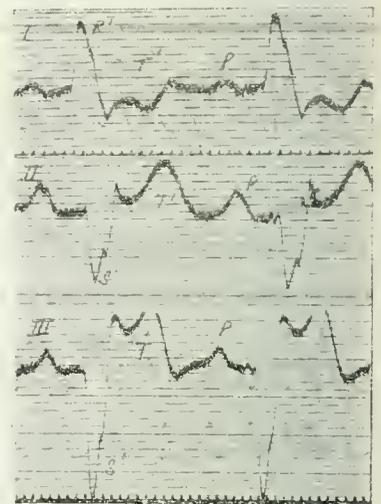

Fig. 12.—Electro-cardiograms from a case of aortic disease, taken on August 18th, 1912, and shortly after the admission of the patient in a slight febrile attack. The heart was beating regularly. Each auricular contraction *P* was succeeded by a ventricular contraction *R', S', T'*, of anomalous form. The type of ventricular curve in the three leads is one which indicates functional impairment of the right branch of the auriculo-ventricular bundle.

A bookbinder, aged 32, who had enjoyed good health until six years previous to his admission to hospital, complained of shortness of breath while walking. This had been present for six years; for several months precordial pain of an aching character was experienced. These were his chief symptoms. He had been

The case reported by James,⁸ in which a deep ulcer invaded the bundle, and that reported by Jelinek and Cooper,⁹ in which a localized area of anaemic necrosis, presumably of non-rheumatic origin, affected the upper part of the ventricular septum, do not materially affect the argument.

feeling more seedy than usual for some days, sought advice, and was admitted. He was found to have considerable enlargement of the heart, and free aortic regurgitation was present.

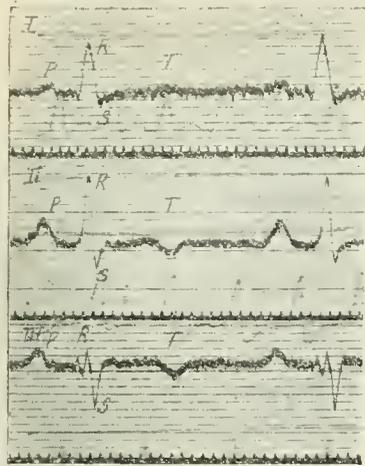

Fig. 13.—Electro-cardiograms from the same case taken on the following days. The heart was beating regularly as before, but the auricular contractions P, which themselves remain unaltered in form, are now followed by the physiological type of ventricular curve, indicating in this case the subsidence of the conduction defect in the right branch of the bundle.

type was maintained during his stay in hospital.

The change may be interpreted in precisely the same manner that we have interpreted transient heart-block. It is probable that in this case, too, an invasion of the myocardium—which, from the temperature chart, we should be inclined to regard as infective—happened some little while before admission. The damage of the bundle branch was the sole sign detected, and this sign, like the heart-block of our other cases, was transient. It vanished, and the subsidence of the fever was not long delayed.

This is an isolated instance. I have little doubt that the observation will be often repeated, but as to the actual frequency of the phenomena I have but little knowledge. I have described the sign to you, although its value in general practice is negligible, for it serves to impress the lesson that important events occur in the hearts of our patients which we cannot detect by ordinary means; in the investigation of disease the sign is certainly of importance.

In conclusion, let me remind you that in a very large percentage of chronic heart cases we are unable to trace the cause of the disease; chronic heart disease is not always referable to definite illness from which our patients are known to have suffered; oftentimes the reverse is the case and the disease develops silently. If we can discover any indications which help us to recognize the presence of active processes in these patients from time to time—and such I believe are the physical signs which I have described—our knowledge of the disease moves forward by a distinct step.

OWING to the greater demands made upon the British Fire Prevention Committee for testing facilities, it has been decided to enlarge the testing station and to add to the plant. The main building is being rearranged so that the principal rooms will be available for the committee's technical and historical collections. It is anticipated that the alterations will be completed early in April, when the testing operations of the new session will be commenced with several tests on fire-resisting doors, various forms of glazing, and some new extinguishers; certain further tests with concrete floors, etc., and with partitioning materials, will also be carried out.

MANIFESTATIONS OF A HEALTHY HEART.

BY

W. BEZLY THORNE, M.D. ST. AND., M.R.C.P. LOND., LONDON.

THE novel thesis set forth in Dr. James Mackenzie's article published in your issue of December 21st last, to the effect that irregularities of pulse frequency and functional murmurs are manifestations of a healthy heart, is one which demands careful consideration. I, for my part, beg to submit that those phenomena are partial expressions of a syndrome of which the fundamental conditions have to be sought elsewhere than in the heart. They are, in fact, signs of a consequential impairment of the heart muscle and of the arterial tunica media. They occur in association with a dirotic pulse characterized by feeble development, or complete absence, of the pre-dirotic and post-dirotic waves. The arteries, in fact, do not receive their normal fill of blood, and are practically empty during an undue proportion of the cardiac cycle. Such phenomena point to two defects: an inactive tunica media and consequent deficiency of recoil and of conductivity, and an actual defect of myocardial energy the importance of which is relatively aggravated by the fact of the central organ being called on to perform a considerable part of the work which should be carried out by the arterial heart. Under some circumstances, such as moderate exertion, or even menstruation during a period of invalid repose, the impoverished tunica media seems to pass temporarily out of action. It is easy to understand how great is the danger of heart strain if any effort be persevered in while that condition lasts. The syndrome in question is one of atony of the whole cardio-vascular system.

An almost universal symptom of that condition is an undue degree of postural tachycardia. The pulse is abnormally accelerated by the act of rising from the recumbent or sitting posture, and that acceleration will, in some cases, be indefinitely maintained until a position of repose is resumed.

The murmurs, also, which are so often to be heard in these cases, are so largely influenced by posture that in many instances they subside on the erect position being assumed, and are, in any case, loudest while the patient is in the recumbent position—that is, as Dr. Foxwell pointed out some years ago, while a distended right auricular appendix is pressing on the root of the pulmonary artery. It is difficult to determine whether the systolic apex murmur, which is sometimes to be heard, should be attributed to papillary weakness, to asthenic dilatation of the auriculo-ventricular ring, or to conduction. Dilatation of the pupil is a common feature of these cases, especially in the young. Irregularity of the pulse, if not actually present, is liable to be induced by any additional call on myocardial energy, or by vaso-dilatation however induced; though in the less severe cases the balance may sometimes be redressed by the stimulus of moderate exercise. In some, as has been stated by Dr. Mackenzie, the irregularity follows the respiratory rhythm; that is, the pulse falters synchronously with the descent of the diaphragm. In the majority of cases there is some degree of extension of the area of cardiac dullness. In childhood and adolescence the blood pressure is low.

As regards the etiology of these cases, careful investigation, especially when it can be carried back to the early stage of life, lights on some form of autotoxis. The most common is that of gastro-intestinal origin. In other subjects a rheumatic or gouty taint seems to bear a causative relation to the syndrome. Not a few subjects bear the rachitic stamp in the form of beaded ribs, retraction of the lower part of the sternum, or a tendency to pigeon-breast. But whatever the cause the result is a general impairment of power and efficiency, and a consequently diminished ability to bear strain, whether mental or physical. Such are the children and adolescents who become the subjects of the strain usually attributed to athletics. Sound and healthy lads do not strain their hearts in ordinary and legitimate forms of game and sport, but those under consideration, short of wind, subject to palpitation and tumultuous action on exertion, and lacking in staying power, albeit full of pluck and will-energy, may meet misfortune in a football match, a paper-chase, a boat-race, or a game of rackets—1 quote cases within

my knowledge. Even if they escape some form of breakdown, they plod on with something less than normal energy which may suffice to meet the requirements of a routine life; but they live on a lower plane than is their due. In manhood some are invalidated because they are unable to bear the strain of an active life at home or abroad, especially under the influences of a subtropical and humid climate. Others fail in route marching or break down in manoeuvres, having persevered, in opposition to their instincts and judgement, under the influence of assurances that there is nothing organically wrong with them, and that their monitory symptoms and their misgivings are "all nerves." As they enter on or pass beyond middle life, the atrophied tunica media and the weakened myocardium being unable to accomplish the treble task of emptying the chambers of the heart, filling the aorta, and then driving the blood through the peripheral vessels, these subjects begin to experience the troubles and disabilities generally referred to as indicative of arteriosclerosis, but, as I would prefer to call it, atrophic dilatation as opposed to the hypertrophy to which the late Dr. Savill gave the name of "arterial hypermyotrophy."

The treatment to be adopted consists primarily in the correction of autotoxis, whether gastro-intestinal, rheumatic, gouty, or due to some pyogenic process. The greatest attention should be paid to diet and general hygiene, exercise being regulated in accordance with the response which may be expected from the circulatory mechanism. Baths and exercises administered according to the Schott-Nauheim method are of great value. Among pharmaceutical remedies, iron is not indicated; digitalis is sometimes useful, but adrenalin, administered by the mouth in doses of from 5 to 10 minims of the hydrochloride solution, stands pre-eminent. Its special office is to bring the tunica media into action, and, it would seem, to restore it to functional efficiency. I have employed it for years, and in every case made frequent manometric observations, which enable me to give unqualified denial to the prevailing suspicion that, thus administered, it raises blood pressure.

It is necessary to add that, during the period of growth and development, progress in the more marked cases is generally slow, and relapse the not uncommon penalty of undue and especially of sustained exertion.

Such in brief are the reasons why I should regard it as a misfortune were it accepted that functional murmurs and irregularities of pulse frequency are manifestations of a healthy heart, and as such to be regarded with complacent acquiescence.

By way of illustration I append the following sphygmograms. Fig. 1 is taken from a youth of 18 who had a functional murmur at the apex from ages 4 to 10. He broke down after a game of rackets at a public school in 1911. The tracing is typical of cardio-vascular atony.

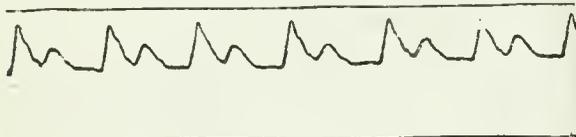

Fig. 1.

Fig. 2 illustrates a severer form of the syndrome, and is taken from a lad of 13, who, after breaking down at school, developed loud apical and basic murmurs in conjunction with dyspnoea, palpitation on exertion, and some cyanosis. After a year's limitation of activity he recovered his health

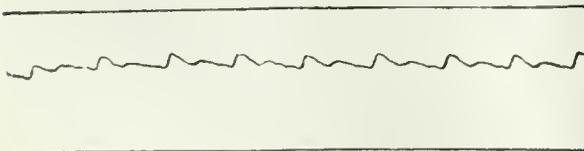

Fig. 2.

to a great extent and the murmurs disappeared. He was then assured by a specialist that he might return to school and join, without restriction, in the usual games. The result was a relapse and a return of the murmurs.

The following illustrate the effects of treatment. Civil engineer, aged 30, treated for cardio-vascular atony in 1900. Health failed in India at the end of 1911. Figs. 3 and 4 were taken on the first day of treatment (February

stand the strain of manoeuvres. Figs. 7 and 8 taken on the first day of treatment (August 7th, 1911); Figs. 9 and 10 on completion (September 12th, 1911). Nauheim baths, adrenalin, gastro-intestinal correctives.

THE VENTRICULAR RATE IN COMPLETE HEART-BLOCK.

By A. E. NAISH, M.A., M.B., B.C. (CANTAB.),
M.R.C.P. (LOND.).

ASSISTANT PHYSICIAN, SHEFFIELD ROYAL HOSPITAL.

In the great majority of cases published so far, when complete heart-block was present, the spontaneous ventricular rhythm has been between 30 and 40 per minute; most commonly in the neighbourhood of 32. Windle¹ has published a case in which the rate was usually 50, and at times rose to over 60 per minute. Lewis² has put on record a case in which, while the auricles were fibrillating, the ventricles beat regularly at about 90 for a few days, and Mackenzie³ mentions a similar case with a ventricular rate of 70; presumably complete heart-block was temporarily present in these two instances. In spite of these 3 cases it is very generally held that the idio-ventricular rate in man is a very constant one, varying but little from 32 per minute.

During the past year I have come across 2 cases in which the rate was not infrequently over 50 per minute, and another one in which the rate was as low as 17. I subjoin a short record of the two former, since it may well turn out that a comparatively rapid idio-ventricular rate is less uncommon than usually supposed, cases remaining undetected owing to there being no remarkably slow pulse-rate to call attention to the condition. As a matter of fact, one of the two had been for some time under the observation of a medical man without special attention having been drawn to his heart.

Erlanger and Blackman,⁴ having succeeded in producing chronic heart-block in 5 dogs, found that even under normal conditions there was a considerable difference between the lowest and highest ventricular rate. In 1 dog there was a variation of 40 beats per minute (maximum 74, minimum 34), and the average variation for the 5 dogs was nearly 25 beats per minute. Under abnormal conditions—for example, nervous states, running exercise, ether, etc.—the maximum rate was usually much higher. Individual dogs also varied from one another, the lowest under normal conditions averaging 35 beats per minute and the highest 50.

The first case, which I have reported more fully elsewhere,⁵ came under observation on April 26th, 1912, and from then up to June 10th showed complete heart-block with the exception of five days in May, when the rhythm was 2:1. During these six weeks the ventricular rate varied from 32 to 52 per minute. The slower rate was only seen after a shower of extra-systoles, which were usually produced by exercise. When resting the rate was most usually about 48, but was sometimes approximately 52 for considerable periods.

In the short stretch of tracing seen in Fig. 1 the average ventricular rate is 50 per minute. It will be seen that the rhythm of the ventricles is not perfectly regular, and in other parts of the tracing the irregularity was even more marked. In Dr. Windle's case irregularity was also noted.

In the second case, a man aged 66, who has shown complete heart-block for the past three months, the ventricular rate has varied between 38 and 54, being most frequently between 40 and 50. Fig. 2 shows the ventricles beating at approximately 52, and the auricles at nearly 65 per minute, a very low auriculo-ventricular ratio.

Apart from the possibility of such cases being overlooked altogether, the faster ventricular rate is more likely to give to a simulation of partial block. With the ventricles beating at 32 per minute the auricles have to beat as slow as 64 or as fast as 96 before there can be an appearance of partial block, and these are both rather unusual for the auricles under ordinary conditions. With the ventricles, on the other hand, beating in the neighbour-

hood of 40 per minute, it is obvious that a partial block must be much more frequently simulated, since the human heart commonly varies between 70 and 90 under conditions of rest or mild exercise. Wardrop Griffith has recorded 2 cases in which the difficulty of distinguishing between complete and partial block was considerable. Erlanger,⁶ in his classical experiments, sometimes found the same difficulty. He says: "Occasionally the ventricular rate in complete block may be an aliquot part of the auricular rate over long intervals of time, and in such instances the ventricular beats may so follow the auricular beats as to appear to be caused by them."

THE AURICLE IN MITRAL STENOSIS.

BY

D. W. SAMWAYS, D.Sc., M.D., M.R.C.P.,

MENTONE.

THE somewhat complex series of murmurs audible during the course of a case of mitral stenosis seem to me to find an easy and natural explanation if it be granted that the contraction of the auricle may not cease when that of the ventricle commences, but may continue for a longer or shorter period to overlap it.

Such an assumption is by no means unreasonable.

The late Professor Potain always maintained, basing his conclusions on repeated observations, that the contraction of the auricle continued normally till the time of opening of the aortic valves.¹ Dr. Barclay wrote: "The two cavities (auricle and ventricle) do not contract and dilate alternately, but the contraction of the one overlaps to some extent that of the other."² Roy and Adami gave a series of simultaneous curves, showing the relation in time of the principal elements which united constitute the heart-beat. Those curves show the contraction of the auricle maintained in full force into the time of the outflow of blood from the ventricle into the aorta.³ Dr. Galabin, commenting on his heart curves, and on those of Professor Marey, wrote: "From a comparison with Marey's tracings we have come to the conclusion that the beginning of the ventricular rise coincides with the first increase of the intraventricular pressure, whereas the auriculo-ventricular valves appear in general to close when the half or the third of the ventricular rise is accomplished."⁴

I am, therefore, not astonished that Dr. James Mackenzie says: "The curves of auricular pressure by different physiologists are very perplexing, some getting a rise of varying duration during ventricular systole."⁵

Now in mitral stenosis a tendency for the auricle to prolong its contraction still further is to be expected, as it would take longer to expel its contents through a stenosed than through a widely open orifice, and considerable evidence has accumulated to indicate that this is so.

If, then, the auricle in mitral stenosis can prolong its

contraction into ventriculo-systolic time, the following results would occur:

1. The presystolic murmur would go up to and into the first sound.

It would not necessarily stop with the advent of the first sound, for, as I showed in my article in the *BRITISH MEDICAL JOURNAL* of January 11th, 1913, the pressure on its contents which a contracting auricle can exert varies, roughly, inversely as the cube of its diameter.

The auricle having expelled most of its contents into the ventricle before the contraction of the latter commences, it could contract on the residue of its contents with far greater effect, and exert a far greater pressure, than the ventricle could on the full total of its contents. An auricle when small is more than a match for a ventricle when large; the auricle, in fact, is in somewhat the same position as the small piston of a Bramah press, which can overcome and force up the larger in virtue of its being the smaller. Blood would therefore flow from the contracted auricle into the large contracting ventricle, and the murmur, like the blood, would go into ventriculo-systolic time. The murmur would be crescendo in character, in harmony with the increasing pressure under which, as it contracts, the auricle can expel its residual contents into the ventricle. (In my communication "On the Genesis of the Venous Pulse" I pointed out why regurgitation from the auricle, in the absence of valves at the great veins, could not occur.)

2. A systolic murmur might be absent for years, though the auriculo-ventricular valve was incompetent.

Patients with mitral stenosis often live for long periods without any signs of regurgitation occurring, yet the auriculo-ventricular valve suggests from its appearance after death that it has been incompetent through, perhaps, most of the time. Why has this incompetent valve not leaked? or why has it leaked only towards the end of the illness? The rounded, hypertrophied auricle one often finds in these cases⁹ has for a long period prevented regurgitation by prolonging its contraction into ventriculo-systolic time. It has nearly emptied itself and become small—say, half its initial diameter—by the time the ventricle starts contracting, and it continues to try and drive its residual contents into the ventricle. It could now exert greater pressure on its contents, urging them forwards, than the ventricle could oppose to them, for the ventricle can never raise a pressure greater than that in the aorta without its contents escaping into it.

The auricle, therefore, would allow no regurgitation from the ventricle so long as the auricular contraction continued, and consequently the incompetent stenosed mitral valve would not leak. In fact, any leak would, so to speak, take place forwards from the auricle to the ventricle during the early part of ventricular contraction in cases of mitral stenosis accompanied with an auriculo-systolic murmur.

Incidentally it is interesting, as showing what auricles may do, to recall the case observed by Allan Burns where the ventricles were calcified, and the auricles had accomplished for a long time the whole work of the circulation.⁸

3. A systolic regurgitant murmur would replace the presystolic crescendo murmur when the auricle failed to contract to a sufficiently small chamber before the oncome of the ventricular systole.

If the auricle does not get small in time, because of the difficulty of expelling its contents quickly enough into the ventricle, the oncome of the ventricular systole would catch it before it had the physical advantage of being small enough to exert sufficient pressure on its residual contents to match or master the ventricle. Regurgitation into the auricle would then occur, a systolic murmur appear, the auricle would speedily dilate, and cardiac breakdown take place.

Rest or bleeding might temporarily give the auricle a chance of recovering its function, and becoming small in time to oppose the ventricular contraction. In that case the systolic murmur would again disappear, and be replaced by the presystolic. In time the breakdown would occur again in the same way, and probably be permanent, the auricle remaining dilated, and allowing regurgitation from the ventricle.

As soon as it is recognized that the auricle may be to the ventricle what David was to Goliath, simply because it starts first, the auricle will "come into its own" and be

respected as it deserves. Not recognizing this has misled and wronged many a good observer. Dr. Barclay wrote: "The more powerful contraction of the ventricle must overcome that of the auricle if there exists anything like antagonism between them." This false conclusion must have made it very difficult for him to accept the evidence of his own senses and affirm so correctly that "the essential character of this (presystolic) murmur is that it continues up to the first sound, during which it ceases."⁹

Dr. Dickinson, on the other hand, because the auriculo-systolic murmur was heard by him during the apex beat (as also it was by Professor Potain) concluded that it must be ventriculo-systolic in origin and regurgitant.¹⁰ He was forced to a false interpretation of a true observation through imagining relative muscle was everything and relative size was nothing in any struggle between the auricle and ventricle.

The Goulstonian Lectures

ON

DEATH BY ELECTRIC CURRENTS AND BY LIGHTNING.

DELIVERED BEFORE THE ROYAL COLLEGE OF PHYSICIANS
OF LONDON.

BY A. J. JEN-BLAKE, M.A., M.B., B.Ch., OXON.,
F.R.C.P. LOND.,

ASSISTANT PHYSICIAN TO ST. GEORGE'S HOSPITAL AND TO THE
HOSPITAL FOR CONSUMPTION, BROMPTON.

LECTURE II.—DEATH BY ELECTRIC CURRENTS (concluded).

SOME excellent experiments further illustrating the importance, so far as life is concerned, of the quantity of current traversing the thorax in electric accidents were published in 1911 by Weiss and by Zacon. These were made on dogs anaesthetized with chloral; the electrodes were placed either in the mouth and rectum or on the head and leg, and the amperage, voltage, and the duration of the current received by the animal in each case were noted. Tracings of the femoral blood pressure and the respiratory movements are given. These authors concluded that the resistance of the dog's tissues to alternating currents (12 to 75 periods per second) was the same as to continuous currents, and that chloral anaesthesia gave no protection against electric shocks. With alternating currents given for a few seconds, death would occur when about 70 to 100 milliamperes traversed the thorax with the heart *en route*; with continuous currents, death was not caused unless the current was as large as 300 milliamperes, roughly speaking. If, however, smaller electric currents were administered for long periods, it was found possible to produce death by tetanus and asphyxia; thus currents of 35 to 45 milliamperes were too small to produce cardiac fibrillation, but after about ten minutes' application caused death by continued inability to breathe, and slow asphyxiation. It was observed that large currents—400 milliamperes or more—could be passed through the head with comparative impunity, the heart continuing to beat though rather irregularly, and the respiration stopping only for so long (35 and 58 seconds in two instances) as the current passed. With still large currents, however, thus passed through the head and central nervous system, respiration might fail to begin again when the current was turned off, and death from asphyxia would then occur. The resistance of the animals generally diminished about 10 per cent. during the passage of the current.

Death by Alternating Currents of High Frequency.

It is necessary to go back a little at this point and consider more carefully the frequency of the alternating currents that have been used to produce death. Hitherto I have considered only the ordinary alternating currents that are so widely used domestically and industrially, in which the direction of the current is changed perhaps from 50 to 300 times in a second. Such currents are, as we have just seen, three or four times as dangerous to the life of animals, *cæteris paribus*, as continuous currents. The question arises: How far does the rate per second of these alternations affect the dangerousness of these currents? The answering is extremely surprising and interesting. In 1891 Tesla, in America, experimented with alternating currents in which the number of alternations per second was very great indeed, and found that very large quantities of electricity could be passed with impunity through the human body when at these very high rates of alternation. Thus, d'Arsonval (1892), using currents alternating from 400,000 to 1,000,000 times a second, found he could pass as much as 1 ampere through his body with impunity, and later (1893) took currents up to 3 amperes. These currents were twenty or thirty times as large as those required, under similar conditions, to cause death in the case of the ordinary alternating currents at much lower frequencies and pressures. Yet he felt no painful sensation while they traversed his body; there was no burning of the tissues at the points where these large currents entered and left him, and his muscles were not thrown into tetanus. Various explanations of these observations were offered. Jones (1893) assumed that, as a matter of fact, the currents passing through the body were to be measured in milliamperes rather than in amperes, its effective resistance being immensely increased by the high rate of frequency of the alternations; similar explanations were offered by Hedley and by Swinton. Others assumed that such high-frequency currents travelled by the surface of the body only, and did not penetrate to the deeper tissues owing to the very brief duration of each alternation. Sutherland quoted the view that one alternation might not have passed fully through the body before it was wholly or partly neutralized by the succeeding current of opposite sign, a view that is quite unimaginable to an electrician. The most reasonable and, no doubt, the correct explanation was furnished by d'Arsonval, who assumed that human muscle and nerve are so constituted as to be insensitive to alternating currents of very high frequency. The same explanation was given by Thomson (1894), who found that, using currents of over 10,000 alternations a second and very high voltage (100,000 to 200,000 volts), he could take a current, equal in heating effect to over 1 ampere of ordinary current, from one hand to the other, without pain and with only a moderate sensation of warmth at the points where the current entered and left the skin. Using electrodes with a surface of 6 sq. in., he found the virtual resistance of the human body from hand to hand to be about 700 ohms; using his two hands and wrists immersed in saline solution as electrodes, he could take a current of 1.5 amperes, the body absorbing power at the rate of 800 watts, without appearing to be in any way injured by it. In other words, alternating currents at these high frequencies were at least twenty or thirty times less dangerous to human life than alternating currents of the ordinary frequencies—25 to 150 cycles a second—used industrially. That animals can be killed by these alternating currents of very high frequency was shown by Bordier and Lecomte, among others; a couple of rabbits after receiving currents of 300 and 400 milliamperes for a minute became paraplegic, and died in twelve and fourteen days, and a third rabbit died in general tetanus from failure of the respiration two minutes after having a current of 500 milliamperes passed through it for thirteen minutes. Similar results were obtained with guinea-pigs and rats. Kennelly and Alexanderson have recently made further experiments with high-frequency currents of various frequencies. The experimenter's hands were placed in vessels full of saline solution, and the current was sent across from one hand to the other. At the slow rate of 60 alternations a second, only 8 milliamperes (at 5 or 6 volts) could be borne; at 11,000 alternations (12 to 20 volts) 30 milliamperes could be taken, and at 100,000 alternations (200 to 360 volts) no less than 800 milli-

amperes. If high-frequency currents are passed through animals for long periods they may succumb to the heating effects of the currents, as d'Arsonval has shown (Bordier and Lecomte).

Some admirable investigations into the influence of the alternations on the morbidity, so to speak, of alternating currents were made in 1900 by Prevost and Battelli. Using dogs as the subject for experiment, they found that the optimum or most fatal frequency was about 150 alternations per second. Thus, using a continuous current, and with the electrodes in the mouth and rectum, different dogs required pressures of from 50 to 80 volts to produce death by cardiac fibrillation. When the continuous current was replaced by an alternating one, it was found that with alternations up to 150 a second currents at only from 15 to 25 volts were needed to produce death; at 200 alternations a second 40 volts were necessary; at 300 alternations, 50 volts. An alternating current of 350 alternations a second was about as fatal as the continuous current; at 500 alternations 150 volts were needed to produce death, and at 1,720 alternations a second no less than 400 volts. In other words, the cardiac muscle of the dog, and in all probability that of man too, is least tolerant of alternating currents at a frequency of 150 alternations a second; it is about three times as tolerant of continuous currents, and about twenty times as tolerant of alternating currents of the relatively high frequency of 1,720 alternations a second. There is no doubt that this must rest on some physiological property of the heart muscle; one may compare the fact, noted by d'Arsonval and by Thomson, that high-frequency currents taken by the hands are painless, even at a strength of 2 or 3 amperes, whereas even so little as 20 or 30 milliamperes of an ordinary low-frequency alternating current taken in the same way give rise to tetanus and very severe pain indeed; Trotter found the pain of a 35 milliamperes continuous current taken for three seconds through an area of four or five square inches of his hand almost insupportable. Deaths by electricity would be very much fewer than they are now if high-frequency currents could be used in place of the ordinary alternating and continuous currents universally employed. Hence it is a thousand pities that the economical production of high-frequency currents on the commercial scale is not possible for mechanical reasons, and that the electrical properties of such currents unfit them for industrial usage.

Summary of the Experimental Results.

The chief experimental results obtained in the electrocution of animals by both alternating and continuous currents have now been placed before you, and they may conveniently be summarized here under a number of different heads.

1. Living animals of different species are killed by electricity with very different degrees of facility. For example, many experimenters have endeavoured to electrocute frogs, but all, I believe, without success, whatever the current used and however it may have been applied. The frog survives electric shocks and the prolonged passage of electric currents at all sorts of voltages—10, 100, 1,000 volts and more—and shocks from induction coils and charged Leyden jars. The only inconveniences it suffers appear to be transient pareses or paralyses, and, in the case of strong currents passed for many seconds or minutes, the formation of burns. The frog is thus immune because its heart always begins to beat again regularly and normally after the passage of the electric current, and because its respiration does the same; and also, as Priestley pointed out in 1767, because "its constitution enables it to subsist a long time without breathing." At the other extreme of the scale comes the dog, which can be killed with certainty by an alternating current of perhaps 15 volts or 60 milliamperes applied so as to pass largely through the heart muscle for a couple of seconds only. The dog is very easily killed by electricity because its heart muscle is thrown into a state of fibrillary contraction by comparatively weak currents, and very rarely (except in the puppy) can recover from the fibrillation and beat normally again. In addition, there is the fact that currents that are too strong to throw the dog's heart into a state of fibrillation are yet able to kill the animal by respiratory paralysis and asphyxia, so that a current that may not be fatal to the dog by its action on the heart

may yet kill it by action on its central nervous system. Birds and other living creatures—such as apes, horses, cats, rabbits, guinea-pigs, rats, mice, and so forth—appear to come between the frog and the dog in the scale of liability to death by electricity at relatively low voltages, the rat's heart always recovering spontaneously from the state of fibrillation into which it is thrown during the passage of the current, the rabbit's heart often recovering spontaneously, the guinea-pig's rarely, the adult dog's never. It is generally found that young animals are less easily killed by electricity, other things being equal, than adults of the same species; thus Battelli found that cardiac fibrillation would cease spontaneously in electrocuted newly-born puppies, though not in adult dogs, and Kronecker¹⁷ has produced transient cardiac fibrillation by electrization of the heart of a newly-born child with ectopia cordis, though there is no reason to suppose that this fibrillation is ever recovered from by adult human beings in whom it has been induced a point, however, about which we have no certain knowledge. In the case of discharges from Leyden jars and condensers, the young animal is killed by relatively smaller quantities of electrical energy than the adult. It should be added that different animals of the same species often show different degrees of susceptibility to electric currents that can only be explained by idiosyncrasy.

II. The sudden or rapid death of animals killed by the application of electric currents may be brought about experimentally in several different ways, of which the following are the most important:

(a) By asphyxia due to prolonged muscular tetanus and inability to perform the movements necessary for respiration, when the current is passed and the tetanus maintained for as many minutes as are necessary to complete asphyxia. The heart in these circumstances goes on beating to the end. A dog may take ten minutes to succumb in this way (Weiss); presumably living and breathing creatures of any kind could be killed by this method.

(b) By primary heart failure. In a typical case, the heart muscle is thrown into a state of fibrillary contraction, and the heart ceases to beat as soon as the current is turned on, while respiration continues. When this happens the blood pressure in the femoral artery falls steadily, reaching zero in ten or fifteen seconds in the case of the dog; should the heart for any reason begin to beat again, the animal will probably recover—the rat always recovers thus, the dog hardly ever.

(c) By primary failure of the respiration, due to the action of the electric current on the central nervous system, or Brown-Séguard's inhibition. Animals apparently killed in this way will often recover if artificial respiration is perseveringly carried out. This mode of death occurs when large currents at high voltages are sent through the body.

(d) By simultaneous failure of both heart and respiration; seen, for example, in dogs receiving an alternating current at from 240 to 600 volts for two seconds, from mouth to rectum.

(e) Death may occur after the lapse of hours or days, as the result of the injuries to the tissues caused by the passage of strong currents.

III. After being exposed to currents of high voltage, say 600 volts and over, animals tend to show a number of signs that indicate grave involvement of the central nervous system. This is more marked in small animals than in large, other things being equal, as the current density will be greater in the smaller animal. Such signs are arrest of respiration and its resumption in an irregular manner; the occurrence of clonic spasms (such as are not seen in man); loss of sensation and the reflexes; great prostration and slow recovery. All these phenomena are absent when one is dealing with electric currents of low electromotive force. They may be taken as evidence of nervous shock or Brown-Séguard's inhibition.

Special mention may be made at this point of the "electric sleep" produced by Robinovitch in animals by the use of interrupted continuous currents (the so called "Leduc currents") at from 5 to 10 volts and about 1 milli-ampere. The cathode is applied to the head, the anode to the trunk of the animal. This electric sleep may be kept up for eight hours or more; it is associated with a rise in the arterial blood pressure, and is said by Robinovitch to be due to central inhibition.

IV. The particular electrical details and considerations that determine whether a certain electric current will be fatal or not to an animal in any given instance are very complicated. Hence it is not possible to say off-hand that a current of such-and-such a voltage or character or strength will cause death; there are at least six factors that must be considered separately here, although when one comes to work out their influence in any particular instance they must be considered together.

(a) *The Voltage of the Current.*—Given the optimum conditions, continuous currents are not fatal to dogs at voltages below about 60 volts. An ordinary alternating current at 15 volts will kill a dog, and a similar current at any voltage up to about 600 volts will be equally effective, by causing the dog's heart to fibrillate. But the alternating currents passing at pressures of from 1,200 to 4,800 volts, administered under the same optimum conditions, are not necessarily fatal, because they are too large to cause the dog's heart muscle to fibrillate; although if continued long enough they may cause death by permanent paralysis of the respiratory centre.

(b) *The Amperage of the Current.*—Given the optimum conditions for causing death—that is to say, such an arrangement of the electrodes as will cause the current to traverse that part of the thorax in which the heart lies—the dog will be killed by an alternating current of as little as 70 milliamperes or a continuous current three or four times as great. But the very much larger currents forced through the thorax by much higher voltages—1,000 to 5,000 volts—are not fatal, because they do not throw the heart into a state of fibrillation; thus Weiss passed an alternating current of 7 amperes (at 4,600 volts) through a dog weighing 22 lb. for three seconds without killing it. These large currents may prove rapidly fatal by respiratory paralysis, or, after the lapse of days, by the burns and other injuries they may have inflicted on the tissues at the electrodes.

(c) *The Duration of the Current.*—The time during which the animal is exposed to the current is of great importance. As has been mentioned already, quite small currents at low voltages, that have no apparent influence on the action of the heart or on the central nervous system, but are strong enough to tetanize the muscles, may cause death by asphyxia if kept on for long enough—over ten minutes in the case of the dog. With the stronger currents at higher voltages, that kill by cardiac fibrillation, Battelli found that contacts up to one second in duration were often not fatal to the dog, though contacts of from one to three seconds invariably were fatal. Weiss showed that alternating currents as small as 70 milliamperes passing through the thorax required not less than four or five seconds to produce a fatal result. Again, with very high voltages (several thousand volts) and alternating currents of several amperes, with which death when it occurs is due to injury of the central nervous system, the passage of the current for several seconds may be survived by a large animal, though one second may be fatal to a small animal of the same species. Crole and Macleod found alternating currents at 2,300 volts fatal to anaesthetized dogs in twenty seconds, but not necessarily fatal in one, five, or ten seconds. The same thing is seen with continuous currents. Some of the differences seen here between different animals of the same species must be set down to idiosyncrasy.

(d) *The Character of the Current, Continuous or Alternating.*—Continuous currents, whether from a dynamo or a battery, are much less dangerous at comparatively low voltages than the ordinary alternating currents used industrially. Thus a continuous current applied for a few seconds will not be fatal to a dog below pressures of 60 or 70 volts, while an alternating current with from 25 to 150 periods a second will be fatal at a pressure of 10, 15, or 20 volts. But at higher pressures, where death, when it occurs, is due to failure of the respiration by nervous inhibition, the continuous current may be the more dangerous of the two, because its passage is the more injurious to the central nervous system. Thus an alternating current at 600 volts passed from the head to the feet of a rabbit for three seconds may do it little injury, while a continuous current of 550 volts electromotive force may be fatal to it in one second in similar circumstances. Again, with alternating currents, the number of alternations per second

is of the greatest importance in determining the dangerousness of the current. Ordinary alternating currents and the very similar polyphase currents so widely employed commercially alternate from, say, 25 to 300 times a second, and, other things being equal, are three or four times as dangerous to life as direct or continuous currents. But increase in the frequency of the alternations per second brings about a great diminution in the dangerousness of such currents, because it lessens their tendency to produce fibrillation of the muscle of the heart. Thus, at 350 alternations per second, alternating currents are no more dangerous than continuous currents, and at 1,720 alternations are about six times less dangerous, in the case of dogs. When the alternations are increased to tens or hundreds of thousands per second, as is the case in the so-called Tesla or high-frequency currents, the danger to life is still further reduced.

(c) *The position of the electrodes* with regard to the heart and the central nervous system. The importance of this factor is enormous, and was perhaps never widely appreciated until it was emphasized by the work of Prevost and Battelli. Even now it seems to be neglected by d'Arsonval and by many other writers upon the subject of death by electricity. It may be illustrated by a single experiment. If the two electrodes are applied to the two hind legs of a dog, alternating currents of about 4 amperes at 1,200 volts are not fatal to the animal, because with this arrangement the amount of current passing through the heart is not enough to cause it to fibrillate. If the two electrodes are now shifted to the two fore-legs, alternating currents up to 270 milliamperes and below about 80 volts are not fatal, for the same reason. But if the electrodes are placed on either side of the thorax, so as to concentrate the current on the heart, death is produced by alternating currents at only 15 volts pressure and a strength of about 50 milliamperes. Yet the resistance between the two electrodes is much the same—about 300 ohms—in each of the three cases. To me it does not seem possible to imagine a better demonstration than this of the importance of the current-density through the heart, or, to put the matter more definitely, the number of milliamperes per square centimetre of cross-section through the heart at right angles to the direction in which the current flows, in determining the danger to life incurred by exposure to electric currents. One cannot believe that the shock to the dog's nervous system, to which alone d'Arsonval attributes such a death by electricity, was greater at 15 volts than at 80, or at 80 than 1,200 volts, in the three variations of the experiment described above.

(f) *The Resistance at the Electrodes.*—This extremely important factor is very variable in amount unless great care is taken. It is obvious that it should be reduced to the lowest practicable value in any experiments designed to bring out the dangers of industrial electric currents to life, and to ascertain the lowest voltages that may be fatal. To quote an example, Grange in 1884 failed to kill dogs by alternating currents at 825 volts pressure, simply because his electrodes were so ill applied that the dogs' resistances were about 80,000 ohms, so that only 10 milliamperes of current can have flowed through the animals, a quantity much below the lethal dose. Later experimenters have found that the more careful and rational application of the electrodes makes the dog's resistance, in circumstances otherwise similar, only 300 ohms or thereabouts. Cunningham cut this resistance down still further to about 77 ohms in one instance—an error in the opposite direction. His electrodes must have been so large as not to concentrate the current satisfactorily on the sensitive spot, the heart. The result was that continuous currents of 700 milliamperes or more, sent through the thorax from one side to the other, were not necessarily fatal to the dogs he employed, while Zacon and Prevost and Battelli found 200 or 300 milliamperes of continuous current to be fatal to the dog if suitable electrodes were applied. Crile and Macleod observed resistances of about 1,000 ohms in their experiments on dogs.

Death by Electric Currents in Man.

We are now in a position to summarize what is known and what may be inferred as regards the killing of human

beings by electric currents. This may conveniently be done on lines similar to those adopted above in the case of animals. I must ask to be allowed some repetition here, in the hope of making an obscure business clearer; for the literature of the subject makes it plain that the various factors controlling the results of electric accidents in man are by no means generally appreciated at their proper value or understood.

I. It is often assumed that different persons are differently vulnerable by electricity, and that in identical circumstances shocks that would be fatal to some would not be fatal to others. This is certainly true of the lower animals—for example, Battelli found an alternating current of ten volts fatal to one dog, but not to two others which were killed at 15 volts. It is probably true of man, but experiments to prove the point are naturally lacking, and it is not possible to prove or disprove it by the evidence of fatal or non-fatal electric accidents, because there are so many variable factors that determine the result in these besides that of idiosyncrasy. In other words, one is not justified in concluding that it is idiosyncrasy that has protected a person "A" from death by electric shock that has proved fatal in apparently similar conditions to another person "B," unless one is able to prove that all the other conditions really were identical; and that, practically speaking, can never be done. There are three other factors that have been emphasized as important in determining the result in electric accidents, and these are *fright*, *general anaesthesia*, and *sleep*. Much stress is laid on *fright* by d'Arsonval, who says that sudden physical surprise often has disastrous results for the vital functions, so that a shock that is unexpected may be fatal, but not fatal if it is expected. He even attributes the comparative failure of the methods employed in the electrocution of criminals in America to the fact that surprise at the moment of shock is lacking in this operation. Jellinek has recorded a case in which a man died of fright alone, having come into contact with a conductor which he believed to be carrying a current at high potential, but actually was not electrified at all. Great importance is attached by d'Arsonval to the *status somaticus et psychicus*, the state of body and mind, of anybody exposed to and receiving an electric shock; Aspinall supposes that persons of weak intellect can stand stronger currents than normal persons. This, again, is a matter that can only be determined by experiments made in definitely known conditions, and none such have been made; there is no evidence that fright increases the liability of the lower animals to death by electric currents. It is said that persons under the influence of *general anaesthetics* are able to survive exposure to currents that would be fatal were they conscious; several experimenters have found that general anaesthetics do not afford protection in this way to the lower animals, though Jellinek says that they do—much probably depends upon the depth of the anaesthesia obtained. As regards *sleep*, this also is generally believed to protect life against electric currents that would be fatal during waking hours; in modern literature one often sees quoted the case of a man who was severely burnt but not killed by contact during sleep with a conductor carrying a current at 5,000 volts, recorded by Aspinall. Here again there is need of further evidence. The analogous idea that sleep protects against death by lightning stroke is at least as widely spread, and dates from the time of Seneca.

In the vast majority of cases death by electric currents is due to accident; but in Italy both suicide and murder by electricity have been attempted, the former with success (Jellinek).

If. The death of human beings may be brought about by electric currents in several different ways.

(a) There is no doubt that it might be due to prolonged tetanus of the muscles, which could prevent the performance of respiratory movements, and so lead to death by asphyxia after some minutes. But I am not able to find that it ever has come about in this way as a matter of fact, the victim always being able either to break the contact and interrupt the passage of the current for himself, or to call for help and get the contact broken by somebody else before asphyxia has occurred in this way.

- (b) In man primary heart failure is undoubtedly the commonest mode of death by electric currents. The experiments on animals already detailed show that such deaths are due to fibrillation of the ventricles of the heart. This fibrillation has been seen occurring in the hearts of two criminals electrocuted in America and examined immediately after death (Schumacher); a few minutes later the left ventricle was firmly contracted and empty, while the right ventricle and the auricles were relaxed in diastole and full of blood. It is probable that in the adult man, as in the dog, horse, and ape, fibrillation of the heart, once it is established, is irremediable, practically speaking.
- (c) and (d). Death by failure of the respiration while the heart continues to beat, brought about by nervous inhibition, or by failure of both heart and respiration together, is probably not so common in man. There is a great want of evidence on this point; naturally enough, as the people who are present at deaths by electric shock are generally workmen who do not busy themselves with observations of the pulse and the respiration of the victim. A good many cases have been recorded in which death did not occur until ten, twenty, or forty minutes after the shock had been received, and was then apparently due to failure of the respiration to re-establish itself. The experiments upon animals would lead one to believe that such deaths are really due to failure of the respiratory centre in the central nervous system. The *post-mortem* evidence in such cases should suggest death by asphyxia, and such evidence has sometimes been found after death by electric shock.
- (e). Brief reference may be made to the fact that a good many cases have been recorded in which the victim of an electric accident has died after a few days or weeks from complications (shock, gangrene, suppuration, exhaustion following extensive amputations) arising out of the injuries caused by the electric current. Mills and Weisenburg have recorded fatal cases of bulbar and bulbo-spinal paralysis, apparently due to electric shock.

III. Severe nervous shock, with or without some more definite lesion such as the paralysis of a limb or a paraplegia, is not rare in industrial electric accidents, and makes permanent invalids of a number of persons who survive the shock. Brief loss of consciousness is common in non-fatal cases of electric shock, and may be followed by an appearance of intoxication or even by mania—a fact that finds no parallel in the experiments done on the lower animals; just as in the lower animals attacks of convulsions are often determined by non-fatal shocks, but do not seem to occur in man (Battelli, Robinovitch).

Opinions as to the importance of nervous shock in fatal electric accidents are divided into two groups. On the one hand, Battelli and a number of writers believe that it is a transient affair, functional in nature, not important. On the other hand, d'Arsonval holds that it is by nervous shock alone that electric currents produce sudden or rapid death, by a sudden affection of all the vital functions. Jellinek goes further, and is more definite, setting down sudden death by electricity to a local trauma of the cells in the central nervous system, caused by what he calls a dynamogenic working of the electric current that may be compared to the local trauma of the nerve cells met with in the *commotio cerebri* of direct or indirect violence. He brings forward the elaborate details of his histological researches to prove that these minute lesions of the nerve cells and other tissues are to be met with in men and animals killed or injured by electric currents; but, as Schumacher points out, the cell changes and small hæmorrhages found by Jellinek are in no way specially characteristic of death by electricity. It must be remembered that, as a rule, large amounts of electric energy and long periods of exposure to the passage of the current have been employed in cases in which marked changes have been found in the central nervous system after death; whereas in the majority of fatal accidents by electric shock as they actually occur, only a small current has passed through the victim and only for a short time, while

none of it has had occasion to travel by way of the central nervous system.

IV. All the electrical and physical details of the circumstances in which electric currents pass through the body are of the greatest importance in determining whether the result will be fatal to a human being or not. For the sake of clearness they are best discussed under six heads.

(a) *Voltage of the Current.*—With alternating currents, death has occurred from shocks at voltages as low as 65 volts, and a good many instances of death at such pressures as 100 to 120 volts have been recorded. It is only in very exceptional circumstances that these low voltages can cause death; unless the patient's skin is wet and he makes a good contact not only with the electric conductor, but also through wet boots or clothes (according as he is standing or sitting) with the ground or some other conductor, there is not the smallest chance of death by currents at such low voltages. As the voltage rises so does the ease with which a fatal amount of current may be forced through the victim increase, and so it is that the large majority of deaths by electric currents are brought about by the alternating currents at much higher pressures—say 500 to 5,000 volts—that are in common industrial use. But here comes in a paradox. It would appear that *if good contact is made* currents at very high voltages become less dangerous to man, just as we have seen that they do to animals, and probably for the same reason—that large currents passing through the body do not happen to throw the heart into irremediable fibrillary contractions. Thus a number of instances have been recorded in which men have received industrial currents at 10,000 volts without being killed at once, although making good and prolonged contacts in such a way that large currents, too large to be fatal, one may say, must have streamed through the chest and heart. A very good example of this was recorded by Mr. Clement Lucas; others have been reported in Franco and Monte Carlo.⁶⁶ But if the victim makes a bad contact, or a contact of high resistance, either with the conductor at high voltage or with the ground, then the amount of current diverted through him may be small enough to kill him by cardiac fibrillation.

One often hears the question asked: What voltage is dangerous to life? No simple answer can be given to this question; the degree of danger depends on so many factors besides that of the voltage of the current from which danger is apprehended. As regards continuous currents of electricity, I have not found records of many fatal accidents at voltages below 220 volts, but in one case a direct current at only 95 volts caused death, in another a current at 110 volts.⁶⁶

(b) *The Amperage of the Current.*—All the industrial electric currents met with in daily life, the currents used for lighting, heating, cooking, driving machinery of all sorts, have ample intensity (measured in amperes) to cause death if applied to the human body under favorable conditions. The only sources of electricity that might be expected to kill, but fail to do so for want of sufficient amperage, or rather milliamperage, are the induction coils used by x-ray specialists and others.

As regards the minimum number of milliamperes required to kill a human being under conditions favorable for killing there is no certain knowledge. Weiss calculates that from 70 to 90 milliamperes of an ordinary alternating current would be enough if the current went through the chest and heart; d'Arsonval states that much less than 100 milliamperes suffice to kill. One can make a rough calculation in some of the fatal accidents that have occurred; a number of persons have been killed by alternating currents at about 110 volts, passing from one hand to the other or from the hands to the feet, and experiments show that the resistance of the human body from hand to hand or from the hands to the feet may be from about 1,000 to 1,500 ohms, when the skin of both hands and feet is wet, so that one may guess the fatal current to have been from about 70 to 110 milliamperes in these instances. The experiments of Dixon Mann showed that alternating currents of from 15 to 30 milliamperes sent through the chest do not upset the heart's action; and Trotter found that continuous currents up to 35 milliamperes, though almost insupportably painful, were not fatal when passing from the hands to the feet.

When very large industrial currents are forced through the body by high voltages, we meet again with the paradox that, while small currents may kill instantaneously, large currents are much less fatal. For example, the American electrocutions have shown that currents of 5 or 8 amperes may pass for many seconds through the body without causing permanent arrest of the heart or respiration. In the non-fatal cases of shock by currents at 10,000 volts, of which I spoke a few minutes ago, it is true that no measurements of the amperes passing through the victims were made, but it is reasonable to suppose that they may have amounted to several amperes. It is plain, then, that currents of a fraction of an ampere may cause sudden death by throwing the ventricles of the heart into fibrillary contraction, though much larger currents of several amperes do not act thus and so are not fatal. But I do not know of any examples or experiments to show at what point or amperage the transition from small dangerous to large non-dangerous currents takes place.

(c) *Duration of the Current.*—The animals experiments showed that this is a factor of great importance in determining death or survival. And so, probably, it is in human beings; but its importance could only be determined by a series of comparative experiments under known conditions, and these are for obvious reasons not likely to be made. The fact that electric currents produce muscular tetanus, and often cause the victim to grip firmly any conductor from which he may be receiving a current of electricity, tends to make contacts of long duration; for example, Mr. Clement Lucas's patient clutched his 10,000 volt cable for thirty seconds before he was rescued.

(d) *Industrial alternating currents* are, other things being equal, more dangerous than *continuous currents*. So far as one can guess, in the absence of any experimental proof, it seems that a continuous current must be two or three times as strong as an alternating current, to kill a human being. In cases that are not immediately fatal it seems that the after-effects are more serious with continuous currents, no doubt because these electrolyse the tissues through which they pass, and thus leave behind them chemical and physical traces of their passage; whereas alternating currents naturally effect little permanent electrolysis or polarization in the tissues through which they travel.

(e) *The position of the electrodes*, or the points at which the current enters and leaves the body, are of great importance, as has been emphasized by Aspinall among others. For all practical purposes the heart is the danger point in persons making accidental contacts with conductors carrying electric currents. For it rarely happens that contact is made by the head, so that current has the opportunity to pass through the central nervous system (cases recorded by Zwaluwenberg, Zacon), and even then it is more than probable that death, if it does occur, is due to cardiac paralysis, and not to inhibition or action on the consciousness or psychical functions. Hence it is safe to say that, so far as sudden death is concerned, electric currents are dangerous to man in proportion to the degree to which they tend to pass through the heart. Thus a current travelling from one hand or arm to the other, or from a hand to the feet, or from the neck or the top of the trunk to the feet (as in a case recently described to me by Dr. R. S. Trevor) is highly dangerous; similarly, currents going through the left side of the body are commonly supposed by electricians to be more dangerous to life than those on the right side. But currents entering by one foot or leg and leaving by the other are, practically speaking, free from the danger of sudden death, because the strength (in milliamperes) of the current that flows through the heart under these conditions is necessarily far below the lethal minimum, however strong the current passing through the lower part of the body may be. For this reason, if one has to rescue the victim of an electric accident while he is still exposed to the current, it is advisable to try and draw or push him away with one's feet rather than with one's hands, unless one can be sure that one's hands are well insulated from the victim by dry clothes, etc. The desire to protect the cardiac region against the passage of electric currents has led to several brilliant but not practical suggestions that persons exposed to accidental electric shocks should wear garments woven of copper wire. Such a copper undergarment,

closely applied to the skin of the upper and lower parts of the trunk, but insulated by a belt of indiarubber from the middle zone in which lies the heart, would divert the bulk of any current from that region, it is said,⁴¹ and so save life.

(f) *The resistance at the electrodes*, at the points where the current enters and leaves the body, is a factor of the very greatest importance. This is best illustrated by a few actual examples:

A man in a factory stood barefooted in a mixture of sugar and potash, and with his hand touched a bare conductor carrying a continuous current at 95 volts, and was killed on the spot (Jellinek); the resistance between his hand and his feet, between the ground and the conductor, that is to say, cannot have been more than perhaps a few hundred ohms in these conditions. Had his hand or his feet been dry he could have handled the conductor with impunity, even without discomfort.

Zwaluwenberg details the case of a carpenter at work in an attic 4 ft. high at a temperature of about 100° F.; he was in a state of extreme perspiration, and kneeling on a well-earthed gaspipe, when his head came into contact with a cable carrying a 50-cycle alternating current at 100 to 110 volts, at a point where the insulation was worn away. The man made an outcry, was rescued in a few minutes, was seen to gasp several times, but died at once in spite of artificial respiration and traction of the tongue. In this case also the skin at the points of contact, the head and knees, was soaking wet, and so the resistance at the electrodes was reduced to so low a point as to permit the passage of a current strong enough to throw the heart into a state of fibrillary contraction and cause death. Had the man's skin been dry, or had he not been kneeling on a good conductor, he would not have lost his life.

Many other instances might be quoted to show the great danger of wetness to the skin or of the feet and boots, conditions that are inevitable among operatives and labourers of all sorts when there is risk of contact with conductors carrying electric currents at even these low voltages. There have been fatal accidents in domestic and in public bath-rooms even, when persons in baths or standing barefoot on wet floors have laid wet hands on electric lamps or bare wires that chanced to be directly connected with electric light mains carrying currents at a couple of hundred volts or so.

But with these electrodes, the hands and feet, in their more normal condition of dryness, the case is quite different; the danger to life is *nil*. The resistance of the human skin to the passage of electric currents is relatively great, and the skin is by far the most resistant of the tissues of the human body. Thus, Trotter quotes many experiences with himself and other people, showing that when the hands and feet are dry, conductors carrying continuous currents at 500 volts may be handled freely with impunity, for the normal resistance of the dry skin at the electrodes (the hands and feet) and of the boots is so great as to permit only a few milliamperes to pass through the body to the ground. When he was wearing old boots worn into holes and thoroughly wetted by walking in muddy streets and grasped the 500-volt conductor for three seconds, only 35 milliamperes of current passed through him; his resistance from boot to boot was reduced to 13,000 ohms, in place of the normal 45,000 to 200,000 ohms with ordinary boots that were not wet. One often reads accounts of people who have touched live conductors with high voltages without suffering material injury; in the great majority of such cases their immunity has been due to the high resistance presented to the current at the points where it had to enter and leave the body. The effect of the resistance at the electrodes and in the body in determining the result of electric accidents is shown schematically in the following table, in which it

| Total Resistance of Body assumed to be: | Result of Brief Exposure to Passage of Alternating Current at a Pressure of: | | |
|--|--|--------------------------------------|---|
| | 100 volts. | 1,000 volts. | 10,000 volts. |
| Very low, with good contacts, 1,000 ohms | Certain death, slight burn | Probably death, marked burns | Survival, burns and other sequelae very severe. |
| Higher, about 10,000 ohms | Painful shock, but no injury | Certain death, burns probably slight | Probably death, severe burns. |
| High, with bad contacts, 100,000 ohms | Scarcely felt | Painful shock, but no severe injury | Certain death, burns slight if resistance remains high. |

is assumed that the current traverses the thorax on its way through the body.

Prognosis.

The prognosis in cases of severe electric shock has been very variously estimated. Cunningham (1899), for example, speaks of artificial respiration as "the only and almost invariably futile, method in vogue in electrical accidents at the present day," for the resuscitation of persons apparently killed by electric shock. The opposite view is held by Lauffer (1912), who says "there are few cases of electrical accident where the victim cannot be restored from the electrical shock, if appropriate immediate efforts at resuscitation are instituted" by performing artificial respiration with only a few seconds' delay. Jellinek (1905) is almost equally encouraging, stating that death by electric shock is in most cases only apparent death, and advocating immediate artificial respiration. This holds for cases of sudden death by electric currents; in the instances where death occurs many hours or days after the shock, it is caused by the burns or thromboses or other lesions due to the intensity of the current. There may be excellent general health after very extensive and severe electrical injuries; Weiss quotes the case of a man who was so badly burned by electricity that both legs and both forearms had to be amputated, yet he subsequently enjoyed good general health.

Treatment.

In spite of all the experimental work that has been done on the electrocution of the lower animals, the treatment of persons apparently killed by electric currents remains much where Priestley left it in 1767. He tried artificial respiration, and artificial respiration is still the most successful treatment available. It is best carried out by the prone pressure method of Schäfer, because it is the simplest and the least dangerous in the hands of the inexpert; by some authorities Sylvestre's method, in which the victim is placed on his back and not on his stomach, is preferred (Brauchbar). The French generally recommend that rhythmical traction of the tongue should be performed at the same time, as was first recommended by Laborde (1894). This, however, could not be done easily with the patient in the prone position. Gibbons recommends the use of a special form of bellows. Atropine, recommended by Eggleston, has not proved of much service. The importance of getting to work with the artificial respiration without a moment's delay has often been emphasized by those who have had much experience of electrical accidents. No less important is the necessity for continuing artificial respiration until it is certain that death has occurred; nothing less than cooling of the body or the onset of rigor mortis should be considered to be evidence of death here.

Recovery after two hours of apparent death is mentioned by d'Arsonval (1910), who gives a first-rate account of the steps that should be taken in rescuing and resuscitating the victims of electric shocks. It must be remembered that the great majority of electrical accidents take place in workshops and other places where immediate skilled assistance is very rarely available, so that any but the simplest of treatments could not, practically speaking, be employed.

It is worth while to mention two other possible methods of treatment. It has been seen that in most cases death by electric shock is due to cardiac failure, the heart being thrown into fibrillary contraction. Prevost and Battelli, and others after them, have shown that the fibrillating hearts of the lower animals can be made to beat regularly and rhythmically once more by passing strong electric currents through them within a given time—a few minutes: so that the apparently dead animal is brought to life again. It is more than probable that the same treatment—a hair of the dog that bit them—could be applied with success to human beings apparently killed by electric currents, but there are two practical difficulties here. In the first place there is no experimental evidence, in the case of man, to show what voltage and what strength of current should best be employed in this method of resuscitation. In the second place, there would usually be great difficulty in providing the current at the required voltage for use on the spot and within a few minutes. Still, this method is well worth further investigation and

trial. The second mode of treatment I wish to mention is that tried, though without success, by Stanton and Krida. These authors started out from the work of Crile and Dolly on the resuscitation of animals killed by chloroform and by asphyxia, which showed that recovery after apparent death was possible if the pressure in the coronary arteries could be raised sufficiently, by the arterial injection of salt-solution and adrenalin, to restore some sort of circulation through the substance of the heart. If this was done mechanical stimulation of the heart through the chest wall would then cause it to beat vigorously again, and the animal seemingly killed by chloroform or asphyxia, as the case might be, would be brought back to life. Stanton and Krida tried this method of resuscitation on dogs subjected to the ventricular fibrillation caused by electric currents of low voltage, but it did not prove successful.

NOTE.—A list of references to the literature will be given at the end of the third lecture.

Memoranda :

MEDICAL, SURGICAL, OBSTETRICAL.

SODIUM CARBONATE IN RINGWORM.

The following method was shown me by a conscientious but rather ignorant woman who has had charge for many years of a home for waifs and strays. She said that she had never known more than two applications necessary. Take a piece of sodium carbonate (the household washing soda) about the size of a walnut, and hold it against red hot iron (I use the poker heated in the consulting room fire); then rub the melted end freely into the ringworm, and particularly thoroughly if it is in the scalp, which must have had the hair round cut short. One application is sufficient on the body, but on the scalp it may be necessary to repeat it six or seven days later. Usually no dressing is necessary, though if sore boric acid ointment may be used. This apparently heroic treatment is practically painless, leaves no permanent mark, and, so far, has not failed me.

ON

MEDICAL AND SURGICAL PRACTICE IN HOSPITALS AND ASYLUMS.

COUNTESS OF DUFFERIN HOSPITAL, BARODA.

CONGENITAL ABSENCE OF RECTUM AND LARGE INTESTINE.

(By CLIFFORD MAYER, M.D., B.S. Lond., Chief
Medical Officer, Baroda State.)

B. D., a Hindu female infant aged 3 days, was admitted on November 23rd, 1912, for intestinal obstruction. The history was that the child, soon after birth, had passed some meconium, and since then only a little mucus and blood. Castor oil had been given and glycerine enemata tried by a local practitioner with no effect. There had been vomiting since the day before.

On admission, the temperature was subnormal and the pulse hardly perceptible. The anal canal admitted the tip of the little finger. The abdomen was very distended, and on palpation a doughy, sausage like mass on the right side was imperfectly made out. Intussusception was diagnosed. The child was infused. The pulse improved, and two hours after admission the abdomen was opened by an incision in the right rectus close to the middle line. On incising the peritoneum a blind end of much distended gut projected for about six inches. The bowel was relieved of its contents, a Paul's tube tied in, and the gut securely fixed to the abdominal opening.

The operation was well borne, and for the first four days progress was very satisfactory, the child taking its feeds very well. On the fourth day the Paul's tube came out, and on the fifth day a pemphigoid rash broke out on the

buttocks, and the stools became greenish. Ointment and hydrarg. æ creta were prescribed. On the ninth day the bowel prolapsed during the night, and was replaced under chloroform by the house-surgeon. On the twelfth day there was again a slight prolapse of bowel, and the skin of the abdomen round the wound was raw. On the eighteenth day the stools had improved, the rash and soreness of the abdomen were much better, and the appetite good, but the child was much wasted. It never picked up again, began to vomit its feeds on the twenty-third day, and died on the twenty-fourth day.

On *post-mortem* examination it was found that the anal canal was patent for about an inch, but the rectum and the large intestine were represented by a white, thin, cord-like band in the whole of their course. There were a meso-sigmoid and transverse mesocolon, and a minute appendix near the caecal end. The blind end of the gut, which had been opened at the time of the operation, was quite free from mesenteric attachment for about 6 in., and belonged to the ileum.

It was evident that no meconium could possibly have been passed soon after birth as stated in the history, which with the passage of blood and mucus and the doughy feeling caused by the free sausage-like end of the blind ileum, had misled me, perhaps pardonably, into a diagnosis of intussusception.

British Medical Association.

CLINICAL AND SCIENTIFIC PROCEEDINGS.

EDINBURGH BRANCH.

CLINICAL MEETING.

The winter clinical meeting of this Branch was held in the Royal Infirmary, Edinburgh, on Friday, February 21st, and was attended by about 100 members.

Museum.

The museum was exhibited in Ward 4, where a large number of specimens were shown from the surgical, gynaecological, and pathological departments of the university, as well as by individual members of the profession. Those who exhibited were Drs. Cranston Low, Conrict, Ford Robertson, Barbour, Spence, Edmund Price, and Eason, and Messrs. Caird, Stiles, Dowden, Beasley, Wilkie, Wade, Struthers, and Carmichael.

Demonstrations.

Demonstrations were given in the Lock department by Mr. SCOT-SKIRVING, in the skin department by Dr. NORMAN WALKER, and in the eye wards by Dr. GEORGE MACKAY. The therapeutic uses of radium were shown by Dr. DAWSON TURNER, and the modern methods of hydro-electro-therapeutics by Dr. WEBSTER.

Clinical Cases.

The clinical meeting was held in the large surgical theatre. Dr. JAMES CARMICHAEL, President, was in the chair, and a large number of cases of medical and surgical interest were shown by the members of the staffs of Chalmers Hospital, the Royal Hospital for Sick Children, and the Royal Infirmary.

Dinner.

An enjoyable dinner was attended by about thirty members in the Carlton Hotel. It was presided over by Dr. JAMES CARMICHAEL. The guests included Dr. Munro Moir (Inverness), Dr. Haig (Crieff), Dr. Crerar (Maryport), while amongst those present were Professor Alexis Thomson, Mr. Cathcart, Dr. George Mackay, Dr. Luke, Dr. Carlyle Johnston, and Dr. Hamilton (Hawick).

After the loyal toast had been responded to, the CHAIRMAN gave the toast of "The British Medical Association," and Dr. HAMILTON (member of Council) replied in a vigorous and rousing speech. The sentiment of prosperity to the Association was enthusiastically received. Mr. CATHCART proposed the toast of "The Guests," and welcomed those present. Dr. CRERAR (Maryport) and Dr. HAIG (Crieff) replied. Dr. HAMILTON made an innovation on the toast list in proposing the health of "The Senior Secretary," and in a complimentary speech alluded

to and thanked him for his services during the past ten years on behalf of the Association. Dr. DEWAR replied. "The health of the President" was proposed by Mr. STRUTHERS; and that of "The Secretaries" by Dr. HAIG, to which the JUNIOR SECRETARY replied.

BURMA BRANCH.

A MEETING of the Burma Branch was held in the Civil Hospital, Maymyo, on January 24th. Colonel HEHR, I.M.S., was in the chair, and there was a large attendance. The following cases were shown by Major HAMMOND, I.M.S.:

CASE I.—A case of tuberculous dacrylitis cured after operation in which a Pott's curvature was developing. The curvature was very acute, and there was a posterior abscess.

CASE II.—A case showing a good result after a complete mastoid operation.

CASE III.—A case of unilateral exophthalmos. The eye was bulging forwards without pain, paralysis, loss of sight, or other symptoms. The cause and treatment were discussed.

CASE IV.—Recurrent epithelioma in the groin after excision of the penis and glands.

CASE V.—A case of puncture of the eyeball by a sewing needle. The puncture had healed, but the sight was lost, and the question of sympathetic ophthalmitis was discussed.

Colonel HEHR, I.M.S., then commenced a paper on undiscovered points in malaria, which will be concluded at the next meeting.

Reports of Societies.

ROYAL SOCIETY.

Thursday, February 20th, 1913.

Sir ARCHIBALD GEKIE, K.C.B., President, in the Chair.

Rhythm arising from Rivalry between Antagonistic Reflexes.

PROFESSOR C. S. SHERRINGTON, F.R.S., read a paper on reflex stepping as the outcome of double reciprocal innervation, in continuation of work on the reciprocal innervation of symmetrical muscles recently communicated to the society. The observations were almost wholly upon the decerebrate preparation. The symmetrical muscles used in the experiments were the extensors of the right and left knee. Taking an afferent nerve which produced steady reflex excitation of the muscle, and another which produced steady reflex inhibition of the muscle, it was found possible by stimulating both nerves concurrently to obtain regularly rhythmic contractions and relaxations of the two muscles, the rhythm being about 2 per second. To do this required certain somewhat narrowly adjusted proportions of strength of the two paired stimuli. The stimuli were both of them continuous, in the sense that they were faradic, and of a frequency (about 40 per second) much above and bearing no causal relation to the rhythmic reflex produced. In the rhythmic reflex the right and left muscles each contracted and relaxed alternately and moved reciprocally, the contracting phase of the right muscle being synchronous with the relaxing phase of the left, and conversely. This rhythmic reflex was shown clearly to be reflex stepping. In short, under the equipoise of the two opposed and, so to say, equiposed continuous stimulations, the limbs exhibited reflex walking. With certain other paired intensities of stimulation of the two antagonistic afferent nerves, it could be arranged that only one muscle of the pair stepped—the left muscle if the right nerve stimulus were the stronger, and conversely. In this unilateral walking or running the other leg was kept steadily flexed by the reflex, that is, the extensor muscles were kept steadily inhibited.

The Synthesis of Protoplasts.

D.S. W. CRAMER and J. LOCHHEAD, in a continuation of previous contributions to the biochemistry of growth, showed that glycogen disappeared more rapidly from the liver of tumour-bearing rats than from the liver of a normal rat. Since observations on the gaseous metabolism showed that there was no increased oxidation of carbohydrate material in tumour-bearing animals, the results confirmed the conclusion arrived at previously from observations on pregnant animals, that in growth carbohydrate material is used for the synthesis of protoplasm.

Dr. FREDERICK TAYLOR, President, in the Chair.

*The Prognostic Significance of Secondary Polycythaemia
in Cardio-pulmonary Cases.*

Dr. F. PARKES WEBER, in a paper on this subject, said the frequent occurrence of polycythaemia in those cases of congenital heart disease, especially congenital pulmonary stenosis, which were associated with some cyanosis, was well known. A few such patients reached adult life, as in two cases which he had exhibited, whose blood changes he had investigated. They seemed to support the modern doctrine that the excess in the number of red corpuscles was of a conservative or compensatory nature, an attempt on the part of the bone marrow to make up for imperfect oxygenation of the blood and tissues of the body by a numerical increase of the red cells. But the figures obtained by blood counts might lead to an under-estimation of the total numerical excess of erythrocytes in the body, because the total volume of blood in the body was likewise excessive. In one case the same conclusion was indicated by an estimation of the total haemoglobin and the total blood volume in the body by Haldane and Lorrain Smith's carbon monoxide method. The secondary polycythaemia in cases of congenital heart disease was seldom rivalled in degree by the secondary polycythaemia which sometimes occurred in chronic valvular affections and in cases where there was adherent pericardium. It was more nearly approached by the secondary polycythaemia sometimes found in the late stages of pulmonary emphysema, chronic bronchitis, asthma, old bilateral pleuritic adhesion, chronic interstitial pneumonia, and pulmonary fibrosis. In the cardio-pulmonary cases he regarded the outlook as very grave at the stage when cyanosis and a great degree of polycythaemia became striking clinically. Dr. Weber proceeded to describe a typical attack, during which the red blood cells were 7 millions or more. With increasing cyanosis and chronic carbonic acid poisoning there was often marked somnolence, which might proceed to actual coma, and death might be directly due to carbonic acid poisoning or to intercurrent bronchopneumonia. An important etiological factor seemed to have been the abuse of alcoholic drinks. Some of the cases improved, at all events temporarily, under prolonged rest in bed, small doses of potassium iodide, cardiac stimulants, diuretics and expectorants, oxygen inhalation, and perhaps also moderate blood-letting. The bone marrow was examined in one case, and showed a decided erythroblastic reaction. Dr. Weber concluded by relating eleven illustrative cases.

Some Cases of Polycythaemia.

Dr. GORDON R. WARD said it was customary to divide these cases into (a) relative, (b) absolute. The first included those in which there was a concentration of the blood due to excessive loss of fluid from the body, as in cholera, the rapid formation of pleural or other effusions, excessive perspiration, etc. But the absolute form was distinguished by the presence of an actual increase of red cells above the normal number for the whole body. This class included erythremia, the polycythaemia so frequently associated with congenital heart disease, and that of acquired lung disease. The absolute class would show signs of increased formation of red cells, such signs including increase of red marrow, dilatation of vessels due to the compensatory hydraemia following increased viscosity of the blood, the presence in the circulation of immature red cells, and the otherwise inexplicable hypertrophy of the left ventricle. Yet it was not always easy to differentiate the two classes. For example, one man had acute heart failure; when first seen, his red cell count was 7 millions, but in four days they had fallen to just half that quantity as the cardiac condition improved. This would appear to be a simple case of concentration, yet here was irrefutable evidence of rapid new red cell formation in the shape of a blood crisis. If the case had not recovered from the heart failure, there would have arisen a compensatory polycythaemia in addition, and this would have been

permanent—in fact, an absolute polycythaemia. He found it quite impossible to group into absolute and relative the 24 cases he was narrating in this paper; therefore he had recourse to a classification which was partly etiological and in part purely clinical. The first group he called congenital polycythaemia, and all the cases in it were associated with cyanosis, and probably all had clubbing of the fingers. It was a congenital abnormality presumably in the nature of deficient development. Next came the first idiopathic group—cases of possible erythremia, and one case was probably unique in that it was hereditary. The second idiopathic group consisted of cases which showed sparseness of subcutaneous fat, a polycythaemia reaching 7 millions, and a brick-red complexion and dry skin. Blood pressure was much above the normal. The cases in the third idiopathic group all had polycythaemia with excess of subcutaneous tissue, and a generally fat and unhealthy appearance. His fifth group he called the compensatory, and the sixth the reactive. The compensatory polycythaemia followed a stimulus to which the only true reaction was true polycythaemia; but reactive polycythaemia was met with in cases in which there was no discoverable need for polycythaemia, though there was need for repair of a previously impoverished blood. It was, in other words, an excess when all that was really demanded was a return to the normal. Dr. Ward's new group was therapeutic polycythaemia, and these cases resembled the last, except that there was reason to suppose the nature of the stimulus causing the polycythaemia was known. Group eight were the mixed cases, and group nine those of doubtful causation.

The papers were briefly discussed by the PRESIDENT, Dr. R. HUTCHISON, Dr. BATTY SHAW, Dr. ELLIOTT, and Dr. PARKINSON; and the authors replied.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF OBSTETRICS.

Friday, February 7th, 1913.

Mr. A. J. HORNE, F.R.C.P.I., President, in the Chair.

Two Cases of Rupture of the Uterus.

Dr. MADILL read notes of these cases. In the first the patient was a 5-para, aged 34. After being in labour for seven hours a severe pain occurred, and no more ensued. Two hours later she was admitted into hospital. The fetus could easily be defined on palpation of the abdominal walls. Supravaginal hysterectomy was performed; all the fetus, except its head, lay free in the abdominal cavity, the rest lay on the left side of the uterus, in which organ the placenta lay loose. There was much free blood in the peritoneal cavity. The patient recovered. The abdomen was very pendulous. The second patient, a 6-para, aged 32, had intermittent pains for a fortnight; the forceps was applied without success, and then she was sent moribund into hospital. Abdominal section was performed; a hydrocephalic fetus, weighing 9½ lb., lay with the placenta free in the peritoneal cavity; there was an extensive laceration on the right side of the uterus, and the bladder was badly torn. Hysterectomy was performed, but the patient succumbed almost directly afterwards. Dr. JELLET congratulated Dr. Madill on the success of his first operation; he himself had reported another, last session, which also succeeded. Dr. SOLOMONS related an instance of rupture of the uterus from neglected brow presentation; the body of the child escaped into the peritoneal cavity, but delivery was effected by forceps, the placenta removed manually, and the rent plugged with iodoform gauze. The patient recovered. Dr. PUREFOY, who had assisted at both Dr. Madill's operations, said that no hard and fast rules for diagnosis and treatment could be laid down. Rupture occurred sometimes without any of the usual signs.

Wertheim's Hysterectomy.

Dr. E. H. TWEEDY exhibited a cancerous uterus removed from a woman aged 38. There had been haemorrhages, one causing syncope, and she believed herself to be a bleeder; she was plugged, and then sent into hospital. The entire lip of the cervix was involved, but the uterus was mobile, and there was no cachexia. When the uterus was removed, a small myoma was discovered in its cavity.

surrounded by clot; had it not caused the hæmorrhage, the patient would not have applied for relief till later. As it was, glands were discovered far from the original growth. Dr. PÉREROY questioned whether a uterus the seat of a fibrioma was specially liable to become cancerous. Malignant disease of the cervix soon extended to distant glands.

Surgical Treatment of Septic Pelvic Thrombosis.

Dr. JELLET, in a communication on pelvic thrombosis, referred to a case of pyæmia in the Rotunda Hospital, with thrombosis of the ovarian vein, as detected at the necropsy, and he decided, in considering that case, to operate in future. He recorded three cases, in all of which the first symptoms were recurrent rigors, high temperature, and rapid pulse. He preferred abdominal section in the first case, removing with perfect success a large thrombosed and suppurating vein. In the second, where he operated much later—namely, on the thirty-ninth day—he removed a thrombosed ovarian artery and vein; a few rigors followed, yet the patient recovered. The third was similar to the first, but the whole of the ovarian vein contained pus and there were two abscesses in its vicinity. The patient improved for a few days, then grew worse, and on the thirtieth day after labour a second operation was undertaken in order to tie the internal iliac vein, which he suspected to be thrombosed. It was not plugged, however, but there was apparently thrombosis and suppuration of the uterine vessels. Hysterectomy was performed, but the patient died on the thirty-fourth day with symptoms of pulmonary sepsis. In all three subjects thrombosis developed on the right side and primarily in the ovarian vein, favourably placed for operation. Early surgical interference was always advisable. The early symptoms and the thickening or swelling of the broad ligaments, with relatively little pain or tenderness, were diagnostic. Professor SMITH noted that the opinion among operators experienced in the surgery of pelvic thrombosis seemed to lay more stress on conditions detected bimannually than on high temperature and relatively slow pulse. If infection spread from the placental site it was possibly carried through the ovarian vein. Professor Smith agreed with Taylor of Birmingham as to choice of operation by the vaginal route in suitable cases. Dr. SHEILL suggested that the relative frequency of infection on the right side was attributable to the fact that most doctors were right handed, the examining finger being passed along the right side of the genital tract. Possibly ulceration of the cervix might supply the infection. Mr. PEARSON held that the subject was suited for the Section of Surgery. With regard to the technique, before proceeding to follow up the veins, the ovarian vein should be exposed where it entered the vena cava or left renal vein, and divided. It was important to start as far away as possible from the focus of infection, as there was a great danger of embolism if the general circulation were not cut off before the septic parts were dealt with. Cases in which thrombosis existed were apparently more favourable than those where there was no clot in the vein. Vaccines were of little use in cases of acute infection, and it seemed irrational to give a vaccine in acute sepsis, but Mr. Pearson had seen benefit from serum in several cases. After-treatment was as important as operation. The patient should be saturated with as much liquid as possible to aid the kidneys in eliminating the toxins. Dr. ROWLETTE dwelt on the unsatisfactory results of vaccines in thrombosis in the United Kingdom, whilst in America the cases of sepsis where there was thrombosis did best. In nearly every case of thrombosis in this country there was mixed infection—hence, perhaps, the unsatisfactory results of vaccines. Dr. Rowlette had successfully employed vaccine in two cases. In the first there was acute puerperal melancholia with pyæmia, and an autogenous *Staphylococcus aureus* vaccine was administered. In the second there was not only thrombosis, but also infarcts in the lungs, and the patient was very ill. It was thought that she could not bear an anaesthetic, still less an operation. A growth of streptococci was obtained from the venous blood and a vaccine prepared. The temperature and pulse came down step by step and the general condition

improved. In a week the patient was convalescent, and, though an attack of pleurisy supervened, she recovered completely. It was one of the worst cases of puerperal sepsis he had ever seen. Dr. PÉREROY considered that Dr. Jellett was correct in stating that 60 to 70 per cent. of septic thrombosis cases did not recover. Dr. JELLETT, in replying to the remarks, said he did not mean to suggest that no cases of pyæmia recovered, but when there was thrombosis of veins with suppuration the mortality must be something near 100 per cent. In cellulitis an infection first passed into the connective tissue—say, from a torn cervix. This started the cellulitis, and thrombosis in the veins might or might not follow. In septic thrombosis, on the other hand, the infection passed straight into the open veins from the placental site. It had been questioned whether it were better to attack the thrombosed ovarian vein from below or from above. In the majority of cases the transperitoneal operation was the better. He was indebted to Mr. Pearson for his remarks about the ligature on the upper part of the ovarian vein. Dr. Sheill's suggestion might account for infection of the vaginal mucous membrane, but not for infection of the placental site. He recognized that the question of operation in these cases was still a very grave matter, but that in cases such as those he brought forward it was positively indicated.

SECTION OF ANATOMY AND PHYSIOLOGY.

Friday, January 21th, 1913.

Dr. B. J. COLLINGWOOD, President, in the Chair.

The Adequate Stimuli of the Respiratory Centre.

PROFESSOR T. H. MILROY described the methods of studying the influence of nervous factors in the production of apnoea, and also the effects of various gas mixtures on the quiescent centre. The following conclusions were tabulated: (1) Alterations in the rate or degree of distension of the pulmonary alveoli when the amount of ventilation is constant do not affect the duration of the apnoeic pause in any constant direction, but a repetition of ventilation periods tends to prolong the pause. (2) Removal of the vagal control does not interfere with the production of the apnoeic pause. (3) Any rise in the CO₂ content of the air used for ventilation shortens the apnoeic pause, and any increase in the carbonic acid content of the gas mixture used to distend the lung after pulmonary ventilation with air shortens the period. With increased CO₂ content of these gas mixtures irrespective of the amount of oxygen, the apnoeic pause proportionately decreases. (4) Injection of small quantities of acid solutions directly into the carotid during the pause leads to respiratory movements of an exaggerated type, as does also injection into the central end of the carotid and into the external jugular vein to a lesser degree. (5) With the excitation of such respirations during the pause there is associated an increased passage of carbonic acid from pulmonary blood to air. (6) These effects are produced after removal of the vagal control, but the excitability of the centre under such conditions seems to be diminished. (7) The passage of CO₂ from alveolar gas mixtures to blood, or from blood to alveoli, seems to depend entirely upon the difference of the pressure of that gas in the blood and air in the alveoli. (8) It seems most probable that the effective stimulus of the respiratory centre rendered quiescent by over-ventilation is a rise in the carbonic acid concentration in that centre, whether brought about by the normal rise in carbonic acid formation during the pause, with its associated rise in the CH₄, or primarily to a rise in the CH₄ from the formation of acid products of incomplete oxidation giving rise secondarily to an increase of the free CO₂ tension. Professor W. H. THOMPSON, Dr. O'CONNOR, and the PRESIDENT spoke; and Professor MILROY replied.

Thrombin and Antithrombin.

Mr. M. T. McMAHON gave a demonstration of the action of thrombin and antithrombin. The PRESIDENT pointed out that this preparation of thrombin acted equally well in purpura hæmorrhagica and in hæmophilia. Mr. SHERIDAN had used this preparation with success for persistent bleeding after extraction of teeth.

Creatinin and Urea.

Professor W. H. THOMPSON described some new standard solutions for the estimation of creatinin by Folin's method, and also described a modification of Benedict's method for estimating urea. The PRESIDENT and Professor MILROY spoke, and Professor THOMPSON replied.

OXFORD MEDICAL SOCIETY.

A MEETING was held in the Radcliffe Infirmary on Friday, February 14th, the President (Dr. W. DUGAN) in the chair. Mr. A. P. DODDS-PARKER showed the following series of cases of fracture treated by modern methods: (1) Fracture of upper end of humerus in a young man, treated by a Lane's plate; perfect union. (2) Fracture of olecranon in a woman, treated by wiring; very good result. (3) Fracture of olecranon in a man, treated by wiring; very good result. (4) Fractured femur in a boy, treated by a Hodgson's splint; perfect union, no shortening. (5) Fractured tibia in a man, treated by a Lane plate; there was delayed union and much callus, but a good result. (6) Fractured humerus of the middle third in a man, treated by a Lane plate with a good result. (7) Fractured tibia and fibula in a man, treated by a Lane plate for non-union; good result. (8) Fractured patella in a man, treated by a wire and a Lane plate; good position of the patella and walks well. (9) Fractured ulna and radius in a man, treated by a Lane plate with a good result. All the cases were illustrated by x-ray photographs before and after, taken and demonstrated by Mr. R. H. SANKEY. Dr. W. TURRELL then showed a case of *Lupus of the cheek* in a woman who had had no treatment for twelve years, whom he was in process of treating by diathermy. Five applications had been given, and the effects of various intensities of the treatment were demonstrated in a piece of fresh liver tissue. Dr. W. COLLIER related the histories of two unusual cases of *Diphtheria*, the first in a woman, aged 28, who was admitted into the Radcliffe Infirmary for chorea of pregnancy. The patient became maniacal, and as the child was viable labour was induced. A parotid abscess developed in which staphylococci were found. Later, six weeks after her entry into hospital, her voice became husky, there was respiratory stridor, and she died. At the *post-mortem* examination a diphtheritic membrane, in which *B. diphtheriae* was found, extended from the vocal cords to below the bifurcation of the trachea. The second instance was that of a nurse who had been in attendance on a very bad case of septicaemia of doubtful nature. The nurse subsequent to leaving her patient developed a high temperature, great cyanosis, and rapid failure of strength. There were a few rales in the chest, and *B. diphtheriae* with numerous cocci were found in the sputum, but none of the ordinary clinical signs of diphtheria were present. Antidiphtheritic serum had no effect. At the *post-mortem* examination diphtheria bacilli were detected in the mucus of the trachea and smaller bronchioles. The lungs were oedematous and partly solid, but did not sink in water, and no other lesions were discovered.

BRISTOL MEDICO-CHIRURGICAL SOCIETY.

AT a meeting on February 12th, Dr. WALTER SWAYNE, President, in the chair, a discussion was held on the *Treatment of chronic constipation*. It was opened by Dr. F. H. EDGEWORTH, who said that constipation might exist, although the bowels were opened daily. Delay in passage of the intestinal contents over the normal forty hours could be easily shown by the administration of charcoal bisenits to colour the faeces. Salines were particularly efficient in patients with high blood pressure. In order to retain its effects, cascara must be given in increasing doses, but with aloe the dose need not be increased. In cases combined with neuroses bromides were efficient, and when the chief difficulty was the emptying of the lower bowel enemata had to be given, glycerine being unsuitable for constant use owing to its injurious action on the mucous membrane. Mr. CARWARDINE had been able to cure several cases by the division of adhesions in the ileo-caecal region, but he was doubtful as to the advisability of performing such extensive operations as removal of the colon. Mr. F. G.

BERGIN pointed out that by locating the situation in which delay occurred a bismuth x-ray examination was of great help towards correct treatment. Dr. BERTRAM ROGERS regarded constipation in children and infants as the result of bad habits combined with a deficiency of fats in the food, and particularly of water. Dr. MICHELL CLARKE regarded neglect in children as the most frequent cause, and insisted on a routine rectal examination in cases of constipation. Mr. LANSDOWN had once been asked to remove the colon to cure a case of constipation, but had given relief by removal of enlarged ovaries impacted in the pelvis. Mr. FRENCH had treated a chronic case by appendicostomy and lavage, but had been compelled later to remove the colon.

LIVERPOOL MEDICAL INSTITUTION.

AT a meeting on February 20th, Mr. ROBERT JONES, President, in the chair, Mr. T. R. W. ARMOUR read a note on two cases of *Recurring dislocation of the shoulder* in which "Clemmout's" operation had been performed by Mr. Robert Jones. The first patient had had his right shoulder dislocated seventy-six times and his left twenty-eight times. Capsulorrhaphy had been performed on both joints without success. The operation consisted in bringing a long flap of the posterior margin of the deltoid through the quadrilateral space in front of the capsule of the joint and stitching its end in front under the coracoid process. This deepened the socket and tightened the capsule. Care was needed to avoid injury to the nerve and arterial supply of the muscle. In the first case the operation, performed in June, 1912, had not been a success. The second, done last November, had been so far quite satisfactory. The first had failed from faulty technique. The deltoid flap had not been long enough and the tunnel not wide enough to allow easy manipulation; nor had the fixation of the flap been sufficient to prevent it from returning to its original place. In the second case care had been taken in these points, and so far with good result. The operation was only on its trial. Mr. THURSTAN HOLLAND read a paper on *X-ray examination of the stomach*. Half to three-quarters of a pint of bread and milk, of the consistence of bread sauce, mixed with three or more ounces of bismuth carbonate, or barium sulphate, which was much less expensive, was given to a fasting patient. The stomach was then seen to be much longer and narrower than was depicted even in contemporary anatomical works. The lower end came to the level of the iliac crest, and the whole organ was to the left of the middle line. The movements were rhythmical at the rate of one in twenty seconds, and did not pass along to the duodenum. The food did not lie at the lowest part of the stomach, but was distributed through the length when full. The normal stomach emptied in about three and a half hours after this test meal. Mr. Holland showed lantern photographs of the normal stomach and its variations and contractions; also of three cases of transposed viscera; of cases where gastric enterostomy had been done; and of cases of gastropexy. He demonstrated a photograph of dilated stomach where the lower end lay quite in the pelvis; also photographs of malignant disease and of hour-glass contractions of the organ. Dr. T. R. BRADSHAW said that Mr. Holland was recognized as an expert authority. The x-ray method afforded invaluable assistance in the diagnosis of very many cases. Dr. HILL ABRAM said that the physician would still be obliged, especially in places remote from elaborate equipment, to rely on the older methods of diagnosis. Dr. BRADLEY-HUGHES and Dr. R. J. M. BUCHANAN also spoke; and Mr. THURSTAN HOLLAND replied. Dr. EDGAR STEVENSON read a paper on *Some points in modern eye practice*. Cocaine hydrochlorate appeared to be the most useful of all local anaesthetics. A weak mydriatic, such as homatropine, was safer than the stronger preparations. Among silver preparations, the nitrate was the most useful. Subconjunctival injections of mercury oxychloride had been found of value in septic cases. Aspirin in trauma and in iritis cases, and sodium salicylate in large doses in sympathetic ophthalmia, were of service as internal remedies. Dr. Stevenson's experience of salvarsan, of vaccines, and serums had not been very favourable. Of physical remedies, Dr. Stevenson condemned

cold applications as dangerous, and found heat more useful. Depletion by leeches was highly beneficial. Two preparations illustrating Tote's operation for dacryocystitis were exhibited. Mr. T. H. BICKERTON objected to the use of silver nitrate in gonorrhoeal ophthalmia. For sixteen years he had never used that salt. He applied iced compresses, and had never lost an eye. Dr. W. T. CLEGG called attention to the omission of urotropin, which he had found useful in wounds of the eye. He did not think subconjunctival injections were better than ordinary subcutaneous injections. In the treatment of dacryocystitis he was satisfied with the older methods of treatment, and thought excision of the sac should be of very limited application. Mr. NIMMO WALKER agreed with Dr. STEVENSON in the condemnation of the use of ice-pads in gonorrhoeal ophthalmia, and was convinced that warm moist applications were the best in the acute stage. He had not tried blood-letting in glaucoma. In routine examinations of the blood pressure in cases of chronic glaucoma he had failed to find any definite relationship between changes in circulatory and ocular tensions. In dacryocystitis slitting the canaliculi and probing were worse than useless. The new operation described by Dr. STEVENSON was well worth trying. Mr. MALCOLM SPOCKDALE agreed that the old-established drugs, such as cocaine, atropine, and boric acid, still retained their place in eye work. The use of silver nitrate solutions, he thought, should always be very limited. In gonorrhoeal ophthalmia the infection, being at first on the surface, could be washed away by a mild lotion, such as boric acid. In advanced lacrimal disease he had found excision of the sac to yield satisfactory results. Dr. HARCOURT and Dr. LOGAN also spoke; and Dr. STEVENSON replied.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.

A MEETING of the society was held on February 23rd, the President (Dr. DOBSON) in the chair. Dr. W. CUTHBERT MORTON read a paper on *The present crisis in anatomical nomenclature*. The Basel Nomenclature, which was promulgated by the German-speaking anatomists in 1895, had made such progress in America and the colonies, and even in the United Kingdom, that the Anatomical Society had been forced to discuss its adoption, not merely as an international code, but for ordinary use. There were grave objections to the new nomenclature, which did not claim to be more than a list of names, acceptable to German-speaking anatomists, submitted to anatomists speaking other languages. In spite of much that was excellent, the principles on which it was based were not scientific, and it did not sufficiently regard the needs of medicine and surgery. Moreover, in some respects it was not up to date. Dr. Morton therefore pleaded for a commission of British anatomists and teachers of final subjects to prepare a complete British nomenclature as far as possible in harmony with the Basel Nomenclature. An international conference might then be called to evolve a truly international nomenclature. He rapidly reviewed the principles upon which such a nomenclature should be based, and sketched out the manner in which these principles might be applied to the abdominal cavity and its contents. Mr. J. STEWART showed specimens from six recent *Abdominal operations*, illustrating difficulties in diagnosis. Mr. ALEXANDER SHARP showed a specimen of *Squamous-celled carcinoma of the larynx*. Mr. CONSTABLE HAYES showed a specimen (with photograph) of a large *Osteoma*, which caused secondary mastoid disease in a case of suppurative otitis media. Mr. WALTER THOMPSON exhibited a large *Malignant tumour of the bladder*, which had been successfully removed by a wide operation. Recurrence of the growth had, however, taken place after an interval. Dr. C. W. VISING showed a case of *Hysterical stupor*, which was improving under treatment. Mr. LITTLEWOOD showed a specimen of *Tuberculous mesenteric glands* which he had removed by operation. There had been a sinus communicating with the surface, and he had removed the sinus, glands, mesentery, and associated loop of bowel, performing an end-to-end anastomosis. The patient had made a good recovery. Cases and specimens were also shown by Dr. HELLIER, Mr. L. A. ROWDEN, Mr. E. W. BAIN, and Dr. M. J. STEWART.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.

At a meeting held on February 20th, the President, Dr. STANLEY RISLEY, in the chair, Mr. ARTHUR CONNELL, in a paper on the *Importance of careful treatment in injuries and infections of the fingers*, dealt specially with the infective conditions and their treatment by fomentations, etc. He referred to the great importance of making incisions so as to avoid infecting healthy tissues. When suppurative conditions developed about the nail it should be removed immediately. When an interphalangeal joint became infected amputation was preferable to excision. Mr. J. B. FERGUSON WILSON showed a specimen of *Torsion of the spermatic cord*. There was great enlargement of the testicle due to extravasation of blood into the epididymis and body. The condition began with a sudden onset five days before removal. There had been no injury and the testicle was fully descended. Dr. A. G. YATES showed two cases of *Exophthalmic goitre in men*. One patient had been taking thyroid extract for several months, but the result appeared to be wholly unsatisfactory. The desirability of operative treatment in these cases was discussed. Dr. R. G. ABERCROMBIE showed three forms of *Apparatus for treating injuries of the hands*: (1) A contrivance for exercising the grasp muscles, in which the principles of the lever were utilized so that at the beginning of the act of grasping, when the muscles were weak, the resistance was small; at the middle of the grasp, when the muscles were strongest, the resistance was at its maximum; and at the end of the grasp when the muscles were again weak, the resistance was again small. (2) A steel wristlet, provided with finger-stalls and straps, designed to overcome loss of flexion of the fingers caused by stiffness. The straps were to be gradually tightened, thus bringing the fingers into the position of flexion. (3) A grooved wooden wedge, intended to obviate the tendency, after a disarticulation of the finger at the metacarpophalangeal joint, of the two adjoining fingers to fall together, thus weakening the hand. The wedge was to be worn at night. Mr. GRAHAM SIMPSON showed a *Loose cartilaginous body* removed from the elbow-joint. It was about the size and shape of a bean and showed no fractured surface.

BRADFORD MEDICO-CHIRURGICAL SOCIETY.

At the general meeting of the society, held on February 18th, a discussion on *Puerperal eclampsia* was introduced by Dr. E. W. SHARP. The "fit" was a common symptom, not the whole disease, which was a toxæmia where certain well-marked pre-eclamptic manifestations, notably headache, disturbance of vision, swelling of the face and extremities, and diminution in amount of urine, were commonly observed. The condition was quite distinct from uræmia and albuminuria, and the toxin was not microbial, but akin to certain venoms, since it contained the same five elements—thrombotic, hæmolytic, hæm-agglutinative, endotheliolytic, and neurotoxic. Although apt to recur in subsequent pregnancies, eclampsia did not result in permanent nephritis. It occurred not only in normal but also in sterile molar pregnancies. It had been ascribed to imperfect balance of the internal secretions, those of the suprarenal and pituitary being increased, as evidenced by high blood pressure—a prominent feature of the disease—whilst the secretion of the thyroid diminished. Prophylaxis was of high importance in preventing the eclamptic attacks. When premonitory symptoms set in, rest, a strict milk and vegetarian diet, and a daily action of the bowels, were essential. When the attacks occurred Twedy's methods were to be followed. The avoidance of external stimuli, the use of morphine, and the elimination of toxins by lavage of stomach and colon, were important measures. A concentrated solution of magnesium sulphate should be left in the stomach, and a pint of sodium bicarbonate in the rectum. Attempts should be made to lower the blood pressure; in many cases venesection was valuable, as was veratrum viride or nitroglycerine. Where intravenous infusion became necessary sodium bicarbonate was better than normal saline fluid. If swallowing were possible frequent draughts of water should be given, but no food. Diaphoresis was not recommended, and lumbar puncture was useless. Dr. Sharp was not in favour of inducing labour. When it occurred it should be assisted.

but not forced, natural delivery being preferable to artificial methods. *Accouchement forcé* was not good practice. When the os would not dilate, and pains were strong, Caesarean section was greatly to be preferred.

NORTH OF ENGLAND OBSTETRICAL AND GYNAECOLOGICAL SOCIETY.

At a meeting held on February 21st, Dr. W. E. FOTHERGILL (Manchester), President, in the chair, Dr. GEMMELL (Liverpool) showed a specimen of *Adhesion of the vermiform appendix to the right Fallopian tube*. The left tube and ovary were the seat of a tubo-ovarian abscess. The history showed that the primary mischief was probably appendicular. Dr. GRIMSDALE (Liverpool) brought forward a specimen of *Carcinoma of the body of the uterus* from a patient whose ovaries were removed three years previously, and showed suspicious appearances suggesting malignancy. Dr. GEMMELL exhibited two cases of *Ectopic gestation*: (1) A secondary abdominal pregnancy with seven months fetus and with a very clearly defined history; (2) an isthmal pregnancy in the left tube of six weeks' duration, the source of very severe intraperitoneal haemorrhage. The abdominal osium was free from any sign of haemorrhage and no laceration of the tubal wall or sac could be detected. Dr. FLETCHER SHAW (Manchester) showed a *Fibromyoma of the uterus complicated by an abscess in the right broad ligament* from which a pure culture of streptococci was obtained. Eight years previously abortion and septic infection had occurred, but from that time until the sudden onset of the pelvic inflammation the patient's health had been good. Dr. BLAIR BELL (Liverpool) showed a case of *Superinvolution of the uterus with exophthalmic goitre* in a woman aged 25. Her health had been good until the birth of her first child, eleven months previously. Lactation failed within a few weeks and the thyroid enlarged, all the symptoms of exophthalmic goitre developing in a short time. The uterus was very small, the cavity being reduced to 2 in. in length. The case was of great interest owing to the fact that superinvolution appeared more likely to follow deficient thyroid secretion than the reverse. Dr. CATHERINE CRISHOLM (Manchester) read a paper on *The nature and extent of menstrual moulting during adolescence*, based upon the menstrual history of 500 girls attending school between the ages of 10 and 20. The majority, 58.6 per cent., experienced no discomfort. In 33.6 the pain was slight and often only occasional; those suffering discomfort experienced rather local symptoms than general disturbance such as headache or general lassitude. The tendency to disturbance did not appear affected by the age of onset. Severe cases of pain, so far as there was opportunity for examination, were associated with local abnormalities. The largest number of cases with discomfort and pain occurred among anaemic girls with profuse loss. The best physically-developed girls showed over 70 per cent. without any disturbance and with no cases of pain which incapacitated them from work. Hard mental and physical work under healthy conditions did not appear to affect the freedom from menstrual disturbance.

HARVEIAN SOCIETY.

At a meeting held on February 20th, a discussion on the *Diagnosis of acute abdominal conditions in children* was opened by Dr. EDMUND CAULEY. The diagnosis of acute abdominal conditions necessitated a mental inventory of all the affections which might give rise to the observed symptoms. For accurate diagnosis an exploratory operation might be indispensable. Cases could be quoted illustrative of the difficulty in diagnosing severe intestinal colic from organic disease; others in which exploration had been done unnecessarily; and lastly, others in which such treatment would have saved the life of the patient. The question essentially turned on diagnosis. It was admitted that the "look and see" method of diagnosis was sometimes justifiable, but it was a moot point whether the surgeon was always the right person to decide if there were sufficient evidence to warrant exploration. The modern physician was not ever averse to operative measures; indeed, he was often more surgical

in his opinion than the surgeon. Many acute abdominal conditions might be mistaken for affections amenable to surgical treatment. Pleurisy, pneumonia, Henoch's purpura, haemorrhagic colitis, and the onset of coma in diabetes, had all been explored on account of intestinal symptoms suggestive of abdominal disease. The main symptoms and physical signs on which a differential diagnosis could be based were vomiting, abdominal pain, constipation, the condition of the abdomen, the abdominal facies, collapse, toxæmia, pulse-rate, respiration and body temperature. These were considered in relation to the chief diseases, notably appendicitis, intussusception, intestinal obstruction, peritonitis, and simple colic. Special attention was paid to Henoch's purpura, because it might be mistaken for intussusception, a complication which might occur during its course. Many diseases could be excluded in the case of children mainly on account of their rarity, still it was necessary to bear in mind as possibilities—gastric crises in tabes dorsalis, perforation of simple gastric or duodenal ulcer, acute pancreatitis, cholecystitis and gall stones, renal colic, embolism or thrombosis of the mesenteric artery, and lead colic. Tuberculous peritonitis might give rise to misleading symptoms of obstruction due to bands or adhesions, the vomiting and constipation being really signs of the onset of meningitis. Of the utmost importance in inflammatory affections was the absence of abdominal movement and the presence of abdominal rigidity and tenderness. The rigidity might be the chief sign indicative of danger during the temporary improvement due to the relief of tension in a case of appendicitis. In all cases of colic a dietetic cause must be sought for, but the presence of such a factor was not always the explanation. Many cases of appendicitis in the early stage were ascribed by parents, and even doctors, to unsuitable food. A rise of temperature in such cases was of considerable assistance. Probably in all doubtful cases it was to the advantage of the patient that both a physician and surgeon should be called in consultation before deciding that exploration was essential. Mr. EDRYD CORNER pointed out the probable cause of acute abdominal conditions depended greatly on the age of the individual. Sir JAMES GOODHART related a number of interesting cases, and Mr. LOW, Sir JOHN BROADBENT, Mr. FITZWILLIAMS, Dr. CLAYE SHAW, and the PRESIDENT all took part in the discussion.

HUNTERIAN SOCIETY.

A CLINICAL afternoon was held at the London Hospital on February 26th, the President (Mr. A. H. TUBBY) in the chair. Dr. PANTON demonstrated cases and blood films illustrating the various types of the *Non-granular leukaemias*—acute myeloid leukaemia; chloroma, with the blood changes of acute myeloid leukaemia; the myeloblastic stage of chronic myeloid leukaemia; acute lymphoid leukaemia; and also 5 cases of chronic lymphoid leukaemia. Dr. S. GILBERT SCOTT exhibited radiograms of *Bone diseases*, innocent and malignant, and of *Pituitary tumour*, etc. Dr. LEWIS SMITH brought forward a case of *Polycythaemia* associated with congenital morbus cordis in a boy. Dr. J. H. SEQUIERA showed a remarkable instance of *Multiple lupus*. Dr. HUTCHISON showed: (1) A photograph of a girl, aged 3 years, the subject of *Acute myeloid leukaemia* with infiltration of both parotids and swelling of all the lymphatic glands. (2) A case of probable early *Acromegaly* in a man of 42. Mr. HUGH LEFT demonstrated a case of *Cervical ribs* in a woman, aged 27. There had been pain along the inner side of the right arm and forearm for two years. The corresponding hand grew tired more easily than the left, and was very susceptible to cold weather; it showed marked wasting of the interossei and the muscles of the thenar and hyperthenar eminences. There was some loss of sensation on the inner side of the forearm and hand. The pulse in the right radial artery was relatively small. No bony tumour could be felt in the neck, but a skiagram showed two bony projections, apparently $1\frac{1}{2}$ in. long, extending downwards and outwards from the transverse processes of the seventh cervical vertebra. Mr. L. J. AUSTIN, Surgical Registrar, showed: (1) A case of *Pancreatic cyst*, under Mr. Furnivall. This patient, aged 52, presented a large tenso glandular swelling in the upper part of the abdomen, which had developed nine months after a severe

blow with the pole of a cart. (2) A case of *Osteitis deformans*, under Dr. F. J. Smith. The characteristic changes in the skull, spine, and tibiae were marked; some satisfactory x-ray plates were also exhibited. (3) A specimen of *Chronic gastric and duodenal ulcers*, from a case under Mr. Sherren, which had ended fatally by haemorrhage, and a series of 7 cases of *Duodenal ulcers*, showing the results of surgical treatment.

LONDON DERMATOLOGICAL SOCIETY.

AT a meeting held on February 18th, Dr. MORGAN DOCKRELL in the chair, Dr. J. L. BUNCH showed a man, aged 50, with a marked hereditary and symmetrical *Dupuytren's contraction of the fingers*. This malady had existed in the patient's family for the past 300 years, commencing about the age of 25 and reaching the maximum at about 40. The father, grandfather, and so on, had had exactly the same lesions, and so his two sons both had it, the contraction just beginning in one of them, a man aged 26. Dr. Bunch also showed a woman, aged 64, with some *Scarring* on the nose and a small *Tumour* on back of neck. The former was either tuberculous or syphilitic, whilst the latter was a cyst. The PRESIDENT, Drs. VINRACE, PROSSER WHITE, GRIFFITH, SIBLEY, WELLS, and PHIBBS discussed the cases. The PRESIDENT exhibited a man, aged 35, with some old-standing *Specific scars* and depressions on the scalp, the severity of which was associated with a tuberculous soil. Dr. GRIFFITH showed a man who presented a *Diffuse area of livid red skin*, involving the whole of the bathing drawers area. The Wassermann reaction was negative, and histologically it presented the condition of parakeratosis, and he considered it one of erythrodermia. Dr. KNOWSLEY SIBLEY showed a case of advanced *Leucoderma* in a girl, aged 18. The treatment consisted in increasing the pigment in the pale areas by local hyperaemia, and removing it from the pigmented ones by lotions of mercury perchloride, applied by ionization. Dr. Sibley also showed a case of extensive *Scrofuloderma* in a girl, aged 9; some of the lupous lesions he was treating with ether carbon dioxide, and others with ionization of zinc sulphate solution. Dr. PROSSER WHITE of Wigan read a paper on the *Sociological aspect of syphilis*, in which the point was emphasized that the first thing to enable a disease to be controlled was to know its extent. In Scandinavian countries compulsory notification of syphilis was enforced, its seriousness being only too well recognized, and rational attempts were made to check it. Venereal disease was probably more disastrous to the health of a country than either tubercle or alcohol, yet the public showed apathy towards the former, as compared with the interest it took in the two latter questions. Again, syphilis was much more easily controlled by treatment than either the other conditions. Modern intensive treatment by healing up the early and secondary lesions of syphilis proved valuable, especially as a prophylactic measure. The Continent, America, and the colonies were demanding free treatment by experts. How long must we delay? The PRESIDENT, Drs. SIBLEY, VINRACE, GRIFFITH, and REEVE joined in the discussion.

THE report presented to the annual meeting of the County of London Branch of the British Red Cross Society, held at Grosvenor House on February 28th, showed that during the year one men's and nine women's detachments had been raised, while one women's detachment had been disbanded, leaving the total number in existence at the end of 1912 at four men's and forty-eight women's detachments. Sir Launcelet Gubbins, Director-General of the Army Medical Service, in moving the adoption of the report, said that the Red Cross now had 1,959 detachments, with a strength of nearly 60,000, of which about 20,000 were men. It was very desirable that voluntary aid bodies should keep themselves up to the mark of efficiency for any duties that might fall upon them in time of emergency. Sanction had been given to the formation of cadres, to consist of three officers and five of other rank, to help in co-ordinating and training in peace time the voluntary aid detachments, and also on mobilization to take some of the burdens off the shoulders of the county director.

Rebielus.

THE HOUSE OF LIFE.

THERE are few severer tests of mastery than the writing of a short and simple book upon a great and difficult subject. Professor KEITH, in his contribution to the "Home University Library" of a short account of the development, structure, and leading functions of *The Human Body*,¹ has produced a work which, while in the main it will prove intelligible to the general reader, is also full of interest for the professional student. The author has wisely refrained from the impossible task of compressing within some 250 brief pages a comprehensive account of human anatomy and physiology, contenting himself with a successful effort to indicate the broad features of our present knowledge, the central problems that still confront us, and the methods by which our surest results have been attained in the past and may be enhanced in the future. Thus, in the chapter dealing with the brain, an interesting account of Charles Bell's great discovery of the distinction between sensory and motor nerves at once serves to illustrate the nature of scientific induction and to impress upon the reader's mind a fact of fundamental importance. In the third chapter we are given a brief survey of the considerations determining the assignment of man to one of the three families included among the higher primates. Of these three families the central position is occupied by the great anthropoids, while the gibbon, on the one side, has adhered to the ancestral form, and man, on the other, has aberrantly evolved to his present position. The existence of the great anthropoids is, Professor Keith thinks, menaced by the extension of civilization. The big forms of primates (gorilla, chimpanzee, orang, and man) form a group of approximately uniform size; and since fossil remains of big anthropoids, belonging presumably to the same ancestral stock, have been found in Miocene strata, the size of our bodies may be regarded as an inheritance which has come down to us unchanged through millions of years. The human form of foot, associated with the erect posture, is also a very ancient character, very much more so, for example, than the large brain.

One of the most valuable features of the book is its wealth of confirmatory evidence of the general evolutionary position. Among these may be mentioned the transition during the later months of embryonic development, from the pronograde to the orthograde type of mesenteric attachment; the occasional presence in man of the levator elavienlae, used by pronograde monkeys to advance the shoulder in running; the vestigial survival of the plantaris longus and the psoas minor muscles; the human liability to hernia, resulting from that weakening of the abdominal wall which has been produced by the adoption of the upright posture; the occasional persistence of the urogenital cloaca, and the occurrence of supernumerary nipples. Such facts are explicable only on the supposition that man has been evolved from the lowest forms of animal life. The fact that the ancestral stages of man's development are but imperfectly recapitulated by those of intra-uterine life, is attributed by the author to a modification of the latter process evoked by the special conditions under which it takes place.

In the chapter dealing with sexual traits Professor Keith explains the predominantly thoracic respiration of women by the necessity of minimizing the pressure to which the fetus is subjected during pregnancy. Tracing the sexual differences found in man and the anthropoids to that common primate stock which appeared in an early stage of the Miocene period, he concludes that, since these differences have remained stable for many millions of years, there is no foundation for the view held by certain feminists and others that civilization will in the near future produce a structural or functional equality of the two sexes. An interesting point in connexion with the human hand is the fact that the flexion lines on the palm, which most people would agree to regard as acquired characters, appear on the fetal hand before its movements have actually begun. In view of this fact, Professor

¹ *The Human Body*. By Arthur Keith, M.D., F.L.D. Home University Library of Modern Knowledge. New York: H. Holt and Co. London: Williams and Norgate. 1913. (Fcap. 8vo, pp. 256. 1s. net.)

Keith inclines to the belief that use-characters may under some circumstances be inherited. The author adduces reasons for his opinion that retrograde changes are at work on the faces and jaws of highly civilized peoples, probably due to the adoption of a diet which makes an insufficient demand upon the functional potentialities of these parts. To the same cause he attributes that retrogression of the appendix and the colic system which has led Metchnikoff to condemn these structures as useless and dangerous encumbrances of the human organism—a condemnation which, however, the author declines to endorse. In the same chapter he sounds a much-needed note of warning as to the mischievous effects produced by excessive and faulty muscular training upon the lungs and heart.

The concluding chapter deals with the question of the antiquity of man. His traces can be followed back to the end of the Pliocene period; that of the primates leads up from the Eocene to the middle of the Miocene. Somewhere between these two lies the point at which man emerged from this ancestral stock.

We have indicated but a few of the interesting features which make Professor Keith's little book a source of interest and delight. It only remains to express our appreciation of the charming style in which its wealth of information is conveyed.

SPECIFIC FEVERS.

THE book on scarlet fever² by the late Professor ESCHERICH and Dr. BÉLA SCHICK belongs to the series of Nothnagel's *Spezielle Pathologie und Therapie*, now edited by Professor von Frankl-Hochwart. It well maintains the high standard of the earlier volumes. Owing to the lamented death of Professor Escherich after the completion of the chapters on the history, epidemiology, and pathogenesis of scarlet fever, the later sections are entirely written by Dr. Béla Schick, who claims faithfully to have presented his teacher's views. The book is written in a scientific spirit, and embodies the latest researches. As was to be expected of a work for which the well-known Viennese professor was chiefly responsible, it is by no means a mere compilation. Popischill's observations on 2,372 scarlet fever patients, half of whom were given meat and half an exclusively milk diet, seem to show that the prophylactic value of milk as regards scarlatinal nephritis is illusory. The authors hold that the results warrant a relaxation of strictness, if milk becomes repugnant. They recommend that even the mildest cases should be kept in bed for four weeks, for, though the patient may appear to be in perfect health, the disposition to relapse and to post-scarlatinal diseases increases during the third and fourth week. This may be due to the formation of reaction-bodies towards the end of the second week, which usher in a period of specific hypersensitiveness. Probably these anaphylactic bodies are at first formed more rapidly than the antitoxic reaction-bodies. Professor Escherich was an enthusiastic believer in the efficacy of Moser's immunizing serum, and the section dealing with this method of treatment is of great interest. As the dose is no less than 200 c.cm., serum sickness is common after its administration. Hence it should be used only in cases in which the prognosis is obviously bad. The best results are obtained in toxic scarlet fever, in which the danger arises from the severity of the specific infection. In severe septic cases—that is, cases with suppurative and necrotic complications in the throat, nose, ear, and cervical glands due to secondary infection—it is useless, unless given at the first onset of dangerous symptoms. The book should prove valuable both to the specialist and general practitioner.

In the preface of Dr. CLAUDE B. KER's little book, *A Manual of Fevers*,³ it is stated that the object with which it was written is "to give in a compact form the information likely to be required to supplement the practical work" of the demonstrations in the wards of a fever hospital. For such a purpose the book is eminently adapted. The clinical teacher in the fever hospital has

to make use of opportunities as they present themselves, and he is seldom in a position to demonstrate the events of disease in their complete sequence. But the student, if he is to get the full value of the demonstrations, should possess a general knowledge of these events, and to obtain this knowledge he will find this book exceedingly useful. It is one to be read just before attendance on a course of instruction at a fever hospital. Clinical details will be pointed out at the hospital, and details on other subjects—epidemiological, pathological, etc.—can be looked up, as occasion demands, in one of the large textbooks, of which there are now several. For the general practitioner this manual is hardly full enough. On one or two points we differ from the opinion of the author. Is 20 lb. to the square inch really necessary for satisfactory penetration of the steam in a disinfecting machine provided with a vacuum producer? Are the prodromal rashes of measles rare? In London they occur in about 40 per cent. of the cases. Is the scarlatina patient more likely to suffer from a relapse than is the convalescent from any other eruptive fever? Dr. Ker must for the moment have forgotten enteric fever when he wrote this statement. In the discussion on the diagnosis of small-pox the student should be warned against mistaking the haemorrhagic form for purpura haemorrhagica. We have more than once known this error to be made with disastrous results. Omissions such as this are, however, very few, and we hope that the speedy appearance of a new edition will enable them to be supplied. We may add that the book is provided with several excellent black-and-white reproductions of photographs of typical eruptions.

We are very glad that Dr. WOOLLACOTT's book, *The Nursing of Infectious Diseases*,⁴ has reached a second edition. We have had occasion to remark when noticing other books on this subject, that they appeared to be designed rather for junior practitioners than for nurses, in that questions of treatment were discussed which were really no concern of the latter. This work is quite free from that blemish. The nurse who has carefully studied it, what time she has been going through a course of fever training, should be well fitted to undertake the nursing of infectious cases. The facts which it is essential she should know are stated in simple and clear language, and we have not detected any serious omission. We hope the book will continue to be widely read. We can strongly recommend it to those nurses who intend to present themselves for the examinations of the Fever Nurses' Association or other like tests. We suggest to the author that in the next edition he should enter into a little more detail on the subjects of intubation, and of barrier, cubicle and separate room nursing; and add a short chapter on erysipelas, cerebro-spinal fever, and puerperal fever.

DISEASES OF THE SKIN.

ALTHOUGH many books have been written during recent years upon *x* rays, *The X-ray Treatment of Skin Diseases*,⁵ by Dr. FRANK SCHULTZ, is the first work which we remember to have seen dealing exclusively with the *x*-ray treatment of skin disease. The author divides his subject into three parts—a physical part, a section on general *x*-ray therapeutics, and lastly a section on special therapeutics. In the last section every skin disease which is susceptible to *x*-ray treatment is mentioned separately, and the result which may be expected from the prescribed method of treatment is indicated. The physical section is very clear and well put, but does not contain anything very new or striking. There is a very good account of the apparatus required for the production of *x* rays, including various devices for reducing reverse current, for measuring the hardness of the rays and the quantity of radiation. In this section are also to be found the various methods of measuring the dose of *x* rays administered. Dr. Schultz

² *Scharlach*. By the late Professor Dr. Theodor Escherich and Dr. Béla Schick. Vienna and Leipzig: Alfred Holder. 1912. (Roy. 8vo, pp. 263; 59 charts, 3 plates. Mk. 7.60.)

³ *A Manual of Fevers*. By Claude Buchanan Ker, M.D., F.R.C.P. Edin. London: Henry Frowde and Hodder and Stoughton. 1911. (Post 8vo, pp. 328; 6 plates, 14 charts. 7s. 6d. net.)

⁴ *Lectures upon the Nursing of Infectious Diseases*. By F. J. Woollacott, M.A., M.D., B.Ch. Oxon., D.P.H., Senior Assistant Medical Officer, Grove Hospital, Metropolitan Asylums Board. Second edition. London: The Scientific Press, Ltd. 1912. (Crown 8vo, pp. 158. 2s. 6d. net.)

⁵ *The X-ray Treatment of Skin Diseases*. By Dr. Frank Schultz, Physician-in-Chief of the Light Department at the Royal University Polyclinic for Skin Diseases, Berlin. Translated by James Burnet, M.A., M.D., M.R.C.P. Edin. London: Rebnan, Limited. 1912. (Roy. 8vo, pp. 174; figs. 81. 12s. 6d.)

employs the Sabouraud-Noiré pastille in combination with a milliampere and parallel spark-gap whereby the constancy of the tube is controlled. In the section on general therapeutics several interesting questions are discussed. Dr. Schultz holds the generally accepted opinion that there is no such thing as a hypersensitivity of normal skin to x rays, but he gives an example of limited hypersensitivity occurring in disease—the case of a woman who had neurodermatitis of the face, which after a very mild radiation gave a reaction of the second degree. As regards the explanation of the selective action of x rays on different kinds of tissue, Dr. Schultz refuses to accept the theory that embryonic and young cells are particularly sensitive. He lays stress on the specific sensibility of each kind of cell, but he holds that this specific sensibility is not connected with a special variety of cell recognizable histologically. As it is well known that the physical property of every material which conditions its power of absorption of x rays is its specific weight, the author holds that the specific weight of the various tissues exerts a great (although not the only) influence in determining their sensitiveness to the rays. Another new feature of some interest is the author's employment in certain cases of extremely soft tubes. It has long been known that a Sabouraud pastille dose from a very soft tube will cause a marked reaction, although the same dose delivered from a harder tube will not cause any reaction at all. Advantage has been taken of this fact to use very soft tubes (2.5 Wehnelt) for treating, apparently with excellent results, superficial naevi and also certain rodent ulcers which have proved refractory to harder rays. At the same time a warning is given that only very superficial malignant growths should be treated with these very soft rays because they have very little penetrating power. It therefore follows that any malignant tissue at a greater depth than about 3 mm. will receive not a killing but an irritative dose, and thereby will be encouraged to proliferate. The section on special therapeutics shows well what a wonderful power for good x rays can exert in skilled hands, but Dr. Schultz does not hesitate to warn us against their use in unsuitable cases. This section—and, in fact, the whole book—is written in a praiseworthy spirit of impartiality and with strict regard for scientific accuracy. It should be read by all dermatologists and radiologists, but preferably in German, for the translation is very far from good, and sometimes fails clearly to convey the meaning of the original.

In his treatise on diseases of the skin, Dr. WILLMOTT EVANS⁶ has written a very useful book. This work is among the first volumes issued by the new University of London Press, and it may not be out of place here to remark that the general style and get-up is neat and attractive. Dr. Evans has, he tells us in the preface, been struck with the advanced character of most books on dermatology, which often can only properly be appreciated by those who are of considerable experience in the subject. He has, therefore, written the present work in as simple a style as is consistent with correctness and accuracy of description. Furthermore, the reader is aided in his perusal by clear headings to the chapters and paragraphs. The classification of skin diseases is a notoriously difficult subject, and it is always interesting to observe how an author approaches it. In the present instance a mixed classification is adopted; where possible, diseases of a definite and similar etiology are grouped together; where this has not been possible a pathological scheme has been followed, and, finally, diseases of the sweat glands, sebaceous glands, hair follicles, and nails have received separate attention. Such a classification, which, as Dr. Evans admits, is not strictly scientific, is justified on grounds of convenience. Although he has written a comparatively short book, he has produced a very complete treatise, for practically every pathological condition of the skin receives its meed of attention—in fact, perhaps, the usefulness of the volume to beginners in dermatology, for whom especially it is intended, would be enhanced, were some of the very rare conditions omitted, or at least the space devoted to them reduced, and the more important diseases

of the skin discussed more fully instead. For example, only a page and a half is given to rodent ulcer, while six pages are taken up by leprosy; for this country, at all events, the proportions ought to be reversed. In some cases the directions for treatment are rather vague. For example, it would be impossible for any one who knew nothing about the intramuscular administration of mercury in syphilis to learn from reading this book how to give mercury in that way; nor, although salvarsan is mentioned, are any directions given for its administration by any method whatever. Apart, however, from a few omissions such as this, the student will be able to gain a very sound knowledge of diseases of the skin from the study of Dr. Evans's work. The illustrations, which are almost all original, are suitable, good, and well reproduced. The typography is very correct; in fact, we have detected only one misprint—on page 113, *Tinia* for "Tinea."

In reading Dr. KNOWSLEY SIBLEY'S little book on the *Treatment of Skin Diseases*⁷ it is easy to see that he is an enthusiast for the application to dermatology of Bier's methods of producing hyperaemia; the longest section of the work is devoted to this subject. There is no doubt that these methods are worthy of more attention than has been paid to them by most dermatologists. The whole book consists of three parts. The first is devoted to the description of special methods of treatment, among which the production of hyperaemia is most conspicuous; the second consists of a list of skin diseases in alphabetical order, with the appropriate methods of treatment indicated in each case; and the third of a large number of prescriptions of rather unequal value. An experienced dermatologist would be able to pick up valuable hints in some cases, but for other readers the directions given are not always precise enough to be of much help. Long lists of drugs and local applications are given which are said to be useful in various diseases, but no definite plan of campaign is laid down. The book suffers from a want of attention to literary style.

The first edition of Dr. SCHAMBERG'S *Diseases of the Skin and the Eruptive Fevers*⁸ was favourably reviewed in these columns some years ago. In preparing the second edition the original has undergone complete revision, and new chapters have been added. As is well known, the subject of pellagra has been claiming much attention in the United States, numerous cases having come to light there. The details on this disease have been amplified, and should prove useful, especially at the present moment, when the distribution of pellagra has been shown by Drs. Samton and Chalmers to include Great Britain. Grain-itch has been added. Dr. Schamberg and Dr. Goldberger have had special opportunities of studying this affection in Philadelphia, where a number of cases came under their observation. Fresh chapters, too, are those on sporotrichosis, vaccine-therapy, and CO₂ snow treatment. The rashes of the acute exanthemata and of various infectious diseases are included, and form a useful addition to a good account of diseases of the skin. The illustrations are uniformly good.

LAW FOR MEDICAL MEN.

DR. FRED. J. SMITH, Physician to the London Hospital and editor of that standard work *Taylor's Medical Jurisprudence*, supplies a most valuable addition to the library of the practitioner in *Law for Medical Men*,⁹ a volume well worth the half-guinea which is its price.

Dr. Smith points out that the National Insurance Act, 1911, which has disturbed and shaken the medical profession through and through, may be regarded as the

⁷ *The Treatment of Diseases of the Skin*. By W. Knowsley Sibley, M.D., M.R.C.P. London: Edward Arnold, 1912. (Cr. 8vo, pp. 236, 7 photographs. 5s. net.)

⁸ *Diseases of the Skin and the Eruptive Fevers*. By Jay Frank Schamberg, A.B., M.D., of Philadelphia. Second edition. Philadelphia and London: W. B. Saunders Company, 1911. (Med. 8vo, pp. 573; 235 figs. 13s. net.)

⁹ *Law for Medical Men*. A Book for Practitioners containing Extracts from Acts of Parliament interesting to Medical Men. By Fred. J. Smith, M.D., F.R.C.P., Physician to the London Hospital, editor of *Taylor's Medical Jurisprudence*, Referee under the Workmen's Compensation Act., etc. London: J. and A. Churchill, 1913. (Demy 8vo, pp. 414. 10s. 6d. net.)

⁶ *Diseases of the Skin*. By Willmott Evans, M.D., B.Sc., F.R.C.S. London Medical Publications. London: University of London Press, 1913. (Demy 8vo, pp. 386, with 1 coloured plate and 31 other illustrations. 10s. 6d. net.)

conversion of the medical profession into a branch of the Civil Service of the State—an uncovenanted service it may be added. Legislation during the last hundred years, and especially the frenzied legislation of the last ten, compels medical men to a knowledge of Acts of Parliament which are now becoming so numerous and intricate that it is impossible to master the full details of them all, and extremely difficult for officials to be certain whether they may exercise final authority under a given Act or whether they may not find themselves struggling against a superior authority under another amending Act.

Hence the value of this work, which deals very clearly with a very large number of Acts so far as they affect medical men, who, by reference to the complete index, can readily find the information they require. The author's notes are valuable, and we quote a reasonable suggestion of his with regard to the proof of drunkenness which may be of interest to divisional surgeons—and others.

The events of a recent railway strike in the North of England will be fresh in the minds of our readers. An engine-driver was convicted of drunkenness when off duty by a local bench of magistrates, and consequently was dismissed by his board of directors. Other railway servants, resenting this, went on strike by way of insisting upon the reinstatement of the engine-driver. After much hardship and suffering, honour was eventually satisfied, and peace and hilarity restored by the visit of a London stipendiary magistrate, who held an inquiry into the circumstances of the case, and found that the engine-driver, on the occasion of his conviction, had not been "drunk in the police-court sense." On this point Dr. Smith is very interesting in his comments upon Section 1 of the Inebriates Act, 1898. His definition of drunkenness is: "Drunkenness is the [not an] effect of alcohol [and certain other substances] upon a person." He suggests:

If the Court is satisfied from the evidence that the offence was committed under the influence of drink—and my contention is that a medical man (or a policeman or other witness for that matter) is, or should rather, not be called upon to say whether a man was or was not drunk (in the common acceptance of the word) but simply to prove the fact (usually very easy) that he had drunk some intoxicating liquor—this in my definition is "drunk," and then it is for the Court to decide, after hearing all the evidence as to his manner, etc., whether the offender would have done what he did do if he had not taken the liquor; if "No, he would not," then he was drunk within the meaning of the Act; if "Yes, he would," then the Court decides that he was not drunk within the meaning of the Act. This at any rate would throw the onus on the Court, and would do away with the mass of conflicting evidence, always given, as to whether he was drunk or not in the ordinary acceptance of the term, which on the above words of the section is quite irrelevant; for the Court has to decide whether the act was done under the "influence" of drink quite irrespective of the degree of that influence.

There seems to be much sense in this, as indeed there is in most of the comments of the author of this excellent work of reference.

TROPICAL MEDICINE FOR LAYMEN.

*The Prevention and Treatment of Disease in the Tropics*¹⁰ is the title of a useful little handbook by Dr. EDWARD S. CRISPIN, Assistant Director of the Sudan Medical Department. It has been compiled chiefly to meet the needs of officials in the Sudan, for, as the author states in his preface, any officer may be called upon to act medically in the tropics, and it is as well that the layman should have some handbook such as this to guide him. It is divided into two parts, dealing with prevention and treatment respectively. The first part includes an account of methods of destroying the various disease-carrying insects, and for protecting man from their attacks. Personal hygiene, including clothing, food and drink, are next considered. Under the head of treatment most of the common tropical complaints are dealt with; and two appendices deal with antiseptics, diets, weights and measures, dosage, and lists of drugs, appliances, etc. The handbook is purely meant for the layman, and as such can be recommended. It would be as well to mention under blackwater fever that the patient must on no account

be allowed to get out of bed, that the quantity of urine should be accurately measured, and that the temperature should be carefully taken at least every four hours. Blackwater fever is a disease for which careful nursing will do far more than any drug. Still, a handbook is a handbook, and too much detail cannot perhaps be incorporated in it. It is in this that handbooks often fail—too many pages but not enough in them. The layman will find a fund of information contained within the pages of the little book, however, and, as already stated, it can be thoroughly recommended to him.

Some Factors Influencing Health in Tropical and Subtropical Countries is the title of a little handbook¹¹ by Dr. GARRY that will be found useful by the laity. It contains much useful information, and is for the most part accurate and to the point. It is not, of course, correct, when talking of insects acting as intermediary hosts, to say that the bacilli multiply and develop and finally originate a variety of diseases, such as malaria, trypanosomiasis, etc. The layman of the present day is not quite so ignorant as that, or, even if he is, there is no reason why he should remain so. It is better to avoid such loose statements and to stick accurately to facts when writing handbooks for the public of the present day. One chapter of special interest is that on the type of man suited for service in the tropics; this very important question ought to be thoroughly inquired into. The unfit and physically unsound are certainly much better out of the tropics, and the mentally unstable should be added to the frivolous woman type specially commented on by the author. In the chapter on the prevention of disease a serious charge is laid against the humble ant; Dr. Garry states that he has satisfied himself by some recent preliminary investigations that these creatures are largely responsible for the wide prevalence of diseases due to animal parasites, and that in bilharzia they act at least as one of the principal modes of infection. It would have been interesting and instructive if Dr. Garry had stated how. Though some of the scientific facts are somewhat loosely stated, the other matter is quite good, and may with safety be read and digested by the would-be sojourner in the tropics.

NOTES ON BOOKS.

AMONG the more special of the papers in the thirty-ninth volume of the *St. Thomas's Hospital Reports*¹² is that by Mr. C. M. Page on the results of the operation of suprapubic prostatectomy, 1906-10. In 1910, out of 13 radical operations for enlarged prostate, 11 recovered and 2 died; out of 15 similar operations in 1911, 13 recovered and 2 died. Prostatectomy in general hospital practice shows a distinct inferiority when compared with the figures of individual operators, but hospital patients are often in a very bad general condition. From the *St. Thomas's Hospital* figures, taken from the tables of cases of enlarged prostate under every kind of treatment, Mr. Page finds that the death-rate for cases treated by simple catheterization or suprapubic drainage is practically the same as for cases in which the complete operation has been performed. Here, again, as Mr. Page points out, many of the cases entering hospital have been long neglected, and secondary kidney changes are therefore common. Dr. Atholl Ross contributes the important Salter Research Report, 1910, a General Survey and Analysis of Cases treated by Bacterial Vaccines at *St. Thomas's Hospital*. There are besides several other instructive clinical, surgical, and laboratory work.

We have received the *Official Year Book of the Scientific and Learned Societies of Great Britain and Ireland* (London, Griffin and Co.) twenty-ninth annual issue, being, as the title page informs us, a record of the work done in science, literature, and art during the session 1911-12. It is a useful publication, largely on account of the lists of names of papers read before various societies, as, for instance, at the annual meeting of the Association, and before the now numerous sections of the Royal Society of Medicine.

¹¹ *Some Factors Influencing Health in Tropical and Subtropical Countries*. By T. Gerald Garry, M.D. London: John Bale, Sons, and Danielsson, Ltd. 1911. (Cr 8vo, pp. 106. 2s. 6d. net.)

¹² *St. Thomas's Hospital Reports: New Series*. Edited by Dr. J. J. Perkins and Mr. C. A. Ballance. Vol. xxxix. London: J. and A. Churchill. 1912. (Demy 8vo, pp. 250. 8s. 6d. net.)

Thus it will save many of us great trouble involved in hunting up the now numerous archives of our societies in which so many hundreds of carefully prepared papers rest unworthily forgotten or overlooked.

The multiplicity of learned and other societies is staggering and yearly becomes worse. Amalgamation is one remedy for this evil, and we have witnessed it in the well-known instance of the Royal Society of Medicine. A central office for intercommunication is another agent for avoiding intellectual waste. Dr. EIJKMAN explains his views on the maintenance of such an office in *L'Internationalisme Scientifique*.¹³ His exposition fills 108 pages of the text, and the remainder of the volume is taken up by notices of the names and objects of 614 societies. The Hague is the seat of pacifism, and already Dr. Eijkman has compiled another work, *L'Internationalisme Médical*, similar to but, as its name implies, more specialized than the book now under notice. The explanation of his system is based by Dr. Eijkman on the principles to which we have referred above. We all feel when we read the words "scientific" and "international" together that great as is the wastage of good work in any one country it must be far greater in the case of all good work imbedded in the archives of foreign lands. The notes show that Dr. Eijkman has the broadest views about science, or, rather, he not only desires science to be international but he also aims at making internationalism a science, so that associations for the diffusion of Esperanto, for Zionism, anti-Zionism, Theosophy, pure literature, and so forth, are included in his notes. The Salvation Army, which is hardly scientific but decidedly international, is to be found amidst rubber testing committees, Catholic, Protestant, and Liberal Christian associations and societies for the promotion of the rights of women. Dr. Eijkman groups all these divergent bodies under their proper classes. He concludes that the development of international organizations has made great strides, even within his own experience. The main aim, after all, he openly avows, is pacifism: the international organization of science aids men in nearing, if not attaining, that noble object. The author does not seek to make the Dutch official metropolis into a scientific Rome, but the Permanent Committee of International Medical Congresses, already in working order, has shown how such a general bureau may be worked. Dr. Eijkman seeks to establish such a bureau, and offers suggestions as to how his object may be effected. Of necessity it is held advisable that all associations of the types included in the author's wide programme should communicate with him.

The volumes of the work edited by Professor SOMMER on the clinical aspects of psychic and nervous diseases,¹⁴ which are before us, contain some excellent articles and some material which is less good. It is a disadvantage to publish such a series as this, for the appearance of the several parts is so irregular that the interest is frequently lost before the volume is completed. We cannot discuss the merits of each article separately, partly because their number is large and partly because they form only a fraction of a whole, the remainder being still in the press. The end of the fourth volume contains *inter alia* some trite deliverances on dipsomania and psychic epilepsy by Römer. In the first part of the fifth volume is a good article by Becker on the methods of testing intelligence, an interesting description of the transactions of the Psychiatric Section of the last International Medical Congress by the editor, and several other articles. The fourth part of the same volume is valuable on account of an article by Professor Sommer on the theories in connexion with marriage between relatives and the consequent limitation of ancestors in human beings and animals. The first part of the sixth volume deals chiefly with the associations in mania, etc., and the most prominent author is Killian. The second part of this volume contains some good articles, including one by Margulies on hystero-epilepsy. In the third part are articles on the methods of psychological examination by Sommer, on the methods of testing the intelligence by Mikulski, and on the psychological profile by Rossolimo.

¹⁴ *Klinik für psychische und nervöse Krankheiten*. Edited by Professor Dr. Robert Sommer. Halle: Carl Marhold. Vol. iv, part 4, 1909; vol. v, parts 1 and 4, 1910; vol. vi, parts 1, 2, and 3, 1911. (8vo, 3 each vol.)

Nova et Vetera.

IN PRAISE OF THE PHYSICIAN.

IN an earlier article¹ an attempt was made to set forth proverbial medicine in dispraise of the doctor, and no difficulty was met with in finding troops of adages in which the medical man was made to appear in a bad light. He was an atheist in two cases out of three; when his treatment was successful, it was to Nature and not to the doctor that the credit was due; diet and quiet were of more worth than he; nay, there was more danger from the doctor than from the disease; he was a fool; he suffered sometimes from the very maladies which he professed to cure; and, worst of all, in the end he died just like other people, perhaps a little earlier too.

When, however, search is made for proverbs in praise or in appreciation of the medical man, the searcher meets with a most humiliating disappointment—humiliating, that is, if he be himself a doctor or the friend of the doctors; for apparently there are no such proverbs, Iceland, in common with Ireland, enjoys the privilege of being free from serpents, and medicine in common with law seems to suffer under the discommendation of having no proverbs of commendation, far less of acclamation, laudation, or of benison. In proverbdom there is no territory, not even the smallest plot of ground, set aside for the cultivation of those delightful plants and flowers of common speech, the appreciative adage and the complimentary saying.

The absence, or at any rate the extraordinary paucity, of proverbs in praise of the doctor is somewhat disconcerting. The profession may hold its head haughtily in the air and agree to disregard this tiny note in the general concert of appreciation which pleasingly fills its ears. But no, this will not do; like the leader of the orchestra in which the piccolo player from modesty or fancied unimportance was silent, the medical man at once feels the lack of the delicate flute-like tones. Or the physician may say of those who failed to bring him the little attention of a eulogistic proverb what James Boswell affirmed of the "cold-blooded and morose mortals who disliked his book" (on Dr. Johnson), that he would not for a thousand pounds have their temper.

Whether, however, it be treated with disregard or with silent contempt, this lack of laudative proverbs is a sore thorn in the side of the self-esteem of the profession, pricking and jaggng in a really most irritating manner and calling aloud for some lenitive to mitigate the hurt that pride has had. One wonders if there be no means of collective investigation whereby some pleasing proverbs could not be found in some out-of-the-way place or little-known book? Might not one do, as it is said Sir Walter Scott did when he wished to have appropriate quotations for the headings of his chapters, write them himself, and say they came from "old plays"? One might easily construct a few fairly satisfactory ones, such as "Who is so dear as the doctor?" "As the doctor goes out through the door the drugs may depart through the window"; "A doctor in time may save you from crime"; "Dop to the doctor and give him good e'en," or "As sure as a surgeon."

Apart, however, from the pleasantries of the preceding paragraph, the question does seem to demand some sort of answer. Why are there no commendatory proverbs about doctors? To attempt to find a solution of this problem is really to go to the very roots of proverbology. It suggests other questions: Why, for instance, are there proverbs on one set of circumstances rather than on another, why on one class of people more than on another, and why on the less commendable qualities rather than on the praiseworthy? A partial answer has been given already in the article dealing with proverbs in dispraise of the doctor, where it was shown that the unpleasant aspects of an illness are apt to impress themselves more permanently on the patient's mind and memory than the pleasant, which are also the scarcer. The doctor suffers the damage due to his association with a trying or painful experience in the patient's life, and the latter is content to forget all about it after it is well over, and to try to re-establish the belief in the innate healthiness and

strength of his own constitution which he had held before his attack by disease. So the patient lays that flattering unction to his soul that it was his own recuperative powers that saved him, and that perhaps the medical man after all did very little for him. There is also another and a simpler reason, and that is the child's one that the doctor's coming is associated with the taking of nauseous drugs, with restricted liberty, and with preparatory threats.

Whilst, however, proverbs in praise of the doctor are wanting, or so few as to be almost undiscoverable, some appreciative phrases are not altogether lacking, and literature, both ancient and modern, abounds in eloquent expressions of the gratitude and regard felt by authors towards their medical attendants. There is, for instance, that high compliment paid to the profession when a member of it was called *Manus Dei*. Here is a passage from Burton's *Anatomy of Melancholy* bearing and illustrating this phrase. "Next therefore to God in all our extremities (*for of the Most High cometh healing*, Eccles. xxxviii. 2) we must seek to, and rely upon, the Physician, who is *Manus Dei* [the Hand of God], saith Hierophilus, and to whom He hath given knowledge, that He might be glorified in His wondrous works. With such doth He heal men, and taketh away their pains" (Eccles. xxxviii. 6, 7). Continuing to quote from Ecclesiasticus, Burton says: "When thou hast need of him, let him not go from thee. The hour may come that their enterprises may have good success" (verse 13). Burton, however, knows about quacks: "It is not therefore to be doubted that, if we seek a Physician as we ought, we may be eased of our infirmities, such a one I mean as is sufficient, and worthily so called; for there be many Mountebanks, Quacksalvers, Empiricks, in every street almost, and in every village, that take upon them this name, make this noble and profitable Art to be evil spoken of, and contemned, by reason of these base and illiterate artificers; but such a Physician I speak of as is approved, learned, skilful, honest."

To Burton, then, we are indebted for this fine phrase (*Manus Dei*) dug up out of Hierophilus, but he could not leave the profession with nothing but praise, and he went on to speak of "the hungry Chirurgeon who often produces and wire-draws his cure, so long as there is any hope of pay," and of the physicians, who, to get a fee, "will give physic to every one who comes, when there is no cause, and who do so *irritare silentem morbum* (as Heurnius complains) stir up a silent disease." Nevertheless, we thank Robert Burton for his definition of physicians as "God's intermediate ministers."

Leaving the Apocrypha, Hierophilus, and Burton, we turn to the greatest man of the first century of the Christian era and to his age-defying description of his doctor. Surely never was there a more laconic appreciation of a medical man's services than St. Paul's four words about Luke; and yet the phrase is so warm, so fitting, so touching, so true, that it has established its place for all time as the highest meed of praise which a patient can confer upon his physician. We can be sure that not without emotion were these words written, falling like a glittering tear on Paul's parchment as he penned his signature to the epistle to the Colossians. *Αὐκᾶς, ὁ ἰατρὸς ὁ ἀγαπητός* (Luke, the physician, the beloved!). Our English Authorized Version worthily rendered the phrase, "Luke, the beloved physician," and the Revised Version could not improve upon it; but, as a matter of fact, the translation might very well have been "dear," "dearly beloved," or "well beloved," for in all these ways is the Greek word *ἀγαπητός* rendered in our New Testament. Long ago Luther, in his *Table Talk* (428), said: "St. Paul was very rich and flowing in words; one of his words contains three of Cicero's orations, or the whole of Isaiah or Jeremiah"; and Luther's estimate, although carrying the impress of the less carefully guarded language of easy conversation, is admirably exemplified in the instance to which reference has just been made. Not only in Greek and in English, but in other European tongues also, the phrase is striking, and lends itself readily to translation without losing its warmth and appropriateness. In German it becomes *Lucas, der Arzt, der Geliebte* (which is very close to the Greek); in Dutch it is *Lukas, de medicijnmeester, de geliefde*; and in Danish *Lukas, Lægen, den Elskelige*. The Vulgate translates it briefly, *Lucas medicus*

charissimus, and the French amplifies it a little, giving *Luc, le médecin, qui m'est très-cher*. The Spanish is somewhat bald, *Lucas, el médico amado*: whilst the Portuguese is warmer, *Lucas Medico, nosso carissimo irmão*. In all these linguistic garbs the words have still an abundant vitality and arrest the reader's attention. To Paul, the lonely man, getting lonelier as he became Paul the aged, Luke must often have brought not only light (as his name signified), but also healing, comfort, and literary sympathy and appreciation; and the great Apostle has drawn out of an overflowing heart the four burning words in which he spoke (so far as they could be spoken) his gratitude and affection.

In modern times there have been many appreciations of the physician both in verse and prose. Everyone, for instance, knows Henley's lines on Lord Lister when he was in the Edinburgh Royal Infirmary; but Crabbe's verses in *The Village* may be less familiar, whilst they are no less appreciative and indeed contain phrases which possess almost proverbial force. To the profession he sings:

Glorious your aim,—to ease the labouring heart,
To war with death, and stop his flying dart;
To trace the source whence the fierce contest grew,
And life's short lease on easier terms renew;
To calm the frenzy of the burning brain,
And heal the tortures of imploring pain;
Or, when more powerful ills all efforts brave,
To ease the victim no device can save,
And smooth the stormy passage to the grave.

From the other side of the Atlantic, too, the beautiful lines come over to us in which Whittier calls upon his young medical friend and upon all of us who are of like spirit with him:

Beside the unveiled mysteries
Of life and death go stand,
With guarded lips and reverent eyes,
And pure of heart and hand.

For,

The holiest task by Heaven decreed,
An errand all divine,
The burden of our common need
To render less is thine.

In prose there are many appreciations of the profession, but from two authors alone will our space permit us to quote, from Carlyle and from Stevenson. The reader does not approach the writings of Thomas Carlyle, "the truest Diogenes of these times" as George Gilfillan called him, with any very hopeful anticipations of finding smooth sayings about doctors in them. Sarcasm, biting and caustic, he expects; denunciations, fulminations, bitter pleasantries perhaps, but scarcely smooth sayings. What is his amazement, then, to find two such passages as the following, the one a measured tribute to the profession of medicine at its best, and the other a warm appreciation of a man who truly practised it at that high level. The first of the two passages begins in grumbles and ends in growls, low mutterings of a coming storm, but in the heart of it are some sentences of quiet eulogy, very precious to the physician who is setting the highest ideal before himself:

Medicine, guarded too by preliminary impediments, and frightful medusa-heads of quackery, which deter many generous souls from entering, is one of the half-articulate professions, and does not much invite the ardent kinds of ambition. The intellect required for medicine might be wholly human, and indeed should by all rules be,—the profession of the Human Healer being radically a sacred one and connected with the highest priesthood, or rather being itself the outcome and acme of all priesthods, and divinest conquests of intellect here below. As will appear one day, when men take off their old monastic and ecclesiastic spectacles, and look with eyes again! In essence the Physician's task is always heroic, eminently human; but in practice most unluckily at present we find it too become in good part *beaverish*: yielding a money-result alone. And what of it if it is not beaverish,—does not that too go mainly to ingenious talking, publishing of yourself; ingratiating of yourself; a partly human exercise or waste of intellect, and alas a partly vulpine ditto;—making the once sacred *ἰατρὸς* or Human Healer more impossible for us than ever!

So with high appreciation of the best in medicine, but with no kind word for the worst in it, for the pride and love of money that are in it, did the great "slayer of shams" deal with our profession in one of his *Latter-day*

Pamphlets, date, May 1st, 1850.² But the medical man is more grateful for another passage, written some seven years earlier,³ where Carlyle with his heart burning within him denounces the iniquities of the Poor Law, and quotes Dr. Alison's evidence on the state of things in Edinburgh, although he himself must have known not a little at first hand of what Alison reported on:

So many hundred thousands sit in workhouses; and other hundred thousands have not yet got even workhouses; and in thrifty Scotland itself, in Glasgow or Edinburgh City, in their dark lanes, hidden from all but the eye of God, and of rare benevolence the minister of God, there are scenes of woe and destitution and desolation, such as, one may hope, the Sun never saw before in the most barbarous regions where men dwell. Competent witnesses, the brave and humane Dr. Alison, who speaks what he knows, whose noble Healing Art in his charitable hands becomes once more a truly sacred one, report these things for us: these things are not of this year, or of last year, have no reference to our present state of commercial stagnation, but only to the common state.

Then, as if his thoughts were being directed by his allusion to this famous physician, Carlyle continues in a sentence, full of medical similes, to criticize the proposed remedy:

Not in sharp fever fits, but in chronic gangrene of this kind is Scotland suffering. A Poor-law, any and every Poor-law, it may be observed, is but a temporary measure; an anodyne, not a remedy.

Dr. William Pulteney Alison, to give him his full name, was, it is interesting to recollect, a writer of books as well as a professor of physiology and a medical man; and we remember his name with warm affection, and are grateful that he was the cause of Carlyle's so generous and kindly recognition of our profession and its true practitioners. Nor can we afford to neglect the fact that Thomas Carlyle had a favourite younger brother, John Aitkin Carlyle, who was a medical man, and also, by reason of his prose translation of Dante's *Inferno*, a literary one. In his close association with his brother Thomas in Edinburgh, John Aitkin Carlyle must have had many opportunities of speaking to him of Professor Alison, for the last named was elected to the chair of physiology in 1822, the year in which Thomas Carlyle was enabled through his appointment as tutor to a wealthy gentleman's sons to invite John to come to study medicine in the Scottish capital and to share his rooms with him. Thomas Carlyle never wrote a more generous or a more affectionate letter than that which he sent off to John in January, 1822, bidding him come to Edinburgh, for the necessary money for fees was forthcoming. "Where is the risk then, my boy Jack?" he cheerily asked. But of the close companionship thus begun, and of its influence on both the brothers, we have not time now to speak; let us gratefully take note of the fact that Carlyle paid so hearty a compliment to the medical profession and to William Pulteney Alison, his brother John's teacher.

A much more delicately and deftly expressed compliment was offered by Robert Louis Stevenson in his dedication of *Underwoods*; and it is not without quiet humour, daintily set forth:

There are men and classes of men that stand above the common herd: the soldier, the sailor, and the shepherd not infrequently; the artist rarely; rarer still the clergyman; the physician almost as a rule. He is the flower (such as it is) of our civilization; and when that stage of man is done with, and only remembered to be marvelled at in history, he will be thought to have shared as little as any in the defects of the period, and most notably exhibited the virtues of the race—Generosity he has, such as is possible to those who practise an art, never to those who drive a trade; discretion, tested by a hundred secrets; tact, tried in a thousand embarrassments; and what are more important, Heraclean cheerfulness and courage. So it is that he brings air and cheer into the sick room, and often enough, though not so often as he wishes, brings healing.

Then, in a paragraph in which humour and pathos are twined round the sentences and peep out from between

the semicolons, Stevenson charmingly returns thanks to his doctors:

Gratitude is but a lame sentiment; thanks, when they are expressed, are often more embarrassing than welcome; and yet I must set forth mine to a few out of many doctors who have brought me comfort and help; to Dr. Willey of San Francisco, whose kindness to a stranger it must be as grateful to him, as it is touching to me, to remember; to Dr. Karl Ruedi of Davos, the good genius of the English in his frosty mountains; to Dr. Herbert of Paris, whom I knew only for a week, and to Dr. Calsot of Montpellier, whom I knew only for ten days, and who have yet written their names deeply in my memory; to Dr. Brandt of Royat; to Dr. Wakefield of Nice; to Dr. Chepmell, whose visits make it a pleasure to be ill; to Dr. Horace Dobell, so wise in counsel; to Sir Andrew Clark, so unwearied in kindness; and to that wise youth, my uncle, Dr. Balfour.

With exquisite grace, Stevenson adds: "I forget as many as I remember; and I ask both to pardon me, these for silence, those for inadequate speech"; and he brings his dedication to a close with a special expression of gratitude to Thomas Bodley Scott of Bournemouth:

Will he accept this, although shared among so many, for a dedication to himself? And when next my ill-fortune (which has thus its pleasant side) brings him hurrying to me when he would fain sit down to meat or lie down to rest, will he care to remember that he takes this trouble for one who is not fool enough to be ungrateful?

Stevenson's dedication is, indeed, a radiant gem of praise in a matchless literary setting; it would be hard to find its equal among the many other kindly sayings respecting the profession and the men who practise medicine, although Ruskin has sentences almost as fine and warm, and in fiction Anthony Trollope's proudly-humble Dr. Thome of Greshamsbury and Ian Maclaren's doctors hold up their heads among the throng. But enough has been said to prove that if the profession has been left without the added glory of complimentary proverbs passed down to it from the past, it is not poor in appreciations coming from the highest literary sources. It can never forget that in its ranks stood Luke, the beloved physician, and that the humblest practitioner may be, if he will, *Manus Dei*.

GASWORKS PITCH INDUSTRIES AND CANCER.

IN THE BRITISH MEDICAL JOURNAL of January 4th some account was given of the investigations made by H. C. Ross and J. W. Cropper into the nature of the relation between gasworks pitch and cancer. These two investigators have continued their researches in the laboratories of the John Howard McFadden Researches, and have made the additional observation contained in the following report, which is ready to be presented at the Home Office Inquiry on the subject which is to meet next week:

AN INVESTIGATION OF THE AUXETICS AND KINETICS IN COALS FROM VARIOUS SEAMS.

Chimney-sweep's cancer in the workmen employed at the briquette (patent fuel) manufactories seems only to supervene when the predisposing conditions of swarthy skin, warts, and ulceration have been going on for some time. These predisposing conditions are caused by the pitch which is a constituent (from 5 to 10 per cent.) of the briquettes. It is ground up, and the men's skins become covered with the dust either from the air or from actual handling. But it is only one class of pitch in which this action has been observed. Coal-tar pitch is generally dangerous; blast-furnace pitch is harmless.

In the present paper we propose to describe a continuation of our experiments in this subject, and in particular those made with a view to elicit the reason for this difference between the two forms of pitch.

In the BRITISH MEDICAL JOURNAL of January 4th, 1913, a leading article described the incidence of swarthy skins, warts, and epithelioma occurring in the workmen engaged in tar distilleries and briquette manufactories. Some remarks on the subject which we have already published¹ were also mentioned. We believe that the skin conditions are due to the presence of substances—auxetics and kinetics—which have been detected in gasworks tar

² *Latter-day Pamphlets*, No. V, Stump-orator
³ *Past and Present*, Bk. I, c. 1, Midas.

¹ *The Problem of the Gasworks Pitch Industries and Cancer* (London: John Murray, 1912).

and pitch. Blast-furnace tar and pitch, on the other hand, only contain a trace of auxetic and no kinetic at all. Both gasworks tar and pitch give rise to the pathological lesions: neither blast-furnace tar nor pitch have this action. The question arises, therefore, as to why the gasworks tar and pitch should contain large quantities of auxetics and kinetics, when the blast-furnace tar and pitch do not.

Pitch is the residue of the distillation of tar; tar is a product of the dry distillation of coal. Any substances which are not volatile below the temperature of 300° C. will be found more concentrated in pitch than in tar. In the tar they are found in a more concentrated state than in coal. Briquettes do not contain tar, but are composed of a mixture of pitch and coals, and the briquette makers suffer a great deal (about 90 per cent. have swarthy skins, which apparently is an early stage of the other conditions); tar distillers only continuously handle the tar and the pitch more or less intermittently, and they suffer less; coal miners apparently are not liable to the skin lesions at all, although a few isolated cases of chimney sweep's cancer (hitherto not attributed to the coal dust) have occurred amongst them. Therefore pitch is more dangerous than tar, and tar is more dangerous than coal. But outstanding beyond these facts is the indisputable evidence that those who work with either pitch or tar derived from the blast furnace do not suffer in any way. It is the tar derived from the gasworks and the pitch made from it which are the dangerous commodities, and probably that also from the coke ovens.

Although the auxetics and kinetics in tar and pitch have not yet been actually isolated chemically, we know by experiment that they are not volatile below a temperature of 320° C., which will explain why they are more concentrated in pitch than in tar. But both forms of pitch are the residue from a similar process of distillation, yet one form is dangerous and the other is not.

There are two explanations to offer for this difference. One is that, although both forms of pitch are made in a similar way, the tar derived from the blast-furnace comes over at a lower temperature² than gasworks tar, and it has been suggested that the auxetics and kinetics may be produced in the latter owing to some chemical process occurring at the higher temperature of distillation. Another explanation is that nearly all the blast-furnace tar is made from a different type of coal (Scottish splint coal) than gasworks tar, which is a product of the distillation of ordinary bituminous coal. Scottish splint coal does not soften when heated. Ordinary bituminous coal cannot be used in the blast furnaces because it softens and cakes into masses at the bottom of the furnaces. Scottish coal does not cake into masses but retains its form in the furnace.

The first explanation that the auxetics are high temperature products is rebutted by the fact that coal tar produced at a comparatively low temperature of carbonization contains auxetics, whereas blast-furnace tar (which is also a low-temperature product) is comparatively free from auxetics. The second explanation, when these former experiments were done, seemed more reasonable, because auxetics had been detected in ordinary house coal and in petroleum.

Therefore the investigation of coal has been continued. Coals from various seams have been tested, and there seems to be no doubt that the auxetics and kinetics in tar and pitch are not manufactured during the process of distillation, but are derived from the original coal from which those substances are made. These results are tabulated below, and they also show that the difference between blast-furnace tar and pitch and gasworks tar and pitch is probably due to the different varieties of coal employed in their manufacture and not to the temperature of distillation of the coal.

The method of testing has already been described in detail. Various quantities of watery "extracts" of pitch, tar, or coal, as the case may be, are mixed up with "coefficient jelly," and white blood cells are placed on the jelly film. If after ten minutes' incubation at 37° C. the majority of the lymphocytes show division figures, the extract is labelled as containing auxetic. If at room temperature they show exaggerated amoeboid amounts, the extract is labelled as containing kinetic. It is noteworthy, however, that when testing pitch or tar it is only necessary to employ 1 per cent. extracts, but when testing coals 10 per cent. extracts are required, which shows how much more concentrated the auxetics are in tar and pitch than they are in coal.

Samples of Coal.

| No. | Source. | Auxetic. | Kinetic. |
|-----|--|-----------------|-------------------|
| 1 | Daufermline splint seam (Fife) ... | Yes | Yes. |
| 2 | Splint seam (Haddington) ... | No | Yes (feeble), No. |
| 3 | Diamond seam (Edinburgh) ... | Yes (poor) | No. |
| 4 | Splint seam (Edinburgh) ... | Yes | Yes. |
| 5 | Little splint seam (Fife) ... | No | No. |
| 1 | Anthracite ... | Yes | No. |
| 2 | Second-rate anthracite ... | Yes | No. |
| 3 | Dry steam coal ... | No | No. |
| 4 | Best steam coal ... | Yes (poor) | Yes. |
| 5 | Highly bituminous coal ... | Yes | Yes. |

| 16 | Coal from seam in Gloucestershire ... | Yes | Yes. |
| 17 | Cannel | No | No. |
| 18 | Bottom softs | Yes | Yes. |
| 19 | Hards | No | No. |
| 20 | Top softs | Yes | No. |

Remarks.—We have omitted the names of the actual collieries. As regards auxetic, No. 5 (second series) appears to be the more effective, then come Nos. 1 and 13 in that order. As regards kinetic, No. 16 is the most effective, then No. 5. Therefore No. 5 seems to be the most dangerous of all.

Mr. Poole, of the Mines Department at the Home Office, comments as follows:

In addition to No. 5, Nos. 13, 16, 18, and 20 (second series) would be bituminous coals, and No. 4 (best steam coal) would be semi-bituminous. From No. 16, briquettes used to be made some ten to fifteen years ago. No. 5 of the Scotch samples (little splint seam) is from a different bed of coal from No. 1, in which there was both auxetic and kinetic. No. 17, in which there was neither auxetic nor kinetic, is, at the mine from which it was obtained, of an oily shale nature corresponding somewhat to samples 6 to 12, in none of which also is auxetic or kinetic found.

At our request, all the coals were sent to us (from the Mines Department Home Office, through Dr. Legge, His Majesty's Medical Inspector of Factories) each merely distinguished by a number, so that even if we were biased in favour of one form of coal, we were not in a position to know which that coal was until we had compared the results of our experiments with the key to the numbers, which was kept by Dr. Legge.

It will be seen, therefore, that, judging by the presence of both auxetic and kinetic, the soft or bituminous coals are the ones which give rise to the dangerous tar and pitch. And this result is borne out by the incidence of the pathological lesions amongst the workmen. Scottish splint coals and sometimes many hard ones produce harmless commodities. Cannel is a coal of recent origin; shale is the mineral from which oil is distilled in Scotland. There have been a few isolated cases amongst the men at the shale-oil works. The difference between various portions of the same seam in the one colliery is interesting, but is apparently quite consistent with the results here expressed.

An important point suggested by this investigation is whether it would be feasible for gasworks which now carbonize only highly bituminous caking coals to mix with the latter a percentage of harder and less highly bituminous coals. Such a procedure would in all probability reduce the incidence of the pathological conditions amongst the workmen at the briquette works and tar distilleries. But, in addition to a difference in the quality of gas and coke, the question of extra freights

² An attempt to isolate them is now being carried out at the Lister Institute.

³ Although a higher temperature is reached in the blast furnaces the tar comes over at a lower temperature than does gasworks tar.

comes in, especially in those large gasworks which use sea-borne soft coal. The importation of other coal might be a serious matter to them. We may state that at a recent deputation of tar distillers to the Chief Inspector of Factories at the Home Office the distillers were very adverse to our proposal of washing the auxetics and kinetics out of the tar. They said that such a process would cause great difficulty and expense in separating the water from the tar. Therefore we now publish this suggestion of trying the mixture of a certain percentage of hard coals at the gasworks. Of course, it would not be so useful as elimination of auxetics, but it might be considered as an alternative for experiment, provided suitable hard coals can be found for gas-producing purposes.

In the meantime we hope that medical men practising in the colliery districts will report cases of swarthy skins, warts, or ulceration occurring in the miners. Should any occur, it is of importance to know by which seams the cases are caused.

In conclusion, the question as to why hard coals, especially Scottish splint coals, should have less auxetic and kinetic than the bituminous ones is really a problem for the geologist and chemist. We are also interested in the matter in connexion with our own working hypothesis, about which there is some strong evidence.⁴ We believe that cell reproduction is caused by auxetics, which are specific agents set free by cell death. These agents occur after cytotoxicity, both in the animal and vegetable kingdoms. Coal, in a way, is also a product of cytotoxicity; and it is interesting to think that these products, after having lain buried for centuries, are dug up, subjected to an elaborate process of artificial distillation, are converted into briquettes, and then give rise to cell reproduction in the shape of swarthy skins and warts, leading to epithelioma in the workmen employed at the factories.

Our acknowledgements are due to Mr. W. J. Butterfield, M.A., F.I.C., Assoc. Inst. of Civil Engineers, to Dr. Legge (His Majesty's Medical Inspector of Factories), and to Mr. Poole (His Majesty's Inspector of Mines), for advice, and for assistance in obtaining the samples of coal.

THE AFTER-CARE ASSOCIATION.

THE annual meeting of this association, formed in 1879 by the late Rev. Henry Hawkins, for many years chaplain of the Sussex County and Colney Hatch Asylums, for the purpose of facilitating the readmission into ordinary social life of poor persons discharged recovered from asylums and hospitals for the insane, was held on February 25th at the house of the Medical Society of London. Sir JAMES MOODY, Medical Superintendent of Cane Hill Asylum, presided over a large gathering, which included many ladies.

The adoption of the report was moved by Sir GEORGE SAVAGE, who pointed out how relapses were prevented by the benevolent operations of the society.

The BISHOP OF CROYDON, who seconded, remarked on the practical Christian character of the assistance the society gave to poor and often helpless convalescents from mental disease in rehabilitating them for work.

The election of vice-presidents, council, and officers was moved by Dr. THOMAS (A.M.O. at Hellingly Asylum), and seconded by Dr. NEEDHAM, who spoke of the great value placed upon the work of the society by the Lunacy Commission.

Dr. C. HUBERT BOND then read a paper on After-care in Cases of Mental Disorder, and the Need for Extending its Scope to the Case of Patients leaving the Asylums "on Trial" as to Recovery. He pointed out that while all the persons discharged from asylums in England and Wales (about 7,000 a year) must of necessity benefit by suitable after-care, for nearly a quarter of them it was urgently required. Not only was that after-care demanded on humanitarian grounds, but, by reason of its preventive power in respect of relapses, it might be fairly regarded as being economically worthy of generous support. To be effective, after-care must be organized, and its organization should aim at branches of the association, which should at least be as many as there were local authorities, either acting alone or in combination for lunacy purposes. It would, he said, facilitate the work of the association if its rules could be so modified as to permit its executive to commence, in certain

cases, such work during a period while the patients were away from the asylum "on trial," and to further permit such patients being received while "on trial" into one of the association's cottage homes. He also advocated that the Visiting Committee of Asylums should be urged more frequently to take advantage of the provision in the Lunacy Act whereby patients who appeared to have recovered might, instead of being at once fully discharged, be allowed out "on trial," and might during such period be granted an allowance not exceeding the cost of their maintenance in the asylum. That practice, which was habitually adopted by certain committees, was of the utmost value to the patients, and by its adoption early relapses were materially prevented. It would enable a weekly sum to be paid that association, which would rather more than half meet its expenditure on patients temporarily boarded at its cottage homes.

Sir JAMES MOODY raised the point whether it would be legal for asylums to make payments towards the society for the care of patients "on trial"; but Mr. A. H. TREVOR (a legal Commissioner in Lunacy) replied that under the circumstances mentioned by Dr. Bond such payments would not be illegal.

DRS. HELEN BOYLE, LORD, BOWER, PERCY SMITH, RAYNER, and the BISHOP OF CROYDON and Mr. ROBEY took part in the discussion, the last speaker strongly advocating the extension of the society's operation to cases "on trial."

THE BRADFORD ANTHRAX INVESTIGATION BOARD.

SUMMARY OF INVESTIGATIONS.

THE Anthrax Investigation Board for Bradford and District issued its seventh annual report for the year ending October 31st, 1912. The objects of the Board are: (1) The investigation of anthrax generally, (2) to determine more precisely the classes of wool and hair in connexion with which the danger of anthrax arises, and (3) the discovery of further means of prevention. The area of its operations has been confined to the worsted and woollen industries of the West Riding of Yorkshire. The value of the present report is increased by the inclusion in it of an analysis of the observations in the 88 cases of anthrax notified to the Board since 1905 as arising from the use of textile material in the district. The analysis had been made with a view to determining as far as possible the relative danger of infection.

During the year, 1,258 samples of wool, mohair, etc., were tested for the presence of anthrax spores. Of these, 1,038 were blood stained (190 only slightly). Anthrax spores were discovered in 84 samples, and of these 24 were not blood stained. The hope expressed in a previous report that it might prove possible to say, "No blood, no anthrax," must therefore be given up; nevertheless, the presence of blood should always be regarded as a danger signal. Of alpaca, 206 samples were taken (196 blood stained), and in no case could anthrax bacilli be cultivated. From 268 samples of skin van mohair (205 blood stained) 35 separate cultivations were obtained; 8 samples contained no blood, and only in rare instances could the amount of blood be called a clot. The fellingmongering process used was the "wet" process; by it the blood clots would be partially dissolved and the anthrax spores disseminated among the previously non-infected material. "Skin" wool and "skin" mohair may be classed under three heads: (1) That which has been "clipped" from the skin of the sheep or goat; (2) that which has been "pulled" in the usual (wet) fellingmongering lime process; (3) that which has been "pulled" in the chemical or dry process, or has been "pulled" dry from the rotten or rotting pelt. That contamination can take place in the "wet" process is obviously possible; to what extent, if at all, it takes place in either of the dry processes is not yet known, but the blood clots found after "the clipping" and the "dry" pulling process were more numerous and heavier than those found after the "wet" pulling process, with consequently more concentration of the danger if the anthrax spore were present. In any case, the anthrax spore of contamination can be killed more readily than the spore imbedded in the blood clot. With regard to East Indian wools, anthrax was found seventeen times in 132 samples. Excepting in one

⁴For example, see article by Mr. Drew on induced cell reproduction in the protozoa, *Nature*, February 20th, 1913.

instance, all the cultivations from materials without trace of blood were isolated colonies, showing apparently that the material had been contaminated. This contamination would seemingly take place when the wool or hair is subjected to some "wet" process, such as washing or lime fellmongering. It is very doubtful if contamination takes place in the dry state. If the washing be done in running water or a lake, infection is evidently less likely to take place than if the material be "tub washed." In the latter process the releasing and spreading of the anthrax spore in such a restricted space seems calculated to ensure contamination. It would be interesting to know to what extent "tub washing" of wools is in vogue in India. Anthrax was cultivated twenty-four times in 545 samples of Persian, and six times in 84 samples of mohair other than "van"; in both these classes the spores were only found in blood-stained samples.

A satisfactory germicide, capable of killing the anthrax spore without injury to the fibre, has not yet been discovered. Steaming of blood clots will kill anthrax spores in about fifteen minutes when the wool is in a loose state, but the difficulties in the way of disinfecting wool in bulk by steam make the method impracticable for ordinary use. Of chemical methods, experiments made with Schattenfroh's and Seymour-Jones's processes have been disappointing; the hydrochloric acid in the one process and the formic acid in the other being neutralized by alkalis in the wool and tap water. Blood clots can in most instances be softened by bacterial action in twelve to eighteen hours at 37° C. Bacteria possessing this property are contained in the wool itself. It would seem that clots so softened are but slowly hardened by the subsequent addition of germicides, such as formaldehyde or the higher phenols.

An analysis has been made of the 88 cases of anthrax notified to the Board since 1905 with a view to determine the relative danger of infection. It appears that mohair and Persian have been the most frequent carriers of anthrax. Russian camel hair is probably the other scheduled material the most likely to have been a carrier. Some suspicion attaches to East Indian goat (possibly all "goat") and to East Indian wool. Alpaca has probably been harmless. In many cases the source of infection was doubtful, and some cases are inexplicable. Cases arising from the shorter sorts occurred more frequently in the processes of manufacture than in the handling of the raw material; in the longer sorts the reverse was the case.

The greater number of cases occur, as was to be expected, amongst the Commission combers handling the lowest and the more dangerous sorts, but cases occur in factories where combing and the subsequent processes are carried on. Some factories, though continuously using some scheduled materials, have never had a case of anthrax, and in others cases are rare. No instance is on record in this district of the early diagnosis of the internal form, and the application of remedies for the external form is often delayed. The use of Selavo's serum, injected intravenously and in sufficiently strong doses, has proved beneficial.

In view of these results the present regulations for wool sorting and wool combing are considered to require revision. When they were drawn up, dust was thought to be the means whereby anthrax was spread, but now that the source of danger is known to lie in the blood clot, regulations should be based upon the underlying principle of eradicating this source, and of preventing danger of infection after sorting and washing processes. But no regulations will prove satisfactory that do not provide for some adequate disinfecting process for those sorts most likely to contain the anthrax germ. Every inducement should be given to workers of scheduled materials to throw out all blood-stained material, not only for their own safety, but more especially for the safety of workers in subsequent processes; but, until further progress has been made in the effort to find satisfactory disinfectants and a satisfactory disinfecting process, the Board deprecate any attempt to restate the present rules.

Seventeen cases have occurred during 1912: 2 were females and 15 males; 3 were internal cases, 14 external. The deaths numbered 5, 3 of the internal, 2 of the external type, 1 of these being probably unique as to the point of entry of the virus, namely, between the left tonsil and the larynx. Four of the cases which got well were severe, and probably owed their recovery to the use of Selavo's

serum. With one exception all the cases had come into contact with either mohair or Persian, and it is quite possible that these sorts were responsible for all the 16 cases.

Little or no improvement is yet visible either in the number of cases recorded or in the percentage of the death-rate, although there is distinct encouragement in the number of severe attacks which have yielded to modern treatment.

SCIENCE NOTES.

In a lecture at the Royal Institution, not yet published, and in a letter to *Nature* of February 13th, Sir J. J. Thomson has described some experiments which are interesting intrinsically, and also as affording another explanation of the observations of Professor Norman Collie and Mr. Patterson (*BRITISH MEDICAL JOURNAL*, February 8th, p. 304, and February 15th, p. 360). They, it will be remembered, found that in a vacuum tube containing sufficient hydrogen to conduct an electric discharge helium made its appearance after sparking for some time, and that in another tube containing a little oxygen, with which the first tube was surrounded, neon and helium appeared, the formation of neon being apparently conditional on the presence of oxygen. They suggested three possible explanations: (1) The transmutation of one or more of the elements in the glass or electrodes into helium or neon; (2) the transmutation of hydrogen into helium and neon by the electric discharge; or (3) the conversion of the energy of the electric discharge into these two gases. Collie and Patterson, who were supported by Sir William Ramsay, appeared to be in favour of the second of these hypotheses. Sir J. J. Thomson's evidence is in favour of a hypothesis allied to, but not quite identical with, the first of Collie and Patterson. Using the method of positive rays, which is more sensitive than spectrum analysis, and furnishes more definite information, he has during the last two years found evidence of the existence of a gas with the atomic weight 3. This gas was frequently accompanied by another gas with atomic weight 20, which is the atomic weight of neon. There seemed to be no obvious connexion between the appearance of either and the nature of the gas that, at very low pressure, was used to fill the tube in which the discharge took place. Experiments were then directed to discovering the circumstances which favoured the production of the gas with atomic weight 3, called provisionally X_3 , and to ascertain whether it was triatomic hydrogen produced by the discharge, or a new element. The second question does not seem to have been definitely answered. The conditions which led to a considerable production of X_3 generally gave rise to the appearance of helium and neon. The amount of the two latter might be very small, and mere traces might be accompanied by large quantities of X_3 . In most of the experiments this gas was produced by bombarding platinum with cathode rays. The cathode was curved, and thus focussed the rays on to a table on which the platinum was placed. After bombardment on one day, the gases were drawn off into a testing tube; the line due to X_3 was very strong, and those due to helium and neon conspicuous. The gases after a second day's bombardment were the same, and there was no appreciable diminution. After a third day the X_3 had diminished considerably, the other two perceptibly. After a fourth day's bombardment the lines of X_3 and helium were barely visible, and that due to neon was not perceptible. When old lead was bombarded X_3 appeared in considerable quantities until the sixth day, when the experiment was stopped, while helium ceased to be perceptible after the second day. Sir J. J. Thomson believes that the X_3 is expelled from the metal by the bombardment, and that more came off from the lead than from the platinum, because the lead was melted, so that fresh portions were continually being exposed, whereas the platinum did not melt. In another experiment performed in a different way—by an arc discharge between iron wires in hydrogen at a comparatively high pressure— X_3 , helium, and neon were found on two successive days. On the third day, using oxygen, a trace of X_3 was detected, but no helium or neon. On the fourth day, still using oxygen, no one of the

three gases was detected. This looked as though the gases had been produced by the arc passing through hydrogen, but when the oxygen was completely replaced by hydrogen, the arc gave no one of the three gases. When the old iron wires were replaced by new and the arc passed, the three reappeared. This experiment gave strong support to the conclusion that the gases were in the terminals to begin with, and were removed from them by the long continued sparking, and were not produced *de novo* by the arc. This explanation, though less revolutionary than the hypotheses of transmutation of matter or its origin from the energy of the electric discharge, presents difficulties of its own. One is how the gases get into the metals. Thomson found none in lead just precipitated, and says that X_2 "does not appear to occur to any appreciable extent in the atmosphere." Another is that, if the gases pre-exist in the metals, having somehow made their way into them, they must be held there with extraordinary tenacity. That they cannot be expelled by heating appears to be shown by an experiment in which Thomson kept lead in a quartz tube boiling in a vacuum for three or four hours until all but a quarter of the lead had boiled away: in the gases given off neither X nor helium could be detected. The hypothesis he suggests in a tentative way is that they may "represent the partially abortive attempts of ordinary metals to imitate the behaviour of radio-active substances," but that, "whereas in these substances the alpha particles and the like are emitted with such velocity that they get clear away from the atom, in ordinary metals they have not sufficient energy to get clear, but cling to the outer parts of the atom, and have to be helped by the cathode rays to escape."

LITERARY NOTES.

GERMANY is the land of *Rundschaus* and similar useful serial compendiums of scientific work. A new *Zentralblatt* series has just appeared, published by Mr. Julius Springer of Berlin, and edited on similar lines to its well-known namesakes. We have received the *Zentralblatt für die gesamte Gynäkologie und Geburtshilfe sowie deren Grenzgebiete* and the *Zentralblatt für die gesamte Chirurgie und ihre Grenzgebiete*. The first number of both appeared on February 25th, 1913. The surgical *Zentralblatt* is edited by Bier (Berlin), Frh. von Eiselsberg (Vienna), Hildebrand (Berlin), Köhler (Berlin), Küster (Berlin), de Quervain (Bâle), and Schmieden (Berlin), directed by C. Franz of Berlin. The gynaecological and obstetrical *Zentralblatt* is edited by Bantner (Geneva), Döderlein (Munich), Ph. Jung (Göttingen), Krönig (Freiburg), Menge (Heidelberg), Pankow (Düsseldorf), Wertheim (Vienna), and Zangemeister (Marburg), under the direction of Runge (Berlin) and Zangemeister. This new *Rundschaus* promises to be an excellent work of reference, and the first numbers, to which we referred above, include full notice of foreign as well as German works and papers.

We have to apologize for the failure to notice much earlier *A Shakespeare Glossary*,¹ by C. T. Onions, but the first impression was not altogether favourable, and we were loth to express an unfavourable opinion of any lexicon issued by the Oxford University Press, especially when the author was one of the staff of the *Oxford English Dictionary*. Greater familiarity has tended to increase the appreciation of the good qualities of the glossary, and to make its defects seem smaller. They are mainly in the direction of redundancy. In the preface we are told that the aim has been "to supply definitions and illustrations of words or senses of words now obsolete or surviving only in provincial or archaic use, together with explanations of others involving allusions not generally familiar, and of proper names carrying with them some connotative signification, or offering special interest or difficulty in the passages in which they occur." The author admits, also in the preface, that he has gone very much further than this, and that many "who glance over" the pages will express the opinion that more is taken in than is necessary for the guidance of a reader of average literary knowledge, but he thinks that "a careful

examination made with a view to ascertaining what proportion of the vocabulary . . . can be truly described as present-day English will prove such a criticism ill founded." This is a good defence up to a certain point, but not all the way. For instance, the whole entry under *modest* seems superfluous, as the secondary meaning of the word, which is that illustrated, is quite common in present-day English. In the opposite direction, the definition of *pigeon-livered* as "meek, gentle" is disappointing. Other examples in both directions might be quoted. Nevertheless, the book is a thoroughly sound piece of work, and we believe that the more it is used, the higher will be the respect inspired for it. For the industry which has gone to the making of its nearly ten thousand articles, to the ingenuity with which so much labour and learning has, partly by the use of conventional signs and contractions, been condensed into so little space, and for the care with which the whole has been edited, there can be nothing but unstinted praise.

The injunction to verify references is an axiom of literature and science, but to obey it ceases to be possible when the reference is to some spoken epigram which may have been variously recorded by the hearers, or when the same thought has been expressed by different speakers on different occasions and perhaps in different languages. An instance is afforded by a recent curious correspondence in the *Times*. In a leading article our contemporary had stated that it was said of some philosopher who was jesting with his disciples that he suddenly changed his manner and said, "Here comes a fool. Now we must be serious." The *Times* had prudently attributed the remark to "some philosopher," but a correspondent with more boldness assigned it to Archdeacon Paley. Yet another found the same remark in Boswell's dedication of his *Life of Johnson*, where it is attributed to Dr. Clarke, the fool in this instance being Beau Nash. Even this does not seem quite conclusive, for, as the same correspondent points out, in the *Dictionary of National Biography* the story is given on the authority of Thomas Bott, who once found the divine "swimming on a table" and on the approach of a solemn coxcomb on some such occasion heard him say, "Boys, be wise, here comes a fool." Shakespeare with his extraordinary visual memory hits off the type in one of those vivid pictures he flashes on the mental eye like a bright landscape seen momentarily from a darkened room:

There are a sort of men, whose visages
Do cream and mantle like a standing pond.

Or rather there are two flashlight pictures, for just before Gratiano has asked—

Why should a man, whose blood is warm within,
Sit like his grandsire cut in alabaster?

An illustration of the uncertainty of verification in sayings is afforded by the Latin lines quoted, in the article on proverbs regarding alcohol in the *JOURNAL* of February 22nd, p. 399, on the authority of Lord John Russell. Dr. Stennett Redmond sends us the following version which he says was used by Archbishop Whateley as an example of a false syllogism:

Qui large bibit, bene dormit;
Qui bene dormit non cogitat malum
Qui non cogitat malum, non peccat,

Ergo Qui large bibit, non peccat.

With reference to the same article, we have received the following note from Dr. R. W. Leftwich, who prudently guards himself by stating that he quotes from memory. He says: "Those who like myself appreciated very highly the articles on Proverbial Medicine, especially that in relation to the use of alcohol, may be interested in the following anecdote of Goethe. The poet had been twitted by a party of students for mixing water with his wine, and replied with the following impromptu verse:

Wer trinkt nur Wasser wird stumm
Das zeigen im Teich' die Fische:
Wer trinkt nur Wein wird dumm
Das zeigen die Herrn am Fische:
Wer will gesund und geistreich sein
Mischt immer Wasser mit seinem Wein.

I write from my recollection of a conversation held many years ago, for I have not seen this in print, and confess that my memory of the fifth line is so vague that I must accept the responsibility for it."

¹ *A Shakespeare Glossary*. By C. T. Onions, M.A. Oxford: The Clarendon Press. 8vo, pp. 271. 2s. 6d. net; India paper, 3s. 6d. net.)

British Medical Journal.

SATURDAY, MARCH 8TH, 1913.

THE NATIONAL INSURANCE ACT AT WORK.

WE have received from the National Committee for the Prevention of Destitution, a body which was instituted for the dissemination of the views contained in the Minority Report of the Poor Law Commission, the final number of their organ, *The Crusade*, which is now to give place to a more ambitious project, a new weekly review called *The New Statesman*. The number of *The Crusade* is accompanied by a supplement written by Mr. Sidney Webb, and entitled, "The National Insurance Act at Work, what it is Effecting and where it Needs Amending," and a most interesting document we have found it. It contains information as to the working of the Act which we have not found elsewhere, and its collection is another evidence of that passion for information for which Mr. Webb is famous. It contains also some of the most penetrating criticism of the Insurance Act which we have seen. The author, while naturally sympathetic to many of the objects of the Act, has a keen eye and an unsparing pen for its defects.

We can recommend all our readers who wish to get a bird's-eye view of the working of the Insurance Act, with all its possibilities and disappointments, to secure a copy of this supplement. It is quite easy to disagree with Mr. Webb, but no one can fail to be interested and informed by him.

When he deals with the medical benefit we find, as was to be expected, that he is dissatisfied because the provision of medical benefit is not on the lines recommended in the Minority Report. He contrasts the "fearful and wonderful network" of medical benefit with the simplicity of the public health service, very much to the advantage of the latter, and urges that it would be better to assume that as regards medical attendance all insurable persons are insured in one great national society and are in benefit, that all changes of residence should be ignored, and every person treated wherever he happened to fall sick when he presents his card to any doctor on the national panel. Under Mr. Webb's scheme every doctor who cared to accept service would be a servant of the State, either on whole or part-time salary, with, of course, the usual hierarchy of administrative officials. Mr. Webb is good enough to tell us that in the recent fight the doctors were badly organized and badly led, and displayed "quite a curious incapacity to explain their own case either to the Government or to the public perhaps because they only dimly realized what it was." It would have been kinder, perhaps, if Mr. Webb had interfered at an earlier stage and had offered to state the doctors' case for them, as no doubt he could have done much better than those personally interested. It is just probable, however, that if Mr. Webb had

done so he would have been considerably surprised at the remarkable unanimity with which the profession would have rejected his proposals for its salvation. From our knowledge of the profession we make bold to say that, whatever its uncertainty as to what it wants, it is particularly clear that it does not want to be a whole or part time Government service. It is because of its strong objection to such a development that the profession accepted the panel system, which, with all its drawbacks, allows comparatively free choice of doctor by patient, and of patient by doctor, and continues that healthy emulation among doctors which is inconsistent with Mr. Webb's ideal. It may be that the profession is very misguided in taking this line, but we can assure Mr. Webb that, on the whole, the profession believes that the change from the panel system to his Government service would be from the frying-pan into the fire. Mr. Webb and his followers fail to realize that the medical profession is, on the whole, the most individualistic profession in the world. Every member of it is constantly dealing with elementary human nature, and is thrown at nearly every moment of the day on his own resources to an extent unknown probably to any other calling, and, as a result, there has been developed in the medical profession a profound mistrust of the regulations and restrictions inseparable from whole or part time service, so far as general medical practice is concerned.

Mr. Webb is of opinion that there are only two methods of payment of medical attendance which are free from the "insidious degradation that attends all contract practice"—either so much for each attendance or so much per annum. Mr. Webb remarks that the doctors would have liked the former, but "neither they nor the Chancellor of the Exchequer could find any way of protecting public funds against the unscrupulous and often collusive 'jobbing' of cases, which would have caused an unlimited drain on the Insurance funds." That method is therefore put out of court. He thinks that the friendly societies and the officials would have preferred a salaried service of whole or part timers, but the doctors, "short-sightedly enough," were up in arms against a salaried service. It is true that certain officials were in favour of a whole-time service, but there is not the slightest evidence to show that the rank and file had any leanings that way. The official mind naturally prefers this solution. It is "so simple." Whether it is "short-sighted" is another matter. With the choice limited to the panel system or the whole-time system the profession and the great bulk of the public would, we believe, prefer the former, because it leaves greater freedom to both patients and doctors, and on the whole gives greater confidence to the public. The profession as a body has spoken as strongly against the degradation of contract practice as even Mr. Webb could desire; but it is not at all clear that contract practice, when cleared of certain outstanding and non-essential evils, is more open to objection than the acceptance of a salary. In both cases the employed person accepts a fixed sum for more or less indefinite work. If contract practice is divested of the two things which have made it a byword in the profession in the past, namely, unsatisfactory remuneration and monopoly—that is, the denial of free choice on both sides—there is nothing more derogatory about it than there is in the acceptance of a fee for each visit or an annual salary. Some of the best work in the world has been done on contract, and it is taking a very superficial view to denounce the whole system uncritically, as is so often done and is

done in this essay. Mr. Webb is quite as emphatic as the Government was about the impossibility of an income limit. That was to be expected from him. We have always realized the difficulties in the way, which are not altogether unconnected with the necessity for securing or retaining votes. But we are just as convinced as ever that, apart from political exigencies, there is ample justification for an income limit, and cannot help thinking that if Mr. Webb and his friends were really in earnest in their denunciation of contract practice, and had thought out all that is therein implied, they would welcome a method which would go far to restrict it within necessary limits. Mr. Webb prophesies that there will be a great increase of work under the panel system, and in this, judging from the reports which have come to our notice, we are inclined to agree with him, though it is yet too soon to say to what extent this increase will be permanent. At present, owing partly to the novelty of the arrangement, people are flocking to the surgeries of the doctors with quite trivial ailments for which in the past they would have taken some domestic remedy. The result of the wide circulation of the model rules of the approved societies regulating the times at which insured persons may see their doctors and send their messages, together with the representations of the Local Medical Committees, will doubtless have a considerable effect on the situation. Up to the present these rules seem hardly to be known to the insured persons, and the Committees have not yet got into their stride. When Mr. Webb estimates that the amount of medical attendance per head of the insured population is going to be perhaps three or four times as much as that given under the old club practice, we are inclined to offer the old advice, "Never prophesy unless you know." At the present moment it is impossible either for him or for any one else to judge on this subject with anything like certainty.

Mr. Webb sees that many minor adjustments will be required to be made before the panel service can be worked with anything like satisfaction. He notes the difficulties of securing attendance for those whom none of the panel doctors will accept. Here again we think that, except in some rural areas, there will be little difficulty, though when it does arise it will be a particularly awkward one, needing all the tact and forbearance of the practitioners concerned. In the urban areas it is possible that the younger men who have yet to gain a footing in practice will be glad to take any reasonable number of patients, and they will at any rate have the satisfaction, denied to them in the past, that for all attendances on insured persons they will get some payment, even if it be inadequate. We have no doubt that during the next few months many prophecies concerning the Act will be proved to have been badly founded. Difficulties and grievances will arise which have not been foreseen, and some of the points on which most stress has been laid may prove in practice to be much less formidable than was anticipated.

Mr. Webb makes a powerful attack on what he terms the illegal limitation of medical treatment. He protests strongly that the Commissioners in limiting medical treatment as they have are exceeding their powers. He believes that such a restriction is a violation of the law and that the Courts at the first opportunity will say so. He is anxious that for the insured person the very best medical treatment should be provided and should include every emergency likely to arise. This is, of course, the ideal, and towards the fulfilment of that ideal we believe

the Commissioners will be gradually forced by public opinion. It is simply a question of money. For the remuneration at present offered the medical profession cannot give unlimited medical and surgical treatment. The Government has recognized this and has said that with the money at present available it can only offer a certain amount of medical treatment. Anything outside this must be provided either by the patient himself or by resort to a medical charity. It is an unsatisfactory position and one which the British Medical Association did its best to bring home to the Government; and the profession will watch future developments with interest.

In conclusion, we freely admit the force of many of Mr. Webb's criticisms, and appreciate his sympathy with many of the difficulties of the medical profession, but it is as well that he should understand that his suggested remedy—namely, that of a whole or part time service, which, as far as we have been able to see, is incompatible with anything approaching free choice of doctor—is regarded by the profession, and we believe by the majority of the public, as an evil to be escaped. Private medical practice may have its drawbacks, but it accords best with professional traditions and preference. If the ideal of universal private practice cannot be attained, so that every patient shall be free to call in his own doctor and able to pay him the ordinary fees prevalent in the district, then we say with conviction that the profession as a whole vastly prefers the panel system to Mr. Webb's State service.

A PHILOSOPHER AND HIS DOUBLE.

A STRIKING example has recently been added to the number of those curious intellectual coincidences of which the almost simultaneous formulation by Darwin and Russell Wallace of the principle of natural selection is among the most familiar. This time it is Professor Bergson who is revealed as the possessor of a spiritual double, in the person of Mr. Henry Mills Alden, "dean of the American editorial world, for forty-three years editor of *Harper's Magazine*, and the monthly penman of the 'Editor's Study' in that publication." In an article entitled, 'The Bergson Method Confirmed,' Mr. J. W. T. Mason calls attention to the extraordinary resemblance of the views set forth by Mr. Alden, in a book entitled *A Study of Death*, to those already familiar to all readers of the distinguished French philosopher. Yet Alden's book was published twelve years before Bergson wrote *Creative Evolution*; in fact, there is not the least doubt that the two authors arrived quite independently at practically identical conclusions. The parallelism of ideas is all the more striking on account of the fact that the two thinkers concerned have reached these conclusions by contrary routes, the one by a train of thought originated by meditation upon death, the other by self-identification with life in its fullness and essence. And whereas one—the American—speaks primarily as a *littérateur* and a critic, the other has at his disposal the equipment of a professional philosopher, a student of science, and a learned psychologist. But from points of view so distinct and dissimilar both have arrived at the same world-conception of an eternal creative process, a vital flux whose substance is real time or duration; at the primary nature of the differentiation between reason and instinct, and the concurrent loss and gain involved by our sacrifice of the latter to the former mode of consciousness: at the continuity of

the real, and the falsification resulting from its being broken up into the isolated "facts" of conceptual knowledge; and at the anticipation of an "ultimate mysticism" defined by Mr. Alden as "one with native intuition, but including a perspective commensurate with the visible universe."

Nor is the consensus of these two minds confined to fundamental conclusions; it extends even to such comparatively external matters as the choice of illustrative metaphors. Readers of *Creative Evolution* will recall a famous passage in which, contrasting the negative or descending movement of matter with the positive or ascending movement of life, Bergson compares the latter with "the fiery path torn by the last rocket of a firework display through the black cinders of the spent rockets that are falling dead." Mr. Alden concludes a sentence referring to the transition from the incandescent nebula to the cooled and contracted earth crust as of the nature of a descent, by the remark that "we cannot but regard the progression of cell life as an ascension, as if from the cinders of extinguished fires some new flame had arisen, more nearly imaging the flame of the spirit." The following quotation from *A Life after Death* might also be mistaken for a translation from any of Bergson's works: "Generally the terms of science are unvital. . . . Science is confined to a formal conception of existence, and is concerned with quantity . . . rather than quality." Mr. Mason gives a number of such excerpts, but we must refer those interested in the matter to the original article. The writer claims, not without some justice, that the occurrence of so remarkable a coincidence, under circumstances precluding the possibility even of unconscious plagiarism, constitutes a vindication of the Bergsonian method and of the truth and objectivity of its results. "The conclusion," he says, "therefore becomes inevitable that at least this one fact of the intuitional method is proven: *it works*." It suggests also that the succession of those constantly varying modes of conceiving reality of which philosophic systems are the formal expression is not arbitrary, but governed by economic and other conditions, in such manner as to exhibit a quasi-logical sequence and to summarize the spirit of the times. "In philosophy," says Hegel, "the latest birth of time is the result of all the systems that have preceded it, and must include their principles; and so, if on other grounds it deserve the title of philosophy, will be the fullest, most comprehensive, and most adequate system of all."¹

MEDICAL PROVERBIOLOGY.

THE series of articles which have been appearing in the JOURNAL,² recently must have discovered to many a reader an altogether unsuspected richness in the field of medical proverbiology. Every medical man is now and again meeting with proverbs in his daily experience; sometimes his patients cautiously produce them in order to get their own way or to criticize their doctor's management of their illness; sometimes he himself employs a wise saw to enforce a necessary but irksome kind of treatment or a prolonged degree of rest in bed; sometimes the midwife cheers her fainting parturient primipara with the phrase, "Sick labour, quick labour," whilst the obstetrician who dreads the forceps says sententiously, "Meddlesome midwifery is bad"; and sometimes (too often perhaps) the ungrateful patient,

in presence of his doctor's little bill, falls back with relief upon the many saws which declare that to Nature, who really worked the cure, and not to the physician, the fee ought to go (Nature, conveniently enough, having no bank account into which cheques can be paid). But, even allowing that proverbs play their part in medical practice, who would have thought that there were so many wise sayings about such matters as prognosis, diet, symptomatology, alcohol, and the doctor himself as have been set forth in the series of articles referred to? The subject, indeed, has not been exhausted, and there may yet appear a second series dealing with proverbial sayings about special drugs and methods of treatment, about midwifery practice, and about children's diseases.

The study of medical proverbs raises two sets of questions: the first set contains the problems which are common to all proverbs, medical or lay; the second set deals with those which are special to medicine. Let a glance be cast at one or two in each class.

First, then, what is the part played by proverbs in daily life; what do they do for us that they should be so long-lived and, generally speaking, so much respected? To this question there are several answers possible; but, in the first place, proverbial sayings throw the note of emphasis upon important things in life. They serve to indicate the red-letter matters in experience; they are as sublineations or italics are to the printed page; they are the asterisks of popular thought. Perhaps the writer of the articles throws too heavy an emphasis when he calls every proverb "a precious stone of experience laboriously cut and polished until every facet of it flashes forth the bright light of wisdom"; but he can claim that proverbs do indeed receive very generally an amount of respect bordering upon worship from many people who are not deficient in worldly wisdom. Many a time an orator has brightened a dull part of his speech or strengthened an infirm section of his argument by the opportune employment of a pithy and appropriate piece of proverbial wisdom; the weak controversialist has sometimes snatched a victory out of the hands of a strong reasoner by a wise saw of three or four words, very much as Byron, we are told, "vanquished Berkeley with a grin." Again, proverbs have been used as guides to conduct in circumstances where decision was difficult; but it is to be remembered that they do not of themselves constitute a body of wisdom, for, whilst "Solomon made a book of proverbs, a book of proverbs cannot make a Solomon." Indeed, the adage as an arbiter of conduct is a dangerous guide, although the danger is lessened by the common experience that there are generally opposed proverbs, which, coming together, destroy one another, and leave the person who is trying to direct his steps by them to seek another and a surer pilot. These two aspects of proverbs—that they underline the *notabilia* or *memorabilia* of life, and that they have been used as guides in ethics—are evident not only in the general affairs of existence, but also in the special circumstances of medical practice. Thus the saying, "Joy, temperance, and repose slam the door on the doctor's nose," if somewhat unkindly worded, yet emphasizes the great value of prevention by other things than medicine, and Dr. Diet and Dr. Quiet are, beyond all doubt, formidable rivals to the general practitioner. There are doctors, too, whose canons of practice are not unlike those of the people who try to steer the harque of conduct by the rudder of popular proverbs; they prescribe by rule of thumb

¹ *The Logic of Hegel*. Translated by W. Wallace. Page 23.

² BRITISH MEDICAL JOURNAL, ii for 1911, p. 1381; i for 1913, pp. 178, 291, 398, and 502

and work by empiricism, and so sometimes they come perilously near the confines of quackery.

There are aspects of medical proverbology which are special thereto. Why, for instance, should there be crowds of proverbs in dispraise of the doctor, and hardly a single one in his praise? A prophet is not without honour save in his own country and in his own house; but the doctor seems (so far as proverbs go) to lack honour both at home and abroad. In the articles several possible causes of the unpopularity of medical men with the makers of proverbs are suggested, and some of them are in keeping with experience. Perhaps most weight should be given to the fact that few wish or try to remember unpleasant or distasteful times in life, such as illnesses, which come to check gaiety and suggest gloomy reflections, and that since the doctor is inevitably associated with these times he shares the general reprobation. Stevenson, it is true, said of one of his doctors that "his visits made it a pleasure to be ill"; but it is not every doctor who has his Stevenson, and indeed it is not every doctor who deserves to have him. We are touching fundamentals here when we wonder what it was in Stevenson's doctor which made his visits pleasant. It can hardly be believed that it was simply on account of the prescriptions he left or the medicines he sent for the relief of pain or distress; it may have been, it is very likely that it was, because the medical man had a mind large enough to find room for other matters than the business of his profession: indeed it may be hazardous that he had a fine taste for the beautiful in literature. Is there not here subject for thought? Is the medical man of the future to be worried out of the humanities and forced to be no more than the prescriber of pills and the writer of sickness certificates? Are his visits to be no more highly valued than the matutinal calls of the milkman? We have wandered somewhat far away from medical proverbs, but there may be a closer connexion between the paucity of adages in praise of the doctor and the commercialization of practice than is immediately apparent.

To one other special question a word may be given. Why should the proverbs on alcohol be so divided? Here again fundamentals are being dealt with; when it is known what is the factor or factors which determine the genesis of a proverb, what it is which decides the sayings that are to survive and those that are to pass stillborn away, then perhaps it may be discovered why proverbial medicine is a divided house on the subject of alcoholism.

THE BUILDING OR EXTENSION OF SANATORIUMS.

THE Local Government Board has issued a memorandum, prepared by its architect and medical officer, on the planning and construction of inexpensive buildings for the treatment of cases of tuberculosis. The Board states that it is necessary to adopt forms of construction as economical as is compatible with efficiency, and we may add that, on other grounds than that of immediate financial exigencies, it is undesirable to erect costly buildings in a manner insusceptible of modification and improvement in the future. While advising that the additional accommodation, which in many areas is immediately necessary, may, as a rule, be more expeditiously provided at, or in connexion with, existing hospitals and sanatoriums where provision for administration already exists, the Board states that complete institutions may be built in a comparatively short time if the suggestions contained in the memorandum are followed. The advice is repeated that a sanatorium for

the treatment of early cases of tuberculosis should, where practicable, contain at least 100 beds, but if the population of an area does not justify provision on this scale, and it has not been found feasible to arrange for a combination of areas, the Board will be willing to consider proposals for providing institutions with fewer beds. The memorandum contains two sketch plans, one for a suggested pavilion for 50 patients, showing one ward for 12 beds, six for 2 beds each, and one for 1 bed in each wing, with a verandah in front of the seven smaller wards. The two wings are shown separated by a dining hall used by both sexes, and a site for kitchen and offices. The administration block and the laundry and boiler-house would be detached buildings at a short distance. The other plan shows a pavilion for 20 patients of one sex; it is again in two wings, each containing five bedrooms with 2 beds each. Those responsible for erecting new buildings or additions to existing buildings may be glad to be reminded of the full report by the late Dr. Bulstrode on *Sanatoria for Consumption and certain other Aspects of the Tuberculosis Question*,¹ issued in 1908 as a supplement to the report of the medical officer of the Local Government Board, 1905-6. The memorandum now issued by the Local Government Board concludes by an admonition to the councils of counties and county boroughs in England as to the importance of organizing without delay an efficient system of dispensaries, on the ground that a large proportion of cases suffering from tuberculosis at any one time can be properly treated at an efficient dispensary, and that the selection of suitable cases for treatment in residential institutions will be more satisfactorily effected where a dispensary system is in operation.

RECENT OBSERVATIONS ON ATHEROMA OF SEPTIC ORIGIN.

It has long been recognized that arterio-sclerosis may be set up in the later stages of infectious disease, and positive results have been obtained after experimental inoculation with the typhoid bacillus, staphylococcus, and an organism obtained from a case of ulcerative endocarditis. These experiments, however, have been somewhat limited in scope, and hence a series of observations conducted on a larger scale in Professor Metchnikoff's laboratory, by Dr. Y. Manouélian, deserve special attention.² Full particulars are given as to the strains of staphylococcus used and as to the elaborate methods of staining the sections of the affected vessels, the results of which are shown in some excellent plates. Rabbits and a few monkeys were the animals employed. Aortic changes are not uncommon in the adult rabbit, and have been said to occur in from 4 to 19 per cent. of the cases observed. This fact has to be borne in mind when assessing the value of the results following artificial introduction of the staphylococcus, but as it is recorded that no less than 84 per cent. of the observations gave positive results, there can be no doubt as to their significance. In the case of the monkey the positive results were even more striking, as 5 out of 6 were positive. It may be noted that the most marked effects were produced by repeated injections of the weaker strains of coccus, the effects of the stronger strains were often too rapidly fatal. In appearance the atheromatous patches presented the familiar superficial aspect, and almost all were situated about the arch, and not in the course of the vessel. In a few instances the arterial disease was found to be advanced and tending to aneurysm, the walls containing calcareous or cartilaginous material. Microscopically, the changes were found to be mainly due to degeneration of the elastic tissue and of the muscle fibres, but the calcification is stated to have arisen from the elastic tissue only. The effect produced upon

¹ London: Eyre and Spottiswoode, 5s.
² *Annales de l'Institut Pasteur*, January, 1913.

the aortic wall was not always the same. In some cases marked thickening was seen, and in others the reverse. In the thickened cases the main change was found in the middle coat, while in the plaques of long standing no trace of elastic tissue could be discovered. Many of the experiments extended over a considerable period of time, and details are wanting as to the symptoms shown by the animals during their long course of acute and subacute septicaemia. No positive microscopic evidence is given as to the direct relation of the staphylococcus with the aortic lesion. So high a percentage of local disease produced by the artificial induction of chronic poisoning must be regarded as throwing considerable light upon the possible causation of the aortic atheroma so commonly met with, after middle age, in man.

NON-ABSORPTION OF DRUGS ON INTRAMUSCULAR INJECTION.

A RADIOGRAPHIC curiosity of very great interest was recently described by Spéder.¹ In skiagrams of the hips of a patient the image of the bone was obscured by a number of abnormal and at first unaccountable shadows, arranged in radiating lines, their direction corresponding exactly to the form of the muscular fibres. Normally, as we all know, the muscles give little or no radiographic image. The hypothesis of osteomata was eliminated by the localization and general form of the shadows, and pathological calcifications fail to give this appearance with the x rays. There remained the hypothesis of a modification in the transparency of the tissues, owing to the introduction of foreign bodies, and this was confirmed by the history of the patient. He was aged 39 years and had suffered at various times from acute rheumatism, ultimately affecting the hips. In 1909 chronic arthritis of the coxo-femoral articulations was diagnosed, but a radiograph made at the time, and again at the beginning of 1911, showed nothing abnormal beyond the osseous and articular lesions. More important evidence was, however, obtained. The patient, it was elicited, had contracted syphilis, and had received a large number of intramuscular injections of mercurial salts. Three series of such injections were made from 1907 to 1911. In the latter year one medical man, connecting the lesions of the coxo-femoral articulations with the syphilitic infection, submitted the patient to a series of intramuscular injections with a different solution, which was probably iodipin (that is, iodine combined with oil of sesame), and thirty such injections were made in the muscular masses at the hip. The skiagrams revealing the curious opacities just described were made twelve months after these injections, and as those made previous to the injections showed nothing abnormal, it seemed reasonable to attribute the appearances to the non-absorbed drug. It is well known that a number of preparations used in medicine, including the iodine group, are somewhat opaque to the x rays, and all radiographers agree as to the persistence of shadows due to injections of iodoform paste in fistulous tracts and osseous cavities. But medicaments which might be expected to be easily absorbed usually disappear rapidly. Among patients submitted to a series of injections of mercury binitodide, Spéder sought in vain for any traces of the medicaments persisting after some days. In another patient iodipin was absorbed within nineteen days after injection. The state of the muscles, apparently, is of importance, and it was thought probable that in the patient who showed the strange opacities, a year after injection, there had occurred a fibrous proliferation, due to the many previous injections of mercurial salts in the muscular masses at the hip, thus rendering the muscle less capable of absorbing such a salt as iodipin. From the radiating arrangement of the shadows, the opaque bodies appeared to be localized in the

interfascicular cellular tissue. The interest of the observation from the therapeutic point of view lies in the fact that the radiograph may indicate whether or not the absorption of the drug has taken place in a normal manner.

THE MNEMIC THEORY.

PROFESSOR JAMES WARD, in his choice of *Heredity and Memory*¹ as the subject of the Henry Sidgwick Memorial Lecture for 1912, has earned the thanks of all who are interested in the important and highly controversial problems which the topic inevitably suggests. The lecture was without question a serious and weighty contribution to the growing volume of dissentient criticism of Weismann's conception of heredity. No doubt, in a sense—and many will be glad to have the full text, which has recently been published by the Cambridge University Press—Weismann's conception may still be said to occupy the central position: it is to-day the orthodox view. But the attacks upon it are growing daily stronger and more confident; many biologists are already convinced of its inadequacy; still more, we venture to think, have at least their secret misgivings upon the point. So long ago as 1895 Delage succinctly stated the Weismannian dilemma, though he had been preceded by Professor Hartog of Cork in 1891. "Without the inheritance of acquired characters there can be no new ancestral plasma, and without ancestral plasma more complicated than those of the protozoa there can be none of the superior animal." To extend the range of natural selection from the environment to the intragerminal constituents does not advance matters, for by no possible shuffling of protozoan unit-characters can such variations as will avail to produce metazoan progeny be brought about. To account for that, some new factor must be hypothesized; whether that be the inheritance of acquired characters or some other and unknown potentiality, matters little; in either case the absolute continuity of the germ plasma, which is the base principle of Weismannism, has to be given up. Professor Ward does not, of course, advocate the revival of the Lamarckian contention that all acquired characters are heritable; as we understand him, he would limit the possibility to those which have been so thoroughly mechanized by habit, perhaps in the lives of several successive generations, as to become, in Hartley's phrase, "secondarily automatic." Regarding the germ cell as a definite psychic unity and its nucleus as the functional analogue of a central nervous system, he attributes its recapitulation in palingenesis of the main events of racial history to the momentum of organic memory. "We may," he says, "compare it (the germ cell) to a company of actors awaiting behind the scenes the call to begin their play. Each one knows his part by heart and also knows his cue. The routine or orderly rhythm of the performance is thus ensured, and the play, though continually condensed at one end and extended at the other, has been so often repeated as to be acted without a hitch or hesitation, save, perhaps, in the case of its latest amendments."

THE "INDEX CATALOGUE."²

It is hardly a year since the sixteenth volume of the second series of the *Index Catalogue* of the Surgeon-General's Library at Washington was noticed in the *JOURNAL* (vol. i, 1912, p. 799), and now the seventeenth is ready for use. With the appearance of each new volume the impression of the vast extent of modern medical literature is strengthened. We may take as an instance the subject of syphilis, which occupies 200 closely printed

¹ *Heredity and Memory*. By James Ward, Sc.D. Cambridge: At the University Press, 1913. (Cr. 8vo, pp. 56. 1s. 6d. net.)

² *Index Catalogue of the Library of the Surgeon-General's Office, United States Army*. Second series, vol. xvii. Suaheli-Testut, Washington, 1912.

pages in this volume; these pages contain nothing more than the titles of the various books and articles which have been written on the various aspects of this disease since the publication of the corresponding volume of the first series in the year 1893. If eighty or ninety references to articles or books be the tale for each page, and roughly speaking it may be put at eighty, we have the enormous total of 16,000 papers on syphilis in twenty years! If a student of the subject had been reading some fifteen or sixteen of these articles a week all these years he would only just have kept himself abreast with the literature pouring from the world's press on this one subject. Then when we come to analyse the subheadings under which the subject is catalogued the wonder grows; there are about 220 of them. If one of these be taken—say congenital syphilis—it is found to be treated under the following heads: Blood in congenital syphilis, cases and statistics, causes and pathology, complications and sequelae, contagiousness, death and sudden death, diagnosis, effect upon descendants, eye in congenital syphilis, haemorrhage in manifestations of congenital syphilis, cutaneous, late, and pseudo-rheumatic manifestations, prevention and treatment, with salvarsan (606), prognosis, reinfection, serodiagnosis, teeth, treponema, urine in syphilis; and these, let it not be forgotten, are only the subheads under a subhead (congenital syphilis). To turn, however, to some of the many other matters catalogued in this volume. There is symphysiomy, with twelve pages and eight headings; there is syringomyelia, also with twelve pages; two pages sufficed for each of these subjects in the first series of the *Index Catalogue*. There are suprarenal bodies and extract with thirty-two pages; in the first series suprarenal bodies had four pages, and suprarenal extract did not appear. Then here are some of the new headings (omitting authors' names): Sych-naria, sygggnoseism (with its cross reference to hypno-tism), symbiogenesis, symmetroscope, sympathectomy, symphora, symphytum officinale, synaesthesia, synch-ytrium, syncytiolysis, syncytioma, syncytium, syndrome, synchotomy, synergia, synkinesis, synophthalmia, syn-ovectomy, synoviotomy, syringobulbia, syringocystoma, and sysoma. Perhaps, nay, certainly, the most interest-ing pages are those in which the treasures of the Washington Library in the department of texts illustrating the history of medicine are set forth in order, beginning with pre-Hippocratic medicine, and running on through Greek and Graeco-Roman, Mohammedan, and Jewish, Mediaeval, Renaissance, seventeenth century, and so down to the modern period. It may be safely predicted that many a medical bibliophile's mouth will water as he reads over the list of texts and incunabula gathered together in this library, and many a worker in the subject of medical history will wish he lived near Washington. But why are these treasures entered under the heading "Surgeon-General's Office, Library of the."? Who will think of looking for them under that rubric? Doubtless they will be cross referenced, however, under "Texts" or "History of Medicine."

SLEEPING SICKNESS AND BIG GAME.

At a recent meeting of the Society of Tropical Medicine and Hygiene a paper by Dr. A. G. Bagshawe detailing recent advances in knowledge of sleeping sickness was read. A very full and detailed account of the large amount of work that has been done on the subject during the last year was given, and an animated discussion afterwards took place. Dr. Yorke, who had just returned from Africa where he had been serving on one of the sleeping sickness commissions, was able to relate experiences of the greatest value. A careful study of the epidemiology of the disease has brought him to the opinion that all game that is capable of being infected with trypanosomes of man and domestic stock should be destroyed; for

practical purposes this would mean the destruction of all the African fauna in inhabited regions. The game he believes stands in the way of the progress of civilization. Dr. Moffat, and other speakers competent to judge on the subject, were also, though with regret, of the same opinion. Dr. Moffat went so far as to suggest that the Chartered Company should destroy all game south of the Zambesi, an experiment which would show whether the disease would spread south into a gameless tract. His belief is that man cannot live and farm by the side of big game, as the latter brings trypanosomiasis; and he suggests that zoological interests might be conciliated by making large reserves in the districts to the north. Many other speakers pointed out the difficulty, amounting almost to impossibility, of exterminating game. There is no doubt that the subject is one of immense importance, and a decision sooner or later must be made. Sir David Bruce is now working at the question, and the results of his labours will be anxiously awaited by every-one, be he scientist, hunter, colonist, or Government official.

RACIAL RESPONSIBILITY.

A CONFERENCE organized by the Eugenics Education Society, and held at the University of London on March 1st, was largely attended by schoolmasters and schoolmistresses of the elementary and secondary schools and training colleges. Major Darwin, the president of the society, who was in the chair, explained that the conference was convened as an indirect consequence of the growing interest in eugenics. No one could deny that the world would be greatly the better if it contained fewer of the insane, the feeble-minded, the drunken, the diseased, and the unemployable, and as many individuals as possible of high character and good ability and physique. For the present energy might well be concentrated on an attempt to eliminate all the types which were unquestionably bad, whilst encouraging the appearance of those which were unquestionably good. Any marked success in such an effort would mean that our descendants would come very near to the attainment of the eugenic ideal. Mr. W. A. Nicholls (ex-President of the National Union of Teachers), in referring to the difficulty of introducing eugenics into the public elementary schools, said that the subject required such cautious handling, and must be so carefully and gradually led up to, that in view of the little spare time left to the teacher in an already crowded time table, he could see no prospect of its being incorporated in the school curriculum. In the present condition of public opinion the only persons who could do it with safety were the parents, and every parent, at all events at present, should be left to judge for himself in the matter. Mr. J. H. Badley (Head Master of Bedales School, Petersfield) said that, as with all social problems, the subject must be attacked from two sides—from without by the moulding force of the environment, and from within by such personal influence as could be brought to bear upon the individual child. The surroundings and conditions of the child's school life should be such as would foster wholesome habits and a wholesome attitude of mind; and good sense and good feeling should be appealed to, not by moral lectures or inquisition, nor by books or pamphlets, but by quiet, friendly talk. The Head Master of Eton said that some misgiving existed as to the ideals of eugenics being in some sense divergent from those of religion. But all might agree that the aim of both was correctly described as the implanting of truth in growing minds, or, better still, the training of young minds into truth. The religious aim would be primarily a bringing of the human into touch with the Divine mind; the eugenic aim would not conflict with this, but would emphasize the indispensable character of training in science, the fostering of the scientific spirit, so that the

action of heredity and environment might be discerned and the claim of posterity on the present generation clearly recognized. Probably it was correct to say that eugenics hoped to supplement the religious ideal with something of a more intellectual kind, for many who belonged to the new movement found that the older school of thought lacked the scientific spirit, especially in matters of race training, where the English disposition to ignore the connexion between cause and effect had told, and was still telling, with disastrous results to the racial development at the present day. At the close of the meeting Major Darwin proposed: "That the Minister of Education be asked to receive a deputation requesting an inquiry as to the advisability of encouraging the presentation of the idea of racial responsibility to students in training and children at school." This resolution, which was seconded by Mr. Mortimer, the delegate of the National Association of Head Teachers, was carried unanimously.

BINOCULAR VISION AND FATIGUE.

PROFESSOR DUFOUR of Nancy, in a paper read before the Biological Congress, which met in that town at the end of last year, pointed out that fatigue might under certain conditions render binocular vision very difficult. In general, when we look at a luminous point, the images perceived by the two eyes are fused without conscious effort. The visual apparatus is so constructed that binocular vision is almost mechanically produced. But if the natural desire for fusion be abolished by using a prism or a Maddox rod the two images do not invariably fall together. The streak of light formed by the glass rods does not always pass through the image of the source of light seen with the other eye. To fuse the two the natural position of repose and equilibrium should be found when the axes of the eyes are parallel. This is by no means always the case. In cases where they diverge or converge single vision is only obtained by an effort, conscious or unconscious. It is attained by the aid of the retinal reflex or the reflex of Parinaud. This reflex is always called into action by those whose optical axes are not parallel, those, in other words, who do not possess orthophoria. If the axes diverge we speak of exophoria, if they converge, of esophoria. This reflex is more difficult to excite when the subject is fatigued, and the difficulty may pass into impossibility. Such an individual will complain that when he has read for a certain time he sees double. The constant use of Parinaud's reflex may be in itself a cause of fatigue. Sensitive persons, especially those with a tendency to neurasthenia, may experience chronic headache, usually referred to the occiput, which is solely due to this heterophoria, and this can often be relieved by the use of appropriate prisms. Dufour alluded only to a tendency to diverge; but a convergence in the resting position may be equally effective in causing headache and other symptoms of eye-strain. Still more must we regard hypophoria—a tendency of one eye to turn up or down—as a cause of asthenopia. These errors of muscle balance are never overlooked by the careful ophthalmic surgeon, who always tests his patients for heterophoria with the Maddox rod and other phorometers, and in many cases achieves success with suitable prisms. When the error is great operative treatment may be called for; but it is rarely thought necessary, at any rate on this side of the Atlantic. In America Stevens and others carry out partial tenotomies, and claim many brilliant cures.

THE TREATMENT OF PLACENTA PRAEVI.

PROFESSOR G. ZINKE of Cincinnati¹ urges that a better form of treatment for placenta praevia is required than those now in general use. He reviews present-day methods of treatment, and as to rest in bed, with a bag

of ice on the abdomen, he says that it does not save many women. With regard to plugging, he admits that at times a mother, and rarely even a child, may thus be saved; but he thinks it doubtful whether this method can be regarded as satisfactory. He discusses next the Braxton-Hicks or similar methods, in which uterine contractions are stimulated either by bringing down a leg or by perforating the membranes; this method is freely used, but something approaching 10 to 20 per cent. of the mothers and 65 to 75 per cent. of the fetuses are lost. The fourth method is by dilating bags, such as those of Barnes, Champetier de Ribes, Braun, and Vorhees, or the metal dilators; but he commits Bossi's murderous instrument to collections of relics of a barbarous time. Lastly, he speaks of vaginal and abdominal Caesarean section. Now, the strange thing about Professor Zinke's attitude is that, while he claims that he was the originator of this treatment for placenta praevia, and although he discusses at some length its life-saving possibilities, he admits with frankness that he has never yet treated this condition by opening the uterus. Others have done so, and Pankow has succeeded in delivering eight mothers by this method with the loss of only one fetus. All the mothers recovered. Others have followed this example, but Professor Zinke does not attempt to give anything approaching collected statistics. On theoretical grounds, it would seem that the risks to both mother and child could be reduced to a minimum by such a procedure. But, even if it is, the country practitioner will be hard put to it if he be required to perform a major abdominal or vaginal operation in every case of placenta praevia. It seems, therefore, that there is still room for the discovery of a method of treating which shall be at once simple and efficient.

THE SPIROCHAETES OF RELAPSING FEVER.

Four different kinds of spirochaetes have been found in different types of relapsing fever. The European fever is due to Obermeier's spirochaete; the African fever to a parasite discovered by Ross, Milne, Dutton, and Todd, and named after Dutton; a second African variety to a spirochaete discovered by Koch; and the American variety to a spirochaete called *S. novyi*, after Novy and Knapp, who discovered it. The Obermeier organism does not lend itself readily to cultivation by passage through rats and mice, but monkeys can be infected with it. The other three can be grown in the bodies of rats, mice, and monkeys. H. Noguchi¹ states that all attempts to cultivate these spirochaetes outside the animal body have failed up to the present. His success in respect to the spirochaete of syphilis and *S. pertenuis* incited him to employ the same method with the parasites of relapsing fever. He collected the blood from infected rats or mice two or three days after infection. The blood was withdrawn from the heart by a sterile glass pipette, and was kept fluid by the addition of sodium citrate solution. The mixture was well shaken until a satisfactory suspension was obtained. A portion of rabbit's kidney, removed with aseptic precautions and immersed in sterile ascitic fluid, which must not be too old, forms the culture medium. About 10 drops of the blood suspension is added to the medium, and 15 c.cm. of the ascitic fluid introduced, and sterile paraffin oil is added to one of each pair of tubes. The tubes are then incubated at 37°C. The growth is controlled by examination with the dark field microscope. With *S. obermeieri* and *S. novyi* the maximum increase is usually attained about the eighth day, with *S. duttoni* and *S. kochii* about the ninth day. Shortly after having reached the maximum the parasites show a change, in that the individuals become less active, and may lose their power of motion altogether. Within the course of a few days many degeneration forms are seen. A

¹ *Deut. med. Woch.*, November 21st, 1912.

¹ *Munch. med. Woch.*,

temporary regeneration can be attained by the addition of fresh ascitic fluid. Noguchi has succeeded in subculturing these spirochaetes through four and more generations, inoculating the new culture medium with 0.5 to 1 c.cm. of the old culture, and using as far as possible the same ascitic fluid, provided that the growth has been satisfactory. Koch's spirochaete is the most easily cultivated, and Noguchi has succeeded in keeping one strain going for six months through twenty-nine generations.

INTERNATIONAL COURTESIES.

THE welcome usually accorded to leaders of scientific thought by nations other than their own is one of the pleasant features of modern life, and an agreeable contrast to the feelings engendered by perpetual reference to the ever-increasing preparations for international strife. Whether they be pioneers of modern advance or heroes of bygone scientific triumphs, their names invariably attract an enthusiastic audience when they elect to appear on a foreign stage. We have lately been privileged to hear from his own lips the latest developments of Professor Metelnikoff's labours, but it is not often that a leading position is accorded to a British writer in an important foreign journal. Hence it is with particular pleasure that we note the publication in a recent number of the *Berliner klinische Wochenschrift* of a long article on functional diseases of the arteries from the pen of Sir Lauder Brunton. The subject is one which has engaged his thoughts for many years, but it has not, perhaps, received the amount of general attention its importance would justify. The superficial phenomena of abnormal pulsation in a great artery, the various degrees of morbid flushing of smaller vessels, the vascular disturbance manifest in Graves's disease, and the no less evident contractions resulting in pallor and gangrene, are well known examples of functional disorder, but there remain a large number of conditions which may reasonably be attributed to functional derangement, although not so easily demonstrated. Foremost among these is migraine, a disease by no means uncommon in the medical profession, and one of which Sir Lauder Brunton is able to speak from personal experience, as did Professor Emil Du Bois-Reymond in his turn. A considerable portion of the article which appears in our Berlin contemporary is devoted to the probable causation of the pain and the ocular symptoms which so frequently accompany an acute attack. Spasmodic contraction of the temporal artery was discovered in their own persons by both of the distinguished sufferers, and the almost instant relief afforded when the spasm was overcome by mechanical or medical means was noted in each case. The tendency for the disease to subside as years advance corresponds also to the lessened liability of the arteries to functional disturbance of all kinds. Sir Lauder Brunton's paper covers the whole subject, and may be described as a summary of his long experience, as a physiologist and a physician, of a study to which he has devoted some of the best years of a long life.

AGED AND INFIRM MEMBERS OF APPROVED SOCIETIES.

WE have on several occasions recently called attention to the history of the arrangement which was entered into between the representatives of the British Medical Association and of the friendly societies at the conference held at the Treasury in October, 1911, with regard to attendance on aged and infirm members of those societies. On behalf of the Association it was agreed that the old and disabled members should not be charged any more than insured persons for their medical attendance, although, from a merely business point of view, it is evident that they might well be charged at a much higher rate. It appears, however, that the friendly societies are now trying to evade this obligation, and as this attempt was countenanced by

Mr. Masterman in the speech he made in the House of Commons just before the adjournment (SUPPLEMENT to the BRITISH MEDICAL JOURNAL, February 22nd, p. 199), the British Medical Association has thought well to send a reasoned letter to the National Insurance (Joint) Committee, of which Mr. Masterman is chairman, setting out the facts. This letter will be found in the SUPPLEMENT for this week, p. 238.

HOLIDAY MAKERS AND CONVALESCENTS.

A CONFERENCE on the provision of medical attendance for insured persons temporarily absent from the area in which they usually reside was held at the office of the Insurance Commission for England on March 5th. Mr. J. Smith Whitaker presided, and with him was Mr. Schuster and other members of the Commission. In the invitation to attend the meeting it was indicated that though it was recognized that the question is one which affects doctors working under the Insurance Act, more or less, in every area, it was of special difficulty in its effect on those doctors who practised in holiday resorts and those who practised in the large centres from which the holiday makers are drawn. The medical men present were drawn for the most part from these two areas. After various aspects of the question had been put forward by medical men attending the conference, Mr. Schuster made a statement, in the course of which he said that it was not within the scope of the conference to consider the establishment of a fund to meet such cases from any other source than the general fund now allotted for medical attendance. It seemed to be generally agreed that it would be difficult to devise any method to meet the case which did not provide for the payment of medical men in holiday and health resorts for attendances in accordance with a tariff. It was pointed out that a deduction fixed in relation to the length of absence of holiday makers or convalescents from home might operate very much to the disadvantage of the doctors who were working the Insurance Act in the area in which the insured persons commonly resided and earned their living. It was also pointed out that the position of the holiday maker and the convalescent differed materially, and that not only was more consideration due to the latter, but also to his medical attendant. The Commissioners undertook to consider the views expressed, but the net result of the conference would seem to be that the matter, so far as health and holiday resorts on the one hand, and industrial centres on the other are concerned, could only be settled by a financial adjustment between the two groups.

A CENTENARIAN VETERAN.

By a slip it was said in the article on "Mutiny Veterans," published last week, p. 474-5, that Surgeon-Major Hinton was born three months, instead of two years and three months, before the battle of Waterloo. By a coincidence our correspondent in Adelaide tells us in a private note received this week that Dr. Hinton's friends in South Australia, where he resides, were looking forward to congratulating him on attaining his hundredth year of life this week. We hope that this expectation may have been fulfilled. If so, Dr. Hinton is probably the oldest living member of the British profession, and it may be doubted whether the profession in any other nation can boast a centenarian.

THE Council of the Royal Society has recommended fifteen persons for election as Fellows. Among them are Dr. William Bulloch, Professor of Bacteriology in the University of London, and Bacteriologist to the London Hospital; Dr. T. R. Elliott, Lecturer on Practical Medicine at University College, London; and Professor Arthur Keith, Conservator of the Museum of the Royal College of Surgeons of England.

Ireland.

(FROM OUR SPECIAL CORRESPONDENTS.)

RESIGNATION OF MEDICAL STAFF OF NEWCASTLE
SANATORIUM.

A VERY unfortunate condition of affairs has arisen at the Royal National Hospital for Consumption for Ireland, which was established near Newcastle, co. Wicklow, in 1896, for the treatment of poor patients suffering from pulmonary consumption in its incipient or early stage. The number of beds has been gradually increased from 24 to over 100. The number of patients treated in 1911 was over 400. The honorary medical staff consists of seven consulting physicians representing the clinical hospitals in Dublin and two visiting physicians who are also physicians to Dublin clinical hospitals; there are in addition two resident medical officers.

In April, 1911, the two visiting physicians were asked to attend a meeting of the board to express their opinion on a proposal to invite an outside medical man to try a special treatment of tuberculosis at the hospital and to place two wards at his disposal for this purpose. The two visiting physicians and one of the consulting physicians, the only medical member of the board present, expressed disapproval of the project, and it was dropped. Six weeks later the board invited the consulting and visiting staff and the resident medical staff to consider whether it was desirable to adopt any special treatment at the hospital, including that referred to at the previous meeting. The whole staff expressed the unanimous opinion that medical treatment was a matter solely for the medical staff, and that in any case it was undesirable, in the interests of the hospital, that methods unproved by scientific research should be adopted.

No further action was taken by the board at the time, but last December the visiting physicians received a letter informing them that the medical man above referred to had been appointed as an additional physician. The visiting physicians brought the letter before a meeting of the honorary medical staff, and the consulting and visiting staff thereupon addressed a letter to the board recapitulating the above facts and resigning their position on the staff. They felt that a slight had been put upon them by the appointment of the additional visiting physician without consultation with the medical staff, and considered that the action of the board made it plain that it was resolved, whenever it pleased, to dictate the medical treatment in the hospital. The staff consented, for the sake of the hospital, to withhold their resignations till the board had had a further opportunity of discussing the matter, and on the invitation of the board a friendly conference was held between four members of the board and four members of the medical staff. As a result, it appeared to be the unanimous opinion that the differences between the board and the staff could, and should, be removed on the following conditions: (a) A return to the *status quo ante* December, 1912; (b) that the medical staff should for the future be represented on the board by at least two members to be chosen annually by the staff. It was also suggested by the representatives of the board at the conference that in the event of the board assenting to these conditions the medical staff would be prepared to accept the medical man who had been appointed an additional visiting physician as pathologist to the hospital. The medical staff subsequently wrote to the board approving the conditions (a) and (b), and accepting the suggestion with regard to the change in the nature of the appointment of the additional physician.

On February 21st, however, the medical staff received a letter informing them that the board would not retreat from the position it had taken up in its letter of December, 1912, and that it would not carry out the conditions which had seemed to have the approval of the conference. Accordingly the whole honorary medical staff have finally resigned their connexion with the hospital. The following are the names of the honorary medical staff:

Consulting Physicians.—Wallace Beatty, M.D., F.R.C.P.I., Physician to the Adelaide Hospital; Michael F. Cox, F.C.,

M.D., F.R.C.P.I., Physician to St. Vincent's Hospital; J. Magee Finny, M.D., ex-President Royal College of Physicians, Ireland, Consulting Physician to Sir Patrick Dun's Hospital; John W. Moore, M.D., ex-President Royal College of Physicians, Ireland, Physician to H.M. the King in Ireland, Senior Physician to the Meath Hospital; Joseph O'Carroll, M.D., F.R.C.P.I., Physician to the Richmond Hospital; William J. Thompson, M.D., F.R.C.P.I., Registrar-General for Ireland. *Consulting Surgeon.*—William Ireland De Courcy Wheeler, M.D., F.R.C.S.I., Surgeon to Mercer's Hospital.

Visiting Physicians.—Alfred R. Parsons, M.D., F.R.C.P.I., Physician to the Royal City of Dublin Hospital; James B. Coleman, M.D., F.R.C.P.I., Physician to the Richmond Hospital.

CERTIFICATION OF DEATH AND PREMATURE BURIAL.

A meeting was held recently in a committee room of the Royal College of Physicians, Dublin, in order to consider the present system of death certification. The chair was taken by Sir David Harrel, and several Fellows of the Royal College of Physicians and Surgeons were present. Mr. B. R. T. Balfour, D.L., drew attention to a bill which had been introduced in the House of Commons under the name of the Deaths and Burials Bill, and read the memorandum explaining the objects of the bill, which were to provide greater precautions against (1) secret crime, and (2) premature burial. He quoted from the last report of the Registrar-General of Ireland, showing that 22 per cent. of the deaths during the previous three months had not been certified. It was resolved that Mr. Balfour be requested to send a copy of the bill to the Royal College of Physicians and the Royal College of Surgeons, asking the opinion of the Royal Colleges on it.

THE BRAIN OF PRIMITIVE MAN.

On February 23rd Professor G. Elliot Smith, in a lecture to the Royal Dublin Society on "The Brain of Primitive Man," said that in discussing the subject of the primitive characteristics of the earliest forms of the human brain thoughts would naturally turn to the great loss which investigators of that class had suffered during the last few years by the death of the man who laid the foundations upon which future investigators would build their knowledge of this subject. He referred, of course, to Professor Cunningham, who was for so many years the Professor of Anatomy in Trinity College, Dublin. The great difficulty in this study was to obtain material. He exhibited a number of slides showing details of the brain development of various types of the human race. After illustrating the difference between the primitive human brain and the highest simian type, he traced the development of the monkey brain from the most elementary mammalian forms. The brain developed under the stress of circumstances, which had made it necessary to use arms, and that led incidentally to the perfect erect attitude and to the adoption of speech. These things did not come first, but followed the expansion of the brain.

ST. PATRICK'S NURSES' HOME.

At the annual public meeting in connexion with St. Patrick's Nurses' Home, Dublin, the Dean of St. Patrick's presided, and the Countess of Aberdeen was present. According to the report, the number of visits paid during the year had increased and amounted to 58,545, and 2,986 new cases had been undertaken, which, with the cases remaining on the books at the end of the previous year, made a total of 3,388. Up to the present, the National Insurance Act had been a source of loss of income to the home, but it was hoped that an arrangement could be made with the societies by which they might employ the nurses so that the home might gain some pecuniary benefit from the nursing of insured persons. Dr. Ninian Falkiner spoke from experience of the benefit to the poor of the district nursing system. It was established in 1877, and in 1889 the dispensary doctors began to send cases to the nurses. The statistics of the Dublin death-rate showed that the district nurses had something to do with the greater reduction of the rate during the period from 1889 to 1912 than during the preceding period. Another speaker pointed out that there were three points in favour of the institution—first, the nurses taught sanitation to the poor whom they visited; secondly, the system prevented the homes of the poor from being broken up; and, thirdly, the sick poor had in their homes some of the care and attention that they received in hospitals.

TYPHUS FEVER IN DUBLIN.

Early last week a notice appeared in the daily press that there was an outbreak of typhus fever in the north side of Dublin. But since then Dr. Russell, assistant medical superintendent officer of health, stated that there was no need for alarm or fear of an epidemic. There had been no case, he said, since January 25th, when there were 5 cases in a poor slum quarter at Summerhill. There had been no death, and the precautions then taken were so effective that no case had occurred there since. Three typhus patients in the North Dublin Union had been removed to the Hardwicke Hospital.

OVERCROWDING AND ENTERIC FEVER IN AN ASYLUM.

The resident medical superintendent of the Ballinascloe Asylum informed the Committee of Management at its last meeting that the institution was overcrowded to the extent of 247 patients. There were, he said, three ways by which a remedy might be found—to take over a workhouse as an auxiliary asylum; to board out a certain number of the lunatics in a workhouse and pay a certain sum for them; or erect new buildings. The committee decided to make inquiries as to any local workhouse that might be available. At the same meeting the medical superintendent reported that there had been 15 cases of enteric fever in the institution, and that 1 death had occurred during the month. In such circumstances it would seem that the overcrowding calls for immediate remedy.

MEDICAL CERTIFICATES.

At a special meeting of the doctors of North Tipperary, held in Roserea to consider the question of medical certificates in connexion with the working of the Insurance Act, the following resolutions were passed unanimously:

1. That we, the North Tipperary Medical Committee, comprising every medical man practising in the county, seeing that the health societies are seeking to obtain certificates of illness from clergymen, magistrates, and others, in order to save the expense of medical certificates, for which provision in money has been made by Parliament, hereby direct our Honorary Secretary to send notice to all health societies having existence in North Tipperary that we will withdraw our offer of granting medical certificates at the small charge of 2s. 6d. per certificate (payable by the societies, not by the insured persons), unless medical certificates are required in all cases of illness attended by medical men, and will in future charge a full fee of £1 1s. if only called on to certify where the present methods of the societies break down.
2. That we tender our thanks to the clergy and magistrates generally of the county who, with so few exceptions, have refused to interfere with our patients or to sign certificates for them in medical matters.

At a meeting of the medical practitioners of co. Wexford, held recently at Enniscorthy, the following resolution was passed:

That we give notice to the various societies that the medical men of co. Wexford will not give any certificates under the National Insurance Act pending the arrangement of a reasonable fee with the Insurance Commission.

ROYAL HOSPITAL FOR INCURABLES, DUBLIN.

The Royal Hospital for Incurables in Dublin has been in existence since 1743. It is non-sectarian and non-political, and is supported by voluntary contributions. The patients, who come from all parts of Ireland, pay nothing. There were 209 patients in the hospital at the commencement of the year. During the year 158 candidates applied for admission, all duly certified as incurable and in poor and necessitous circumstances. Of these only 47 were successful in obtaining admission, and the Managing Committee has decided to erect two new wings, increasing the number of beds from 213 to 248. It is to be hoped that the charitable public will respond in such a manner as to allow this much-needed extension to be carried into effect without delay.

WORK DONE BY NURSES IN IRELAND.

Some idea of the amount of work done by nurses for the poor in Ireland may be gained from recent reports. A report read at the annual meeting of the Sligo District Nursing Association showed that 720 cases had been attended by the nurse during the year, and 5,696 visits paid. The total number of hours she was on duty during the year was 1,937. At the last monthly meeting of the

St. Patrick's Nurses' Home it was reported that 531 cases were nursed, 233 new cases undertaken, and 4,531 visits paid during the month.

PRESENTATION TO DR. GEORGE SIGERSON.

Last week, in the rooms of the National Literary Society, Dublin, Dr. George Sigerson was presented with a portrait of himself painted by Mr. Joseph Lavery. Dr. Sigerson has been President of the National Literary Society since its foundation twenty years ago. The Right Hon. M. F. Cox, M.D., performed the ceremony of unveiling the portrait, and made a suitable reference to Dr. Sigerson's work and career in Dublin.

Scotland.

[FROM OUR SPECIAL CORRESPONDENTS.]

MEDICAL INSPECTION IN SCHOOLS IN SCOTLAND.

On March 1st appeared the first report on the medical inspection of school children in Scotland: it contains about a hundred pages, and has been drawn up by Dr. Leslie Mackenzie, medical member of the Local Government Board. The report is founded largely on the information furnished by the school medical officers for the year 1911. There are a number of matters which make Dr. Mackenzie's report most interesting. For instance, it is now proved beyond a doubt that the gloomy forecast based on the investigations made by the Royal Commission on Physical Training (Scotland) was no exaggerated alarmist statement, but sober inference from facts. Medical inspection has not only revealed actual disease, but has also shown that in thousands of cases diseased conditions have been permitted to develop which, if taken in hand at earlier stages, could have been prevented. Thus, through inspection, the opportunities of prevention have clearly been pointed out; and in many cases the revelation of the facts has been followed by treatment, although much still remains to be done. The service of nurses which has been set up in some places should be extended, the following up of cases should be more complete, and the necessity for school clinics has become still more evident. Meanwhile, the teaching of hygiene goes on, and has already done much good. It can hardly be doubted that in a few years school boards will be doing much more than educating the children in the ordinary sense of the word; they will also be playing a powerful part in securing the health and strength of the future generation of citizens.

INDIAN STUDENTS AT EDINBURGH UNIVERSITY.

On February 25th the rooms of the Edinburgh Indian Association at 11, George Square, were formally opened by Principal Sir William Turner. The association was founded as far back as 1883, and in 1902 efforts began to be made to establish a club for Indian students. Some money was obtained, and the amount was increased by the Indian fair held in 1907 and in other ways until a total of over £5,000 was reached. About three years ago the present house, adjacent to the medical buildings, was got at a reduced rent from Dr. Barbour. There are three stories and a basement, with reading, writing, smoking, and billiard rooms, and a bedroom for any new-comer who has not found lodgings. Sir William Turner referred to the fact that there are more than two hundred Indian students attending the university, and to the need which existed, therefore, for some such building as that which he was declaring open. The Indian students formed a family in the university; they were also citizens of a metropolis. The Principal was then honoured by being garlanded in Indian fashion by the president of the association, Mr. B. P. B. Naidu.

ROYAL PHYSICAL SOCIETY.

At a meeting of the Royal Physical Society on February 24th Dr. W. E. Agar brought forward facts bearing upon the transmission of environmental effects. If one of the *Cladocera*, a group of crustacea including the water-fleas, was placed under certain abnormal conditions changes took place in its structural features, and if it were removed again to normal conditions its offspring exhibited the same

peculiarities as it had acquired, and even the offspring's offspring showed them, although in a much slighter degree. The next generation, however, showed a marked reaction in the opposite direction. It was suggested that the apparent "inheritance" of the acquired character was due really to the passive transference of a toxin-like body and the later production of an antitoxin. Principal J. Yule Mackay, of Dundee, at the same meeting exhibited some ancient Peruvian skulls showing curious deformities which he judged to be due to the use of the portable cradle by the aboriginal tribes.

ROYAL VICTORIA HOSPITAL FOR CONSUMPTION.

The report presented to the annual meeting of the Royal Victoria Hospital for Consumption, Edinburgh, when the President (Sir Alexander Christison) was in the chair, pointed out that

It would be a great mistake to suppose that, because of the provisions of the Insurance Act, everything has been accomplished in relation to the prevention and treatment of the disease, and that the need for voluntary effort has ceased. Contrariwise, the claims of the consumptive poor are only beginning to be realized and understood. The treatment of insured persons affected by tuberculosis—even if we include the treatment of their dependants—covers a small portion of the field only. This is little more than the fringe of the subject. The problem of prevention before the nation is immensely wider. The effective solution will only be achieved by a close and harmonious co-operation between all the agencies, official and voluntary, which can be pressed into a concerted, intelligent service.

Up to date, 2,085 resident patients had been under treatment in the hospital. To this number must be added 329 patients who had attended the hospital daily as "visitants." The farm colony was proving successful from an economical point of view, and since the date of opening to the end of the period dealt with in the report, 50 patients had been transferred from the hospital to the colony. Up to March 31st, 1912, 23,118 individual cases had received treatment at the dispensary. Sir Robert W. Philip stated, in reply to a question, that the hospital was in communication with the Public Health Committee of the city and with the Insurance Committee, and a conference would probably take place at an early date.

WOMEN'S FIRST AID CORPS INSPECTION.

The annual inspection of the Scottish Women's First Aid Corps took place on February 26th, in the hall of the 6th Royal Scots, Edinburgh. Several members of the medical profession were present, including Colonel Arnott, Dr. Boyd Jamieson, Dr. Morrison McIntosh, Dr. Cattanach, and others. About eighty members of the corps were on parade; stretcher drill, semaphore signalling with flags, and the first aid to wounded soldiers (impersonated by boy scouts and other school-boys) were tested. The inspecting officer, Sir Joseph Fayrer, Bart., M.D., K.C.S.I. (honorary surgeon of the corps), expressed his satisfaction with the inspection and congratulated the corps and its commandant (Mrs. Maxtone Graham). He said that in first-aid work simplicity and common sense must go together. A little knowledge was a dangerous thing, it had been stated; but in first-aid work a little knowledge simply applied with common sense might be, and often had been, the means of saving valuable lives.

England and Wales.

[FROM OUR SPECIAL CORRESPONDENTS.]

LONDON.

TUBERCULOSIS TREATMENT IN MIDDLESEX.

The Local Government Board has signified its approval of a scheme prepared by the Middlesex County Council for the treatment of tuberculosis. The Public Health Committee reported to the Council on February 27th that the sum available for general tuberculosis treatment having been reduced in consequence of the decision of the Government to earmark 6d. per insured person in respect of remuneration to general practitioners for domiciliary treatment, only 350 instead of 450 beds could be provided in hospitals and sanatoriums. The

Council should let it be clearly understood that no further beds would be provided until an increased grant from the Exchequer was assured.

The Council approved this report, and authorized the Public Health Committee to appoint five tuberculosis officers at a salary of £500 a year each, and two assistant tuberculosis officers at £300 a year each, and to make arrangements for obtaining premises in various parts of the county suitable for dispensaries.

LONDON COUNTY COUNCIL.

Further Provision for Tuberculosis Treatment.

The London Insurance Committee having asked that accommodation may be found for 200 tuberculous cases, in addition to the 300 already provided for at the Downs Sanatorium, the Public Health Committee reported to the London County Council on March 4th that arrangements had been made with the Metropolitan Asylums Board for the reception of 100 women patients and 100 observation and educational cases at the Northern Hospital, Winchmore Hill. The first patients were received there on March 3rd.

Lunacy Statistics.

The Asylums Committee reported that a summary of the returns furnished by the clerks to the London boards of guardians showed that on January 1st, 1913, the total number of lunatics under certificate in London county asylums or in other public asylums under contract with the boards of guardians, and of lunatics in workhouses or with relatives or friends was 28,638. This figure, compared with a total of 28,011 on January 1st, 1912, gave an increase of 627, the largest recorded since 1909. The last previous increase which exceeded this figure was 767 on January 1st, 1905. The average annual increase for the last twenty-three years had been 533. Of the total of 28,638, the number of lunatics for whom the county of London was responsible to find accommodation was 20,931. This gave an increase of 502 over the corresponding figure for the previous year, and was the largest increase since 1905.

Effects of Changes in Poor Law Administration.

The census of homeless persons taken every year in London, on a night in February, this year showed a total of 649, which was fewer by 554 than that for 1912, and the lowest recorded. This was accompanied by a fall of 973 in the number of inmates of common lodging houses. The Public Health Committee, reporting to the London County Council on the matter on March 4th, expressed the opinion that this remarkable result pointed to the fact that, in addition to changes in the administration of the Poor Law, there were other unrecognized forces exercising a determining influence on those sections of the community. The committee noted that although the Metropolitan Casual Paupers Order, 1911, had brought about a considerable reduction in the number of persons resorting to casual wards in London, there had not been any increase in the number of vagrants in casual wards in areas adjoining the county of London.

BIRMINGHAM.

THE BIRMINGHAM HEALTH INSURANCE PHARMACOPŒIA.

A serious item in the large amount of clerical work which must be done by medical practitioners under the Insurance Act is the writing of a prescription on every occasion when medicine is ordered, even if only a repetition of what has been taken before, so that the insured person may be free to obtain the medicine from any pharmacist on the panel. Obviously, this work can be much lightened by greatly increasing the number of preparations of various sorts that can be ordered by a single name instead of by writing the full formula, and for this a comprehensive formulary analogous to the pharmacopœias of the various hospitals is required. Since the amount of public money available for drugs under the Act is very limited, another useful object to be served by such formularies is the substitution of less expensive for more expensive preparations wherever the therapeutical effect is not sacrificed by so doing, and the reduction to a minimum of expensive ingredients, like alcohol, when only used as solvents.

The formulary of the *British Pharmaceutical Codex* contains a large number of prescriptions for mixtures, etc., but it was compiled before the passing of the Act, and evidently without any special regard to cost of ingredients. At present, therefore, we see the production of various local formularies which may perhaps some day be merged in a national one. We have recently received from Dr. E. Osborne, Honorary Secretary of the Birmingham Medical Committee, a copy of the *Birmingham Health Insurance Pharmacopoeia*, 1913 (price 2s. 6d.), which has been compiled by the Medical Committee with the co-operation of the Midland Pharmaceutical Committee. It contains about a hundred and twenty formulæ for mixtures, pills, lotions, etc., representing all the most frequently required combinations; some of these are *Codex* formulæ, and are not given in full but indicated by the letters *B.P.C.*; other formulæ are given fully. With a view to further reducing the clerical work in prescribing every formula is numbered, so that it may be ordered by number instead of by name if desired. The reduction of cost does not appear to have been closely studied in some cases, spirit of chloroform being frequently ordered where the equivalent of chloroform water might be used, and tinctures being rather much in evidence. A note at the beginning invites suggestions for alterations and additions for the next edition; it is, of course, inevitable that a first issue of such a formulary should be in some degree tentative, but there is no doubt that the Birmingham Medical Committee has produced a very useful little book.

INFANTS' HEALTH SOCIETY.

The fifth annual report of the Birmingham Infants' Health Society and School of Mothercraft states that 429 women with infants attended the consultations. During 1912 there were 2,373 attendances, as against 2,249 in 1911, 1,296 in 1910, 1,021 in 1909, and 850 in 1908. The average attendance at each consultation in 1912 was over 50. Of the 554 infants registered 22 were lost sight of and 13 died before reaching the age of 12 months. Of the 342 newly-registered in 1912, 240 (or 70.1 per cent.) were being wholly fed on the breast at the time of registration. In 1908 the percentage was 63.3, in 1909 it was 68.8, in 1910 it was 66.8, and in 1911 it was 63.1. In 1912 the average weight of the breast-fed infants at 12 months old was 19 lb., and of the bottle-fed infants only 17 lb. 14 oz. The average weight of all infants, irrespective of feeding, was 18 lb. 11½ oz. This weight is a marked advance on that of preceding years, and it is probable that the boom in work and wages in the past twelve months has been reacting on the infants. Probably the somewhat higher percentage of breast-feeding during the past year, and the efforts of the society to produce a greater care in feeding and a higher standard of motherhood, have had some substantial share in bringing about the result.

BRISTOL.

THE ROYAL INFIRMARY.

THE annual meeting of the subscribers to the Royal Infirmary was held on February 25th, under the presidency of Sir George White, who said that the past year had been very memorable for the institution because of the great increase in the scope of work and the addition of the new wing and alteration to the nurses' home, and, further, by a royal visit. In respect to financial matters the year had been most gratifying, for the list of subscribers had increased to 3,587, and subscriptions by nearly £300. The only item that showed a decrease was the contributions from the employees, which had diminished by about £100, at which he expressed surprise. To provide for the new buildings and the increased accommodation for nurses very large sums had been drawn from investments, and he hoped that the public would respond to the appeal for funds. The total ordinary expenditure exceeded the ordinary income by a sum of from £4,000 to £5,000. The committee in conference with the honorary staff decided not to follow the example of those hospitals which had framed new rules with regard to insured persons, and the doors of the institution would be open as before to all. During the past year the number of in-patients was

5,049, and out-patients 53,923. The usual votes of thanks were passed. Mr. J. Paul Bush, C.M.G., having retired from the active staff after thirty-seven years' service, was elected an honorary consulting surgeon.

On February 24th Mr. Bush was entertained by his old dressers and residents at St. Stephen's Restaurant at dinner, and presented with a handsome piece of plate.

Special Correspondence.

PARIS.

Causes of Arterio-sclerosis.—Arsenic and Treatment of Chorea.—Radium as a Therapeutic Agent.

At a recent meeting of the Hospitals Medical Society Dr. Pissavy discussed the etiology of arterio-sclerosis in the light of the history of 400 cases. Only 5 per cent. of the total cases occurred between the ages of 20 and 40. The disorder was more frequent in men than in women—in the ratio of 6 men to 1 woman. Among the etiological factors he cited syphilis, alcoholism, plumbism, malaria, and tobacco poisoning; together they accounted for 89 per cent. of all cases of arterio-sclerosis. Syphilis accounts for only 13 per cent., and Dr. Pissavy believed that the importance of syphilis as the prime causal factor of arterio-sclerosis had been greatly over-estimated.

At the same meeting Dr. Triboulet discussed the use of arsenic in the treatment of chorea in children. He believed that it was an empirical remedy, and reported 350 cases of chorea, 335 of which had been treated successfully by hygiene and rest without the administration of any drug. Arsenic, even in small doses, might give rise to toxic symptoms, and thus tend rather to delay than to hasten the cure. In Triboulet's opinion chorea was best treated without arsenic, as patients usually recovered without the aid of drugs.

Professor Dominici, in a recent communication to the Academy of Medicine on the therapeutic value of radium in various tumours, thought that it was most useful as a curative agent in deep-seated angiomata and in superficial cancer. He had noted complete clinical cure of some deep-seated cancers of the parotid, neck, and uterus maintained after three to four years.

Correspondence.

DIVISIONS AND INSURANCE AREAS.

SIR, In last week's SUPPLEMENT (p. 219) you published a letter of mine in which I referred to the necessity for a rearrangement of our Divisions and Branches, and I suggested that the only practicable plan was to make them coterminous with the areas of the Insurance Committees. Our existing Branches grew up around the towns where corporate medical life was most active; as medico-political work became more necessary, it was found that the constitution of the Association was not adapted to the work, and among other reforms the Branches were broken up into Divisions; these were planned largely with a view to convenience of meeting, but of late years our political work has brought us more and more into contact or conflict with those local authorities that in one way or another deal with affairs of public health, and these authorities represent the counties or county boroughs. It has been evident for some time that our Divisions are not convenient for this work, and to meet the difficulty joint committees of Divisions have often had to be formed.

The advent of the Insurance Act made it imperative to form Provisional Medical Committees for the areas of the Insurance Committees, and local medical unions were in many instances formed for these districts, but the machinery of the Association was not easily adapted to this arrangement, and in many instances the recognized Divisions and Branches have, as far as the Insurance Act is concerned, done practically nothing. In considering any scheme we must remember that convenience of meeting is very different from what it was even thirteen years ago—in the country districts motor cars have made medical

men to a large extent independent of train services, and the latter, too, are much improved of late years.

As to the work of the Divisions, it is important that the members of any one Division should have a common interest in it, and the conditions of practice and the requirements of medical men in the large towns are so different from those of men living in the country areas that, apart from other considerations, it seems at once evident that the natural divisions for political work should be counties and county boroughs; a short experience has shown that these are the most useful, and that the corresponding medical unions are the most effective organizations. It is, for obvious reasons, most essential that all these local organizations should be worked together under the British Medical Association, and I would suggest that our Divisions and Branches be re-arranged, without any consideration of existing Divisions, so as to correspond to the insurance districts. Some of these districts will naturally form complete Branches, but in the great majority of cases insurance areas may conveniently be the areas for Divisions, and the county borough Divisions could combine with their respective county Divisions to form Branches, so that they would not be divorced from one another. This is important, on account of the scientific work, for the best conduct of which it is almost essential that country and town should co-operate—in fact, in some districts, in order that scientific work might be advanced or, at any rate, not interfered with, it might be necessary for special arrangements to be made, but there need be no difficulty about this.

The exact grouping of Divisions can only be considered by the appropriate committee and in committee, but whatever is done I hope it will be begun soon and in earnest. With a better organization, a more convenient arrangement of our working units, I believe that our strength and usefulness would be greatly increased, and if the various local medical unions which would practically constitute our Divisions so desired they could form themselves into trade unions, and so, if it should be generally desired, bring about by an easy process the change that many consider to be so essential to our constitution.—I am, etc.,

Bradford-on-Avon, March 2nd.

CHARLES FLEMMING.

THE ETIOLOGY OF PUERPERAL FEVER.

SIR,—I was much gratified to read your impartial criticism of my book, *Statistics of Puerperal Fever and Allied Diseases*, which appeared on December 14th, 1912. Your reviewer evidently studied carefully my figures, and treated them on their merits, and his criticisms prove him to be master of his subject, and show his appreciation of the difficulties involved in any attempt to obtain reliable data upon which to base conclusions liable to be affected by many conflicting conditions. His criticism was chiefly directed against my deductions from the effect of the coal strike last March upon the statistics of puerperal notifications for that month, and I welcome his criticism, since it gives me an opportunity of stating the exact figures upon which my summary was based, figures withheld lest I might overburden the text with details, although a detailed analysis accentuates their significance, a significance I am anxious that your readers should have an opportunity of appreciating.

In brief, I contend (a) that puerperal fever is caused generally by septic material conveyed through the medium of those conducting the labour. (b) That this septic material is as often conveyed by medical practitioners as by midwives. (c) That the source of the septic material is septic wounds, which general practitioners in industrial districts are called upon to dress almost every day. The most common cause of septic wounds is accidental wounds, and it follows therefore that where accidents abound there also will be found septic wounds in abundance, and therefore puerperal fever.

I venture to think most impartial critics will admit that my statistics go far to prove my thesis, and I must refer them to the book for confirmation of this assertion.

Meantime let us confine ourselves to the point raised by your reviewer—namely, the significance of the figures in reference to the coal strike. He writes:

Thus he finds that, whereas the average number of cases of puerperal fever notified in the month of March for over a period of ten years was 4, only 2 such cases were notified in that month of the present year. This is a result Dr. Geddes is disposed to attribute to the diminution of accidents consequent upon the coal strike. The attribution may be correct, but if in a series of ten months 40 cases of disease occur, and if the distribution in months of the series be a random one, the chance is about 1 in 5 that we shall find 2 or less cases in a month.

Let me say at once that if this was the only significant factor brought out by the figures for the month of March your reviewer's criticism would be fatal to my thesis. But it constitutes only an insignificant straw which indicates the direction in which the wind blows. The significance of the whole wind current will be appreciated from the following table, which calls for explanation. After reading your review and referring to the original documents upon which my summary was based, I thought they were capable of being misconstrued, and appealed to Dr. Sergeant for enlightenment, and discovered that the figures for March only included cases notified, while those for April included cases notified and also cases that had died although not notified. This discovery explains the figures shown in brackets, and they represent the corrected figures after including fatal cases not notified, the existence of which was only ascertained by reference to the records of the registrars of deaths. My insistence on this ugly feature of puerperal notification shocked one of my reviewers. A perusal of the table fully justifies my censure.

I refer the reader to columns 11 and 12. Notice that the figures for 1912 in mining districts are the only figures below the average for the ten years. In all the other districts the figures in column 12 are equal to or above the average. This peculiarity is even more apparent in column 14, where the total for the two months of 1912 are compared with the figures for the same two months for the previous ten years. The total figures for all the districts reach the average for the ten years, and the figures for mining districts are the only figures below the average. I need not labour the point.

Now, what theory other than the one advanced by me will explain this coincidence? If my critics will not admit my deductions, I may reasonably challenge them to suggest an alternative explanation that will explain the facts. Your reviewer suggests that "the age constitution of the married population may vary considerably, and it is not impossible that the age of a parturient is

a factor of some importance in relation to the etiology of puerperal fever." I have been unable to find any authority who suggests age as a factor in the causation of puerperal sepsis. If your reviewer will indicate at what age a parturient is liable to become infected I will gladly investigate the point. I intend to pursue my research, and will welcome the co-operation of any one interested in the subject. Being a general practitioner myself, I am in a position to appreciate the difficulties under which we labour, and I am convinced we must be held responsible for the deplorable and avoidable mortality from this disease.

I chose Lancashire as my field, being familiar with the county, and I have embodied in the appendix the results of my labours in the classification of registration districts and corresponding sanitary areas, which will enable the merest tyro to test the accuracy of my figures for each district.

My book was written as an appeal to my fellow-practitioners, who I confidently hope will respond, each in the county or district with which he is familiar, and I feel sure he will be amply rewarded.

No single individual could do justice to the statistics of every district in every county of Great Britain in the same manner as I arranged Lancashire, but from the knowledge gained by a cursory examination of the districts outside Lancashire, including several Scottish and Welsh counties and boroughs, I feel certain they could all show similar results to those obtained by a classification of the districts arranged in the same classes as those in Lancashire. Derbyshire, for example, should prove a fertile field for research, and I shall be delighted to proffer any assistance in my power to any one inclined to undertake the task.

I would refer the reader to your advertisement column, page 6, for information as to the scope of the book and the press notices.—I am, etc.,

Heywood, Lancs., Feb. 24th.

GEORGE GEDDES, M.D.

THE TEMPERATURE IN CHILDREN OF SCHOOL AGE.

SIR,—In the report, for 1911, of the Chief Medical Officer to the Board of Education, on p. 53, a reference occurs to an investigation of mine into the temperatures of school children. Sir George Newman expresses the hope that other investigations will be made on the same lines. He quotes my statement that "the maximum percentage is that of children exhibiting a temperature of 100°, . . . and 55.5 per cent. have temperatures not under 99.6°."

In your issue for February 8th Mr. E. C. Hoar¹ states that "whenever continued fever occurs we may be almost certain that an infective process is at work." The fever I described is a condition which I am now showing persists over years.² Hence it would appear that Sir George Newman is outlining medical investigations of considerable importance.

But in order that the results of such investigations may be comparable, and accurate, care must be taken in the technique, and the methods used must be identical. One investigation has already been made on dissimilar lines, with dissimilar results.

The popular idea that the "half-minute" thermometer will record, in two or three minutes, the body temperature, when placed in the mouth, is a delusion. If the mouth has not been kept shut, the temperature of the interior of the mouth is not the temperature of the body, but less. If the room is cold, and the child's cheeks thin, there is so much heat lost through the cheeks that even keeping the thermometer *in situ* for fifteen minutes may not give a correct result.

I much hope that other school inspectors will follow Sir George Newman's suggestion, and I therefore venture to give the lines on which we have worked:

1. The temperature of the room in which the temperatures are taken must be not less than 56° F., preferably about 60° F.
2. The thermometer should be placed in the mouth, with the bulb under the tongue, as far back in the mouth as possible. The end of the thermometer which is not in the mouth should point upwards.

¹ Vaccines and Fever.

² Details and mathematical proofs will shortly appear in an Eugenics Laboratory memoir.

3. The thermometer should remain in position at least ten minutes.

4. The children should be watched to see that they keep the lips closed.

5. The observations should be made between the hours of 10 a.m. and 4 p.m., and should not be within half an hour after a meal, nor immediately after exercise.

6. The thermometer must be Kew-certified.—I am, etc.,
Colwall, Malvern, Feb. 15th. MARY HAMILTON WILLIAMS.

ACUTE PNEUMONIA DURING TREATMENT WITH ARSENIC.

SIR,—Dr. Parkes Weber's paper is very valuable in that it draws attention to the effect of arsenic on the respiratory tract.

For some years I have made it a rule to stop arsenical treatment as soon as there is evidence of respiratory catarrh. Sooner or later, generally the former, a patient under treatment with arsenic begins to cough, and expectorates a gelatinous mucus.

I believe this symptom, in the majority of cases, precedes neuritis and herpes. It is a warning signal. And whether arsenic is being used as a diagnostic aid in lymphadenoma, or for the treatment of any of the un-ravelled diseases, I am at present persuaded that the onset of respiratory catarrh is the time to stop the administration of arsenic. The good to be derived from it has by this time been obtained, and persistence in its use, without a pause, is to court danger.

I have found no special mention in textbooks of the effect of arsenic on the deeper parts of the respiratory tract—the bronchial tubes and possibly the alveoli—(I may not have read wide enough) and Dr. Parkes Weber has done a service in reading out to us a disregarded page of the book of clinical medicine.—I am, etc.,

S. M. HEBBLETHWAITE, M.D. LOND., M.R.C.P.
Cheltenham, Feb. 18th.

THE AFTER-EFFECTS OF GASTRO-ENTEROSTOMY.

SIR,—The report of the discussion on the after-effects of gastro-enterostomy, at the Surgical Section of the Royal Society of Medicine, in your issue of February 22nd, p. 392, and the paper by Mr. A. W. Bourne in that of March 1st, p. 438, give cause for serious inquiry into this subject.

These communications tend to shake the confidence of the average surgeon and the profession generally in the efficacy of the operation of gastro-enterostomy, and I do not think they should be allowed to pass without comment.

During the past fortnight I have communicated with all patients on whom gastro-enterostomy was performed during the year 1909 and during the past twelve months, with the exception of malignant cases and, of course, of those who died immediately after operation. Previous to 1909 I consider that my operative procedure in these cases was imperfect, hence I think it would serve no good purpose to go back further than that year, but the cases done in 1909 may reasonably enough be looked upon as providing "late" results, while those of the last twelve months provide "immediate" effects. Mr. Bourne's statistics must, of course, be judged from the same standpoint, but at the same time it does not appear from his paper that the technique pursued at St. Mary's Hospital has been altered since 1910. I communicated with 61 patients and received replies from 53. Six of the remaining 8 had, in the language of the Post Office, "gone and left no address." Of the 53 remaining, 50 declared themselves to be absolutely free from symptoms which had existed previous to operation, and, further, that none of the symptoms detailed by Dr. Hertz, who introduced the discussion at the Royal Society of Medicine, were present. Of the 3 cases who had complaints, the operation in 1 was done in 1909. This patient states that, while she is relieved of her stomach symptoms, she has a discharge from the bowel and a swelling in the left iliac region. She is known to be an alcoholic. So far as I can make out her symptoms are due to meso-sigmoid adhesions and accompanying colitis. Of the 2 cases in 1912, 1 complains of occasional "bilious attacks," but is otherwise well, and the other, who had possibly carcinomatous ulcer which could not be excised, states abruptly that he is not improved and suffers from "pain in the stomach, swelling, cough." I

This gives 5.7 per cent. which are not entirely relieved. Such after-results can surely be due only to the technique of the operative procedure adopted!

In a paper published in the *Lancet* (December 3rd, 1910, p. 1610) I drew attention to the principles on which I considered a proper operative procedure should be based, and the only modification of that procedure which I now adopt is the excision of every ulcer, when practicable. To recapitulate shortly, I consider that the following are the most important points to attend to: (a) The position; and (b) direction of the opening in the stomach (as near the pylorus as possible without causing angulation of the small intestine proximal or distal to the stoma); (c) the size of the opening (I make the opening in the stomach from the lesser to the greater curvature); and (d) the treatment of any extragastric abnormality which might possibly have a deleterious reflex action on gastric function. It will be seen that rapid drainage of the stomach is less aimed at than an attempt to make the post-operative conditions conform to normal function. As indicated in my paper referred to, even in so-called atonic stomachs the tone can be restored by appropriate after-treatment, while I find, further, that cases of normal acidity do as well as those with hyperacidity, and cases where no evidence of present or previous ulcer is found do as well as cases where such conditions are present.

I believe still what I have previously said, that the motor and secretory functions of the cardiac and pyloric parts of the stomach are distinct in action, there being a sacular cardiac portion and a tubular pyloric portion during digestion, which are more distinctly marked the more normal the stomach. The commencement of the pyloric tubular portion is indicated by what I have termed, for the sake of brevity, the "middle sphincter." One should appreciate, in the performance of gastro-enterostomy, the effects of the tonicity of the pyloric tube and place the stoma somewhere in it.

Dr. A. F. Hertz gives details of "certain unfavourable after-effects" in "many patients" subjected to gastro-enterostomy and afterwards investigated by him. Dr. Hertz (*Lancet*, December, 1910) criticized very adversely my interpretation of the motor and secretory functions of the stomach on which I base my operative procedures. The results I now publish appear to confirm strongly my interpretation, and should, I think, lead Dr. Hertz to modify the adverse views he then put forward.—I am, etc.,

Aberdeen, March 3rd.

II. M. W. GRAY.

P.S.—Since writing the above, three more replies have arrived. All the patients express themselves as entirely relieved by the operation. This gives approximately 95.5 per cent. of my series who are entirely relieved.

IMMEDIATE OPERATION IN APPENDICITIS.

SIR,—I should not have ventured to communicate with you further in this matter had it not been that you mentioned some figures of mine in a leading article on February 22nd.

As a matter of fact, your quotation was not quite accurate, for I have operated on 173 cases of acute appendicitis with limited infection, with a mortality of 2.3 per cent. There are, however, other figures available which abundantly prove, at all events, the comparative safety of operating in the early stages of appendicitis, and if we take those published by my friend and colleague Mr. Richardson,¹ and my friend Mr. Burgess,² and add them to my own, we obtain a total of 464 cases with 6 deaths, or a mortality of only 1.3 per cent. Since his last communication to your journal, Mr. Burgess has operated on a further series of cases, and he tells me that he has now brought his mortality down for cases operated upon in this early stage to 0.55 per cent.

You state in your article that some of Sir George Beatson's patients were suffering from localized abscesses, whereas the figures that I have just quoted refer to cases in a much earlier stage. I have operated upon 184 cases of primary localized appendix abscess with 6 deaths, or a mortality of 3.26 per cent. If these are added to the series with limited but not localized infection we have 357 with 9 deaths, or a mortality of 2.5 per cent.

¹ BRITISH MEDICAL JOURNAL, September 28th, 1912.

² *Ibid.*, February 24th, 1912.

The object of my present communication is to suggest that the time has arrived when we should find out the true mortality of all cases of appendicitis whatever the stage, and if those who countenance the delayed operation can then show a lesser mortality than those of us who believe in operating in practically every case we may have some grounds for altering our practice. The figures published as yet, with which I am familiar, are all in favour of the earliest possible operation.

Up to the end of last year I had operated on 681 cases of appendicitis of all varieties, with a mortality of 5.13 per cent., and during last year I operated in all on 118 cases with a mortality of 1.7 per cent.

I should feel that an apology were necessary for quoting all these figures were it not that the public, I am afraid sometimes guided by the profession, are only too ready to seize on any excuse for delaying operation, and we have found in this district that the views from time to time expressed in favour of a delayed operation have tended to do considerable harm. It is encouraging to note that the general tendency is in the opposite direction, for I find that cases come to hospital earlier and earlier each year and that the mortality from appendicitis is steadily diminishing—in my own series from 12.5 per cent. to 1.7 per cent.—and the figures of our infirmary show that the mortality has been exactly halved during the last ten years.—I am, etc.,

Newcastle-on-Tyne, Feb. 26th.

G. GREY TURNER.

SIR,—I cordially agree with Mr. Edmund Owen's plea for immediate operation. To diagnose appendicitis is easy; to allocate the exact position of the appendix is generally possible, but neither skill nor experience infallibly indicate the subsiding appendix.

The difficulty lies in the fact that the same train of symptoms indicate a healing lesion or mask a gangrenous perforation; in many cases it is not possible to decide, even after a considerable experience, between these diverging alternatives.

The prognosis and the course of the disease is largely influenced by the anatomical position of the organ and the virulence of the organisms which attack it. If the appendix lies behind the caecum, the most devastating changes may go on without much outward and visible sign; but, in the case of an organ lying free among the intestines, the course is more rapid, the symptoms are more intense, and the need for treatment is more urgent.

The risk of operating on an acute appendix is very slight, but that of watching it is hardly so.—I am, etc.,
Birmingham, March 4th.

E. MUSGRAVE WOODMAN.

OPERATIONS ON CHILDREN IN THE OUT-PATIENT DEPARTMENT.

SIR,—I was interested in Mr. Nicoll's paper and Mr. Andrew Fullerton's letter. I was for several years in charge of a large out-patient department of a dispensary. As we had no beds, only two courses were open to me: either to operate on the children myself, and send them home, or else send the case direct to the hospital. I chose the former, gradually increasing the scope of my operations from adenoids and tonsils, naevi, dermoid cysts, harelip, etc., to hydrocele, hernia, torticollis, tenotomy, etc. I operated on one boy 6 years old, who had a large psoas abscess, by emptying the abscess cavity and then filling it with bismuth emulsion; skiagraphs taken at intervals of twenty-four hours showed that the bismuth eventually reached the eleventh dorsal vertebra. This boy did very well, and in six weeks was running about. In this way the hospital was relieved of a large amount of work. The surgical out-patient department of every large hospital can be utilized as a nursery for young surgeons waiting to take their places on the senior staff.

The same applies to operations in private practice. Many cases can be undertaken at the surgeon's consulting rooms if he has a small theatre fitted up, and the patients then sent home to be under the care of their own medical man. I have found that many parents are willing and able to pay a reasonable fee for an operation; what they dread, because they are unable to afford it, is the cost of the nursing home, and many cases are sent to a hospital solely on this account.—I am, etc.,

Lincoln, March 4th.

STANLEY GREEN.

THE NEGLECT OF VACCINATION.

SIR,—Will Dr. C. Killiek Millard explain how "the future as regards small-pox prevention in this country lies with the medical officer of health rather than with the public vaccinator"? Do the Leicester authorities, in the event of small-pox, advocate or omit the vaccination of medical attendants and nurses, and contacts? If they omit it, how do they check the spread of infection? Will "sanitary reform in its widest sense," and "increased attention being paid to public health measures," diminish the susceptibility of the community to small-pox infection? The outbreaks of small-pox in the East End of London in 1911, and in Kirkecaldy last autumn, were due, one would think, not only to having "originated in mild unrecognized cases in vaccinated persons," but also to the victims being unprotected or imperfectly protected by vaccination; seed cannot grow without suitable soil. In Germany, with universal vaccination and revaccination, what few cases of small-pox occur are sometimes admitted to a medical ward of a general hospital without fear of other patients becoming infected; is there any hospital in England where this could be done?—I am, etc.,

Brent Knoll, Feb. 25th.

J. W. PAPILLON, M.R.C.S.

SIR,—The annual meeting of the Association of Public Vaccinators has, as usual, temporarily directed attention to the vaccination question, but only temporarily; in a couple of weeks it will all have been forgotten, until the next annual meeting of the official vaccinators again directs an ephemeral interest towards it.

Sir James Crichton-Browne hit the nail on the head when he said: "It was difficult in these days for the still, small voice of scientific wisdom to make itself heard, but any turbulent and noisy coterie was allowed to influence the course of legislation." The reason is that the "noisy coterie" can influence votes and is organized for this purpose, whereas the "still, small voice of scientific wisdom" is crying in the wilderness, as far as votes are concerned; and we must remember that we now have what will probably be a series of Parliaments moved solely by votes and not by wisdom or reason. Sir James Crichton-Browne also said: "The number of conscientious objectors who proved to the satisfaction of one stipendiary magistrate, or two magistrates in petty sessions, that they believed that vaccination would be prejudicial to the health of their offspring was increasing largely." All this is perfectly true as regards the main conclusions, but inaccurate in a minor detail. Objectors have not to *prove* their objection "to the satisfaction" of the sitting magistrates. They have merely to assert it on oath, and the magistrates cannot then refuse the relief asked. Magistrates have to administer the law, not to make it; and even as regards interpretation of the law they are entirely in the hands of their official legal adviser, the clerk to the justices. Magistrates, most of them, hate signing these exemption certificates, and personally I never sign them if I can help it, passing on the duty—for duty it is—to non-medical colleagues whose qualms cannot be as urgent as mine.

Every one of these certificates of exemption is nothing but a licence for some poor defenceless little infant to have small-pox; if a girl, not improbably to the ruin of any good looks Nature may have intended her to have; and we, who ought to be the guardians and protectors of these innocent, helpless little ones against the dangers of ignorance, prejudice, and superstition—we are made the instruments for carrying into effect this legislation.

I have had over twenty years' experience as a county magistrate, and have also sat on a county borough bench as long as this has been in existence.

Surgeon-General Evatt made some very appropriate and vigorous remarks about "the public duty of applying a scientific preventive remedy to the population against a very dreadful disease of which he had seen so many terrible examples among unvaccinated people in India." He also said: "Medical men knew the truth about these things, and it was their duty to educate the people." Have we not been trying to educate the people with all our might for several generations? What is the result? There is less vaccination than ever, nearly 50 per cent. of the population being now unvaccinated. What have we as a profession got by our disinterested efforts? Nothing

but abuse and offensive suggestions that it is vaccination fees we are after.

It is time we gave up this utopian dream of our "duty to educate the people." We get no thanks for our foolish philanthropic self-sacrifice. Let us do as other sections of the community are doing so effectively—look after ourselves. Leave the education of the people to the Government which takes our money for the purpose.—I am, etc.,

Blackpool, Feb. 25th.

WM. HARDMAN.

SIR,—I hasten to express my sincere regret to Dr. Maude if my letter—in your issue of February 22nd—appeared to him at all offensive. I can assure him that my criticism was not intended to refer to him in any personal sense, but only in his capacity as representing the Association of Public Vaccinators.

Dr. Maude asks me if I am "aware of the elementary fact that small-pox is extremely fatal in infancy, and if I am aware of the dangers which an infantile population still runs." This is a part of the orthodox case in favour of compulsory vaccination which I feel bound, after my experience as medical officer of health for a largely unvaccinated population, to take exception to. I believe this particular provaccinist argument has lost much of its weight. I admit that the *fatality* of small-pox in infancy is high, and in bygone days, when small-pox cases were not isolated, and modern methods of small-pox prevention as now practised were virtually unknown, no doubt the *mortality* in infancy was also high, and unvaccinated infants ran a very serious risk. No doubt, too, in places where modern methods are not efficiently practised, the risk still exists. But I contend that since the introduction of modern methods the position is entirely changed, and in support of this I can adduce the experience of Leicester.

During the past twenty-five years 142,000 children have been born in Leicester, of whom, on an average, less than 10 per cent. have been vaccinated. Now, as to the small-pox figures, I will confine myself to the twelve years* that I have been medical officer of health. During this period I have had to deal with over 700 cases of small-pox. How many deaths does Dr. Maude imagine have been caused by the disease in infants under 12 months old? Only three! Strange, and contrary to expectation, but none the less true. Had Dr. Maude, or any other strongly provaccinist medical man, had a similar experience I venture to think that his views, like mine, might have undergone considerable modification as to the "danger which an (unvaccinated) infantile population still runs." Perhaps Dr. Maude may reply that we have been very fortunate in that, on the whole, the type of small-pox which has chiefly prevailed in Leicester has been very mild. Granted; but as the total number of infants under 12 months old who have been attacked was only 12, the mortality could not have been very high even if half the cases had proved fatal. It is the low attack-rate rather than the low fatality which is the really remarkable thing.

The explanation of this surprising immunity seems to me to be this: The danger of infection, under modern conditions of small-pox prevention, does not now lie so much in the home, where the infant chiefly resides, as in the crowded haunts of men, where the highly modified vaccinated case stalks undetected.

Or, take the period of childhood: The child population of Leicester is, of course, equally unprotected, yet never have I thought it necessary to close a public elementary school on account of small-pox.

Incidentally, I may remind Dr. Maude that, whilst the fatality of small-pox in infancy is above the average, during childhood—that is, after the first year or two—it is comparatively low. I am speaking, of course, of the unvaccinated. The fatality of small-pox in childhood in vaccinated subjects is, I am quite aware, practically nil.

Dr. Maude also says that it is "better to have a population which presents mild cases of small-pox . . . than severe ones." This sounds a truism, but I venture to suggest that, from the point of view of prevention, the conclusion is not so obvious as it appears. Moreover, the

*The small-pox figures for the twenty-five years 1883-1912 are: Total cases, 1,120; cases under 1 year of age, 20; deaths under 1 year, 5.

terms "mild" and "trifling" usually applied to the highly modified and abortive form of the disease which so frequently occurs in vaccinated subjects are most unfortunate and misleading. These cases are only "mild" and "trifling" so far as the particular individuals attacked are concerned; but from the vastly more important point of view of the community they are most dangerous, and frequently spread the disease to unprotected persons in its most virulent and fatal form. In this respect they present a marked contrast with the behaviour of small-pox in the natural and unmodified form usually seen in unvaccinated subjects. If severe, or moderately severe, the cases are then (with the one exception of the very rare hæmorrhagic type) easily recognizable, so that the necessary steps for the prevention of the disease can at once be taken; or, if very mild, such as might escape detection (and such cases do occasionally occur even in the unvaccinated), then they are, in my experience, really mild and spread a mild type of the disease. To put it in another way, infantile vaccination only masks the disease without affecting the type. The virulence is there all the same; and under modern conditions I suggest it is conceivable that infantile vaccination is hindering our efforts at stamping out the disease quite as much as it is helping us.

Lastly, let me assure Dr. Maude that I give place to no one as regards my belief in and advocacy of vaccination used as it is used in Leicester—that is, when it is really needed. I think I may claim without boasting that I have made as many converts to vaccination as any medical man in Leicester. Certainly I think I have persuaded more antivaccinists to submit to vaccination. I know their side of the case well, and I can sympathize with it; but a photograph of my wife and young family (recently vaccinated) sitting in the Leicester Small-pox Hospital at the bedside of a bad confluent case of the disease is a powerful pictorial argument which has given me a great advantage.—I am, etc.,

C. KILLICK MILLARD, M.D., D.Sc.,
Medical Officer of Health.

Leicester, March 1st.

SHIP SURGEONS.

SIR,—As a former ship surgeon the letter on that subject (p. 472) was indeed welcome. Surely now is the time for the British Medical Association to take up the cause of the ship surgeon, for unless the subject is taken up by the whole profession it is useless for individuals to strive for higher pay.

The difficulty lies in the differences of ships and in the class of the passengers. For example, I was three months with one line which paid me £12 a month, yet I was far better off with another which only paid me £8, owing to the fact that now and then I got some good private fees from the passengers.

My chief object in this letter is to draw attention to the conditions under which ship surgeons have to work on emigrant ships. Last December I took a boat from Glasgow to Canada, and for the paltry pay of £8 a month I had to look after about 300 passengers. As the majority were travelling steerage I had to examine each one for vaccination marks and, if necessary, vaccinate them. As the weather was very bad almost everybody was either seasick or had a bad cold; the result was I was working almost all day. On the return trip scabies, pediculi, pubis, etc., broke out among the passengers and crew, and so added to my work. Another objectionable part of my duties was visiting the firemen in their cabin when ill, or supposed to be ill. They all lived and ate in a small dirty unventilated cabin where the air was thick with tobacco smoke, and a heavy foul odour seemed to overcome me when I entered.

As I have only crossed the Atlantic once, other ships may not be so bad, but I am sure if all the members of our profession and the ship owners themselves knew the conditions under which medical men at sea have to work, they would soon raise the pay. Hoping that some former ship surgeons who now, perhaps, are high up in the profession will take the matter up, and let the true facts of the case be widely known.—I am, etc.,

ARTHUR D. CLANCHY.

Liverpool, March 2nd.

NATIONAL MEDICAL UNION.

SIR,—It has come to the knowledge of the Executive Committee of the National Medical Union that misleading statements as to the methods and objects of this association have appeared in many newspapers during the last few weeks throughout the country. These statements must have been founded on a mistake, the authors having confused the aim of two separate societies, the names of which are somewhat similar.

The National Medical Union has been in existence for nearly fifteen months, and is well known. The National Medical Guild is a new body which has been lately originated in London, and which is now making application for recognition as a trades union.

The National Medical Union as constituted at present is a society composed exclusively of medical men who do not intend to take service of any kind under the National Insurance Act as it now stands after April 14th, 1913. The Union exists primarily for the interests of these men. It has no intention of working on trades union lines. It aims at uniting "non-panel" men all over the country, at furthering their interests, and at defending their rights; it seeks to preserve the honour, independence, and efficiency of the profession, and it hopes to form a "rallying ground" for doctors who, having accepted service on panels and found out the impossibility of doing sound work thereon, are desirous of retiring therefrom.

The Union will work for the provision of adequate medical attendance for the industrial classes at reasonable remuneration on the lines of general practice, and it will seek for such amendment of the National Insurance Act as will secure this and safeguard the interests of both patients and doctor.

The National Medical Union, whilst sympathizing with the general attitude of the National Medical Guild, is not at the present time in favour of the promotion of their common aims by trades union methods.—We are, etc.,

G. A. WRIGHT,

President.

WILLIAM COATES,

Chairman.

J. WEBSTER WATTS,

Secretary.

E. M. FLOYD,

J. SKARDON PROWSE,

Honorary Secretaries.

Manchester, Feb. 27th.

Universities and Colleges.

UNIVERSITY OF CAMBRIDGE.

THE following degree has been conferred:

M.D.—W. R. Honeyburne.

UNIVERSITY OF SHEFFIELD.

THE Council at its last meeting appointed Miss Sophia T. V. Witts, M.D.Lond., to the newly instituted post of Lady Tutor in Anatomy.

UNIVERSITY OF GLASGOW.

Students' Council.

AT a special meeting of the Glasgow University Students' Representative Council called to consider the motions from the Inter-Universities Conference recently held at Aberdeen, the following among other resolutions were passed:

That the President of the Students' Representative Council attend Senate meetings when Students' Representative Council motions are under discussion.

That an inter-university committee, composed of members of the Senatus of the different Faculties of the four Scottish universities, be appointed to obtain information with regard to vacancies in Government and other services, and to publish a list of any such vacancies at the four universities for the benefit of students.

That this conference approves of the action of the Scottish universities in resisting the application of the inclusive fee in the Faculty of Medicine, and particularly desires that the extra-mural schools be not injured.

That there be three final professional examinations per annum in the Faculty of Medicine.

That the University Courts be urged to give a grant to the athletic club of each university, the sum, if necessary, to be obtained from an increase in the matriculation fee.

SOCIETY OF APOTHECARIES OF LONDON.

THE following candidates have been approved in the subjects indicated:

Surgery.—W. H. Broughton, G. M. Cordingley, H. Cox, W. H. Edmunds, A. M. L. Greaves, E. M. Morris.

MEDICINE.—*W. H. Edmunds, *T. H. W. Idris, †C. W. Jenner, *†A. Lowndes, †E. M. Morris, *S. Zarchi.
 FORENSIC MEDICINE.—W. H. Edmunds, J. T. E. Evans, A. Lowndes.
 MIDWIFERY.—J. T. E. Evans, H. C. C. Hackney, J. W. Harrison, A. Lowndes.

* Section I. † Section II.

The diploma of the Society has been granted to G. M. Cordingley, H. Cox, A. M. L. Greaves, J. W. Harrison, and C. W. Jenner.

Public Health

AND

POOR LAW MEDICAL SERVICES.

“POOR LAW DOCTORS’ STRIKE.”

UNDER this heading the *Burnley Express and Advertiser* publishes a report of a recent meeting of the Burnley Guardians. Some months ago all the district medical officers of the Burnley Union resigned their offices on account of the inadequacy of the remuneration, after repeatedly endeavouring to get redress from the guardians; and in so doing acted on the advice of the Burnley Division of the British Medical Association. The local profession has loyally supported the Poor Law medical officers, and the guardians, fearing there would be little chance of locally filling up their posts, have promoted various schemes of redistribution of the area of the respective districts, all more or less unsatisfactory in the opinion of the local profession. The following letter of protest to the Local Government Board from the Poor Law Medical Officers’ Association of England and Wales, a copy of which was sent to the Burnley Guardians, shows pretty clearly the matter in dispute:

Right Hon. John Burns, M.P.

Sir,

I am directed by my Council to bring to the notice of your honourable Board the faulty arrangements for medical relief in the Burnley Union. For a long time past the district medical officers have been paid at a rate much below the average in adjoining unions, and after repeatedly petitioning the guardians for redress to no purpose, have, as a last resort, resigned their offices. The matter has attracted the notice of the Burnley Division of the British Medical Association, and that body has also approached the guardians on behalf of the medical officers of the union. The sympathy of the local profession is altogether with the medical officers, and it is likely the guardians will have considerable difficulty in filling up the vacant posts. In the meantime the guardians have decided to divide the union into twelve districts, paying £40 a year for the medical work in each, and making each medical officer public vaccinator in his own district.

My Council specially desire me to draw your attention to the following points:

1. Although by this arrangement the sum paid by the guardians for medical attendance on the sick poor of the union will be some increase as compared with the present scale of payment, it will still remain far behind the average of that paid in adjoining unions, where the same local conditions obtain as in Burnley.

2. The alteration in the vaccination districts is specially to be deplored. It has always been the policy of your honourable Board to encourage the formation of vaccination districts distinct from Poor Law districts, and to forbid the use of fees for public vaccination to eke out the payments of Poor Law medical officers. My Council is of opinion that the object of the Burnley Guardians in making each district medical officer a public vaccinator is to induce the applicants to undertake the Poor Law work at a lower salary than such work might fairly demand. They consider that such an arrangement does not tend to efficiency of public vaccination generally, and is detrimental to the welfare of the Poor Law medical service and the sick poor in their care.

I am, yours truly,

MAJOR GREENWOOD, Hon. Sec.

The comments of the guardians on this letter do not appear to have much cogency. They admit that they pay their medical officers less than adjoining unions, but are of opinion the latter should take a lesson from them, and similarly underpay their medical officers. They complain that no mention was made of some increases in the salaries of their medical officers last June. This only brings into prominence the terribly low rate of payment previous to last June. The suggestion that some of the resignations were brought about by professional pressure outside is an old story. Wherever united action is taken by the profession, those who consider themselves aggrieved invariably raise the cry of coercion. The figure £40 a year is also challenged as being incorrect, as also the proposal that the medical officer should be appointed public vaccinator. It is to be hoped that both these statements are incorrect, but they were taken from reports of

meetings of the Burnley Guardians, published in the local press. A special committee has been appointed to consider the whole matter again, and it is to be hoped wiser counsels will prevail, and that the Burnley Guardians will come to an agreement with the local profession. In the meanwhile the profession at Burnley is to be congratulated on its united action, and we trust no practitioners from outside will be so wanting in professional spirit as to undersell their brethren at Burnley.

UNUSUAL ILLNESS AMONG WEAVERS OF COTTON CLOTH.*

MUCH interest attaches to the investigation of the causation of illnesses in industrial centres contracted by employed persons in the course of their employment and arising directly therefrom. In 1910, 1911, and 1912 an unusual illness was prevalent among weavers of cotton cloth at Colne and Burnley. The symptoms were constriction of the chest beneath the sternum followed by rapid breathing and a persistent irritating cough, expectoration of a thick yellow or yellowish green sputum, and a sweetish taste in the mouth. Later the symptoms assumed an asthma-like form, preventing sleep. Food might be rejected, and epistaxis was observed. There was general malaise, aching limbs and back, severe headache (usually frontal), and the temperature might rise to 102° in the evening. There was loss of weight, and in pronounced cases other symptoms were observed, such as herpetic eruptions, palpitation, smarting and running of the eyes.

In one instance at Burnley the weavers suffered so severely that the shed had eventually to be closed. Dr. Edgar L. Collis, H.M. Inspector of Factories, has issued a report on the subject, in which he traces the cause to mildew developing on the cotton threads following the process technically known as “taping” or “tape-sizing” with a preparation principally composed of flour (derived from wheat, sago, or potatoes), tallow, China clay, and water. In the class of manufacture on which the stricken weavers were engaged it appears antiseptics are omitted, as the dyers specify that no chlorides shall be present in the goods they buy. The practical result of Dr. Collis’s observations is to confirm the advantage of the use of formaldehyde, which had already been suggested as an antiseptic where chlorides were forbidden.

The report is by no means conclusive. Visible moulds which are bluish-grey in colour are frequently observed on warp threads, and no such illness has been associated with their presence. Dr. Collis mentions that no “visible” signs of mildew were present in the warps at Colne and Burnley. He suggests that “possibly some unusual mildew, of which the growth is similar in colour to the cotton threads, was present on these warps and was the cause of the illness.” Such growth could have been demonstrated by microscopic examination if it had been possible for the suspected material to be examined in this way. No such examination is mentioned in the report. Various forms of mildew were found (in the flour used) by the experts called in. Dr. Collis suggests that one of these moulds may have been pathogenic and caused the symptoms, although Dr. Markham at Burnley failed to find any unusual mildew present in the sputum examined. The unusual illness described is fortunately of rare occurrence. As the occupation is exceedingly common, obviously the cause is some obscure variation the exact nature of which is still in doubt.

POOR LAW MEDICAL OFFICERS’ ASSOCIATION OF ENGLAND AND WALES.

A COUNCIL meeting of this association was held at 34, Copthall Avenue, E.C., on February 13th, when Dr. D. B. Balding, J.P., was in the chair.

What Constitutes a Legal Order?

A communication was read from a country member asking what constituted a legal order. He had received from his relieving officer a portion of a postcard on which was written a name and an address, with the word “lunatic” inscribed below and the initials of the officer. He visited this case, and payment was offered him. Could he properly have accepted it? The honorary secretary had written that if the case had been referred to him by his relieving officer, any attendance on it must be reckoned as forming part of his official duties, and no payment could be taken. This was approved by the Council, and the unanimous opinion was that a Poor Law medical officer

* Reports of Unusual Illness among Weavers of Cotton Cloth. By Edgar L. Collis, H.M. Medical Inspector of Factories. Printed for His Majesty’s Stationery Office by Darling and Son, Ltd., Bacon Street, London, E. 1913.

could not be too careful in guarding himself against the charge of accepting payment for attendance on any cases that came within the scope of his official duties.

Refraction.

The question whether the testing of errors of refraction with a view to ordering glasses formed part of the duties of a Poor Law medical officer, referred to the Council by the Medical Defence Union, was discussed. The unanimous opinion was expressed that such a duty had never hitherto been imposed, and that, generally speaking, Poor Law medical officers were not competent to undertake such work. The necessary apparatus was not possessed by one Poor Law medical officer in a hundred, and even if it were supplied, as it would have to be, by the guardians, until the officer had gained experience in its use the results were likely to be far from satisfactory. In the case of dentistry, the General Orders specially laid down that the duties of a Poor Law medical officer went no further than the extraction of teeth. It was unreasonable to think, therefore, that duties such as in ordinary medical practice were universally referred to a specialist should be expected from a Poor Law medical officer. In the interests of the elementary school children of the country it was necessary to oppose such an imposition. School medical officers who were required to deal with this subject had always to produce credentials of competence in this branch of medicine. If the association admitted that work regarded universally as properly belonging to the province of a specialist should be held to be one of the ordinary duties of a medical practitioner, the interests of a large portion of the medical profession might be seriously affected. The Regulations under the National Insurance Act defined what work was to be considered to come within the scope of an ordinary practitioner. They were by no means clearly set out, but if it were admitted that dealing with errors of refraction formed part of the duties of Poor Law medical officers, it would be difficult to exclude them in the case of practitioners on the panel. The Honorary Secretary was instructed to take the earliest opportunity of bringing this matter before the Local Government Board and pressing upon it the views of the association.

Officers of Boards of Guardians.

A letter was read from the Manchester and District Assistant Clerks' Association, asking for support to a petition it was proposed to send to the Local Government Board praying that sanction should not be given to the appointment of inexperienced persons to the respective offices of clerk and first assistant clerk to boards of guardians. The petition was approved by the Council and the Honorary Secretary instructed to state that the Poor Law Medical Officers' Association would give any assistance in their power.

Resignations of Medical Officers at Burnley.

The Honorary Secretary reported that he had written, as instructed, to the Local Government Board, pointing out the way in which medical relief was being administered in the Burnley Union; that the Burnley Guardians, to whom the letter had been sent for comment, had contented themselves with questioning the accuracy of some of the statements in the letter, and had made no reply to the more important criticism therein. With regard to the inaccuracies, if any, they were culled from the reports of meetings of the Burnley Guardians published in the local press, copies of which had been sent with the letter to the Local Government Board. In the meanwhile a special form of order was in use in the Burnley Union, which might be taken to any practitioner, but, as a matter of fact, by agreement among the local profession, was referred to the late district medical officers. For attendance under this order the guardians guaranteed payment at the usual private rates current in the district. Such an arrangement would be far more expensive than the old, and the ratepayers suffered, because the guardians refused to treat their medical officers with equity. Up to the present no sanction had been given by the Local Government Board to any scheme of the Burnley Guardians, and the local profession were loyally assisting their Poor Law brethren. The Council did not think it desirable to take any further action until an answer to their letter had been received from the Local Government Board.

Annual Meeting.

It was decided that the date of the annual meeting, which is to be held in London, should be either during the last week of June or at the beginning of July. It was thought advisable that there should be two papers read dealing with Poor Law subjects, one from a Poor Law medical officer, and the other, if possible, from a non-medical Poor Law official. It was also resolved that the usual dinner should be held in the evening.

Insurance Act.

It was pointed out that many cases were being referred by panel doctors to relieving officers with a view to their admission into Poor Law infirmaries. Where institutional treatment was necessary there was no objection, but some of the cases could not be placed in that category, and if medical attendance were given by the Poor Law, it would have to be by the district medical officer at the patient's home.

The Council was unanimously of opinion that in no circumstance should an insured person entitled to the service of a panel doctor be treated by a Poor Law medical officer except in the wards of a Poor Law institution. It might happen that under the Poor Law Orders a district medical officer was com-

pelled to visit an insured person in receipt of Poor Law relief, to give the necessary certificate; but the treatment of these cases should be left entirely in the hands of the panel doctor.

With regard to the maternity benefit, it was pointed out that the dependants of insured persons not infrequently went into the infirmary to be confined. The guardians could make no claim on this benefit, which was received by the husband with no deduction. It was to his interest, therefore, that his wife should be attended in the infirmary, but the main object of the benefit in question was to meet expenses incident to the confinement. It was possible for the guardians to make demand on the husband for a contribution towards the cost of his wife's attendance in the infirmary; but this was seldom done, and the husband's position apart from the maternity benefit might not warrant any demand being made.

The Council was of opinion that the framers of the Act had hardly contemplated the employment of maternity benefit in this manner; nor was it fair that provision should be made out of the rates in respect of services for which Parliament had already made a grant. Overlapping was the curse of the Poor Law, and it seemed not unlikely that one of the effects of the Insurance Act would be considerably to increase this evil.

Obituary.

SIR COLVIN COLVIN-SMITH, K.C.B.,

SURGEON-GENERAL, INDIAN MEDICAL SERVICE.

SURGEON-GENERAL SIR COLVIN COLVIN-SMITH, K.C.B., Madras Medical Service, retired, died at his residence, 5, Cresswell Gardens, South Kensington, on March 1st, 1913. He was the son of the late Rev. Robert Smith, D.D., of Aberdeen, and was born on August 4th, 1829, and educated at King's College, Aberdeen, where he took the M.D. in 1851, as well as the L.R.C.S. at Edinburgh in 1850. He entered the Indian Medical Service as Surgeon on November 3rd, 1851; became Surgeon on December 14th, 1864; Surgeon-Major on November 3rd, 1871; and Deputy Surgeon-General on August 5th, 1879, retiring with an honorary step of rank on September 29th, 1884.

He had a long list of war service, beginning immediately after his arrival in India with the second Burmese war of 1852-53, when he served in the operations before Rangoon in April, 1852, at the capture of the White House stockade and of the Shwe Dagon pagoda, and the occupation of Prome, and received the medal with a clasp. In the Indian Mutiny he was in the field for two years, 1857-59, serving with the Kampti movable column and with the Sagar Field Division; he was present in the affairs at Khoni Pass, Narampur, Nimkaira, Budgam, and other minor skirmishes on the Great Dekkan road; also in operations in the Palamau district, and in the march to Jabalpur. He received the Mutiny medal with a clasp. In 1881 he was appointed Deputy Surgeon-General of the Haidarabad Subsidiary Force and Haidarabad Contingent, and while holding that post was chosen as Principal Medical Officer of the force dispatched from India to the Egyptian war of 1882. There he took part in the battle of Tel-el-Kebir, and in the forced march to and occupation of Zagazig, was mentioned in dispatches in the *London Gazette* of November 17th, 1882, and received the Egyptian medal with a clasp, the Khedive's bronze star, the third class of the Osmanieh, and the C.B. After retirement, he was appointed an Honorary Surgeon to the Queen on July 5th, 1899, thus holding that honour in three reigns; received a Good Service Pension on January 18th, 1903, and was promoted to K.C.B. on June 26th, 1903.

In 1864 he married Marian, daughter of the Rev. Henry Phillips, of Great Welnetnam, but lost his wife in 1908. A memorial service was held at St. Columba's Church, Pont Street, on March 4th; the interment took place at Kingston cemetery on the same day.

WE regret to have to announce the death of Dr. ALFRED AUGUSTUS BEERS, of New Silksworth, Sunderland, which took place at the Fever Hospital, Sunderland, as a consequence of an attack of scarlet fever. He was taken ill on February 14th, and was removed on February 17th to the hospital, where he died on February 21st. His sudden illness and death has been a great shock to his many friends. It is to be feared that the hard harassing work in connexion with the conditions imposed by the Insurance Act greatly debilitated his system, and he doubtless contracted his fatal illness while attending his duties in this

depressed state of health, which had been further lowered by a severe cold. He was educated at Dollar Academy, and was a student at the School of the Royal College of Surgeons of Edinburgh. He obtained the diplomas of L.R.C.P. and L.R.C.S. Edin., and L.F.P.S. Glas., in 1901. In February, 1902, he became assistant to Dr. Bernard, of Silksworth, and shortly afterwards joined him in partnership. Dr. Becks joined the Territorial Force and attained the rank of Captain, R.A.M.C. (T.F.). He was attached to the Northumbrian (County of Durham) Brigade, and in this capacity and as honorary surgeon to the St. John Ambulance Brigade he won the respect and friendship of all with whom he served. He was a member of the British Medical Association and took a keen interest in its work. He was buried with military honours, and the funeral was very largely attended by residents in Silksworth and by representatives of the profession in the district.

The Services.

MEDICAL BENEFIT FOR CIVILIAN SUBORDINATES.

INSTRUCTIONS relative to the administration of medical benefit to civilian subordinates (including pensioners) who are insured under the Insurance Act are published in Scottish Command orders: All insured civilian subordinates are entitled to receive medical benefit under the Act. Medical attendance will therefore no longer be given to insured pensioners who do not reside within the precincts of barracks (including schools, colleges, hospitals, magazines, Government quarters, etc.). They will be attended by the panel doctors. In the case of insured civilian subordinates living in barracks, etc., for whom medical treatment has hitherto been provided by medical officers of the War Department (military medical officers or civil medical practitioners under agreement), it is desirable, both on grounds of general convenience and in the interests of discipline, and with a view to the avoidance of all possible sources of friction, that the present practice should be continued, medical attendance, drugs, etc., being provided from army funds in return for capitation fees to be paid by the Local Insurance Committees and credited to Army Appropriations in Aid.

TERRITORIAL NURSING SERVICE.

The annual meeting of the 1st Southern General Hospital Territorial Nursing Service was held in the Council House, Birmingham, on February 24th, Lady Fairfax Lucy presiding. The principal matron of the hospital, Miss M. A. Buckingham, reported that the nursing staff consisted of 10 matrons of hospitals, 11 district nurses, 46 hospital ward sisters, 48 private nurses, and 5 trained nurses of no occupation at present, a total strength of 120. Miss F. Clarke, one of the matrons of the hospital, took a course of training in August last at Shorncliffe Military Hospital, at the same time as the R.A.M.C. (T.) of the 1st Southern General Hospital were doing their annual training.

NEW HEAD QUARTERS OF THE FIRST LONDON DIVISION R.A.M.C. (T.F.).

The new head quarters of the First London Division (Territorial Force) Royal Army Medical Corps, in the Duke of York's School, Chelsea, were opened by Major-General W. Fry, C.B., C.V.O., commanding the First London Division (Territorial Force), on March 1st. Major-General Fry said that some people had objected that so many units should be brought together in the Duke of York's School, but he did not share those fears, and had always found the medical corps very popular. One reason was that in the medical unit there was a close bond between the officer and the man. Where the officer was the instructor of the man the discipline was miles ahead of that of corps in which the actual technical instructors were the only people to teach the rank and file.

As was mentioned last week, the Committee of Management of the Mount Vernon Hospital for Consumption and Diseases of the Chest at Hampstead and Northwood will ask the governors at the annual meeting on Wednesday next to sanction the sale of the hospital at Hampstead. At this meeting the Chairman of the Medical Board (Dr. F. W. Tunncliffe) will move the following amendment: "Considering that the entire medical and surgical staff has expressed the considered opinion that on medical grounds it is not practicable to conduct a chest hospital in the true sense of the term at Northwood, this meeting directs that the further consideration of the Chairman's resolution be deferred until March, 1914, and that the Committee of Management be called upon to exercise, if necessary, the powers conferred upon them at the last meeting of governors to separate the two institutions, with a view to a further and better perpetuation of the hospitals at Hampstead and Northwood."

Medical News.

The annual general meeting of the Medical Graduates' College and Polyclinic will be held at 22, Chenies Street, W.C., on March 14th, when Sir William J. Collins will take the chair at 5.15 p.m.

The late Dr. William Howship Dickinson bequeathed £1,000 in memory of his son to the Samaritan Fund of St. George's Hospital, to be known as the Lee-Dickinson Memorial Fund. The total estate was £39,790 gross.

THE ARIS and GALE Lectures before the Royal College of Surgeons of England by Dr. Blair Bell, on the genital functions of the ductless glands, will be given on Monday and Wednesday next, at 5 p.m. on each day. The lectures will be illustrated by lantern slides.

DR. S. N. GALBRAITH, D.P.H., acting resident medical officer at Brompton Hospital, has been appointed assistant tuberculosis officer under the Lambeth Borough Council, at a commencing salary of £300 a year. There were fifteen applications for the appointment.

SIR FREDERIC EVE commenced a course of two lectures on malignant tumours of the long bones, their pathology, symptoms, and treatment, at the London Hospital on Tuesday last. The second lecture will be given next Tuesday at 1 p.m. The attendance of members of the profession and students is invited.

THE International Congress of Physical Education, which has been organized by the Faculty of Medicine of Paris, with Professor Gilbert as President, is placed under the patronage of no less than three Presidents of the French Republic—M. Fallières, M. Loubet, and M. Poincaré. It is to be held in Paris from March 17th to 20th. As many as twenty-five nations are sending representatives to take part in this congress, at which the methods of physical education now in vogue in different countries will be discussed and criticized, in the hope that the free interchange of opinions and experiences will make it possible to place the present system of physical culture on a more rational and scientific basis. There will be two sections. The first section will comprise discussions on the whole range of athletics, from military gymnastics to feminine sports: whilst the second will consist of a series of demonstrations by expert gymnasts from almost every country in Europe. An interesting exhibition of physical education and sports has been organized by Dr. Albert Weill in connexion with the congress, and is to be on view from March 17th to 26th. Reduced fares have been granted by the French railway companies to all members travelling to Paris, and a fee of 20 francs (in the case of members' relatives, 10 francs) will admit each member to the various fêtes and demonstrations, besides entitling him to all publications issued by the congress. Subscriptions and inquiries should be addressed to the Secretary, Dr. Henri Dausset, 41, Avenue Montaigne, or to the Treasurer, Dr. Lagarde, 9, rue de Bassano, Paris.

LAST year the King conferred on the British Medical Benevolent Fund the title of Royal, and to celebrate the first year of the Royal Medical Benevolent Fund a dinner of those interested in the fund and its guild, both ladies and gentlemen, will be held under the chairmanship of H.R.H. Prince Arthur of Connaught on Wednesday, April 30th, at the Hotel Cecil, London. A large number of members of the profession have already consented to act as stewards, among whom are Sir Clifford Albutt, K.C.B., Mr. Gilbert Barling, Sir Thomas Barlow, Adeline, Duchess of Bedford, Sir J. Rose Bradford, the Dowager Lady Broadbent, Lady Willoughby de Broke, Dr. H. Langley Browne, Dr. J. Mitchell Bruce, Sir Lauder Brunton, Dr. C. Buttar, Dr. Wm. Collier, Sir Anderson Critchett, Sir Dyce Duckworth, Mr. J. Swinford Edwards, Mr. E. Hurry Fenwick, Sir David Ferrier, Sir J. Kingston Fowler, Sir Alfred Frupp, Sir Rickman Godlee, Sir James Goodhart, Sir Alfred Pearce Gould, Dr. Walter Griffith, Dr. de Havilland Hall, Mr. Arbuthnot Lane, Sir Trevor Lawrence, Mr. C. B. Lockwood, Sir Donald MacAlister, K.C.B., Mr. G. H. Makins, Professor Howard Marsh, Mr. J. H. Morgan, Sir Malcolm Morris, Dr. F. Needham, Lady Northcote, Dr. J. A. Ormerod, Sir Wm. Osler, Mr. Herbert Page, Sir R. Douglas Powell, Sir James Reid, Dr. H. D. Rolleston, Sir Ronald Ross, Sir George Savage, Mrs. Scharlieb, Lady Shaftesbury, Sir R. M. Simon, Mr. H. J. Stiles, Mr. Charters Symonds, Sir StClair Thomson, Dr. W. Thornburn, Dr. Nestor Tirard, Dr. D. F. Todd, Sir William Turner, Sir John Tweedy, Dr. J. C. Utthoff, Katherine, Duchess of Westminster, Dr. Hale White, Sir John Williams, Dr. J. Burney Yeo, and Mr. Parker Young. Communications relating to the dinner may be addressed to Mr. G. Bethell, 11, Chandos Street, Cavendish Square, W.

and subscriptions sent to the Treasurer, Dr. Samuel West, 15, Wimpole Street, London, W.

THE third of the series of Galton laboratory lectures on "National Eugenics," delivered by Miss Ethel Elderton at University College, London, dealt with the relation of fertility in man to "social value" in the parent, the term being used to designate fitness of one human being to become the parent of another. Her own observations amongst the working classes in the North tended to prove that the greater the social value the less the fertility; and the truth of this statement was confirmed by statistics dealing with the decline in the birth-rate amongst the population north of the Humber between the years 1851 and 1906. This fall, which had taken place throughout the whole of the North, was most marked in the residential and industrial districts, particularly those engaged in the textile industries. Miss Elderton contended that though the Malthusian school had shown that limitation of the family was possible, their views would not have spread unless the wish to have children had diminished owing to some social or economic factor. It had been suggested that the restriction of child labour, possibly combined since 1891 with the restrictions on the mother's labour after childbirth, had caused the fall in the birth-rate in the textile districts. Unfortunately it was the thrifty, hard-working section of the community who limited their families, and this could not fail to have a disastrous effect upon future generations. In considering suggestions that the half-time system should be abolished, that the age of school attendance should be raised to 16, and that the mother's work should be curtailed, it should be borne in mind that many parents would find it impossible to keep their children during these additional years, and some of them, in consequence, would be obliged to restrict their families still further. Such a change would have little effect upon the thriftless and careless; but it might make a considerable difference to the intelligent and careful, unless it could be accompanied by some endowment of healthy, thrifty, and intelligent parents. Legislation on these points would have to proceed with caution, for in striving to better the condition of the individual it might only be adding another burden to the class whose children were one of the most valuable assets of the State.

A MEETING in support of the Women's Guild of the Royal Medical Benevolent Fund was held on February 25th at 49, Upper Brook Street, by permission of Mr. and Mrs. Makins. Dr. Acland, who presided, said that the object of the Guild was not only to seek out cases of distress amongst the families of medical men and report them to the Fund, but to see that they obtained the relief they deserved. A short account of the foundation of the Guild was then given by Mrs. Scharlieb, who reminded her audience that it had begun in a very small way, but, thanks to the energy of Lady Tweedy, had since been able to establish branches in most of the large towns in the kingdom. These provincial branches had soon outstripped London; and the latter, in consequence, had been divided into districts, which at the present moment were in a very flourishing condition. The Guild had a special fund for the orphan children of doctors. The children were sent to good schools and afterwards were put in the way of earning their own living, and these were the cases that constituted the best investments of the Guild. The whole of England had been thrilled by the heroism of Captain Scott and his companions, but it should not be forgotten that there were other heroes in our midst who faced death daily just as bravely as those who died amidst the Antarctic snows, and oftentimes with the knowledge that they were leaving those dependent on them totally unprovided for. Sir Ronald Ross, in commending the work of the Guild, said he could imagine no more terrible plight than that of a widow left with a young and helpless family, and unfortunately this was too often the case when a doctor died suddenly. He instanced the case of one of the greatest medical heroes of modern times—Dr. Walter Reed—who, with his helpers, found out how yellow fever, the pest of Central America, was carried. Shortly after making this important discovery, Reed broke down and died, leaving a widow and some little children. It was only with the greatest difficulty that the scientific and medical men of America were able to persuade the Government of that rich country to give a pension to the widow of the man who had conferred so great a benefit upon humanity. He was quite certain that there were many cases of a similar nature in this country; they had the strongest possible claim upon the help and sympathy of the whole profession. A short speech by Dr. Etlic Sayer followed, and the meeting closed with a vote of thanks to Mr. and Mrs. Makins.

Letters, Notes, and Answers.

Queries, answers, and communications relating to subjects to which special departments of the BRITISH MEDICAL JOURNAL are devoted will be found under their respective headings.

QUERIES.

HAMPSHIRE PHYSICIAN will be glad to hear of a desirable holiday resort in the North of France; country preferred, or small town or suburb.

ALOPECIA UNIVERSALIS.

J. A. R. asks for advice in the treatment of a middle-aged man who, four months after a severe mental and physical strain, began to lose his hair; after a few weeks not a hair was left on his body. Treatment with nerve tonics has been tried without success.

WHEN WAS POTASSIUM IODIDE FIRST USED?

DR. J. P. KEENAN (Ballinalee, Edgeworthstown) writes: In the Literary Notes in the JOURNAL of February 15th, p. 353, it is said that "to Dr. Wallace of Dublin belongs the honour of first using potassium iodide in syphilis." In the JOURNAL of January 26th, 1907, Dr. J. McNamara wrote that "the introduction of iodide of potassium in the treatment of tertiary syphilis . . . was due to a humble Irish practitioner, named Welch." What was the true form of the name of our humble Irish predecessor, who conferred such a boon on Britain and civilization? Dr. McNamara went on to say that "the name of Dr. Welch, instead of being forgotten, as it is, should stand high on the roll of fame." Alas! it seems that we do not even know how to spell it. Was Welch Wallace, or Wallace Welch, or both of them Walshe?

ANSWERS.

W. C. S.—We have no knowledge of an "International Congress on Nose and Throat to be held in London next August." In connexion with the Seventeenth International Congress of Medicine, to be held in London on August 6th to 12th of this year, Section XV will be devoted to rhinology and laryngology. Possibly our correspondent refers to this. If so, the better way would be for him to communicate with the General Secretary, at the Central Office, 13, Hinde Street, London, W.

TESTS FOR DEATH.

L. A. P.—(1) Icard's test for death is performed by injecting under the skin a solution of fluorescin and sodium bicarbonate. Life is proved by the rapid development of a greenish-yellow discoloration of the general surface of the body and mucous membranes (Hawthorne, *For. Med.*, p. 42). We are unable to express any opinion as to its reliability, but there seems no inherent improbability: whether it could ever be of use is another matter. (2) We have no information as to Icard's lead acetate test.

LETTERS, NOTES, ETC.

THE LATIN FOR "BEER."

DR. R. CARMICHAEL WORSLEY (Coventry) sends us the following, which he seems to wish us to believe a true story. New Casualty Dresser (referring to entry in register): "Porter, what does this entry mean—C₂H₅O?" Porter (with superior smile): "That, sir, is the Latin for beer, sir."

A DISCLAIMER.

WE have received the following:

Sir,

We regret that our names have appeared in an article on the treatment of consumption which was published in the *Daily Telegraph* on the 1st inst., and wish to state that the article in question was written and published without our knowledge and consent.

Yours truly,

J. CAMPBELL McCLEURE.
F. MEHARTO.
J. HORNE WILSON.
KENNETH ECKENSTEIN.
R. TANNER HEWLETT.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

| | £ | s. | d. |
|-----------------------|-----|-----|--------|
| Eight lines and under | ... | ... | 0 4 0 |
| Each additional line | ... | ... | 0 0 6 |
| A whole column | ... | ... | 2 13 4 |
| A page | ... | ... | 8 0 0 |

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Wednesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *postes restant* letters addressed either in initials or numbers.

ALIMENTARY TOXAEMIA.

PAPERS READ AT THE OPENING OF A DISCUSSION AT
THE ROYAL SOCIETY OF MEDICINE.

GENERAL INTRODUCTION.

BY W. HALE WHITE, M.D. LOND. AND DUBL.,
PHYSICIAN TO GUY'S HOSPITAL.

THE term "alimentary toxæmia" at once shows our ignorance, for it is unscientific to group cases of poisoning according to the point of entrance of the poison; they should be grouped according to the variety of the poison; it is a minor matter whether our murderer comes in at the window or the door. Further, the term is too wide; an illness due to any poison absorbed anywhere from the mouth to the anus is strictly an alimentary toxæmia, but the phrase would hardly cover a case of opium poisoning. The user of it probably wishes to suggest that an illness is due to poisons made by micro-organisms resident in the alimentary canal, although, with our present knowledge, he can never name the poisons, nor is he certain of the offending micro-organisms; still we are equally ignorant of the poison in uræmia and diabetic coma. But it is not clear that it may not be used when micro-organisms from the alimentary tract—for example, *Bacillus coli*—pass into the blood and so cause illness, and it is somewhat confusing that if infected food causes poisoning we talk of food poisoning, not food toxæmia; on the other hand, when the food is not infected by pathogenic micro-organisms but makes the person who eats it ill, he is by some said to be suffering from alimentary toxæmia—for example, as in a person who has urticaria after eating strawberries.

The simplest alimentary toxæmia is that due to pyorrhœa alveolaris. This local trouble in the mouth leads to imperfect mastication, hence large pieces of food are swallowed which cannot be digested, and if they contain micro-organisms which, if the mass were properly masticated, would be set free in the stomach and destroyed there, they may indirectly lead to the production of poisons in the intestine. Further, the micro-organisms discharged in the pus from the gums may be swallowed, and it is possible that the gastric secretions, being abnormal or deficient, may not kill them, or that if the stomach is well filled with solid food and the micro-organisms are then washed down with a draught of water, they, suspended in the water, will be rapidly passed through the stomach on the top of the solid food, and hence reach the intestine and cause intestinal toxæmia. It may be that in some diseases micro-organisms found in the intestine have been excreted from the blood, and that such organisms may when in the intestine manufacture poisons. Micro-organisms taken into the blood from the diseased gums may perhaps cause intestinal toxæmia in this way. Lastly, the micro-organisms in the gums may pass into the blood, and cause septicæmia varying from mild to severe. I have met with several fatal cases, and very many persons owe general ill-health or chronic indigestion to pyorrhœa. It is surprising how often this is overlooked. When seeing a patient for the first time, it is as important to examine the teeth as to feel the pulse. Although most common among poor, ill-educated people, pyorrhœa is often to be found in those who presumably clean their teeth properly and frequently; sufferers from it are unaware that they have anything amiss with their teeth. Its presence does not prevent the patient from having other illnesses; sometimes these are wrongly attributed to pyorrhœa. It is dangerous to remove too many affected teeth at once, for a rapid absorption of micro-organisms may take place by the damaged vessels. The value of vaccines will be discussed later by others. My own practice is to give them, for I have never known them do harm in this condition, and I think I have seen them do good.

When we consider bacterial poisons formed in the gastro-intestinal tract, the difficulties are so great that we may almost despair of understanding the subject. External temperature is said to play a part, for although in temperate and tropical climates the lower intestines of animals which have been weaned swarm with micro-

organisms—a human being excretes daily 128 billions, 99 per cent. of which are dead, in the faeces—yet the intestinal contents of arctic animals are by some observers stated to be sterile, or almost so, suggesting that it would be a good thing to establish at Spitzbergen a health resort for those thought to be suffering from alimentary toxæmia. Ill understood alterations in the gastro-intestinal contents must influence their bacteriology; thus, *Bacillus coli* is usually confined to the large intestine, but I know a woman suffering from severe dyspepsia and in whom lavage always shows the contents of the stomach to be swarming with *Bacillus coli*. Then the presence of one micro-organism affects others; for example, one of the chief functions of the *Bacillus coli* is to smother others, either by making bodies poisonous to them or by withdrawing their nourishment; it thus kills typhoid bacilli—a fact of interest when we remember that *Bacillus coli* may often be found in the urine of those afflicted with typhoid fever. On the other hand, the *Bacillus coli* may itself be killed by invaders—for example, Morgan's bacillus, *B. suispestifer*, *B. enteritidis*. Then the same micro-organism may act differently in different hosts—for example, one person's strain of colon bacillus often differs from another's. Again, alterations at one part of the intestine will affect processes going on lower down; for instance, colon bacilli have no effect on proteins, but they decompose (putrefy) peptones. If, therefore, there is complete absorption in the small intestine no peptones will reach the large, and so there will be no putrefaction, nor will there be if only unaltered proteins reach the large intestine, but any peptones will putrefy. We hope to hear from the bacteriologists which are the micro-organisms causing alimentary toxæmia. Herter taught us that there are probably three groups of cases:

(a) The indolic, in which the probable fault was that the colon bacillus invaded the lower part of the small intestine, and the patient was unable to digest carbohydrates, and usually passed abundance of indican.

(b) The saccharo-butyric, in which the organism mostly concerned is the *B. arroyensis capsulatus*; the abnormal changes here occur in the large intestine.

(c) A group combined of a and b.

We must, when thinking of alimentary toxæmia, bear in mind that the culture medium itself is as important as the bacteria, and therefore alterations of diet may influence the production of intestinal poisons as completely as bacteria themselves. A good instance of this is the improvement that follows the withdrawal of carbohydrates in cases of carbohydrate dyspepsia.

Those who ascribe most to alimentary toxæmia are unable to tell us what the poisons are. Much work has been done on the excretion of indican and ethereal sulphates in the urine, and there is no doubt that an excess of indican is often associated with serious intestinal disturbance, but many persons pass large amounts of indican for many years and remain in good health; on the other hand, indican is not passed in many instances in which the patient might be thought to have alimentary toxæmia. It is generally allowed that the poison is not indol, indican, or ethereal sulphates. Indeed, just as we do not know what the poison is in uræmia or diabetic coma, so we do not know what it is in the illnesses ascribed to intestinal toxæmia, nor do we know for certain which are, in any case, the offending micro-organisms, nor do we understand the circumstances favouring their appearance and development, and, unfortunately, the circumstances cannot be exactly reproduced in the laboratory. Further, it would not necessarily follow that if, say, by subcutaneous injection certain symptoms were produced, the same would follow when the poison was absorbed from the intestine; mercury inhaled causes tremors, but not when taken by the mouth. Surely all this being so, statements should be made cautiously; yet one reads that indol-forming organisms must be harmful because they are prominent, and many equally foolish arguments. Nevertheless, some very suggestive work has been recently done by Mellanby and Twort and others, who have isolated creatin-destroying micro-organisms from the alimentary canal, and their experiments show that in the intestines of animals another bacillus forms β imidazolethylamine, which is a powerful poison, from histidine, but the process cannot take place in an acid medium. This poison is probably destroyed in the liver,

and it is suggested may be a cause of cyclic vomiting. It would be very interesting to see if it is present in a piece of gut excised at an operation on the human subject. Bertrand and Berthelot have called the micro-organism *B. aminophilus intestinalis*.

But even if we knew all about the formation of the toxin, and had identified it in the intestine, our difficulties would not be at an end, for before it reached the general circulation it might be altered in its passage through the intestinal wall or in the liver. Indeed, it is possible that sometimes alimentary toxæmia may be a hepatic disease, in which substances absorbed from the intestine in all human beings are so altered in the liver of some that they become poisonous, or abnormal bodies arriving at the liver may so alter it that it produces poisons. Anyhow, there is strong evidence that an important function of the liver is to protect us from poisons absorbed from the intestines, and that its efficient performance of this function depends upon carbohydrates. The difficulty is well illustrated by cirrhosis of the liver, which was formerly always ascribed to alcohol; but now we know that it occurs in some who do not take alcohol, it does not occur in some who do, nor in animals poisoned by alcohol, and it is a part of some diseases in which alcohol plays no part—clearly some other substances than alcohol can set up the cirrhotic process; and probably, under circumstances of which we know nothing, alcohol can accelerate the formation of these substances, which may well come from the intestine, and, if so, cirrhosis of the liver may be a form of alimentary toxæmia.

I am afraid our knowledge is not sufficient for us to argue that because certain processes go on in the intestine there must be a clinical condition to which the term "intestinal toxæmia" may be applied; but it does not follow that there are not assemblages of symptoms of which an alimentary toxæmia is such a likely cause that we may with reason assign them to this cause until some other cause is shown to exist. The best example of such an assemblage is that known as carbohydrate dyspepsia. An infant afflicted with this has pyrexia; it loses flesh, but its tissues gain in water; its abdomen is distended by the accumulation of gas in the bowel; it is pale, fretful, and sleeps badly; it is often sick and has diarrhoea. The stools contain green colouring matter and an excess of fatty acids; they irritate the skin round the anus, leading to dermatitis. These symptoms may be produced in a previously healthy child if an excess of carbohydrate is given, and will pass away if that excess is withheld. I would suggest that these are the cases of intestinal toxæmia that should be first studied, for in them we see the problem at its simplest, the illness being induced by a single simple article of food. As this is carbohydrate and the intestines are distended with gas, there is every probability that excessive fermentation accompanies the formation of some poison which is capable of causing pyrexia; indeed, much older children often suffer from attacks of pyrexia which may be prevented by abstention from carbohydrates. Enterogenous cyanosis is a form of intestinal toxæmia from which we might learn much if it were commoner, for we know that in the methæmoglobinæmia variety there is a nitrite in the blood probably derived from some abnormal intestinal process, and that in the sulph-hæmoglobinæmia variety hydrogen sulphide is concerned with the production of the disorder, and as the cyanosis has disappeared when the accompanying constipation has been overcome there is every probability that the complaint is really an example of alimentary toxæmia. As nitrites and hydrogen sulphide are simple chemical bodies, it is particularly disappointing that we can discover nothing about the abnormal intestinal processes at the bottom of enterogenous cyanosis, and this should make us particularly careful of dogmatizing when we do not even know what the poisons are. Certainly sufferers from enterogenous cyanosis have not the symptoms which it is the fashion now to assign to alimentary toxæmia.

Lately it has been urged with much insistence that many suffer from ill health due to absorption of poisons from the bowel which are formed there because the bowel is imperfectly emptied; or, in the modern terminology, these patients are said to have intestinal toxæmia due to intestinal stasis. That such is the case is very likely. Most people feel miserable if their bowels are not open

for some time. Advertisements of medicines designed to keep the bowels open assail us all over the world, many health resorts flourish exceedingly because their natural waters are aperient, colossal fortunes have been made out of the sale of purgatives, the *Pharmacopœia* contains more examples of the aperient than of any other class of drugs, and the improvement in health that follows keeping the bowels properly open is often so striking that, from the clinical point of view, there is strong evidence that we may suppose such an alimentary toxæmia secondary to intestinal stasis, although we are unable to indicate the poison or to say how it is formed. But it must never be forgotten that individuals vary exceedingly about their bowels; some are perfectly well if the bowels are only open once a week. Presumably, if intestinal stasis is an important factor in causing alimentary toxæmia, these persons do not readily form poisons, or, if they do, they are immune to them. It has, however, been stated recently that the results of chronic alimentary toxæmia are much more numerous than was previously thought, and that the cause of the failure to empty the bowel is frequently mechanical and has been often overlooked.

To take the last point first. It is not necessary for the production of alimentary toxæmia that there should be any mechanical obstruction to the passage of the contents of the bowel. If the poisons are bacterial the quantity of them produced will depend upon the number of micro-organisms and the suitability of the medium for their growth, which, for example, might be so favourable that toxæmia would result without any stasis; therefore, toxæmia is not proof of stasis. Those who attach great importance to mechanical stasis differ much among themselves as to its cause. Some attribute it to excessively large valves of Houston, some to pericolicitis, some to dropping of the colon, some to adhesions around the ascending colon, some to spur formations at the hepatic and splenic flexures, some to abnormal mobility of the caecum, although others say that the mobility of the caecum thought to be abnormal is normal, and some to the development of various bands and abnormal mesenteries that drag the bowel and kink it; but the reasons given for thinking that these bands are evolutionary are by no means convincing, most observers regard them as inflammatory. We have no sufficiently large number of cases proving that any of these conditions are more common in those supposed to be suffering from intestinal toxæmia than in those who are not, and it is strange that when the bowels are by chronic peritonitis matted into one mass, so that there must be many abnormal kinks and great interference to peristalsis must exist, yet the symptoms said to be indicative of alimentary toxæmia are not constantly present, and even intestinal obstruction is rare. Although it may be that some of these mechanical causes lead to alimentary toxæmia, the matter cannot be regarded as proved, and it must be remembered that the coexistence of two phenomena does not prove that they stand in the relation of cause and effect; they may have a common cause—indeed, it is possible that the abnormal bands and the toxæmia are induced by the same cause. Much investigation with *x* rays has been performed upon those thought to be suffering from alimentary toxæmia, and there is no doubt that the *x* rays have added and will add enormously to our knowledge of intestinal movements, both normal and abnormal, but we must bear in mind that although *x* rays may show a kink, they cannot show the cause of the kink; that if large amounts of such a heavy substance as bismuth are used, the bowels can hardly be said to be acting normally; that we ought to be provided with dozens of *x*-ray pictures of dozens of healthy people taking the same amount of bismuth; that when we look upon a screen we only see a plane picture. All inferences from *x*-ray examinations as to whether the duodenum or any other part of the bowel is dilated must be received with caution, for the rays from the *x*-ray tubes are divergent; we are dealing with a plane picture, and usually the statement is made that the duodenum, for example, is dilated without stating its size or that of the normal duodenum.

We may now turn to the symptoms which these sufferers from alimentary toxæmia are said to show. There is no need to detail them, for they have been recently described over and over again in the medical press. I am one of those who think it probable that they

freely. It is well known that anaërobic conditions favour profound chemical cleavages in the medium in which bacteria are growing.

While the reaction of the greater part of the alimentary canal is alkaline, and thus favourable for bacterial growth, the local acidity presented by the gastric contents is not merely unfavourable but actually destructive to the more sensitive bacteria ingested. The pneumococcus, common in the mouth, does not seem as a rule to reach the intestine, and it is believed that normal gastric acidity is a safeguard against cholera.

There is a lack of repose in the contents of the alimentary canal; its tenants are liable to daily expulsion. Too much stress must not be laid on this, for a bacterium can multiply a thousand-millionfold during the average time occupied by its transit from mouth to anus, and vast numbers must remain in the various recesses of the canal or adherent to its mucosa. Nevertheless, stasis is a fertile adjuvant to bacterial multiplication, and hence to alimentary toxæmia, whether in a dilated stomach or under the commoner form of constipation.

THE BIOLOGICAL CHARACTERS OF THE NORMAL FLORA OF THE CANAL.

If we knew as much about the protozoan inhabitants of the alimentary canal as we do about its bacteria, we should probably find much the same laws governing both, but we know little on this subject, and I must pass the fauna by.

Of the flora of the canal we can safely affirm that it is *sui generis*. Certain groups of bacteria have specifically adapted themselves to life under the conditions just outlined, and have practically abandoned other modes of existence. Such are the bacilli of the colon group, the majority of the streptococci, and certain anaërobes. So characteristic are these of the alimentary canal of man and animals that by the universal consent of bacteriologists they are taken as indices of the faecal pollution of water, milk, earth, and other substances. They constitute the enormous majority of the normal tenants of the canal. Their biological properties have been moulded by their environment; they grow best at body temperature, they are potential anaërobes, and they show a high capacity for splitting up various foodstuffs, primarily for their own use, but incidentally to the occasional detriment of their host. Moreover, they can withstand considerable periods of desiccation, for, owing to their wholesale expulsion with the faeces, their chance of reaching a new host is thus increased.

THE NUMBERS OF BACTERIA IN THE ALIMENTARY CANAL AND THEIR VARIATION IN CHARACTER AT DIFFERENT LEVELS.

Our knowledge on this point is limited to the bacterial species which can grow on our ordinary culture media. It is likely that agar cultures give us an imperfect idea of the total flora, but we can control our observations by stained films, and in the case of the faeces it would appear that agar cultures, aerobic and anaërobic, yield a moderately true picture of the real state of affairs. In the crypts of the fauces and in dental cavities, on the other hand, there would seem to be many organisms which we cannot cultivate. In the following remarks I can only pretend to deal with the organisms which can readily be cultivated.

In the secretions of the healthy *buccal cavity* bacteria are present, according to Gordon, to the number of 10 to 100 millions per cubic centimetre. The most striking feature of this buccal flora is the overwhelming preponderance of streptococci, which form at least nine-tenths of the total.

In the *stomach* and *duodenum*, on the contrary, bacteria are extremely few. For in health, when the stomach empties itself properly after each meal, it is well scoured, and a large proportion of the bacteria swallowed perish during digestion.

In the *small intestine* bacterial multiplication recommences, but so long as the contents are fluid and pass rapidly along the gut, the numbers are not very high, though they increase in passing downwards. The influence of the bile, which is supposed to check intestinal putrefaction, is of a selective character, for certain of the most typical intestinal bacteria have so acclimatized themselves to it that their powers of growth are in no way impaired.

Bacteriologists commonly add bile or sodium taurocholate to their culture media when studying intestinal bacteria, in order to take advantage of this selective action. We have thus learned that bacilli of the colon group can all grow well in presence of bile, and that certain of the hardier streptococci can do the same. On the contrary, the more delicate streptococci and the pneumococcus will not grow in its presence, while such organisms as *B. proteus* are much restricted in growth.

In the *cæcum* and *colon* the conditions for bacterial multiplication become more favourable than anywhere in the alimentary tract. The intestinal contents are here mechanically delayed in order that the last remnants of nutriment may be absorbed, and the numbers of bacteria found in the faeces surpass even those of the buccal cavity. According to Houston the number per gram of normal faeces ranges between 100 and 1,000 million. Supremacy in numbers is divided between the streptococci and members of the *B. coli* group, sometimes the one and sometimes the other predominating. I have usually found *B. coli* the more numerous. In the colon, too, anaërobic bacilli begin, in lesser degree, to assume prominence, while *B. proteus* and sometimes *B. pyocyaneus* are not uncommon.

THE NAMED BACTERIAL SPECIES OF THE FLORA OF THE ALIMENTARY CANAL.

This subject is one of much difficulty. At any time one is beset with doubts as to the criteria to be employed in deciding specific differences amongst bacteria; it is possible that they scarcely exist in the sense to which we are accustomed amongst higher plants and animals. And nowhere is the difficulty so great as amongst the coliform bacilli and the streptococci, which present infinite gradations in their biological characters. I cannot attempt to deal with this subject here, but must content myself with a few general statements.

The members of the *B. coli* group are roughly classified according to their fermentative reactions with certain sugars and alcohols, and in a more refined manner by their agglutination reactions. The commonest variety is that now recognized as the classical *B. coli communis*, which ferments lactose and dulcitol but not saccharose. Hardly less common is its saccharose fermenting variety, whilst the various types known as *B. lactis aerogenes*, *B. acidilactici*, etc., are frequently met with. Less common are *B. faecalis alkaligenes* and members of the Gaertner group.

As regards the *streptococci*, terminology is even more difficult. The attempts to assign provisional names to the more frequently occurring types, by Horder and myself amongst others, have met with a good deal of adverse criticism, because the sugar reactions, introduced by Gordon, upon which we chiefly relied, have been considered by others to be too variable for the purpose. This is not the place to discuss this very controversial subject, but it will be admitted that the common streptococci of the mouth and intestine are of a relatively harmless nature as compared with *Streptococcus pyogenes*. Personally I believe that a legitimate distinction may be drawn between the streptococcus most abundant in the mouth and upper air passages and a form which is common in the faeces, though it must be admitted that intermediate forms occur, so that one is probably not entitled to regard them as species. These are the types which Horder and I described as *S. salivarius* and *S. faecalis*. Even if all sugar reactions were discarded, it would still, I think, be possible to distinguish the much greater hardiness, vigour of growth, and metabolic activity of the faecal form from the feebleness of the salivary one. I have never been able to find *S. faecalis* in the buccal cavity, though the salivary type is common in the faeces.

Our knowledge of the *anaërobic bacilli* of the alimentary canal is very imperfect. The most abundant appears to be the organism which has been variously termed *B. aerogenes capsulatus*, *B. welchii*, and *B. enteritidis sporogenes*, but, with this, the ordinary putrefying anaërobe, which Klein terms *B. cadaveris sporogenes*, but which has also been described under other names, appears frequently present. In the colon, at all events, free oxygen is so far absent that these organisms, and probably other less well-known anaërobes, can flourish, and it is clear that their activity in breaking down proteins is of a very high order.

While members of the three foregoing groups of bacteria constitute the great mass of the intestinal flora, every plate culture shows that other organisms are also present in small numbers—staphylococci and sarcinae, *B. proteus*, in more than one form, and *B. pyocyaneus*. The last named organism is one with which I have repeatedly met in the intestine, and it is of interest as one which forms soluble metabolic products. As regards *B. proteus*, it would appear that its powers of decomposing protein have been a good deal exaggerated.

THE EFFECTS UPON THE HEALTHY BODY OF THE NORMAL ALIMENTARY FLORA.

It is sometimes supposed that the intestinal flora performs certain "functions" in the economy of its host. Attempts have been made by more than one observer to rear mammals or birds under germ-free conditions from birth. In many cases the creatures thus treated have not survived for many weeks, but the experiments teach little, for it is at least as likely that premature decease was due to the wholly unnatural conditions under which it was needful to keep the animals as to the absence of bacteria from the alimentary canal. I do not know of any good evidence that it is of benefit to have our intestines swarming with bacteria, many of the products of which seem harmful to us. Bacteria are not actuated by any sentiments of altruism. They take advantage of the favourable conditions offered by the alimentary canal purely for their own good; and if they do us little harm, it is because the whole race of higher animals has been evolved under these necessary conditions, perpetually present from the beginning, so that there has been ample time for the evolution of such protective mechanisms as are needful to neutralize the labitual effects of bacterial commensalism. I refer not merely to defence against bacterial invasion, but to a neutralization of their toxic products. It is conjectured that such injurious substances, absorbed from the alimentary canal, as may escape the alchemy of the liver are neutralized by the secretions of certain of the ductless glands—for example, the thyroid. There can, however, be no doubt that the intestinal flora is not without influence upon the body, even in health, for the more actively metabolic bacteria carry out protein splitting to a point beyond that which can be exercised by the ordinary digestive ferments, and of the soluble products some are known to be toxic.

THE INFLUENCE OF PATHOLOGICAL CONDITIONS UPON THE FLORA OF THE ALIMENTARY CANAL.

Owing to the extreme rapidity with which bacteria can multiply, rapid changes can readily occur in the flora of any part of the alimentary tract, as may be seen in infective conditions. Further, any part of the tract in which retention of the contents is brought about is apt to show an abnormal bacterial flora.

In the mouth and naso-pharynx infective changes are extremely common, and an invading microbe, such as the pneumococcus, *Micrococcus catarrhalis*, or *Streptococcus pyogenes*, may speedily predominate in the local flora. In chronic conditions of oral sepsis, such as dental caries or pyorrhoea alveolaris, there may be an excessive abundance of streptococci of lesser virulence.

Gastric dilatation and incompetence afford an instance of a radical change in the normal flora. The natural acidity of the gastric contents is disturbed, and in the absence of proper emptying and scouring of the viscus, yeasts, sarcinae, and other unnatural tenants come to multiply in the stagnant contents, and may form a conspicuous microscopic feature in the vomit.

Nor, in considering the bacteriology of the alimentary canal, must we forget the gall bladder, which is not rarely the seat of chronic bacterial infection. Usually such infection is by some normal inhabitant of the canal, such as *B. coli*, whereby no great change is brought about. But the infecting agent may be a foreign organism, such as the typhoid bacillus, and when this condition is persistent, as in a typhoid carrier, a more or less permanent addition is made to the flora of the intestine.

The bacterial contents of the small intestine may be profoundly modified in disease. In the rapid peristalsis of acute diarrhoeal conditions the normal inhabitants of the gut are quickly swept away and a new flora may be substituted. Thus, in Asiatic cholera, the contents of the

ileum may yield almost a pure culture of the cholera vibrio.

In the colon diarrhoeal conditions may produce a similar effect, so that the liquid dejections may show a predominance of whatever microbe is at the root of the trouble, be it cholera, dysentery, or Gaertner poisoning. But from the point of view of intestinal toxæmia, constipation plays a much more important part than diarrhoea, and its effects must form an essential element in this discussion. Retention of the intestinal contents affords a fruitful field for the multiplication of the normal bacterial flora, and for the full exercise of their fermentative activities, and at the same time it gives opportunity for the absorption of whatever toxic products may be formed.

THE PART PLAYED BY BACTERIA IN THE CAUSATION OF ALIMENTARY TOXAEMIA.

Having thus shortly considered the nature and properties of the bacteria of the alimentary canal, I must address myself to the second and more difficult part of my task, that of attempting to assess the share which is borne by bacteria in the causation of poisoning from the intestines. If, in this attempt, I trespass in any way on the branches of the subject allotted to others, I must ask pardon.

In the first place I think it necessary, if this discussion is to be of any value, that we should endeavour to reach clear conceptions as to what we mean by "alimentary toxæmia." There are few terms more loosely employed, because we have so little accurate knowledge on the subject. The very terms "toxin" and "toxæmia," though they drop so easily from our lips and soothe our minds with the feeling that at least we have a name for these things even if we know nothing about them, are in truth but confessions of ignorance. The word "toxin" is a convenient one for chemical poisons of which we do not know the composition, but it might be better for clear thinking and the advance of knowledge if we were less ready to cloak our ignorance by the too common use of the term. Our hope of salvation rests with the chemists. The word "toxæmia" is equally vague, and in danger of loose usage, but it is a legitimate word if we employ it to mean the circulation in the blood of chemical poisons whereby they are enabled to attack the cells or tissues for which they have the requisite chemical affinity. By "alimentary toxæmia," therefore, I understand the absorption from the alimentary canal of chemical poisons, of known or unknown composition, in sufficient amount to cause clinical symptoms, the blood having served as the channel of distribution to the tissues which are poisoned.

This definition would exclude all those cases in which actual bacterial invasion of the blood occurs from the alimentary canal, though not those in which there is absorption of the toxic products of bacteria concerned in purely local infection of the canal. I would lay some stress on this because I think it is hardly realized how commonly slight invasions of the blood stream take place; evidence is gradually accumulating to show that the normal intestinal bacteria are constantly gaining access to the blood in trivial numbers, and as constantly destroyed by the various protective mechanisms which the body has been compelled to evolve in order to avert the danger. Only when these mechanisms are in default does serious trouble arise, but it is possible that some of the cases of local disease attributed to toxæmia are really of infective nature.

There are certain alimentary toxæmias which are clearly not of bacterial origin. We subsist on foreign proteins, hydrocarbons and carbohydrates, and of these there is abundant evidence that alien proteins may be toxic and sometimes highly so. The normal processes of digestion break down the foreign protein into somewhat simpler, though still complex, atom groups, which, after absorption, are carried to the liver, whose business it is to reconstitute the protein in a form adapted for human needs. One of the primary functions of the liver is to act as a shield against the toxicity of foreign proteins, and we have evidence that when, by the formation of an Eck's fistula, this function is eliminated, serious toxic results occur. It follows that grave hepatic disease may be the cause of a toxæmia, partly, at least, alimentary in origin, and instances of this, in acute yellow atrophy and some puerperal eclampsias, will at once occur to the mind.

The bacteria in the alimentary canal, in virtue of the high fermentative activity which many of them possess, carry out protein cleavage to a point beyond that which the body demands for its own nutritional needs, and certain of the products which thus arise are actually harmful to the host. But this has always been so, ever since bacteria took up their residence in the alimentary canal of animals, and it has been necessary for animals to evolve some means of chemical antagonism to neutralize this harmful effect. We are still in comparative ignorance of the precise chemical mechanism by which this permanent menace is met in health, but that it is so met is certain, for in health we remain untouched. It is conjectured that one of the functions of the thyroid gland is to deal with this matter. A number of observations by different workers have shown that the activity of this gland is excited by the presence of bacterial toxins, and it has been asserted by certain observers that thyroidectomized animals are abnormally susceptible to infective processes. It is possible that the antitoxic functions of the thyroid extend to chemical poisons other than bacterial toxins. Be this as it may, it is clear that the body in some way compensates the ordinary activities of bacteria in the intestinal tract, so that no harm results. Only when such bacterial decompositions are excessive, and when faecal retention affords unusual opportunities for the absorption of the products, are symptoms manifested.

Thanks to the labours of chemists, our knowledge of the protein decomposition products is fairly extensive, though our knowledge as to their toxicity is incomplete. Most of them appear to be of feeble toxic powers, but it must not too hastily be assumed from animal experiment that such substances as, for example, indol are so harmless as they would appear. I am very far from agreeing with the recent hypothesis suggested by Metchnikoff as to the rôle of indol and allied substances in the causation of arterial degeneration, for the evidence put forward seems to be wholly insufficient. But we can to some extent measure the absorption of indol by the excretion of indican in the urine and correlate its excess with clinical phenomena. The excessive indicanuria in conditions of mental depression and melancholia, for a knowledge of which I have to thank Mr. Mackenzie Wallis, may be of great pathological significance, and may outweigh any negative evidence derived from animal experiment.

There is also a possibility, for the suggestion of which I again owe my thanks to Mr. Wallis, that excessive bacterial activity in the intestine may have its negative as well as its positive influence. Thus, still to take indol as an instance, it is known that this substance is derived from the tryptophane element in proteins. If tryptophane is an important element in tissue nutrition, it may be that excessive splitting up of this substance in the intestine by bacteria may lead to tissue starvation in an important detail. An element in a supposed alimentary toxæmia may possibly be due not so much to the positively toxic action of the derivative as to the absence of the needful substance from which it has been derived. I must leave such considerations to those who follow in this discussion.

Bacteria, however, may do more than provoke merely fermentative changes in the medium in which they are growing. They produce, in virtue of their own intrinsic metabolism, substances of unknown chemical composition which are deleterious to their hosts, and which we must be content to term "toxins" in the absence of more exact knowledge. It is established that a very few—bacteria produce soluble toxins which pass out into the surrounding medium without any disintegration of the bacterial body. These are the pre-eminently "toxic" bacteria, of which the diphtheria and tetanus bacilli are the commonest examples, and they lie outside our present subject. Indeed, almost the only essentially toxic bacterium which could be dragged into the discussion is van Ermengen's *B. botulinus*, present in certain ham poisonings, though *B. pyocyaneus* might perhaps also be included. But the great majority of pathogenic bacteria, and practically all those which are normally saprophytic in the alimentary canal, form no soluble toxins; so far as they possess toxic properties, these reside in the bacterial protoplasm itself and are liberated only on its dissolution—so-called "endotoxins."

Bacteria are, of course, constantly undergoing dissolution in the alimentary canal, and one cannot dispute the possibility of harmful effects from such endotoxins on absorption. But we are in almost complete ignorance of the extent to which alimentary toxæmia rests on such a basis. So far as concerns the normal intestinal flora, I should be disposed to believe that poisoning by bacterial endotoxins plays a comparatively negligible part in the process. As soon as evidence is brought forward showing this to be the case I shall be ready to accept it, but so far there is none, and it is probable that the endotoxins of most of the normal inhabitants of the alimentary canal are of very feeble virulence, though those of the colon bacillus may perhaps prove of some importance. This does not, of course, apply to cases of infective enteritis, in which the absorption of bacterial toxins plays a large part in the production of the constitutional symptoms.

To sum up what I have said as to the part played by bacteria in alimentary toxæmia, it seems to me reasonable to lay down the following propositions:

1. In an important group of cases the poisoning is by foreign proteins, as such, the defect lying in the liver, which ought to shield the body from their effects. With this bacteria have, as a rule, nothing to do.

2. The main effect of bacterial activity in the production of alimentary toxæmia lies in their ability to carry out protein cleavages beyond the capacity of the ordinary digestive ferments, with the formation of products which, when in excess, the body is unable to neutralize.

3. There is at present little evidence that true toxins, derived from the ordinary flora of the gut, soluble or intracellular, play much part in alimentary toxæmia.

ALIMENTARY TOXAEMIA : ITS SYMPTOMS AND TREATMENT.

BY ROBERT SAUNDBY, M.D., LL.D., M.Sc.,

F.R.C.P. LOND. AND I.,

PROFESSOR OF MEDICINE IN THE UNIVERSITY OF BIRMINGHAM.

The doctrine of intestinal auto-intoxication was originated by Bouchard, and has formed the foundation for far-reaching speculations. There is little evidence that the normal products of intestinal fermentation and putrefaction are capable of producing disease, and if acetic and butyric acids, indol, skatol, and the like are harmful their effects must not be exaggerated. Sulphuretted hydrogen is only present normally in traces, and much larger quantities may be injected into the rectum without hurt, although admittedly this gas is more harmful when formed in the small intestine or the stomach. Ammonia is converted into harmless urea, while volatile fatty acids and acetic and butyric acids only produce local stimulation, even when present in quantity. Acetone, diacetic acid, and beta-oxybutyric acid are present in the urine, together with various symptoms of disturbed digestion, but this does not prove that the symptoms are due to them. The first two are found in the urine of starving animals with no digestive disturbances, and merely indicate the breaking down of tissue protein. Ptomaines may be present in excess in intestinal contents without any toxæmic results, as, for example, in cystinuria. On the other hand, there is a widespread belief, not without evidence in its favour, that many diseases depend upon the absorption of poisons from the intestine, either introduced with food or formed from it by the fermentative or putrefactive processes in the alimentary tract.

FOOD POISONS.

In former days food poisoning referred to the accidents that result from the ingestion of substances rendered harmful by the poisons contained in them, but modern research has added to these the effects of microbes and the toxins due to their activity. These last are exclusively produced from animal food; the danger of vegetable food depends solely upon its natural poisons or its accidental contamination by microbes in the water with which it has been washed or in the dust lying on its surface.

Vegetable Food Poisons.

Among the best known poisons from vegetables are those contained in many kinds of mushrooms, and the poisonous effect varies not only with each kind, but with season and place, some being poisonous at one time of the year and not at others, some dangerous in warm countries but harmless in colder climates; some of these poisons are destroyed by boiling, the water in which the mushrooms are cooked becoming highly poisonous.

Phalline, the poison of *Amanita phalloides*, determines destruction of the blood cells and causes choleraform symptoms, with vertigo, delirium and somnolence that may pass into coma, convulsions, and death; or final fatal icterus may occur after a remission of the symptoms has taken place, while should the patient recover, convalescence is slow and the myocardium and kidneys may remain damaged.

Muscarine, the poison of *Amanita muscaria*, causes nervous symptoms resembling alcoholic intoxication with cramps, convulsions, contracted pupils, rapid small pulse, and death in collapse, or recovery may follow a prolonged sleep.

Flour is sometimes poisonous by the accidental admixture of the seeds of tares, cow-wheat, smut, ergotized rye or vetch with the meal of wheat, maize or rye. Adulteration from tares and cow-wheat gives rise to nausea, vomiting, colic, disturbed vision, vertigo, somnolence, and lassitude, which disappear in a few hours. Cow-wheat may also produce convulsions. Smut contains a poison called "githagin," which may determine intense colic with diarrhoea and hæmorrhage from the bowels. Ergotized rye causes nausea, vomiting, lassitude, with constipation or diarrhoea, and subsequently local symptoms such as cramps of certain muscles or gangrene of the fingers and toes; vetch poisoning induces spasmodic paraplegia with disorders of sensation and tremors.

Potatoes sometimes produce poisonous symptoms from the presence of solanine, causing slight vertigo, headache, vomiting, dilated pupils, and rapid action of the heart.

Animal Food Poisons.

The putrefaction of animal food leads to the production of (1) ptomaines and (2) leucomaines. The first are formed by putrefaction, the second by the excessive destruction of protein.

Certain poisons are developed spontaneously and apart from microbial infection—for example, oxybetaine from meat and putrefying bones, choline from herring pickle, muscarine from decayed fish, methylgadinine from putrid horseflesh, and ptonatropine from salted sturgeon.

On the other hand, the *Bacillus botulinus* and other microbes of the type Aertryck and the type Gaertner cause a poison, botulin, in putrid ham. Other poisons are formed by the paratyphoid bacillus, by enterococcus and proteus, while the *Bacillus coli* may under certain circumstances enter the blood and make the meat poisonous—as, for example, in United animals. Meat preserved in various ways, especially in cold storage, seems to be liable to undergo poisonous decomposition. This is also true of gelatine, cream, and Rouennaise ducks: these last are killed without loss of blood by puncturing the medulla, and are then beaten so as to effect the diffusion through their tissues of anything absorbed from the intestine. Certain fish, the herring and the conger, and certain roes are at times poisonous; mussels contain a poison which has been called mytilotoxine (Virehow and Brieger) and mytilocongestine (Richelet), while oysters sometimes contain similar poisons. It is not known how these poisons are produced; by some (Thesen) it is thought that they are formed in sea water. Young veal is highly poisonous when the cow has suffered from septic fever or puerperal metritis. The meat of animals suffering from septic diseases, metritis, pneumonia, and typhus is undoubtedly poisonous. Hunted game is sometimes also poisonous from the intestinal microbes entering the blood.

Preserved meat, potted meat, sausages and the like, may be infected before being packed or during preparation, and in hot weather the microbes develop and produce poisons. Eggs may be contaminated in the oviduct, and when used in confectionery—especially when mixed with such favourable media for the cultivation of microbes as sugar, milk, and gelatine—may develop poisons. Cheese is also occasionally the seat of poisonous putrefaction.

There is little doubt that certain foods become poisonous from the absence of some principles normally present, but which have been removed or disappear when the food has been kept too long. Of these beri-beri, although only known to Western medicine in recent years, is the example in which this relation has been most clearly established. The belief that it depended upon some dietetic defect was maintained as long ago as 1878 by Wernich, supported later by Van Leent, and the practical value of the doctrine was demonstrated by Takaki, who, by the reform of the diet of the Japanese navy, wholly eradicated the disease from that service. But it was Braddon who was the first to show the connexion between the consumption of white rice and the prevalence of the disease, and the conclusive proof has been worked out by Fletcher, Stanton, and Fraser, who have shown that rice completely denuded of its pericarp, if used as an exclusive diet, causes beri-beri, while the disease may be prevented by mixing a proportion of the "cleanings" with the diet, and conversely that the disease does not arise when imperfectly husked rice is consumed.

Although the position of pellagra as a food disease is disputed, the belief is general in the United States, where its incidence has extended widely during the last few years, that this spread is due to the fact that maize, which was formerly consumed where it was grown, is now transported long distances and stored for use. The cases that have been observed in Scotland are also thought by some to be due to an analogous change in oatmeal.

Scurvy or scorbutus has been long recognized as related to insufficient diet, and should be included among diseases due to dietetic error or defect, for the suggestion that it is caused by a poison formed in tainted meat receives small support from the experience of those who have seen most of the disease. This view impressed itself upon the mind of Captain Robert Scott, as in the second year of his former Antarctic expedition, when he had plenty of fresh seal meat, the disease disappeared; but fresh meat contains the necessary principle. There is strong evidence of the value of varied diet, of fresh or preserved vegetables, and lime juice; the use of the last article coincided with the practical disappearance of the disease from the British navy.

Barlow's disease is another result of dietetic defect, as, like scurvy, it depends upon the want of some principle usually present in fresh milk but absent in patent and preserved foods. Cases have been alleged to occur in children who were fed on breast milk; but the breast milk may have been defective owing to the impaired health of the mother.

Speaking generally, the results of food poisons may be classified into slight, medium, and severe: (1) In slight cases there may be only some digestive trouble, nausea, vomiting, colic, headache, pain in the back, with recovery in two or three days, or there may be urticaria without digestive trouble, or simply diarrhoea. (2) In medium cases, in addition to the symptoms already described, there may be a persistently dirty tongue, slow convalescence, a disposition to relapse, accompanied by constipation and enfeebled digestion lasting for weeks. (3) Severe cases may present (a) the typhoid state, with high temperature, epistaxis, diarrhoea, gurgling in the right iliac fossa with enlarged spleen, such cases often giving rise to considerable difficulty in diagnosis; (b) the choleraform type, with violent vomiting and purging, pains, cramps, dyspnoea, thready pulse, sweating, purpuric and scarlatiniform eruptions, low temperature, collapse and perhaps death, or a reaction with return of diarrhoea and vomiting, followed by gradual improvement, slow convalescence, and prolonged weakness; (c) the icteric type, characterized by jaundice which may be malignant in form and results especially if the kidneys are diseased. Many doubtful cases of disease are due to these toxic infections.

Botulism is a special form in which, after two or three days of colicky pain, vomiting and diarrhoea set in with dryness of the skin and mucous membrane. There may be constipation. External and internal ophthalmoplegia may occur. There is no fever, but there is difficulty in deglutition owing to the dryness of the pharynx. These symptoms may gradually disappear and slow convalescence follow, or death may result from cachexia,

bronchopneumonia, or asphyxia from food sticking in the pharynx.

In Captain Ejnar Mikkelsen's book, *Lost in the Arctic*, which describes his adventures and hardships during his expedition to Greenland, he tells how, when hard pressed by hunger, he and his companion were driven to eat the liver of freshly-killed dogs, and suffered in consequence. Their symptoms were peculiar, as they consisted of an uncontrollable desire to sleep, their sleep lasting ten or twelve hours; when they awoke they suffered from a splitting headache; some days later the skin peeled, and Mikkelsen says his companion Iversen had "big sores all over his body." In an earlier part of the book it is stated that a dog was made ill by eating dog's liver, but somnolence was not a symptom. The livers, when eaten by Mikkelsen and his companion, were cut in slices and "fried in water," so that the meat was imperfectly boiled. The poison was probably toxic albumose, which was all the more active as the meat was freshly killed and only partially cooked.

Sir Lauder Brunton, Dr. A. C. Farquharson, and others have drawn attention to the symptoms produced by food poisons which in many cases resemble the action of a paralysing narcotic, but Farquharson attributes this effect, not to a direct soporific poison, but to dilatation of the gastro-intestinal blood vessels with consequent anaemia of the brain.

Many skin eruptions are attributed to the absorption of intestinal poisons—for example, erythematous rashes, urticaria, pemphigus or pemphigoid eruptions, and pruritus. The effects of fish, shellfish, and certain fruit in causing erythematous eruptions are well known. Coffee may cause pruritus and sweating of the palms of the hands and soles of the feet. A hospital patient had many recurrent attacks of herpes iris, with large bullae in the mouth and pharynx and over the elbows and knees, which invariably followed a bout of beer drinking.

Cyclic or periodic vomiting, or food fever, is a condition which occurs in childhood, from the second or third year onward up to puberty, and is attributed by most writers who have concerned themselves about it to disturbances of digestion, especially the digestion of carbohydrates. It does not always cease at puberty or at the age at which puberty generally occurs. A case of this kind, under my care a few years ago, was a lad of 18, as undeveloped as a boy of 12; he weighed only 4 st. 9 lb.; his attacks of vomiting occurred every few weeks, and were accompanied by severe headaches; he was quite unable to earn his living. At the urgent request of his father his abdomen was opened and gastro-enterostomy was performed, without any definite condition being discovered or any improvement resulting. Acetonuria has been observed in this affection, but there is little likelihood that the cause is acetone poisoning.

It is doubtful whether there is any sound foundation for Nothnagel's view that certain cases of infantile marasmus, cachexia, and pernicious anaemia result from atrophy of the intestinal mucous membrane. It is possible that pernicious anaemia may result from the absorption of poisons from some part of the alimentary tract which destroy the blood, but the atrophy of the stomach or intestinal mucous membrane is probably associated or secondary (Knud Faber). The relation of pernicious anaemia to intestinal intoxication, although possible, has by no means been proved, and Schmidt says he has not met with sufficiently severe fermentation or putrefaction to support this theory. Chlorosis and leukaemia have also been attributed to intestinal intoxication, but without any adequate proof, and there are now few persons who would support Sir Andrew Clark's view that chlorosis is due to intestinal poisons, and may be cured more efficiently by purgatives than by iron.

Certain affections of muscles may result from severe digestive disorder, as in the cases of polymyositis acuta described by Senator and Albu.

Oxaluria or oxalacemia may be fairly reckoned to be of alimentary origin, for oxalic acid is introduced preformed in the food, or is the product of carbohydrate fermentation in the stomach which may occur when the hydrochloric acid is deficient; hence the old Edinburgh treatment by nitro-hydrochloric acid is well founded.

Arterio-sclerosis is one of the conditions attributed to

auto-intoxication, but the argument seems to be that, as only a small percentage of cases give a Wassermann reaction, they are not all due to syphilis; and if not to syphilis they must be due to auto-intoxication (Aufrecht), which only shows how comprehensive this doctrine may become. Indeed, Combe makes it play the same universal part that others assign to uric acid, while Tissier, in an equally wide generalization, maintains that the decomposition of animal protein in the intestine prepares a favourable soil for the growth of all pathogenic bacteria, and is therefore the source of most diseases.

It is sufficient comment on these theories to say that, however plausible, they do not rest upon a solid foundation.

POISONING BY FAECAL STASIS.

It is tolerably certain that there is little evidence in favour of the popular notion that mere faecal retention favours the production in the bowel of fermentative or putrefactive changes giving rise to poisons which are absorbed into the blood and cause various pathological symptoms.

Simple constipation does not lead to any increase of decomposition in the faeces, and infrequent evacuation of the bowels is consistent with perfectly good health and longevity. But it is a not uncommon cause of chronic intestinal catarrh which may go on to ulceration and even perforation, and it is to these inflammatory consequences that must be attributed the various symptoms which are associated with constipation. Faecal retention is not inconsistent with a daily action of the bowels, as in a case reported by Mannaberg of a public official who asserted most positively that he had always made a point of getting a daily evacuation, but who died of perforative peritonitis caused by a large number of enormous faecal masses nearly as hard as stones.

While, therefore, we may be reasonably sceptical about "copraemia," "faecal fever," and other alleged results of faecal fermentation or putrefaction, nothing is more certain than that many symptoms may result from constipation where alterations in the wall of the bowel have taken place. Nor is it inconsistent with this view that thorough emptying of the bowel should be followed by temporary relief to these symptoms, but at the same time we should expect that the simple evacuation of the pelvic colon would not effect a cure.

Without inflammatory changes the natural protective agencies existing in the alimentary canal can keep us safely from such toxins as are formed in the bowel; so long as the several organs concerned are structurally healthy the intestinal contents are practically outside the body and are powerless to injure us.

PROTECTIVE AGENCIES.

Against the long catalogue of supposed evil influences of intestinal microbes and toxins must be set the very real protective agencies by which under physiological conditions their entrance into the circulation is prevented. The general harmlessness of pathogenic microbes and their toxins in the digestive tract is supported by strong evidence. The healthy mucous membrane presents such a barrier by its relative impermeability that their diffusion takes place slowly, and time is allowed for the action of the digestive secretions which destroy the microbes and neutralize the toxins. This action is effected most efficiently in the stomach and small intestine, less so in the large intestine and rectum; but dogs and rabbits can withstand the rectal injection of cultures of diphtheria and tetanus, of which a fractional dose would be fatal if injected under the skin or into the circulation. More quantitative variations in the amount of the digestive secretions do not appear to interfere with this protective action, but in *achylia* infective microbes and toxins are not destroyed in the stomach, and pass rapidly into the duodenum. Even here they have to run the gauntlet of the pancreatic and intestinal digestion, which possesses almost equal destructive and neutralizing properties.

The bile has a much weaker action, its antitoxic effect being apparently due to its saponifying power as an artificial solution of soda palmitate possesses the same antitoxic coefficient. Roger attributes the antitoxic action of the bile to its power of modifying pathogenic bacteria so

that they no longer secrete toxins; but he maintains that so far from neutralizing toxins already formed, it actually increases their toxicity. Should these poisons enter the portal circulation, in spite of the destructive neutralizing or attenuating effects of the digestive secretions and the barrier of the mucous membrane, the liver itself possesses the power of arresting poisons or of converting them into harmless or less poisonous substances. Further, the intestinal mucus which coats the lining of the bowel delays absorption and prolonged contact with the mucous membrane neutralizes toxins.

Finally, the ordinary intestinal microbes are able to neutralize the toxins secreted by allied species and can inhibit the putrefactive power of others, while they can also neutralize toxins although to a much less extent than the digestive juices.

Inflammation of the mucous membrane of the bowel favours the absorption of toxins and its permeability seems to be normally greater in infants and young animals as shown by experiment. It is claimed that diphtheria antitoxin may be administered successfully to infants by rectal injection (Chantemesse) and that other antitoxins and vaccines may be so employed.

Further, it is found that various vegetable toxalbumens are not completely destroyed by the digestive juices but diffuse through the intestinal wall into the blood, and it is said that tuberculin differs in this respect from the other microbial toxins, behaving like these toxalbumens.

TREATMENT.

The treatment of these conditions cannot be discussed in detail, but the principles may be laid down.

In the first place, it is essential that food should be wholesome, that articles of doubtful nature should be avoided, that preserved foods, especially animal foods, should not be eaten when fresh can be obtained, and that as far as possible all food should be prepared by submitting it to cooking at a temperature of not less than that of boiling water. The eating of all uncooked food is attended by a certain amount of risk, and although we all run this risk at times it is unwise to eat such food when we know little about its origin or handling. For example, many English travellers suffer from eating fruit and salads in hotter countries, and even at home oysters are justly shunned unless we know their source.

In the second place, all food should be eaten slowly, properly masticated, and mixed with saliva. Defective teeth should be repaired or replaced, and the mouth kept in a healthy condition.

Provided these conditions are all fulfilled the stomach, if healthy, may be trusted to perform its share, but no doubt Trousseau's traveller was right who concluded each meal in strange places by taking a few drops of hydrochloric acid to reinforce the action of the gastric juice.

By all means let the diet be a mixed one of carbohydrate, protein, and fat, and consist of such things as are suited to the individual, avoiding excess and remembering that while every stomach can digest small quantities of most things no stomach can digest large quantities of everything. In youth amounts of food can be assimilated with advantage that in middle age tend to obesity and gout, and in later life to disordered digestion and many evil consequences. Moreover, mode of life must be allowed to regulate the quantity of our food, and as we become less active we should eat less.

Alcohol should be regarded with doubt and suspicion, for, while capable of conferring a certain amount of pleasure and at times of promoting appetite and even digestion, its general effect is to slow the digestive process and in large quantities to check it and to inhibit those protective agencies upon which our safety depends.

While due time must be given to meals and resting afterwards assists digestion, daily exercise favours absorption, maintains the circulation of the blood and lymph, prevents constipation and promotes elimination by the lungs and skin.

When alimentary toxins have been absorbed and passed into the circulation, the most rational treatment would be the administration of an antidote if we possessed one; failing that, we should try to prevent the further formation of poisons, and to favour their elimination.

Nature endeavours to get rid of the poison by setting up diarrhoea, vomiting and sweating, more rarely by diuresis, all of which may be imitated, guided, or controlled.

The means by which we may endeavour to provoke the prevention of the further formation of poisons and the destruction and elimination of those already present may be by (A) cutting off the supply of material; (B) reinforcing the digestive juices; (C) bacterial action; (D) drugs; (E) hydrotherapeutics.

A.

We seek to cut off the supply of further material for the formation of poisons by simplifying the diet. In acute conditions, after washing out the stomach, we may give nothing but hot water, or the same with the addition of a little milk or milk diluted with lime water, soda water, or barley water; in subacute and chronic conditions it is best to rely on lacto-farinaceous diet. As a general rule eggs, milk, and cheese are allowed, but some forbid even these, and give only vegetable protein, carbohydrates, and fat (Tissier). In all cases it is better that the food should be varied, well cooked, and moderate in quantity.

Fasting is a perfectly sound method of diminishing toxins if combined with copious draughts of water or mineral water (Guelpa).

Fruit "cures"—such as the strawberry cure that enabled Linnaeus to get rid of his gout, the grape cure and the like—probably act partly as fasting cures, partly by supplying a non-toxic and moderately purgative diet. The advice of Albu to take the juice of two or three fresh lemons three times a day, and to abstain from milk and fatty food, is based on similar principles.

The so-called Salisbury diet, which consists of three small meals of finely minced lean meat, each followed at an interval of two hours by half a pint to a pint of hot water, is a starvation diet, and acts probably very much like fasting, while the hot water promotes elimination.

Schroth's dry diet is also a cure by inanition, but the rational basis of the plan in all its details is not apparent, as after four or five days' abstinence from all drink and all food except five or six small dry rolls, the patient is encouraged to take a litre or a litre and a half of light wine, which, as might be expected, often causes intoxication; but the results of the Lindewiese cure, as reported by a recent observer (F. Sandoz), are on the whole not unfavourable.

B.

Physiology teaches us how to stimulate the secretion of the various digestive juices as the whole series depends for its efficient working on the proper initial start. Careful mastication not only divides the food mechanically and mixes it with the saliva, but stimulates the salivary glands to secrete and the saliva in turn provokes the flow of gastric juice and thus the other secretions. Therefore the habit of hasty eating and imperfect mastication from any cause may impair the whole process of digestion, while conversely due attention at this stage is calculated to ensure the complete carrying out of the entire function. As we have seen that these digestive agencies are the most powerful means we possess for destroying or neutralizing alimentary toxins, the importance of this point can hardly be exaggerated, although to chew food until it is tasteless and remove the residue from the mouth, as recommended by Mr. Fletcher, goes beyond what is reasonably necessary.

C.

We have seen that the ordinary intestinal bacteria afford a protective agency which, although weaker than the digestive juices, checks the action of putrefactive and pathogenic bacteria and neutralizes the toxins formed by them. Of the ordinary bacteria which play this useful part the best known is the lactic acid bacillus—a normal inhabitant of the intestine which has been made famous by Metchnikoff, but the value of butter-milk in remedying the results of a debauch has long been known in the North of Ireland. Bulgarian sour milk or Yoghourt when properly prepared is a pleasant article of food which promotes the normal action of the bowel, and the use of this or of butter-milk should be encouraged.

D.

As the stomach is the place where the food first rests and remains longest, it possesses the most efficacious antitoxic properties. The healthy stomach is sterile, and all food during its stay within its cavity is sterilized as a result of peptic digestion, and this is carried out in the presence of sufficient hydrochloric acid and pepsin. Pepsin is deficient in only the rarest instances, but the supply of hydrochloric acid may be defective or altogether absent. Under these circumstances the administration of hydrochloric or nitro-hydrochloric acid is indicated, but should be in larger doses than those commonly administered. Ten or fifteen drops of hydrochloric acid (*B.P.*) may be added to half a pint of sweetened water, and this quantity used as a drink during or after each meal. Mercurials, especially blue pill or calomel, act as antiseptics in the stomach and duodenum, but most of the so-called intestinal antiseptics have not justified the claims made for them, and it is doubtful whether any antiseptic drug in practicable doses can preserve its bactericidal capacity after passing a short distance down the intestine.

Purgatives unquestionably eliminate toxins, and are among the most powerful means we possess, but many act only on the pelvic colon and rectum, and do not clear the whole length of the large intestine. Senna possesses this valuable property, and one of the best aperients for chronic faecal stasis is an infusion of senna pods taken every night at bedtime.

E.

The practice of drinking large quantities of water, especially of the milder mineral waters, has much in its favour. Unmineralized water is apt to stay in the stomach and so to cause discomfort, but this does not seem to be true of hot water, which many people take on rising and again at bedtime. Small quantities of salines, especially magnesium chloride or sodium phosphate or sulphate, may be added to the water with advantage. This helps elimination by preventing the drying of the faeces in the colon, and stimulates peristalsis. To ensure complete evacuation of the large bowel irrigations or ascending douches are among the most efficient means, but there is a risk of inducing atony of the bowel when their quantity is excessive or their use is continued too long. The "entero-cleanser" of Anton Brosch is the most elaborate of ascending douches, the chief advantage claimed for it being that, as it is administered under water, the external pressure supports the bowel and prevents over-distension. When the above described methods have had a fair trial, and there is reason to believe in serious pathological changes in the colon permitting the continued absorption of toxins, its exclusion or removal should be considered.

CONCLUSIONS.

1. Under physiological conditions the natural protective agencies in the alimentary system are sufficient to shield the body from the dangers of poisons formed therein or of those introduced with the food, provided that these are not in overwhelming amount.
2. Infrequent or incomplete evacuation of the colon is not in itself a cause of disease.
3. Such morbid symptoms as arise result from a breakdown in the protective machinery, in consequence of functional defects or pathological changes in the organs concerned.
4. Wholesome food in reasonable quantities may consist of animal or vegetable protein, carbohydrates, and fat in due proportion, and the evidence does not justify the entire exclusion of animal protein, as being directly or indirectly the cause of toxæmia.
5. When toxæmia is present treatment should be based on the principles of eliminating the poison already present, preventing any further introduction and reinforcing the natural protective agencies.
6. Where there is extensive disease of the wall of the colon the exclusion or removal of this organ is a justifiable proceeding after a reasonable trial has been given to medical methods.

CONSEQUENCES AND TREATMENT FROM A
SURGICAL POINT OF VIEW.

By W. ARBUTHNOT LANE, M.S., F.R.C.S.,
SURGEON TO GUY'S HOSPITAL.

I WILL endeavour to give a brief summary of the surgical treatment of the auto-intoxication and other effects which result from chronic intestinal stasis. The causation of stasis and the consequent infection of the gastro-intestinal contents are due to improper feeding in early life, and subsequently to the prolonged assumption of the erect posture of the trunk.

The changes that result in the drainage scheme are evolutionary in nature, and simply mechanical in origin. To meet the tendency to downward displacement of the viscera which results from an accumulation of faecal matter at first in the large intestine, and later in the small intestine and stomach, membranes or mesenteries develop. These bands represent the crystallization of resistances. They form, in the first instance, as thickenings on the peritoneum, and later as distinct membranes or mesenteries, which support the viscera and tend to obviate their prolapse. Some observers regard these new developments as being congenital in origin, while others consider that they are inflammatory products. Against both these hypotheses are the facts that they do not exist at birth, that they can be seen in every stage of development during the lifetime of the individual, that they vary distinctly with occupations, that they commence at that point in the mesentery which is most distant from the bowel, and are obviously developed for the purpose of securing that particular portion of the intestine more closely to the abdominal wall, that they appear only on one surface of the mesentery, and that surface is the one along which the greater amount of strain is exerted, and that they correspond exactly in situation and direction to the lines of force. Besides this, they occur in the layers of peritoneum in which the main lymphatic trunks do not run, while they do not develop on such peritoneal surfaces as are chiefly in relation with the lymphatic glands and vessels.

At their commencement they serve a useful purpose. Later they tend to impair the function of the part and consequently to shorten life. This is a common characteristic of such evolutionary changes as develop during the lifetime of the individual.

While the effluent through any portion of the intestine may be controlled by some mechanical means applied externally, as, for instance, by a band, membrane, or appendix, the contents of the intestine may also be dammed back merely by the accumulation of material in the bowel beyond. This is illustrated by the puddling and obstruction in the much elongated pelvic colon seen so frequently in tuberculosis and rheumatoid arthritis in young people, and again in the delay of the contents of the ileum, and their consequent infection when material is accumulated in a large dilated caecum occupying the true pelvis, or occasionally when the caecum is fixed immovably in the iliac fossa. In any case the result is the same—namely, stagnation of the intestinal contents and the changes consequent on such delay.

The result of this stasis of the intestinal contents manifests itself in two distinct ways, which may or may not be obviously associated clinically. The mechanical results of such delay in the small intestine are interference with the effluent from the duodenum and consequent distension changes in the duodenum, more especially in its first part. This obstruction produces engorgement of, and later inflammatory changes in, the mucous membrane of the bowel, and may finally cause ulceration and perforation, or cicatrization and stenosis of the first part of the duodenum. Spasm of the pylorus follows on distension of the duodenum, and this brings about dilatation of the stomach with hypertrophy of its walls. Because of the strain exerted by the heavy contents of the stomach, often increased by the weight of an habitually loaded transverse colon, engorgement, inflammation, ulceration, and finally cancerous infection of the mucous membrane may develop along the lesser curvature at the site of greatest strain. This area of excessive tension approximates to the

pyloric end but varies with the position of the liver. Spasm of the lower end of the oesophagus occasionally complicates this condition and material may accumulate in the oesophagus. The term "cardio-spasm" has been applied to this condition, which exists in very varying degrees of severity and intermittency. Its symptoms and treatment have been fully described by Dr. Plummer. The alteration that takes place in the contents of the stomach and small intestine, due to their infection by organisms and consequent chemical changes, produces a quantity of gas, etc., and this determines the symptoms which are grouped under the comprehensive term "indigestion."

The ducts of the pancreas become infected by the direct extension of organisms along them, and induration, inflammation, and cancer of that organ may result. Similarly in the case of the liver, gall stones are developed with all the troublesome sequelae of their presence, the last of which is too frequently cancer. The infection of the ducts may extend up into the liver and inflammation of that organ may result.

Besides the mechanical changes in the gastro-intestinal tract and in the ducts which open into it, the chief trouble consequent on the stasis is the auto-intoxication produced by the absorption from the gastro-intestinal tract, and especially from the small intestine, of a greater quantity of toxic material than the liver and kidneys can deal with. This auto-intoxication produces a degeneration of every tissue in the body. It is particularly manifest in the organ which converts the poisons, in the heart and vessels which convey them, and in the kidneys which excrete them. The effect of the poisoning is shown especially by a loss of fat and by a degeneration of all the muscular tissues of the body. These factors are of especial importance in the female, whose function of accommodating and transmitting a fetus renders her more liable to change in consequence. The outline of her body is lost because of the dropping of the breasts and abdomen and the wasting of the buttocks. The uterus becomes soft and heavy and bends about. It drops backwards in most cases, so that the gorged heavy fundus rests on and tends to obstruct the rectum. The kidneys, being no longer cushioned in fat, prolapse, as do all the other viscera of the abdomen. In this manner a vicious circle is set up, by which the stasis and consequent auto-intoxication are still further exaggerated. Thus a condition of premature senility is brought about. The skin becomes thin and stained and its secretion frequently offensive.

The breasts undergo degenerative changes, manifested in the first instance as induration, to be followed by inflammatory and cystic degeneration, and possibly, lastly, by cancerous infection. The thyroid may enlarge, form tumours, and symptoms of exophthalmic goitre may not infrequently develop. The circulation is much affected. In some cases the blood pressure is abnormally high when it is associated with pretty obvious changes in the heart and aorta, while in others it is subnormal. The general body temperature is subnormal, whereas that of the extremities is always so, sometimes in such a marked degree as to suggest Raynaud's disease.

Microbic cyanosis may also be present.

The cerebro-spinal system is affected in a very marked manner by the poison. The patient is always depressed, feels stupid and unfit for physical or mental exertion, and suffers from headache which varies in character and intensity. Neuralgia or neuritis are frequently complained of. The sufferer sleeps badly, tends to fall asleep at all times of the day, dreams greatly, and awakes from sleep without feeling refreshed. These and other symptoms may exist in any degree of severity. In some cases the individual is mentally so dull as to appear imbecile, while in others the misery is so great that the patient willingly resorts to drugs, drink, or suicide as the only available means of alleviation or freedom from suffering. The eyes are definitely affected in many ways from the auto-intoxication. The condition of the conjunctiva is characteristic of its presence and degenerative changes in the tissues of the eyes are brought about. The sense of hearing also becomes defective in some cases, probably on account of degeneration in the nerve tissue or of infection in the spaces in connexion with the middle ear. The resisting power of the tissues to the entry of organisms is lowered. The effect of this is seen, perhaps, most

commonly in the sockets of the teeth, and especially around the lower incisors. Organisms establish a foothold in the gum about the fang, and produce a condition of inflammation which may sooner or later destroy the teeth. The products of suppuration from the infected gums being swallowed increase the infection of the upper portion of the gastro-intestinal tract, and seem to aggravate the general depression. A similar infection may occur in the sinuses and lymphatic tissues about the nose and throat. The genito-urinary tract of the woman is particularly liable to infection, and innumerable troubles affect her in consequence and interfere with the satisfactory performance of her functions. These patients readily develop tubercle or rheumatoid arthritis. I do not believe that these diseases can exist except in the presence of auto-intoxication. The evidence in favour of this statement is that these cases invariably show very definite clinical and x-ray evidence of stasis, and that the symptoms disappear and the patients recover sometimes with startling rapidity when the condition of stasis has been effectually dealt with. I would remind you of the remarkable confirmation of the extreme importance of effective drainage which Carrel's experiments afford. He has shown that tissue is immortal provided that it is properly drained, and that it obtains sufficient food. The difficulty that has to be met by us does not lie in the supply of sufficient nutrition, but in dealing with the defective state of our drainage apparatus. Carrel's observations are of the greatest possible service at the present moment, since they afford us the same confidence in our methods of treatment that x rays did in the case of operation for simple fractures, when the opposition to that form of treatment was intense and to a great extent unscrupulous in its methods. If we wish to deal with primary causes and not merely with effects, it is our business in all cases of auto-intoxication resulting from intestinal stasis to improve the drainage of our bodies so that material is no longer allowed to stagnate, decompose, and poison our patients. We cannot now pursue obsolete methods and be satisfied with the treatment of end results. We must deal with the defective condition of the intestines, the prime factor in the development of disease and death. Whether this can be effected sufficiently by the use of lubricants, abdominal pressure and diet, or whether some operative treatment is required, must depend on the nature of the stasis and the condition of the patient. Here again x rays afford us very great assistance, since they indicate not only the rate of passage of the contents through the several portions of the tract, but they often demonstrate the exact nature of the obstruction. Besides this, they show many of the changes in the heart and aorta, which are often serious complications of auto-intoxication.

In the vast majority of cases the ileal effluent is at fault. Sometimes this can be met by the removal of an appendix controlling the passage of the ileal contents into the caecum, or by the division of a membrane or a ligament reducing the lumen of the last two or three inches of the ileum, while at other times the best result is obtained by fixing the divided ileum into the pelvic colon, and by exaggerating the last kink by means of a suture, so as to avoid the ascent of faecal matter into the iliac colon. This last method of treatment is by far the most efficient, and results in immediate benefit in the vast majority of cases. Within a few hours of the operation the patient asserts that she is quite different, and that she has lost that feeling of intense misery and depression from which she had suffered for years. The feel of her hands, etc., is altered, and she looks a greatly improved woman. In a certain proportion of cases it is advisable to remove the large bowel at the same time or subsequently. This is particularly called for when the condition has existed for a long time and there is much change in the large intestine. The only risk of these operations is that common to all abdominal operations—namely, the formation of adhesions, which may anchor or obstruct the lumen of pieces of small bowel. This can be best prevented by rigid asepsis, and by avoiding exposure and manipulation of the intestines, and by approximating the edges of peritoneal surfaces as accurately as possible. It is now too late for mere quibbling, and for the negation of facts that are perfectly obvious and capable of demonstration in the clearest manner possible. This condition of defective

drainage has already been dealt with by surgeons all over the world, as well as by myself, and those who have had a large experience in the operative treatment of these cases are arriving at definite conclusions as to the best mode of dealing with them. Chronic intestinal stasis is a subject that is growing very rapidly in importance, and it cannot be decided merely by conjecture or on previous experience, but by the light of hard facts as afforded by the results of operative interference.

The Goulstonian Lectures

ON

DEATH BY ELECTRIC CURRENTS AND BY LIGHTNING.

DELIVERED BEFORE THE ROYAL COLLEGE OF PHYSICIANS
OF LONDON.

BY A. J. JEX-BLAKE, M.A., M.B., B.CH. OXON.,
F.R.C.P. LOND.,

ASSISTANT PHYSICIAN TO ST. GEORGE'S HOSPITAL AND TO THE
HOSPITAL FOR CONSUMPTION, BROMPTON.

LECTURE III.—DEATH BY LIGHTNING.

HAVING discussed the subject of death by industrial electric currents very thoroughly in the last two lectures, I am in a position to approach the obscure subject of death by lightning-stroke with the more confidence. This form of death is much commoner in most countries than it is in ours. In England and Wales the Registrar-General reported 124 fatal instances of lightning-stroke, 108 in men and 16 in women, during the ten years 1901-1910, a yearly average of only 12.4 deaths, or 0.36 per million living. In the twenty-nine years 1852-1880 there were 546 such deaths, the yearly average for that period being 18.8, or 0.88 per annum per million living. The number of these deaths varied widely in different years; three people were killed by lightning in 1863, 46 in 1872. The annual death-rate from lightning also varies widely in different parts of England. In the North Midlands from 1852 to 1880 it was 1.8 annually per million living; in the metropolitan district only 0.13 (Lawson)—a figure that should be of comfort for anybody who is in London during a thunderstorm. On the Continent much higher yearly death-rates are found. In Hungary the annual death-rate from lightning is said to be sixteen per million living (Milham); in Styria and Carinthia about ten per million, in Prussia 4.4, in France and in Sweden three, in Belgium two, so far as the imperfect statistics available go (McArdie and Henry). In the United States of America the annual death-rate per million is high, about ten, in consequence of the frequency of thunderstorms on the one hand and of the large percentage of the inhabitants engaged in outdoor labour on the other; about 700 or 800 deaths from lightning were estimated to occur in the United States every year by Henry in 1900, in a population of 76 millions.

Many more people are struck by lightning than are killed. For example, Jack records an instance in which a church was struck; 300 people were in it, 100 were injured and mostly made unconscious, 30 had to take to their beds, but only 6 were killed. Weber gives an account of 92 people struck in Schleswig-Holstein; 10 were killed, 20 paralysed, 55 stupified, and 7 only slightly affected. In 1905 a tent with 250 people in it was struck, and 60 were left on the ground in various states of insensibility; one was killed outright, another breathed for some minutes before dying, the rest recovered.⁴¹ As many as eleven⁴² and eighteen⁴³ persons have been killed by a single stroke of lightning. Vincent mentions a stroke that threw down 1,200 and killed 556 out of a flock of 1,800 sheep. Dechambre believes that children are perhaps less liable to be struck than adults; but statements such as these are really not capable of proof or disproof.

The Nature of Lightning.

Nothing was known or even, apparently, guessed as to the true nature of lightning and its connexion with electricity till 1708, when Wall drew attention to the similarity

between it and electric sparks obtained by rubbing a piece of amber. The identity in kind of electric sparks and lightning was proved in 1752, when the experiment suggested by Franklin in 1750 was carried out in France by D'Alibard, and ordinary electric sparks were obtained, during the passage of a thunderstorm, from an insulated iron rod forty feet high set up in a garden at Marly-la-Ville. A few months later Franklin proved the same thing by his celebrated experiment of flying a kite up into a thunder-cloud during a rain-storm, and drawing sparks from the wet cord that held the kite. In this way it was proved that a flash of lightning is no more than a particularly large and powerful electric spark.

When electric sparks and their methods of production are examined, it is found possible to determine a large number of physical data about them—the voltage that is required to produce a spark of a given length, for example, the duration of a spark, the direction of its flow, the quantity of electricity (measured in coulombs) it contains, the rate of flow in amperes of the current that produces it, the amount of energy (measured in joules) expended in its production, and the rate and number of the oscillations composing it—for in a great many cases an apparently simple and single electric spark is really a complex built up of a rapid succession of sparks of diminishing intensity, first in one direction, and then back again in the opposite. All these measurements can be made with some accuracy, and many of them are of importance in determining the lethal or non-lethal effects of electric sparks upon animals.

But with lightning flashes the dangers of such investigations as these are obvious, and not one of the measurements just described above has ever been made as yet with any approach to accuracy in the case of lightning. One only has a number of vague suppositions and a few somewhat sketchy experimental facts to go upon. Still, such as they are, these are worthy of consideration.

1. *Voltage.*—This has never been measured, but has always been assumed to be very high. Lodge calculated that the production of a flash a mile long might require a difference of potential of five thousand million volts, and reckons the difference of potential concerned in an ordinary flash at millions or hundreds of millions of volts. Most authors content themselves with saying that the voltage of a flash must be millions or many millions of volts. Trowbridge found that his battery of twenty thousand small secondary batteries joined up in series gave him initial sparks 3.5 to 4 cm. in length, at a voltage of about 40,000 volts; but, when the two sparking terminals were quickly drawn apart, he could get a flaming discharge 60 cm. in length. He also found that the apparent resistance of the air was much diminished, and the sparking distance at any given voltage was increased, when large quantities of electricity were employed and transmitted in the spark.

2. *The quantity of electricity in a flash,* in coulombs, never has been measured. Faraday believed that it was quite small, not enough to decompose a drop of water into oxygen and hydrogen, and later writers have agreed with this estimate. Lodge, for example, mentions seventy coulombs as the quantity in a certain flash, enough to decompose only one-tenth of a grain of water.

3. *The amperage,* or rate of flow of the electricity, has always been assumed to be large. Here, at last, we meet with a quantity that has been measured, though not by a method capable of very accurate results. Pockels has described some experiments made with the lightning flashes that struck lightning rods on an observatory in the Apennines; and from the amount of permanent (remanent) magnetism induced in some small basalt prisms by the current flowing down the lightning conductor when it was struck, he has calculated that in these particular lightning flashes the current was from 11,000 to 20,000 amperes. Trowbridge's view that with sparks of large amperage the resistance of the air seems to be reduced has been mentioned already.

4. *The duration* of lightning flashes has not yet been investigated as carefully as it ought to be; it is a matter for the meteorologists to settle by actual observations. Schmidt's experiments showed that the duration of many flashes was under $\frac{1}{100000}$ second, while others were multiple or oscillatory in character, and lasted for $\frac{1}{10000} - \frac{1}{20000}$ second, and yet others lasted for longer than $\frac{1}{1000}$ second.

Flashes passing from one cloud to another high in the air may last for as long as one second, according to Hann. Lodge, on the other hand, assumes that a single flash lasts for "some extremely small fraction of a second, say $\frac{1}{100000}$ or thereabouts," and so does Sylvanus Thompson.

5. *Direction and Course.*—A clearly-seen flash of lightning gives one the impression that the flash starts at one end and runs rapidly to the other end of its course. There is no reason to suppose, however, that what one sees here has any relation to the reality. A lightning flash is generally over in so small a fraction of a second that the retina has no time to form any accurate judgement as to which end of the flash began first; such impressions really depend upon the unequal sensitiveness of different parts of the retina to light. Meteorologists calculate that two-thirds of the flashes first run, as a matter of fact, from the earth to the clouds (Mache and von Schweidler). One's eye is equally deceived as to the course taken by the flash in a great number of cases, as is shown by the many published photographs of lightning. These photographs prove that most flashes are multiple, meandering, and branched, and quite unlike what the eye sees. The tendency of lightning to send off branches or side-flashes at points where it changes its course has been illustrated and reproduced in the laboratory experiments of Trowbridge; who also draws attention to the explosive force that seems to be exerted at the points where either lightning flashes or electric sparks of large amperage change their direction.

6. *Oscillatory Character.*—Lodge has brought forward theoretical reasons for supposing that a lightning flash is an oscillatory discharge like that of a Leyden jar, and not a single rush of electricity; in other words, an alternating and not a continuous current of very brief duration. His view seems to be generally accepted, though not universally (Mache and von Schweidler). These oscillations would have an enormous frequency, possibly millions a second, according to Lodge; Emde has made elaborate calculations to prove that the frequency may be much less than this, and that the number of alternations may be only from 2,000 to 8,000 per second. Many of the photographs of lightning taken with a moving camera prove that what appears to the eye a single flash is built up, in reality, of a succession of flashes, travelling along the same path or closely similar paths (Milham).

7. *The Energy in a Flash.*—This has never been measured; but judging by the very violent disruptive or explosive effects of some flashes on such things as rocks and trees, it must be very great. Lodge calculates that the discharge from as little as an area of ten yards square of a cloud fully charged with electricity at a height of a mile would give a flash of over 2,000 foot-tons energy, or 101,000 joules—enough to convert about 40 grams of water at 18 C. into steam at atmospheric pressure. The energy in a great many lightning flashes must be very much larger than this.

Particular attention must be drawn to one feature of lightning flashes that distinguishes them from the ordinary industrial currents of electricity. Given a choice of several alternative paths to travel along, ordinary industrial currents travel along them all in quantities directly proportional to their conductances, or, as it is more usually put, inversely as their resistances. But the very brief alternating current got by discharging a charged Leyden jar behaves quite differently; for it will leave a good conductor such as a coiled up thick copper rod in order to spark across an extremely badly conducting air-space, preferring a path of low self-inductance (or low impedance) to one of low resistance. The same is true of lightning, as was first emphasized by Lodge; it explains the tendency of lightning to send side-flashes out of good conductors like lightning-rods into any objects near by, and the frequent failure of such rods to protect the buildings on which they are fixed from damage by lightning.

Classification of Lightning Flashes.

Seneca (died 65 A.D.) distinguished three varieties of lightning—the penetrating, the shattering, and the burning. His classification persisted more or less until Arago offered a new system, and wrote of the forked, sheet, and ball lightning, with which we are all familiar. But for scientific and practical purposes⁷⁹ lightning flashes are now divided into two varieties—the A flashes and the B flashes of Lodge. The A flashes are the less sudden and

less violent variety, and protection against them can be afforded by lightning-rods; they correspond to the "cold lightning" of the Germans. The B flashes are more sudden and violent, very destructive in their effects, and they contain a far greater amount of energy to be dissipated than the other variety; they correspond to the German "burning lightning," and often cause disastrous fires. No system of lightning-conductors will protect against them. Both varieties may be fatal to man. In all probability ball lightning is the result of a B flash striking the ground; it is a rare and very striking form of lightning. For some reason that I have not been able to fathom, medical writers who deal with lightning devote a great deal of attention to the "return strokes" of Mahon (1780) and Tyndall.⁸⁰ These have been rehabilitated by Lodge, who explains them as oscillations and overflows of electricity induced by the original flash; he describes them as electrical echoes, so to speak, due not to a statical disturbance of equilibrium as was at first supposed, but to induction and electro-magnetic inertia. Such induced flashes might be fatal to man, but there is no evidence to show that as a matter of fact they often are thus fatal; they are described by Vincent as "lateral flashes."

Theories of Death by Lightning.

This has long attracted the attention of the human kind. Lightning is represented by weapons of destruction in the oldest records of it that we have—the seals, cylinders, and bas-reliefs (dating from perhaps three or four thousand years B.C.) found in the ruined cities about the Tigris and Euphrates,⁸⁰ a country where thunderstorms are common. The Greeks in the classical times took an optimistic view of death by lightning, arguing that Justice or Piety profited, though the victim, who might be buried with divine honours, perished; a non-fatal stroke was regarded as a sign of the favour of the gods. The Romans, contrariwise, took a gloomier view—considered death by lightning a punishment, and buried the victim without his just funeral obsequies; thunderstorms counted for a good deal in their science of augury, which seems to have been of great political service to the Romans. In literature and art the symbols representing lightning were borrowed from Zeus by Alexander the Great, as tokens of his own royal and divine power, and have been extensively so used since by other sovereigns; and one of them—the trident⁸³—has now figured as such, on the reverse of our own bronze coinage, in Britannia's right hand, since the year 1797.

The ancients believed lightning to be generated in the clouds, either from the cosmic fire or from heat coming from the sun and the planets. Theories as to the way in which it caused death had no interest for them, and do not seem to have been formulated until much later. To quote a few early examples out of many, Janichius, writing in 1606, says that lightning kills man by very rapidly penetrating the pores and viscera of the whole body and changing all its parts very quickly, imbuing its fount of life—the heart—with a poisonous quality, and suffocating it with a sulphureous malice; or it may rupture the chambers of the heart by suddenly distending them with spirit and heat through fear. Kising, in 1673, sets death by lightning down to the fire it contains; the fire rarefies the blood by its dilatatory force, dispels the nervous spirits, and stops the heart. Both these authors, it may be observed, arrive at the truth that death by lightning is often due to paralysis of the heart; but they get there through such a maze of erroneous reasoning and misstatement of fact that it is hard to give them much credit for the discovery on which they thus happened.

Very similar essays on death by lightning continued to be produced for, at any rate, the first two-thirds of the eighteenth century, and new modes in which such deaths might take place were elaborated by the impossible method of deduction. Thus Heffmann, in 1703, asserted that persons killed by lightning died from want of air suitable for breathing, being asphyxiated by the quantity of sulphurous exhalations emitted by the flash. Roser (1704) attributed some of the deaths to a supernatural cause, the just judgement of God; others to such natural causes as the explosion of sulphureous and nitrous particles within the body caused by the flash, or to suffocation, or to injuries of the animal faculty or sense. Münnich (1732)

concluded that lightning killed either by expanding the air in and around the body and so preventing respiration, or else by causing a vacuum which made the blood give up its gases and tear the weaker blood vessels, particularly those of the brain or medulla, leading to the extravasation of blood and death. He supposed, in fact, that the proximate cause of death by lightning was deprivation of external air. Stock (1734) enumerated three possible causes of death by lightning—first, terror; secondly, suffocation by inhalation of the nitro-sulphureous particles left in the track of the lightning; thirdly, the sudden expansion of the aerial particles in the spirits and humours of the body, whereby the spirits were dissipated and the humours rarefied to such a degree that vital movement and respiration could no longer be carried on. Rasbach (1737) stated that death by lightning was brought about by the narcotic effects of the sulphurous effluvia of the lightning, which penetrated the lungs and intercepted life by abolishing their vital functions. Vollmar (1765) attributed it to suffocation and the consequent symptomatic apoplexy, or to fear, or to the vacuum produced by lightning, or the expansion of the air inside the body, or, finally, to the reduction of the body to ashes. Hoffmann (1766), in a very elaborate and carefully written thesis, concluded that the main cause of sudden death by lightning-stroke was some lesion of the nerves and brain, inaccessible to the senses and too delicate to be demonstrable. He went on to enumerate six ways in which the brain and nerves might be fatally affected by lightning, all of them speculative and fanciful, none of them actually observed. Marherr (1766) ascribed death by lightning-stroke to tearing open of the blood vessels in the lungs, comparing it to the deaths caused by the wind of cannon balls on fields of battle, when the victim is not actually touched by the cannon ball but is killed suddenly by the vacuum caused by its passage near him.

It was perfectly natural that all these new theories as to the cause of death by lightning should arise in the seventeenth and in the first half of the eighteenth century. Great advances were then being made in physical science on all sides, and it was only to be expected that van Helmont's discovery of the existence of different gases in 1610, that the wholesale introduction of chemical ideas into the art of medicine by de la Boë (Sylvius) in 1650, and that von Guericke's discovery of the air pump and methods of producing vacuums in 1652, should lead to well meant, if crude, attempts to explain death by lightning-stroke in the terms of the advancing sciences of chemistry, physics, or physiology.

But there was little hope of any real progress in the matter until some explanation of the nature of lightning itself should be furnished, and this was done by Franklin. A fairly efficient frictional machine had been invented by von Guericke in 1662, and had been much improved since; the Leyden jar for storing electrical energy was discovered in 1745 by von Kleist, and now that the identity in kind of frictional electricity and lightning had been proved, it became possible, and natural, after a time, to utilize experiments with frictional electric machines and Leyden jars to throw light on the mode of death by lightning-stroke.²

Andrew Gordon, a Scottish Benedictine monk teaching at Erfurt, seems to have been the first to try the effect of electricity on the lower animals with fatal results. His cylinder electric machine gave currents strong enough to kill chaffinches. In the next year, 1746, Galath similarly killed beetles, worms, and birds; Nollet noted that on dissection these birds showed ecchymoses similar to those seen on persons killed by lightning. Similar experiments were made by a number of people in the various countries of Europe, particularly in France, Germany, England, and Holland, where much general interest was excited by the recent progress of electricity; for at this time and for many years to come the science of electricity, such as it was, formed an ideal field for the activity of the practical joker. The results of these experiments narrowed the field of causes of death by lightning, and it came to be recognized that several of the current views were untenable. Thus Bidermann, in 1768, discussed them all under five different heads, rejecting many of them—for example, suffocation by concussion or compression or rarefaction of the air, combustion, apoplexy, congelation of the animal spirits. He concluded that lightning kills

by a sudden injury to the nerves of the brain, caused by the rapid movement of the electric material, which abolishes their function; he believed that the nervous fluid was identical with or very nearly related to the electrical fluid. Abildgaard three years later proved that this was correct, and that shock to the nervous system was at any rate one way in which electricity, and therefore presumably lightning, might bring about death. He also made the very important observation that fowls killed by electric sparks remained dead if left alone; but that they could be recalled to life by the passage of another electric discharge through them from breast to back.

Brodie, in 1823, expressed the view that in most instances lightning killed by destroying the functions of the brain, and advised that the persons struck should be kept moderately warm, and have their lungs inflated by bellows so as to imitate natural respiration; similarly Auzouy (1858) and Dillner (1865) both laid great stress on respiratory paralysis in certain cases of death by lightning-stroke. In contrast to these interesting experiments of Brodie's may be quoted the gloomy and also erroneous views of two anonymous writers in the *Lancet* of 1830 and 1831. One says that speculating upon the mode in which lightning operates in producing death would be a vain and useless discussion; the intensity of the electric action instantly annihilates all connexion between soul and body, hence all means of resuscitation are vain. The other states that when the body is struck by lightning, complete death ensues; in asphyxia of this kind no vitality exists on which to act, for organic and animal life are both extinct. Oesterlen, in 1831, ascribed such deaths largely to an uninvestigated change in the blood, perhaps in the juices of the body in general also. Boellmann, in 1838, put death by lightning down to mechanical violence in the form of what he called cephalo-rachidian shock applied to the central nervous system through the cerebro-spinal fluid; he supposed the fluids in the lymphatic sheaths round the vessels to undergo a sudden increase in tension, thereby producing anaemia of the nervous centres and abolition of the function of the nerves. The part played by the heart and the continuance or stoppage of its action after a lightning-stroke does not seem to have attracted much further attention till many years later, though they are undoubtedly very important. Dillner (1865) laid great stress on it, assuming that the heart went on beating after apparent death in all persons who had been struck by lightning and yet were capable of being brought to life again. Should the heart cease beating for more than a short time, recovery would be, he considered, impossible. B. W. Richardson, in 1869, as a result of his experiments with a large Apps induction coil and Leyden jars, similarly attached great importance to the heart's action here, and stated that recovery was impossible if the heart was paralysed; and that in all cases where it was instantaneous, death by electric shocks was due to the sudden expansion of the gaseous part or atmosphere of the blood, combined in extreme degrees of shock with a sudden conversion of animal fluid from the fluid into the gaseous condition. He gives no detailed record, however, of the discovery of any such liberation of gas in the vessels of animals killed by electric sparks, though his papers are full of detail on other points. Here again we have a theory evolved from the imagination of its author, and lacking experimental proof of any kind. Dürck, in 1895, writing at a time when a good deal more had been found out as to the modes of death by electricity, came to the conclusion that death by lightning was due to permanent paralysis of the cardiac or the respiratory nervous centres, caused by the passage of the discharge; and Pélissier's conclusion was very similar.

Post-mortem Lesions after Death by Lightning.

The lesions produced by lightning in fatal cases of lightning-stroke are of the most varied extent and description imaginable. One may begin a brief account of them by saying, *hibernicè*, that in a large number of cases no lesion whatever, either external or internal, may be found *post mortem*. Such cases are not at all rare, and have been recorded both in man and in domestic animals. Sestier, for example, found no external injuries in 19 out of 119 cases of death by lightning. The great

majority of victims show superficial burns and scorchings of various depth and extent. Most commonly the burns are of the first or second degree, in the form of streaks that are taken to show the paths followed by the lightning, or in the form of isolated spots or areas. Singeing of the hair growing on these burns is highly characteristic of lightning-strokes, and may take place either with or without any singeing of the clothes in contact with the burnt skin, and also without any burning of the skin itself. Usually the burns are in the shape of bands or ribbons of hardened, discoloured, parchment-like skin, running down the trunk or legs. A very exceptional case is recorded by Cipriano, in which there were burns of the second degree on the neck, chest, and leg, while practically the whole of the rest of the body showed a burn of the first degree; the patient made a slow and difficult recovery. Vincent quotes the case of a woman who was struck and received burns of the first to the third degree from head to foot, and died from exhaustion after six months' suppuration. Less often the burns go deeper, and may even char the underlying bones or the tongue (Clark and Brigham) or the abdominal viscera. In many cases the deeper burns heal readily, if the victim survives; but in others slow healing with much pain and suppuration have been recorded. Patches of hair and of skin may be quite torn off. Persons struck or killed by lightning are said to exhale a peculiar or characteristic odour, oftenest described as resembling the smell of burning sulphur or of ozone; other writers compare the odour to such various smells as those of nitrous fumes, gunpowder accidents, acid, dilute sulphuric acid, sulphuretted hydrogen, nitrous acid, ammonia, electric sparks, and lighting matches, and it has also been described as *sui generis*.

Very characteristic, or even diagnostic, of lightning-stroke are the so-called "lightning-figures" often seen on the skin in both fatal and non-fatal cases. These consist of reddish, brown, or purple discolorations of the skin, described in different instances as resembling such things as coral, fronds of ferns, branches of fir-trees, trees, palms, pieces of outdoor scenery, or even "in outline a perfect map of North America, all of the important features being outlined with remarkable clearness."¹⁷ In the eighteenth and the earlier part of the nineteenth century there was a great tendency to regard these lightning-figures as due to the direct transfer of particles from the neighbouring objects represented (trees, etc.) to the skin of the person struck, by some mysterious action of the lightning, which was even supposed to take the place of a photographic lens in some way. They are now thought with more reason to be analogous to the electric dust figures, described by Lichtenberg, that indicate the distribution of electricity at a very high voltage on bad conductors. But it must be added that microscopic examinations of sections of skin showing these lightning-figures have not yet succeeded in demonstrating either their exact situation in the epidermis or cutis vera, or their mode of production. They may be the result of vasomotor paralysis. They do not seem to be generally due to haemorrhage (Haberda, Heusner, Schmitz), or to have any relation to the pressure of the clothes. They do not follow the course of the underlying bones, vessels, or nerves, as has been variously alleged on the strength of different isolated instances (Becher, Sonrier, Fischer). Mangin has suggested that they may be ideoplastic impressions, akin to hysterical stigmata in their method of production.

Considerably less common are lacerations of the soft tissues or the blood vessels, but when they do occur they are often very bizarre and striking. Lacerations of the scalp exposing the pericranium or bone are not rare, and in an unusual case recorded by Knaggs there was a lacerated wound of the right ear, which was almost torn off upwards. The formation of a haematoma in the neck, that might easily have been mistaken for an extensive bruise produced by mechanical violence, has been recorded (Macintosh, Niederbeitmann); haemorrhages on either side of the dura mater are not rare, and bleeding from the external auditory meatus, with or without fracture of the bones of the skull, is fairly common. Iano described laceration of the membrana tympani. Very curious lacerations of the abdominal walls and thighs have been described by Dutt and others. In Dutt's case there

was a lacerated wound five inches long two inches below the umbilicus; a penetrating wound of the abdominal wall two and a half inches long above and parallel to the left Poupart's ligament, had four feet of dark red, singed, and contracted small intestine protruding from it; and there was a four-inch lacerated wound in the left thigh below and parallel to Poupart's ligament. One might hazard the supposition that the victim in this case was struck while sitting or squatting on his bunkers. Wheeler described an instance in which lightning appeared to blow a cavity measuring three inches by one inch, and three-quarters of an inch deep, in the thigh; Vincent records an example in which six pounds' weight of flesh were lost from the thigh of a person struck by lightning.

To find a laceration in the heel or the sole, with or without comminution of the os calcis, is not very rare in persons struck when standing up or sitting out of doors, and may be taken as evidence that the electric discharge has changed its direction or met with increased resistance to its passage at this point. Penfold describes an instance in which the dense integuments of each heel "were cut as if with a sharp knife, and were torn open sufficiently to admit one's index finger easily, while the calcanea were comminuted into many pieces." The cut on the left heel was stellate, that on the right heel straight and in an antero-posterior direction. Similar cases have been recorded by Wilks, Daxenberger, Phayre, Davies, and others.

Lacerations of structures inside the body are not common, and when they do occur are not easily explained. Schneider has described rupture of the diaphragm, possibly by some sudden and violent change in the intrathoracic air pressure, in a soldier struck and killed while standing under a chestnut tree. Banham has met with a similar lesion in a horse, and quotes an example in which laceration and rupture of the heart was observed in three out of four horses struck and killed. I have been able to find only one instance of rupture of the heart by lightning in man—that recorded by Liman, who observed a hole two centimetres in diameter at the apex of the heart, with irregular walls and opening into both ventricles, which contained clots. Liman does not make any statement about the presence of blood in the pericardium in this case. A very curious instance has been reported in detail by Ouvrard, in which, although there was no external lesion of the thorax, the lower lobe of the right lung exhibited four wounds like those caused by small shot, and there was a haemothorax; the diaphragm below this was perforated, there was a slight tear in the liver, ecchymoses were seen on the gastro-hepatic omentum, there was a small round hole with bruised edges in the splenic region of the stomach, the left suprarenal and kidney showed ecchymoses, and the spleen itself was stripped of its capsule, which could not be found. The victim in this extraordinary case was seen to be struck, and cried out as she fell and died; the *post-mortem* examination was made within twenty-four hours. A small pulmonary apoplexy was found in Phayre's case. Another very unusual case was described by Claes. A sailor was struck on his ship, and showed characteristic ribbon-like burns and excoriations, due to the passage of the lightning down his trunk and limbs. He died in about twenty-four hours, after alternate periods of stupor and agitation, and towards the end with distended tender abdomen and stercoraceous vomiting. *Post mortem*, Claes found three pints of blood stained serum in the abdominal cavity, with faecal matter, and exudative peritonitis on the intestines; there were six large black (and presumably necrotic) patches on the jejunum and ileum, in situations corresponding to the marks left by the lightning on the abdomen. It would appear, therefore, that the lightning in this case burnt the small intestine and allowed microbes to pass through its wall and set up a fatal peritonitis. Cases in which a fetus was killed *in utero* by lightning, while the mother was only rendered senseless for a few minutes and recovered, have been recorded by Franke and by Carpi; Harting describes the converse. In at least two instances women carrying children in their arms have been killed, the children being uninjured.

Injury to the tissues of the brain has often been assumed to be the cause of death by lightning, but the number of recorded instances in which it has actually

been seen is small. Phayre described a case in which there was reason to believe that the lightning had entered the left side of the head; he found the left hemisphere to be wholly disorganized, an almost homogeneous liquid of deeply greyish colour, only a small part of the corpus striatum looking normal. Somewhat similar changes were noted by Johnston and by Dürck; Bauer found the brain very soft and anaemic in his case, and the cord had apparently deliquesced to a grey fluid substance. A doubtful case has also been recorded by Barnes; Dunscombe-Honeyball found the brain in parts almost diffuent in one of his fatal instances of lightning-stroke.

Fracture of bones by lightning appears to be common in animals, and is not rare in man. Extensive fractures of the skull were noted in Knaggs's case, extending from the left parietal eminence across the right parietal bone, in which fine fissures radiated from the main crack and down to the base across the middle fossa, the orbital plate of the frontal bone (as in Heffernan's case), and the cribri-form plate of the ethmoid. Dunscombe-Honeyball describes two cases in which extensive fractures of the skull were found. An excellent diagram of the elaborate fissures of the skull in a case he describes is given by Schottin; in this instance two ribs were also fractured, but without injury to the underlying tissues. Gem has recorded fracture of the humerus and the spinal column. Fractures of the tibia, or of both the tibia and fibula, by lightning-stroke have been recorded by Roy, Wilks, and Penfold; in the last case the victim was sitting down at the moment when he was struck, and there was no contusion at the seats of fracture, so that one seems able to exclude the possibility that the fracture was due to falling or to the application of external violence in any way. To illustrate the extensive fractures of bones sometimes exhibited by animals I may quote Free, who describes the case of a man who was struck by lightning and rendered unconscious, and then developed acute Bright's disease. A horse that was with the man was struck at the same time as the man and was killed. Free says that "the dead horse was as soft as a jelly, partly owing to the fact that every large bone in its body was comminuted." The exact mechanism by means of which lightning fractures bones is obscure. In cases where the heel is lacerated and the os calcis comminuted, one may perhaps imagine that an extra development of heat and steam has taken place here, with the result that the electric discharge has, so to speak, blown its way out of the body. The example described by Clark and Brigham proves that enough heat may be developed in so deeply situated a bone as the orbital plate of the frontal bone to char it, so that it is not unreasonable to suppose that small steam explosions may result if the lightning develops a less degree of heat in a moist tissue. But it is not quite easy to imagine how the tibia and fibula could be broken, without showing any external injury, as in Penfold's case, if the fractures were caused by small steam explosions taking place inside these bones. Yet there is no alternative explanation to offer. For I do not think it is imaginable that any known forces of electric attraction or repulsion³⁷ could exert enough violence to break bones. At any rate, the physicists appear to know nothing of electric forces of the magnitude that would be required here.

In a few well recorded instances which are extraordinary almost to the point of being incredible, strokes of lightning have effected amputations. Sycenko quotes a case occurring in Russia, in which a boy of 12, who had had a flexed and ankylosed right knee for some years, was struck when riding on horseback. He was thrown to the ground and rendered insensible. At the same time the lightning amputated his right leg just below the knee-joint, leaving the patella and the cartilaginous upper end of the tibia intact. The boy made a good recovery; the amputated limb was afterwards found near the spot where he was struck. Vincent refers to a case in which an arm was amputated by lightning, but he did not see it himself. Dunscombe-Honeyball records the fact that he has known lightning to amputate a man's fingers. There seems no reason to doubt that such amputations might be the results of local developments of heat by the passage of the lightning through the tissues, with the sudden production of steam or other hot gases in sufficient quantity to blow the limb off. The alternative explanations that these

amputations are due to "electro-æustic action," or to violent electric repulsion, appear to me unsatisfactory.

Rapid putrefaction of the bodies of persons killed by lightning has occasionally been recorded, but is not of common occurrence. Rigor mortis, on the other hand, partial or of the whole body, may appear in a few minutes, and seminal emissions are not rare.

Evidence Derived from Deaths Produced by Sudden Electric Shocks.

It seems likely *a priori* that electrocution by the sudden and violent discharges of Leyden jars, condensers, and induction coils—that is to say, by discharges of high voltage and very brief duration—is more likely than electrocution by industrial electric currents to resemble death by lightning-stroke. The experiments on death by these sudden discharges have already been laid before you; it is not necessary to do more than summarize them here, and to say that such deaths may be due either to primary arrest of the respiration, or to primary arrest of the heart's action by ventricular fibrillation. These discharges seem to produce a profound degree of nervous shock.

(To be continued.)

THE
NECESSITY OF RECOGNIZING MIDWIFERY
AS A BRANCH OF SURGERY.*

By VICTOR BONNEY, M.S., M.D., B.Sc.LOND.,
F.R.C.S., M.R.C.P.,

ASSISTANT OBSTETRIC AND GYNAECOLOGICAL SURGEON TO THE
MIDDLESEX HOSPITAL; SURGEON TO THE CHELSEA
HOSPITAL FOR WOMEN, ETC.

THE object of this paper is to urge the importance of definitely and finally recognizing midwifery as a branch of surgery.

Obstetrics and its offspring gynaecology have in the past been considered as appanages to medicine, and regarded as provinces of the physician.

The operative triumphs of the latter, however, have of late years become so insistent that its inclusion amongst the branches of recognized surgery is now nearly complete.

It is otherwise with obstetrics, whose status still remains indeterminate. I had the curiosity to look up the official titles of the staffs of the obstetric departments of the great general hospitals and of the chief lying-in hospitals of England and Scotland. In twenty-five of these the title is that of "physician"; in twelve an indifferent denomination, such as "accoucheur"; while in ten only is the style of "surgeon" used. I further noted that in the official list of the Council of the Obstetrical Section of the Royal Society of Medicine the medical qualifications, and not the surgical, are appended to every name.

Founded on the art of the female midwife, midwifery was, in fact, the first special department of our profession. But unlike the other special departments, it arose, not as an offshoot or branch, the result of the exuberant growth of medical knowledge, but as a more or less independent subject which has in process of time become grafted on to the main stem. That that process is not yet complete is shown by the fact that medical art is still commonly divided into three primary divisions—medicine, surgery, and midwifery—some examining bodies even granting a separate diploma in the last-named subject.

The isolated position of obstetrics is early brought to the notice of the medical student. His textbooks of physiology do not deal with the phenomena of normal labour; the diseases and disasters of childbearing find no mention in the lectures on general pathology; the curriculum is divorced from either medicine or surgery, as though the morbid processes with which it concerns itself were fundamentally of a different nature to the rest of disease. He finds a separate physiology, a separate pathology, a separate clinical teaching, a separate examination.

He sees in most institutions its exponents, though styled "physicians," practising their calling almost

* Read before the Harveian Society of London.

entirely by mechanical or operative means. In the theatre attached to the lying-in wards he witnesses labour conducted with all the circumstances of modern surgery, whilst in the extern department he finds the same procedures carried out under conditions which would make any of the operations of recognized surgery unjustifiable.

What wonder, then, if, in the face of all these anomalies and contradictions, the conception of obstetrics as a separate art to which the tenets of surgery only partially apply, grows up within the student, from him is passed on to the practitioner, and finally reaches the public.

As a result of the affiliation of midwifery to medicine in the past, the analogy between reproduction and other natural processes has been too much insisted on. Child-bearing is, of course, a physiological process, but it stands alone amongst such, in that while the rest of them are exercised for the good of the individual, reproduction is exercised for the benefit of the race at the cost of the individual. The toll reproduction exacts from womankind is very definite and is levied on civilized and aboriginal alike; animals, whether domesticated or wild, do not escape it. At no other time in the life of a healthy woman is ill health so imminent as during the periods of childbearing. Pregnancy is normally associated with altered metabolic processes, closely verging on auto-intoxication; labour is an example of Nature's rough surgery, puerperal a time of healing of self-inflicted wounds.

Midwifery is an almost purely surgical art. Therapeutic treatment finds less place in it than perhaps any other department of our profession. The means it employs are almost entirely mechanical. Its operations, as compared with those of other branches of surgery, are to the full as difficult, and require, from the circumstances under which they are usually carried out, a far greater average degree of care, skill, and fortitude. Further, the liability for infection to follow them is much greater, because asepsis of the operation area is much less under the control of the operator.

Attendance on the puerperium resolves itself into the care and treatment of wounds of the genital canal—wounds naturally produced, indeed, but of the character of lacerations or abrasions, often associated with much bruising, and situated, as regards the placental site, in a position unfavourable for drainage, and as regards perineal tears in one impossible to render aseptic.

It follows, therefore, that the obstetrician stands more in need of modern surgical surroundings, accessories, and assistance than any other class of surgeon if he is to carry out his work in keeping with the present-day standards of aseptic surgery.

These statements are truisms, I venture to think, to all who give to the subject any degree of thought, yet the layman has a very imperfect understanding of them.

The unqualified reiteration of the "naturalness" of childbirth, the false conception derived from the profession itself, that midwifery is dissociated from the rest of medical science, has led the public to belittle the medical importance of labour, which, in the lower orders at least, tends to be regarded as analogous on a larger scale to defecation or micturition. Hence has arisen, and is maintained by custom, a want of comprehension of the necessity for making proper provision and prearrangement against the time of labour, and a disinclination to expend on the event the amount of money commensurate with its importance.

It is a fact to ponder upon that amongst the working classes much more money is outlaid on a funeral than on a birth. The Jewish community, I believe, spend more on weddings than on burials; herein the members of that remarkable race show a better appreciation of the relative importance of the events, because the significance of marriage lies in the procreation which it legitimizes. But Christian and Jew alike fail to recognize that it is the ceremony of birth which should have first claim on the pocket of the community. Would that we could see some of the money now devoted to funeral and child-death insurance diverted to childbirth insurance. The Insurance Act in this respect has made a step in the right direction, but the amount paid is meagre in comparison with what the ideal conduct of labour demands.

There are in all great cities numbers of houses unfit for

the habitation of human beings; thousands of tenements stinking and verminous. The patient is filthy, the bed-clothes are filthy, the supply of water limited to one small kettle, the utensils to a single bowl or basin, the room clogged with lumber, dusty furniture, and frowsy garments. In such surroundings it is the custom, against which no vigorous voice is raised, to perform difficult surgical operations peculiarly fraught, under any circumstances, with the risk of post-operative sepsis.

Who is not familiar with the general surgeon who relates with pride that he successfully operated for, say, a strangulated hernia, in a dirty cottage by the light of a single candle and the assistance of only one other medical man and a nurse. But what of the obstetric surgeon who, alone and unaided, amidst similar surroundings, acts the part of anæsthetist, operator, and nurse in his single person?

The absence of the conception of the "surgicalness" of midwifery, however, is not limited to the lower classes.

Consider the average lying-in room in the average middle-class house. A double bed is the first object that strikes the eye, unwieldy and inconvenient. In one corner is the baby's cradle and a pile of baby clothes; in another the washhand stand, and on it toothbrushes, bottles of hand and hair lotion, the husband's shaving materials, and various other objects. The dressing-table absorbs much of the floor of the room and most of the light from the window. It is littered with the implements of the toilet—brushes, combs, hair-pins, trays, boxes, vases, photograph frames, and other rubbish. In another corner stands the cast-clothes basket. A large wardrobe obtrudes itself on the already limited space, and a chest of drawers, piled with books, knick-knaws and various odds and ends, takes up much of the remainder. Add to these several chairs and a commode, and the picture is complete.

In this room lies a woman threatened with the possibility of surgical intervention. Were its nature any other than obstetrical, the room would not be left in that state. It would be cleared and converted, as far as possible, into an impromptu operating theatre.

From time to time articles appear in the medical press dealing with the causes of mortality and morbidity in childbirth. One such, by Dr. Haig Ferguson,¹ I have lately read. It formed the presidential address to the Edinburgh Obstetrical Society and was well worthy of the occasion. In it he gives the following striking figures:

In England and Wales puerperal fever and the accidents of pregnancy and childbirth caused the death, during the ten years 1897-1906, of 1 mother to every 228 births.

| | |
|-------------|-----------------------------------|
| In 1907 ... | ... 1 mother to every 261 births. |
| In 1908 ... | ... 1 mother to every 280 births. |
| In 1909 ... | ... 1 mother in every 270 births. |

Puerperal sepsis alone caused the death of:

| | |
|-------------|------------------------------------|
| In 1907 ... | ... 1 mother to every 602 births. |
| In 1908 ... | ... 1 mother to every 684 births. |
| In 1909 ... | ... 1 mother to every 609 births.* |

The morbidity-rates due to this cause, could they be estimated, would obviously be very much greater.

All papers dealing with puerperal morbidity and mortality deplore the continued prevalence of puerperal fever after home-conducted labour, and variously indicate where the fault lies. Thus the doctor is blamed for not carrying out Listerian principles, or the midwife is arraigned for carelessness and uncleanness.

But not one of them that I have read goes to the root of the matter—namely the utter want of surgical environment under which labour ordinarily takes place, a custom, I maintain due to the fact that the "surgical idea" as applied to midwifery is only partially recognized by the profession and not at all by the public. So long as these unsatisfactory conditions remain, the mortality and morbidity of childbirth will continue unduly high. The transgression against the canons of modern surgical asepsis is too great to be washed away with a bowl of antiseptic lotion however diligently used.

If we consider the results of surgical operations other than obstetrical, when carried out in hospitals and private houses respectively, it will be found that those performed in private are, on the whole, the most successful. Compare this with the results of obstetric work carried out in

* Modified from Dr. Haig Ferguson's paper.

hospitals and private houses respectively. The contrast is striking. In lying-in hospitals puerperal sepsis in its graver forms is almost abolished; in private houses it is responsible for the wastage of life and health to which Haig Ferguson and others have so forcibly directed attention.

It may be objected that the comparison is not fair, because the operations of surgery other than obstetrical are not customarily carried out in private houses unless the means of the patient permit of the surgical environment being created in the house.

But that is just the point I want to push home. In all other surgical work the medical man postulates surgical circumstances and surroundings as a necessity for the successful performance of his duties, and without them, except under great emergency, he refuses to undertake the case. Further, the public, educated as regards recognized surgery, supplies his requirements without demur, or, being unable to do so, appreciates at once the necessity of having the patient transferred to a hospital or home.

But in obstetrics a vicious circle obtains. The imperfect conception of the position of the art by the profession results in the public underrating its importance and belittling the gravity of labour. Hence has been established a custom by which childbirth takes place under conditions that outrage all the requirements of modern aseptic technique, yet in no other branch of our profession does success obtain so little praise or failure so much obloquy.

This attitude of the public in turn reacts on the medical man. He finds, when he enters practice, that it is customary to conduct labour under the faulty conditions to which I have drawn attention, and in the face of long usage he hesitates to deal with labour as with any other surgical problem. The conversion of the lying-in room into some semblance of an operating theatre, relatively aseptic surroundings, efficient assistance, and an independent anaesthetist, are looked upon as academic ideals not to be pressed for in everyday work.

The carrying out of an operation without sufficient assistance is as disadvantageous to its performance in midwifery as it is in any other branch of surgery. The thought of a surgeon euretting the uterus or ligaturing piles without an anaesthetic brings a smile to the lips, yet in obstetric work the practitioner is frequently diffident of asking for such assistance, because, by general conception, custom, and habit of thought, the public expects him to combine the offices of surgeon and anaesthetist.

The slight demands made by the obstetrician on behalf of his art results in the public habitually underpaying him. I have made inquiries amongst a number of my friends engaged in general practice for the purpose of comparing the relative amounts of the fees paid for a confinement with those received for the performance of such operations as they themselves frequently carry out.

Thus I learn that, assuming the patient's position to be such that a fee of 5 guineas is charged for the labour, then the charges for the following operations would roughly be:

| | |
|---|---|
| For removal of tonsils and adenoids ... | 3 to 5 guineas and anaesthetist's fee. |
| For euretting... .. | 7 to 10 guineas and anaesthetist's fee. |
| For ligation of haemorrhoids ... | 7 to 10 guineas and anaesthetist's fee. |

Now the outfit, skill, and care required of the obstetrician are at least as great as those demanded for the performance of these operations—they may, indeed, be much greater—while the time, trouble, and general wear and tear that attendance on a confinement involves is out of all proportion greater. Many men, indeed, have told me that midwifery does not pay, except in so far as it acts as an introduction to other forms of practice—a wrong principle, for underpaid work can never be the best work.

This low rate of remuneration is an expression on the part of the public of the small regard in which they hold obstetric art as compared with recognized surgery. In fact, obstetricians are taken at their own valuation, for they have up to now made no claim to be considered surgeons—nay, more, they have strengthened the popular belief in the trivialness of their calling by legalizing attendance on labour by a less educated class of practitioner—the midwife.

That the trained product of a maternity school is an enormous advance on the foul beldam who used to preside over childbirth goes without saying. Since the passing of the Midwives Act a marked fall has taken place in the annual number of cases of puerperal fever. Thus I find, on referring to the report of the Registrar-General for 1910, that the death-rate from this cause has decreased to 1 to every 727 births in that year.

But in so far as the Act tends to the employment of midwives *instead* of doctors, I believe it to be a step in the wrong direction. The aim should be not to cheapen the cost of labour, but to increase it; to make the public understand the importance of the event, and to teach that its proper conduct requires the environment of surgery, for the provision of which the layman must co-operate with the obstetric surgeon by prearrangement and adequate payment.

That great difficulties lie in the way of attainment to the ideal is obvious. Many of them will require years of education and social reform to overcome. Insurance against childbirth on a much extended scale, the establishment of municipal lying-in institutions where women could be attended by their own medical men under circumstances of true surgical asepsis—these are shadows cast on present thought by, let us hope, events coming somewhere in the future. But we must begin by setting our own house in order and definitely and finally recognizing midwifery as a special branch of surgery.

Memoranda :

MEDICAL, SURGICAL, OBSTETRICAL.

INJURY TO THE ELBOW INVOLVING THE ANTERIOR INTEROSSEUS NERVE.

A GIRL, aged 7 years, fell and struck the inner side of the right elbow. She was treated by a "bone-setter" until it was found that the elbow could not be flexed beyond a right angle.

She was brought to me six weeks after the accident, when extension at the elbow, pronation, and supination were complete, but flexion could be obtained only to a right angle. There was fullness about the lower end of the humerus, just above the joint, especially about the internal condyle, and some wasting of the flexor muscles covering the forearm and of the pronator quadratus. Flexion of the distal phalanx of the thumb and of the index finger was very deficient, but not entirely absent, while flexion of the distal phalanx of the middle finger was good. A skiagram did not reveal the exact nature of the injury.

From these signs it would appear that the anterior interosseous nerve was injured by the accident or involved in the callus produced after fracture at the lower end of the humerus. In the latter case the origin of the nerve from the median must have been higher than usual. The escape of the deep flexor of the middle finger, which in normal cases receives its nerve supply from the anterior interosseous, is also peculiar.

The case is perhaps sufficiently rare to warrant its being recorded.

TREATMENT OF MORTON'S METATARSALGIA BY FORCIBLE MOVEMENTS.

THOSE of us who have the opportunity of seeing a fair number of cases of Morton's disease during the year know not only the misery which this condition entails, but also the unsatisfactory results of treatment, and therefore I make no excuse for publishing a method which I have adopted lately in a few cases with uniform success.

The method consists of grasping the foot with both hands, one on either side, and forcibly moving the metatarsal bones upon each other, and also forcibly flexing and

extending the foot and toes. This method is more easily shown than described, and was adopted on the presumption that possibly some small adhesion was the cause of the pain. At all events, whatever the explanation may be, the few cases which I have treated in this way were at once permanently relieved of all symptoms. One case occurred in a man of 60 years of age, who had had the condition for ten years, but he was easily cured in the manner I have described. Possibly this method may have been tried by some orthopaedic surgeons, but if it has I have not yet succeeded in finding any record of it, and therefore I have no hesitation in publishing it for what it is worth.

T. PAGAN LOWE,
Surgeon to the Mineral Water Hospital, Bath.

Mr. J. M. COTTERILL, President, in the Chair.

Carcinoma of Rectum.

PROFESSOR CAIRD gave an analysis of 43 cases occurring between 1900 and 1910. Rectal cancer was more frequent in males. The ages in most were between 40 and 60. The duration of symptoms from their onset to diagnosis of the cancer was on an average six months—an unfortunate and quite remediable state of affairs, as diagnosis per rectum was easy. As to symptoms, bleeding was present in every case, and was often the only symptom. Pain was only present in those cancers close to the anus, and was absent in those higher up in the rectum (about half the cases); there were often irregularities in the bowel action, constipation alternating with diarrhoea, tenesmus, passage of mucus, and in only one case the passage of pipe-stem stools. A more uncommon symptom was reflex dysuria and frequency of micturition. The tumour was palpable per rectum in every case but one, where there was a peculiar fixation and kinking of the bowel. A tumour which appeared fixed on rectal examination was not seldom found mobile on bimanual examination. An extensive operation was not advisable over the age of 60 or when there was glandular involvement or fixation of the tumour. As to choice of operations, the disadvantages of the Kraske were the frequent recurrence in the lower segment, the infrequent healing by first intention ending sometimes in stricture. A modified Lisfranc was the better operation—that is, a perineal excision, aided, if need be, by a parasacral or an abdominal incision. In a lantern demonstration the macroscopic appearances of many of the tumours *in situ* were shown, and some of the difficulties and sequelae of the operation were shown in specimens obtained from fatal cases.

The PRESIDENT agreed as to the superiority of the perineal operation. The abdomino-perineal operation was seldom required. Mr. WALLACE said that the question of technique was all-important. A functioning anus in the perineum was seldom obtainable and should not be aimed at. Where the case was not too far advanced the first step should be an inguinal colostomy, followed by thorough removal by the abdomino-perineal operation. Where patients came too late for removal of the tumour, an inguinal colostomy should alone be performed, when a considerable degree of comfort and control was often obtained. Mr. STILES said that in tumours high up in the rectum the knee-elbow position was of value, combined with straining efforts on the part of the patient, when the finger received the sensation of ballottement from the tumour. With regard to operation, he advised a preliminary colostomy. This was followed by great improvement in the digestion and general health. In the subsequent removal of the tumour, points of importance were the freeing of the pelvic colon, closure of the colon, packing and drainage of the cavity. By these means the risks of sepsis were reduced and a short convalescence secured. The abdomino-perineal operation was seldom required. An inguinal anus, in his experience, gave better control than one in the perineum. Mr. ALEXIS THOMSON agreed as to the superiority of the inguinal anus. He

described the conditions present in a large series of Continental cases which he had seen where sacral anuses had been left and where the control was generally inefficient. Dr. DARLING described a case which had been the subject of a Kraske operation, living for twelve years and dying of another condition. Professor CAIRD replied.

ROYAL SOCIETY OF MEDICINE.

DISCUSSION ON ALIMENTARY TOXAEMIA.

Monday, March 10th, 1913.

Sir FRANCIS CHAMPNEYS, Bart., M.D., President, in the Chair.

A DISCUSSION on alimentary toxæmia, its sources, consequences, and treatment, was opened by Dr. HALE WHITE, who gave a general survey, and Dr. W. F. ANDREWES, who dealt with the bacteriology of the alimentary canal. These papers are published elsewhere in this issue.

The Toxins of the Alimentary Canal.

Dr. VAUGHAN HARLEY said considerable difficulties occurred in the study of toxins of the alimentary canal, since pure toxin, like pure enzyme, had not yet been isolated, even from bacterial culture. Yet more difficulty confronted one in dealing with those toxins which might be formed in the alimentary tract, since an examination of the faeces would only yield the toxins which had not been absorbed. The more easily absorbed toxins would not be recovered in the stools. The occurrence of erythema and urticaria, in common with some digestive derangements after taking pure food, could only be explained by the formation of toxins in the alimentary canal. He had noted urticaria and erythema after even simple rectal lavage with normal saline solution when there was considerable constipation. Halliburton and McKendrick tried to recover the toxin in the retained stomach contents from a case of dilated stomach, in which the patient had suffered from tetany, but without success. He proceeded to mention the products occurring in the alimentary canal which might be more or less poisonous. These might be derived from the protein, fat, or carbohydrates taken in the food, or from the secretions into, or excretions from, the alimentary tract, either in health or disease, during ordinary digestion, or from putrefaction and fermentation in the canal. The secretions of the tract could undergo some putrefaction during starvation, the urine of fasting individuals containing aromatic substances. In an experiment on a man during a fast the indican in the urine decreased day by day, while phenol progressively increased, so that by the ninth day it was from three to seven times as much as in the ordinary man. The substances derived from carbohydrates and fats had little toxicity. Protein during ordinary digestion, even without the action of bacteria present in the intestine, might yield toxic products. The proteoses and simpler products, when injected directly into the circulation, could be rapidly eliminated by the kidneys, but were apparently toxic; they inhibited blood coagulation, had a lymphagocytic effect, caused a fall of arterial pressure, and a febrile reaction, while large doses in animals caused death. In children and people of advanced age the epithelial cells of the alimentary canal were apparently thin, and perhaps this explained the greater frequency in them of toxic attacks. Healthy digestive processes were accompanied by an enormous amount of bacterial action; one-third of the total faeces in man consisted of bacteria, and this proportion was increased in diarrhoea. The decomposition products of protein putrefaction were practically the same whether formed by the action of bacteria or by the enzymes in ordinary digestion. If not present in too great quantity, bacteria in the intestine might be useful to the organism, and might assist in breaking down such substances as cellulose in the food. Indol, skatol, phenol, and cresol were aromatic substances formed by the breaking down of protein by various bacteria in the alimentary tract. These substances were fixed in the living cells. Indol was more easily detected in the faeces, and indican in the urine, and consequently had been more studied than had skatol, phenol, and cresol. Jaffé found that ligature of the small intestine, but not of the

large, was followed by a considerable increase of indican in the urine. The indican appeared to be derived in the bowels from the protein product tryptophan. In adults, even in health, the bacteria of the bowel produced indol as well as skatol, phenol, and cresol, while in breast-fed children these substances were not formed. Delay in the intestines led to a marked increase of aromatic substances in the bowel, which were eliminated as aromatic sulphates. But the quantity of these sulphates found in the urine did not always indicate the true condition occurring in the bowel. The quantity of fluid in the alimentary canal also influenced the putrefaction, putrid substances being formed in larger quantity where there was a decreased water absorption in the bowel. Indol was not readily absorbed by the lower part of the colon. In atony or dilatation of the caecum there was marked increase of indican in the urine. The condition of the stomach had apparently an influence on the intestinal putrefaction. Where there was delayed motility of the stomach, especially with decreased hydrochloric acid secretion, the protein putrefaction might commence in the stomach itself, hence there was an increased formation of aromatic substances in the alimentary canal. In the most advanced forms faecal vomiting occurred. Anaemia was present in all cases where the indican in the urine was increased; in some instances this anaemia seemed to be due to the increased intestinal putrefaction. In cases of pancreatic obstruction there was a marked increase of intestinal putrefaction, the increased protein remaining in the bowel being due to decreased fat absorption and the absence of trypsin, so that the protein was not properly digested in the small intestine. Experiments by Richards and Howland showed that reduced oxidation in the tissues might explain the more marked toxicity of indol in some persons. The persistence of an increased quantity of indican and aromatic sulphates in the urine was significant, and was apt to occur in middle-aged people who were in the habit of taking too much protein in their diet. In children increased protein putrefaction had a greater significance than in adults or aged people, and there was often marked retardation of growth, with mental irritability and anaemia and muscular fatigue. Adults with increased indicanuria had a muddy complexion, with lassitude and headache. In some cases there were arthritic and muscular pains. He believed a true neurasthenia could be caused by the continual absorption of indol, skatol, phenol, and cresol from the bowel. Premature senile decay with early arterio-sclerosis was apt to occur in people who had an increase of indol and urobilin in their stools. In contradistinction to putrefaction, he said it was as well to use the term "fermentation" for the breaking down of the fats and carbohydrates. Probably one never found a pure case of increased fermentation unaccompanied by putrefaction in a man after middle life. The ether extract of the stools had been shown by several observers to have a haemolytic action on the blood corpuscles. The acids when not broken down in the blood stream might contribute to acidosis by fixing some of the alkali of the blood, and this might be a serious factor in children. Gerhardt had demonstrated that in a case of obstruction of the bile duct no urobilin was present in either faeces or urine, but on the administration of bile by the mouth urobilin appeared in the stools and in the urine. The increased quantity of bile pigment present in the alimentary canal was converted by the bacteria into urobilin, some of which was absorbed and eliminated in the urine. Under ordinary conditions the bile pigment could be traced in the ileum as far as the ileo-caecal valve.

Treatment: Medical and Surgical.

The papers on the consequences and treatment from a medical and surgical point of view respectively were read by Professor Saundby and Mr. Arbuthnot Lane. These papers are published elsewhere.

Consequences and Treatment from the Dental Point of View.

Mr. J. F. COLYER said that he entered into the debate because there seemed to be some misconception on the part of his medical friends as to the amount of dental disease prevalent. There were two main causes of oral sepsis—(1) caries; (2) gingival disease leading to periodontal disease. Caries consisted of the progressive

destruction of the tooth substance, eventually leading to the opening of the pulp cavity. A septic inflammation was set up in the pulp, and in time led to a similar condition in the periodontal membrane about the apex of the tooth. The amount of oral sepsis arising directly from caries of the tooth was small compared with the sepsis from the conditions started by their presence. The effect of carious teeth was to render the teeth in the neighbourhood functionless, so that stagnation areas were formed, and from these and the collections of food marginal gingivitis ensued. Gingival disease, leading to periodontal disease, was by far the most fruitful source of oral sepsis. The gums might appear to the untrained eye almost healthy, yet the tooth socket might in places be destroyed almost to the apex of the tooth, and pus might be present in the pocket around the tooth. The progress of the disease was slow, especially in the early stages. Its extent could only be accurately gauged by examining each individual tooth with a fine probe so as to ascertain the depth of the pockets. The disease was more intractable and more serious in its results in mouth-breathers. He considered that the relationship of nasal obstruction to dental disease had not received the attention it deserved. Mouth-breathing in the child led to persistent marginal gingivitis, most marked around the lower incisors, and this eventually led to periodontal disease. Children the subjects of marked oral sepsis were below the normal weight. In adults the condition might lead to other pathological processes in two ways: (1) by direct absorption of the organisms and their toxins; (2) by the swallowing of the septic matter, leading to the setting up of gastritis. He did not claim that oral sepsis was as important as intestinal sepsis, but it was a prolific source of ill health. Where the teeth of children were bad he did not hesitate to render them edentulous; removal of ten, twelve, or fourteen teeth in a child under 5 was not at all uncommon. The supposed narrowing of the dental arch owing to this was not a serious matter, and the small extent to which this took place could be remedied by proper means; this would prevent crowding of the oncoming permanent teeth. It should always be remembered that chewing could be well carried out even where gingival disease was present; and when such children had their teeth removed they always gained in weight. He knew no means of curing periodontal disease except by free extraction.

The debate will be continued on April 14th.

SECTION OF THE HISTORY OF MEDICINE.

A MEETING of this Section was held on Wednesday, March 5th. Sir WILLIAM OSLER, Bart., F.R.S., President, in the chair. Dr. W. K. Sibley was elected an ordinary member of the Section, and the following gentlemen were elected Corresponding Honorary Members under the rule which allows of the election of such persons for distinguished services rendered to the history of medicine: Professor Barduzzi, Dr. Iwan Bloch, Dr. Chauffard, Professor E. F. Cordell, Dr. Fielding H. Garrison, Professor Hollander, Professor Kavvadias, Professor van Leezum, Professor Letulle, Dr. V. Maar, Lieutenant-Colonel Walter D. McCaw, Professor Karl Sudhof, and Dr. W. H. Welch.

Circumcision under the Romans.

Mr. JOSEPH OFFORD, member of the Associazione Archeologica Romana and of the Egypt Exploration Fund, read an essay treating of the Roman Imperial regulations with regard to circumcision. In association with the Jews much was already familiar to Latin scholars, but new evidence was brought forward respecting circumcision of Egyptian priestly youths devoted to the cult of the ancient deities in Egyptian temples. This information had been supplied by a few manuscripts found among the many thousands of papyri of Roman times that had recently been obtained from Egypt and were now undergoing preparation for speedy publication by specialist editors. Circumcision was an old sacerdotal and, indeed, almost universal custom in ancient Egypt, and therefore, to retain the good opinion of the priests, the Roman Imperial legislators, with certain reservations, permitted the practice in the province that was so valuable a granary, and, until exhausted, a mine of taxable wealth. The importance of the papyri

consisted in their being actual documents properly engrossed in the correct phraseology for obtaining the permission to circumcise and the administrative replies granting the request. Altogether eight such manuscripts were referred to and abstracts of the contents of several of them were given, and from these a good idea of the formalities required, and therefore of the legislation governing the matter, was obtained.

A New Egyptian Medical Papyrus.

Mr. Joseph Offord also read notes on a newly discovered Egyptian medical papyrus, a much older treasure than the documents on circumcision, dating as it did from some 2000 years B.C. Its contents, concerning the list of remedies prescribed and diseases enumerated, was very similar to that of the famous Ebers papyrus published some thirty years ago, and the comparison of the two manuscripts proved that both were to a large extent made up of copies of one or more earlier collections of medical and magical texts or formulae. The contents of this new papyrus and of the Ebers and four or five more medical papyri known indicated that they were not derived from the celebrated "divine" medical, Hermetic, books, which, according to the classics, the Egyptians treasured up in certain temple libraries, but that all were textbooks used in daily work by the medical practitioners of that period. Some of the recipes were ascribed to the gods, and others to a foreign origin, but the new papyrus came from the ruins of a house in a small provincial town, and was probably an inexpensive copy, carelessly written, intended for a country doctor. The new papyrus did not advance our respect for the ancient Egyptian medicine; indeed, it depended more upon magic for cures than did the Ebers treatise. In none of the works did any conception of the fact of contagion appear; and many worse than useless remedies were recommended. Whilst it was regrettable that the new papyrus was so similar in contents to the Ebers sample, and so did not provide fresh material for the study of Egyptian medical learning, yet, as the manuscripts in many cases mutually explained each other, scholars would now be enabled to translate them both, and then medical historians would be able to scrutinize their value with greater precision than before.

Lady Sedley's Receipt Book.

Dr. LEONARD GUTHRIE read a paper on the Lady Sedley's Receipt Book, 1686, and other seventeenth century receipt books. Lady Sedley was the wife of Sir Charles Sedley, wit, poet, and boon companion of Charles II. Their only child was the notorious Catherine Sedley, mistress of James II, created by him Countess of Dorchester in 1686, the year when the receipt book was written. Dr. Guthrie gave instances of prescriptions for a variety of ailments, some serious, others trivial. Many of the receipts were written by such eminent physicians as Sydenham, Lower, and King. Attention was also drawn to other manuscripts and to some printed receipt books.

Drug Pots.

Mr. J. D. MARSHALL, of Messrs. Bell and Croyden, showed a fine collection of early drug pots. He stated that no fragment of pottery connected with pharmacy had yet been found dating from palaeolithic times. The Egyptian tombs contained small pots made of unglazed terra cotta, and pharmacy pots were often found in excavations at Pompeii and Herculaneum. The pharmacy jars of mediaeval times were divisible into Maiolica and Faience, Maiolica being a pottery formed of calcareous clay gently fired and then covered with an opaque enamel composed of lead, tin, and sand, the biscuit being generally a light yellow tint or colour disappearing under the opacity of the enamel. It was manufactured chiefly in Spain and Italy, whilst Faience, which was generally of a later date than Maiolica was principally Dutch and English. The earliest examples of Maiolica were Hispano-Moresque lustreware, made by the Moors when they occupied Spain. The vessels were copied from Oriental designs; they were decorated and were painted with metallic colours. The Italian Alberelli were much superior in design and finish to the Spanish examples. The shape was an elaboration of the joint of the bamboo in which drugs were packed and imported

from the East. They were usually decorated in a single colour, the design being a combination of horizontal bands and discs, usually with some small ornament, such as a trefoil or slight wavy line. These, the earliest examples, were said to be in "camaieu," but as the art of the potter advanced the decorations became more beautiful and were executed in polychrome. Allusion was made to the vases dated 1500, which were in the Musée de Cluny, and to the set of pharmacy jars made for his domestic pharmacy by order of the Duke Gui d'Urbino in the latter part of the fifteenth century. They were probably the most costly in the world, and they were still preserved at Loreto. Many examples of very beautiful Faience ware were made in France, and the Strassburg ware was well known. The productions of the Belgian, German, and Swedish potteries were generally of a poorer quality. Delft began to be made about 1600, and was an attempt by the Dutch potteries to imitate as closely as possible the blue and white Chinese porcelain that was being imported into Holland and Italy. The manufacture of Delft was begun in England by Dutch potters, the first pottery being started at Lambeth about 1671 by John Ariene Van Hamme. The industry prospered, and there were soon twenty potteries at work in Lambeth alone. Bristol and Liverpool quickly became great centres for the manufacture of pharmacy jars. Richard Frank and Thomas Flower were well known makers in 1697, whilst Zachariah Barnes made pharmacy jars a speciality at Liverpool. The Delft of Dutch origin and that made at Lambeth, Bristol, and Liverpool, was similar in shape, but Mr. Marshall showed by examples that it was not very difficult to discriminate between them. The English body was harder, coarser, and less resonant, whilst the decoration was decidedly inferior to the Dutch workmanship. Attention was then drawn to dispensing pots, and Mr. Marshall brought forward examples to show that they had been made in England from a very early date, and that the English forms had developed certain peculiarities by which they could be distinguished from the Alberelli of Italy. The paper was illustrated by lantern slides, some of which reproduced the original colours with remarkable fidelity.

English Herbals.

Mr. H. M. BARLOW read notes on English herbals published between the years 1525 and 1640. The earliest work of this class printed in England was a small quarto volume published anonymously by Richard Banckes in 1525. Its various editions were extremely rare, but three were known to Pulteney in 1790, and these are the only editions referred to by Meyer in his standard history of botany in 1856. Despite its variety, this work was the most popular of all the English herbals, as is shown by the seventeen editions which Mr. Barlow has been able to trace, nine or ten of which are not recorded by Ames. Some appeared with different titles, and have been regarded by bibliographers as original works by Walter Lang, William Copland, Anthony Achem, and Maer. Besides assigning approximate dates to some of the undated editions, Mr. Barlow showed that not one of these writers had anything to do with the authorship of the work. *The Grete Herball*, printed by Treveris in 1526, was a translation from the French work *Le Grant Herbier*, the origin of which was thought by many writers to be derived from the German *Herbarius* or *Hortus Sanitatis*, but Professor Camus proved it to be in part a translation of the popular Latin work on simple medicines erroneously attributed to Matthew Platerius, a Salernitan physician of the twelfth century. *The Grete Herball* was superseded by the learned and more original work of William Turner, the complete edition of which was printed in Cologne in 1568. Next appeared the Latin work of Pena and Lobel, printed at London in 1570-71, followed by Lyte's popular translation of Dodons's herbal in 1578. The celebrated herbal of Gerard was published in 1597, but its history was not creditable to the writer. It was really a translation of the *Pemptades* of Dodons made by Dr. Robert Preest, a Fellow of the College of Physicians. On the death of the translator, the work fell into the hands of Gerard, who altered the arrangement and published it as a work of his own. The last of the old British herbalists was John Parkinson, whose great work, *Theatrum Botanicum*, contained descriptions of 3,800 plants

—nearly double the number in Gerard. The works of Morison, Ray, Grew, and others did not come within the scope of the title "Old English Herbals." By the time they were published the science of botany had grown up to an independent position, and was no longer a branch of medicine. The writers, moreover, were botanists in the modern sense rather than herbalists. Nor do the works of Culpepper and Cole, the ardent supporters of astrological botany and the doctrine of signatures, come under this heading. Besides their scientific value, Mr. Barlow showed that these old herbals had an artistic interest, the woodcut figures of plants being of great importance in the history of wood engraving. The paper was illustrated by a number of old herbals kindly lent by Mr. Bernard Quaritch.

SECTION FOR THE STUDY OF DISEASE IN CHILDREN.

Friday, February 28th, 1913.

Mr. A. H. TUBBY, President, in the Chair.

Exhibition of Clinical Cases.

AMONG the cases shown were the following:—Dr. F. PARKES WEBER: Slight *Congenital deformity of the hands* in a child. It consisted of partial flexion of the fingers at the metacarpo-phalangeal joints. The PRESIDENT, in the discussion which followed, thought the deformity was due to congenital tightness of the palmar fascia. Also a case of *Infantilism due to mitral stenosis*. The patient, a girl aged 15, had the development of a girl aged 10. Dr. F. G. CROOKSHANK: A case of a *Mongoloid boy* in whom ethnic characters of racial Mongolism occurred. The child was not a typical example of Mongolism, but had a yellow skin, dark hair, and Chinese profile. The canine teeth were long and tusk-like. The pelvis was "high." There was considerable hypotonia of muscles. Mr. J. E. ADAMS: Two children of the same family with *Congenital fusion of the radius with the ulna* a short distance below its head. The condition was very rare. A specimen of the deformity was shown and a similar case quoted. Mr. DOUGLAS DREW: *Lymphangioma of the axilla* in a baby aged 9 months. The tumour had occupied the whole axilla, and needed removal of the pectoralis minor and an extensive dissection to excise it. Also a case of *Separated epiphysis of the femur treated by plating*. The child was shown because the plate had not been removed. It caused no inconvenience, and did not hinder growth or movement. Mr. EDRED M. CORNER: *Costo-transversectomy* for spinal caries and mediastinal abscess. The operation had allowed the abscess to be opened and drained at the level of the eighth dorsal vertebra. Also a case of *Congenital absence of fibula, deformity of tarsus, and absence of the fifth toe*. One centre of ossification represented both the astragalus and calcaneum, and the fifth metatarsal bone was also absent. Dr. EDMUND CAUTLEY: *Chronic albuminuria, with hepatic enlargement*, in a girl aged 8 years and 2 months. The urine contained white blood cells, granular, hyaline, and epithelial casts. Von Pirquet's reaction was negative, and there was no evidence of syphilis. The Wassermann reaction had not been done.

Summer Diarrhoea and Summer Heat.

Dr. H. C. CAMERON read a paper on this subject. He emphasized the importance of environment and temperature as direct causes of summer diarrhoea, in contradistinction to their more remote effects in producing infection.

MEDICAL SOCIETY OF LONDON.

Monday, March 10th, 1913.

Sir W. WATSON CHEYNE, President, in the Chair.

Rapid Section of Tissues for Microscopical Diagnosis.

Dr. E. H. SHAW gave a demonstration of his method of rapid section of tissues for this purpose. He said that the method had proved to be of value in the diagnosis of obscure tumours over and over again. There were two factors to be taken into account: First, the manual dexterity required to cut a frozen section; and, secondly, the knowledge and experience of the pathologist in interpreting the section so obtained. He showed lantern slides

made from actual fresh sections. The stain used in all cases was methylene blue, and the sections were mounted in the watery solution of the stain without previous fixation or clearing. There was a group of cases in which an accurate knowledge of their malignant or innocent nature was not possible without a microscopic view of the section. It was in these that a rapidly prepared section was of the greatest value. The organ which presented more problems for clinical diagnosis than any other was the breast. His experience of this work extended over nearly fourteen years, and he was convinced more than ever that it was a most useful method and one that should be used more frequently.

Celluloid Splints.

Mr. H. J. GAUVAIN read a paper, illustrated by numerous lantern slides and models, on the use of celluloid in the mechanical treatment of tuberculous disease of the spine.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF SURGERY.

Friday, February 21st, 1913.

Mr. R. D. PUREFOY, President, in the Chair.

Nephrectomy.

Mr. C. ARTHUR BALL pointed out that nephrectomy had not been discussed much of late. The mortality was high; improved methods of diagnosis had greatly reduced this mortality, but there still remained a risk attached to nephrectomy which was probably greater than that of any other major operation—namely, the danger of haemorrhage. Enough attention was not attached to this danger in the teaching of the subject. The kidney could be more readily reached from the front by an iliac extraperitoneal incision extended upwards and backwards in the direction of the external oblique fibres if more room were needed. This was the incision Mr. Ball always employed; the vessels of the pedicle could be readily exposed, and any abnormal vessels easily seen and dealt with. Lumbar nephrectomy should be classed with lumbar celotomy and given up. The PRESIDENT related a case which showed that a renal affection might very closely simulate an ovarian cyst. Mr. MAUNSELL asked for precise information about the position in which the patient ought to be placed. The large incision was more desirable when the diagnosis had been formed and a nephrectomy undertaken. It seemed a little severe to make this incision where the operator was going to expose the kidney and possibly save the organ. He had seen deaths from haemorrhage, but never in his own practice, and this he attributed to the fact that where he found a kidney very adherent and matted from chronic disease he adopted subcapsular nephrectomy. When the kidney was very adherent he thought it was useless to try and get it out by any other method. He had used the incision advocated by Mr. Ball when he was searching for a stone low down in the ureter, before the present x-ray appliances were available. In another instance he used the incision for a large multicystic kidney in a young child, and it worked very satisfactorily. Lastly, the ordinary lumbar incision made slightly longer, and an incision cut at right angles up along the external oblique, gave plenty of room for operative manoeuvres. Sir JOHN LENTAIGNE said he agreed with the last speaker. He considered that the efficiency of the other kidney was the point most important to ascertain. In tuberculosis there was real danger, as in a late stage of the disease it spread down the ureter to the bladder, and then almost at once an ascending tuberculosis started which would surely attack the other kidney. The cystoscope alone would not tell at once whether the other kidney was working, nor would segregation of the urine settle the point. It was once thought that by diverting the urine from each ureter into separate channels the surgeon could tell whether the other kidney was functioning or not. Ureter catheterization was the only reliable test, but unfortunately this was a procedure which could not always be easily carried out. Even the most expert men had found it impossible to use the ureteral catheter in every case. In about 30 per cent. of cases this method was unavailable. He found a

double incision very efficient. By cutting down on both kidneys and palpating, it was possible to tell whether the kidney and ureter on opposite sides were sound, and the patient appeared to be nothing the worse. He did not consider the danger of haemorrhage quite as great as Mr. Ball asserted. In cases of perinephric inflammation he had found the subcapsular method the best. Mr. KENNEDY was also at a loss to know how far the incision was carried upwards. He considered that it began rather too low down, as the ureter itself could be explored through an incision not extended far downwards. By combining the incision at right angles with the lumbar incision the largest kidney could be taken out. In a case of very slow-growing tumour of the kidney, lasting over eleven years, where he operated over a year ago, he carried out the incision spoken of by Mr. Maunsell and found no trouble, although the kidney was greatly enlarged. He referred to the use of a clamp for removing haemorrhage. If the pedicle of the kidney was taken up and clamped before isolation of the vessels they could afterwards be tied individually and haemorrhage would be averted. It was, he said, astonishing the amount of room provided by the freeing of the last rib. Mr. PEARSON considered that the incision described was the ideal procedure. The case with which the operator could see what he was doing was very remarkable. It was really lateral, it was not too long, and was better than the lumbar one. The application of the clamp to the pedicle in a fat subject was not easy. The instrument might not be got round all the vessels; some might easily escape, and there was considerable danger of the pedicle being cut so close to the clamp that other vessels might slip out of it. Mr. H. STOKES said that the practice of a surgeon who had performed forty nephrectomies without a single death was not to tie himself to any particular incision. It was best to plan the incision according to the type of case that was being dealt with. Mr. C. A. BALL, in speaking of the position of the patient, said he generally started by laying the patient on the back, inclining the body a little to one side. He usually started with a small incision of about four or five inches, and if there was not room enough he extended it higher up. It was astonishing what a small incision would do with a thin patient. No one now hesitated to open the abdomen for an exploratory operation, and he therefore saw no reason why this incision might not be made. He also recommended the incision for removing calculi, as he had seen kidneys very seriously damaged by the lumbar wound. He had only once seen the subcapsular operation, and had never performed it; but in cases of tumour of the kidneys it was an operation that could not be used. His object was not so much to try and convert those who had performed lumbar nephrectomy satisfactorily as to show that if students were taught that this anterior incision was a much safer method it would be an advantage. There was no reason to ask those who had found the lumbar incision satisfactory to change their technique. He considered the T-shaped incision more damaging to the muscles. Referring to Sir John Lentaigne's remarks, he said that, of course, the efficiency of the other kidney should be defined beforehand, and the kidney could easily be palpated, if desirable, by this incision. He had made use of this incision, opening the peritoneum for exploratory purposes, and the opposite kidney could be palpated in this way much easier than by the double incision of both kidneys. Mr. MAUNSELL explained that the slight opposition shown by him towards the operation described was founded on a misconception, as he did not understand from the original explanation that the incision was a short one. He thought Mr. Ball meant cutting the patient right down to Poupart's ligament.

The Location of Pus in the Hand.

Mr. A. A. MCCONNELL read a paper on the above subject illustrated by specimens and lantern slides. There were definite spaces in the hand independent of the tendon sheaths in which pus might collect; the diagnosis of pus in these situations could be made, and special incisions were required for adequate treatment. He adopted the nomenclature introduced by Kanavel, of Chicago, and in the main advocated the treatment employed by the latter. Clinical cases were cited, however,

which went to prove that adequate drainage of the middle palmar space could be carried out by placing an incision behind the web of one or more of the fingers, and introducing a drainage tube. This incision avoided the digital vessels and nerves, and proved as effective as Kanavel's palmar incision. He demonstrated specimens and lantern slides illustrative of his remarks, to show that the majority of anatomical and surgical textbooks gave an inadequate account of the anatomy of the hand and the treatment of its affections. The PRESIDENT said that the fact that these injuries to the hand were so frequent, and might have such disastrous results if not well treated, invested the subject with the greatest importance. Dr. KEEGAN observed that very little was said about this subject, yet surgeons could not pass a week without seeing many cases. There was no doubt that the anatomical lines which should be followed for the correct treatment of cases of the kind were clearly pointed out, and Mr. McConnell's diagrams demonstrated the many reasons why failure was met with in the early convalescence of such cases. Professor DIXON had enjoyed an opportunity of seeing the excellent preparations which Mr. McConnell had made, and they were even more convincing than his diagrams. The arrangements of the septum which he had described were very easily shown even without injections. Mr. H. STOKES said that he had come across the subject about a year and a half ago in the *Journal of Obstetrics and Surgery*, but Mr. McConnell had put the matter yet more clearly. Dr. ADRIAN STOKES asked if the pus had progressed farther than it should have done would the incision suggested be still sufficient to drain the palm of the hand, or did Mr. McConnell suggest that the other incision spoken of would give better drainage. Mr. GUNN had felt for a long time that in hospital practice septic fingers and hands were left very much to the residents and house-surgeons, and that very disastrous results were often experienced where incisions were made in wrong positions. There were few subjects of more importance than this, and he thought it deserved a great deal more attention. Mr. CRAWFORD thought it important to note that this method of making an incision of the web of the finger was new, and had only been performed by Mr. McConnell himself. He had had only one case of the kind since he had learnt the method from Mr. McConnell, and in that instance, although the whole hand was oedematous, he determined to try drainage through incision of the web of the little finger, and the result was very good, all the symptoms having subsided in three or four days. Mr. A. A. MCCONNELL, replying to the remarks, said that the only question he had to answer was with regard to the extension of the pus upwards into the forearm. He demonstrated by means of a slide the best way to allow of efficient drainage when pus was extending upwards into the forearm. Two incisions were advisable whenever there was pus in the forearm.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.

At a meeting held on March 6th at the Royal Infirmary, the President, Dr. STANLEY RISELEY, in the chair, the following cases were shown:—Mr. SINCLAIR WHITE: (1) Cases illustrating the operative treatment of fractures; (2) two cases to illustrate the necessity for after-treatment after operations for talipes; (3) operations for resection of the colon in three stages; (4) papilloma of lip with early epitheliomatous changes; (5) enclosed bilateral branchial cysts in the neck. Mr. ARTHUR CONNELL: (1) Double cervical rib with pressure symptoms in arms; (2) hypernephroma of kidney, excision, recurrence, disappearance under Coley's fluid; (3) congenital ossification of intertransverse ligament of lumbar vertebrae; (4) union of fracture of shaft of femur by Lane's plates in a patient, aged 72, under intraspinal stovaine. Mr. ARCHIEALD CUFF: (1) Cases to illustrate after-effects of gastro-enterostomy performed for gastric and duodenal ulcers; (2) congenital syphilitic disease of knee-joint in a child. Mr. ERNEST FINCH: (1) Cases of infective arthritis of knee and wrist; (2) recurrent carcinoma after removal of both breasts, with extensive secondary growths on chest, neck, and in liver. Mr. W. S. KERR: (1) Epithelioma of middle-ear cleft in a man aged 50; the cleft was eroded by vascular grey granulation tissue, the facial nerve being exposed for the whole of its vertical length; the patient

had persistent pain in the right side of the head; there were exuberant granulations which bled easily; there was a history of middle-ear disease since childhood. (2) Extradural abscess with mural thrombosis of sigmoid sinus; ligation of internal jugular. (3) Tuberculous disease of maxillary sinus in a woman aged 58; Caldwell-Luc operation for infraorbital pain and swelling of cheek and dullness on transillumination; mucous membrane found thickened in places. On section typical tubercle giant-cell systems were seen. No tubercle were detected elsewhere. (4) Recurrent sarcoma of ethmoid after a year, treated by free removal (temporary ligation on carotid) and cauterization with Paquelin's cautery. The upper jaw was removed at the primary operation. The cavity was now almost completely epithelialized. (5) Sequestrum, removed by operation from static portion of labyrinth, showing one canal nearly complete and part of another. The patient had symptoms of cerebellar abscess, but exploration was negative. Mr. G. H. POOLEY: (1) A case of interstitial keratitis treated by mercury and salvarsan. (2) A case illustrating the different varieties of cataract and injuries. (3) A middle-aged man with ulcers on each cornea, the result of a ganister accident. The patient had glycosuria, and the only beneficial treatment for the ulcers had been by zinc ionization. (4) A girl, aged 22, with proptosis of the left eye. The eye could not be moved in any direction. Wassermann's reaction was negative. After exploration of the orbit, which was negative, immense swelling of the lids took place, which had persisted for many weeks. (5) A case of pituitary tumour in a middle-aged woman; bitemporal hemianopsia. The patient was treated for a time by thyroid and pituitary extracts. The right eye became completely blind. Cases were also shown by Dr. W. S. PORTER, Dr. A. G. YATES, Mr. HERBERT EMMERSON, and Dr. PERCIVAL HAY. Dr. RUPERT HALLAM showed a series of skin cases and gave x-ray demonstrations.

GLASGOW MEDICO-CHIRURGICAL SOCIETY.

A MEETING of this society was held on February 7th, Mr. FREELAND FERGUS, President, being in the chair. Mr. J. HOGARTH PRINGLE showed two patients operated on for *Aneurysm*: (a) Subclavian, (b) popliteal. Mr. PRINGLE and Professor W. K. HUNTER showed a patient operated on for *Acromegaly*. Dr. J. GOODWIN TOMKINSON showed cases of *Coccogenic syphilis* under treatment.

The next meeting of the society was held on February 21st in the new clinical laboratory of the Western Infirmary, where a pathological demonstration was given on work carried out in connexion with the laboratory. Dr. J. KERR LOVE, discussing *Syphilis and congenital deafness*, distinguished (1) post-natal deafness due to congenital syphilis, coming on during the school period, accompanied by keratitis, and characterized almost always by a positive Wassermann reaction; (2) congenital deafness due to congenital syphilis, indicating an extinct or nearly extinct blood infection, and often characterized by a negative reaction; (3) hereditary deafness complicated by congenital syphilis, a type of deafness probably Mendelian in incidence, and one whose family history was not long disturbed by the introduction of syphilis. These three types were illustrated by numerous family trees. Dr. C. H. BROWNING discussed the significance of the Wassermann reaction and some clinical applications. Dr. W. HYSLOP MANSON dealt with the reaction in ophthalmology. Dr. H. FERGUSON WATSON stated some results he had obtained from reactions done in 1,700 cases of children's diseases. Children suffering from true congenital heart disease all gave a positive Wassermann reaction, a proof of the syphilitic origin of the valvular lesions, while those exhibiting heart disease of the infantile type and of rheumatic origin all yielded negative reactions. Positive reactions were also obtained in all of 15 cases examined of meningitis with hydrocephalus, and in all of 85 cases, some apparently healthy, the children of tinkers, gipsies, and tramps. Dr. T. J. MACKIE demonstrated and discussed the occurrence of Gram-negative bacilli in pyogenic infections of the urinary tract. Dr. W. KIEP gave an account of the treatment of 4 cases of typhus fever by intravenous injections of salvarsan. In two of these (one severe and one mild) the course of the disease appeared to be aborted by a single

injection, but in the other cases (one severe and one moderately mild) the pyrexia resumed its ordinary course within eighteen hours of the injection, and subsequent injections, given after an interval of one or two days, produced similar results. Dr. G. A. ALLAN showed microscopic preparations from the liver, spleen, and cerebrospinal fluid of a child who had died, aged 12 weeks, of tuberculous meningitis. The tubercle bacilli found presented on culture the characters of the human type, but by inoculation into a rabbit reacted like the bovine type. Dr. J. CRUICKSHANK discussed, with demonstration, the detection of tubercle bacilli in sputum, urine, etc., by microscopic examination and culture, and their differentiation from other acid-fast organisms. Dr. W. J. LOGIE discussed the urea: ammonia nitrogen ratio of the urine, and its significance in cases with glycosuria.

UNITED SERVICES MEDICAL SOCIETY.

PORTSMOUTH BRANCH.

A MEETING of this society was held at the Alexandra Hospital, Cosham, on Tuesday, March 4th, Colonel S. WESTCOTT, C.M.G., R.A.M.C., President, in the chair. Fleet Surgeon F. H. A. CLAYTON, R.N., read a paper entitled *Three unusual medical cases*, and exhibited specimens. In an interesting paper on the treatment of *Diffuse septic peritonitis due to appendicitis*, Major G. J. STONEY ARCHER, R.A.M.C., emphasized the following points: Operate as soon as possible; do not irrigate or swab out the peritoneal cavity; remove the appendix; use glass drainage tubes; use iodized formalin catgut for sewing up the wound; keep the patient's thorax raised during the operation and nurse him in Fowler's semi-sitting position. Commence proctoclysis at once and continue this till the patient is able to drink freely without vomiting. The paper was illustrated by four recent and consecutive cases, which were seen afterwards in the wards. In the discussion which followed, the President, Fleet Surgeon MOON, R.N., and Major ADYE-CURRAN, R.A.M.C., took part. Captain J. B. GROGAN, R.A.M.C., read a paper on three cases of *Malarial fever contracted in England*. In all of these benign tertian parasites were demonstrated in the blood. The President, Fleet Surgeon F. H. A. CLAYTON, R.N., and Fleet Surgeon G. A. WATERS, R.N., took part in the discussion, and several interesting hypotheses as to the possible methods of infection were advanced.

SIR GILBERT WILLS, M.P., and his family have contributed the sum of £5,000 to the Royal Victoria and West Haunts Hospital, Bournemouth, towards the building of an administrative block at the Boscombe branch, in memory of the late Sir Frederick Wills, who was at one time President of the Royal Boscombe and West Haunts Hospital before its amalgamation with the Royal Victoria Hospital, Bournemouth.

Dr. W. M. GRAHAM, Director of the Medical Research Institute, Lagos, in a report on blackwater fever in Southern Nigeria, 1899-1911 (London: Waterlow and Sons, 1912) expresses the belief that if it be a specific disease it must be originally and most frequently acquired from the native. Analogy with malaria, he states, would suggest that a native population which at the age of puberty had acquired practical immunity to malaria would also have acquired concurrently a similar immunity to blackwater fever, which in a protected population of adults would present itself under a modified and less acute form, and might even run its whole course without the occurrence of haemoglobinuria. If this were so the diagnosis in the native might easily be missed. In support of this contention, he draws attention to a series of sudden deaths in the Lagos Hospital, but he does not produce evidence that these were in fact cases of blackwater fever. Infection from the native, he thinks, might either be indirect or direct, and he suggests that whichever hypothesis be accepted, either the malarial or specific origin, the presence of native women, and their corollary, native children, in a European household is undesirable. He seems to suggest that sexual intercourse with native women may produce the disease; but here again he brings forward no evidence in support of his theory.

Rebiefus.

SPIRITISM AND INSANITY.

Of the long series of volumes of the *Bibliothèque de Psychologie Expérimentale et de Métapsychie*, edited by Dr. RAYMOND MEUNIER, many of which have been reviewed from time to time in our columns, that entitled *Spiritism and Insanity*,¹ for some not very obvious reason, was apparently the first to be translated into English.

Perhaps it should be said here that the term "metapsychism" was suggested by M. Charles Rebief to the Congress of Psychology, held at Rome in 1906, "to define the ensemble of those phenomena concerning which the psychological sciences have not yet furnished conclusive results." The volumes of this series are of very unequal value, and, owing, perhaps, to invincible ignorance on our part, those of a "metapsychic" order appear the least satisfactory. Dr. VIOLLET's volume belongs to this class. It is not easy to discover his position with regard to the claims of spiritualism. Apparently his attitude is one of hopeful expectancy. In any case, he is not a dogmatic sceptic, for, after showing the analogies between hallucination and the visions of spiritists and between delusions and the beliefs of these people, he says:

But, I affirm it here, the incredulous man of whom I speak, and who wishes to believe that the spiritistic doctrine is delirium, is not myself. Philosophically, I would not dare to do so, persuaded as I am of the frailty of human knowledge, all things being probably equal in "vanity" in the eyes of Infinite Wisdom. Equally as a physician for the insane, I would not say so, because the origin of delirium, in all things arbitrary, differentiates it from that doctrine which takes its point of departure, at least, from the human "finite," and which proceeds, not at all arbitrarily, but with the judiciously eclectic concurrence of anterior knowledge and of anterior religious and philosophical doctrines.

It is evident that such a chain of reasoning, which, on account of the belief that all things are probably equal in vanity in the eyes of Infinite Wisdom, would accept as of equal value deductions from ascertained fact and the superstitious beliefs of, say, the aborigines of Australia, must lead to a practical negation of the results of every branch of positive science. Looking at these matters, however, from the detached point of view of superhumanity, Dr. Viollet discusses in interesting enough fashion the various types of spiritist devotees, and in particular the mentally disordered who may be attracted by séances, and the types of spiritistic insanities. Notwithstanding much cloudy rhetoric, there is not a little of interest in the book, and the author concludes by giving excellent advice to the neuropath: "Do not complicate your life with all these mysteries and with all these miracles; avoid curiosity and live simply and quietly," and to the savants—the Crookeses, Wallaces, and Oliver Lodges—"establish a sanitary customs house at the entrance to your séance rooms." Probably, however, if this latter injunction were carried out and the mentally disordered were excluded, the "séance rooms" would be empty—deserted even by the savants with no material to investigate.

The publishers would have been well advised to have had the proofs revised by a medical man. Delirium is hardly the exact rendering of *détire*, and the need for staphyloorrhaphy in a syphilitic subject "by the perforation of the palate consequent on the growth of a gum" would then not have puzzled the reader.

TROPICAL MEDICINE.

Sprue: its Diagnosis and Treatment,² is a book worthy of careful study. Its author, Dr. BEGG, is the advocate of a form of treatment for sprue by yellow santonin which in his hands would seem to have worked in an

almost magical manner. The volume deals with the geographical distribution, morbid anatomy, pathology, diagnosis, and treatment of the disease, and a series of cases showing the results of treatment is appended. Greatest stress perhaps is laid on the treatment, and especially on the treatment by yellow santonin. Students of tropical medicine will remember an interesting and instructive paper on this drug, read by Dr. Preston Maxwell at a meeting of the Society of Tropical Medicine and Hygiene on March 17th, 1911, a paper which gave rise to a very animated discussion, in which Dr. Begg himself joined. Several of the cases treated by Dr. Maxwell had undoubtedly done well, but though this was so the consensus of opinion amongst the experts present was against Dr. Begg's line of treatment. When such a state of affairs as this exists—when, that is, one man is using a drug with success whilst another has no success—the simplest explanation would seem to be that one term is being applied to diseases of different pathology; there is no doubt that many chronic diarrhoeas or post-dysenteric conditions are often classed as sprue though they are not really examples of this disease. Be this as it may, the fact remains that many cases of sprue treated both at home and abroad with yellow santonin have not benefited in the least, and those who have had this experience are entitled to be sceptical. On the other hand, cases of diarrhoea and other bowel troubles of unknown etiology have often been benefited and sometimes cured by this same line of treatment; and it is therefore not one to be lightly cast aside. In view of Dr. Begg's successes, it would seem that it should be given a trial in all cases of sprue, or at least in those that are not doing well under the ordinary methods of treatment. We have one quarrel with Dr. Begg. On page 109 he states that he has not always noted the ages of his cases, but that this is the least important of the particulars. With all due deference to Dr. Begg, however, we venture to suggest that this is a most important point, since the prognosis becomes correspondingly grave with the advance of years. In other words, the older the patient the less chance of cure, and this is due, no doubt, to the general principle that the recuperative powers diminish with age. There are other points in the book, such as the treatment of chronic cases, which are open to criticism; but space will not admit of this here. The book is clearly written and the matter simply put. There is no gainsaying the fact that Dr. Begg pleads his cause with ability, and by so doing may well win converts to his belief.

The third and final part of Dr. C. W. DANIELS's book on *Tropical Medicine and Hygiene*³ deals with diseases due to bacteria and other vegetable parasites, to dietetic errors, and with diseases of unknown causation. Part I, it may be remembered, dealt with the diseases due to the protozoa, Part II with the diseases due to the metazoa. That three volumes should have been required demonstrates how tropical medicine as a distinct subject has grown in the last twelve years. The author believes that the attempt to group tropical diseases according to their causations and not according to symptomatology is practicable and simplifies the conception both of the diseases and of the prophylactic measures required. Some very important tropical and subtropical diseases come into this volume, notably plague, undulant fever, cholera, enteric fever, dysentery, leprosy, beri-beri, and pellagra. All those subjects are well dealt with and the reader is thus enabled to form a clear conception of the disease and everything connected with it. The material included is generally orthodox and the information accurate. A few errors do creep in, however, such as the statement that the occurrence of undulant fever in West Africa is doubtful, for positive cases have been definitely reported from there. These are small points, however, in a book covering so much ground. The book forms a fitting sequel to the other two volumes and should take its place amongst the standard works on tropical medicine.

(Demy 8vo., pp. 258. 7s. 6d. net.)

A useful little manual on *The Care and Treatment of European Children in the Tropics*,⁴ by Dr. MONTAGU HARSTON of Hong Kong, should prove of value to tropical practitioners. Though many books have now been written on tropical medicine, there was room for one dealing with these diseases as seen in children, for a practitioner accustomed to ordinary tropical practice among adults might fail to diagnose malaria or helminthiasis in an infant or child, and would not know the doses suitable, or the precautions which it would be necessary to take, or how to allay the anxieties of the mother and other relatives. Dr. Harston's book will teach him all these things and many others. It is easy to see that it is written by one with considerable experience of his subject, and first-hand knowledge of this kind is always the most valuable. An introductory chapter is followed by four on "The climatic factors influencing European children in the tropics"; "The incidence of disease in European children in the tropics"; "Certain considerations of hygiene and the general welfare of European children in the tropics," and "The care of European infants in the tropics." Then the several diseases are discussed, and a chapter on repatriation closes the book. Interspersed through the text are 47 figures, and there is one coloured plate. A copy of this interesting work should be in the hands of all practising in tropical and subtropical countries.

The fact that a second edition of Professor GABBI'S manual of tropical diseases of Southern Italy and Sicily⁵ has been called for within less than two years of the first shows that it has fulfilled a real want. Knowledge of tropical diseases progresses at such a rate and the number of people interested in the subject, whether as patients, workers, or observers, increases so rapidly that it is not surprising that there should be a strong demand for books dealing therewith. When we recall the mixture of acute observation, and complete ignorance as to the real cause of these diseases, which filled the textbooks of only a few years ago and contrast this with the result of modern research, it is no wonder there should be a need for standard books on the subject. Amongst such books Professor Gabbi's deserves a favourable place. The greater part of the book is devoted to Malta fever and to various forms of what the author calls Leishmaniosis (kala-azar, oriental sore, etc.), and one of the features of this edition is the exposition of the later views with regard to the Leishman parasites and an attempt to group the various forms of disease which they cause. In order to help the man who cannot avail himself of the decisive (when positive) tests of the bacteriological laboratory, and also in those cases where these tests are negative, the author goes rather carefully into the differential diagnosis from the clinical point of view. Other sections of the book are given up to "three-day fever," dengue, and bubo. There are some good chromolithographs of the blood and associated parasites; the book is of a size handy and convenient either for reading or for carrying in the pocket.

Dr. F. O. STORR has published in French a book on sleeping sickness in Katanga.⁶ The material contained in it is the result of his two years' work in that region. The most important part is undoubtedly that bearing on the prophylaxis of the disease and the measures required to prevent its further spread. He goes into these in great detail, and on the whole his suggestions seem sound, though some of them would appear to be difficult of execution. It is to be hoped, however, that the Belgian Government will see its way to act upon them where possible, for, as Stohr says, it is a subject of the very greatest importance, both from the point of view of commerce and of prestige to that nation.

⁴ *The Care and Treatment of European Children in the Tropics*. By G. Montagu Harston, M.D. Lond., Ophthalmic Surgeon to the Tung Wa Hospital, Hong Kong; Examiner in Materia Medica and Therapeutics, Hong Kong College of Medicine, etc. With Introduction by Sir Patrick Manson, G.C.M.G., M.D., LL.D., London: Baillière, Tindall, and Cox, 1912. (Cr. 8vo, pp. 248, plates 17, 7s. 6d. net.)

DEVELOPMENTAL PERITONEAL ADHESIONS.

ANATOMISTS have always been careful to educate us thoroughly—sometimes to weariness in our student days—in the various normal complicated folds and layers of the peritoneum, and they have not been slow to point out aberrations and irregularities in its arrangement. But of late years the attention of surgeons has been attracted to some dispositions of peritoneal layers with pathological consequences of great moment. Mr. Arbuthnot Lane was the first to classify the symptoms associated with intestinal stasis and to maintain that it was a clinical entity of distinctive and not uncommon type; the existence of the "ileal kink" described by him is now recognized as one cause of stasis. Then, Dr. Jackson in America described a diaphanous membrane which he had observed stretching over the ascending colon from the hepatic flexure to 3 in. above the caput and enveloping the colon. This membrane gave rise to a kink at the hepatic flexure with obstructive symptoms. Next, Professor Payr in Germany described a splenic kink brought about by a short tense phreno-colic ligament with secondary adhesions of transverse and descending colon; and at the same time it was found that there were adhesions or bands of similar nature fixing the meso-sigmoid to the left iliac fossa.

The origin of these structures found at the four angles of the colonic square has been a matter of some discussion, and it is thought they are much more common than we have hitherto believed. That, at least, is the opinion of Mr. H. M. W. GRAY and Mr. ANDERSON, of Aberdeen, who have published a most interesting pamphlet on *Developmental Adhesions Affecting the Lower End of the Ileum and the Colon*.⁷ Mr. Gray is in complete agreement with other writers as to the chain of symptoms due to intestinal stasis, but he regards the stasis as the effect and not the cause of the adhesive peritoneal bands found in the lower end of the ileum and in the colon. He quite frankly says that he does "not believe that in the first instance any of these adhesions are due to crystallization of the lines of strain," which is Mr. Lane's explanation. Nor can he accept the theory that Jackson's membrane is due to pericolic inflammation. Equally summary is his dismissal of C. H. Mayo's explanation that Jackson's membrane is of congenital origin formed as a result of the burrowing of the caecum behind the posterior parietal peritoneum, as there is no evidence that such a mode of descent ever takes place. Mr. Gray believes that all these forms of adhesion are due to "excess of physiological fusion." If they do not manifest themselves till adult life the congenital origin is not discounted any more than the late appearance of an inguinal hernia is evidence against the congenital origin of the sac. He explains the formation of Lane's membrane as the product of developmental changes. Towards the end of fetal life the lower end of the ileum enters the caecum from behind or even from the outer side; the peritoneum covering the under surface of this part of the ileum and its mesentery may become fixed to the dorsal parietal peritoneum of the iliac fossa. In the subsequent development and distension of the ileum and caecum the peritoneum reflected from the iliac fossa to the bowel is partly pulled out (that is, by ileum) and partly pushed out (by caecum) in the form of a roughly quadrilateral or triangular membrane. Similarly, Jackson's membrane is to be regarded as simply the right margin of the great omentum (which ordinarily reaches as far as the hepatic flexure) thinned out and fatless. Excess of physiological fusion more easily explains the adhesive bands at the splenic and sigmoid corners.

The writers of the essay before us believe that these congenital peritoneal deformities have much to do with the production of visceroptosis, and they call attention to the relation frequently seen between visceroptosis, narrow build or physique, and the finding of developmental adhesions. As to this last factor in the relationship, their experience is that "Lane's membrane was found in 10 per cent. of all cases in which thorough examination of the right iliac region was possible." This seems a high percentage, but it may easily be checked by observations in *post-mortem* examinations in various parts

⁷ *Developmental Adhesions Affecting the Lower End of the Ileum and the Colon*. By H. M. W. Gray, M.B., F.R.C.S., Edin., Surgeon and Lecturer on Clinical Surgery, Royal Infirmary, Aberdeen; and William Anderson, M.B., Ch.B., Aberdeen University Press, 1912. (1s.)

of the country, for this disease may vary in different parts of these islands. The essay may be commended to the notice of the profession, for the subject is one requiring more numerous observations and a keener outlook for cases of the kind.

FIELD SANITATION FOR TERRITORIAL OFFICERS.

LIEUTENANT-COLONEL AVERILL'S *Field Sanitation*⁸ should be welcomed by all officers of the Territorial Force, but especially by the regimental medical officers, who are usually busy men and have little leisure for studying books of regulations or textbooks on military hygiene. On the other hand, if they go into camp without any definite notions of their duties, beyond that of prescribing for the minor ailments of the daily sick, they are not likely to acquire much useful information during their training or to give to the commanding officer the assistance desired in maintaining the health of the battalion. A short study of this little manual will show them how much there is to be done and how to do it.

The book begins with a short sketch of the organization by which the health of the territorial army is to be maintained in time of war. Next comes some very practical advice on the hygienic precautions to be observed on the march and in camp; the sanitation of camps is well explained, and the book concludes with a summary of the medical officer's duties in camp.

Under "Purification of Water" we may perhaps be permitted to make one or two minor criticisms. A blanket is very little use as a rough filter after the addition of alum; its texture being coarse, the precipitated particles are not caught in its meshes. To get the best value out of alum and wood ashes, the latter should be well rubbed into a wet sheet nailed on to a wooden frame, so as to form a trough; the water, with the added alum, should then be gently poured into this. On page 14 sodium sulphate is mentioned as a chemical for the purification of water; presumably the acid sulphate is intended.

This is an excellent little book, which may confidently be recommended to all medical and combatant officers of the Territorial Force.

NOTES ON BOOKS.

DR. C. CLARK BURMAN, of Alnwick, Northumberland, has issued a short pamphlet dealing with *The Responsibilities, Rights, Duties, and Privileges of Insured Persons and Medical Men under the Insurance Act, particularly in Rural Districts*.⁹ The object is to place before insured persons those particular points in which medical service under the Insurance Act differs from private practice, meaning by this the position of doctors and patients under a capitation system. The writer complains that one great imperfection of the Act is its omission to provide for the extra expenses which country practitioners have to meet in carrying out their share of the work. He appeals to insured persons to exercise a sympathetic consideration for the doctor in respect to the demands made on his services, especially referring to night visits and calls out of hours; stress is laid also on the duty of patients to go to the doctor instead of expecting him to visit them whenever possible. The duties of doctors are considered under four heads—first, to give treatment such as can properly be given by a general practitioner of ordinary professional competence and skill; secondly, to visit patients at their homes only when the patient cannot go to the doctor's surgery; thirdly, to attend at places specified at fixed hours, which both doctor and patient should strictly observe; and fourthly, to attend personally when possible or when precluded from personal attendance to provide another practitioner as deputy. Some danger is seen in the fact that popular medical men may choose for their list only patients likely to need little attention, leaving cases that seem likely to be troublesome to other practitioners, who may thus get an undue share of work while only receiving the same capitation fee. The author considers that "some obligation rests on the profession to view with a charitable reserve deficiencies and imperfections which are incidental to the setting into motion of such a massive piece of legislation," and

⁸ *Field Sanitation for Territorial Officers*. By Lieutenant-Colonel C. Averill, V.D., M.D., D.P.H., R.A.M.C.(T.F.), Sanitary Officer, Welsh Division, Territorial Force, Aldershot: Gale and Polden. 1913. (Demy 8vo, pp. 34. 1s. net.)

⁹ Pp. 15. Published at the *Guardian* Office, Alnwick.

thinks that the experience gained during the first three months' provisional service will provide data on which a system on a more equitable and less irksome basis may be established.

Dr. Desfosses, *La Presse Médicale*, 120, Boulevard Saint Germain, Paris, asks us to state that a copy of the handbook to medical institutions in Paris noticed in the *BRITISH MEDICAL JOURNAL* of February 22nd, p. 397, will be sent free to any British medical man who applies to him.

MEDICAL AND SURGICAL APPLIANCES.

Celluloid Splints and Appliances.

FOR a good many years celluloid has been used, chiefly abroad, for spinal supports, splints, and other apparatus, and, indeed, for nearly all purposes for which stiff leather is used. In this country, however, it has been very little employed, and for two reasons: First, because its application involves a rather troublesome technique with which surgeons themselves have not cared to grapple, while the instrument makers have not laid themselves out for this kind of work; secondly, because of the inflammable nature of the material, which constituted a very real danger to the patient. Both these objections have lately been removed, for a method of preparing celluloid splints has been patented under the name of Pexuloid, for which it is claimed that there is no danger of fire. This claim, as far as our experience goes, is certainly justified. We have held a strip of one of these splints in the full blast of a gas blowpipe, and find that it slowly chars, with the evolution of a very little flame. As soon, however, as the strip is removed from the blast it ceases to smoulder and quickly cools, thus showing that at any ordinary temperature the material is incapable of combustion. Nevertheless, it retains all the useful qualities of celluloid: strength, lightness, and impermeability. Surgeons need no longer undertake the tedious and troublesome processes involved in making these splints, for they are placed on the market and made for all sorts of deformities and defects by Mr. W. Longmate, of 56, Weymouth Street, Portland Place, W.

MEDICINAL AND DIETETIC PREPARATIONS.

Pure Olive Oil for Medicinal Use.

OLIVE oil has long been employed in medicine, but principally in various preparations for external use. More recently its internal employment, usually as a laxative, has increased considerably, large doses being given both by the mouth and by the rectum. For such purposes it is obviously desirable that a pure oil of fine quality should be employed. We have recently received from Messrs. Cosenza and Co. (28A, Clarges Street, London, W.), a sample of an olive oil which they have put on the market particularly for medicinal use. Our determinations of the constants of this oil gave the following results: Specific gravity, 0.9163; refractive index (at 20° C.), 1.4685; saponification value, 190.1; iodine value, 83.9; melting point of fatty acids, 25° C. These figures are all typical of a pure olive oil, and special tests for arachis, sesame, and cotton-seed oils showed them to be absent. The acid value was found to be 2.1, representing about 1 per cent. of free oleic acid, and the flavour of the oil was excellent.

THE Hunterian Society's Annual Medal will be awarded to A. Graham Stewart, M.B., Ch.B.Aberd., for his essay on "Raised Arterial Pressure and Arterio-sclerosis" at the annual meeting of the society on April 23rd, when Dr. Stewart will read a paper founded upon the essay.

AMONG recent leaflets issued by the Board of Agriculture is one (263) on the mustard beetles. *Phaedon betulae*, about one-eighth of an inch long, prefers the mustard plant, but will feed also on the cabbage, turnip, swede, cress, and charlock. In the spring the beetles, which have lived through the winter in crevices or the hollow stems of wild plants, come out and lay their yellow eggs on the under side of the leaves. The beetles and larvae can be shaken off into receptacles containing paraffin or tar, but a badly-infested crop should be dug in. The turnip, mustard, and cabbage flower-beetle (*Meligethes aeneus*), only one-twelfth of an inch long, may also be very destructive; it lays its eggs in the opening buds. Another *Phaedon*, which lives on cow-parsnip and hogweed, may attack celery and parsley. Other leaflets deal with the cultivation of onions (264) and utility rabbit-breeding for smallholders (265).

DAVID LIVINGSTONE.

BORN MARCH 19TH, 1813.

ON March 19th, 1813, David Livingstone was born in a house in Shuttle Row, in the village of Blantyre, on the banks of the Clyde, in north-west Lanarkshire, Scotland; he died on May 1st, 1873, in a hastily built hut, in Chitambo's village, in the country of Ilala, to the south of Lake Bangweolo, Central Africa; and in those sixty years he had literally, and without any exaggeration, opened up the Dark Continent to the light of medicine, of civilization, and of Christianity. He was great as an explorer and geographer, for he travelled twenty-nine thousand miles and explored a million square miles of territory; he had great visions of the future and indomitable courage, for he foresaw the linking up of the Cape with Cairo, the carrying of education and of Christianity to the teeming millions of Africa's children, and he never faltered in his belief that the slave trade would ultimately be crushed out; but he was also a medical man, and it would ill become the profession of which he was a member to allow the centenary of his birth to pass without notice. Medical men may well delight to honour the memory of the man who has been called the "Columbus of Africa," although the comparison with the discoverer of America is not altogether a happy one. Of Livingstone it has been said that it would not be out of place to designate the whole interior of the African continent a memorial to his genius for exploration and to his heroic sacrifices and achievements.¹

This is not the place for an appreciation of Livingstone's work as a missionary or as an explorer; but some attention may quite suitably be given to the medical aspects of his early life in this country, of his later life in Africa, and to the medical developments which have taken origin in the enthusiasm which sprang up when the full significance of his life's work and of his lonely death began to be recognized.

Young David Livingstone became a doctor that he might be a missionary. One of his boyhood's heroes was Dr. Gutzlaff, the medical missionary to China, and he at first looked to China also. At the age of 10 he had gone into a cotton mill in his native Blantyre as a "piecer," his duty being to tie together the broken ends of any threads which might chance to break in the spinning; and here he made a beginning for getting a qualification in medicine by studying Latin in his spare minutes. The story is that he propped up Ruddiman's Latin *Rudiments* on the top of the spinning frame, and got by heart his declensions and the like whilst walking to and fro in front of it. This was during the day from 6 a.m. to 3 p.m., and at night he worked at his books at home. One of the books which he delighted in at this time was Culpepper's *Herbal*, in which it may well be imagined he found information as strange as any he was afterwards to obtain in the wilds of Africa. This was his first medical reading. He saved enough money by his work to enable him to take out medical and divinity classes in Glasgow, for he had become a spinner in the mill, and so able to draw better wages. There was no Carnegie Trust in Scotland in these days to give financial aid to young lads with brains enough to pass the examinations for the learned professions; but the London Missionary Society came to Livingstone's assistance, and, after some time spent at Chipping Ongar in 1838, and later in the London hospitals, he was admitted (in 1840) a Licentiate of the Faculty of Physicians and Surgeons of Glasgow. Meantime he had met Dr. Moffat, with whom he was to be more closely related ere long, and had had his thoughts turned somewhat from China, to which he had felt strongly attracted, and directed to Africa instead. Moffat said to him one day that if he would push on beyond his old station in South Africa he would come to a vast unoccupied district, where on a clear morning he (Dr. Moffat) had seen the smoke of a thousand villages, and no missionary had ever been. So at the close of 1840 Dr. Livingstone set sail for Algoa Bay, and it is characteristic of him that he learnt how to use the quadrant from the captain on the voyage.

It is noteworthy that in his gaining of a medical

qualification Livingstone showed that same determination to achieve his purpose of which his life in Africa gave so many evidences. It is told of him that as a boy he not only climbed to a higher point in the ruins of Bothwell Castle than any other, but also carved his name up there. He had some stiff climbing to do in Africa, and he left his name cut out there too.

During all the many years he spent in the heart of the Dark Continent, making the discovery of the lakes Ngami, Shirwa, Nyassa, and Bangweolo, and of much else, he never forgot that he was a doctor as well as a missionary. His writings are full of his medical experiences, and one must admire the extraordinary accuracy and insight of many of his observations. Even in the twentieth century his name is constantly cropping up in books on Africa. In an article, for instance, on "Some Tribal Customs in relation to Medicine and Morals of the Nyam-nyam and Gour People,"² published in 1911, Livingstone is quoted eight or nine times. "I have an immense practice," he wrote once; "patients walk 130 miles for my advice; this is the country for a medical man, but he must leave fees out of the question."

It is very interesting, too, to take notice of how often medical phraseology tinges Livingstone's ordinary conversation and gives point to his utterances. Take that most memorable message of his to the *New York Herald*, in which he spoke of the slave trade these piercing words: "All I can say in my loneliness is, May Heaven's rich blessing come down on every one—American, Englishman, Turk—who will help to heal this open sore of the world." Take, again, this reflection, written in his Journal under the date June 24th, 1872: "The medical education has led me to a continual tendency to suspend the judgement. What a state of blessedness it would have been had I possessed the dead certainty of the homeopathists, and as soon as I found Lakes Bangweolo, Moero, and Kamalondo pouring their waters down the great central valley, bellowed out, 'Hurrah! Eureka!' and got home in firm and honest belief that I had settled it [the source of the Nile] and no mistake. Instead of that I am even now not cocksure that I have not been following down what may after all be the Congo."

But medicine did more than tinge Livingstone's language and thought. Dr. A. G. Miller³ has found evidence in the great explorer's *Missionary Travels in South Africa*, published, let it be remembered, in 1857, that he was a pioneer and discoverer in medical science as well as in other things. The time referred to was 1852, and Livingstone wrote:

On the 30th of May I was seized with fever for the first time. . . . The temperature in the axilla, over the heart, and region of the stomach was in my case 100 deg., but 103 deg. at the nape of the neck and throughout the course of the spine. There were pains along the latter, and frontal headache. . . . Anxious to ascertain whether the natives possessed any remedy of which we were ignorant, I requested the assistance of one of Sकेलेतु's doctors. . . . After being stewed in their vapour baths, and smoked like a red herring over green twigs, I concluded that I could cure the fever more quickly than they can. The native treatment is, however, of service if employed in conjunction with a wet sheet, and a mild aperient in combination with quinine. . . . There is a good deal in not "giving in" to this disease.

Dr. Miller remarks:

This experience of Dr. Livingstone's was in 1852, when clinical thermometers and the wet pack were practically unknown in the treatment of fevers. The administration of quinine along with a laxative is a method which I have found most useful in my own practice. The laxative seems to increase the activity of the quinine and prevents unpleasant symptoms, even when the quinine is administered in large doses. Dr. Livingstone's concluding remark is quite up to date. His testing the native doctor's powers on himself was very characteristic of the man.

Space, however, fails to refer to more than these medical incidents and reflections in Livingstone's books and journals; but it may be said in passing that medical men who have not read the various works he published and the letters and records he wrote have, even from the purely professional point of view, a treat in store. No sadder story may be found than that of the weary, disease-stricken explorer's death in the swamps to the south of

¹ Dennis, J. S.: *Christian Missions and Social Progress*, iii, 424, 1902.

³ *Edinburgh Med. Missionary Soc. Quarterly*, xiii, p. 124, 1913.

Bangweolo, brightened as it is to some degree by the marvellous fidelity and resource of his native servants, who, after doing a rough and ready *post-mortem* examination and after burying his heart under a tree in Chitambo's village, faced extraordinary difficulties and dangers in carrying his body to Zanzibar. An account of the necropsy performed in London by Sir William Fergusson is given in the pages of this Journal,⁴ and it is touching to read that the body was identified with absolute certainty by the condition of the left arm bone, which showed the results of the bite of the lion received thirty years previously. Recently the question has been raised by Dr. Sander of Berlin as to what was the exact nature of the disease from which Dr. Livingstone died⁵; and not a little evidence is led, from a perusal of Livingstone's *Last Journals* and our present knowledge of the symptomatology of tropical maladies, that he was suffering from trypanosomiasis. If this be so, then the greatest medical problem of the Central Africa of the present time is linked pathetically with the death of the man who did so much for the welfare, bodily and moral and spiritual, of that wonderful continent.

Livingstone's death was not an end, it was rather a new beginning of Africa's enlightenment. We have not here to do with the political and religious results which may truly be said to have had their origin in the life work of the intrepid and heroic medical missionary; but their greatness is confessed by all. His work also has not been left without memorial, for Livingstone is the new Rhodesian capital near the Victoria Falls, the "sounding smoke" which so fascinated and puzzled David Livingstone, till he saw with his eyes these wonderful falls on the Zambesi, twice as large as Niagara. But a few sentences must be written here regarding the medical memorials of his work as a physician and a missionary which have sprung up both in Africa and at home.

In addition to the mission to Central Africa established during Livingstone's lifetime by the universities of Oxford and Cambridge, and in response to his appeal, the Church of Scotland gave the name of his birthplace (Blantyre) to its industrial mission in the Shire highlands, about the year 1875. The Livingstonia Central Africa Trading Company, better known as the African Lakes Corporation, put steamers on Lake Nyassa soon after the explorer's death; the Stevenson Road, too, was another result of his pioneering work. The United Free Church of Scotland's work in Livingstonia is another memorial to Livingstone, and as it has a strong medical work going on under the veteran physician, Dr. Laws, a few words may be given to it.

Whilst Dr. Livingstone was still alive he had a great admirer and helper in another medical man, James Stewart, afterwards to be known all over the world as Dr. Stewart of Lovedale. When Livingstone died, Dr. Stewart was one of those who helped to bury him in Westminster Abbey, and from there he went direct to the General Assembly of the Free Church of Scotland in Edinburgh, and made an appeal which ended with the following words:

I would humbly suggest, as the truest memorial of Livingstone, the establishment by this Church, or several churches together, of an institution at once industrial and educational, to teach the truths of the gospel and the arts of civilized life to the natives of the country, and which shall be placed on a carefully selected and commanding spot in Central Africa, where from its position and capabilities it might grow into a town, and afterwards into a city, and become a great centre of commerce, civilization, and Christianity, and this I would call Livingstonia.

This was in 1874 (May), and soon thereafter the necessary funds were forthcoming. Dr. Robert Laws was found and others with him, and, just twelve months after Stewart made his appeal, the Livingstonia party sailed from London, taking with them the little steamer, the *Itala*, to be built up and set afloat on the lake. Now, after thirty-six years,⁶ there are in Livingstonia over seven hundred preaching stations, a church of over eight thousand communicants with eight thousand candidates for baptism, over seven hundred schools with thirteen hundred teachers and nearly fifty thousand scholars, and

over it all presides Dr. Laws. With him are some thirty-five missionaries, of whom seven are medical missionaries from Scotland. Indeed, the medical work has always been a strong element in the success of Livingstonia, and the Livingstonia doctors have done no small service to tropical medicine in many of its departments, their word carrying weight in connexion with sleeping sickness and all such matters.

There are other memorials to Livingstone in the land which he so dearly loved, but some reference must now be made to memorials at home. In a recent article in the *Cornhill Magazine*,⁷ Sir Harry Johnston sympathetically and appreciatively deals with Dr. Livingstone's life and work; but he brings his article to a close with the following sentences, which may well excite surprise:

So far as I am aware, no notable statue, or a statue of any merit or publicity, has ever been erected to commemorate this great man in a public place in England or Scotland. The British South Africa Company has put up a memorial to him at the Victoria Falls, but Great Britain and British South Africa have still to acquit themselves in some way for the immense debt that they owe to David Livingstone.

Now South Africa, with its Livingstonia, Blantyre, Lovedale, and other missions and centres of commerce and education, may be looked to for an answer to this surprising statement, but something requires, perhaps, to be said from the home side.

First, as to statues. No traveller arriving in Edinburgh by the North British Railway can leave the Waverley Station without passing within a few yards of the bronze statue of Livingstone which stands in the East Princes Street Gardens. It was inaugurated in 1876, and came from the hands of Mrs. D. O. Hill, the sister of Sir Noel Paton. There may be two questions whether it worthily commemorates the great explorer—indeed it may safely be said that Livingstone was not thinking of statues when he made his appeal to close the open sore of Africa—and the statue itself is rather overshadowed by the great and imposing mass of the adjacent Scott Monument; but there it undoubtedly stands and can be seen of all men.

There is, however, a better memorial of Livingstone in Edinburgh, one more after that man's own heart. It is the Livingstone Dispensary and Institute of the Edinburgh Medical Missionary Society in the Cowgate. Soon after Livingstone's death the directors of this society, with the full approval of Livingstone's family, resolved to rebuild the entire dispensary and mission premises in order that they might better serve for the training of young men who desired to go out as medical missionaries. A bazaar, under the patronage of H.R.H. the Princess Louise, was held, and money came in other ways, so that in 1877 the venerable Robert Moffat, Livingstone's father-in-law, was able to lay the memorial stone, and in the following year the premises were opened. The Livingstone Dispensary was in 1903 again rebuilt and extended to cope with the increasing work, and in it during all these thirty-five years medical students, men and women, training as missionaries, and attending the medical classes of the Edinburgh University and Extramural School, have learnt how to deal with the sick and poor, and have carried the knowledge so gained to the ends of the earth. At the present time no fewer than a hundred fully qualified medical men and women, who received their practical training in 39, Cowgate, are serving under various missionary societies in all parts of the world. Dr. Livingstone was not a man whose religion could be made to fit into the groove of any sect, and in this respect the dispensary which carries his name would fully have earned his approval, for in it have been trained students belonging to practically all the Protestant churches of Great Britain, and applicants have not been refused from the Protestant churches of Germany, Denmark, America, and other lands. Its old students are now at work abroad under the C.M.S., the L.M.S., the B.M.S., the S.P.G., the Church of Scotland, the United Free Church of Scotland, the English Presbyterian Church, the Danish Missionary Society, the Wesleyan Missionary Society, the Presbyterian Church of Victoria, the China Inland Mission, the Salvation Army, the Sudan Pioneer Mission, and some twenty other bodies: so that it is widely enough represented to be truly called interdenominational

and unsectarian. A further memorial has been raised in it to Livingstone within the past few months. About this time last year the directors appealed for £1,000 to be called the Livingstone Centenary Fund, the interest of which was to be used to pay the class fees of a "Livingstone Student" of the Edinburgh Medical Missionary Society. At the time of writing all the money required has been received, so that this additional memorial to David Livingstone has been assured.

Near London also (at Leyton) there exists a medical memorial to Livingstone in the Livingstone College, with Dr. Charles F. Harford as Principal and Secretary. This college, which was established twenty years ago, does a work which has also earned the approval of Livingstone's friends and relatives. It gives a carefully arranged course of elementary medical training for missionaries going to lonely places; its students do not become medical missionaries, and they sign a declaration that they will not take that name, but they gain knowledge concerning the prevention of disease, and the use of simple treatment, which is of great service to them abroad. This college also is endeavouring to raise a Livingstone Centenary Fund of £10,000 to establish itself more fully and securely.

In London itself there is a scheme on foot to raise a memorial to David Livingstone, and the form which it is to take is the freeing of Charing Cross Hospital (at which the explorer was for some time a student) from the burden of debt which keeps some of its wards closed. For this purpose a Centenary Million Shilling Fund is being formed.

In Glasgow, too, a Livingstone Centenary Memorial Fund is to be collected for the promotion of medical missionary work in Central Africa, for the foundation of a Livingstone scholarship in Anderson's College Medical School, and for the promotion of the scientific study of geography in the University of Glasgow, and the endowment of a Livingstone lectureship or professorship. An appeal, too, is being made for funds to build a Livingstone Memorial Training College on the shores of Lake Nyassa, where already there is a David Gordon Memorial Hospital.

A proposal to endow, improve, and extend the Cottage Hospital at Blantyre as a fitting means of celebrating the centenary of Dr. Livingstone has been set on foot by the County Council of Lanarkshire. As the hospital is in the parish of Livingstone's birth, it is thought that no more appropriate place could be selected for a monument, and that no more worthy purpose could be chosen. The institution will be known as the "Livingstone Memorial Hospital," and an appeal is being made for funds to carry out the proposed scheme.

Surely there are not a few memorials in being or about to be; and the life and work of David Livingstone are not likely to be forgotten for lack of medical, educational, religious, and even plastic monuments.

During the next few days memorial meetings and services are to be held in many places in this country and in South Africa, and no doubt the medical aspects of Livingstone's life will not be forgotten in any of them; but here in this JOURNAL, as was, of course, fit and right, attention has been mainly directed to the explorer as a physician and to his missionary work in its medical aspects. At the same time, no one can read or think about him without at once recognizing that the true and only centre of his life was the Cross; all else was adjunct and auxiliary and subordinate to that.

The concluding stanza of the lines which appeared in *Punch* on April 25th, 1874, is equal to any of that journal's best utterances:

He needs no epitaph to guard a name
Which men shall prize while worthy work is known;
He lived and died for good—be that his fame.
Let marble crumble: this is Livingstone.

THIS year the medical pilgrimage organized by the central German committee for medical educational tours will visit the British Isles. It will start from Hamburg in a Hamburg-American liner on August 3rd, and will land its passengers to attend the International Medical Congress in London from August 6th to 12th. It will then go on to Scarborough, Leith (for Edinburgh and the Scottish lakes), Aberdeen, the Hebrides, Glasgow, Belfast, Dublin, the Channel Islands, and Rotterdam, reaching Hamburg again on August 28th. The address of the committee is Berlin, W., 9, Potsdamstrasse, 134 b.

VERONAL POISONING.

VERONAL, or di-ethyl barbituric acid, has been very extensively used as a hypnotic during the past few years. It was placed on the market as a harmless hypnotic by the German chemists who introduced it, and it is only as the result of numerous fatalities following its use that the dangerous properties of the drug have become recognized.

Cases of veronal poisoning are becoming increasingly frequent in this country, and there must be few medical men in practice who have not seen most alarming if not even fatal symptoms as the result of taking this potent drug.

Very many medical men have come to look upon the drug as a dangerous hypnotic, and on this account a large number of practitioners have wisely discontinued its use. It is, however, of urgent importance that the public should be protected against themselves, since veronal and drugs of this character can be freely bought from pharmacists and, indeed, from any one who chooses to sell them. The drugs need not be labelled poisonous and there is nothing to warn the purchaser of the danger from taking an excessive dose.

Organic chemistry has made such rapid strides during the last few years that as soon as a drug like veronal is placed on the market numerous derivatives and homologues are manufactured, and these in like manner are introduced, some special virtue being usually ascribed to the modification of the parent drug.

In the case of veronal a considerable number of derivatives have already been introduced, which may have a similar dangerous effect on the human body. Among derivatives are—medinal (the sodium compound of veronal), propional (di-propyl barbituric acid), luminal (phenyl ethyl barbituric acid), luminal sodium, etc., while adalin and bromural are related to veronal in composition.

It is a matter of most urgent public importance that not only veronal but the allied drugs should forthwith be placed upon the poisons schedule.

In the case of veronal and the allied drugs there is to be considered not only the risk of fatal consequences following the use of these compounds, but, what is of equal importance, the great danger resulting from the acquisition of the drug habit.

Veronal is a drug which if taken regularly produces grave disorder of the nervous system, such symptoms as ataxy, hallucinations, and tremor being very marked. In addition a deterioration of the moral sense occurs, just as in the case of the morphine and cocaine habits. It thus follows that in those who have acquired the veronal habit a recklessness in the use of the drug may result, so that dangerous poisoning, often the result of a deliberate overdose self-administered, is the consequence.

In the recent inquiry at Hove in the case of Hugh Eric Trevanion, deceased, it was determined that about thirty-two hours before death a dose of approximately 150 grains of veronal was taken. The jury in this case showed a very intelligent appreciation of the dangers to which the public were exposed by the valuable riders appended to their verdict as follows:

1. That veronal, its derivatives, and allied substances should forthwith be placed on the poisons schedule.
2. That it be illegal to supply any hypnotic drug without the prescription of a medical man.

This case was of considerable value, since it called attention to many of the important toxicological features relating to veronal poisoning. Veronal is only slightly soluble in cold water, so that a large fatal dose would require a considerable quantity of liquid for its administration, about 2½ pints of cold aqueous liquid being required to dissolve 150 grains. In the case of hot water about three-quarters of a pint of liquid would be required to dissolve this amount, supposing it to be drunk in hot solution.

Medinal, the sodium compound of veronal, is very soluble in water, and 150 grains would dissolve in 2½ oz. of cold water. In the case of veronal and medinal, the solutions of the drugs have a bitter, nauseous taste, which would be easily recognized.

It is thus seen that veronal cannot be easily administered with homicidal intent without the person taking the drug being aware of the fact that a nauseous substance is

being given him, which in a normal person would give rise to suspicion. No doubt a large dose of veronal might be purposely given to a veronal taker instead of a moderate dose without his being aware of the fact at the time.

The determination of the fatal dose of veronal in a case of fatal poisoning is a matter of some difficulty, because death does not, as a rule, occur within twenty-four hours, and during the period intervening before death a considerable quantity of the drug would be excreted in the urine. Probably only about one half of the dose taken would be present in the body at the time of death.

Veronal when absorbed appears to be evenly distributed over the various organs of the body. There is not that special selection of absorption by particular organs which is characteristic of many poisons. Hence in calculating the amount present in the body at the time of death the total weight of the soft tissues must be estimated, and the total poison in the body is calculated from the proportionate amount found in a given weight of the organs examined.

Veronal being an acid is extracted by ether from the acid solution obtained by the Stas process of extraction for alkaloids. The poison is recognized by its characteristic crystalline appearance and physical properties, and also by special chemical tests.

The Council of the Pharmaceutical Society, at its meeting on March 5th. acting under the Pharmacy Acts, 1868 and 1908, adopted the following resolution:

That diethyl-barbituric acid and other alkyl, aryl, or metallic derivatives of barbituric acid, whether described as veronal, proponal, medinal, or by any other trade name, mark or designation; and all poisonous urethanes and ureides ought to be deemed poisons within the meaning of the Pharmacy Act, 1868, as amended by the Poisons and Pharmacy Act, 1908, and ought to be deemed poisons in the Second Part of the "Schedule of Poisons" to that Act.

FINAL REPORT OF THE COMMITTEE ON TUBERCULOSIS.

The Departmental Committee on Tuberculosis, of which Mr. Waldorf Astor, M.P., was Chairman, has issued its final report.¹

THE PRESENT POSITION.

It is pointed out that since the interim report was presented in April, 1912, two important changes affecting the funds available for the campaign against tuberculosis have been made; the first was the announcement in the letter of the Chancellor of the Exchequer of July 31st, to Mr. Henry Hobhouse, Chairman of the County Councils Association, that the Treasury would meet approximately half the estimated cost of treating non-insured persons as well as the dependants of insured persons. The Committee holds strongly that no campaign against tuberculosis could have had a reasonable prospect of success if provision were made for the treatment of a section only of the population. The second change referred to is the allocation for domiciliary treatment of 6d. per insured person out of the 1s. 3d. provided by Section 16 of the Insurance Act.

THE PURPOSE OF THE PRESENT REPORT.

The final report now presented deals mainly with the measures which in the opinion of the Committee should be taken for the prevention of tuberculosis in general, with special reference to the questions relating to bovine tuberculosis and tuberculosis in children, and to a scheme for dealing with the annual sum of money available in the hands of the Insurance Commissioners under Section 16 (2) of the National Insurance Act for the purposes of research.

PREVENTION.

Prevention of the Entrance of Tubercle Bacilli.

The Committee believes that by means of treatment and education the risk of infection, even from persons in the more acute and advanced stage of the disease who live in intimate contact with others, may be largely diminished. Infection is frequently disseminated by persons suffering from advanced pulmonary tuberculosis who are in the habit of

entering and leaving Poor Law institutions, having regard merely to their own convenience, and not to the interests of their family or of the community in which they live.

The Committee recommends the compulsory isolation of certain cases in a state of high infectivity, particularly when the patient's surroundings are such as to increase the risk of other persons becoming infected. It recognizes that such isolation should be carried out with all possible regard to the feelings of the patients and their families and friends.

The systematic and thorough disinfection of premises which harbour tubercle bacilli is mentioned, and stress is laid on the importance of early diagnosis of the disease.

Prevention of Development of Active Disease in Persons Infected.

The Committee believes that material prosperity of the community as a whole will be reflected in a decreased incidence of tuberculosis, and makes special reference to the necessity for the improvement of housing conditions, and the value of schemes for town planning and garden cities.

BOVINE TUBERCULOSIS.

The Committee is of opinion that the ultimate eradication of animal tuberculosis is not impossible of achievement, but is likely to be a slow process, and must depend upon co-ordinated and continuous effort. No single or purely local effort will suffice. The Committee, while welcoming the proposed legislation dealing with the question of the milk supplies, expresses the opinion that it should include the whole country, and should contain provisions conferring special powers upon local authorities, the central authority having the right of enforcement in the event of default by local authorities. It recommends that in the preparation of any scheme for the eradication of bovine tuberculosis the following points should be provided for:

1. County councils and county borough councils should have powers and be required to inspect herds, dairies, and farm buildings and to administer all enactments relating thereto, their work being subject to adequate supervision by a central authority. As regards the local inspecting authorities, this recommendation may require some modification in Scotland where local government is somewhat differently organized.
2. Only guaranteed tuberculin should be used, and facilities should be given, subject to such conditions as may be thought desirable, for the free testing of cows by qualified and authorized persons.
3. Certain cows should be slaughtered, both in the interest of the public and of the dairy industry, the premises thoroughly disinfected, and no tuberculous animals added to the herd.
4. Measures should be uniform in character and the same principles should be applied to the whole country.
5. The public should be educated so as to appreciate the greater value of pure tubercle-free milk and milk products.
6. Farmers should be taught that tuberculosis in cattle is infectious and not hereditary.

CHILDREN.

The Committee considers the evidence that children are infected through tuberculous milk, as well as from other sources, convincing, and makes the following general observations:

The Committee are of opinion that additional provision is required for the treatment of children suffering from the disease, including cases of pulmonary tuberculosis, tuberculosis in the bones and joints, and glandular and other forms of tuberculosis.

In addition to the provision of treatment at sanatoriums and hospitals for tuberculous children mentioned in the Interim Report, there is urgent need for a wide application of the principle of open-air treatment and education by means of open-air schools (day and residential), open-air classes, etc. Such institutions should deal not only with tuberculous children, but also with the large number of children who are suffering from ailments which, if neglected, would be likely to increase their susceptibility to tuberculosis. It is also desirable that these institutions should be utilized, as far as possible, to teach the advisability of the adoption of a practically open-air life in the homes of the children.

It is of opinion, further, that the school medical officer should be closely in touch with the family medical attendant, and that the tuberculosis dispensary should as far as possible provide the same service for children as for adults, and continues as follows:

There should not only be a correlation between the dispensary and the various institutions for children, but the institutions

¹ Final Report of the Departmental Committee on Tuberculosis, Vol. I (Cd. 6641). Price 2d. Vol. II, Appendix containing memorandum on sanatoriums prepared by a subcommittee, and various memorandums by witnesses. (Cd. 6654.) Price 1s. 7d. To be obtained through any bookseller.

for children, such as the school clinic, the open-air school, and the sanatorium, should be correlated one with another in order to ensure the easy transference of children from one institution to another.

All appropriate cases should be referred to the tuberculosis dispensary as a clearing house for the confirmation of diagnosis in doubtful cases, for the purpose of clinical record and for treatment where required. Children of school age fit, or likely to become fit, to receive education, even in modified form, should be referred to the school medical officer for education in open-air schools, sanatorium schools, or other special schools, or in ordinary public elementary schools under special care and supervision. The arrangements should be such as to secure the co-operation of the general practitioner.

IRELAND.

The Committee expresses its regret that power to make tuberculosis compulsorily notifiable has not been conferred on the Local Government Board for Ireland, and the hope that the matter will receive the serious consideration of the Government, since compulsory notification is essential to any satisfactory scheme for dealing with the disease.

RESEARCH.

The Committee estimates that under Section 16 (2) of the Insurance Act, which enacts that the sum of 1d. per insured person, payable out of moneys provided by Parliament, may be retained by the Insurance Commissioners, in whole or in part, to be applied for the purpose of research, the sum available at present will be £57,000 a year, and that there may be a small increase in future years. The Committee recommends the establishment of an advisory council and an executive committee, and says:

The duties of the Advisory Council should be to advise, make suggestions, and submit the Executive Committee's budget to the Government, and to advise, criticise, and make suggestions to the Executive Committee.

The duties of the Executive Committee should be to frame a budget which should be discussed and considered with the Advisory Council before being submitted by the Council to the Government; to determine, after consultation with the Advisory Council, the scheme of research work; to make periodic reports to be transmitted by the Advisory Council to the Government; and generally to organize and supervise the research work wherever carried on.

It is evident that when first organizing the scheme both bodies will have to meet frequently, but that when the scheme is in operation there will be less demand on their time.

The Committee considers that the Executive Committee should have as a permanent whole-time secretary an expert of high standing in research, possessing administrative capacity and receiving a salary of £1,200 to £1,500 a year, and that he should, if practicable, act as secretary of the Advisory Council.

The inquiries contemplated by the Committee would include those of a clinical, pathological, experimental, statistical, and sociological character, and it recommends that every sanatorium, dispensary, and other institution for the treatment of tuberculosis and other diseases should have access to laboratory facilities for carrying out routine work and for the collection of data, adding that many of these institutions should have complete laboratories of their own, but that central organization and direction mean economy of time and money.

The Committee received evidence indicating that the funds available for research might be expended on a central bureau, on special institutes, in grants to approved institutions, in grants to individuals, in making special inquiries, and in scholarships and fellowships, and points out that the methods are not mutually exclusive. It recommends that the work should be instituted on the following, amongst other, lines:

- (a) A central bureau should be established and should be the head quarters of the Advisory Council and Executive Committee. The central bureau should have a statistical and sociological department, in the work of which should be included the co-ordination and correlation of results. With regard to statistical investigations, every effort should be made to utilize, where possible, and co-operate with the statistical departments of the different Government departments. Statistics should be so collected and framed as to be comparable with the existing statistics of mortality. There should also be a library and publishing department. The Central bureau should be under the immediate control of the Executive Committee.

- (b) Clinical, pathological, bacteriological, chemical, and other scientific researches should be carried out by competent investigators employed by the Executive Committee in institutions approved by them.

- (c) When the Government, on the recommendation of the Executive Committee, and after consulting the Advisory Council, deem such arrangements desirable, researches of the same nature as those referred to in the preceding paragraph should be carried out in an institution or institutions (including laboratories and hospital wards) which should be under the immediate control of the Executive Committee to the extent and for the purpose in question.

- (d) Money should be available in order that special inquiries—for example, of a statistical and sociological nature—should be carried out by the Executive Committee, if necessary, independently of any particular institution.

- (e) The question whether a sum of money, not exceeding £1,000 per annum, should be available as a prize or prizes for the best original research work done should be considered. The money should only be awarded if the discovery is of sufficient importance and utility.

The Committee recommends that some workers of proved ability should be enabled to devote their whole time to research work, should be given a definite adequate salary and be entitled to a pension, and that efforts should be made to retain young and talented investigators for such work. The Committee goes on to express the opinion that the success of the scheme of research recommended will not be fully secured unless it is accompanied by a general extension throughout the United Kingdom of clinical laboratories for the better diagnosis and treatment of the disease, provided out of funds other than those available under Section 16 (2) of the National Insurance Act.

MEDICAL EDUCATION.

The Committee is of opinion that additional facilities should be afforded to medical students and practitioners to acquire familiarity with the methods of diagnosis of tuberculosis, more especially in its earlier manifestations, and with the methods of treatment, and makes the following recommendations:

1. Medical students and practitioners should be afforded facilities to attend the practice at tuberculosis dispensaries, sanatoriums, and other institutions.
2. It is advisable that tuberculosis dispensaries should, where possible, be directly associated with schools of medicine.

The recommendations in regard to research are further discussed in a leading article at page 571.

FREE CHOICE OF DOCTOR.

FEW experiences are more interesting than that of watching the birth, growth, and full fruition of an idea. To see it taking shape in word, on paper, and in deed is interesting in itself, and this interest is increased when comparison is made with the many ideas which only see the light to die, or having looked upon the sun are blighted and come to an untimely end.

It is with this feeling of deep interest that the medical profession has watched the birth and the ups and downs of the great idea of free choice of doctor. Had it remained in medical hands it would have been to-day a fine, full-grown, clean-limbed embodiment of a great idea, but, unfortunately, the politicians laid rude hands upon it and knocked it about to suit their own purposes, so that now it issues from the political arena so unlike what was expected from its promising inception, that its parents are disposed to disown their child.

Let us follow the progress and fate of this idea. Free choice of doctor—the freedom of the patient to choose his own doctor and the right of the doctor to choose his own patient—was not mentioned by the Chancellor of the Exchequer when, nearly two years ago, he introduced the National Insurance Bill. Two reasons may be assigned for this important omission: First, that he had determined to compel the doctors to accept his own terms; and, secondly, that he was obsessed by the fear that the British working man would ruin the insurance fund by malingering. This latter is, we believe, so far as the vast majority of insured persons are concerned, an unfounded fear, and comes badly from one who is never tired of shouting the battle-cry, "Trust the people." But although

the Chancellor of the Exchequer said no word about free choice of doctor in his speech introducing the bill, the subject was brought up (during the debate on the introduction) by Lord Alexander Thynne, who said:

You must either give a free choice to the patient to choose any doctor he likes in the district, or you must give him a choice of what I may term "a panel of doctors."

On the second reading debate Dr. Addison contended that

There should be provision for enabling patients to choose their own doctor. . . .

And the Chancellor said:

There is nothing (in the bill) to prevent the free choice of doctor.

Evidently, then, both sides of the House were agreed that there should be free choice of doctor. The profession's approval was voiced when the British Medical Association, through a deputation to the Chancellor of the Exchequer on May 30th, 1911, submitted:

That it should be open to every medical practitioner in the district, who is willing to act, to be on the list from which insured persons might make choice, provided that such practitioner had not been guilty of misconduct justifying his exclusion from the list.

Here we note that the service must be a willing service—"every practitioner . . . who is willing to act"—the underlying hope being that the terms and conditions offered to the doctors would be so reasonable that they would willingly and sympathetically do everything in their power to make the Act a success. Two days after, at the Special Representative Meeting, the Chancellor of the Exchequer, speaking of the free choice of doctor, said:

Personally I am strongly in favour of it. . . . I think one of the essentials of curing is that the patient should have faith in his doctor, and you cannot have faith in your doctor if you have doctors thrust upon you whom you have not chosen. . . . Therefore I am myself strongly in favour of the system . . . of setting up a panel on which all qualified medical practitioners will be able to serve—not compelled to serve, no doctor will be obliged to take this work. . . . I should be delighted to see a free panel of doctors set up under the care of the local doctors themselves.

This in plain and unmistakable language is a declaration in favour of freedom for the doctor who will not be compelled to serve and for the patient who will not have doctors thrust upon him. Words, words, words! By the Act and Regulations the faith of the patient in his own doctor and the willing service of the doctor have been both thrust aside with ruthless hands, and in the name of liberty a Liberal Government

"plays such fantastic pranks before high heaven
As make the angels weep."

Again, in October, 1911, Mr. Lloyd George made a speech at Whitefield's Tabernacle, in which he said, among many other things:

The first thing that happens is that he (the insured person) can have free medical attendance. . . . Under this bill he can have the doctor of his choice. . . . So we say to him, Go to the doctor you believe in. . . . That is the first thing that happens; he can go to the doctor whom he believes in, and every doctor who chooses can go on the panel. So there is not only free choice for the patient, there is free choice for the doctor as well. We are going to make this really a free country.

But as time went on the Chancellor of the Exchequer began to see that the conditions and terms of service were not acceptable to the doctors, and that he had more difficulty in bringing them to heel than he expected. So he began to hint that a Local Insurance Committee might be free to organize a service in some other way, and that there must be a limit to free choice of doctor. Hence we are not astonished that when the revised form of the paragraph dealing with this matter came up for debate in the House he went a step further. Mr. Ramsay Maedonald had said:

I cannot see what objection, what sound and serious objection, there really is to allowing each insured person to have his own doctor.

Mr. Lloyd George replied:

There is nothing in the bill to prevent free choice of doctors. On the contrary, I am all for free choice of doctor, *within*

limits. If you give an *unlimited free choice of doctors*, you are taking the direct road to promote malingering. . . . We have so framed our measure that free choice of doctors is allowed. [The italics are ours.]

It is easy for him after this to say, "If he (the working man) gets a good doctor, I do not think he cares whether it is Dr. Smith or Dr. Brown." From this to

No insured person is allowed to make any bargain outside the panel unless it is allowed by the Local Insurance Committee; let that be perfectly clear.

is an easy step in the descent.

Yet another step on the downward course. The insured person was to have not his own doctor truly, but a good doctor, and with that he must be satisfied; the Chancellor of the Exchequer hath said it. In his last speech, however, he gives up the "good doctor," and we reach the bottom of the incline in this utterance: "We cannot guarantee the quality of any doctor. There are good and bad doctors, and some in between . . . but we cannot guarantee them."

MOTOR CARS FOR MEDICAL MEN.

CHEAPER FUEL.

THE British Motor Car Company has made successful experiments with a mixture of paraffin and petrol, in which the latter forms less than one-half. The objection to paraffin has been that it was useless for the purpose of starting. This difficulty appears to have been overcome by an apparatus supplied with pure petrol from a small independent tank, used only for the purpose of starting. Mr. Worby Beaumont has reported to the Royal Automobile Club that the apparatus is simple, effective, and not liable either to derangement, or to be the cause of danger, and that it is applicable to any kind of petrol engine used in motor vehicles.

CHEAP MOTORING FOR MEDICAL MEN.

Dr. A. Mackenzie (Leeds) writes in praise of the Scott motor bicycle with side-car attachment, which he considers is, even apart from the question of expense, as useful to a medical man as a car. He likes its appearance, and finds that it is not necessary to wear overalls, that it is silent, handy in traffic, and easily started. He adds that it is, in his judgement, an excellent machine for a middle-aged man. He has ridden his own machine over 4,000 miles and has used it every day since he got it, and it has not required any repairs.

NAPIER MOTORS, LIMITED.

The firm of Messrs. D. Napier and Sons, Limited, which began business in 1808, has acquired the business of S. F. Edge, Limited, and the business will in future be known as Napier Motors Limited. The Napier works, which are situated in London, make a large variety of vehicles, ranging from the small four-cylinder, 15-h.p., to the large six-cylinder, and in business vehicles from 12 cwt. to 2 tons.

A NESTOR OF THE PROFESSION.

[By Our South Australian Correspondent.]

FOR considerably more than a generation Surgeon-Major Hinton has been one of the personalities of Adelaide and of South Australia generally, and yet he has been but little known outside his own family, except to myself, and to the librarians of the various public libraries. Short and somewhat rotund (not in the least military looking), with an ample white beard, a quaint figure in a sola topee and a tight-buttoned cotton suit reminiscent of India, till about a year ago Dr. Hinton might be seen doing a constitutional of some six or eight miles every day. He had no very fixed place of abode; it is said that at various hotels his demeanour towards the domestics was too suggestive of "India's coral strand," and that it was resented by the democratic instincts of the Australian "help"; landladies, indeed, had sometimes to suggest a change to pastures new. Some year and a half ago he had the misfortune to trip and sustain an intracapsular fracture of the left hip, and since this accident he has come to anchor in a rest home in North Adelaide, generally devoted to the worship of Lucina. Here he devours the latest books and current magazines, reading them without glasses, in possession of all his faculties with the exception that he is deaf. He seems to be enjoying the late autumn of his life, and he affords an illustration of the well-known longevity of pensioners, for he attained to the centenary of his birth on March 7th, 1913. A small eater, a non-smoker, and

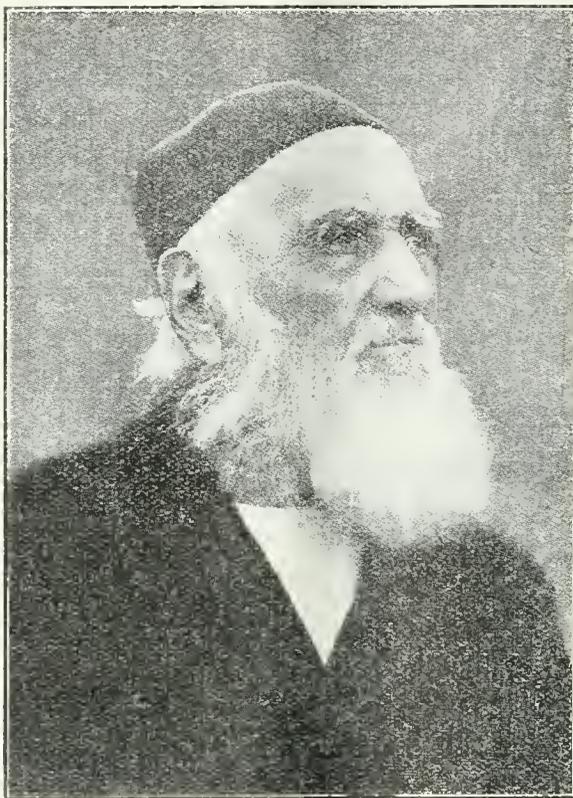

almost a total abstainer, he thinks with Metchnikoff that life may be indefinitely prolonged. When a sprightly young nonogenarian he was startled one day to read in the paper that Surgeon Hinton of the Indian Army had died a centenarian and the oldest member of the profession in Great Britain; this namesake he had never met, nor even heard of; now he seems to have succeeded to the vacancy, unless there be living still men who "qualified" before March 25th, 1835.

Henry Benjamin Hinton came of a long-lived family; both his parents lived to be over 80, and two sisters were nonogenarians. He was born at Southsea, his father, who belonged to the Baptist Church, being the cashier of a local bank. He was at school at Portsmouth till the age of 15, when he began life with a cousin, Isaac Hinton, a publisher, in Warwick Square; the reading of Sir Walter Scott's *Chronicles of the Canongate* first inspired him with interest in India, and he resolved, with his father's permission, to become a surgeon. He was apprenticed for five years to a Mr. S. Cumming of Limehouse, whose wife was alleged to be a descendant of James II. He suffered from headaches due to myopia, and had to wear glasses till he was 50, when a beneficent presbyopia came to his aid. In October, 1832, he commenced work at the London Hospital, attending the systematic lectures delivered by Dr. Pereira. In October, 1834, he entered at Westminster Hospital under Guthrie, the Peninsular and Waterloo veteran, who had seven years earlier published his book *On Gunshot Wounds*, by which and as the founder of the Westminster Ophthalmic Hospital his name is still remembered; the lecturer on medicine was Dr. Ryan, on botany Dr. Epps, and on surgery Dr. McDermott. The most distinguished of his fellow students in after-life was Joseph Toynbee, the aurist, who was the father of the founder of Toynbee Hall; James Hinton, also a well-known aurist in his day, was his cousin. Mr. Hinton's own examination for the M.R.C.S. appears to have been wholly viva voce, and to have been over in one evening; Sir William Blizard was one of his examiners.

No sooner had he received his diploma than he obtained the surgeoncy to an East Indiaman, the *Brechoime*, of 300 tons, and in her he made three annual voyages to Calcutta, a passage taking then about five months; the captain of his ship used his influence with the East India Company to obtain for him a nomination as assistant surgeon in the Bengal Army, and on his return to India he was gazetted on May 28th, 1839, to the 21st Fusiliers at Chinsurah, where his first important duty seems to have been attendance at the flogging of a soldier for some trivial offence. In December, 1839, he volunteered for service in Arracan, and had charge of a native regiment; with it he returned to Bengal in 1841, but in the same year went again to Arracan in a civil capacity. Remittent fever caused his transfer on sick leave to Bengal again, and in 1843 he rejoined his regiment (the 65th N. I.) at Dinapur. In December of that year he was ordered to join the army of Gwalior, but travelling in those days was slow, and when he arrived at Agra he learnt that he was too late to take part in the battle of Maharajpore, in which Sir Hugh Gough routed the Mahrattas; however, he assisted to attend to the wounded, and only failed to receive the

Bronze Star awarded for that campaign on account of professional differences with a superior officer. And here I may remark, if one may rely upon the perusal of Surgeon-Major Hinton's autobiography, that he seems not infrequently to have fallen foul of his superior officers with the usual inevitable result. The defeated enemy was strangely enough converted into the Gwalior Contingent, and to the 4th Infantry Regiment thereof Mr. Hinton was gazetted, and subsequently to the 7th Infantry.

In January, 1846, the banks of the Sutlej were the theatre of war, and Surgeon Hinton served through the greater part of the First Sikh Campaign, though he missed the disasters of Moodkee and Ferozeshah. He served under Sir Harry Smith at Aliwal in January, 1845, and fought under him again at Sabraon next month. After this campaign he was sent in charge of invalids to Meerut. Incompatibility of temperament with a senior officer led to his transfer to the 51st N.I. in Ferozepur in 1846. Then he obtained a garrison appointment at Delhi in January, 1847, where he saw the aged and feeble emperor (Bahadur Shah) in a bath chair.

SURGEON-MAJOR HINTON.

The Sikhs were defeated, but not vanquished, and it fell to Dr. Hinton's lot once more to serve under Lord Gough in 1848 to 1849, and take part in the crowning mercy of Goojerat with the 32nd N.I. He was afterwards stationed at Wuzzeerabad, where his medical duties appear to have been combined with the oversight of the post-office, and here again he succeeded in falling foul of the leading officials. Amongst other unpardonable offences he seems to have attended a church parade in a white jacket instead of a red. February, 1854, found him in Goruckpore, and in 1856 he was stationed at Bowsee, where next year they experienced a foretaste of the mutiny, and later on the reality. The 32nd N.I. was marched to Raneengunge to be disarmed, and only by the miscarriage of a native's letter did its officers escape being massacred on the road. This was all Surgeon Hinton saw of the mutiny, but it was tough and go. In November, 1857, one of the disarmed native regiments (the 70th), to show their loyalty, volunteered for

service in China, and Surgeon-Major Hinton changed into it shortly after, landing at Canton in April, 1858, where he served for two years. After the China war seven more years were served in India, but these were comparatively uneventful; thus closed a strenuous life of twenty-nine years in India, during which much history was being made, and many geographical boundaries were altered. For some forty-five years he has drawn his pension; long may he continue to do so in comfort!

THE mental hygiene exhibit prepared for the International Congress of Hygiene in Philadelphia includes charts, photographs, and models illustrating past and present methods of treating the insane.

ACCORDING to the *Boston Medical and Surgical Journal*, the New York Supreme Court has upheld on appeal the conviction of a driver of a milk wagon for having in his possession unwashed milk bottles. The employer contended that the statute which made this an offence was unreasonable and drastic, but the court said "the danger to be apprehended from the use of unclean receptacles for milk intended for human food is so well known that drastic measures to prevent the possibility of such use are reasonable and justifiable."

British Medical Journal.

SATURDAY, MARCH 15TH, 1913.

THE INSURANCE ACT AND RESEARCH.

AMIDST the turmoil of controversy regarding the Insurance Act, the fact has almost been lost sight of that it provides the first great contribution from the State towards research in scientific medicine. By Section 16 (2), one penny per insured person, payable out of the moneys provided by Parliament, may be retained by the Insurance Commissioners to be applied for the purposes of research, and the total sum thus available will at present amount to about £57,000 per annum. While the main concern of this part of the Act is to combat tuberculosis, the Commissioners have been advised that the money may properly be applied to research in connexion with any disease which may affect insured persons.

A year ago a Treasury Committee was appointed to advise the Government and local bodies on the problem of tuberculosis in the United Kingdom in its preventive, curative, and other aspects, and an interim report was issued last April dealing with the practical measures to be adopted in combating the disease. The recommendations therein contained regarding the establishment of dispensaries, sanatoriums, and hospitals, seem to have found very general acceptance, and are being widely followed by local authorities in carrying out the Act. In a final report just presented to the Treasury, the whole ground of the reference is covered and a scheme for the administration of the research fund promulgated. The Committee did not include any representatives of those actively engaged in scientific work in human pathology. Thus, although heads of various laboratories in the kingdom were invited to give evidence, most of the members of the Committee in dealing with the question of research must have found themselves on very unfamiliar ground and have been in the position of a criminal lawyer called on to sift the evidence in a complicated patent case. The recommendations of the Committee must thus be looked on as of a preliminary and tentative character, but they may form a foundation upon which a successful scheme can be established.

In looking at the scheme of the Committee certain general considerations must be kept in view. The attack on tuberculosis is, next to that on cancer, probably the most complex task which scientific medicine has ever had to face, as is evidenced by the slowness with which practical results have been obtained, notwithstanding the immense amount of work already done. The disease has its own peculiar problems, such as those relating to the channels by which infection occurs and to the existence or non-existence of immunity towards it. From the standpoint of pathology in its practical application to the problem tuberculosis must be regarded as one member of the group of infections, and facts gleaned from work on different members of the group have led to the emergence of the principle that certain general processes are common to all infections. These have to do with such matters as the factors by which the causal organisms are enabled to multiply in the body,

to the essential pathological changes underlying fever, and to the phenomena of recovery. Many facts support the view that once any of these common processes is elucidated for one disease, the explanation will be very generally applicable in other affections. It is to be noted that tuberculosis is in many ways a disease unsuitable to afford opportunity for the solution of the common problems of infection, chiefly because when a question is put the slow development of morbid lesions delays the answer. This opinion finds support in the fact that in institutes largely devoted to general investigations on infection, such as the Rockefeller, and even the Pasteur Institute, comparatively little work has hitherto been done on tuberculosis. Such considerations as these are important in their bearing on the present scheme, for it follows from them that every research which advances knowledge of infection, *ipso facto* throws light on tuberculosis. The Committee anticipates that for the present the moneys available will be applied to research in connexion with tuberculosis and allied problems. It is, however, of the highest importance to realize that, as has been stated, the money can be devoted to diseases of insured persons other than tuberculosis, and we trust that the broader investigation of infection as a whole which is thereby rendered possible will from the outset be brought into the programme of research.

The principle laid down by the Committee, that in any scheme the aim should be to stimulate and to co-operate with existing voluntary agencies for research, is thoroughly sound, as also is the practical application that "clinical, pathological, bacteriological, chemical, and other scientific researches should be carried out by competent investigators employed by the Executive Committee in institutions approved by them." The way is thus at once opened for the organization of the work in the medical schools of the country. These schools must in any case provide the corps of workers required, and it is well to recognize that the existing resources will require augmentation. Putting clinicians aside, there are at present probably not more than 150 men engaged in research work in medicine in the country. One reason for the fewness of the labourers is that many men who have a leaning to research must perforce enter practice to gain a livelihood. The research scheme, with the future development of permanent appointments to which it will inevitably lead, will direct the best talent into channels where it will be best utilized. The working of the scheme through existing laboratories will further place at the command of the Government the wide experience of research possessed by the heads of these institutions, and will facilitate the organization of co-operative effort by different branches of science all over the kingdom. Again, the whole clinical material of the country will be available for investigation, and the routine work of local administrative bodies, such as that relating to the supply of tubercle-free milk, will be co-ordinated with higher scientific work. The distribution of work will also have another far-reaching effect which is not immediately obvious. It is important that the practitioners who are in charge of the insured should recognize the value of, and be inspired by the results of, research. Such a spirit can only be developed if the teachers of medicine and pathology with whom medical students come in contact are active participants in the work which is going forward.

Certain points in connexion with the machinery of administration call for comment. While no objection can be taken to the setting up of two bodies, one,

the Advisory Council—representing general interests, governmental, educational, and scientific, and the other, the Executive Committee, composed chiefly of experts, the proposed relations of these two bodies to one another are unusual. Both are to be appointed by the Government, but apparently the Advisory Council has no control over the Executive beyond offering advice and criticism and transmitting its proposals to the Government. In fact, it would appear to be intended by the Committee that in the particular event of the Executive wishing to arrange for research under its own control, it should have the power of approaching the Government direct. Thus, in case of a difference between the two bodies, an unfortunate Minister might be called on himself to settle whether some line of research should or should not be pursued. It seems obvious that even if the Committee's suggestions were adopted in their present form, no differentiation should be made between the various proposals of the Executive so far as the channel of approach to the Government is concerned. The Committee's plan for defining the functions of the two administrative bodies should be considerably modified. The committee of experts (which might either be an independent body or a subcommittee of the larger body) should submit its proposals for any year to the larger body (constituted as recommended in the Report) for consideration and, possibly, for amendment. A matured scheme would thus go to the Government with the weight attaching to its recommendation by a board on which all views on the subject were represented, and any subsequent discussion regarding it should take place between the Government and the larger body. When finally adjusted, the scheme could come back to the experts to be carried out. Another proposal, to which exception may be taken, is that the Executive should have as secretary a highly-paid expert of high standing in research. Why, with a wealth of expert opinion on the Executive, an individual of this kind should be asked to spend his time in performing administrative duties is not at all apparent. On the other hand, the recommendation of the Report that statistical and sociological inquiries should be directly under the control of the Executive and should be carried on in a central bureau will probably meet with general approval. Such inquiries constitute almost the only department of work relating to tuberculosis where centralization is necessary to efficiency.

While we are of opinion that the recommendations of the Tuberculosis Committee as a whole furnish a basis on which a successful edifice can be built, we cannot conceal from ourselves the fact that the next steps to be taken are of the most critical nature. Unless they are tentative, and unless the unknown resources of the country are most carefully investigated, this great movement may end in disastrous failure. The mere offer of such a large sum of money is in itself a temptation to useless and ill-considered prodigality, and we doubt whether, in saying that the whole of the money could usefully be spent in research on tuberculosis, the Committee has fully realized the magnitude of the question it was asked to advise upon.

We hope to return to the subject in an early issue, and to point out what we consider to be some of the dangers underlying the research scheme, and some of the opportunities which a wise statesmanship will find in it. Meantime we would strongly urge the appointment of a body having the constitution of what the Committee describes as the Advisory Council. This body will necessarily include repre-

sentatives of those actually engaged in research; and could consider the whole situation before an executive is appointed or any definite plans as to actual research are framed.

ADRENALIN MYDRIASIS IN DIAGNOSIS.

DR. CORDS of Bonn has recently collected¹ all that is known of the dilating action of adrenalin upon the eye of man and the lower animals, and has added to a masterly summary of the work of others an account of his investigations.

In 1898 Radziejewski was the first to test the action of a 10 per cent. extract of the adrenal bodies when instilled into the human conjunctival sac: in no one of 500 persons did he detect any effect upon the size of the pupils or upon accommodation. Lewadowski showed in 1898 that when adrenalin was injected into the veins of cats the effects produced—mydriasis, slight exophthalmos, and slight widening of the palpebral slit—were the same as those which follow stimulation of the cervical sympathetic. These changes were not neutralized by eserine. Other observers showed that subconjunctival injection of adrenalin caused mydriasis in man, and instillation dilated the pupil if the cornea were ulcerated or otherwise rendered more permeable. In other words, the physiological effect was dependent on the amount of adrenalin which reached the iris: the normal cornea was not sufficiently permeable, but a wounded cornea allowed enough to transfuse. Subsequently, Wesley found that the repeated instillation of a strong solution dilated the pupil even with a normal cornea. Meltzer and Clara Meltzer Auer showed that the action was greater after extirpation of the superior cervical ganglion than after subganglionic division of the nerve or than in a normal animal. It has since been discovered that this increased sensibility soon disappears, and that some days later no difference can be detected between the side with and without the ganglion. The seat of action is probably, as Langley has suggested, in the receptive substance of the dilator muscle. The mydriasis is most certainly not due to vasomotor action. The eye of the frog is so sensitive to adrenalin that it may be used to detect the presence of minimal amounts of the substance.

Cords understands by adrenalin mydriasis a dilatation produced with intact cornea by a single or repeated instillation of a 1 in 1,000 solution of the drug. In using the test it is best to make three instillations in five minutes and then close the eyes for ten minutes. It is well to make the observations in a subdued light. The cornea must be carefully examined for small defects or a source of error may be overlooked. Adrenalin mydriasis is observed in all conditions which are associated with increased excitability of the sympathetic system. All states of the body in which the equilibrium of the internal secretions (hormones) are disturbed in the sense of an excess of the chromaffine system are associated with an increased sensibility to adrenalin. Such conditions are—functional disturbance of the pancreas, overaction of the thyroid gland, diabetes mellitus, and perhaps exophthalmic goitre. These facts were pointed out by Loewi, and the effect is known as "Loewi's sign." It is probable that in all these states the adrenalin content of the blood is increased.

¹ *Die Adrenalinmydriasis und ihre diagnostische Bedeutung.* Von Richard Cords in Bonn a. Rh. Wiesbaden: J. F. Bergmann. Glasgow: F. Baumeister. 1911. (Sup. roy. 8vo, pp. 62. Price unbound. Mk. 1.60.)

Unfortunately the sign is very inconstant. Some cases of diabetes show it, others do not, nor has the severity of the disease any effect upon the reaction. It may be given by mild cases of diabetes, may be absent in severe, and the reverse is equally true. In abdominal lesions such as peritonitis and injuries to the intestines the sign is sometimes obtained and is probably due to an increased amount of adrenalin in the blood.

The fact that prompt mydriasis follows the instillation of adrenalin into the eyes of animals whose superior cervical ganglion has been recently removed is of especial interest. The operation causes an enormously increased excitability of the receptive substance (Langley) in the dilator muscle cells. The same phenomenon has often been observed in man. Preganglionic division of the sympathetic nerve has no such action.

The reaction may help in the exact localization of the seat of the lesion, causing paralysis of the fifth nerve. The sympathetic joins this only a few millimetres on the distal side of the ganglion, and the sympathetic enters the orbit combined with the first division of the fifth nerve. If complete paralysis is caused by a lesion distal to the junction of the two nerves, the sympathetic is generally paralysed as well and adrenalin mydriasis is present. If the lesion is proximal to the junction—as in most cases of fifth nerve paralysis caused by cerebral syphilis at the base of the brain—no dilatation of the pupil follows the use of adrenalin. Cords failed to obtain the reaction in such a case of complete paralysis of all the divisions of both trigeminal nerves. The sign is, however, inconstant. Six cases of paralysis of the fifth nerve are cited associated with sympathetic paralysis, in which no adrenalin mydriasis was obtained. It would appear that a post-ganglionic lesion of the sympathetic frees the dilator from the inhibitory action of the superior cervical ganglion, and so enables adrenalin mydriasis to occur.

In adrenalin, therefore, we possess a diagnostic aid which, though uncertain and inconstant, may yet be of great help in a difficult case. The positive action of the drug is of much more value than failure in action.

ALIMENTARY TOXAEMIA.

DR. JOHN BROWN, in his lay sermons on health to working people, told a story of an odd old man at Greenock who left at his death a number of sealed packets to his friends; on opening them they found a Bible, £50, and a box of pills with the words, "Fear God, and keep your bowels open." It is a never ending source of astonishment to the medical profession that this apparently simple function can be so grossly neglected. Corporate bodies and municipal councils and communities will spend any amount of time and money in elaborating the drainage system of their town, yet the individual members may be, and often are, guilty of the grossest sins of omission in the care of their own drainage system. Some of these sins of the public may possibly be laid at the door of the medical profession, which has sometimes been apt to deal with the poisonous conditions which arise as the result of constipation in a too haphazard fashion; scientific study of the matter is only in recent years finding its true place. Bacteriology, and surgery also, thanks largely to Mr. Arbuthnot Lane, have shown that the range of troubles which may be attributed to this auto-

intoxication is much wider than used to be generally recognized.

The discussion on alimentary toxæmia, opened at the Royal Society of Medicine last Monday, has been very happily timed; Dr. Hale White's introductory paper is full of suggestions and points the way along which inquiry must go. He assails at once the term "alimentary toxæmia." It is a term which shows our ignorance, since it simply indicates the route of entry of the poison. It implies that the illness is due to poisons manufactured by micro-organisms resident in the alimentary canal, but we cannot name these poisons nor are we certain of the offending organisms. Pyorrhœa alveolaris is a common cause of alimentary toxæmia, and the patient is commonly much surprised when the damage it does is pointed out. Farther on in the gastro-intestinal tract the difficulties in the consideration of the bacterial poisons are enormous. We have to consider many things: the influence of external temperature on the vitality of organisms; and the effect of one organism upon another—for example, the *Bacillus coli*, a normal inhabitant of the great bowel may have for its function the destruction of other organisms, such as the typhoid bacilli, while it may itself be the victim of other invaders. There is the well-known fact that the strain of an organism differs in different individuals, and the further fact that alteration in the culture medium may effect a change in the life of the organism. A case in point is the withdrawal of carbohydrates in carbohydrate dyspepsia, probably the simplest form of alimentary toxæmia, and one which Dr. Hale White recommends for more earnest study.

The nature and composition of the poisons in alimentary toxæmia is still unknown, but that is equally true of uræmia and diabetic coma. Dr. Vaughan Harley's contribution to the discussion, which dealt with the toxins of the alimentary canal from the chemical point of view (p. 555), shows the extreme complexity of the subject. Among other points he brought out was that the decomposition products were practically the same whether formed by the action of bacteria or by the enzymes in ordinary digestion, but he had to admit that hitherto pure toxin had not been isolated even from bacterial cultures. In adults in health the bacteria of the bowel produced indol as well as skatol, phenol, and cresol, and he believed that the continual absorption of these substances could produce true neurasthenia, while premature senile decay, with early arteriosclerosis, was apt to accompany an increase of indol and urobilin in the stools.

Dr. Hale White has much to say of the twentieth century doctrine of intestinal stasis. He considers that the theory of mechanical obstruction as a cause of alimentary toxæmia is by no means proved; its advocates differ much as to what precisely the mechanical agent is, let it be enlarged Houston's valves, pericolicitis, various developmental adhesions of the peritoneum, the formation of bands and abnormal mesenteries; indeed, the abnormal bands and the toxæmia, it is said, may be induced by the same cause. There is reason to fear that in trying to explain the symptoms of intestinal stasis we may "invoke the aid of alimentary toxæmia in the same reprehensibly loose way as gout, uric acid diathesis, and congestion of the liver have been called in to explain various vague symptoms we do not understand."

Dr. F. W. Andrewes, in discussing the bacteriology of the alimentary canal, considered the nature and properties of the bacteria and the part they play in

producing the poisoning. He appreciates Dr. Hale White's difficulty in defining the term. The words "toxin" and "toxaemia" convey certain notions to our minds, but they, after all, are only names for things we know very little about. He regards "alimentary toxaemia" as the "absorption from the alimentary canal of chemical poisons of known or unknown composition in sufficient amount to cause clinical symptoms, the blood having served as the channel of distribution." Now, it is difficult to specify the source of these chemical poisons. Bacteria are constantly undergoing disintegration in the intestinal tract, and there is possibility of harmful results from absorption of the endotoxins, but to what extent the toxaemia depends upon these we cannot tell. Probably it depends very little, so far as the normal flora are concerned. Dr. Andrewes lays down three propositions beyond which he cannot go, first, that poisoning is in some cases by foreign proteins, the liver being at fault; secondly, that the main effect of bacterial activity in the production of alimentary toxaemia lies in the ability to carry out protein cleavages beyond the capacity of the ordinary digestive ferments, and that this is attended by the formation of products which the body is unable to neutralize when in excess; and, lastly, that there is at present little evidence that true toxins derived from the ordinary flora play much part in the alimentary toxaemia.

Professor Saundby's contribution is worthy of diligent reading. It deals mostly with foods and food poisons. In regard to poisoning by faecal stasis his view is that "there is little evidence in favour of the popular notion that faecal retention favours the production in the bowel of putrefactive changes giving rise to poisons which are absorbed into the blood and cause various pathological changes." Without inflammatory changes the natural protection afforded by uninjured intestinal structures is sufficient. When toxaemia is present treatment should be based on the principles of eliminating the poisons already present, preventing their further introduction, and reinforcing the natural protective agencies; surgical intervention may become necessary when medical treatment, long continued, has failed and where there is distinct evidence of disease in the colon wall.

Mr. Arbutnot Lano summarized his well-known views on the consequences of intestinal stasis and its surgical treatment. These are once again presented in forceful, emphatic style, and need no recapitulation here. Suffice it to say that a clear, definite, clinical picture is presented. Whether the author proves his contention that these patients readily develop tubercle or rheumatoid arthritis, or whether his belief will be generally accepted that these diseases cannot exist except in the presence of auto-intoxication, it remains for the future to decide. The great variety of symptoms and diseases which are swept into the net of intestinal stasis makes it necessary that many series of cases shall be published from all parts of the country and by many observers, with ample notes, photographs, statistics, and all the paraphernalia of a scientific investigation, before the theory announced and the practice adopted by Mr. Arbutnot Lano can be presented as textbook surgery.

This discussion has already done something to light up the dark ways of the alimentary canal, and further light may be expected before it is concluded. The subject comes within the daily experience of every practitioner, and it is in just such a subject that the special opportunities of the general practitioner will prove really helpful.

MEMORIAL TO LORD LISTER.

At a meeting held at the Examination Schools, Oxford, on March 8th, under the presidency of the Vice-Chancellor, it was resolved to form a representative committee from Oxford and the district to assist in raising the memorial proposed by the Royal Society to commemorate Lord Lister's services to humanity. Sir W. Watson Cheyne said that it was hoped to establish a real living monument in the form of a fund for the advancement of surgery. It was desired, in the first place, to establish some valuable prize for work done, not so much for the advancement of work in the early days of a man's life, but as a recognition of good work well completed—in fact, of the nature of the Nobel prize. Sir William Osler said that Lister's work had saved more lives directly than probably that of any individual man. The nineteenth century had witnessed four advances of the first importance—preventive medicine, initiated by Jenner, which had really been one of the great glories of British medicine; the discovery and confirmation of the germ theory of disease, initiated by Pasteur and carried on by Koch; anaesthesia, which humanity owed to America; and, finally, the great system of treatment devised by Lister. This last work was remarkable for three things—its universality, its life-saving and health-giving features, and the enormous saving of pain which had been effected through it.

TREATMENT OF AMOEBIC DYSENTERY AND HEPATIC ABSCESS.

At the meeting of the Académie de Médecine on February 25th, M. Chauffard, Professor of Clinical Medicine in the University of Paris, related a remarkable case of hepatic abscess opening into the bronchi, which, after lasting five months, was cured in five days by the hypodermic injection of emetine in the manner described by Professor Leonard Rogers of Calcutta in our pages on June 22nd, August 24th, and September 28th (p. 828), 1912. Professor Chauffard's patient suffered from irregular fever, and was expectorating daily on an average nearly a pint of the characteristic crushed strawberry material. On the second day of the treatment the temperature fell to normal and the amount of expectoration was much reduced. On the fifth day it ceased, the leucocytosis had greatly diminished, and the patient began rapidly to gain in weight. The physical signs in the thorax disappeared, and ulceration of the rectum, which had been seen before the treatment was begun, rapidly healed. The drug produced no unpleasant effects, and by the second day the patient declared himself distinctly better. Professor Chauffard is, of course, unable to say that no relapse will occur, but clearly he saw no reason to fear such an occurrence, and cited two cases recorded by Rogers in which, after death from accident not long after the treatment had been concluded, intestinal ulceration was found completely cicatrized. He pointed out the extremely interesting fact, from the purely scientific point of view, that the effect of emetine explained the good results obtained in some cases of dysentery by the administration of ipecacuanha, and absolved that traditional mode of treatment from the unexplained factor which made it rather unsatisfying to the medical mind. "It marks," he said, "one more stage on the road from empiricism to rational therapeutics." The almost instantaneous cure of a dysenteric abscess in which the amoebic process must have been active since the pus was haemorrhagic, can only be understood if we recognize "that the emetine directly attacked and killed the intrahepatic amoebae, and that the method thus attained the *therapia sterilans*, the ideal too seldom reached, of anti-infectious therapeutics. We have here, then, a notable fact in the history of dysenteries and of amoebic abscess of the liver." He went on to point out that as the two chief types of dysentery differ in their pathogeny, so their quality is shown also in the field of therapeutics;

each is curable by a different specific treatment, the bacillary dysenteries by sero-therapy, the amoebic by emetine. The facts, he says, compel the conclusion that in this instance we have to do with a specific amoebotropism, "comparable to the most specific tropisms known, such as the action of quinine in malaria or of salvarsan or mercury in syphilis." And then in a few sentences of real eloquence which won the applause of the Academy, Professor Chauffard said that he could not but hope that the method would prove to be one more magnificent victory for therapeutics. "What benefits will not Rogers's method bring with it if it renders it possible to cure amoebic dysentery, and to prevent or arrest amoebic abscesses of the liver which are so often fatal? How many human lives would be saved, and we, conquerors of Morocco, colonisers of Madagascar, of Indo-China, and of West and Equatorial Africa, what a debt of gratitude we should owe for so priceless a discovery!" The debt of Britain would be even greater.

THE CARE OF THE DEFECTIVE IN AMERICA.

MISS WINIFRED MUIRHEAD, L.R.C.P.Edin., Pathologist at the Royal Edinburgh Asylum, has given (in the January issue of the *Journal of Mental Science*) an interesting and instructive account of a recent visit to institutions for the care of the defective in three of the American States—namely, Massachusetts, Pennsylvania, and New Jersey. In Massachusetts the laws for the control and care of the defective of all classes are administered by the State Board of Insanity, much as is contemplated will be the case with the "Board of Control" in this country if the Mental Deficiency Bill becomes law in the form in which it left the Committee stage last session. Miss Muirhead points out the advantage of unity of control by one central body and the facilities resulting for the transference of patients from one type of institution to another as may prove desirable. She then describes in some detail the admirable organization, under the direction of Dr. Fernald, of the associated School for the Feeble-minded at Waverly and its large farm colony at Templeton, accommodating an aggregate of 1,500 patients; 250 adult males are employed on the farm, which extends to about 2,000 acres, and is distant 61 miles from the parent institution. Both establishments consist of "scattered" cottage units; those at the school each accommodate about 100, and at the farm from 50 to 60. The structural cost works out at about £75 a bed for the school and £40 for the farm, the maintenance, etc., at 15s. 6d. a head. All the farm produce is consumed by the inmates of the two establishments, and bread, clothing, etc., made by Waverly labour, are supplied to the farm. Miss Muirhead was impressed with the practical character of the instruction given even to young and low-grade children at Waverly, where time is not wasted by trying to impart mere scholastic knowledge to those found incapable of such attainments, but manual occupations are early entered upon so as to train for industrial usefulness in after-life. It is found that a large percentage of the boys who show no aptitude for school subjects become good workers at the farm, where only 25 per cent. have successfully gone through scholastic education. It will be remembered that our Royal Commission reported in highly commendatory terms of Dr. Fernald's labours, and it is to be hoped that his establishment will form a model for the new institutions which will arise in this country. Visits to the State institutions for feeble-minded at Elwyn (Penn.) and Vineland (New Jersey) are also recorded, and it is remarked that in these States the absence of power of permanent detention of adult cases is a drawback to the complete success of the work. The subject of sterilization is referred to somewhat doubtfully in the absence of a sufficient body of reliable statistics. The Monson State Hospital for Epileptics (Massachusetts) is briefly

described, and seems to afford admirable accommodation for this class in groups of cottage homes extending over an estate of 1,000 acres. Miss Muirhead concludes that "the small Commonwealth of Massachusetts has progressed further than we have in the care and segregation of the defective, and that it is alert to the necessity of progressing still further . . . in order to combat the evils . . . which sap the vitality of the race."

CONFECTIONER'S PARONYCHIA.

CONFECTIONER'S paronychia, which is fairly common in preserved fruit factories in the South of France, is not, in the opinion of Strauss,¹ confined to workers in sugar, for, of three patients recently examined by him, one was a cook, another was a scullerymaid, and the third, who was a confectioner, had very little to do with the preparation of fruit. The disease ranges from simple chronic inflammation of the borders of the nails to purulent inflammation of the nail-bed. Its two most characteristic features are a chronic course and relative painlessness. A certain amount of itching and burning may be experienced, but they are seldom severe enough to send the patient early to a doctor. Several fingers are usually involved, either simultaneously or consecutively. An early feature is the presence of small erosions at the borders of the nails; here corrosives, sugar and fermenting dirt accumulate, and the mischief extends thence to the surrounding structures, causing redness and swelling around the nail. Gradually the nails are loosened piecemeal from their lateral attachments, and become dull, brittle, and black. In spite of these changes, the patient frequently continues his work till small indolent, sub-ungual abscesses form, and granulations grow from the borders of the nails near the matrix. The exudation of serous or sero-purulent fluid from these granulations finally forces the patient to seek medical aid. When spontaneous recovery occurs, the gradual detachment of the nail is followed by the fusion of the underlying granulations into a single hump, which gives a club shape to the terminal phalanx. But spontaneous recovery does not readily occur, and, left to itself, the disease tends to become chronic, lasting for several years with remissions. The conditions apt to be confused with confectioner's paronychia include ordinary infectious paronychia, or whitlow, and eczema of the nail. The former is distinguished by its acute and painful character, and by the rapid formation of pus. The nail also falls off in one piece, and no granulations are formed. In the latter the edge of the nail is indented, its substance is stratified, vesicles appear in the matrix, and there is excessive secretion. When psoriasis attacks the nail the periungual tissues are unaffected, while the nail itself becomes thickened and elevated above the surrounding structures. Syphilitic disease of the nail, on the other hand, chiefly affects the periungual tissues, which become red and swollen, while the nail itself becomes dull and brittle. Other manifestations of syphilis, such as paronychia of the toes, should prevent a mistaken diagnosis. In scrofulous paronychia, which may easily be taken for confectioner's disease, several nails are involved, the bed of the nail is livid, the skin swells around the nail, and there is a brownish-red secretion. Characteristic features of this condition are its painfulness, its occurrence in children and young adults, its chronic course, and the failure of the nail to regain its former healthy condition. Great caution should be shown in making the prognosis in confectioner's paronychia. Scrupulous cleanliness is the best treatment. When the disease is treated early, cure may result if the employment is given up for a few months. A healthy condition may then be maintained by frequent washing with soap and warm water, followed by rubbing in glycerine and careful drying. Strauss is not in favour of the antiseptic solutions and ointments commonly

¹ *Deut. med. Woch.* 1912.

recommended. In the advanced stages of the disease a clean sweep of all the structures involved is necessary if a relapse is to be avoided. When the old nail and the surrounding structures have been removed the new nail is at first thickened and brittle.

A CUTANEOUS DYSTROPHY.

THREE cases of family dystrophy of the hair and nails have been reported recently by Eisenstaedt.¹ The condition was observed in three brothers—the third, fifth, and ninth children in a family of nine, eight of whom are living and in good health, while one child, a girl, unaffected, died in infancy. The family thus consisted of six boys and three girls, the affected subjects being all males. The father, a German, is unaffected, and there is no history of the anomaly in his ancestry. The mother, who is dead, was of French-Canadian extraction; she exhibited the condition, and it has been traced in her family through five generations (inclusive of the three children). The relation of the affected ancestors to the children are great-great-grandmother, great-grandmother, grandfather, mother. The author remarks that White's case² was also of French-Canadian extraction. The principal points in the description are: The hairs grow very slowly and there seems to be some anomaly in their implantation, but nothing abnormal in structure was revealed by microscopic examination. The eyebrows are very poorly developed. The hands are normal in contour, save for the distal phalanges, which are noticeably increased in volume. The skin on the distal phalanges shows a moderate increase in thickness. The nails on the hands are all affected to about the same degree, and show an enormous hypertrophy of the nail-bed. The nails are kept short because, if allowed to grow beyond a certain length, they become brittle and crack at the very slightest trauma. The nails of all toes of both feet are affected in a similar manner but to a less degree. There is absolutely no sign of hereditary syphilis in any of the children. No paronychia were found, and the ages of the children (14, 9, 1) did not allow of any definite conclusion as to their grade of intelligence, although the eldest boy seemed normal for his age. The author refers to the possible relationship between this abnormality and *acanthosis nigricans*, a condition which is characterized by dystrophic changes in the dermal appendages; one of these children exhibited papillary hypertrophy similar to that noticed in *acanthosis nigricans*. Another suggestive fact is that the mother, who was also affected, died of some malignant abdominal growth. Nicolle and Hallipré state that the thyroid was absent in their case; Eisenstaedt states that the thyroid was present in the oldest of his three cases, but in the second its existence could not be determined.

ACTIVE AND PASSIVE HYPERSENSITIVENESS TO TUBERCLE BACILLI.

A GREAT number of very competent observers have occupied themselves of late years in the attempt to elucidate the problems of the varying degrees of sensitiveness to the attacks of the tubercle bacillus, as shown by experiment on animals, and incidentally to prove their relation to the tuberculin reaction in man. Results have hitherto been somewhat inconclusive, and a further series of observations carried out by Drs. Thiele and Embleton in the Bacteriological Laboratory, University College, has recently been published.³ Beginning with the production of hypersensitiveness in the guinea-pig by the inoculation of a sterilized emulsion of tubercle bacilli and afterwards by the introduction of isogenous and heterogenous tissues they have tested their animals in every case for the

anaphylactic shock, the temperature reaction, and for any cutaneous changes that might be expected to occur, on further inoculation with active B.E. These changes, as regards general symptoms and pathological appearances, were sufficiently uniform to permit of a typical standard being set up. The temperature variations, although following a more or less constant course, were sometimes irregular. The inoculations of B.E. were made systematically into a vein or into the peritoneum or upon the skin. The results in the latter case appear to have been for the most part negative. The symptoms exhibited on inoculation after sensitization were convulsions, cyanosis, respiratory spasm, loss of corneal reflex, and rapid death. The principal *post-mortem* findings were marked emphysema and expansion of lungs, slow coagulation of the blood, and long-continued pulsation of the heart. These experiments are held to prove that hypersensitiveness to tubercle can be produced in the guinea-pig by injection of finely divided bacilli or by the inoculation of blood from an acutely hypersensitive guinea-pig or highly sensitive human patient. Tuberculous tissues when inoculated produced similar symptoms, but many such tissues contained antibodies as well as bacilli. It is further claimed that the reacting antibody which calls forth fever, etc., with tuberculin in the tuberculous patient, is identical with that which causes anaphylaxis and temperature changes in guinea-pigs which have been rendered hypersensitive. Hypersensitiveness to tubercle in the human subject has been generally regarded, when produced artificially, as being due to the use of too large a dose, but it has been assumed that the injection of tuberculin is powerless to produce sensitiveness in animals. The observations referred to above would seem to show that this assumption is not fully justified.

THE ETHICAL BEARING OF HEREDITY.

ONE of the most serious difficulties in the scientific interpretation of Nature is the reconciliation of a view which seems to bind all facts together by a chain of mere mechanical necessity with any rational theory of human freedom and responsibility. Many worthy persons are deterred from yielding allegiance to the findings of science because it seems to them that by so doing they would be committing themselves to a fatalist philosophy. In a presidential address delivered to the American Society of Naturalists¹ Professor E. G. Conklin has dealt with one important aspect of this problem in a reassuring manner and with a lucidity deserving high praise. He points out that while it is true that our main characteristics, mental, moral and physical, are unalterably fixed by heredity, it does not follow that all the possibilities of good or evil that may be latent in a given personality are bound to develop, or that education and other environmental influences are of no avail. It is our possible, not our actual personalities that are predetermined in the germ cells; as to which of these possibilities shall and which shall not be realized, much must depend upon the circumstances under which growth and development proceed. Growth being a function of the interaction of intrinsic and extrinsic activities, there can be no predetermination of the organism unless that of the environment is also assumed. Faculties of a desirable kind may be strengthened by use until their due response to the familiar stimulus has become a habit; conversely, by denial of the opportunity of response, undesirable tendencies may be starved and eradicated. Professor Conklin defines responsibility as the power on the part of the individual of responding to rational, social, and ethical stimuli or impulses, and of inhibiting stimuli of an opposite nature; and the corresponding expectation on the part of others that the

³ *Zeitschrift f. Immunitätsforschung und Exp. Ther.*

¹ *Heredity and Responsibility*, by Professor Edwin G. Conklin, *Science*, January 10th, 1913.

individual will so re-pou'd. This implies on the part of society a duty of safeguarding those who, from immaturity or other causes, may be incapable of choosing their own environment against extrinsic stimuli of a dangerous or otherwise unfavourable kind. It implies, further, the positive obligation of providing such environmental influences as are calculated to develop the best possibilities of a given inheritance. Professor Conklin quotes Darwin and William James in support of his own belief that most men possess reserve powers which they never exercise, and that individuals differ far more in zeal and determination than in actual capacity. The most urgent problem is, he considers, not so much the improvement of human inheritance as the fuller utilization of existing talents. He therefore deprecates the undue coddling prevalent in the homes of the rich and in many schools and colleges, pointing out the power of hard necessity "to rouse the sleeping giant within us" as evidence of the preferability of a more virile method of training. Professor Conklin disclaims any intention to depreciate the possibilities of eugenics as a means of improving the race, but considers that in the present state of knowledge we cannot safely do more than attempt to prevent the reproduction of the obviously unfit. "Could any one," he asks, "have predicted Abraham Lincoln from a study of his ancestry?" He adduces the fact that national emergencies are wont to lead to the discovery of great men whose powers appear to be specially appropriate to the needs of their time, in favour of his belief that the potentiality of greatness is far commoner than is generally supposed, but in the majority of cases is not fully evoked. Leaving, therefore, the as yet insoluble question whether all the phenomena of life and mind can be explained on a mechanistic basis, he reminds us of the energizing effect of a belief in our freedom and responsibility, and of the debilitating results of the contrary conviction that since all is predetermined our aspirations and efforts are of no avail.

TRAUMA IN THE PRODUCTION OF MAMMARY CANCER.

IN those delightfully colloquial lectures which Dr. John B. Murphy of Chicago addresses directly to those who attend his clinics, or indirectly through the volumes of his *Surgical Clinics* to a wider audience of practitioners, he compresses in short compass much shrewd and pithy information that is applicable not only to the particular cases under discussion, but also serves in place of more abstract papers on the subjects in general. His clinical methods of teaching are models of what clinical lectures ought to be. In the latest bi-monthly number (December, 1912), for example, he discusses an ordinary cancer of the breast, prefacing his operation by remarks on the general pathology, and accompanying it by explanatory remarks on the *rationale* of each step. There is much for agreement and not a little for disagreement in what he says. He considers that the relation of trauma to carcinoma of the breast is peculiar. He adheres to the belief that carcinoma in other situations is the sequence of repeated mild irritations, whereas sarcoma follows one moderately severe irritation or trauma, never a superlative trauma. Thus, carcinoma of the lip does not result from a severe blow to it, but occurs on account of a continuous mild irritation from a tooth. Sarcoma never occurs in a bone as a result of an injury severe enough to fracture the bone, but follows a trauma severe enough to cause pain. The case of the breast, on the other hand, is exceptional, for one single trauma of moderate severity produces a carcinoma after the lapse of six to thirty months. Few surgeons would be prepared to accept such wide generalizations; and though Leaf in this country obtained in 32 per cent. of cases a definite history of injury to the breast affected, yet the probability is that, since the mammae are

so very liable to accidental blows in the ordinary course of events, female patients, noticing a lump in the glands, are apt to cast back their minds to some particular trauma that otherwise would have been forgotten. Murphy, too, performs a rather conservative operation on mammary cancer. He contents himself with removing the fascia over the pectoralis major, leaving the muscles intact, as a rule, basing his procedure on the original report of Bryant, who had seen only one case of recurrent carcinoma in the pectoral muscles in an experience extending over forty years. Many a pathologist who had experience of *post-mortem* examinations of cases dying from recurrent breast cancer when such operative procedure was usual would not be prepared to agree with this, nor with the statement that the sites of metastases are the femur, the bodies of the vertebrae, the liver, and the brain in order of frequency. If operative measures were based on Bryant's statement, the rather gloomy outlook to which Murphy candidly confesses might be more justifiable. The whole lecture teems with points forcibly and arrestingly put by the author, and productive, it may be, of thought and criticism in others, but certainly far from mere sterile platitudes.

SPORT, FAME AND UTILITY.

WHY is the sportsman of distinction, so popular a figure among his contemporaries, forgotten so soon after death has removed him from the scene of his triumphs? This question has recently been raised by Dr. T. Claye Shaw, and in the same article¹ he submits various answers, none of which, we think, he himself would be prepared to guarantee as adequate. He points out the affinity which, although seldom recognized, undoubtedly exists between sport on the one hand and on the other those ideal avocations—*aesthetic, literary or scientific*—whose pursuit is largely its own reward. He claims on behalf of the genuine sportsman that the qualities—*physical, mental and moral*—which confer eminence in his own vocation are worthy of a degree of commemoration which in fact they seldom attain. The explanation Dr. Shaw favours most is that the speedy oblivion which befalls the sportsman is due to the fact that his aims are purely personal and even selfish: "he is of no use to the race." We do not question that there is much truth in this explanation; on the other hand, it is impossible to admit that utility, in the commonly accepted meaning of the term, is the principle upon which permanent fame is allotted. It would, for example, be difficult, we think, to demonstrate the utility in any material sense of a picture by Raphael, a nocturne by Chopin, or a sonnet by Keats. We may and most of us do feel that the world would be a poorer place without such things, but to call them useful and to allege that their creators are immortal on that account are assertions which at once succeed and fall short of the truth. In science, as in art, the criterion of mere utility fails; the highest awards of honour fall to those whose achievements are upon the super-utilitarian plane. The demonstration by Semmelweis of the cause and mode of preventing puerperal fever resulted in an enormous and immediate saving of life. It is true that Semmelweis is commemorated by a monument at Budapest, but is he famous in the sense or degree that Galileo, Newton, Harvey, and Darwin are famous? The note of those kinds of greatness which achieve true fame is, we suggest, not utility, but universality of import; and since the exploits of the sportsman result almost exclusively in the demonstration of his personal prowess, interest in them is naturally confined in the main to those who actually witness or hope to surpass them. Yet, since the maintenance of a high standard of virility is a matter of racial interest, we agree that there

¹ Some Facts in the Psychology of Sport. By Dr. T. Claye Shaw *Baily's Magazine*, February, 1913.

is much to be said for Dr. Shaw's claim on behalf of the notable huntsman or cricketer to at least a memorial tablet.

MODERN MEDICINE AND THE LAYMAN.

It has often been said that at the age of 40 we are all of us either fools or physicians. This somewhat sententious judgement presses a little hard on the layman, who has often, for one good cause or another, had little opportunity of acquiring medical knowledge during the first two score years of his life. The daily press, of course, has done what it can for several years to make up for the possible medical deficiencies of the layman, giving him frequent doses of diluted medical knowledge in forms that may be supposed to suit his untrained powers of scientific assimilation. Experience shows, however, that such snippets of medicine as may be picked up in this way do little more than illustrate the dangers of a little knowledge. The lay reader is apt to accept them as gospel truth, to distort them by prolonged rumination, to reproduce them entirely *mal à propos* when consulting his medical attendant. Dr. F. S. Lee, of Columbia University in the City of New York, has made a very successful effort to remedy this state of affairs by writing a compact book,¹ in which he gives the layman a well-written and fairly comprehensive guide to the aims and attainments of the scientific medicine of to-day. The volume represents eight lectures delivered in the author's university. In these lectures Dr. Lee gave a popular account of the structure and working of the human body, followed by a description of disease, its causes and treatment. The problem of cancer was discussed, and at the end the aims of modern surgery and of modern experimental medicine were outlined. Quackery is a weed of even more vigorous growth in America than in England, and it is to books such as Dr. Lee's that one must look for the most rational check to its growth. Dr. Lee writes with clearness and moderation; he is a pragmatist and an empiric so far as the philosophy of medicine is concerned; and there is little or nothing in his pages that should not be intelligible and interesting to laymen of average education.

MEDICAL EDUCATION IN CHINA.

At the triennial Conference of the China Medical Missionary Association, which took place at Peking in January, the subject of medical education in China was, as has already been stated, the principal matter for discussion. For some time past the association has been engaged in an endeavour to co-ordinate the medical training which has been carried on for many years in different mission hospitals in China. It is now felt that the time has come when no training school should profess to send forth qualified practitioners unless it is able to attain a certain standard of efficiency. Certain resolutions have been passed arranging for a curriculum modelled on the British plan, and with a somewhat similar standard of educational efficiency for those entering a medical school. The most important point, however, is in the matter of the staff, and the association has formulated the principle that no school should be regarded as efficient which has not a staff of at least ten qualified teachers, European or Chinese, with some means of providing for furlough vacancies. The association strongly recommends the use of Chinese as the medium for teaching, though it recognizes that students should know at least one foreign language, which would give access to suitable medical literature. Whether this should be English or German may, perhaps, be determined by the Chinese education authorities, and it is thought that the German language may be selected by them. This might prove a serious difficulty for the

medical schools contemplated by the association, and it is greatly to be hoped that English will at least be allowed as an alternative language. The centres selected by the China Medical Missionary Association as most suitable for medical schools under mission auspices are Moukden, Peking, Chinaufu, Nanking-Hanchow, Hankow, Chengtu, Canton, and Foo-chow. It is understood in each case that the school would be a union school, in which representatives of different missionary societies would combine at each centre to provide a proper staff and equipment, and it is felt that only in this way can adequate teaching be provided. It is not yet at all certain that all of these schools can be efficiently maintained, and there is the possibility of some of them becoming schools for the training of medical workers of a class similar to the hospital assistants in India. But, in any case, it should be understood that several of these schools are only in process of formation, and that the programme set out by the China Medical Missionary Association may require modification.

THE Oliver Sharpey Lectures, to be delivered by Professor A. D. Waller, F.R.S., before the Royal College of Physicians of London on April 8th and 10th, will deal with the electrical action of the human heart.

Medical Notes in Parliament.

The King's Speech, delivered at the opening of Parliament on March 10th, contained the following paragraph: "You will be invited to give renewed consideration to proposals for the better care and control of the feeble-minded and for the further restriction of the industrial employment of children." The speech also stated that proposals would be submitted for the development of a national system of education. Lord Crewe afterwards said that it was not the intention of the Government to force through Parliament this session a vast measure dealing with national education, but only to place the country in possession during the coming session of the general lines of the intentions of the Government. One object would be to ensure that the education given in the primary and secondary schools and colleges respectively merged the one into the other. Attention would also have to be given to the physical needs of the children. No mention was made in the speech of legislation with regard to National Insurance, but it will of course be necessary to introduce a bill to authorize the allocation of the sum of £1,825,000 to carry out the promises of the Chancellor of the Exchequer made at the conference of the Advisory Committee held on October 23rd. It seems probable also that an amending Act may be introduced to deal with various matters, among others with casual labour and the aged members of friendly societies. Further, if, as seems probable, the Committee which has recently been taking evidence in Ireland recommends the extension of medical benefit to that island, an amending bill or clauses in such a bill will be necessary. The Government appears also to be under an obligation to give legislative effect to the recommendations made by Sir John Dewar's Committee on Medical Aid in the Highlands and Islands, a matter which is regarded as urgent by all acquainted with existing conditions.

Scottish Universities and the Treasury Grant.—Mr. Masterman, in replying to a question by Sir Henry Craik, on March 6th, said he could make no statement at present on the subject, except that he was in communication with the university authorities; he had not yet received their answer.

Milk and Dairies Bill.—Mr. Asquith informed Mr. Bathurst, on March 12th, that the Government hoped it might be possible to carry this bill this session.

Tuberculosis Prevention (Ireland) Act, 1913.—This measure has received the Royal assent.

England and Wales.

(FROM OUR SPECIAL CORRESPONDENTS.)

LONDON.

THE MEDICAL SOCIETY OF LONDON.

THE ancient, but still extremely active, Medical Society of London must not, as Dr. Leonard Guthrie said, be judged by years, for in spite of its 140 winters no trace of senility or decay can be traced in its works. Ample testimony to the success of the society, both from the scientific and the social aspect, was borne by the speakers at the anniversary dinner, which was held at the Hotel Metropolo on March 5th. Sir Watson Cheyne, Bart., the President of the society, occupied the chair, and over 100 members and their friends were present.

Sir Francis Champneys, President of the Royal Society of Medicine, proposed the toast of the Medical Society. Though it had refused to be swallowed up in his own society, a feeling of cordial friendship, he said, existed between the two societies. Sir Watson Cheyne, in reply, discussed in some detail the beginnings of the Royal Society of Medicine and its mother society, the Royal Medical and Chirurgical Society, and observed that during the past year the majority of the communications made to the Medical Society were on surgical subjects.

Mr. C. J. Symonds, in proposing the health of the guests and the kindred societies, spoke highly of the excellence of the Army Medical School. Sir Rickman Godlee, in his reply, delighted his audience with a bright sketch of the Quaker beginnings of the Medical Society. Dr. Leonard Guthrie replied for the other societies. Dr. Macnaughton Jones proposed the toast of the "President," who concluded a brief reply by proposing the health of the secretaries, Mr. Corner and Dr. Young, and the registrar, Mr. Bethell, all three of whom responded.

PROPOSED REGULATION OF FRIED FISH VENDORS.

The Public Health Committee of the London County Council on March 13th submitted to the Council for approval a series of by-laws for regulating the conduct of the businesses of fried fish vendor, fish curer, and rag and bone merchant. After the proposed regulations have been considered by the metropolitan borough councils, the Local Government Board will be asked to confirm them. The by-laws with regard to a vendor of fried fish are intended to ensure precautions to prevent effluvia arising from the operation of preparing the fish, and that garbage, etc., shall be speedily removed.

Scotland.

(FROM OUR SPECIAL CORRESPONDENTS.)

LIVINGSTONE CENTENARY CELEBRATION IN EDINBURGH.

TO-morrow, Sunday, March 16th, is to be observed as Livingstone Sunday in the churches. On Monday the Lord Provost and Council hold a civic reception in the Royal Scottish Museum (where also a special Livingstone exhibition will shortly be opened); and on Wednesday, the 19th, which is the actual birthday of David Livingstone, a memorial service will be held in St. Giles's Cathedral at noon, and a public demonstration in the evening in the Synod Hall. There will also be meetings on March 20th and various children's demonstrations.

THE LIVINGSTONE MEMORIAL DISPENSARY.

One of the most interesting parts of the premises occupied by the Livingstone Memorial Dispensary at 39, Cowgate, is the Chapel of St. Mary Magdalene. Since the dispensary was built in 1874 in memory of David Livingstone, the chapel has been used by the Edinburgh Medical Missionary Society in connexion with its work of training students for the foreign field; this is with the permission of the Protestant Institute of Scotland whose property the chapel is. This building was visited on Saturday, March 8th, by the Scottish Ecclesiological Society, whose members were much interested in the

fact that it contains the only ancient (pre-Reformation) stained glass in Scotland of a coherent design and still in its original position. In this chapel the General Assembly of the Church of Scotland met in 1578, and it was here also, a little more than a hundred years later (1685), that the body of the Earl of Argyle was temporarily placed after his execution. In a few days services in commemoration of the Livingstone Centenary will be held here, and every week crowds of patients gather within the walls of this interesting bit of old Edinburgh, which was originally founded by one Michael Macquhosen, "being greatly affected by a grievous distemper and oppressed with age."

LAURISTON PLACE HOME FOR MATERNITY RESCUE WORK.

This home for maternity rescue work plays a useful part in the prevention of abnormal labours and the diseases of pregnancy, as well as serving as a means of rescuing young girls illegitimately pregnant for the first time. The young expectant mothers are under medical supervision whilst in the home, and thus deviations from the normal healthy state of pregnancy can be at once detected and often cured; in more serious cases the woman can be transferred to the pre-maternity ward in the Royal Maternity Hospital, which is situated within a stone's throw on the opposite side of the street. If all goes well the patient enters the hospital when labour pains come on. At the annual meeting of subscribers, held on March 6th, it was reported that in 1912 seventy-one unmarried girls about to become mothers had passed through the home. Some of them were no more than children; one was 13 years old, and there were three of 15, two of 16, and three of 17 years.

THE CHILDREN IN THE STREETS.

Dr. John Thomson, in a touching letter to the *Scotsman* newspaper for March 4th, makes a strong appeal for the Play Centres Society, whose object is to draw poor children off the streets and out of the gutters where they spend their play time in winter and gather them into warm rooms, where they can play at games or practise scrap-painting, wood-carving, etc., under kindly supervision. There are at present six play centres in operation, but there should be many more. The value of such means in the prevention of children's maladies, and it may be of lifelong bad health, is obvious.

NEW PHTHISIS BUILDINGS AT THE EDINBURGH CITY HOSPITAL.

In the Colinton Mains Hospital it has been customary for some years past to accommodate advanced cases of phthisis; but, in order to meet requirements consequent upon the arrangement made between the Town Council and the Insurance Committee of Edinburgh for dealing with this class of patient, new buildings must now be provided, and the Town Council has approved plans for new buildings forming an instalment of a scheme to provide ultimately 112 beds; 63 beds (36 for females and 27 for males) will be at once provided, and already a number of revolving shelters, each containing 2 beds, have been erected. The new buildings, placed about 300 yards apart, are situated to the south of the permanent hospital buildings. The permanent administrative buildings will be utilized in connexion with the new ward. The new buildings will be of timber secured to a concrete foundation. A combined dining and recreation room forms the centre of the south-west range, while nurses' rooms are placed at the angles. Sanitary annexes, with dressing rooms, will be provided at the north end of each set of shelters, and along the south side of the buildings verandahs will be erected. The city architect, Mr. Williamson, in collaboration with the medical officer of health, Dr. Maxwell Williamson, has prepared the plans, and, though purposely devised to be constructed in the most economical manner, the building is regarded as likely to completely fulfil all the requirements necessary for the special object in view.

GLASGOW'S WATER SUPPLY.

The prospect of a still further extension of the Glasgow water supply is already being considered. The present aqueducts are capable of bringing 110 million gallons of water daily from Loch Katrine into the city. The average yield, on the basis of the three driest years since the

inauguration of the Loch Katrine scheme, is 75 million gallons a day. In addition, the old Gorbals Waterworks give a daily supply of 5 million gallons. Glasgow's present demand is about 66 million gallons daily, but the rate of consumption is increasing yearly by 10 million gallons a day, so that in about ten years the present sources of supply will be insufficient, and the extension of the catchment area will have to be considered. The Loch Arklet extension staved off for the time a bigger work, but in the not very distant future a new source will in all likelihood have to be added. Loch Vennacher is stated to be out of the question, and there are engineering difficulties in the way of the Strathyre watershed. Perth is credited with having desigus on Loch Lubnaig, and Glasgow may have to tap the lochs on the Braes o' Balquhiddier. The Loch Katrine undertaking, inaugurated fifty-two years ago, was considered a gigantic scheme, as indeed it was, and was then thought to be an inexhaustible source. Whether the Government scheme in connexion with the nation's water supply, indicated recently by Mr. John Burns, will have any bearing on this matter, or, indeed, will affect Scotland at all, remains to be seen. If, as thought probable, the Government deal with rivers, then Scotland will not benefit much, as rivers are not looked upon with favour in the North as sources for water supply.

BELLEFIELD SANATORIUM, LANARK.

The annual report submitted to the Glasgow and District Branch of the National Association for the Prevention of Consumption by the Medical Officer at Bellefield Sanatorium shows that for the year ending September last 165 cases were admitted and 151 dismissed. On the whole the results were satisfactory, but, as on a former occasion, the medical officer expressed regret that many patients on leaving the sanatorium returned to unhealthy environments and undesirable occupations.

The patients at Bellefield continued to engage in graduated labour with beneficial results. The work done included (heaviest class of labour) cutting down trees and putting in fencing, removing soil to sand pits, repairing cinder path, delving round in grazing field, assisting gardener and cutting grass; (intermediate) weeding croquet green, trimming walks, weeding about the grounds; and (lightest labour) cleaning brasses, picking up litter, and keeping the verandah platforms in order. There was no doubt about the benefit derived from regulated work in the open air, provided the cases were suitable. The temperature was taken as an indication in regulating graduated labour.

At the out-patient department in Glasgow there were 296 applicants for treatment during the year. The physician there reports that neither the notification of phthisis nor the greater interest now taken in the disease by the public has made any difference in the percentage of early cases. An analysis of the 157 cases selected as medically suitable for treatment at Bellefield showed that in 2 cases the diagnosis was doubtful; 10 cases were in the very earliest stage; 45 were early cases; 78 were in Class II, or intermediate cases; and 22 cases of advanced disease were selected, generally on account of their condition and physique being good in comparison with the extent of the disease in their lungs, and the probability that they had acquired a resistance to the disease. Most of these cases did very well, some making considerable improvement, but the risk of an active development of the disease at any time was much greater in this class of case than those in an earlier stage of the disease.

RECONSTRUCTION OF DUMFRIES INFIRMARY.

At the annual meeting of the governors of the Dumfries and Galloway Infirmary, it was stated that a sum of £7,000 was still required to complete the reconstruction scheme in connexion with the institution which was started a year ago. It was agreed that, if necessary, £5,000 should be drawn from the reserve funds to complete the scheme. It was reported that there was a deficit of £1,200 on the year's working of the institution. The chairman (the Rev. J. Montgomery Campbell) dealt with the position of voluntary hospitals under the Insurance Act, and stated that those institutions were now even more necessary than at any other time. The 10s. of aliment paid to insured persons did not provide for the treatment of cases

requiring special nursing. He deprecated the idea of putting infirmaries under State control, and said that if ever that came about it would be a bad day for the sick poor. Mr. H. S. Gordon was appointed chairman of the directors for the ensuing year, and Sir Mark J. MacTaggart Stewart, Bart., was elected honorary vice-president.

NEW INFIRMARY AT PERTH.

The work of erecting the new infirmary has proceeded expeditiously, and the entire buildings, with the exception of the children's block, are now roofed in. It is expected that the main block will be completed by October next.

The directors have now been able to proceed with the erection of a children's ward on a larger scale than before, because of the sum of £1,187 11s. 10d. which had been handed over to them by the King Edward VII Memorial Fund Committee. To this has been added a donation of £750 from the trustees of the late Mr. Charles Anderson of Fettykil. Later, Mr. Peter Whyte, M.Inst.C.E., of Edinburgh, announced that he and his brother, Mr. William Whyte, desired to provide a sum of £1,500 for the erection of a second children's ward, to be dedicated to the memory of their father, the late Mr. John Whyte (Muirhead).

The total amount required to complete the entire building, on the assumption that a sum of £10,000 will be received for the old infirmary buildings, is £2,638 9s. 6d.

ABERDEEN DENTAL CLINIC.

The dental clinic scheme of the Aberdeen School Board was started on February 18th at the clinic rooms, 40, Union Terracc. There are three rooms, efficiently fitted up and furnished, and the dentists' equipment is specially adapted for children. The clinic is in charge of Dr. Campbell, a graduate of Aberdeen University and a dentist. He is assisted by a whole-time nurse, who was previously on the medical inspection staff of the board. Those who will receive treatment are necessitous children in their seventh year.

SCHOOL MEDICAL INSPECTION.

In the third annual report on the medical inspection of school children in the counties of Middlethian and Peebles it is stated that the number of children examined during the year amounted to 7,459. Of these, 2,310 were in their first year at school, 2,578 were in their last year, and 917 were specially presented by the teachers. Of children found defective at a previous examination, 1,654 were re-examined. The School Medical Officer, Dr. Robb, states that medical inspection has proved an incentive to parents to keep their children clean and tidy and to take other measures to maintain them in good health. "The amount of work involved in visiting schools and homes to make these re-examinations is increasing rapidly. It is one of the most important parts of school medical inspection, but it is at present carried out with difficulty, owing to the necessity for overtaking the routine work. It is evident, therefore, that further assistance will soon be required if the best results are to be obtained."

Ireland.

[FROM OUR SPECIAL CORRESPONDENTS.]

RESIGNATION OF MEDICAL STAFF OF NEWCASTLE SANATORIUM.

THE Board of the Royal Hospital for Consumption in Ireland held a meeting on March 6th to consider the resignation of the extern medical staff. In a long letter published in the daily press on March 8th the Board states that it had for some time felt that the management of the hospital might be open to criticism in two respects. First, the large increase in the number of beds, from 24 when the hospital was opened in 1896 to over 100 in 1910, forced the conviction that the visiting staff (two in number), although adequate for 24 patients in 1896, was inadequate for 100 patients. The second was that there was not sufficient employment of treatment except of the simplest character, that is, "open-air treatment." When the medical staff said that the medical treatment of the

patients was a question solely for the medical staff, the Board unanimously adopted the following resolution :

Having read the letter from Dr. Crowe, informing the Board of the resolution unanimously adopted at the meeting of the Medical Committee on May 26th, 1911, the Board are of opinion that they cannot accept the position that the medical treatment adopted at the hospital is a matter solely for the medical staff, as they believe that they should from time to time inform themselves, as a Board, as to the system or systems of the treatment in use at the hospital.

The letter concludes with the gratuitous suggestion that the medical staff resigned their positions and made public their reasons, calculating, if not intending, to deter any other professional brother from giving his services to the institution, no matter what the effect might be upon the institution and however seriously the crippling of its usefulness might affect a suffering class of the community. "Happily," it is said, "the medical arrangements at the hospital preclude the possibility of such an unfortunate result." This is understood to refer to the two resident medical officers at the institution, who are not affected by the resignation or change of the extern staff, and to the appointment by the Board of a new visiting physician.

The real crux of the matter is that a lay board should claim to dictate to the medical staff on what is essentially a professional rather than an administrative matter. The question is considered of such importance that the Presidents of the Royal College of Physicians and Royal College of Surgeons have summoned a joint meeting of the colleges to consider the action of the Board of the hospital, and it is sincerely to be hoped that some reasonable adjustment of the difficulty may be reached, and that the Board will see the necessity of receding from an untenable position by which it is endangering the welfare of the institution for which it is responsible.

BUDAPEST.

Post-Graduate Study in Hungary.—The New Building of the Workmen's Insurance Office.—One and a Half Hours on a Flywheel.—Town Sanatoriums.

THE Central Committee of Medical Post-Graduate Study held its annual meeting on Sunday, February 23rd. Post-graduate study has developed into a powerful organization from a very modest origin. In the past year the Budapest courses were attended by 147 doctors, and the provincial courses by 79, making a total of 226. Sixty-eight of these courses have enjoyed State support. The committee has distributed 6,000 kronen and the municipalities 8,500 kronen in aiding provincial doctors to attend these post-graduate studies. The Ministry of Public Instruction covers all the expenses involved by the administration and lecturers' fees. In the programme for 1913 certain new types of courses have been introduced. Besides the four weeks' courses, which served for more thorough study of a single subject, one-week courses will be held on syphilology, industrial diseases and accidents, and modern therapeutics. Professor Emil Grosz, the chairman of the committee, expressed hopes that this year the number attending would be doubled.

The new central building of the Workmen's Insurance Office, the most expensive building built here in recent years, cost 8½ million kronen (£350,000). It will occupy 10,873 square metres of ground, and will comprise not only a colossal building for the official department, but also extensive out-patient rooms, a large pavilion for experimental therapeutics, and an x-ray institute, all, however, for the exclusive use of insured members.

An overseer at a timber mill in Lagos, while recently going his rounds, attempted to replace the belt which had slipped off a flywheel 12 ft. in diameter. The wheel caught his coat-tails, lifted him off the ground, and revolved him for an hour and a half. Although there were several hundred workmen on duty, the

accident was not known till the machinery stopped. The unfortunate man was then unconscious, and though terribly injured lived for three hours, regaining consciousness before his death, and declaring that he alone was responsible for his fatal accident.

The absence of sanatoriums for the middle classes has long been felt in Hungary. There have been for long public hospitals, maintained by the State or the municipalities, and private sanatoriums where high prices are charged, so that only the wealthiest people seek admission. The public hospitals have two or three wards for so-called "private paying patients," but the number of these wards is limited, eight being the maximum number, even when the hospital has 600 beds. Thus a majority of middle-class patients have the choice of entering wards among people of the lowest class or becoming bankrupt. The first middle-class sanatorium, equipped on the most modern lines but without superfluous luxury, will shortly be established by the authorities of the city of Budapest. It is estimated that the price for a room, medical attendance, foods, etc., included, will not be higher than 10 to 12 crowns (9s. to 10s.) a day. Medical expenses will be defrayed by the city. The new sanatorium will have accommodation for 150 to 180 patients. If this should prove a success, other sanatoriums will be established by other large municipalities.

Correspondence.

TRADES UNIONISM AND MEDICINE.

SIR,—Some members of the profession are very earnestly endeavouring to form the practitioners of this country into a trades union, believing that in this way a solid body may be established and a united front presented to any enemy that may seek to attack it. I venture to express a hope that before such a body be formed very serious consideration be given to the question of its disabilities and powers. The chief advantages which a trades union has over its members are these: The authority to issue orders for a general or partial strike; the "putting down" of tools; and the prevention by actual "peaceable picketing" (with its attendant use of force) of the entrance of "blacklegs" upon the scenes of the strike. Without these powers trades unionism would be a very feeble weapon and absolutely useless to effect the desired end. Can it be possibly contended for one moment that either of these powers could be used by educated professional men exercising the healing art and carrying on medical practice? Can the wildest imagination conceive an order emanating from the central office of the medical trades union ordering all members, irrespective of rank or position, to cease at a given time the care of and attendance upon patients suffering from all forms of disease and sickness? Can any sensible person imagine that such an order would or could be obeyed in any civilized country in the world? Or take the question of "peaceable picketing." Would such a thing be possible amongst medical men? The idea is monstrous; but without these foundations the whole superstructure of trades unionism falls to the ground at once. Union, of course, is strength; but trades unionism on its present lines can never be accepted by members of the medical profession, in my humble opinion. To effect the purpose of trades unionism it would be absolutely necessary to carry it out to its logical conclusion, and that we can never do. We cannot accept its "principles" without its "practice"; and I trust the day is far distant before we descend as doctors to the level of dockers. If our members cannot be united in a common bond of humanity, and keep their clinical and professional pledges without recourse to the basest principles of coercion by force, we must be content to be disunited. Any unity founded upon trades union lines would be degrading and derogatory to professional men in the extreme, and I hope that the suggestion will be scouted and dismissed as utterly untenable.

I am writing as a mere member of the profession, and not as an official of any organization.—I am, etc.

London, W.C., March 12th.

A. GEORGE BATEMAN.

IMMEDIATE OPERATION IN APPENDICITIS.

SIR,—In his letter in the JOURNAL of February 22nd, Dr. Hunt pleasantly finds fault with me for wanting a *second* surgeon to confirm the diagnosis of appendicitis in the event of my becoming attacked with that disease. The reason for my suggesting another opinion was that, as there might possibly be some uncertainty in the making of a very early diagnosis (such as I would desire), some other friend might come in to help (for I should not try to be surgeon as well as patient), and in deciding in favour of an "immediate" operation, I think it right that always *two* medical men should be in agreement. Judging from the manner and purport of his letter, I would deem myself fortunate if the person so called in were Dr. Hunt.

I did not wish to draw too close a comparison between appendicitis and strangulated hernia, but I wanted to insist on the fact that "immediate" operation in the latter condition, instead of the use of "taxis" and hot baths (as in times not long past), had greatly reduced the mortality. And I pleaded for equal dispatch and improvement in appendicitis.

In the JOURNAL of March 1st letters appeared from a general practitioner from Scotland (Dr. Whitelaw), a Welsh surgeon (Mr. Lynn Thomas), and an English physician (Dr. William Ewart). The first-named deals with a matter of real importance in connexion with appendix operations, but he will not mind, I am sure, if I do not discuss it with him in these columns.

Mr. Thomas remarks that after twenty years' experience in operating upon appendicitis he is "not in the present—perhaps passing—fashion," and he writes:

"I have not lost a single case where, in my judgement, it was necessary to try and get the patient out of his attack of appendicitis into a state of quiescence, or, to use a local phrase, which well expresses my meaning, 'drydock him for repairs.'"

He then goes on to say that appendicitis is a "surgical disease" for several hours, "but" that, later on, it

"requires the greatest vigilance, the strictest observance of proper non-surgical treatment, to bring it into a state whereby the offending appendix can be removed with no risk except that of the anaesthetic."

(Surely those early hours were the very time in which the removal could be effected with the greatest safety.)

But he is silent about the early "surgical" cases which, in utter disregard of a distant prospect of "dry dock," spitefully hurry on to disaster. Yet all of them could have been at once rescued by an "immediate" operation. And as it is on this principle alone that one can be *sure* of saving them, its adoption must prove something better than a "passing fashion."

Let me suggest that Mr. Thomas is called early one morning in consultation on a boy who had been seized in the night with acute abdominal pains, that he finds a tenderness in the iliac fossa and rigid muscles over it, the temperature and pulse being at about a hundred. If he would urge immediate operation for this boy, I fail to see why he should claim to stand outside what he calls the "present—perhaps passing—fashion." But if he replies that he would leave him for "vigilance" and for the "strictest observance of proper non-surgical treatment," I say, and I say it with regret, that his teaching may have the effect of putting back the hands of the clock. It is only in the first twelve hours or so that the surgeon can claim to be master of the situation; he is unable to govern or guide the course of an inflammation of the appendix, and it is only by immediate operation that he can hope to do his share in the task of bringing down the alarmingly high death-rate in this disease.

If it so be that the surgeon is in suspense, Mr. Thomas declines to allow him to "look and see," "because," as he somewhat unhappily puts it, "it will inevitably lead to further carelessness."

In Dr. Ewart's broad-minded letter attention is called to the urgent need of making an early diagnosis so that operation may not be delayed. And, with this in view, he advises general practitioners and physicians "to watch for appendicitis always, and to examine for it as a clinical routine," just as they are accustomed to test all cases for a possibly latent renal trouble. Dr. Ewart's views upon

"suspected appendicitis" I cordially accept, as, indeed, I do those of the whole of his letter.

I wish that I could fully agree with the statement of Mr. Musgrave Woodman, in the JOURNAL of March 8th, that "to diagnose appendicitis is easy." It is generally so; but the appendix has as its close neighbours the caecum, colon, ileum, ureter, and ovary, each of which is liable to its own troubles, and it is because of difficulty in making up one's mind in certain rare cases that, in the cause of safety, I would urge the surgeon to "Look and see." The truth of Mr. Woodman's remark that the risk of operating on an acute appendix is very slight, whilst that of sitting by and watching is full of danger, is becoming every day more apparent, and the expediency of immediate operation more fully recognized.

I think that I cannot do better than bring my reply to a close by a quotation from an excellent paper by Mr. Richardson, of Newcastle-on-Tyne, which appeared in the JOURNAL of September 28th of last year:

"Most of the writing, both in textbooks and in periodicals, has reference to the treatment of the complications of appendicitis, rather than to appendicitis itself, so that, in the minds of many, these complications are regarded as though they were actual symptoms of the disease."

—I am, etc.,

London, W., March 10th.

EDMUND OWEN.

SIR,—From the point of view of the public it is regrettable that there should be still any difference of opinion as to the advisability of immediate operation in acute appendicitis.

Without doubt a very large proportion of the deaths which occur every year is due directly to procrastination, and until public opinion be educated by the profession to regard immediate operation as the only safe method of treatment, this sacrifice of life will continue. In America the question has been settled long ago. To Americans, whether doctors or laymen, the position of those who advocate delay is incomprehensible. Last year a well-known American surgeon, on a visit to this country, expressed to me his surprise on reading the discussion which at that time was being carried on in the JOURNAL. "I do not understand," said he "why at the present day it is necessary to state the case for immediate operation." Further comment is needless.—I am, etc.,

London, W., March 10th.

HERBERT J. PATERSON.

SIR,—In response to the suggestion of my friend, Mr. G. Grey Turner, of Newcastle, I have had all cases of appendicitis operated on in the years 1910, 1911, and 1912 in my practice analysed. Although a proportion of the cases has been done by my assistants, Mr. F. K. Smith (Royal Infirmary) and Mr. A. Mitchell (Sick Children's Hospital), yet one can state that the technique adopted by them is practically the same as my own. Including both private and institutional cases, there have been 697 operations done primarily for disease of the appendix during those three years. (This series does not include cases in which the appendix was removed in the course of operations primarily designed for other conditions.)

There were 106 acute cases "with limited infection" with no deaths, 32 of them being in children; 208 cases with more or less advanced infection of other parts (peritoneal and otherwise) with 25 deaths, or a mortality of 12.7 per cent.; interval and chronic cases, 383, with 1 death from sudden cardiac failure several days after operation. The mortality for all cases was therefore 3.7 per cent.

Of the 25 deaths in the acute series, 4 occurred out of 46 private patients—11 out of 61 cases in the Sick Children's Hospital, and 10 out of 101 in the Royal Infirmary. The adult mortality-rate in the advanced acute cases was 9.5 per cent., while that in children was 18 per cent.

These figures surely prove the advantage and necessity of operation at the earliest possible moment, especially in children.—I am, etc.,

Aberdeen, March 10th.

H. M. W. GRAY.

THE AFTER-EFFECTS OF GASTRO-ENTEROSTOMY.

SIR,—The conclusions which Mr. A. W. Bourne draws, in the paper published in your issue of March 1st, from a series of cases of gastro-enterostomy are interesting and instructive to those who are familiar with the present position of gastric surgery, but are bound to convey an entirely erroneous impression to those members of the profession who are unable to interpret them at their true value.

To form any true estimate of the value of gastro-enterostomy for peptic ulcer of the stomach or duodenum one must take as a basis a series of cases in which one has details of:

1. The operative technique.
2. The character of the ulcer.
3. The exact position of the ulcer.

Mr. Bourne furnishes the most meagre information under all three heads. In a series of cases occurring in the practice of a number of different surgeons the operative technique will probably vary within wide limits, and of no operation can it be said with greater truth than an attention to technical details is of the utmost importance to the securing of a successful result. With the exception of the statement that in two cases an anterior gastro-enterostomy was performed, Mr. Bourne gives us no details as to the position or method of anastomosis or the presence or absence of a jejunal loop.

He tells us nothing as to the character of the ulcer; in four cases he states that no ulcer was visible, and one cannot help suspecting that in more than these four cases no demonstrable ulcer existed. It has been repeatedly pointed out that gastro-enterostomy is contraindicated in the young chlorotic woman with pain after food, vomiting, and occasional hæmatemesis, symptoms usually supposed to be due to gastric ulceration. In such cases the external coats of the stomach afford no evidence of the existence of an ulcer, and gastro-enterostomy is worse than useless. Unless the ulcer can be demonstrated both visually and by palpation, no surgical interference with the stomach is justifiable.

Gastro-enterostomy for symptoms alone is the acme of bad surgery, for a careful surgical differential diagnosis at the time of operation is as important as a medical differential diagnosis beforehand. To perform the operation for atonic dilatation, gastroptosis, chronic appendicitis, or tuberculous disease of the lower ileum is only to court disaster, and can do nothing but bring a most valuable operation into disrepute.

Finally we are given few details as to the position of the ulcer. From those Mr. Bourne supplies it is evident that the results were markedly better in duodenal ulcers and those gastric ulcers situated at or near the pylorus. Of the other cases classed as gastric we have no details; possibly they include some in which "no ulcer was found."

Surgeons with an extensive experience in gastric surgery are now in agreement that for ulcers situated on the lesser curvature at a distance from the pylorus, and those upon the posterior aspect of the stomach, the proper treatment is excision, either with or without gastro-enterostomy; gastro-enterostomy alone is productive of no relief. There is no doubt that the operation has been performed in a large number of unsuitable cases, and those who have been the pioneers in the field—Robson, Moynihan, and the Mayos—have been the first to point this out, and it is by a study of their writings and results that a true estimate of the indications for and results of operation in the different varieties of peptic ulcer can be formed.

My inquiries into the end results of Sir Berkeley Moynihan's cases of duodenal ulcer (*Duodenal Ulcer*, 1912 Appendix) show that in a series of 302 cases, extending over a period of eleven years, the mortality is 1.65 per cent., and the cases of complete cure calculated upon the whole number of patients, and not upon those who can be traced only, is 82.7 per cent. This series includes certain cases in which the operation should not have been done, and in the earlier cases the operative technique was imperfect; in the later cases the percentage of complete cures is over 90 per cent.

Similar results are published by W. J. Mayo (*Annals*

of Surgery, September, 1911) in a series of 1,000 cases.

Duodenal and pyloric ulcers treated by gastro-enterostomy with infolding or excision of the ulcer, cured or greatly improved, 98 per cent.

Ulcers of body of stomach treated by excision with or without gastro-enterostomy, cured or greatly improved, 85 per cent.

Mortality well under 2 per cent.

Mr. Bourne's paper and the conclusions which he draws in it are calculated merely to obscure the issue, and to those who cannot read between the lines are positively misleading. It is not the operation itself which is to blame, but the employment of it in unsuitable cases. He appears to have entirely overlooked the main point; the success of operative treatment does not depend on the age or sex of the patient or the presence or absence of excessive free hydrochloric acid, but upon the presence and situation of a demonstrable ulcer.

The removal of the ovaries for abdominal pain has fortunately been relegated to the limbo of obsolete operations, and one had hoped that the performance of gastro-enterostomy for symptoms alone had followed the same fate, but apparently it is not so.

When surgeons realize that they must be prepared to reconsider their diagnosis when the abdomen is opened, we shall hear less criticism of the results of gastric surgery, and an operation which in the right cases is, perhaps, the most successful in the whole realm of surgery will be appreciated at its true value.—I am, etc.,

Leeds, March 10th.

HAROLD COLLINSON.

SIR,—In a letter to the JOURNAL of March 8th, Mr. H. M. W. Gray records the after-history of the 61 patients who survived the operation of gastro-enterostomy performed by him in 1909 and 1912 for non-malignant diseases. Because 95.5 per cent. of the series are at present entirely relieved he asks me to reconsider the adverse criticism of his theory of the anatomy and physiology of the stomach which I published in a letter to the *Lancet* two years ago. I am, however, unable to do so, as increased experience has only confirmed the views I then expressed. These were repeated at the annual meeting of the Association in Liverpool last year, in the opening address on the anatomy of the normal stomach, which I delivered before the combined Sections of Anatomy and Electro-Therapeutics and Radiology, and were received by anatomists, radiographers, and surgeons with practically unanimous agreement. If Mr. Gray will examine a series of normal individuals after a meal consisting of porridge containing 1 or 2 oz. of a bismuth salt or of barium sulphate, or, better still, of an ordinary breakfast with the same addition, I am sure that he, too, will be convinced that no such structure as a "middle sphincter" exists in the stomach.

Mr. Gray has certainly every reason to be pleased with the results of his operation, but I do not think that they are any better than those of most competent surgeons, including those who had operated upon the patients referred to in the paper on the after-effects of gastro-enterostomy, which was read by me before the Surgical Section of the Royal Society of Medicine, and was briefly reported in your issue of February 22nd. I did not suggest that the ill effects I described occurred in a large percentage of cases; my cases represented the somewhat considerable sum of a very small percentage of cases operated upon by many different surgeons. Two of Mr. Gray's incompletely successful cases are probably of the same nature, although the details are insufficient for a definite opinion, and I can quite imagine that the number of cases in which the particular conditions I described occur does not represent a larger proportion than 5 per cent. of all cases. My object in writing the paper was to show how some incompletely successful cases could be rendered completely successful—how, for example, the percentage of Mr. Gray's complete successes could, perhaps, be raised from 95.5 to 98.5.

Lastly, I do not think that Mr. Gray is justified in regarding cases operated upon in 1909 as "providing late results." Only this week a surgical friend has told me of two cases of gastro-jejunal ulcer, one of which formed a jejuno-colic fistula and the other perforated, the first

untoward symptoms having occurred respectively five and ten years after the original operation, so that they would have been included among Mr. Gray's completely successful late results.—I am, etc.,

London, W., March 12th.

ARTHUR F. HERTZ.

OPERATIONS ON CHILDREN IN THE OUT-PATIENT DEPARTMENT.

SIR,—I am indebted to Mr. Andrew Fullerton and Mr. Stanley Green for their letters published on March 1st and 3th, and for the support which their experience enables them to give to my position. At present Glasgow is engaged in building a new and enlarged children's hospital, and the arrangements in contemplation for its working come very near the ideal. If the scope of the out-patient department is made sufficiently wide a children's hospital should be capable of giving a much larger return of work done per guinea charitably subscribed than a general hospital.

The ideal children's hospital on its surgical side should consist of:

(a) The wards and theatres;

(b) A hostel for nursing mothers and sucklings (a cook, a housekeeper, and possibly one maid as staff—the mothers, as in my own little place, doing part of the work gladly);

(c) A well-equipped out-patient department and operating theatre, with a staff of visiting nurses and, possibly, one emergency bed for each surgeon, the term of residence of any patient being strictly limited to forty-eight hours.

There is a reference in the letters of both Mr. Fullerton and Mr. Green to the out-patient department as a training field for junior surgeons. With that idea I am in agreement. No better training in thoroughness can be had. A carelessly tied ligature in even a triviality like a circumcision in the wards may mean a night-call for the house-surgeon from his adjacent room. In an out-patient it may cause alarm and mean serious danger miles away from hospital. The point I wish to draw attention to is, however, that the training of the junior in the out-patient department must be under guidance, as in the wards. In the Glasgow Children's Hospital there are out-patient surgeons and *assistant* out-patient surgeons, and I am sure my junior colleagues, to whose loyal co-operation I have been much indebted, will bear me out that the arrangement under which they learnt their work, relying on the support and advice of a senior colleague, is a good one for them, as it certainly is for the patients.—I am, etc.,

Glasgow, March 8th.

JAMES H. NICOLL.

THE DISSEMINATION OF RECTAL CANCER.

SIR,—In your issue of March 1st last there appears an editorial paragraph headed "Intramural Spread of Cancer of the Rectum," a review of a paper by Mr. Percival Cole in the same issue. With your permission I propose to offer a few remarks upon this paragraph, which in some respects misrepresents my views upon dissemination in rectal cancer.

In a series of about 12 cases of cancer of the rectum I have twice demonstrated appearances which appear to indicate permeation of the mucous lymphatic plexus in apparently healthy bowel near a rectal carcinoma. In a series of 20 cases Mr. Percival Cole has been unable to find any similar appearances. Clearly, therefore, the process of mucous permeation is an exceptional one. Your reviewer says, quite truly: "No support is given to Handley's theory of mucous and submucous permeation" by Mr. Cole's paper. I have not formed any theory on the subject, but have simply stated my observations in 2 cases. It should have been added that neither is any argument adduced by Mr. Cole to show that my observations are incorrect. It is worth noting that upon the strength of a single case in his series of 20, Mr. Cole has himself described permeation of the intramuscular plexus as a mode of spread of rectal cancer. This he is well justified in doing, nor am I entitled to deny the correctness of his observations simply because no similar case happened to be included in my own series. My series has no bearing on this particular question, nor

has his series of cases any value whatever as evidence against the correctness of my observations on mucous permeation as an exceptional process. Your reviewer goes on to say in reference to my work: "It is thought improbable that the discrete well-formed cells which that keen observer described—cells which have no histological resemblance to the columnar cells of the rectal epithelium—were disseminated cancer cells." A careful perusal of Mr. Cole's paper finds in it no basis for this *ex cathedra* statement, which usurps authority from its position in your editorial columns. At this point the limelight is withdrawn, and your reviewer entirely withholds the inside knowledge which he evidently possesses as to the nature of the cells in dispute. I have it on his authority that they are not cancer cells; may I hear on the same authority what they are? I feel, Sir, that in such a debatable question unsupported assertions on either side are not entitled to the advantages of anonymity and authority which your editorial columns give.

May I, in conclusion, express the genuine pleasure which Mr. Percival Cole's valuable work, containing so much that is new, has given me. It has justified the hopes I entertained of the mucicarmine method of staining when I first suggested its use as an instrument for the study of cancer. Incidentally I may add that it has confirmed my main conclusion that "effective dissemination probably, as a rule, occurs through the mesorectum or perirectal tissue opposite the primary growth," a conclusion which may well come as a surprise to those whose knowledge of my views is derived from your reviewer's paragraph.—I am, etc.,

London, W., March 11th.

W. SAMPSON HANDLEY.

The above letter has been read by the writer of the annotation, who replies as follows: Mr. Handley, in his original paper published in the *BRITISH MEDICAL JOURNAL* on April 16th, 1910, recorded the observation that in sections of one particular rectum which happened to contain a carcinoma there were certain cells in the mucous layer that were stained red by mucicarmine. Now another case has been added which also happens to be from a cancer of the rectum. The difference of opinion is not about the observation itself, but as to the theory of very extensive spread of cancer by the mucous layer which Mr. Handley founded upon it. This theory, emanating from such a brilliant investigator, even though it rested on slender grounds, might well convince the ordinary surgeon of the hopelessness of surgical intervention. The onus, however, of proving, in contradistinction to assuming, that the red-stained cells are cancer cells rests entirely on the originator of the theory, and cannot be established by dialectics.

PHYSICAL SIGNS OF MYOCARDIAL INVOLVEMENT.

SIR,—Dr. Thomas Lewis's valuable paper published in your issue of March 8th is of particular interest to students of cardiac rheumatism because of his allusions to the occurrence of heart-block in some cases of that disease. It is nowadays generally recognized that in all cases of active rheumatic carditis the cardiac musculature is besprinkled with inflammatory foci; and, indeed, this disease being so common, it seems probable that of all the localized injuries to which the myocardium is prone, that which is inflicted by the *Streptococcus rheumaticus* is the most frequent. Since this is so, it is not surprising that Dr. Lewis should expect to find in cases of cardiac rheumatism numerous illustrations of those principles of cardiac localization for the discovery and enunciation of which we are so deeply in his debt.

Dr. Lewis says that "heart-block is not an uncommon accompaniment of acute or subacute rheumatism," and there are several remarks to this same effect in the course of his paper. If the point were not one of some little importance, I would not venture even to question the accuracy of so authoritative a statement; but since there is reason to believe that disturbances of conductivity were comparatively rare in cardiac rheumatism, I think the grounds for this belief may be placed before your readers for criticism.

First, the total number of recorded instances of rheumatic or post-rheumatic heart-block of the medium or higher grades is very limited; I believe I am right in

saying that it does not exceed forty. Now cardiac rheumatism is one of the commonest of visceral diseases; many thousands of cases are admitted annually to the hospitals of Britain alone, and since in almost every medical school there is at least one cardiographic enthusiast, it might be expected that if the incidence of heart-block amounted to 1 per cent. of all cases of cardiac rheumatism, we should have heard of a much larger number of examples. My own experience, indeed, can only furnish two instances; and neither of these occurred in routine practice, but both were brought to my notice by colleagues.

Secondly, the occasional dropping of beats—a manifestation of heart-block which does not escape the ordinary observer, though unarméd with apparatus for its graphic registration—is, in my experience, an exceedingly rare phenomenon in active rheumatic carditis; and I find that this is the opinion of others who have studied the disease from a general standpoint. If heart-block were at all common in cardiac rheumatism, surely dropped beats would be encountered in a fair proportion of cases.

Thirdly, I have for some time past been taking polygraphic records from cases of cardiac rheumatism in both the acute and the residual phases, cases of every grade of severity and of every variety, without selection. The number of cases at present investigated lies between 100 and 200. I do not regard this research as complete without application of the more delicate electro cardiographic test, on which Dr. Lewis has taught us to rely; but so far as it goes, it seems to show that rheumatic invasion of the heart does not often lengthen the *a-c* interval.

I said at the beginning of this brief argument that the point is not unimportant. Its significance lies in this: rheumatic myocarditis is a compound of interstitial foci of inflammation with regressive changes within the muscle cells, and thus affords an excellent opportunity for testing the relative susceptibility of the myocardium to focal interstitial and to diffuse intracellular lesions. My own investigations have led me to agree with what Dr. A. M. Gossage argued in a paper published in the *Lancet*, August 21st, 1909, that the direct effect of the inflammatory spots on the myocardial functions is probably small. The comparative rarity of heart-block is a striking illustration, especially if we compare it with the fact (which Dr. Lewis quotes from Professor Aschoff) that the conducting system of the heart is more often a seat of these foci than some other parts of the cardiac wall.

It is probable that Dr. Lewis sees an unusually large proportion of cases of rheumatic heart-block, because they gravitate naturally towards so conspicuous a luminary of the cardiological constellation; and it is therefore all the more necessary that the experiences of those who see the average as well as the special cases should be recorded.

I should like, in conclusion, to express complete agreement with Dr. Lewis's concept of the rheumatic process. Undoubtedly the heart is reinvaded from without by new batches of micro-organisms, which, while dwelling secretly in some part of the body—for example, the tonsil—enter the circulation from time to time, each instalment inflicting fresh damage on an already injured heart. The transient nature of the rheumatic heart-block, to which he alludes, is perhaps partly explained by the fact that the inflammatory spot of cardiac rheumatism is in the beginning a vascular occlusion, so that to its pressure effects it adds that of a hinderer of nutrition, and recovery is in part dependent on the successful re-establishment of nutritive supply.—I am, etc.,

Clifton, Bristol, March 10th.

CAREY COOMES.

RECENT ADVANCES IN THE DIAGNOSIS, PROGNOSIS, AND TREATMENT OF HEART DISEASE.

SIR,—It was with strong feeling that I read in the *BRITISH MEDICAL JOURNAL* of March 8th the address delivered by Dr. F. W. Price to the Academy of Medicine in Toronto.

The expounding of the views of new writers, and the reiteration of facts which they have recorded, is certainly permissible in the columns of a general medical journal—nay, more, it is necessary if our profession is to be acquainted with the progress in medicine. Nevertheless, common courtesy and common custom demand that the

statement of view or of fact should be made with specific reference to its source, except where such view or fact has long been known and is generally accepted.

In the spring of last year I published a small handbook on *Clinical Disorders of the Heart Beat*, an epitome of some five years' steady work, and containing much original matter. Within a few months of its appearance Dr. Price delivered the autumn address at Toronto, which is now printed in the columns of your *JOURNAL*. Without any attempt at acknowledgement, and with never a hint that the basis of his statements—for examples, *vide infra*—was not his own original work, Dr. Price would appear to have transferred to this address much of the substance of my writings, paragraphs therein being, with but slight verbal differences, practically identical in point of language. The teaching of a book which has hardly had time to enter circulation is utilized and scattered broadcast in the thousands of copies of your *JOURNAL*. I could not but protest in the interests of my publishers. Dr. Price has described auricular fibrillation in the manner of an observer at first hand. It would be of interest to hear from him what, if any, new facts he has added to our knowledge of this subject. The matters to which I direct attention are best appreciated by a comparison of the address and my books in their entirety; but I append a list of parallel paragraphs in illustration of my complaint. The paragraphs which I have selected are those which bear the closest resemblance in point of diction. It would be easy to quote other paragraphs or to lengthen those which I have chosen.

THE ADDRESS.

"CLINICAL DISORDERS" AND "MECHANISM OF THE HEART BEAT."

Premature Beats or Extrasystoles.

(p. 479)* "They may be present in people with a history of rheumatic infection, in *excessive tobacco smoking, digestive disturbances, supernal blood pressure, neurasthenia, and as a result of administration of certain poisons, especially digitalis, aconitine, muscarine, physostygmine, and adrenalin.*"

[The italics in this and other instances are my own.]

(p. 44)* . . . "A history of rheumatic infection is certainly common. . . . In young adults, *excessive tobacco smoking* is recognized as an exciting cause of their temporary appearance. *Digitalis* and its allies are not uncommonly responsible. . . . There are also clinical associations between premature contractions, raised arterial pressure and *digestive disturbances.*"

[For the full list of drugs see *Mechanism of the Heart Beat*, 1911, p. 126, my first book. "They [i.e., premature contractions]† are also seen as a result of the injection of certain poisons, and notably *digitalis, adrenalin, aconitine, muscarine, and physostygmine.*"

[As a matter of fact, this statement applies to experimental work and not to clinical cases. It has not been shown that the last four drugs act in this manner clinically. Even the unusual spelling of "physostygmine" is rendered.]

After two lines, the address continues:

"An individual with extrasystoles may be quite unconscious of their presence. On the other hand, he may experience sensations, and these may cause *worry and anxiety*, particularly if they occur after the patient has *retired to bed.* (Nine lines omitted.) The patient may complain of a *sensation of gripping in the throat.*"

(p. 51) "In a very large number of those affected, the disturbances of heart rhythm pass unnoticed. On the other hand premature beats are not an uncommon cause of what patients term 'palpitation.' . . . When numerous, they sometimes occasion actual distress; by calling attention to the heart, they often induce *worry and anxiety.* . . . They are often more noticed after the patient *retires for the night.* . . . consciousness of shock to the chest wall and frequently by a *feeling of gripping in the throat.*"

And a little later:

(p. 479) "The bromides are sometimes of value in *masking or modifying* the symptoms, especially in nervous subjects."

(p. 54) "The symptoms are usually *masked or considerably modified* by the bromides . . . and these drugs are especially useful in tiding a nervous or excitable patient over a period of disturbance."

* Except where the reference is named, the page numbers refer to your *JOURNAL* and to the book *Clinical Disorders*.
† This interpolation is not in the original.

Heart-block.

(p. 480) "The only point I should like to mention is that *heart-block of mild degree*, giving rise to 'dropped beats,' sometimes occurs during the course of infective diseases, and is then frequently the *only sign of myocardial damage*. When present it increases the gravity of the primary disease. As a rule, however, it is temporary."

(p. 35) "But temporary *heart-block of mild grade* is not uncommon during the febrile attacks to which rheumatic patients are liable; it occurs also in pneumonia and typhoid. The appearance of this abnormal mechanism is of great importance, for it is often the *sole sign which indicates that the myocardium has been damaged*. Whenever it complicates an acute infection it consequently increases the gravity of the prognosis; at the same time it should be understood that the normal mechanism is usually recovered."

Pulsus Alternans.

(p. 480) "It is very unfortunate, but undoubtedly true, that in the vast majority of cases it is necessary to take a tracing of the radial artery in order to recognize it. Very rarely in cases in which it affects the pulse continuously it is perceptible by the finger."

(p. 94) "It is an unfortunate fact, but nevertheless true, that most instances of *pulsus alternans* cannot be recognized by other than instrumental means. There are patients in whom it affects the pulse continuously, and in whom alteration in the force of alternate pulse beats is perceptible to the finger; but such cases are rare."

Auricular Fibrillation.

(p. 481) "Rarely or never do two beats of the same character or length follow each other. The irregularity is more pronounced when the pulse is fast. With the slower rates we may have to adopt careful measurements of the tracings, as the variations in the length of pauses are only small. The pauses between the beats show no relationship to each other, and there is seldom any relation between the strength of a beat and the length of the pause which preceded it—that is, a strong beat may succeed a short pause, and a weak beat may follow a long pause."

(Mechanism of the Heart Beat, p. 196) The heart action is never regular, and seldom or never do two beats of the same character or length succeed each other. . . .

(Ibid., p. 196) "It is usually at these fast rates that the disorderly character of the pulsation is so prominent. With the slower rates the irregularity is less marked; nevertheless, it is always present, a fact which can be determined by careful measurement of the tracings. . . . The second criterion consists in the absence of a definite and continued relationship between the strength of a beat and the length of the pause which precedes it."

(Ibid., p. 196) "The pauses between the beats bear no relationship to one another."

(Clinical Disorders, p. 79) "Proportion between the force of an arterial pulse and the pause preceding it is often lost (Figs. 39 and 40); a strong beat succeeds a brief pause and a weak beat succeeds a long one."

(p. 481) "What is meant by auricular fibrillation? By it is meant a condition in which co-ordinate contraction in the auricle is replaced by inco-ordinate contraction. Instead of contracting in an orderly and simultaneous manner during systole, the individual fibres contract rapidly and independently of each other. The result is that *systole, either partial or complete, of the chamber as a whole never takes place.*"

(p. 71) Definition of Auricular Fibrillation.

"Co-ordinate contraction in the auricle is lost," etc.

(p. 72) "The fibres of the auricles do not contract co-ordinately or together, but the tissue is broken up into a number of independently active areas."

(p. 71) "The muscular walls are maintained in a position of diastole; *systole, either complete or partial, is never accomplished.*"

(p. 481) "Patients may also complain of *fluttering in the chest and neck or of irregular action of the heart*. Apparently, however, they never suffer from *angina pectoris.*"

(p. 82) ". . . Patients, who possess the persistent disorder, often experience occasional *fluttering in the chest and neck* and may be conscious of *irregular heart action.*"

(Footnote, same page) "On the other hand they seem peculiarly exempt from *angina.*"

(p. 484) "In the most acute cases of cardiac failure, when it may be desirable to elicit a more rapid effect, . . . *strophanthin* may be administered intravenously, either two or three doses of $\frac{1}{2}$ of a grain at an interval of two hours," etc.

(p. 89) "When a patient who has fibrillation is first seen and the heart beats persistently at 170-200 per minute, the condition is urgent. . . . The intravenous injection of *strophanthin* is also valuable at such times. Two or three doses of $\frac{1}{2}$ of a grain . . . are given at an interval of two hours."

—I am, etc.,

London, W., March 8th.

THOMAS LEWIS.

THE NEGLECT OF VACCINATION.

SIR,—I accept with pleasure the apology so frankly given by Dr. Millard, who invites me to further consideration of the question whether it is safe for this nation to abandon the practice of vaccination, and to rely entirely on isolation of small-pox cases as they occur, for that is the real issue between us.

Dr. Millard endeavours to prove that small-pox is not peculiarly fatal to unvaccinated infants, as is usually believed, because only three infants died during the Leicester epidemic, being 25 per cent. of cases under 12 months old. But Dr. Millard himself allows that this epidemic was of a very mild character; and this opinion was confirmed by Dr. Allan Warren, then resident medical officer of the Isolation Hospital in Leicester, in a paper contributed to the *Practitioner* in 1904. Moreover, an outbreak of only 700 cases is too small for the foundation of new generalizations on small-pox. I prefer to continue to believe that small-pox is very fatal in early infancy.

Dr. Millard admits the efficacy of vaccination as a protection, and states that he yields to no one in his advocacy of it, used as it is used in Leicester—that is, when epidemic small-pox is present and the population are so alarmed that they all rush to be vaccinated, as they do. All of us who have had experience of such periods of alarm know what a difficulty it is to make the existing machinery of public vaccination equal to the strain placed upon it, especially in rural districts. If this machinery is scrapped it will be impossible to get a sudden efficient vaccination of the population, even in a small area, within the necessary period.

Dr. Millard writes and doubtless believes that the whole of the kingdom enjoys a highly organized and well-staffed public health service such as most of our large boroughs possess. But this is not the case universally, and small-pox is not dealt with "according to modern methods," to use Dr. Millard's phrase. We shall unite in regretting that this is the case, but until such methods are universal I maintain that the large percentage of unvaccinated persons in the country is a grave danger—a danger increasing not by arithmetical but by geometrical progression.—I am, etc.,

Westerham, March 9th.

ARTHUR MAUDE.

SIR,—After an experience of seven outbreaks of small-pox, like Dr. Killick Millard, I am a believer in the efficacy of, but not in the universal necessity for, vaccination.

To my mind an outbreak of small-pox can be well likened to an outbreak of fire, and our public health departments to the fire brigade. In both we have "notification" and, as far as possible, "isolation." Vaccination we might compare to the water used. All contacts should be vaccinated. Water should be poured upon all adjacent combustible material. I have seen vaccination, done in the early stage of small-pox, modify an attack. Water used early may suppress a fire.

We might, of course, so soak all buildings and their contents with water that they could not take fire; but I am inclined to think that the inmates would get as tired of it as the general public has of vaccination. With a fire next door we should have no difficulty in getting permission to pour water on a house and, with small-pox next door, we should have no difficulty in getting people to submit to vaccination.—I am, etc.,

Bideford, March 11th.

GEORGE RICE, M.D.

ASSISTANT MEDICAL OFFICERS IN ASYLUMS.

SIR,—The report in your issue of March 1st (p. 454) of Dr. J. Beveridge Spence's paper, at the meeting of the Medico-Psychological Association, is very interesting. Ho very rightly appeals for candidates for these posts who have some knowledge of psychiatry or a desire to acquire it. There is, however, a certain feeling amongst men in the service at present that Dr. Spence's ambition and many medical superintendent's requirements are at considerable variance. The administration of lunatic asylums is watched, both centrally and locally, with a very critical eye, and in case of any irregularity, whether it has a strict medical bearing or not, the question arises

how it was dealt with by the superintendent. Ho for his part has no desire to erib. cabin, and confine himself to the asylum premises all the time, so it is naturally convenient for him to be able to say that, although absent himself, he left two or more experienced men to act in his place. The more men ho leaves the better it looks. The rest is easy to follow. A docile type of assistant is required, who has some common sense, little initiative, and attenuated ambition, content to plod along with routine duties, occupying his far too abundant leisure with cricket, tennis, etc., all about the doors of the institution, who can be relied on not to do anything important in his patron's absence. Such a career would hardly appeal to many of the men Dr. Spence desires to see enter the service. In justice, of course, it must be admitted that many superintendents encourage research, but, when all is said and done, scientific research, irksome if simple duties, and indifferent cricket with patients do not constitute a very complete life for the majority. Let the county councils step out and treat their asylum physicians as they do their other medical employees, relieve them of their schoolboy dependence, let them have full opportunities for ordinary social intercourse, marry after a certain approved service if they feel so inclined, and generally give them the status of a citizen. By doing so they will get picked men, capable of sharing and being held responsible for many of the superintendent's now too many responsibilities, to the great benefit of the patients, the superintendent, and themselves.—I am, etc.

March 3rd.

MORE FREEDOM.

MEDICAL INCUNABULA.

SIR,—In connexion with the German Commission for a General Catalogue of Incunabula, the Bibliographical Society is collecting information upon the incunabula in the libraries and elsewhere in this country. To this I should like to call the attention of those interested. It is easy to get the necessary information from the libraries of the Royal Colleges, but I would like particularly to know of:

1. Any fifteenth century medical works in the libraries of the hospitals and medical societies.
2. Medical incunabula in private collections.

—I am, etc.,

WILLIAM OSLER,

Oxford, March 8th.

President of the Bibliographical Society.

THE IMPORTANCE OF CHEST HOSPITALS.

Professor Koch's Opinion.

SIR,—In regard to the proposed sale of the Mount Vernon Consumption Hospital, the following extract from the late Professor Koch's address at the first International Congress on Tuberculosis, held in London in July, 1901, is of great interest. Speaking of the part played by special hospitals in the prevention of tuberculosis, Professor Koch uses the following words:

The only country that possesses a considerable number of special hospitals for tuberculous patients is England, and there can be no doubt that the diminution of tuberculosis in England, which is much greater than in any other country, is greatly due to this circumstance. I should point to the founding of special hospitals for consumptives and the better utilization of the already existing hospitals for consumptives as the most important measure in the combating of tuberculosis, and its execution opens a wide field of activity to the State, to municipalities, and to private benevolence.

Such words indicate the seriousness of taking such a step as has been contemplated by the Mount Vernon Hospital authorities, contrary to the expressed wishes of the medical staff.—I am, etc.,

London, W., March 12th.

R. MURRAY LESLIE.

A GERMAN Congress on alcohol in youth will be held in Berlin during Easter week, and on Tuesday Professor Aschaffenberg of Cologne, in the course of a discussion on the scientific study of alcoholism, will read a paper on the physiological action of alcohol.

Public Health

AND

POOR LAW MEDICAL SERVICES.

REDISTRIBUTION OF POOR LAW MEDICAL DISTRICTS IN THE BURNLEY UNION.

IN commenting on the difficulty that has arisen between the Burnley Guardians and the local profession with regard to the treatment of their district medical officers (BRITISH MEDICAL JOURNAL, March 8th, p. 533), the hope was expressed that at a final meeting of a special committee of the guardians appointed to consider the matter some means would be found to settle the dispute on an equitable basis. This hope has not been fulfilled, for the committee recommended that the union should be divided into fifteen districts, that the present public vaccinators be given twenty-eight days' notice, and that each of the newly appointed medical officers be made public vaccinator for his own district. These recommendations were carried at the next board meeting by a large majority. This re-arrangement of the medical districts is strongly opposed by the local profession. The Burnley Division of the British Medical Association has approached the Local Government Board, asking that its consent be not given to the scheme. It is urged that the new districts have been made in a very arbitrary manner, and would result in much inconvenience both to the doctor and the Poor Law patient, and that in some which have no poor residents nearly the same salary is allotted as in other districts where there is a considerable settlement of the poor. The Colne and Brierfield District Councils have also protested against the arrangement, so that it does not appear satisfactory to any but the present guardians of the union. It is further alleged that the latter have hurried on the matter in order to establish the proposed scheme before the approaching election of a fresh board. It is to be hoped that the Local Government Board will review the matter very carefully before giving official sanction. We feel sure that the local profession will maintain without wavering its strenuous opposition to a scheme which it regards as harmful to the sick poor and to the profession.

It would appear that the Burnley guardians have already given notice to the present public vaccinators to determine their appointments. This has been done without waiting for the sanction of the Local Government Board, which has invariably refused to permit public vaccination to be utilized for Poor Law purposes, as it has always rightly considered that the duties of a public vaccinator are quite distinct from those of a Poor Law medical officer; and, further, that it is not for the good of the public, nor does it tend to efficient public vaccination to mix it up with the Poor Law. A similar attempt was made some years ago by a metropolitan board of guardians, but permission was refused by the Local Government Board, and we trust that the latter will not hesitate to maintain the same policy in this matter that it has wisely adopted in the past.

LOCAL GOVERNMENT BOARD REPORTS.

Ringwood Rural District (New series, No. 74).—The extensive outbreak of typhoid fever in the town of Ringwood, in Hampshire, in the autumn of last year is the subject of an important report to the Local Government Board by Dr. Hugh A. Macewen, one of the Board's medical inspectors. The outbreak involved seventy-seven persons living in forty-nine houses, and five cases terminated fatally. The population of Ringwood town is about 3,000. In the course of inquiries as to the cause of the outbreak, well-grounded suspicion fell upon a supply of ice cream, but after investigating the circumstances in some detail Dr. Macewen came to the conclusion that it was not an essential factor common to all the cases reported. The water supply of the town is obtained from shallow wells or from the Cockstone stream which courses through a part of the populated part of the town. Although it was not shown conclusively that all those who were attacked had drunk water from this stream, it is certain that the majority of them had. The opportunities for the pollution of the stream were so great through middens, drains, slop water cast directly into it, and other filth found in proximity, that suspicion must be attached to it. A regrettable feature of the report is an account of the attitude of the rural district council in whose administrative area the town is situated in dealing with the epidemic. No provision had been made for isolating any cases of infectious disease, and it was not until a week or two after the commencement of the epidemic, and when forty-eight cases had occurred, that a temporary hospital was established at a disused farmhouse. Still more unsatisfactory is Dr. Macewen's statement that from interviews he had with certain members of the district council, and from

accounts of their meetings, they appeared to be slow and even reluctant to realize the gravity of the outbreak, and he doubted whether, even at its termination, they had fully appreciated the importance of applying the lessons to be learnt from it so as to prevent any similar recurrence.

Obituary.

R. W. PARKER, M.R.C.S.,

CONSULTING SURGEON, EAST LONDON HOSPITAL FOR CHILDREN, AND TO THE GERMAN HOSPITAL, LONDON.

THE announcement of the death, on March 4th, at Freiburg, Baden, of Mr. R. W. Parker, has been received with great regret by those who remember him as a very active worker in the elucidation of disease in children.

Robert William Parker received his medical education at the medical schools of St. Thomas's and of the London Hospital, and after obtaining the diploma of M.R.C.S.Eng. in 1869, was resident medical officer to the Children's Hospital, Great Ormond Street. He also studied at Paris, Munich, and Berlin, and was an excellent German scholar. At the outbreak of the Franco-German war in 1870 he joined the Anglo-American ambulance of the British National Aid Society. For his services at this time he received the decorations of Knight of the Military Order for Merit, Bavaria, and of the Albert Commemoration Order, Saxony. He was appointed assistant surgeon to the Shadwell Hospital for Children in 1876, and, when he resigned in 1902, had been senior surgeon to the institution for some fifteen or sixteen years; he was also surgeon to the German Hospital at Dalston, and at the time of his death was consulting surgeon to both hospitals. He was at one time surgeon also to the Grosvenor Hospital for Women and Children.

We have recently had occasion to refer to the very large part which certain medical societies—especially the Royal Medical and Chirurgical, the Pathological, and the Clinical Societies—played in the medical life of London during the seventies and eighties. Mr. Parker took a prominent part in the work of these societies and contributed a number of papers to their *Transactions*, especially to those of the Clinical Society. The actual list of his papers, however, gives an incomplete impression of the large share he took in the discussion of the many problems presented by disease in children, and especially rickets. He was the author of a book on *Tracheotomy and its After-treatment*. It was an excellent work in its day, and the tracheotomy tube he designed is still by many considered the best. The book reached a second edition, and tracheotomy was the subject of one of the articles which he contributed to Heath's *Dictionary of Surgery*. Among the others were those on surgical affections in childhood, on rickets, and on diseases and injuries of the epiphyses; on these subjects he was an acknowledged authority. He took a very special interest in the Shadwell Children's Hospital; upon his work there we are able to publish the following note from Dr. EUSTACE SMITH, the Senior Physician to the hospital:

"I was for many years a colleague of Mr. R. W. Parker at the East London Hospital for Children, Shadwell, and often had the advantage of his help in the surgical treatment of cases in my wards. His experience in his own department was very large and his opinion in consequence was held in high esteem by the visiting staff. Even the keen critics of the resident staff were often pleased to express their appreciation of his abilities and practical skill, and I never heard that his house-surgeons, who knew his work best, had ever ventured upon a word of unfavourable criticism. Mr. Parker was for a number of years surgeon to the German Hospital at Dalston, and was exceptionally qualified for this position by his experience in the Franco-German war. I remember his telling me once that nothing was so much valued in the commissariat during that campaign as common table salt. Anything else in the way of food or small luxuries the officers and men would willingly share with each other, but common salt every man who was fortunate enough to possess kept religiously for himself. They carried it about in their pockets corked up in hollow goosequills. Mr. Parker had much hard-headed, sound common sense, and although disposed, perhaps, to confine his attention

too exclusively to one aspect of a question, was a most helpful colleague and thoroughly alive to the best interests of the hospital. He thought strongly, and expressed his views at times with bluntness, but his honesty of purpose was too evident for a hasty expression to excite ill feeling amongst those from whom he happened temporarily to differ. He was much liked and respected by all, and I shall never cease to look back with pleasure upon the old times when our work together at the hospital brought us into such intimate association."

On his retirement from the Shadwell Hospital in 1902 Mr. Parker went to live at West Grinstead; later on he moved to Bedford for the education of his two sons. He had married rather late in life, and his widow survives him. About four years ago he went to live on the Continent, and, as has been said, death overtook him at Freiburg.

FREDERICK POYNTON WEAVER, M.D.LOND.,
M.R.C.P., J.P.,

FORMERLY OF FRODSHAM.

THE death of Dr. Weaver, on February 27th, at the age of 79, removes one who to the last was engaged in active work, though he had for many years retired from ordinary practice. He came of a family who lived in or near Chester for generations, his father being surgeon to the Chester Infirmary. He was educated at Queen's College, Belfast, and at Guy's Hospital. He obtained the diplomas of M.R.C.S.Eng. and L.S.A. in 1858, and took the M.B.Lond. with honours in 1860 and the degree of M.D. in the following year; in 1893 he became M.R.C.P.Lond. He held the post of House-Surgeon at the Liverpool Northern Infirmary, and afterwards for thirty years was in general practice at Frodsham, near Chester, where the remembrance of him is still vivid. On retiring from practice in 1892, he took a house at Hampstead—Cedar Lawn, near the top of the Heath—and, instead of seeking a life of ease, at once devoted himself to the various kinds of missionary interest in which he had been interested previously. He became a member of the committee of the Church Missionary Society, and of the Medical Committee, which is responsible for the society's medical missions; since 1898 he had been a member of the Medical Board, which is concerned with health questions affecting the society's missionaries, and on the night of his death he retired to bed early in order to attend the Medical Board on the following day. He was also a member of the Committee of the British and Foreign Bible Society and of various philanthropic institutions, and was an active organizer and worker in the Kentish Town Medical Mission. For several years he was churchwarden of Christ Church, Hampstead; he was a Justice of the Peace for the County of London and for several years Chairman of the Hampstead Bench. He married, in 1866, Mary Berry, daughter of Mr. E. Abbot Wright, of Oldham and Castle Park, Frodsham, who died in 1909, and leaves three sons and four daughters. Dr. and Mrs. Weaver were the centre of a large circle of friends who exercised a very far-reaching influence, and his loss is mourned by those who knew him, and not least by those were engaged with him in work in connexion with the societies referred to, who feel that they have lost a wise counsellor as well as an affectionate friend.

A GREAT many members of the medical profession in Edinburgh remember Sir JAMES GRAHAM, former Mayor of Sydney, whose death was announced on March 8th. He was born in Edinburgh in 1856, and, but for a burgh bursary, would hardly have been able to enter the university. He graduated M.A. in 1879, and M.B. C.M. in 1882, and thereafter for a short time he practised medicine in Leith. During his student career he formed a friendship, which greatly influenced his after-life, with T. P. Anderson Stuart, the Ettles Scholar of 1880, who afterwards became a professor in Sydney. Dr. Graham sailed for Sydney in 1884, having been appointed surgeon on one of the Loch Lorne vessels; he practised and gained a knowledge of hydatid disease in its clinical aspects which enabled him to win a gold medal for his M.D. thesis at Edinburgh University in 1889. He studied in Berlin, Vienna, and Paris, and then returned to Sydney and became associated with his old friend, Professor Anderson Stuart; he held many posts, including those of Lecturer

in Midwifery, Sydney University, and of Honorary Medical Officer of the Lying-in Hospital there. Through his interest in public health he was drawn into the vortex of politics, and this led on to his being made Mayor of Sydney. He received the honour of knighthood when King George V, then Duke of York, visited Australia. He paid several visits to his native city, but it was in Sydney that his death took place at the comparatively early age of 57.

We regret to have to record the death of one of the oldest medical practitioners in the North of Scotland—DR. SELANDERS of Nairn. He was born at Fowes eighty years ago, and received his early education in that town. He took the M.A. degree at Aberdeen University in 1856, and afterwards went to Edinburgh for his medical course, taking his M.D. in 1859. Dr. Selanders became House-Surgeon to the Edinburgh Infirmary, and soon afterwards was appointed assistant to Professor Simpson, in which capacity he served for three years. He commenced practice in Nairn over fifty years ago, and soon acquired a large practice. He was appointed Medical Officer for the burgh over fifty years ago, and performed his duties with ability and success. All along he took a keen and active interest in the welfare of the town and County Hospital, of which institution he was for many years one of the most active medical officers. His hobby was gardening, and he had a rare and delightful collection of flowers and plants. Dr. Selanders was twice married, and is survived by Mrs. Selanders and six sons.

DR. THOMAS H. MEIKLE, the managing director of Strathearn Hydropathic, died on March 3rd. Dr. Meikle was a native of Roxburghshire, where his father held the appointment of factor on the estate of Colonel Sprot, of Riddell. He studied at the University of Aberdeen, and after taking the degree of M.D. succeeded his brother in practice in Aberdeen. Afterwards he took up the active management of Lochhead Hydropathic, near Aberdeen, and later on established the Strathearn Hydropathic. He was one of the county Justices of the Peace, and was warmly interested in the temperance cause. When the Royal Hotel of Crieff was put into the market over a year ago he purchased the buildings at a cost of nearly £4,000, and gave them to the community to be carried on as an institute on temperance lines. Dr. Meikle, who was in his 79th year, had been ailing for some months, and had not lately taken much part in public life, but for several years he was a member of Crieff Town Council, and was one of the honorary presidents of Crieff Unionist Association. He was twice married, and is survived by his widow, and by one son and four daughters by his first marriage.

MANY of his old patients, and visitors to Venice, will be grieved to hear of the recent death of Dr. E. H. VAN SOMEREN, at the early age of 41 years. He was a son of the late Surgeon-General W. J. Van Someren, I.M.S., and was born in 1871, and educated at Mill Hill School and University College, London. He studied at Guy's Hospital, and after taking the diplomas of M.R.C.S. and L.R.C.P. in 1895, held an appointment in the Manchester Children's Hospital. He settled in Venice in 1896, and continued in practice there up to his death. In 1903 he opened a clinic for the reception of private patients. He became specially interested in the study of nutrition, and tried many experiments on himself with the view of ascertaining on how low a protein supply the physiological equilibrium can be sustained. His results were condensed in an article entitled "Was Luigi Cornaro right?" (BRITISH MEDICAL JOURNAL, October 12th, 1901, p. 1032). Van Someren was reluctant to make generalizations, but he kept copious notes at various times for many years of experiments in fasting, low and high protein régimes, and peculiar diets. He read a paper on the water supply of Venice at the Annual Meeting of the British Medical Association in Edinburgh in 1898. About two years ago he discovered that he had diabetes, but in spite of progressive exhaustion and loss of flesh he remained bravely at his work. Last summer he spent a few weeks at Carlsbad and at Mendel in the

Austrian Tirol, but derived no real benefit from the treatment. Early in January he went to Syracuse, in Sicily, feeling the need of change and warmth. Towards the end of January he became comatose, and passed away on February 3rd. He was buried at Syracuse. Van Someren will long be remembered by his friends. A man of strong religious convictions, he was conspicuous for his unselfish character and gentle demeanour. He did much good work among the very poor in Venice. He is survived by his widow, who is a daughter of Mr. Horace Fletcher, and four young children, two boys and two girls.

DEPUTY INSPECTOR-GENERAL EDWARD H. EVANS, who died on February 24th, aged 83, received his medical education at Guy's Hospital, and took the diplomas of M.R.C.S. Eng. and L.S.A. in 1851. He entered the service in 1853, became Staff Surgeon in 1862, Fleet Surgeon in 1876, and Deputy Inspector-General of Hospitals in 1884; he retired in 1888. He served as Assistant Surgeon of H.M.S. *Diamond* during the Crimean war of 1854-5, and with the naval brigade at the fall of Sebastopol.

Universities and Colleges.

UNIVERSITY OF CAMBRIDGE.

THE following degree has been conferred:

M.B.—G. Hoffmann.

UNIVERSITY OF LONDON.

MEETING OF THE SENATE.

A MEETING of the Senate was held on February 19th.

Royal Naval Medical School.

The Naval Medical School of the Royal Naval College, Greenwich, has been admitted as a school of the University in the Faculty of Medicine for the officers of the Royal Naval Medical Service.

Examiners in Physiology.

The following have, together with the external examiners, been appointed examiners for the final examination in physiology for internal students: W. D. Halliburton, Chairman (King's College), E. H. Starling (University College), J. S. Edkins (Bedford College and St. Bartholomew's Hospital Medical School), J. Mellanby (St. Thomas's Hospital Medical School), M. S. Pembrey (Guy's Hospital Medical School).

D.Sc. Degree in Physiology (Internal).

The degree of D.Sc. in Physiology was conferred on Mr. Charles A. L. Evans, an internal student of University College who had presented a thesis on the gaseous metabolism of the heart and lungs, and submitted in addition several further contributions to the advancement of science published independently or conjointly.

Regulations for M.D. and M.S. Degrees for Internal and External Students.

It was resolved:

That the regulations for the M.D. Examination for internal and external students be amended by the substitution for the words "the result of independent research" of the following—"the result of his own independent research," and that the regulations for the M.S. Examination be similarly amended.

Publication of Pass Lists.

It was resolved:

That the date of the announcement of the results of the First Examination for Medical Degrees, of the Preliminary Examination in Veterinary Science, and of the Intermediate Examination in Veterinary Science, Part I, for internal and external students to be held in December, 1913, be the Wednesday in the fourth week following that in which the examinations close, and that in subsequent years the date of commencement of these examinations be the first Monday following December 7th, instead of as at present, the first Monday following December 10th.

Appointment of Representatives.

Dr. F. Taylor was reappointed to represent the University on the General Medical Council, and Dr. F. R. Walters was nominated for reappointment to represent the University on the governing body of the Farnham Girls' Grammar School.

Chairman of Professoriate Committee.

The Vice-Chancellor (Dr. Herringham) has been elected Chairman of the Professoriate Committee.

Staff Examiners for 1913-14.

The following are among those appointed staff examiners for 1913-14:

Anatomy.—Alexander Macphail, M.B., C.M., and Professor A. M. Paterson, M.D., F.R.C.S.

Forensic Medicine and Hygiene—William A. Brend, M.A., M.B., B.Sc., and E. P. Manby, B.A., M.D., D.P.H.
Medicine.—Norman Dalton, M.D., Sidney P. Phillips, M.D., F.R.C.P., H. D. Rolleston, M.A., M.D., F.R.C.P., and W. B. Warrington, M.D., Ch.B., F.R.C.P.
Mental Diseases and Psychology.—Maurice Craig, M.D., F.R.C.P., and William McDougall, M.B.
Obstetric Medicine.—H. R. Andrews, M.D., B.S., and George H. D. Robinson, M.D., F.R.C.P.
Pathology.—Professor R. T. Hewlett, M.D., F.R.C.P., and Professor R. Muir, M.D., F.R.C.P.
Pharmacology.—Professor A. R. Cushny, M.D., F.R.S., and James A. Gunn, M.D., D.Sc. (for 1912-13 also).
Physiology.—Joseph Barcroft, B.Sc., M.A., F.R.S., Professor E. H. Starling, M.D., F.R.S.
Sociology.—W. H. R. Rivers, M.D., F.R.S., and Professor E. J. Urwick, M.A.
State Medicine.—John W. H. Eyre, M.D., D.P.H., and T. Morison Legge, M.D., D.P.H.
Surgery.—Frédéric F. Burghard, M.D., M.S., F.R.C.S., William F. Haslam, M.B., Ch.B., Raymond Johnson, M.B., B.S., F.R.C.S., and H. Betham Robinson, M.D., M.S., F.R.C.S.
Tropical Medicine.—C. W. Daniels, M.B., and Professor F. M. Sandwith, M.D.
Veterinary Pathology.—Sir John McFadyean, M.B., B.Sc., and Professor A. E. Mettam, B.Sc., M.R.C.V.S.
Veterinary Physiology.—Professor G. A. Buckmaster, M.D., B.Ch., and W. Legge Symes, M.R.C.S., L.S.A.

Bureau of Information for the Universities of Empire.

A meeting of the elected members of the "Formative Committee," appointed for the purpose of establishing a bureau of information for the universities of the empire was held on January 23rd, when certain steps were decided upon for the collection of information, and the offer of Dr. Alex Hill to act as honorary secretary to the bureau until its work became sufficiently extended to require the appointment of a paid official was accepted.

Proposed University of London Club.

At a second general meeting of graduates, teachers, and officers of the University held on February 17th, the committee appointed on November 28th, 1912, was reappointed and authorized to establish and organize a University of London Club in or near Bedford Square. It was stated that it was hoped to open the club not earlier than May 1st and not later than October 1st, 1913.

Lectures on Advanced Medical Subjects.

The following are the remainder of a series of free lectures addressed to advanced students of the university and others interested in the subjects dealt with.

Middlesex Hospital Medical School.—March 18th, 5 p.m., Dr. W. J. Fenold: Bacterial variation.
St. Bartholomew's Hospital Medical School.—May 1st, 5 p.m., Dr. M. H. Gordon: Sensitized vaccines.
University College Hospital Medical School.—May 5th, 5 p.m., Dr. T. R. Elliott: Disease and the suprarenal glands.
St. Bartholomew's Hospital Medical School.—May 8th, 5 p.m., Dr. H. Williamson: Some factors of importance in determining the significance of albuminuria in pregnancy.
London Hospital Medical College.—May 19th, 21st, and 23rd, at 4.30 p.m., Dr. H. M. Turnbull: Physiological and pathological changes in the structure of arteries and arterio-sclerosis.
Brompton Hospital.—May 28th, 4.30 p.m., Dr. C. H. Miller: The site of tuberculous lesions at different ages.

Chadwick Lectures in Hygiene.

A course of three lectures on infant welfare—(a) the mother as source, (b) the father as source, and (c) environmental influence, will be given by Professor Karl Pearson, F.R.S., probably during May, under the Chadwick trust. A further course of Chadwick lectures will be given by Sir George Newman, M.D., during the session 1912-13.

University Studentship in Physiology.

A university studentship of the value of £50 for one year will be awarded to a student qualified to undertake research in physiology. Candidates must be matriculated students or graduates of the university. Applications to be sent to the Principal, from whom further particulars can be obtained by May 31st.

Rogers Prize, 1914.

The subject of the essay or dissertation for the Rogers Prize for 1914 will be "The Nature of Pyrexia and its Relation to Micro-organisms." Copies of the regulations for the award of the prize can be obtained on application to the Academic Registrar.

KING'S COLLEGE.

The following appointments have been made in the Department of Public Health:

Lecturer in Sanitary Law and Administration.—Dr. E. W. Routley.
Lecturer in Applied Hygiene in the Tropics.—Colonel W. C. King, C.I.E., M.D.
Lecturer on School Hygiene for Medical Officers.—Dr. W. F. Roach.

The laboratories of the College occupy part of the premises of the Charing Cross Hospital Medical School, 62, Chandos Street, W.C.

UNIVERSITY OF ABERDEEN.

Honorary Degrees.

AMONG those upon whom the honorary degree of LL.D. was conferred on February 25th were Dr. D. W. Finlay and Dr. William Stephenson, Emeritus Professors of Medicine and Midwifery respectively. The same distinction was conferred on Dr. Ronald Campbell Macfie, who is the author of the *Romance of Medicine* and of many poems, including an ode written for the opening of the new buildings at Marischal College, Aberdeen. Dr. Macfie, we may note, has this month received the prize offered through the *Poetry Review* for the best poem submitted: the subject of his composition is John Davidson, the poet and philosopher.

CONJOINT BOARD IN IRELAND.

The following candidates have passed the recent examination for the Diploma in Public Health:

Captain T. C. Boyd, F.R.C.S.I., I.M.S., T. W. Conway, F.R.C.S.I., J. J. Cullen, L.R.C.P., and S. L. C. H. Denham, M.B. (Dub. Univ.), Captain D. L. Harding, F.R.C.S.I., R.A.M.C., J. O'Regan, L.R.C.P., and S. Edin., T. E. Rice, L.S.A., R. F. Williams, M.B. (Univ. Camb.).

* With honours.

The Services.

PARKES MEMORIAL PRIZE.

THE prize of seventy-five guineas and the bronze medal of the Parkes Memorial Fund have been awarded for 1913 to Major S. Lyle Cummins, R.A.M.C., for his essay on "The Causation and Prevention of Enteric Fever in Military Service, with special reference to the importance of 'carriers.'" The subject for the next competition is "Heat-stroke: its Causes, Prevention, and Treatment." (The essay should bear evidence of the personal observations and experience of the writer.) Essays bearing a motto and accompanied by a sealed envelope similarly superscribed, containing the author's name, must reach the Secretary of the Prizes Committee, Royal Army Medical College, on or before December 31st, 1915. The competition is open to medical officers of the Royal Navy, Army and Indian services, of executive rank on full pay, with the exception of professors and assistant professors of the Royal Naval Medical College, Greenwich, and the Royal Army Medical College, London, during their term of office.

INOCULATION AGAINST ENTERIC FEVER.

IT is intimated in the Scottish Command orders that in order to encourage soldiers voluntarily to undergo inoculation against enteric fever lectures will be given at stated intervals by medical officers, showing the advantages conferred by this method of protection. The men should be advised to undergo the operation as soon as they attain the age or service that renders them liable for service abroad, and it is suggested that a quarterly inoculation of men volunteering might take place in each garrison. In the event of the numbers wishing to attend at first being very large, the inoculation might take place at monthly intervals instead of quarterly. The men should not be inoculated until they have completed their recruits' course, and the soldier's training should not be interfered with.

Medical News.

COLONEL W. C. GORGAS, of the Isthmian Canal Commission, Panama, has accepted the task of organizing a sanitary system for the port of Guayaquil, Ecuador, which has been known hitherto as the pest-hole of the Pacific.

THE festival dinner of the National Hospital for the Paralyzed and Epileptic, Queen Square, W.C., will take place at the Hotel Metropole on April 16th under the chairmanship of Lord Strathcona and Mount Royal, who will be supported by H.R.H. Prince Alexander of Teck.

THE issue of *Nature* for last week, the first number of the ninety-first volume, contains an admirable portrait of Sir J. J. Thomson, with an appreciation of his immensely important contributions to physics by Augusto Righi, Professor of Experimental Physics in the University of Bologna.

ON the recommendation of the Lord Lieutenant, the Lord Chancellor has appointed the following gentlemen to the Commission of the Peace for the County of Aberdeen: Alexander Hendry, M.D., Surgeon Apothecary to H.M. Household at Balmoral, Ballater; James Middleton, M.B., C.M., Peterhead.

AT a meeting to which all British practitioners of otology, rhinology, and laryngology were invited, held at the Medical Society's Rooms, Chandos Street, London, W., on March 12th, it was decided to form a new society for the study of diseases of the ear, nose, and throat.

THE Provost, Magistrates, and Town Council of the Royal Burgh of Linlithgow have resolved to take part in the movement which has been initiated by Mr. Alexander Spence, M.P.S., chemist, Leslie, Fife, to celebrate this year the centenary of the birth of Dr. David Waldie, the Linlithgow chemist and doctor who was instrumental in bringing under the notice of Sir J. Y. Simpson the anaesthetic properties of chloroform. Further donations, however small, should be sent to the honorary treasurer, Mr. John McWhirter, J.P., Union Bank House, Leslie, Fife.

THE annual meeting of the Royal Portsmouth Hospital was held in the Town Hall on February 23rd. It was stated that the effect of the Insurance Act on the admission of patients had been slight; only a small percentage were insured persons, and the hospital was as much needed as ever. The Nurses' Home (the local memorial to King Edward VII) which had cost, including furnishing, about £3,000, had been completed and paid for, thanks largely to an anonymous gift of £2,000. There was a slight increase in the amount of annual subscriptions received in 1912, and it was hoped that the day was far distant when the municipalization of the hospital would have to be seriously considered.

THE Society of Carlsbad Physicians announces a prize to be given for the best essay on the treatment of diabetes mellitus, with special reference to balneotherapy. The jury will be: Hofrat Professor Dr. Ritter von Jaksch of Prague, Professor Dr. Luethje of Kiel, Professor Dr. Ortner of Vienna, Professor Dr. Schmidt of Innsbruck, and Dr. Edgar Ganz, President of the Society of Carlsbad Physicians. Either one prize of 5,000 kronen, or two prizes of 3,500 kronen and 1,500 kronen, or three prizes of 2,500 kronen, 1,500 kronen, and 1,000 kronen, may be awarded. The competition is open to physicians of all countries, and any language may be used. Competing essays must be received before December 31st, 1913. Any further information may be obtained from the Society of Carlsbad Physicians in Carlsbad.

THE second International Congress on Life-Saving and Prevention of Accidents will be held in Vienna from September 9th to 13th next. Its business will be conducted in ten divisions; the first two will deal with first aid, professional and lay, in accidents; the third, fourth, and fifth with ambulance work in town and country, on the railway, and at sea; the sixth and seventh with life-saving work in mines and among firemen; the eighth and ninth with life-saving in the mountains and in connexion with sports; and the tenth with the prevention of accidents generally, and with special reference to workmen and public traffic. A British committee has been formed to make arrangements for the congress with the Earl of Lonsborough as president and Mr. S. Osborn, F.R.C.S., as secretary. Other members of the committee are Sir J. R. Andrew Clark, C.B., Sir George T. Beatson, K.C.B., Mr. James Cantlie, Mr. Lynn Thomas, C.B., and Dr. F. M. Sandwith.

THE fifth annual report of the Army and Navy Male Nurses' Co-operation shows it to be in a flourishing condition. During the year 1911-12 as many as 381 cases were nursed by members of the co-operation, whilst the average number of nurses employed throughout that year was forty-two. Three of these men, one of whom unfortunately succumbed to an attack of enteric fever contracted whilst on duty, were chosen for service in Tripoli, under the auspices of the British Red Crescent Society. The annual income of the society during 1911-12 showed an increase of £368 14s. 8d., the receipts for the nursing service having amounted to £3,719 16s. 9d. The committee have thus been enabled to acquire a lease of 11A, Welbeck Street, where offices and a residential home for the nurses have been established. Mr. Edward P. Furber has become honorary medical adviser to the society, which has sustained a severe loss through the retirement of its President, Sir Frederick Treves, and the death of its Vice-President Sir William Allchin, who did so much to assist the Co-operation in its early days. The places thus left vacant have been filled by Admiral Sir John Darnford, K.C.B., D.S.O., and Sir Dyce Duckworth.

CHRISTOPHERS (*Scientific Memoirs of Officers of the Medical and Sanitary Departments of the Government of India (New Series) No. 56, Malaria, Calcutta, 1912, 1s. 4d.*) concludes that the chief carrier of malaria in the Andamans is the *Nysomyzomyia ludlowi*, a species which breeds in and about salt swamps and is not found at a greater distance from salt or brackish water than half a mile. Whether any part is played in the transmission of malaria by the other common species, *Nsm. rossi* and *My. barbirostris*, he believes is doubtful. In any case the latter

could only be an important carrier within the forest, and the mere clearing of land has made it unimportant even in regard to numbers. Owing to the distribution of *Nsm. ludlowi*, malaria in the Settlement is confined to a belt around the margins of the harbour, and is absent, or nearly so, from villages more than half a mile from the sea coast, or the salt swamps associated with this. This freedom from the disease is found even in inland villages situated on the margins of swamps, amidst rice fields and near jungle. The predominating type of parasite among the children in the villages was simple tertian, while amongst convicts admitted to hospital and amongst the convalescent gang quartan infections formed 50 per cent. or over. Though infection with malignant tertian was very little in evidence during the time of Christopher's visit, yet the only two infected *Anopheles* encountered were infected with this type of parasite.

SHAKESPEARE has truly said that "he that is stricken blind, cannot forget the precious treasure of his eyesight lost," and there can be no doubt that for most people blindness would prove the most intolerable of all misfortunes. Moreover, apart from actual loss of sight, perhaps no greater calamity can befall a child than to begin life handicapped by defective vision; yet it is only of recent years that any definite prophylactic measures have been adopted. Dr. A. S. Cobbledick, whose excellent article on The Wearing of Spectacles by Children appeared in the March number of *The Child*, remarks that it is only during the last twenty years that spectacles have been systematically ordered in cases of refractive errors of vision in young children, and that so far the results have been extremely satisfactory. According to Dr. Cobbledick, excessive nervousness and irritability is often a sign of eyestrain in children, and these symptoms disappear as soon as the trouble is relieved by proper glasses. It should be borne in mind, however, that the latter condition frequently exists along with post-nasal growths, whose removal is imperative if a radical cure is to be obtained. Another and very common cause of suffering in children is bad teeth, and the same number of *The Child* contains an interesting description by Dr. Ernest T. Roberts of the excellent dental clinics recently established by the Glasgow School Board, where the children attending the municipal schools receive free treatment from competent dentists. The number also includes an article on the practice of surgery during childhood by Mr. Edred M. Corner, and an interesting account by Mr. W. Kersley Holmes of the free Kindergarten, founded by Miss Lilecn Hardy for the children of the Edinburgh slums.

IN the fourth Galton Laboratory Lecture on "National Eugenics," Dr. David Heron said that it was not generally recognized that, even under present conditions, the great majority of the feeble-minded came under State control; and that although such cases were a source of continual expense, the control of the State was exercised in such a way that practically nothing was done to check their multiplication. Though there could be no doubt that mental defect was hereditary, any attempt to discover precise laws of inheritance encountered many difficulties, owing to the fact that the term "mental defect" covered a multitude of conditions, each of which existed in almost an indefinite number of grades of severity. In some recent attempts to apply Mendelism to such cases the evidence cited told strongly against the theory, and Dr. Heron repudiated the advice that the mentally defective and the insane should intermarry with the normal, and pointed out that on the basis of the Mendelian theory normal individuals could carry the latent possibility of defect for many generations. Such advice, he continued, could only bring the whole eugenic movement into disrepute. What was specially required at the present time was more information. Efforts ought to be made to follow up the children who were passing through the special schools for the mentally defective, and also to trace back the school histories of those who were now mentally defective criminals and paupers. Much yet remained to be discovered regarding the inheritance of mental deficiency; but on the basis of present knowledge it was justifiable to assert that a substantial reduction in the numbers of the mentally defective could be obtained by preventing the feeble-minded from reproducing their kind. The cardinal principle of national eugenics was the distinction between the right to live and the right to parenthood. National eugenics denied to no one the right to live, but it taught that there were certain classes to which the right to parenthood must be denied; and in the case of the feeble-minded it declared without hesitation that their children were better not born.

Letters, Notes, and Answers.

Queries, answers, and communications relating to subjects to which special departments of the BRITISH MEDICAL JOURNAL are devoted will be found under their respective headings.

QUERIES.

A. E. has a patient, aged 70, who suffers from dyspepsia and irritability of the bowels, following severe gastric influenza; these symptoms are accompanied by bacilluria. He has been treated with urotropine, helmitol, and salol, which increases the irritability of the bowel. Dilution with large quantities of water has been tried, and "A. E." asks what can be done to mask the irritant effect.

ANSWERS.

TABES.

W. writes, in answer to "Fairlands," to suggest that the rectal pain in his case of tabes is probably due to intestinal stasis, and that the remedy is to secure the daily action of the bowels. "W." suggests the following: An hour before bedtime three or four teaspoonfuls of agar-agar (cut small) in a small cup of hot milk with a capsule containing ʒss of the liquid extract of cascara sagrada; a saline (as aperita) in a tumbler of hot water one hour before breakfast, and a simple normal saline enema to clear out the rectum at the time the bowels act. If these are not sufficient a 2-grain tablet of cascara with ʒj or ʒij of white vaseline may be taken before bedtime.

LEUCONYCHIA.

UNUS.—Our correspondent's son apparently suffers from leuconychia totalis, a well-known but rare abnormality of the nails. The appearance is due, according to Unna and most other dermatologists who have had the opportunity of studying the disease, to the presence of air spaces in the nail. Such air spaces are caused by an irregular keratinization of the cells which form the substance of the nail. These shrink unduly and leave spaces which are filled with air. The etiology of the condition is obscure. In Unna's patient, a young man of 26, it was congenital, but in most of the cases published the leuconychia seems to have been established after a local depression of the circulation with consequent coldness of the extremities. Even in Unna's case the patient had cold, somewhat cyanotic, hands. Some observers lay stress on the effects of slight traumatism in causing this curious change in the nails, but there must be in addition some predisposing factor. Leuconychia does not appear to have any special significance. As regards treatment, no satisfactory treatment is known, but, as the pathology of the condition appears to be similar to parakeratosis of the skin, it is just possible that x-rays cautiously applied might be of some value.

CHEWING GUM.

DR. S. B. WALSH School Medical Officer, Gillingham, Kent) writes: I agree with Dr. Gilchrist (p. 476) as to the probable beneficial effects of gum-chewing on the development of teeth and jaws. It is a practice in which I must plead occasional indulgence, and my experience satisfies me that it goes a long way towards supplying the cleansing and masticatory deficiencies of modern food. We are told that the food of to-day is too soft and pappy; that it lacks detergent properties; that it fails to encourage the proper secretion of saliva; that it leaves a residue round the teeth to ferment and corrode; and that the present lamentable condition of the national dental apparatus is the net result of the foregoing. Now, the oft-repeated mastication involved in gum-chewing has the following certain effects. It develops the masseters and increases the blood supply of the dental arch and teeth; it flushes the mouth with acid-neutralizing saliva; it acts as an efficient cleansing agent, for the softened gum penetrates the smallest interstices between the teeth; it is mildly antiseptic and markedly deodorant; and, lastly, it is a fine antidote to excessive smoking. I am, of course, well aware that it is a habit which is calculated to irritate somewhat one's aesthetic sensibilities. On the other hand, anything that creates health must be accounted directly or derivatively beautiful, or nearly so—certainly much nearer so than carious malformed teeth. It is worthy of note that a monk who accompanied the Spanish conquerors to Mexico commented on the uniformly regular and beautiful teeth of the Aztec women, which he attributed to the habit, universal among them, of chewing "chicle," the basis of the present-day article. I have often thought that if gum could be popularized among children so as to replace a proportion of the sweets at present consumed, it would result in a noticeable benefit to the teeth of the subsequent adult generation.

TREATMENT OF TAENIA.

A. W.—Our correspondent should consult Sir Kingston Fowler's remarks on the treatment of taenia in the JOURNAL, vol. i, 1905, p. 841. The patient should be kept in bed under close observation; then male-fern will prove the most satisfactory remedy. Private and out-patient cases do not do so well as in-patients simply because they cannot be so thoroughly watched unless they have a private nurse. For two, three, or four days the following diet must be given: Two pints of

beef-tea, one tin of Mason's essence, two rusks, and 4 oz. of port wine, whilst the patient takes 2 grains of extract of cascara sagrada three times daily. On the fourth day he should take, about 5 a.m., 1 oz. of haustus sennae co.; at 9 a.m., 15 minims of the extract of male-fern in a capsule, the dose to be repeated at 9.15, 9.30, and 9.45. At 11 a.m. the haustus sennae must be repeated. If by 1 p.m. the worm has not been passed and the head found, a second course of treatment with male-fern at intervals of a quarter of an hour must be carried out, to be followed in an hour by a purgative draught. If the head be not then found a third course of this treatment must be undertaken. As the worm generally breaks at a distance of about 1½ in. from the head, and as the fragment which remains is an exceedingly slender filament, the most careful scrutiny is absolutely needed. The pan in which the motion is passed should be covered with black crepe, to throw out in relief the fine white filament terminating in the head.

DEATH OF THE EMPEROR NAPOLEON.

M. D.—The officer acting as orderly officer at Longwood during the closing days of Napoleon's illness was Captain Crockatt of the 20th Regiment, who was appointed to that position on April 14th, 1821. Captain Crockatt was entrusted with the official dispatches announcing the death of Napoleon, and on his arrival in England received his majority and a present of £500. He became General Crockatt and died in 1879, at the advanced age of 87. So far as is known, he did not leave any papers relating to his connexion with Napoleon. Crockatt succeeded Captain Englebert Lutyens of the same regiment, who resigned his position of orderly officer on account of his treatment by Lowe and the commanding officer of the 20th Regiment. Napoleon had presented to Dr. Arnott a copy of Marlborough's Campaigns for the library of the 20th Regiment, and Lutyens was commissioned to send them to the regiment. But unfortunately the book was inscribed on the title page with the Imperial "N." and the words "L'Empereur Napoleon." For this reason, and the fact that Lowe thought such a gift might seduce the allegiance of the 20th Foot, the book was sent home to the Duke of York, Commander-in-Chief, for his decision. The Duke of York at once allowed the 20th Regiment to retain the book, saying that "Such a gift from Napoleon to a British regiment was most gratifying to him, and that the safe detention of Napoleon was sufficient testimony that the regiment had done its duty." The book is now in the archives of the 20th Regiment. (See *History of 20th Regiment*, by B. Smythe, M.V.O.)

ACUTE PNEUMONIA DURING TREATMENT WITH ARSENIC. DR. GEORGE PERNET (London, W.) writes, in reply to Dr. S. M. Hebblethwaite's letter in the JOURNAL of March 8th, p. 529, that a reference to the matter will be found in Kobert's exhaustive *Lehrbuch der Intoxicationen*, vol. ii, p. 263 (Stuttgart: Enke, 1906).

LETTERS, NOTES, ETC.

IN PRAISE OF THE PHYSICIAN.

A YORKSHIRE G.P., who, for reasons of modesty, does not sign his name, writes: Apropos of your article "In Praise of the Physician," the following complimentary and touching sentence, addressed to me by an old Yorkshire farmer on his deathbed, may be of interest as an example of personal esteem to be continued even after death: "I've allus respectit ye iver sin' I've knawn ye, an' I'll allus respect' ye efter I'm deid!"

POETRY A DISORDER OF THE INTESTINES.

C. writes: Two weeks ago I inserted in the JOURNAL a query as to the origin of the above statement. My learned friend, Mr. C. W. F. Goss, of the Bishopsgate Institute, has kindly furnished me with what appears to be the solution. He points out that Carlyle in his *Signs of the Times* quotes from Pierre Jean Cabanis (1757-1808), physician to Mirabeau, as follows: "As the liver secretes bile so does the brain secrete thought, but poetry and religion are a product of the smaller intestines."

CORRECTION.

IN the article on The Knowledge of Tropical Diseases in 1813, published in the JOURNAL of March 1st, p. 455, there was an unfortunate misprint: the dose of laudanum used by Mr. Playfair in combination with half a drachm or a drachm of ipecacuanha was 30 to 60 drops.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

| | £ | s. | d. |
|-----------------------|-----|-----|--------|
| Eight lines and under | ... | ... | 0 4 0 |
| Each additional line | ... | ... | 0 0 6 |
| A whole column | ... | ... | 2 13 4 |
| A page | ... | ... | 8 0 0 |

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Wednesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *postes restant* letters addressed either in initials or numbers.

A Lecture

ON

GLYCOSURIA.

DELIVERED AT THE LONDON SCHOOL OF CLINICAL MEDICINE

BY

GUTHRIE RANKIN, M.D., F.R.C.P.,

PHYSICIAN TO THE DREADNOUGHT AND ROYAL WATERLOO HOSPITALS.

ALTHOUGH the main objective features of diabetes—thirst, emaciation, and polyuria—were recognized as early as the beginning of the Christian era, it was not until the seventeenth century that Willis noted the fact that in the majority of such cases the urine had a remarkably sweet taste, "like a solution of honey or sugar," nor until the nineteenth century that various chemical tests were introduced by Trommer, Moore, and Fehling which proved the sweet taste observed by Willis to be actually due to the presence of glucose.

Nowadays it is acknowledged that the ancient clinical syndrome applies to more than one condition of disturbed health, and that in order to justify its classification as a true diabetes the urine must be proved to contain sugar. Glycosuria is, in short, the essential foundation for a diagnosis of diabetes and, in many cases, it is for a long time the only morbid manifestation. A mild degree of intermittent, or even of persistent, glycosuria may last over a long series of years without producing the evidence of general constitutional disturbance which justifies its being called, in the true clinical sense, diabetes, but its existence establishes the fact of a tissue instability which is, in every instance, the potential herald of that grave disorder.

Glycosuria is met with in all conditions of life and in every part of the world, but it is curiously rare in the negro races and conspicuously prevalent among the Jews. Though most common in the fifth decade of life, no age is exempt, but its prognostic significance is much more serious in youthful than in elderly patients. Heredity plays an important part in its incidence, and a record of obesity and gout carries with it an increased liability to a mild type of the disorder after middle life.

DIAGNOSIS.

In 1849 Claude Bernard discovered that the liver stored carbohydrates in the form of glycogen which he believed was converted into sugar under the influence of a diastatic ferment and carried by the hepatic vein into the general circulation according to the needs of the economy. Hyperglycaemia, or the excess of sugar in the blood, might therefore either arise from (a) defective glycogenic activity or excessive carbohydrate intake on the one hand, or from (b) excessive glycogenic activity or defective destruction in the tissues on the other.

In opposing this view Pavy contended that in health the carbohydrates are synthetically assimilated into proteins by the lymphocytes and converted into fat by the epithelial cells of the intestinal villi, whatever portion escapes the villi being converted into glycogen in the liver. Failure of these processes, according to him, results in hyperglycaemia from sugar entering directly into the blood instead of being converted into protein, fat, and glycogen. He showed that sugar may be derived not only from the food carbohydrates, but also from the food and tissue proteins, since in some cases sugar is excreted even when no carbohydrate is ingested.

Until these important discoveries no one dreamed that a protein molecule in the process of breaking up into urea, carbonic acid, and water, could split off a carbohydrate molecule from which sugar was formed, but this is now recognized as an everyday occurrence in the physiological activity of both plants and animals.

Lancereaux described changes in the pancreas which he believed to be constantly associated with diabetes, but in many instances the pancreas after death appears to be quite normal, so that this theory is not universally applicable.

The glycosuria which is produced by the administration of phloridzine is believed to be due to the effect of that

drug on the renal epithelium, which, under its power, is prevented from holding back sugar. The influence of the internal secretions is not yet unravelled, but it will probably be proved ultimately that the part they play is important.

It seems likely that no single cause is responsible for all cases, but physiological investigation suggests that an error in normal glyco-genesis, however produced, is an integral part of the pathological process.

By some observers the presence of sugar in the urine is justification enough to classify the illness as diabetes. But though it may be true that every case of glycosuria is potentially a case of diabetes, it is convenient for clinical purposes to separate the one variety of the disorder from the other, especially when it is remembered that the sequence of events is essentially different in the two conditions. Diabetes should, in my opinion, be used as a descriptive title for those cases only which are acute in their progress and are characterized by polyuria, thirst, hunger, and rapid emaciation, together with the presence of a considerable amount of sugar in the urine. Glycosuria, on the other hand, should be reserved as a suitable designation for those cases that are chronic in their course, occur mostly in persons at or past middle life, are not attended with excessive thirst or serious disturbance of the general health, and contain sugar in the urine either intermittently or in comparatively small constant amount. The term "diabetes" always conveys to the patient an alarming impression of the seriousness of his condition, whereas "glycosuria," probably because the word is not generally understood, has a much less formidable significance. This fact alone should be enough to guide us in our choice of a descriptive designation.

I desire now to consider only the chronic condition of glycosuria—a condition which, though capable of assuming acute proportions, is, in the majority of instances, a chronic process from beginning to end, lasting over many years, and, with due precautions, not interfering seriously with general health or with the average expectation of life.

In true diabetes the attention of the patient is drawn sooner or later to his condition by the occurrence of one or other of the principal results which ensue: Either his notice is attracted by the constant thirst which possesses him, or he becomes concerned about his rapid loss in weight, or he gets suspicious that something is wrong because of the large amount of water which he secretes daily. The glycosuric, on the other hand, may continue over a long period without any doubt arising in his mind that he is not quite well. He may pass somewhat more water than usual or he may become a little thinner than formerly, but neither event, if it happens, is sufficiently pronounced to send him to his doctor. He sleeps, eats, and drinks well, and in a large proportion of cases the existence of sugar in his urine is discovered accidentally in the course of an investigation into his state of health for some reason entirely unconnected with the urinary organs. It is surprising how many people, sick from one or another minor ailment, remain under the care and treatment of a medical man without the formality of a urinary examination ever being considered necessary. We are all familiar with cases of prolonged disturbance of health treated in this casual way on which a flood of illumination is thrown and a guide to treatment immediately afforded by the discovery of sugar in the urine. This happens so much more frequently than most of us believe that the tests for sugar—and albumen as well—ought to enter into the routine examination of every patient seen for the first time as habitually as the common formulary of looking at his tongue or counting his pulse.

It is quite unnecessary to enumerate the many tests which are recommended for the discovery of sugar. To most of us who are busy and practical men Fehling's test is the one which we almost invariably employ. But it is well to bear in mind that there are fallacies connected with it which may from time to time betray us into error, because the urine may contain other substances capable of throwing down the yellow suboxide of copper besides sugar. This may happen under the influence in the urine of excessive quantities of glycuronic acid, uric acid, or lactose. It may also occur in the urine of persons who are under treatment by salicylic acid or its salts. It is

therefore always of importance to employ a second test, especially when the Fehling reaction is slow or indefinite. The most convenient, and perhaps the best confirmatory evidence we can have, is that afforded by fermentation. The addition of yeast to urine containing glucose causes fermentative changes which result in a diminution of the specific gravity of the urine. The amount of sugar may be calculated either by collecting the carbonic acid which is given off in the process of fermentation (one molecule of sugar giving approximately two molecules of carbonic acid), or by comparing the densities of the urine before and after the fermentative process, each degree of density lost being reckoned as equivalent to one grain of sugar per ounce. Another confirmatory test of value depends upon the influence of glucose upon polarized light, which it deflects to the right. In a urine which feebly or doubtfully reduces Fehling's solution, dextro-rotation of the polarized ray would confirm the suspicion of glucose being the cause.

The estimation of the amount of sugar is always troublesome. It involves an expenditure of time which can ill be spared, and yet the progress of any case in which sugar is present in the urine can only be satisfactorily gauged by quantitative analyses repeated again and again. To those of you who may be unacquainted with it I strongly recommend the simple method introduced by Dr. Walker of Peterborough. By its means only a few minutes are required to ascertain the percentage of sugar with sufficient accuracy for all practical purposes. A full description of this method of estimation is given by Dr. Walker in the *Lancet* of 1909.

ETIOLOGY.

Glycosuria occurs under a bewildering variety of conditions, and in the present state of our knowledge no complete system of classification seems possible. We know that it is met with on recovery from chloroform or ether anaesthesia; in poisoning from coal gas; after the administration of thyroid extract and of various drugs; after sudden immersion in cold water; in the later months of pregnancy; as the result of mental shock, etc. It happens as an incidence in many diseases of the nervous system; may be a sequel of the acute infective fevers; and is met with in organic disturbance of the liver, pancreas, and intestinal tube, and also in disease of the thyroid gland or of the pituitary body. Every case of glycosuria requires to be investigated on its own account, and an attempt made to establish the cause upon which it depends, and, where possible, the organic fault to which its continuance is due. For example, an attack of gout may be the primary cause upon which a temporary glycosuria ensues, but repeated attacks of gout may ultimately produce such organic changes in liver, pancreas, and kidneys as to make what was at first a mere transient appearance of sugar in the urine a permanently established evidence of persistent metabolic inadequacy. In illustration I may mention the following case:

A man of gouty antecedents who lived freely came under my observation more than twenty years ago. He was then 52 years of age, and had in his previous life suffered from no serious illness, though subject for about eight years to occasional attacks of typical gout. I first saw him in one of his ordinary attacks, from which he made the usual uneventful recovery. At the end, so far as I remember, of about two years, I discovered, during an unusually acute attack of gout, that he had about 2 per cent. of sugar in his urine. With the disappearance of the inflammation in his toe, the sugar also vanished, but it recurred with each succeeding gouty illness, and after a further period of about eighteen months the glycosuria became permanent, and lasted to the end of his life at the age of 74. For the last ten years before he died the glycosuria was accompanied by albuminuria, the one see-sawing with the other very much according to the care he took in regard to his dietary. It was impossible to persuade him to be sufficiently careful about what he ate and drank, but he never emaciated, and, despite his persistent glycosuria, he lived a fairly active life, free from serious inconvenience of any kind, and exceeded the Psalmist's allotted span before he was gathered to his fathers.

In every case of glycosuria the first point to determine is whether and to what extent it is influenced by the quality and character of the daily food. The limit of toleration for sugar varies with different individuals, but the average person can stand a dose of about 150 grams of glucose without any appearance of sugar in the urine. Under certain morbid conditions this tolerance is lessened,

whereas in others it is increased. This is conspicuously notable in exophthalmic goitre in the one instance, and in myxoedema in the other. In alimentary cases the glycosuria may be dependent upon either sugar or starch in the daily regimen. No amount of starch alone will produce glycosuria in a perfectly healthy person. If, therefore, sugar being entirely withheld, a meal of starchy food results in the appearance of sugar in the urine, we must regard the fact as a distinctive morbid phenomenon, and one which indicates a future possibility of true diabetes. A lowered tolerance of starch is frequently met with in men of about 50 years of age, who are hard workers and of gouty type. It may be temporary only, as in the case of a gentleman I see from time to time. He is a full-blooded man, who works very hard at the Bar, and who comes to me periodically suffering from what he calls a "liver attack." Every time I have seen him on account of such an attack I have elicited the fact that recently he has been hard pressed with work, curtailed in the amount of his sleep, worried by the exigencies of extra mental strain, and careless as to his eating and drinking. As a matter of usual routine he takes no sugar and only a moderate amount of starchy food. On each such occasion the urine has contained sugar in amounts varying from 2 to 4 per cent. There has been no polyuria and no excessive thirst, but the pulse-tension has been high, the liver moderately enlarged and tender, the tongue coated, and the nervous system unstable and irritable. A few days' complete rest, the withdrawal of starch from his diet, together with repeated small doses of calomel and a simple alkaline mixture has always, so far, succeeded in restoring his health, and in banishing completely every trace of sugar from his urine. How long his power of recuperation may last there is no knowing, but as he becomes older, it is tolerably certain that his glycosuria will become a fixed condition unless he consents permanently to "cut his cloth to his measure."

A striking form of alimentary glycosuria is that met with in pregnant women, in many of whom there is a markedly lowered carbohydrate tolerance. The reducing agent in the urine of a pregnant woman or of one who has been recently delivered may be either lactose or glucose. The former is associated with the establishment of the function of lactation, and is of no great importance. The latter may prove to be a mere temporary disturbance dependent upon the pregnant state, or it may be the initial stage of a true diabetes. In some cases sugar is found in the urine during each succeeding pregnancy, but disappears entirely after parturition. In others the tolerance to carbohydrates seems to become hopelessly diminished, and, even under conditions of the most careful dieting, there is an abiding glycosuria. Here is a typical example:

A lady of 43 years of age, the mother of three children, became glycosuric during each of her three pregnancies. Between the first and second, and again between the second and third, the urine became and remained normal, but after the third pregnancy sugar became a continuous element in the urine, and was responsible for a troublesome pruritus vulvae, which caused constant discomfort. She has now suffered from glycosuria for upwards of sixteen years, the sugar varying in amount from 2 to 5 per cent., but during all that time the pruritus has been the only inconvenient symptom of which she has complained. Strict limitation of her diet reduces the amount of sugar, but never causes it to disappear. She is active and well, has no polyuria, and is only a few pounds lighter than the highest weight record she has ever attained.

It is of some interest to remember that during pregnancy enlargement of the thyroid gland is well known to occur, and that the pituitary body has been shown to undergo a series of changes. In exophthalmic goitre where the thyroid gland is disturbed, and in acromegaly, which is dependent upon pituitary hypertrophy, it is not unusual to find that the patient passes sugar in the urine. This suggests the possibility of the pregnant condition having a disturbing influence upon at least two of the glands whose internal secretory function is known to influence metabolism.

Closely allied to the question of dietetic glycosuria is that of hereditary tendency. There are undoubtedly families in which a predisposition to glycosuria runs through several generations.

I have, within recent experience, knowledge of a young man of 32 years of age, of apparently robust health, and without any record of serious illness, who presented himself for exami-

nation for life insurance with the full conviction that he was perfectly well, and was declined because his urine was found, to his surprise, to contain a trace of sugar. His family history justified the insurance company in looking upon this trace of sugar as a serious factor in the candidate's expectation of life, because, on careful inquiry into his antecedents, it was found that his grandfather and father had both suffered from persistent glycosuria, two paternal uncles had admittedly been victims of the same condition in an intermittent form, and an elder brother had died of acute diabetes at 18 years of age.

Of the many instances in which glycosuria occurs as a result of organic disease time will not permit me to recount many examples. It is, however, of such peculiar interest in organic disease of the liver and of the pancreas that I may be allowed to recall two cases in illustration:

The first is that of a gentleman who has all his life indulged freely in alcohol, and who, in consequence, developed cirrhotic changes in his liver of sufficient importance to produce several minor attacks of jaundice and, on at least two occasions, haematemesis and melaena. After some years of careless living he remodelled his life, and subsequently enjoyed a much better level of general health, but he paid tribute to his previous habits by a glycosuria which, though never extreme, became persistent and continues to the present day. It does not seem to impair seriously his general health nor to limit his activities, and though he has now reached 60 years of age and has, in addition to sugar, occasional traces of albumen in his urine, he gets about the ordinary affairs of everyday life apparently as well as his neighbours.

The other is that of a man of 57 who was operated upon six years ago under the belief that, because of deep jaundice and evidences of cholecystitis, he was suffering from the presence of a gall stone in the common duct. No calculus was found, but the pancreas was swollen and inflamed, and the contents of the gall bladder were almost purulent. His condition at the time of operation was so serious that prolonged investigation was impossible, and it was not deemed advisable to do more than drain the gall bladder. He made a remarkable and almost unexpected recovery, and has remained ever since well enough to carry on the duties of a strenuous life satisfactorily and without present evidence of serious health impairment. His urine was frequently examined, both before and after the operation, and had never been found to contain glucose, though it was significant that glycuronic acid had been noted on several occasions. Three years after the operation sugar appeared, at first intermittently, but latterly it has become a constant element, and one that is steadily but surely increasing in amount. His nutrition is not impaired, but the inference in his case is that the cause is a pancreatic fibrosis, which is probably progressive and spells trouble in the future.

Before leaving this large question of etiology there is one other cause of glycosuria, namely, mental shock, to which I must refer, because it illustrates what a large influence the nervous system obviously has on the occurrence of the condition.

A lady, aged 56, who had previously enjoyed excellent health, lost her husband, to whom she was deeply attached, under circumstances of tragic suddenness. She was overwhelmed with grief, and found herself suddenly plunged into a series of financial worries and family troubles which were enough to upset the mental balance of even the most strong-minded. Within a month of her husband's death she developed thirst, hunger, polyuria, and rapid wasting, all of which were accounted for by the presence in her urine of sugar varying from 3 to 5 per cent. Under careful management this acute phase of things gradually became modified, but she is left with a permanent glycosuria, and now, after three years, though the secretion of urine is diminished to a daily average of about 30 oz., and her weight remains steady, there is never less than 2 per cent. of sugar, this level being only maintained by a rigid dietary and a watchful avoidance of over-fatigue and mental annoyance.

Apart from its causative effect, the control of the nervous system over the glycosuric output is well manifested by the aggravating influence of mental overwork, or emotional shock. The share taken by the various organs of the body in the causation of glycosuria is impossible to assess accurately, but the internal secretions are in some as yet undetermined way closely associated with its occurrence; and it is safe to assume that these secretions are regulated by a nervous mechanism.

Since Minkowski proved that complete removal of the pancreas in a dog was rapidly followed by acute diabetes, it has been generally accepted that disturbance of pancreatic activity is closely connected with the excretion of sugar. In malignant disease of the pancreas or in acute inflammatory or haemorrhagic conditions of the gland glycosuria is the exception rather than the rule, but it has been frequently met with in association with pancreatic calculi and under other conditions in which a chronic fibrotic process might be surmised. Fibrosis of the

pancreas may be caused by extension from the biliary ducts, as in cases of gall stones, or by extension of infective processes up the duct from the alimentary canal, or in association with fibrotic changes in the liver, kidneys, and arteries. The prevailing opinion at present is that probably the islands of Langerhans are responsible for the production of the internal secretion of the pancreas, and if this view be correct it is understandable how a chronic process which gradually invades their territory must impair or destroy their activity. The difficulty arises in determining whether the impairment or suppression of this internal secretion is alone responsible for glycosuria, or whether its disturbance is merely an element, either etiological or sequential, which so interrupts the balance of other internal secretions as to disturb their harmonic influence upon the normal processes of metabolism. In cases associated with acromegaly, or psychic disturbance, or cranial injury, the internal secretion of the pituitary gland is probably primarily disturbed, whereas in those occurring in association with acute exophthalmic goitre there is an equal likelihood that the originating fault is in the internal secretion of the thyroid gland.

In reviewing our experience of glycosuria we must all confess that though we have cognizance of cases in which it seemed incontestable that either the nervous system, the liver, the pancreas, the thyroid gland, the pituitary gland, the intestinal canal, or the cardio-vascular system was the prime offender, there remains a residuum of patients in whom we have been unable to locate any organ as being fundamentally responsible for the first departure from tissue integrity. Some primordial morbid cause is almost certainly the true explanation. When this is discovered the existing confusion as to causation will be dissipated, and from our present gropings in the dark we shall emerge to a clear conception of these profound changes in the chemical processes of digestion and assimilation.

TREATMENT.

Until this true knowledge of the pathology of glycosuria has been achieved the question of treatment must remain very much a matter of experiment. We know nowadays that, so far as experience teaches us, the fundamental management is dietetic and depends upon an abstinence from sugar and a rigid limitation of starches, both as regards kind and amount, so as, without entire exclusion, to bring them within the digestive tolerance of the patient. But it is not sufficiently realized that a sudden change in diet from what has been the daily custom of years necessarily involves a marked alteration in the patient's physiological chemistry. On an ordinary mixed diet it is calculated that quite 60 per cent. of the physical energy of the body is derived from foods of a carbohydrate nature, so that when these are wholly withdrawn an equivalent amount must be provided from fats and proteins if nutritional injury is to be avoided. If the fault in carbohydrate metabolism were the only one to consider the treatment of glycosuria would be comparatively simple, but there are other secondary but equally important disturbances to be borne in mind when searching for a dietetic scheme to meet the requirements of each case as it crops up.

In his recent illuminating Harveian Oration Sir James Goodhart has, in reminding us of Pavy's work, recalled the important part played by proteins in the production of sugar. He says:

It has always seemed obvious, when one considers how greatly the output of sugar varies even under the most rigid system of dieting, that the excreted sugar could not be a mere output of what has been taken in; that the human kiln has, in fact, the power of in some way coining sugar out of its own constituent elements; and I believe that Pavy's ultimate credit for a real step onward in this still intricate disease will rest upon his observation that the protein molecule is in some way split up, and that a carbohydrate molecule emerges therefrom.

The haphazard method of immediately cutting off carbohydrates from the diet is both unscientific and unsatisfactory; indeed, its too rigorous application may be absolutely harmful. Here is a case in point:

A man of 53 years of age, who had suffered frequently during several years from attacks of hepatic insufficiency, induced apparently by the stress of excessive work, was sent to Carlsbad for "the cure," and while there it was discovered, for the first time, that his urine contained close upon 2 per cent. of sugar.

He was put upon a very rigid dietary, and in a fortnight's time the sugar entirely disappeared from his urine, but he lost 16 lb. in weight. His general health suffered considerably from the rigid restrictions to which he was subjected, and he has never regained the weight then lost. The sugar, which at first disappeared, soon returned, and now remains constantly present in small amount. He lives carefully as regards his diet, but has not relaxed his assiduous devotion to the duties of an active life. He takes a periodical holiday, and during his periods of vacation he allows himself to indulge moderately in the ordinary mixed diet of the hotels or country houses at which he resides. The result so far has always been to bring about a marked improvement upon his general health without materially influencing the amount of sugar he excretes or the quantity of water he passes. During his last autumn holiday he was even more regardless than usual in regard to his food. He consumed daily a certain amount of carbohydrate, and did not altogether abstain from sugar. On his return his friends were unanimous in their verdict of the marked improvement in his appearance, and the scales recorded an increase in his weight of a little over six pounds. No doubt the relief to his nervous system of idleness and pleasant change of surroundings was responsible for much of the improvement he experienced, but it is surely significant that his carbohydrate tolerance proved equal to the task not only of dealing with a mixed and generous diet, but also of increasing the assimilative power of his tissues to the extent of a quite remarkable increase in his weight.

While it is true that carbohydrates ought to be limited in all cases of glycosuria, it is no less certain that in most instances patients do best with a moderate carbohydrate element in their diet, and in every case the problem to settle is how far starch, in one form or another, may be given without increasing the urinary sugar. For this purpose the first point to determine is the extent to which the glycosuria depends upon carbohydrate intake. If the patient be put for a week on a diet from which all sugar and starch is rigidly excluded, we will by a quantitative examination of the urine ascertain the minimum to which the sugar may be reduced by carbohydrate starvation. During the following week, he may have added to his daily menu one baked potato and a small quantity of gluten or other so-called non-starchy bread. And, in passing, it may be mentioned that most of the biscuits and breads advertised as being practically starchless are found to contain carbohydrate in a definite and often considerable amount. The foodstuffs prepared by Callard, von Abbott, and Blatchley are among the most reliable to be obtained in this country, but there are many others which, though they contain a greater amount of starch, are more palatable, and are preferable, because they contain less starch than, ordinary bread. Almond flour, cocoanut flour, and gluten flour may all be used for the preparation of cakes and biscuits to replace ordinary bread. At the end of a week the urine should again be tested and the starchy element increased or diminished according to the effect upon the sugar output which is found to have occurred. In some instances oatmeal is better tolerated than any of the other cereals, and its influence ought to be ascertained whenever the addition of potato is proved to produce no bad effect. The diminution or annihilation of glucose in the urine is not the only, nor always the safest, criterion of improvement. It is therefore always imperative to keep an observant eye upon the general nutrition. Whatever restriction in the diet be adopted, it is only justified if its modifying effect on the sugar excretion is accompanied by a maintenance of the general health. Continued polyuria and thirst, together with a progressive loss in weight, are evidences that all is not going well, and care must be taken that as the result of too severe dietetic restrictions the diminished amount of sugar is not too dearly paid for. The presence of acetone or diacetic acid ought in all cases to be looked for, and when found should be regarded as an urgent indication for a readjustment of the diet-plan, and probably for an increase in the carbohydrate allowance.

In the matter of dietetic treatment there is one plan which has not received so much attention as it deserves, namely, the effect to be derived from repeated short periods of absolute starvation. In the public mind it is a rooted conviction that complete abstinence from food even for a limited period must inevitably lead to such failure of strength and vigour as to make it a dangerous experiment. Experience proves, however, that this is not the case, and when we reflect how in all acute diseases and in some that are chronic, Nature withdraws all ordinary appetite for food, and leaves the patient to live for a time wholly upon himself, there is little cause for surprise that popular opinion has arrived at erroneous conclusions. Guelpa, of

Paris, has devoted very considerable attention to the value of starvation methods in several disorders of metabolism, and though his enthusiasm may have carried him to generalizations that are too sweeping to be altogether justified by the evidence, there is ample proof that the effect of such a plan is often surprisingly successful in re-establishing a better metabolic balance. I have recently devoted some attention to temporary starvation in cases of glycosuria, and the results have justified me in believing that though it may not be a means of cure it has a striking effect in producing amelioration of the symptoms. The explanation is probably to be found in the fact that during the starvation period the various internal secretions are afforded a chance of re-establishing that proper balance among themselves upon which metabolic integrity seems to depend. At any rate it is certain that in cases of glycosuria complete abstinence from food over a period of two or three days has a definite influence not only upon the amount of urine excreted, and of the sugar it contains, but also upon the subjective discomforts that sometimes accompany this condition.

I could quote many cases in illustration of the fact, and I venture to remind you of two patients during this session in whom I have been able to demonstrate to you the value of the method.

The one, a man of florid complexion, stout build and distinctively gouty tendencies, who may have suffered from glycosuria for a considerable time, was discovered to have sugar in his urine when admitted to the hospital on account of a surgical affection about five months ago. He had no marked polyuria, no excessive thirst, and no loss of weight, but his urine contained 2.5 per cent. of sugar. After a first starvation period of two days the sugar disappeared; after a second such period a week later it again disappeared, but returned to the extent of $\frac{3}{4}$ per cent. when he resumed food; after a third period of two days' abstinence during the following week, it disappeared once more, and when he left the hospital eleven days later the urine remained permanently free from sugar on an ordinary diet, from which, of course, sugar was excluded, but carbohydrates in the form of potatoes and torried bread were allowed in moderate amount.

The other case was an example of true diabetes, in which the man had emaciated to the extent of nearly 3 st., was pursued by unquenchable thirst and continuous hunger, and passed an average of 165 oz. of urine daily, containing from 4 to 5 per cent. of sugar with constant traces of acetone. This man was so hungry that the prospect of starvation at first alarmed him, but being persuaded to screw his courage up to make the attempt, he found to his surprise that after the first day's abstinence his thirst and hunger disappeared and the quantity of water he excreted diminished to half that to which he had been accustomed for months. This man has undergone four starvation periods—two of three and two of two days' duration—and, though his diabetes is not cured, the net result is that to-day his sugar is reduced to about 3 per cent., the amount of urine is never more in the day than from 70 to 80 oz., and he has lost entirely any excessive appetite for food or drink.

To these cases let me add two others from my private case-books:

A man aged 58, who had suffered from mild glycosuria for at least five years, had the following experience: Before a first starvation period of seventy-two hours his urine contained 21 grains of sugar per ounce, and the density was 1028; at its termination the sugar was reduced to 0.7 grain per ounce and the density to 1010. After a month, during which the sugar returned in diminished amount, he underwent another starvation period of sixty hours, before entering upon which sugar was present to the extent of 10 grains to the ounce. At its termination the sugar had entirely disappeared, and there was no recurrence for four days after a return to a moderately restricted diet. After another month, starvation was again practised, this time for twenty-four hours. Before fasting the urine contained 7 grains of sugar, but this again vanished at the end of twenty-four hours. Two days after resuming his usual careful dietary, Fehling's solution was moderately reduced, and gradually sugar reaccumulated to the extent of 3 grains in the ounce. A fourth period of twenty-four hours' fasting, after the expiry of a month, was submitted to, and the sugar, which beforehand measured 5 grains per ounce, again disappeared after the first twenty-four hours' starvation. It did not reappear until a week later, and then only to the extent of 1 grain per ounce. This patient is well nourished and of the gouty type. He has no polyuria, and no subjective symptoms to make him aware that his health is, in any way, seriously disturbed.

A lady, aged 54, the mother of eleven children, also of the florid, gouty type, was apparently quite well, except that within the last eighteen months she had lost about $1\frac{1}{2}$ st. in weight. She had no organic disease, but was passing an average of 80 oz. of urine a day, containing 15 grains of sugar in each ounce. A first period of seventy-two hours' starvation reduced the sugar to 2 grains; a second period of forty-eight hours' starvation caused its temporary disappearance for

several days; and a third similar starvation period, after another fortnight, again resulted in the complete disappearance of sugar, with only a very moderate recurrence a week later. This patient has experienced a decided improvement in her nutrition, and has put on 5 lb. in weight.

During the time of abstinence from food in all these cases the patients were allowed a breakfastcupful of tea morning and evening, and a large tumblerful of aerated water once or twice during the day. Every night at bedtime a pill containing 1 grain of calomel and 3 grains of extract of colocynth was administered with—the following morning—a dose of magnesium sulphate sufficient to produce one or two copious watery alvine evacuations.

Too much must not, of course, be attributed to this plan of treatment, but it may be at least claimed that three important results are established—first, that an immediate, even if temporary, diminution in the sugar output is achieved; secondly, that the sugar, when it reasserts itself, recurs in diminished amount; and thirdly, that the patient, far from experiencing any serious inconvenience from the complete withdrawal of food, rapidly loses all sense of hunger or thirst, and invariably finds a subsequent improvement in general health and in the sense of well-being. It has been suggested that such drastic measures may be fraught with the danger of increasing the risk of acidosis, but in the cases I have watched no such undesirable development has occurred.

Is the result due to a temporary disintoxication of the tissues whereby the normal equilibrium is afforded some chance of restoration? It is not an impossible explanation, and one which may be more readily accepted if it be conceded, as some observers have stated, that the pancreas is responsible not only for the completion of the digestive processes, but also, to some extent, for the scavenging work of the body.

The latest newcomer on the field of experimental therapeutics is radium, whose emanations are said to be able to cure a multitude of disorders, and among them diabetes. In regard to it, as to many others that have been equally loudly extolled, it will be wise to "wait and see."

In the choice of drugs, we are still driven to depend upon opium or its derivatives as our sheet anchor. In my own experience I find codeine the most valuable of all the opiate series, and in a large majority of cases the following combination affords me considerable help: Extract of valerian and pure carbolic acid, of each 2 grains; codeine, $\frac{1}{2}$ to 1 grain; and extract of cascara, $1\frac{1}{2}$ grains. The valerian steadies the nervous system, the carbolic acid disinfects the intestinal canal, the codeine controls the output of sugar, and the cascara provides for the daily evacuation of the bowel.

Salkowski and others have strongly advocated the administration of arsenic, but its only effect would seem to be a secondary result from its tonic influence on the nervous system. On the pancreatic theory of causation it is logical to endeavour to furnish the body artificially with the hormone provided under normal conditions by the islands of Langerhans. There are many preparations of pancreas on the market; but one of the best is issued by Fairchild Brothers, under the name of "Holadin." It is said to contain all the constituents of the gland, both digestive and internal secretory, and is put up in gelatine capsules, each containing 3 grains. I have used it repeatedly, and in some cases it has apparently been of value.

An annual sojourn at Vichy or Carlsbad and an equable, sunny, dry climate is of service to many patients, but so far as health resorts and climate are concerned, individual idiosyncrasy must be carefully considered as well as the indications otherwise which the general health of the individual suggests. One important point in the management of glycosurics, which is of universal application, should never be lost sight of, and that is the prejudicial effect upon all of them of excessive and prolonged strain, whether of mind or body. The more equable and uneventful the daily routine of life can be made, consistently with freedom from ennui and boredom, the more likely is the imperfect metabolism to succeed in maintaining the bodily processes in a condition consistent with a fair measure of good health. In those cases where, as a terminal event, coma threatens to supervene, we must depend upon salines in generous amount, given either by the mouth, or by the rectum, or intravenously, as the one and only slender chance on which we have to depend for saving the situation.

D

THE ACTION OF SALICYLIC ACID AND CHEMICALLY ALLIED BODIES IN RHEUMATIC FEVER.

By RALPH STOCKMAN, M.D.,

PROFESSOR OF MATERIA MEDICA AND THERAPEUTICS IN THE UNIVERSITY OF GLASGOW.

THE following account of the action and relative value of salicylic acid and chemically allied substances in the treatment of rheumatic fever has been drawn up as part of a scheme of work undertaken by members of the Therapeutical Subcommittee of the Association. It is based on results obtained by clinical observation supplemented by laboratory experiments. A number of the substances examined have proved to be inert, but I have included these results as they may have some value for future researches in the same field. Of late years numerous synthetic bodies have been introduced into practice as substitutes for the salicylates, but even a superficial survey of these so-called "new drugs" showed that the great majority of them are merely compounds which originally contain salicylic acid, or which form it in the body, and that they represent no new therapeutical idea or discovery. Their value, in short, can be estimated in most cases by the simple process of calculating their content of salicylic acid. Others of the remedies designated "antirheumatic" are merely analgesics and have no specific curative action. These considerations enabled me to limit very considerably the number of substances to be tested. The report as here presented is partly a critical estimate of the value of certain more or less well-known remedies in acute rheumatic infections, partly an examination of substances which seemed possible improvements on these, and partly a contribution to the relationship between chemical constitution and therapeutical action in these infections.

Unfortunately the bacteriology of acute rheumatism is still an undecided question. Using cultures of the *Micrococcus rheumaticus* (of Poynton and Paine, and Beattie), I have never been able to produce in animals any of the symptoms or lesions of rheumatic fever, and I have also been unable, by using a vaccine of the killed organisms, to obtain any curative effects or any constant reaction in patients suffering from rheumatism. The vaccines were mostly made from cultures obtained from Drs. Paine and Beattie, but some were bought from Messrs. Burroughs and Wellcome, and the doses given varied from half a million to 250 million organisms.

According to present views, the absence of any reaction to large doses of the dead bacteria tells against the specific pathogenic nature of the organism. Further, it is an organism difficult to grow satisfactorily and easily killed. For these reasons I used the yeast plant, a streptococcus, *Bacillus coli*, a hay infusion, or a fungus growth on gelatine, when I wished to test the relative antifermentative and germicidal strengths of any of the substances I was investigating. Their relative toxicity was determined when necessary on rabbits. The observations have extended over many years, but I have compressed the results obtained into as small a compass as possible, and, to avoid entering into details or side-issues, have given references to papers where these are discussed more or less fully.

PHENOL (C₆H₅OH).

The simplest of the aromatic compounds is benzol (C₆H₆), and, what may be regarded as one of its simplest derivatives, phenol, is wholly without any action in acute rheumatism, at least in such doses (2 grains every four hours) as can be conveniently given. Its action in stopping the fermentation of a solution of sugar by yeast is not a powerful one. I found that 1 in 200 completely prevented fermentation, while 1 in 300 delayed it, and weaker strengths had little effect.

BENZOIC ACID (C₆H₅.COOH).

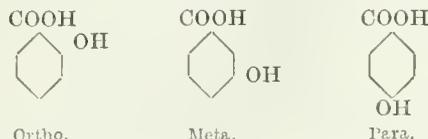

The introduction of the carboxyl group into the benzol ring brings about an important change, and confers a specific remedial action in acute rheumatism. When benzoic acid or sodium benzoate is given in doses of

15 to 20 grains hourly or two hourly, the action is unmistakable, but is very much weaker than that of sodium salicylate. Pain is diminished in two or three days, but it takes from four to seven days until the temperature and pulse-rate are satisfactorily reduced. No sweating nor any poisonous or depressing effects are noticed beyond sometimes slight buzzing in the ears. Yeast fermentation was prevented by benzoic acid in a strength of 1 in 500; 1 in 1,000 checked it, but fermentation still went on slowly for several days, and 1 in 2,000 had a slightly retarding effect only.

OXYBENZOIC ACIDS.

Salicylic Acid ($C_6H_4.COOH.OH$).

There are three hydroxy-benzoic acids formed by introducing OH into benzoic acid. Salicylic acid is the ortho-acid, while the others are known as meta- and para-oxybenzoic acids. They differ in the relative position of the COOH and OH groups in the benzol ring, thus—

and this slight difference in constitution exercises a profound effect on their pharmacological actions. In comparison with benzoic acid, salicylic acid is a much stronger antifermentative and antirheumatic, while the meta- and para-oxybenzoic acids have a very feeble action of any kind, and have lost the specific action possessed both by benzoic and salicylic acids in acute rheumatism.

Para-oxybenzoic Acid was given in 15-grain doses two-hourly, along with an equal amount of sodium bicarbonate, until about an ounce or more had been taken, and *Meta-oxybenzoic Acid* in the same way and dose. There was either no action or a very indefinite improvement, so slight as to make it doubtful whether the drug had had any influence. These two acids have a very feeble effect in preventing yeast fermentation. With both, 1 in 100 prevented it entirely, 1 in 200 delayed it, and weaker solutions had no action, while in the case of salicylic acid 1 in 2,000 inhibited fermentation entirely, and strengths up to 1 in 5,000 delayed it greatly. The relative action on a culture of *Bacillus coli* in bouillon was also marked. When the culture was kept in contact with a solution of 1 in 1,000 salicylic acid in water for three-quarters of an hour no further growth took place in plate cultures; with meta- and para-oxybenzoic acids a solution of 1 in 500 kept in contact for two hours was required.

The toxicity of the three acids to rabbits shows marked differences also. They were given by the mouth neutralized with sodium carbonate, and while in medium-sized rabbits 60 to 90 grains of salicylic acid usually proved fatal, with para-oxybenzoic acid 180 grains was required, and with meta-oxybenzoic acid up to 135 grains was given without any marked action.

Salicylic Acid in 15 and 20 grain doses every four hours has no superiority to sodium salicylate in effectively treating cases of acute rheumatism. It was given as a mixture suspended with mucilage, and did not cause any particular gastric irritation. Salicylic acid was the preparation originally used clinically, but was soon replaced by sodium salicylate, as the latter is more soluble, and also less irritating to the stomach.

SODIUM SALICYLATE.

Sodium salicylate ($C_6H_4.COO.NaOH$) in sufficient doses (90 to 160 grains or more in twenty-four hours) acts very satisfactorily when the infection is recent, when the inflammation is confined to the joints, and when treatment is begun early.¹ It is quite otherwise when the fibrous tissues of the heart valves or of the muscles or body generally are deeply implicated. Then it does not act so rapidly or effectively. Such cases linger on for weeks or months in spite of treatment, and relapses are very apt to occur.² For this reason, and especially to avoid the occurrence of permanent damage to the heart, it is a matter of first-rate importance to discover a more active antirheumatic than the salicy-

lates. In an uncomplicated case of acute rheumatism about 1 oz. of sodium salicylate spread over two to four days is usually sufficient to abolish symptoms, but this does not kill off the infective organisms, and hence relapses are apt to occur unless its administration is kept up in suitable doses for about three weeks or longer, when in most cases the infection has been overcome.

Mendl has advocated the intravenous administration of sodium salicylate,³ and as given thus it very rapidly lessens pain, but it is not an effective method owing to the dose (5 grains) being too small, and to the practical impossibility of giving it often enough to keep the blood sufficiently saturated.

Very large doses⁴ have also been advocated, with the idea of sterilizing the body—up to 400 and even 500 and 600 grains in twenty-four hours; but, apart from the risk of causing acidosis, it is doubtful if the body can be sterilized in this way, and it is not agreed that they are practically more efficient than smaller ones.

Sodium salicylate is a feeble germicide and anti-fermentative. It has almost no action on yeast or bacteria.

SALIGENIN.

Saligenin ($C_6H_4.CH_2OH.OH$) (o-hydroxybenzylalcohol) is chemically the alcohol of which salicylic acid is the corresponding acid, and in the body it is readily converted into the latter ($C_7H_6O_2 + 2O = C_7H_6O_3 + H_2O$), 100 parts yielding 111 parts salicylic acid. It is a white powder without much taste, is readily soluble in warm water and in alkalis, and does not irritate the stomach if pure. I treated four cases with it, giving 10 grains every two hours. Its action was very rapid and satisfactory. In one case the pain ceased in twelve hours and the temperature was normal in thirty-six hours; in another the pain and swelling of the joints had gone in thirty-six hours; in a third after twenty-two hours; in the fourth the fibrous tissue was widely affected, and 1,340 grains were required. It causes a good deal of perspiration, and two of the cases suffered from deafness. Outside the body it has no antifermentative or antiseptic action. In rabbits when given per os its action was rather irregular, but 45 grains was usually a fatal dose.

SALICIN.

Salicin ($C_6H_4.OCH_2OH.C_6H_4O_6$) is the glucoside of saligenin, and is hydrolyzed in the body into its two components, the saligenin being oxidized to salicylic acid. Scheffer⁵ states that this takes place in the blood. It yields only 43 per cent. of its weight of salicylic acid, and therefore needs to be given in a dose twice as large as sodium salicylate (of which 13.3 per cent. is Na). It is quite soluble in warm water, has a bitter taste, and if well diluted does not irritate the stomach. It is excreted in human urine as salicylic and salicyluric acids, never as unchanged salicin. Given in 20-grain doses hourly, or 30 grains every two or three hours, its action in rheumatic fever is highly satisfactory. I have often given 60 grains, and repeated it in two hours without any ill effects. Its action in acute rheumatism depends on the development of salicylic acid in the blood, but both it and saligenin differ somewhat from salicylic acid or sodium salicylate in their general action. A solution of 1 in 250 does not prevent yeast fermentation, and it seems to have in itself little or no effect on low organisms.

ACETYL-SALICYLIC ACID.

Acetyl-salicylic acid ($C_6H_4.COOH.OC_2H_5O$) is scarcely soluble in water, and the solution gives no purple colour on adding ferric chloride (no free salicylic acid). In the presence of alkalis the acetyl group splits off and leaves salicylic acid, a change which takes place in the duodenum, where at the same time sodium and other salicylates are formed. It is doubtful, however, whether the whole of it undergoes these changes, as it is a much more powerful analgesic than sodium salicylate, and this can only be accounted for by assuming that a part of it is absorbed unchanged and exercises this effect. A comparatively slight analgesic action such as acetyl-salicylic acid exerts cannot be satisfactorily studied in animals, but patients agree that even in non-rheumatic affections it lessens pain. This is true only to a very slight extent of salicin or salicylic acid.

In acute rheumatism doses of 15 grains three or four hourly act very satisfactorily. There is no reason to suppose that the action is other than that of sodium salicylate. I have found that it irritates the stomach in many people more than sodium salicylate does, and that it is equally liable to cause perspiration, deafness, and ringing in the ears. Serious drawbacks to its clinical use are that it is incompatible with sodium bicarbonate, that it cannot be pushed to large doses without causing sickness, and that it is insoluble in water and cannot be given as a mixture.

A solution of 1 in 250 does not stop yeast fermentation, so that any antifermentative or antibacterial action must only occur when its salicylic acid is split off and can act by itself.

SALOL.

Salol (phenyl-salicylate) (C₆H₄.COOC₆H₅.OH) is split up in the small intestine into salicylic acid and phenol. The dose is limited by the poisonous action of phenol, and it is therefore quite impossible to give as much of it as will yield enough salicylic acid to treat efficiently a case of rheumatic fever.

QUININE SALICYLATE.

Roughly, one-third of this salt is salicylic acid and two-thirds quinine, and the dose is usually stated as 1 to 5 grains. The quinine part is inert in rheumatic fever, and the salicylic portion is quite insufficient in amount. Cases treated with 10 to 15 grains six-hourly showed practically no improvement. Deafness and ringing in the ears are brought on very readily by it.

METHYL SALICYLATE.

Methyl salicylate (C₆H₄.COOCH₃.OH) can be given internally, in 10 to 15 minim doses every three or four hours, in milk, or on sugar, or in emulsion, and it can be externally applied at the same time to the inflamed joints. Cases treated in this way improve very rapidly, and there can be no doubt about the efficiency of the method.⁶ It is, however, very apt to cause nausea and sickness.

Baas says that 8 to 13 per cent. of it is excreted in the urine unchanged, and the remainder as ethereal salicyl-sulphate.

GLYCOSAL.

Glycosal (C₆H₄.COOC₃H₅(OH)₂.OH) is a glycerin-ester of salicylic acid. Given in 90 to 120 grains per day its action was feeble and unsatisfactory, owing to the insufficient content of salicylic acid.

SALICYLURIC ACID.

Salicyluric acid (C₆H₄.CO(NH₂.CH₂.COOH).OH) is the form in which salicylic acid is chiefly excreted in the urine, accompanied by a certain varying amount of salicylic acid always in very much smaller quantity. It is formed in the body by a combination with glycochol (amido-acetic acid, NH₂.CH₂.COOH). It has lost almost entirely the poisonous and antifermentative and antibacterial actions of salicylic acid, and it is quite inert in acute rheumatism.⁷ The fact that salicylic acid is so rapidly and so largely converted into this inert substance in the body explains why it is necessary to give it in frequently repeated and large doses to maintain its effect.

DIMETHYL-SALICYLIC ACID.

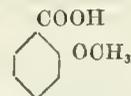

Dimethyl-salicylic acid, methylsalicylate of methyl (C₆H₄.COOCH₃.OCH₃), is an oily volatile substance with a slight odour and an irritating aromatic taste. It gives no purple colour with ferric chloride. Four grains given per os to a rabbit had no action, but 8 grams was fatal after some hours. The urine gave no purple colour with ferric chloride. Doses of 20 minims four-hourly proved absolutely without action in rheumatic fever. It is not converted into salicylic acid in the body, and this accounts for its non-effect. A solution of 1 in 1,000 did not prevent yeast fermentation.

TOLUIC ACID, SALICYLOUS ACID, ETC.

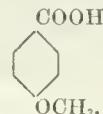

Sodium Methylsalicylate (C₆H₄.COOCH₃.ONa), and Salicyloous Acid (salicylic aldehyde) (C₆H₄.COH.OH), the three Toluic Acids⁸ (C₆H₄.COOH.CH₃) and Disodium Salicylic Acid (C₆H₄.COONa.ONa) are all too irritating to give internally.

METHOXYBENZOIC ACID.

Methoxybenzoic acid (C₆H₄.COOH.OCH₃), methylsalicylic acid—

is the ortho-acid, and Anisic Acid is the para-acid—

The latter has almost no action of any kind. The former has no perceptible action in acute rheumatism in 15-grain doses four-hourly. The urine gives a very faint purple colour with ferric chloride, but practically it is not converted in the body into salicylic acid, and it has little or no action of its own.

Eight grams neutralized with sodium carbonate and given to a rabbit per os had no action on it. A strength of 1 in 500 prevented yeast fermentation in a solution of sugar, but lesser quantities had little or no effect.

POPULIN.

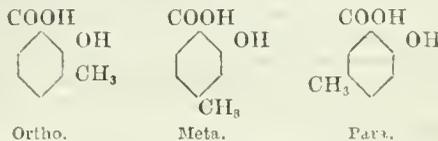

Populin (C₁₅H₁₇ (C₇H₇)₂ O₇) is benzoyl-salicin. It is in white crystals resembling salicin in appearance. Doses of 10 grains hourly and 20 grains three-hourly had no action. The urine sometimes gave a slight purple colour with ferric chloride and sometimes not. Four grams per os had no effect on a rabbit.

TETRA-BENZOYL-SALICIN.

Tetra-benzoyl-salicin was equally without action. I had hoped that the introduction of the benzoyl molecule into salicin would greatly increase its efficiency, but it did not do so.

CRESOTINIC ACIDS.

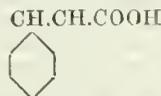

Cresotinic acid (C₆H₃.COOH.OH.CH₃). Three of the cresotinic acids have the following formulæ:

and all three, but especially the ortho- and meta-acids, have a powerful antirheumatic action. They have, however, no special advantages compared with salicylic acid, and as I have described their action in detail elsewhere⁹ I need not go into the matter again here. In all three the COOH and OH groups have the same relationship as in salicylic acid.

CINNAMIC ACID.

Cinnamic acid, C₉H₇ (CH.CH.COOH)

is a combination of phenol with acrylic acid (CH₂.CH.COOH). Sodium cinnamate can be readily taken in 15 or 20 grain doses. In the body it is converted into benzoic acid, and although this exerts a mild but practically unimportant effect in acute rheumatism, in itself the cinnamate has no action. The acid is a fairly powerful antiseptic and antifermentative. A solution of 1 in 1,250 prevented yeast fermentation, 1 in 2,000 did not do so, and 60 grains given to a rabbit in emulsion per os had no apparent action.

COUMARIC ACID.

Coumaric acid (C₉H₇.CH.CH.COOH.OH) has the same chemical relationship to salicylic acid that cinnamic has to benzoic acid.

Only the ortho-acid was used, neutralized with sodium bicarbonate. It proved to be without effect. Six grams did not affect a rabbit, nor did a solution of 1 in 1,000 do more than slightly hinder yeast fermentation.

PHTHALIC ACID.

Phthalic acid, $C_6H_4(COOH)_2$. The ortho-acid given in 20-grain doses four-hourly, neutralized with sodium bicarbonate, has a very slight antirheumatic action. In 8-gram doses it is not fatal to rabbits, and it is very feebly germicidal or antifermentative. *Iso-phthalic Acid*, the meta-acid, seemed to be a quite inert substance in doses of 120 grains daily.

LOCAL APPLICATIONS.

The application of certain salicylic compounds to acutely inflamed joints and muscles greatly eases rheumatic pain, but the number of those which can be absorbed through the skin is very limited.

Methyl Salicylate is the most used and is the most efficient. It is seldom irritating to the skin, and can be rubbed in or applied as a dressing either undiluted or as three parts to one of olive oil. *Ethyl Salicylate* and *Methyl Meta-cresotinate* have the same effect, but their odour is equally pungent.

Mesotan ($C_6H_4COOCH_3OCH_3OH$), a methoxymethyl ester of salicylic acid, is efficient in lessening pain, but has the important drawback of being apt to cause troublesome eruptions.

Spirosal and *Umarene* are oily salicylic ethers without much odour, but also without much action.

A 10 per cent. ointment of *Salicylic Acid* made up with lard and a little oil of turpentine, is absorbed through the skin and has a marked local anodyne action, both when rubbed in and used as a dressing; but it is, on the whole, not suitable for ordinary use, as it damages the epidermis.

I have also used largely *Sodium Salicylate*, 2 or 3 grains in 10 minims of water, injected locally by means of a hypodermic syringe. This lessens or abolishes pain at the spot almost at once, but the effect is very transient and lasts only for about half an hour to an hour. The amount which can be given locally by ionic medication is also too small to be satisfactory in its effect.

None of these substances can be absorbed through the skin in such amount as to influence materially the general infection, and hence their value is merely in lessening local pain.

It is said that decoction of willow bark has been long and successfully used by the Hottentots in Orange River Colony for acute rheumatism,¹⁰ and that in the United States the wintergreen is similarly employed by country people, but as regards our present-day practice we may take it that salicin was first used in acute rheumatism by T. J. MacLagan¹¹ in 1874 and salicylic acid independently by Buss¹² in 1875. I think it is correct to say that the discovery of the specific antirheumatic action of both these substances was a matter of accident, and that in the thirty-nine years which have since elapsed no substantial improvement has been made on them and no new therapeutical path has been struck. So far as I am able to judge, the real efficiency of the numerous compounds which have been recommended by manufacturing chemists in rheumatic affections depends solely on the amount of salicylic acid which they contain or develop in the body. Little is known as to how chemical constitution influences the antirheumatic action of this group of substances. As I have previously pointed out, benzoic acid, formed by the introduction of COOH into benzol, shows this specific action, but when two molecules of COOH are introduced (phthalic acid) the antirheumatic effect is diminished almost to vanishing point.

When, however, OH is introduced into benzoic acid to form salicylic acid, the efficacy is enormously increased, and it looks as if this OH were the determining factor, yet the stereo-isomers of salicylic acid, m-oxybenzoic and p-oxybenzoic acids, have no action. When the OH of salicylic acid is altered into OCH₃, as in ortho-methoxybenzoic acid, all antirheumatic effect disappears.

That the COOH molecule also has a dominating influence is shown by the fact that in cinnamic and coumaric acids,

where it is disturbed, the specific antirheumatic action is completely lost.

Methyl salicylate develops salicylic acid in the body and retains the specific action, while dimethyl-salicylic acid, which does not do so, is inert, and the same holds true in the case of other salicylic compounds, such as salicin (which is active) and populin (which is inactive). The cresotinic acids are the only substances which are known to equal or even approach salicylic acid in efficacy. The prevention of heart lesions, valvular and myocardial, should be the great aim of our treatment, yet it is notorious that heart lesions occur very commonly even while large doses of salicylates are being administered. It is still an open question whether these lesions and rheumatic lesions generally are caused by colonies of microbes or by toxins, nor do we know definitely whether the salicylates act as antimicrobics or as antitoxins.¹³ The most immediate explanation of their action is that they kill or injure a causal microbe, but it has also been maintained that the almost instantaneous although transient effect of a small dose given intravenously points to an antitoxic action, and that when given per os the rapid abatement of symptoms apart from the real cure, as shown by the tendency to relapse, points in the same direction.

It is not seriously held at the present day that any of our germicidal remedies can be given in sufficient amount to kill bacteria in the human body. The most we can hope for is that their vital activity and capacity to produce toxins may be abated, and that thereby the natural defensive agencies of the body will be enabled to deal with them more readily and effectively so that the infection is got rid of. Most probably this is what occurs in rheumatic fever under salicylic treatment, and it explains the tendency to relapse if the remedy be prematurely stopped or not given in sufficiently large doses.

But the most important of the many unsolved problems in the pathology and treatment of rheumatic infections is undoubtedly the discovery of a remedy powerful enough to abolish or greatly lessen the chances of injury to the muscle and valves of the heart. If this were successfully accomplished the incidence of serious heart disease would diminish to something like one-third of its present amount.

THE fifth of the Galton Laboratory lectures on national eugenics was delivered by Mr. W. Palin Elderton, Fellow of the Institute of Actuaries, at University College, London, on March 11th. Mr. Elderton, whose subject was the mortality of the phthisical under sanatorium and tuberculin treatments, said that it was difficult to obtain exact figures, owing to the confusion which existed concerning the stage the disease had reached when the patient began the treatment and the precise nature of so-called cures. It was true that in recent years the mortality amongst advanced cases under sanatorium treatment had decreased considerably, whilst the number of cures amongst incipient cases had greatly increased. This, however, might possibly be due to the fact that advanced and incurable cases were not received in sanatoriums so readily as formerly, whilst, on the other hand, a far larger number of incipient cases were admitted, increased knowledge and experience having rendered it possible to diagnose the presence of tuberculosis in its very earliest stages. At the present moment it was almost impossible to come to a decision as to the relative merits of sanatorium and tuberculin treatment. It was as yet too soon to say definitely which treatment was the more successful; but what was certain was that the mortality amongst consumptives both in and out of sanatoriums was still extremely high. The aim of the medical profession at the present moment was to reduce this heavy death-rate at all costs; and he was confident that the day would come when some means of effectually checking the progress of the disease would be discovered.

The Goulstonian Lectures

ON

DEATH BY ELECTRIC CURRENTS AND BY LIGHTNING.

DELIVERED BEFORE THE ROYAL COLLEGE OF PHYSICIANS
OF LONDON.

BY A. J. JEX-BLAKE, M.A., M.B., B.CH. OXON.,
F.R.C.P. LOND.,

ASSISTANT PHYSICIAN TO ST. GEORGE'S HOSPITAL AND TO THE
HOSPITAL FOR CONSUMPTION, BROMPTON.

LECTURE III.—DEATH BY LIGHTNING (*continued*).

The Mode of Death by Lightning.

It would seem as if sudden death by lightning might occur in at any rate three different ways—by failure of the heart, by failure of the respiration, and by failure of both together. In the vast majority of cases the senses are lost at once, and in most death takes place very rapidly if at all. The extreme suddenness with which it must have occurred, as proved by the natural position of the corpse and its placid expression, has often been noted. As is the case in non-fatal strokes, there is reason to suppose that the nervous system is profoundly affected, though no microscopic lesions may be demonstrable.

1. *Death by failure of the heart*, which may be supposed to be thrown into a state of fibrillation, is assumed to be the commonest mode of death by lightning; in man it is probably final and irremediable, although the respiration may continue for a short time. The face in these instances is pale, free from congestion.

2. *Death by failure of the respiration* from Brown-Séquard's inhibition, while the heart continues to beat until asphyxia stops it, would explain why so many of those killed by lightning present all the *post-mortem* appearances of death by asphyxia. Such deaths might be averted by artificial respiration, continued until the respiratory centre in the bulb has had time to recover from the injury inflicted on it by the stroke. In non-fatal cases it has been noted that the patients' symptoms were those of asphyxia or the breathing of irrespirable gases^{41, 92}; Niek records an instance in which gradual failure of the respiration became complete in about four hours. Apparent death may last for three-quarters of an hour, yet be followed by recovery (Sahut). Kelly has described an instance where the heart was still beating ten or fifteen minutes after the stroke, though respiration had ceased; but in this instance artificial respiration did not restore life.

3. *Death by Failure of the Heart and Respiration together*.—It is probable that this form of death occurs after lightning-stroke, just as it may after the passage of industrial electric currents; but I do not know of any evidence to prove that it does.

4. In a very few cases, mentioned already, gross lesions of the brain have been found *post mortem*, and may well have been the cause of death in these instances. The older *post-mortem* examinations very generally failed to bring to light any pathological changes in the central nervous systems of the victims of lightning-strokes. It is possible that the more delicate modern methods of investigation would not give such negative results here.

Prognosis.

Unless sudden death follows, the probability that a person struck by lightning will recover is large; Dechambre collected 365 instances in which the immediate effects of the stroke were survived, and found that only 15 of these victims died subsequently from late effects of the lightning. It seems to be very generally assumed that immediate treatment would improve the prognosis considerably, and that many of the people killed by lightning are only apparently dead, and still capable of recovery if properly treated during the next few minutes. I do not know of any statistical evidence to prove this point.

Prophylaxis.

The ancient Greeks and Romans protected themselves against lightning by the use of incantations and amulets,

and by wearing the skins of animals like the seal, hippopotamus, and hyaena (Fougères) that were supposed to be immune to lightning-stroke; they also had the good sense to take refuge in caves or cellars during thunderstorms. An Etruscan—Tages—protected his landed property by setting up an ass's head as tutelary deity, suitably enough. In the Middle Ages flight to England was advised, as that country was supposed to be free from lightning—a view sadly contradicted by Müller in 1690.

At the present day only general advice can be given, as the accumulated records have shown that no place is completely protected against lightning. It is certainly safer to be indoors than out, and a large house is much safer than a shanty. The windows and doors of the room in which one is should be shut, and one should keep away from the walls, and particularly from the fireplace, because, when a chimney-stack is struck, the contents of the chimney and the fireplace are often blown out into the room and cause bodily injuries. A great many people have been struck in sheds and barns, especially when they have been near doors or windows, or in currents of air. Turley recommended the centre of a railway carriage at a distance from the engine as the securest place of all; Schefcik, a feather bed. To take refuge in the cellars merely to avoid a thunderstorm is not necessary as a routine, though in exceptional cases it may be advisable.

The advice given by various authors to persons caught out of doors in a thunderstorm is contradictory. It is probably unwise to take shelter in a shed unless one can get out of the way of doors, windows, and draughts while one is in it. A shed containing domestic animals is certainly more dangerous than the open. If one has to remain in the open, there are certain things that should be avoided at any cost. The first of these is the proximity of wire fences, because when such a fence is struck the electric discharge may be carried along the wires and cause death at a distance from the place actually struck. The second is proximity to such things as hedges, ponds and streams, isolated trees, crowds of people and herds of domestic animals. Crowds of people or animals seem to have a mild attraction for lightning, very possibly by virtue of the warmth and dampness they impart to the atmosphere immediately round them. Certain varieties of trees are less dangerous than others; in similar conditions the beech is much less often struck than any other tree that is common in Europe, while the oak is very many (perhaps forty or fifty) times more liable than the beech to be struck and injured. This may be because the electric conductivity of beech trees is low at all times of the year, beech wood being always rich in fat and poor in starchy matter.²⁶ Hence, if one has to take shelter under a tree, that tree should be a beech,³² and one should not be near its trunk. But to take cover in a forest or wood is quite safe, as trees *en masse* are rarely struck. If one is in quite open country, there is nothing to show whether it is better to be on high ground or in a valley; it seems to be agreed that to lie or sit down is safer than to stand up, that umbrellas should not be hoisted, and that riders and drivers should dismount and not stay near their horses or conveyances. It has often been said that to have had the clothes thoroughly wetted by rain and rendered conducting gives some protection to people who are struck by diverting the path and violence of the lightning from the body to the clothes. I have found seven well-recorded instances in which the effect of the stroke was to blow all, or practically all, the wetted clothes off the body, by the generation of steam, as I believe. There can be no doubt that a part of the energy of the lightning was expended on the clothes in these cases, but three of the seven victims were killed notwithstanding. So the protection of wet clothes cannot be considered at all complete.

Vincent makes an ingenious practical suggestion—perhaps too ingenious. It has long been known, he says, that animals are more liable to be struck than men; hence one should always take a dog out walking in order that if a thunderstorm comes on, the dog, already the friend of man, may also serve as his lightning conductor.

* Compare the German proverb:

Vor den Eichen sollst Du weichen,
Vor den Fichten sollst Du flüchten,
Doch die Buchen sollst Du suchen.

In these days, when vaccine therapy is so widely employed, it is not without interest to note that in South Africa both the Zulus and the Caffres inoculate themselves against lightning by rubbing into cuts the flesh of animals (bullocks) killed by lightning (Frazer).

Treatment.

Persons struck and apparently killed by lightning should at once be given plenty of fresh air, their clothes should be loosened, and artificial respiration by Schäfer's or Sylvester's method should be applied and should be continued until either recovery occurs or cooling of the body and *rigor mortis* show conclusively that death has taken place. In the medical writings of from fifty to two hundred years ago one often sees bleeding recommended, and this might well be of service in those cases of lightning stroke in which the heart goes on beating while the respiration stops. If it were immediately—within a few minutes—available, to give strong electric shocks to the *præcordia* would be well worth trying in desperate cases. As regards other remedies—such as stimulants in all forms, hot or cold applications, the inhalation of pungent vapours—very many have been recommended, but none seem to have met with any success.

In conclusion, I may say that it is very highly improbable that any one of us will be struck by lightning. But to the attention of those who are struck and survive may be recommended the French superstition that such people have for forty days the power of curing all kinds of disease by "touching." I may quote for their encouragement the case¹⁸ of a girl of 8 who was struck at Douai, and afterwards "touched" over 600 persons in this way; and, as it is recorded that the parents did not refuse the modest offerings presented by the visitors, one may assume that the girl "touched" their pockets as well as their persons. As regards those who are fated to be killed by lightning, the only consoling thought I have been able to find for them is taken from the recently published diary of Queen Victoria. On June 1st, 1838, the Queen wrote:¹⁰²

"I told Lord Melbourne I never could forgive him for having stood under a tree in that violent thunderstorm at Windsor last year; he said, 'It's a hundred to one you're not struck,' and then added, smiling, 'It's a sublime death.'"

Remarks

ON

THE FOOD REQUIREMENTS OF CHILDREN.

BY

CHALMERS WATSON, M.D., F.R.C.P.E.,

ASSISTANT PHYSICIAN, ROYAL INFIRMARY, BRINBURGH.

As a member of a subcommittee of the Edinburgh School Board, co-opted to advise as to the best means of supplying nutritious meals at small cost to the necessitous and other children fed by the Board, I was led to make the following investigations.

1. To ascertain by chemical analysis the amount of food consumed daily by apparently healthy children, about 5 years old, in good social circumstances.

2. To devise nutritious one-course meals at small cost, suitable for a large number of children (2,000 or more) fed by the school authorities.

The results of these investigations will be shortly stated:

Brief reference may first be made to the part played by proteins in the dietary. In early life proteins have special importance from the physiological point of view because they are the chief tissue builders; the proportion of protein in the dietary of children should therefore be relatively high. It is important to note, however, that the nature and source of the protein require quite as much consideration as the amount consumed. In later life proteins have special significance from the pathological point of view, because, being incompletely oxidized in the body, products of their incomplete combustion are liable to accumulate in the blood and tissues, and there give rise to various manifestations of so-called "autointoxication." The commonly accepted standard of daily food requirements in adults is that associated with the names of Atwater and Voit, namely:

| Protein. | Fat. | Carbohydrates. | Calorie Value. |
|-----------|-----------|----------------|----------------|
| 120 grams | 65 grams | 500 grams | 3,147 |
| (4.2 oz.) | (2.2 oz.) | (17.6 oz.) | |

In recent years considerable doubt has been thrown on the accuracy of this teaching by the important researches of Chittenden, whose results led him to conclude that the standard hitherto accepted as correct is unduly high. In regard to protein in particular, Chittenden has laid down a standard of 80 grams or less of protein as the physiological intake for an adult under ordinary conditions. We are not here, however, concerned with the food requirements in adults, and the above figures are merely cited because of their bearing on what is to follow.

I. THE FOOD REQUIREMENTS OF CHILDREN.

So far as I have been able to learn from the study of textbooks on dietaries of children, authorities give little or no precise information on this subject. Details are given as to the kind of diet suitable for children of different ages, but nothing is said as to the total amount of protein, fat, and carbohydrates that should comprise the diet of a child, say, of 5 or 10 years. When we turn to textbooks of physiology and of dietetics, a definite statement is laid down as follows:

A child from 3 to 5 requires 0.4 the food a man at moderate work.

A child from 6 to 9 requires 0.5 the food a man at moderate work.

A child from 10 to 13 requires 0.6 the food a man at moderate work.

On looking into the subject, it would seem that this estimate has been arrived at empirically, the figures, once laid down, having been reproduced by all subsequent writers on the subject. If for the moment we accept the Atwater standard as a reliable guide for the food requirements of an adult, we find that the daily food requirements of a child of 5 years are as follows:

| Protein. | Fat. | Carbohydrates. | Calorie Value. |
|----------|----------|----------------|----------------|
| 48 grams | 30 grams | 200 grams | 1,270 |

No attention is paid to the salts in the dietary, as these

In his introductory remarks on the health of Colombo, Ceylon, for 1911, Dr. Philip, M.O.H., states that the mean temperature of the year was much the same as the average, but there was, for the ninth year in succession, a great shortage of rain recorded (24.06 in.). The birth-rate during 1911 was higher than the average, but, owing to the large number of children of Colombo parents who are born and registered in districts outside the town, the birth-rate as recorded—24.7 per 1,000 living—does not afford a true measure of the fertility of the population, which is undoubtedly great in the case of the Burghers and Cingalese. The general death-rate—33.8 per 1,000 living—was rather above the average, though there was a reduction in the mortality amongst Europeans. Amongst the principal causes of deaths, only pneumonia and enteric fever showed an increase; but, in the case of enteric, the apparent increase was more than counterbalanced by the decrease in the number of deaths ascribed to simple continued and remittent fever, both of which terms were being, to a large extent, abandoned by the medical profession. The mortality from phthisis had shown a noteworthy improvement during the last two years. The infant mortality, which had been improving steadily for a series of years, was higher than the record low rate of 1910, but was still 22 per 1,000 below the average, the death-rate per 1,000 recorded births being 316. There was a considerable increase in the number of infectious diseases notified and dealt with during 1911 compared with the previous year, which was in a large measure due to the notification of phthisis having been made compulsory, and to an improvement in the diagnosis and notification of enteric fever. Dr. Philip remarks, with regard to the food supply of Colombo, that proper food laws are much required, but that they could not be properly administered unless the council appointed a sufficient staff for the purpose. The housing problem has become very acute, both as regards the insufficiency of accommodation and the existence of unhealthy areas and unhealthy dwellings. A municipal bacteriological laboratory was instituted during the year, and Dr. Hirst assumed duty in July.

are amply provided for in any dietary which will give the above supply of protein, fats, and carbohydrates. In order to ascertain the actual amount of protein, fat, and carbohydrates taken daily by children in good social circumstances, I have made an analysis of the diet of some apparently healthy children—one member of my own family, the others of children of my medical colleagues, who took an interest in the observations and took all possible precautions to furnish accurate data. The equivalent of an average day's diet was set aside, thoroughly mixed, dried to constant weight, weighed, and a known amount taken for estimation of the protein, fats, and carbohydrates. The proteins are calculated from the nitrogen estimation (Kjeldahl), the figures for N being multiplied by 6.1. The fat was estimated by extraction with Soxhlet apparatus, the figures for carbohydrates being arrived at by differences. The age, height, and weight of the children are recorded, and also any points of interest in the composition of the dietary.

TABLE I.—Showing Nature and Composition of Diet in Eight Children Aged 4 to 7.

| Age. | Height. | Weight. | Total Dried Food. | Protein. | Fat. | Carbo- hydrates. | Details of Food. |
|--------------------|---------|---------|-------------------|----------|-------|------------------|--|
| | ft. in. | st. lb. | gms. | gms. | gms. | gms. | |
| 4 | 3 2 | 2 12 | 220 | 44.0 | 41.5 | 134.4 | Mixed diet. |
| 4 | 3 9 | 3 2 | 338 | 52.8 | 104.1 | 181.0 | Mixed diet, por-ridge. |
| 4 | 3 5 | 3 2 | 260 | 64.5 | 39.9 | 175.4 | Mixed diet, grape nuts, cream. |
| 5 | 3 5 | 3 0 | 384 | 74.6 | 60.9 | 248.4 | Mixed diet, grape nuts. |
| 4 | 3 5 | 3 0 | 329 | 75.6 | 58.4 | 195.3 | Lacto-vegetarian diet, fruit in abundance. |
| 5 | 3 7 | 2 11 | 333 | 78.6 | 60.2 | 194.6 | Mixed diet, no red meats. |
| 7 | 4 0 | 4 1 | 398 | 79.1 | 70.9 | 248.2 | Mixed diet, porridge twice daily. |
| 4 | 3 6 | 3 2 | 435 | 108.0 | 117.0 | 210.0 | Mixed diet + three pints milk. |
| Average of 1 to 8. | | | | 72.1 | 69.1 | 198.4 | 1,751 calories. |

The protein intake ranged from 44 grams in No. 1, a fairly sturdy small boy, to 108 grams in No. 8, a boy of excellent physique and high physical energy. The diet of No. 8 included an extra supply of milk, this having been given for some months on account of an enlarged submaxillary gland, a sequel to tonsillitis, which was regarded as possibly of tuberculous origin.

The question then arises whether we should accept the forementioned Atwater standard of 48 grams protein and 30 grams fat as a reliable standard, or 72 grams protein and 69 grams fat, the average figures of this series. A knowledge of the physique, colour, and state of vigour of the children referred to inclines me to accept the latter as the more nearly correct standard. In comparing the figures for protein for the child with those of the adult it should not be lost sight of that much of the protein in the child's diet is in the form of milk, the protein of which is much more easily digested and absorbed than the protein entering largely into the diet of the adult. In the interpretation of the above data I would emphasize three points:

1. Too much importance must not be attached to the chemical composition of the food *per se*—for example, a child of 5 may be able to digest and absorb to advantage a quantity of protein and fat in the form of milk much in excess of what it can advantageously take in the form of meat foods.

2. In children of pronounced tuberculous or gouty tendency special rules apply. In the former the proportion of protein in the diet should be appreciably higher than the accepted standard, the protein being given in the form of extra milk, eggs, and red meats. In the case of child No. 8, for instance, I believe that the extra protein and fat in the dietary given over many months was a physiological one for the child in question. In gouty children, on the other hand, the amount of protein, and more especially in the form of rich animal food, should be judiciously restricted during the whole of the early growing period. I believe that the special advantages of an extra supply of protein in the one condition and restriction of it in the other are explained in great part by the specific effects of the diet on the thyroid gland as revealed by the results of my experimental investigations.¹

3. The third point to which I wish to refer is the importance of pure food. It is probably no exaggeration to say that the medical profession, no less than the public, have a very inadequate idea as to the extent of minor or major adulteration of common foodstuffs. Bread is an important illustration. A large proportion of bread in daily use is now made from flour which has been artificially bleached by the passage of nitrous oxide fumes. These are produced by an electrical discharge, the process being described by the parties interested as "electrified air," and in ignorance accepted by millers and bakers as a process "free of chemicals." The researches of Professor Ladd, U.S.A., Professor Halliburton, and the author, among others, have shown that the digestibility of flour so treated is, *in vitro*, appreciably reduced, and as there are, unquestionably, no compensating advantages in the process from the physiological and dietetic point of view, it is advisable that all bread should be made from the natural product of the wheat. It is conceivable that a child would thrive better on a diet containing a smaller amount of food in a pure form than on a diet which is richer from the point of view of chemical composition, but with its nutritive value impaired by the addition of various preservatives.

4. A further point of importance is the use of "hard" food, adapted for promoting mastication, giving meat in a form which necessitates chewing, bread in baked form for similar reasons, and at the same time restricting indulgence in sugar and sweets, which promote fermentation in relation to the teeth, with resulting caries.

II. NUTRITIOUS MEALS AT SMALL COST.

The question of supplying diets which are both cheap and nourishing is very important. To a man and his wife with three or four children and an income of £1 a week or less the question of how best to expend the sum required for the necessary foodstuffs is, or ought to be, a very vital one. There is, unfortunately, no doubt that inadequate attention is paid to this point, with the result that not a little of the malnutrition seen in the children of the poorer classes at the present time is due to ignorance rather than to actual poverty. This is very clearly brought out in the report of Sir George Newman, chief medical officer of the Board of Education, for 1910. This report not only discloses the fact that a very large proportion of the children are suffering from diseased conditions of various kinds, all of which are calculated to interfere with the conduct of education, and many with the ultimate attainment of sound physical development, but it discloses the fact that a considerable percentage of children are also suffering from a greater or less degree of malnutrition. In plain English, they are half starved. The report leads to the conclusion that it is too widely diffused to be attributable to poverty in more than a small proportion of cases; a more probable explanation seems that afforded by the extraordinary ignorance of English women of the industrial classes concerning food values, cooking, and general economy of dietetics.

Further, additional interest and importance now attach to the subject of cheap and nutritious foods in view of the Provision of Meals Act, 1906, which empowers educational authorities to supply school children with meals, the cost of which is met out of the rates, or, in part, by voluntary subscription. Some idea of the extent to which this power has been exercised will be learnt from the fact that in 1909-10 the cost to the rates of the meals so provided by the educational authorities was £134,105. As the principles to be observed in the feeding of a family of six or seven, where the income is very small, are similar to those applicable when a large number of children have to be fed out of the rates, it is possible to gain information of value for the family from the results of the experience recorded in the past year or two by various educational authorities.

It may be assumed that the essentials to be laid down are the following:

1. The food must be nourishing and ample in amount.
2. The food must be as cheap as possible consistent with 1.
3. The food must be of a nature that can be readily cooked with the limited facilities available in a one or two roomed house.
4. In children, satisfactory rate of growth, increased vigour, and more efficient education must be the result.

Oatmeal, peas, beans, and lentils are, in virtue of the large amount of protein, fats, and carbohydrates present, highly nourishing foods, and have the merit of cheapness.

For example, a bowl of thick lentil soup containing $\frac{1}{2}$ lb. of lentils with a slice of bread, costing about 7d., contains much more nourishment than $\frac{1}{2}$ lb. of meat and a slice of bread, costing about 4d.

The most important meal of the day is dinner. In the case of very necessitous children it is possible to give, if necessary, at least half of the total daily food required at this meal. It may be given in the form of a two-course dinner or a one-course meal. An excellent series of cheap two-course dinners was published in 1907 by Dr. Ralf Crowley in conjunction with Miss Marion Cuff for the City of Bradford Education Committee. This report gives details of seventeen two-course dinners, of which about half contain meat, adapted for a family of seven, the cost of food materials (in 1907) ranging from 11d. to 24d. per head. The average food value of the dinners in protein and fat was 29 grams (1 oz.) and 18 grams ($\frac{3}{4}$ oz.).

The "Bradford" meals are perhaps better adapted for families with an income of 25s. weekly or upwards, as, in addition to the expense, the trouble involved in the cooking is in many instances beyond the facilities available in the restricted house and firing accommodation of the very poor.

When a two-course dinner of soup and pudding is relied on as an ample meal, especially for children, care must be taken to see that the proper amount of nourishing food is given in each course. Some time ago I analysed three two-course dinners which were supposed to be planned on the Bradford system, and found the composition in protein and fat as follows:

| | |
|-------------|------------|
| Protein. | Fat. |
| 20.6 grams. | 1.8 grams. |

The deficiency was accounted for by the soup being too thin and the puddings also lacking in nutritive value.

The question of a good one-course dinner is important. In many of the houses of the poor the cooking facilities—one small open grate—are not well adapted to providing a two-course meal if such were otherwise available, and in connexion with the feeding of large numbers of school children there is certainly economy of time and labour, and possibly of expense, in a one-course as compared with a two-course meal. Experience has shown that a one-course meal at low cost can be made as nourishing and attractive to children as a two-course meal at similar outlay. It is of interest in this connexion to refer to the nutritive value and cost of a series of five one-course dinners recently supplied, on my recommendation, by the Edinburgh School Board. The nutritive value of the food was determined by analysing the total amount of food taken by the "average" child in a school in one of the poorer districts of Edinburgh. The amounts of food were in each case taken by myself in conjunction with the head master of the school. I am aware that in the strict sense there is no such thing as an "average" child, just as there can be no "average" family; but still it is possible to establish what may prove, at any rate, a useful standard which may be practically applied. Any such standard must, of course, be applied intelligently, due allowance being made for those conditions of the concrete problem which differ from those which were presupposed in fixing the standard. The meals in question were greatly enjoyed by the children; the smaller number of children fed on the porridge day is due to the fact that a certain number of children who get a more expensive two-course dinner do not take porridge. Analysis of the five meals gave the results shown in Table II, the composition of the meals and the

TABLE II.—One-Course Dinners.

| | No. of Children. | Protein. | Carbo-hydrates. | Fat. | Cost. |
|---------------------------|------------------|----------|-----------------|------|------------------|
| Lentil soup | 2,000 | 29.5 | 112.6 | 3.7 | £ s. d. 6 3 0 |
| Meat, soup, and potatoes | " | 18.5 | 67.2 | 9.4 | 11 15 4 |
| Plum pudding | " | 36.4 | 151.4 | 20.2 | 12 12 7 |
| Scottish broth | " | 28.2 | 71.0 | 8.1 | 8 4 3 |
| Porridge and hard biscuit | 1,820 | 24.5 | 105.3 | 4.1 | 5 15 5 |
| Average | | 27.1 | 102.0 | 9.0 | 1.24 per head |

figures for cost being kindly given by the officials of the board. The salts in the dietary are not estimated, because we know that any diet of the chemical composition given contains a sufficiency of mineral matter.

A study of the figures in the different columns is very instructive. The average amount of proteins, 27.1 grams, fat 9.0 grams, and carbohydrates 102 grams, may be taken as a reliable standard for a highly nutritious meal, even if anything in a deficiency in fat. If we compare the individual menus we find that—

- No. 1 is a very nourishing dinner at small cost.
- No. 2 is of considerably lower nutritive value, and is out of proportion expensive.
- No. 3 is a rich highly nourishing meal and is proportionally dear; it is only advisable as an occasional meal.
- No. 4 is a good dinner obtained at moderate cost.
- No. 5 is also a good meal, a little below the average in nutritive value; this can be rectified by slightly increasing the amount of milk.

The experience of the head masters in the different schools under the Edinburgh School Board has shown that meals planned on these lines have been followed by satisfactory rate of growth, increased physical vigour and more efficient education of the children, these being the criteria for judging the correctness of any system of feeding.

A highly nutritious, cheap, and palatable day's menu may be summarized as follows. When calculated for a family of father, mother, and five children, the price works out at 16s. per week, which may be regarded as the minimum rate at which a family of that size can be adequately fed.

Menu for a Day.

| | Protein. | Fat. | Cost net— Excess— |
|--------------------------------------|----------|------|----------------------|
| <i>Breakfast</i> —Porridge and milk: | | | |
| Oatmeal 1 oz. | 19.5 | 20.0 | 1.2d. |
| Treacle 1 oz. | | | |
| Milk $\frac{3}{4}$ oz. | | | |
| Bread 2 oz. | | | |
| Margarine $\frac{1}{4}$ oz. | | | |
| <i>Dinner</i> —One course | | | |
| Framed from Table II with footnotes | 30.0 | 10.0 | 1.4d. |
| <i>Tea</i> —Bread and milk: | | | |
| Bread $\frac{1}{2}$ lb. | 21.5 | 19.0 | 1.2d. |
| Margarine $\frac{3}{4}$ oz. | | | |
| Milk $\frac{1}{2}$ pt. | | | |

In the foregoing remarks I have directed attention mainly to the proteins in the dietary. I am well aware that there are many disorders in children which owe their origin to the excessive use of starchy foods, and which are corrected by substituting proteins. The consideration of these cases is beyond the scope of the present paper, but in this connexion it is of interest to note that the average amount of carbohydrates in the series of cases recorded is practically identical with the generally accepted Atwater standard.

REFERENCE.

¹ Appendix to *Food and Feeding in Health and Disease*, Oliver and Boyd, Edinburgh, second edition, 1915.

MESSRS. MAULL AND FOX, 137, Piccadilly, London, have issued a photogravure memorial portrait of Captain R. S. Scott, which is sold at the price of 5s. (post free, 5s. 2d. in the British Isles). The portrait is an excellent reproduction of the late Arctic explorer in his uniform. The publishers have undertaken to contribute an agreed portion of the profits to a branch of the National Fund.

CERTAIN allegations against the nursing arrangements and administration of the York County Hospital made in the issue of the *Hospital* for March 15th were considered at a meeting of the house committee and medical board of the institution on March 18th. The joint committee, while stating that it was satisfied that there was a complete answer to the imputations and charges, resolved that the most satisfactory way of dealing with the question was to obtain the appointment of a competent and independent authority to hold an inquiry. An application has been made to the President of the Royal College of Surgeons of England to appoint some person with a knowledge of hospital management and free from local influence to hold an impartial and independent inquiry.

CASES TREATED BY RADIUM IN THE ROYAL INFIRMARY, EDINBURGH, DURING 1912.

BY

DAWSON TURNER, M.D., F.R.C.P. EDIN.,
M.R.C.P. LOND., F.R.S.E.,

IN CHARGE OF RADIUM TREATMENT AT THE ROYAL INFIRMARY,
EDINBURGH.

Forty-one patients have attended for radium treatment during the past year. Twelve of these suffered from malignant disease, eleven from rodent ulcers, eleven from naevi, one from leucoplakia, one from lymphadenoma, one from spring catarrh, one from tuberculous glands, one from a tuberculous ulcer of the dorsum of the hand, one from a papilloma, and one from hypertrichosis.

Many of these patients received prolonged treatment or attended a considerable number of times; thus, in some of the malignant cases, whenever indeed it was possible, a tube of radium was inserted into the growth and maintained there for periods up to twelve days, while at the same time external treatment was employed so as to subject the growth to a cross fire of rays.

The treatment of port wine stains must also be very prolonged; as a cosmetic effect is desired, very small doses have to be given, and the result carefully observed, lest an atrophic condition of the skin be produced.

Radium treatment, as a rule, is conducted in the following manner: A dose large enough in the experience of the expert to produce the desired effect is administered, and the patient is sent away and told to report himself in two or three weeks, for the full effect of any dose is not manifested for three or more weeks. Another dose, if necessary, is then given, and the patient again sent away for a fortnight. I have not time here to refer to the question of dosage or of screens.

Naevus.

The cases which have been most benefited during the year have been those of naevus and rodent ulcer. Of eleven naevi—of which two were port wine stains—seven were cured, three are under treatment, and one (port wine stain) did not return.

Rodent Ulcer.

Rodent ulcers, if not affecting mucous membranes, cartilage, or bone, are also extraordinarily amenable to radium. The reasons why radium is so superior to carbonic snow or zinc ionization or excision are, first, because the rays penetrate deeply—in fact, right through the body (the gamma rays will penetrate 10 in. of lead), so that the very roots of the rodent are attacked; secondly, because the treatment is absolutely painless; and thirdly, because the cosmetic result leaves nothing to be desired. Of eleven rodent ulcers six were cured, one is under treatment, three did not return, and one was unsuitable for radium treatment. Of the cases that were cured, one affected the upper lip, and was on the point of penetrating it. Three were in the furrow between the nose and cheek; they had received unavailing prolonged treatment with x-rays. One, a case of Professor Caird's, was on the ala nasi; it measured $\frac{1}{4}$ in. by $\frac{1}{2}$ in., and was on the point of penetrating; one dose of 65 milligram-hours sufficed to cause complete healing with a beautiful cosmetic result and no contraction. The disease has, however, recurred in this case a little distance off on the tip of the nose. An application of radium has accordingly been made to it, and I have no doubt of a successful issue. The sixth was above the right eye. In another case of Mr. Caird's a male aged 61 the disease began many years ago as a pimple on the right side of the nose; eight years ago this was removed; on its return it affected the internal canthus, and Mr. Caird operated twice, in 1909 and 1912; on the latter occasion, recognizing that he had not removed all the growth, he recommended him to me for radium treatment. I placed two tubes of radium into the cavity, which was nearly 2 in. deep, and kept them there for thirty hours; no screen but a thin tube of aluminium was employed. This was on May 4th, 1912. In July the cavity had almost filled up, but for precaution's sake I gave a dose of 47 mg. of radium for thirty minutes. In December, 1912, he called, quite cured.

Two of the cases of rodent ulcer were treated by the insufflation of the radio-thorium emanation. One of these was a male, aged 49, recommended by Professor Caird; six years previously enucleation of the left eye had been performed by Dr. G. Mackay. The disease had recurred, and now formed a sloughy ulcer, about the size of half a crown, below the left orbital cavity, leading to extensive excavations beneath the cheek. As the disease was too extensive and too difficult of access for the limited amount of radium at my disposal, the idea occurred to me to treat it by blowing into it the radio-thorium emanation, which would be carried into the remotest corners of the excavations, and would coat the walls with a highly radio-active deposit. I did this some twenty times in the course of a few hours, and the immediate effect seemed to be to diminish the fetor; unfortunately the patient did not return for further treatment. The second case treated by the radio-thorium emanation was a male, aged 60, recommended by Mr. Wallace. The duration of the disease was fifteen years; he had been treated by x-rays, and Mr. Wallace had performed enucleation of the left eye three years ago. A later operation had also been performed by Mr. Wallace. At the time the radium treatment was begun there was an ulcer with everted edges occupying the left superior border of the nose, and extending deeply into the orbital cavity. As he was an inpatient I instructed the nurse to insufflate the cavity with the emanation every half-hour during the day for one minute at a time. This was done for ten days, when it was thought advisable to supplement the emanation by the application of solid radium. After four days of the combined treatment he was sent home. He had had 176 insufflations of the emanation and 235 milligram-hours application of solid radium. A fortnight later he returned very much improved; the nasal ulcer was practically healed. When another fortnight had elapsed he was re-admitted and treated again by the combined method for three days. On his reporting himself a month later (January 8th, 1913) there was further improvement. The total dose was 208 insufflations of the radio-thorium emanation and 675 milligram-hours of solid radium. He has not reported himself since.

Malignant Disease.

Twelve cases of malignant disease attended the department during the year. With one exception they were all inoperable cases; with two exceptions they were either recurrences or secondary deposits. Of these twelve cases one was healed with a sound scar, as well as a recurrence in the neighbourhood; three were improved; one exhibited temporary improvement; one, a carcinoma of the pharynx, was unrelieved and died; of the remaining six, two are still under treatment, one did not return for treatment, one refused treatment, in one a prophylactic dose of radium was given after an operation for removal of a sarcomatous growth in the groin, and in one the growth was so extensive as to render a resort to treatment with a limited amount of radium hopeless.

With the exception of the sarcoma referred to above all the cases were of a carcinomatous nature, and in five of them the upper or lower jaw was the seat of the disease. Brief details of the cases are as follows:

1. A female, aged 49, with a recurrent epithelioma of the right ala nasi, recommended by Mr. Wallace. The patient had long suffered from an ulcer on the ala nasi; prolonged treatment with x-rays and weak radium preparations, followed by excision. Condition on admission on June 25th, 1912: There is an ulcerating crack on the external surface of the right ala nasi. A single dose of 95 mg.-hours of radium bromide screened by glass and aluminium was administered. On July 9th there was a good reaction; the scab did not come away until the middle of September, when the ulcer was found to be completely healed over. On January 28th, 1913, the scar was still in a perfectly sound condition, but a small ulcer had appeared just within the nostril on the septum nasi. This was given a dose of 40 mg.-hours of radium bromide, screened as before by glass and thin aluminium, with a completely successful result.

2. A female, aged 70, recommended by Dr. Sym. Epithelioma of one year's duration affecting the upper lid and canthi of the left eye. Had twenty-four full doses of x-rays. Condition on admission: There is an irregular ulcer eating away the lower margin of the upper lid and involving the canthi; the body of the lid is hard and swollen. Treatment commenced on January 20th, 1912, and continued at intervals to May, 1912. Great improvement followed. The ulcer healed and the swelling disappeared. On May 22nd, 1912, Dr. Sym examined her, and

* Read to the Edinburgh Medico-Chirurgical Society.

wrote: "There is very great improvement, very great indeed, but whether the cancer is all gone or not I can't be sure." On June 20th the patient returned with a hard lump external to the external canthus; this was given one good dose of radium and the patient sent home. On October 29th, 1912, she returned much worse, with the bone affected. Mr. Hodsdon excised the growth by an operation which opened into the frontal sinus. A prophylactic dose of 210 mg.-hours of radium was then administered.

3. A male, aged 44, recommended by Professor Caird. A rapidly-growing recurrent epithelioma of the right upper jaw, operated on twice within five months by Professor Caird. There is a large ulcer extending backwards on the mucous membrane of the buccal cavity on the right side; the skin outside is red and angry looking. On November 7th, 1911, external and internal applications of radium were commenced; the external applications were shielded by a sheet of silver half a millimetre in thickness, the internal by a thin sheet of aluminium. On December 4th, 1911, he was sent home after a total dose of 1,011 mg.-hours. The disease had ceased to extend and considerable improvement was manifest. On January 9th, 1912, he returned in a worse condition; there was a large external swelling, and Professor Caird thought that further treatment would be useless.

4. A female, aged 42, recommended by Mr. Hodsdon. An epithelioma following lupus; duration thirty years. The disease has been treated by both medical and surgical means; it has had courses of x-rays extending over years; it has been scraped, cauterized, and partially excised. Present condition: Below the left nostril there is an irregular ulcer eating into the lip; it is 2 in. broad by 1 in. long, and it has raised margins, except where it is spreading on to the mucous membrane of the lip; there is a perforation below the left nostril. Treatment was begun on November 28th, 1912; 25 mg. of radium bromide (International standard), screened only by glass and aluminium, were applied to successive areas of the ulcer for a few hours daily during a week; the dose amounted to 1,620 mg.-hours. This was followed in three weeks' time by a strong reaction, and afterwards considerable improvement was manifest, healing was going on above, granulation tissue was present, and malignant characters were absent. The patient is to return for more treatment.

5. A male, aged 72, recommended by Dr. Elder. Malignant disease of the fauces and pharynx. Duration more than a year; difficulty in swallowing and speaking. An irregular swelling can be observed, involving the soft palate and uvula and causing great deformity. Left cervical glands enlarged. Both Professors Alexis Thomson and Caird considered the case quite inoperable. With the hope of relieving his symptoms, radium treatment was commenced. On September 19th, 1912, a capsule, containing 40 mg. of radium bromide, was attached to an aluminium rod and held by the patient against the affected part for one hour two or three times a week; only an aluminium screen was used. By November 28th, 1912, the patient had received a dose of 388 mg.-hours. The applications appeared to relieve his pressing symptoms, but he gradually sank and died on December 14th, 1912.

6. A male, aged 35, recommended by Professor Alexis Thomson. Diagnosis: Round-celled sarcoma situated in the groin. Duration twelve months; was admitted to the Royal Infirmary on January 11th, 1913, complaining of a lump the size of one and a half fists in the groin and of increasing weakness; the left leg was oedematous. On January 17th, 1913, Professor Thomson removed the growth, which proved to be a round-celled sarcoma. On January 30th, 1913, a tube of glass in an aluminium cover, containing 10 mg. (International standard) of radium bromide, was inserted into the wound and kept there for twenty-four hours. This was intended to act as a prophylactic measure.

7. A female, aged 54, recommended by Mr. Miles. History: In September, 1911, the patient had been admitted to Chalmers Hospital, complaining of a hard, painful lump in the left axilla. Mr. Stiles removed the mass and the breast; both were found to be the seat of a medullary carcinoma. Readmitted May 28th, 1912, with a rapidly growing recurrence in the scar; this was excised on May 31st, 1912. Returned at the beginning of 1913 with a secondary growth affecting the sternum. The patient recommended to the Royal Infirmary; was admitted by Mr. Miles. Projecting from the sternum was a hemispherical growth, in area about the size of a teacup saucer and raised nearly an inch above the general surface. The skin over it was reddened. The patient complained of spasms of severe lancinating pain. Treatment: Two tubes of radium, each containing 5 mg. (International standard), were introduced by Mr. Miles into the growth, screened only by glass and aluminium, and were kept in for seven and for twelve days respectively, being moved occasionally so as to expose a fresh area to the radiation. At the same time applications of 25 mg. (International standard) screened by silver were made externally. The total internal dose was 2,400 mg.-hours; the total external dose was 800 mg.-hours. Under this treatment the tumour rapidly flattened down, and in six weeks' time had disappeared. Some pus was discharged from the incisions, and a good deal of reaction was manifest on the skin. The lancinating pain disappeared shortly after the applications. The patient expressed herself as very grateful. She is still under observation.

Of the remaining 5 cases 1 did not return for treatment, 2 are still under treatment, 1 refused treatment, and in 1

treatment was refused on account of the extensive nature of the growth.

Leucoplakia.

A male, aged 52, recommended by Professor Alexis Thomson, has attended since October, 1911, for radium treatment. He has a specific history. The duration of the disease was one year. On the surface and side of the left half of the tongue there were several whitish, hard patches somewhat raised above the surface. Ten mg. of radium bromide (International standard) were enclosed in an aluminium box and applied for an hour at a time twice a week to the patches. The effect of the treatment is to improve and check the development of the disease, because if it be inherited, as in the holidays, the condition rapidly becomes worse. The patient refuses operation and he has had prolonged courses of internal treatment, also an injection of salvarsan. Stronger and more prolonged doses of radium would, I think, produce more decided benefit.

Lymphadenoma.

A male, aged 18, was recommended by Dr. Byrom Bramwell for radium treatment in November, 1911. There were growths round the neck and in the groin and axilla. The circumference of the neck measured 17½ in. The neck was treated by external applications screened by silver. No improvement resulted, and after a total dose of 1,933 mg.-hours given in one week treatment was suspended.

Spring Cataract.

A male, aged 9, recommended by Dr. George Mackay, was an old case, whose right eye had already been cured by radium treatment, but whose left eye had not had sufficient treatment. He was given a dose of 5 mg.-hours by the application of a 10-mg. capsule to the eyelid for half an hour. This patient had first attended in March, 1910. Both upper lids were covered on their internal surface with the typical granulations and pavement-like blocks. The lids were much swollen. The right lid only was first treated, and in three months was practically well after a dose of 32.5 mg.-hours. Treatment of the left eye was then begun.

Tubercle.

Tuberculous Glands.—Only one patient, recommended by Dr. J. Barnett, suffering from enlarged cervical glands, attended the department, and he did not return.

Tuberculous Ulcer.—A boy, aged 3½ years, recommended by Dr. Ralston Richardson, attended for radium treatment of tuberculous ulcer on the dorsum of the right hand. It had existed for two years and had been treated with iodine, caustics, etc. There were two patches close together, measuring nearly half an inch in diameter, dark red, and slightly elevated. Treatment was begun on December 3rd, 1912, and continued for a fortnight, by which time the dose amounted to 20 mg.-hours. Only a screen of aluminium was employed. In a month the patches were covered by a good scab, which fell off at the end of January. The patches had almost disappeared, but to aid in the cure a further dose of 13 mg.-hours has been administered. The patient is still under observation.

Papilloma.

A female, aged 51, recommended by Dr. Davidson of Kelso, was admitted on October 8th, 1912, with a papilloma on the left side of the nose. It was half an inch wide and raised a quarter of an inch above the surface, and it was composed principally of horny material. The duration had been about five years, but latterly it had been growing more rapidly. The patient had had a previous growth removed some years ago from a position a little higher up. A dose of 35 mg.-hours, screened by aluminium, was administered by a single application. In a fortnight the growth fell off; in seven weeks there was perfect healing, the site of the growth being covered by a beautiful supple skin.

Hypertrichosis.

A female, aged 25, recommended by Dr. Fleming, attended for a week during September, 1912, for the radium treatment of this condition. The patient had a thick, hairy growth round the lower border of the chin. After the patient had been made aware of the difficulties of the method of treatment, applications screened by aluminium of 5 mg.-hours were made over successive areas. These proved to be insufficient to produce epilation. The patient proposes to return later on.

ARGYLLS LIMITED (Alexandria, Dumbartonshire) have issued an illustrated catalogue of their 1913 cars. In addition to the specification for cars of various powers, there is an interesting note on the braking problem by Mr. G. H. Cuthush. It deals with the application of the diagonal system of braking—that is to say, the application of the brake to the rear wheel on one side and to the front wheel on the other. If the brakes are compensated, retardation is produced on each side, with the result, as it is claimed, that the tendency of the car to turn one way, owing to the loss of adhesion at the rear, is counteracted by the tendency to turn in the other direction, produced by the reduced adhesion at the front wheels. The catalogue also contains a full account of the Argyle single sleeve-valve engine, illustrated by diagrams which make its mode of action clear.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

UNILATERAL IRIDO-CYCLITIS (SEROUS IRITIS) TREATED BY SUBCONJUNCTIVAL INJECTIONS OF MERCURY CYANIDE.

Miss X., aged 26, saw me on February 3rd. During the last six years she had had four mild attacks of iritis. The left eye had been inflamed and painful for fourteen days, with increasing dimness of sight. Vision: fingers at 2 metres. The vision of the right eye was normal. The left pupil was widely dilated (under atropine). The anterior chamber was deep, the aqueous hazy, with many punctate opacities covering the whole of Descemet's membrane and the anterior lens capsule. Tension was normal: the fundus was not visible. Twelve minims of mercury cyanide, 1 in 5,000, were injected under the conjunctiva, partly far back and partly near the cornea.

The eye was very painful all night, in spite of hot fomentations, and on February 4th vision was $\frac{3}{5}$; there were still very many punctate opacities, but the aqueous was distinctly clearer. The fundus was only just visible. Syrup of iodide of iron and iodic drops were ordered. On February 6th the vision was $\frac{4}{5}$, and there were fewer punctate opacities. Another subconjunctival injection of 15 minims of mercury cyanide was made. On February 10th she reported that she had had much pain for two days. There was some oedema of the conjunctiva bulbi. Vision was $\frac{6}{5}$. There were a fair number of punctate opacities on Descemet's membrane. On February 13th there was no pain, and very few punctate opacities on Descemet's membrane. The fundus was distinctly visible. There were many small opacities of the vitreous, and some retinitis. Vision = $\frac{7}{5}$. On February 19th no punctate opacities were visible. The vitreous was clearer and the retina less inflamed. Vision = $\frac{8}{5}$. On February 24th the eye looked perfectly normal, with the exception of slight congestion of the retina. Vision with +0.5 D. = $\frac{9}{5}$.

There was no history of rheumatism or syphilis in the case, but the recurrent attacks of iritis and the excellent results of the subconjunctival injections of mercury certainly make the case look rather suspicious. I have used subconjunctival injections of mercury in many cases, with more or less success. In no case have the results been quite so good as in this case.

ADOLPH BRONNER, M.D.,
Senior Surgeon to the Bradford Royal
Eye and Ear Hospital.

ACUTE EPIDIDYMITIS DUE TO MUSCULAR STRAIN.

I WAS much interested in Mr. J. W. Grant's article published in the BRITISH MEDICAL JOURNAL of July 6th, 1912, and in the view he takes of the doubtful effect of strain as the cause of acute epididymitis. The following case appears worthy of record in this connexion:

A. B., a fine, strong, healthy man aged 27, was present at a flying exhibition on Whit Monday. During the afternoon he felt a desire to urinate, but it was some time before he found the temporary urinal; he then had difficulty in passing water, and had to strain considerably. The following day he cycled ten miles on business, and on retiring to bed the same evening he felt some slight aching and shooting pains in the left groin and testicle, but took no notice of this. On the next (the third) day he noticed some swelling in the left groin, and that his left testicle was much larger than the right. He continued to work until the fifth day, when he came to me for treatment. I found the left testicle hard, tense, and much swollen, but not particularly tender at any spot. There was some thickening and swelling of the cord extending up into the left groin. The condition improved slowly under treatment.

The interesting points in the case are as follows:

1. The delayed onset of symptoms. One would have expected great pain and swelling with tenderness almost at once.
2. Although there was intense congestion, yet there was very little pain at any time.

3. The persistent nature of the symptoms. Usually in three weeks the condition has resolved. My patient was still under treatment five weeks after the injury or strain.

4. The question of secondary infection, in my opinion, may safely be banished, as the patient has been a clean-living, temperate man all his life, and has had no illness except measles as a child.

5. There was no sign of ecchymosis in the region of the groin.

In my opinion, the only conceivable cause was violent contraction of the abdominal muscles producing pressure on the veins, with possible rupture of some small vein.

GEO. A. WOLFENDALE, L.R.C.P., L.R.C.S.
Attleborough, Nuneaton.

COMPLETE INVERSION OF THE UTERUS WITH ADHERENT PLACENTA.

DR. J. B. HELLIER of Leeds recently recorded (August 10th, 1912, page 310) a case of acute inversion of the uterus following delivery in a young primipara.

On August 27th, 1911, I was summoned to a cottage about three and a half miles distant by a message from the nurse that the child was born and that the woman was bleeding profusely. I arrived at the house some two hours after the messenger had left. The nurse told me that after the child had been born the placenta was retained a considerable time, and that there was alarming hæmorrhage. It was with much difficulty that she was able to express the placenta, and when she had done so she could not remove it. The bleeding ceased immediately after expression.

The patient, a 5-para, aged 35 years, gave a history of difficulty at the last confinement with the after-birth, which seems to have necessitated manual removal.

She was very pale, practically pulseless, and suffering from extreme shock.

The placenta was lying at the vulval orifice, and the labia were widely separated by the mass, which was about the size of a fetal head. By abdominal palpation the diagnosis was evident, the hand meeting with no resistance whatever in the pelvis.

The patient was given ether, m 40, hypodermically, followed by strychnine sulphate, gr. $\frac{3}{50}$; she was then placed in the cross-bed position, the parts were well doctored, and, with as strict asepsis as one could observe under the conditions, the placenta was stripped off from the uterus. Much difficulty was encountered, owing to strong fibrous bands running into the uterine substance from the placenta. After removal the uterus appeared to be about the size of a large cocoa-nut. There was no bleeding, and the organ was in a state of tonic contraction. The hand could be passed up alongside of the mass into the vaginal vault, which, along with the cervix, was somewhat inverted.

I tried to reduce the inversion by taxis. At first I could make no headway, but after about five minutes' manipulation the uterus was replaced in position, no difficulty being experienced once the process of reduction had commenced.

A hot intrauterine douche was given and the uterine cavity plugged with Dührssen's gauze. The general treatment of shock was then attended to.

Unfortunately, the patient only lived for seven hours, death undoubtedly being due to shock, as the hæmorrhage was not sufficient to be fatal. There was no history of pulling on the cord.

It may be interesting to state that a very great number of acute inversions of the uterus which have been recorded have occurred in coloured races, such as Kafirs, in whom parturition is effected in the squatting position, and are attended by women whose methods are rather forceful and primitive.

OLDHAM ROYAL INFIRMARY.

A CASE OF VOLVULUS OF THE CAECUM.

(By E. MAUDE MARSDEN, M.B., Ch.B.Vict., House-Surgeon.)

The patient in the following case, a man aged 54 years, was brought to the infirmary at night on June 3rd, 1912, with a history of having been seized with sudden severe pain in the abdomen immediately after dinner the day before. The bowels had not been opened for three days; there had been some vomiting, but it was not faeculent. During the morning of June 3rd there had been a watery discharge from the lower bowel. There was a history suggestive of acute obstruction two years before and a definite story of intestinal obstruction in August, 1910; the condition then subsided, but the man said he had never been well since. For two months before admission he gave a history of attacks of pain in the right iliac region and some constipation.

Condition on Admission.

The man was obviously acutely ill. There was tenderness in the lower abdomen on both sides, but no true muscular rigidity. There was distension localized to the middle line below the umbilicus, rather more to the left than the right, suggesting an over-distended bladder; the abdomen as a whole was not distended. There was no dullness on percussion; the entire abdomen was tympanitic. A rectal examination revealed the fact that the pelvis was filled with a tense mass, which occupied more of the left than the right side of the pelvis. The temperature was 97° F., and the pulse-rate 72 per minute. Before he was removed to the theatre he began to pass flatus by the mouth.

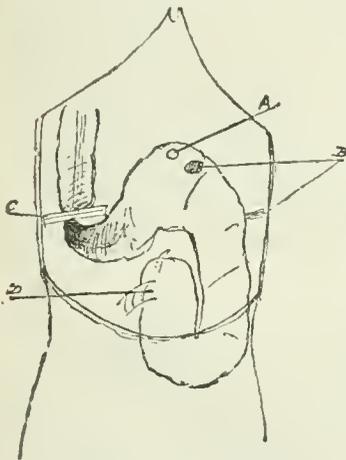

Operation.

Dr. Radcliffe opened the abdomen by a vertical incision in the middle line, and a coil of distended large bowel was

found occupying the whole of the left side of the abdomen, from the umbilical level down into the pelvis. It was adherent to the abdominal wall just to the left of the umbilicus, in the left flank, and also to the pelvic wall on the left hand side, as indicated in the accompanying diagram. These were old adhesions of some strength.

To the right were coils of small intestine, moderately distended, and covering the junction between caecum and ascending colon. These were traced down, and the ileo-caecal junction was found on the anterior surface and right side of the distended portion of gut just above the level of the brim of the true pelvis. The appendix, which was perfectly healthy, was discovered emerging from behind the upper margin of the caecum, and pointing upwards.

It was evident that there was a volvulus of the caecum, which had existed for some time previous to the present attack. With difficulty the cause of the obstruction, a broad band of adhesion running on to the abdominal wall, was discovered across the ascending colon in the right iliac fossa. Just below this adhesion the gut was twisted.

That part of the caecum which was to the right of the umbilicus was covered in front by small intestine. A, Umbilicus; B, adhesions to abdominal wall; C, broad band of adhesions; D, ileo-caecal valve.

The band was divided, the volvulus untwisted, and the obstruction was instantly relieved. The condition of the bowel immediately under the adhesion band was good, and no resection was necessary.

Remarks.

The man made an uninterrupted recovery, and left hospital on June 22nd. The primary cause of obstruction was presumed to be the broad band in the iliac fossa, which had occluded, but not strangled, the ascending colon. The volvulus of the distended caecum was probably a secondary result, which persisted owing to the caecum having contracted adhesions to the abdominal wall. I am indebted to Dr. Radcliffe, under whose care the case was admitted, for permission to publish this report.

ROYAL SOCIETY OF MEDICINE.

SECTIONS OF OPHTHALMOLOGY AND NEUROLOGY.

Wednesday, March 5th, 1913.

Sir ANDERSON CRITCHETT, C.V.O., President, in the Chair.

Disease of the Pituitary Body.

PROFESSOR SCHÄFER opened a discussion on this subject with a very detailed exposition, aided by numerous slides, of the structure and functions of the pituitary body. It was present in all vertebrates which had been examined; its development occurred as an extension of Rathke's pouch, an invagination of the buccal ectoderm towards the brain. This was met by a hollow downgrowth from the thalamencephalon, and the combination of the two into one organ formed the pituitary body. The gland consisted of three parts—(1) pars anterior, (2) pars intermedia, (3) pars nervosa. It was usually separated into an anterior and a posterior lobe. Remarkable alterations occurred in the pituitary body as the result of thyroidectomy, and similar changes had been observed in association with atrophy of the thyroid. The alterations after thyroidectomy included (1) enlargement of the pituitary body, (2) the presence of a colloid substance in the vesicles of the pars anterior and a great increase in that of the pars intermedia, (3) a great increase in the number of hyaline bodies in the pars intermedia and the pars nervosa. It was not easy to explain these changes physiologically, because the functions of the two glands were not identical, though both were probably connected with sexual development, for in the case of removal of either there was a stunting of growth and sexual infantilism. Moreover, castration had been observed by most to be followed by hypophysial hypertrophy. The greatest enlargement of the pituitary body was found in giants and acromegalics; the skeleton of giants was characterized by a disproportionately large sella turcica. The physiology of the pituitary body had been investigated experimentally by methods of both removal and addition, the latter by administration of extracts of the gland and by implantation. The evidence following removal was conflicting. Young animals which survived extirpation had their growth retarded, and their sexual activity remained undeveloped. But some observers stated that total removal was not fatal, death—when it occurred—having been due to the complications of the operation. Mere injury to the pituitary might cause marked polyuria, but it disappeared after a few days. Possibly this was the explanation of the polyuria sometimes seen in association with fracture of the base of the skull. Feeding with fresh or dried gland substance was normally not attended with any obvious result, even in growing animals. There was certainly no retardation of growth, such as had been described. Attempts to graft the organ had usually been unsuccessful. Saline extracts of pituitary, injected intravenously, had a marked effect upon all involuntary muscles; they caused constriction of most of the blood vessels of the body, a powerful and usually slowed action of the heart, the tone of which was increased, contraction of bladder, uterus, and bowel, and the pupil of the excised eye in the frog was dilated. The substance producing these results was of a relatively

simple nature, was soluble in water, and dialysable, and was not destroyed by repeated boiling, nor by long keeping in a dried state or in a sterilized condition. It was insoluble in alcohol or ether. Intravenous injection of pituitary extract excited secretion in certain glands, such as the kidney, and in the mammary gland during lactation; there was dilatation of the renal arteries, though the effect on the general arteries of the body was constriction. The substance producing effects upon blood pressure, heart and kidney, was contained only in the posterior lobe, and it had been found in the cerebro-spinal fluid. According to the observations of Ott, Scott, and Mackenzie, the galactagogue hormone of the pituitary was also confined to the posterior lobe, and it was assumed to be identical with that which caused the other effects upon blood vessels, heart, and kidney. The anterior lobe seemed related to the general growth of the body, especially that of the skeleton; while the posterior, including the pars intermedia, probably promoted the contractility and increased the tone of plain muscular tissue.

Mr. J. HERBERT FISHER commented on the complexity of function of the two portions of the pituitary body, and the supreme importance of the gland to life, and its interactions with other ductless glands. Colloid material was also formed, as in the case of the pituitary, by rare tumours which sometimes developed in the remnants of the post-anal gut. He also remarked on the fact that castration and oophorectomy caused some overgrowth of the pituitary body, while the hypophysis enlarged during pregnancy. Premature climacteric in women or impotence in men developing many months or even years before other symptoms suggested disorders localized to the hypophysis. Observations of gynaecologists might throw light on this question. Hypoplasia of the adrenals was also accompanied by retarded sexual development, while hyperplasia was accompanied by excessive development of secondary sexual characteristics. A case exhibited by Dr. Turney showed pituitary disorder with adiposity and abnormally raised blood pressure, undue pigmentation of skin, and liability to spontaneous bleeding. For diagnostic purposes the ophthalmic surgeon worked chiefly with his perimeter in recognizing and watching pituitary disease. The typical condition was one of bitemporal hemianopia, though that statement did not cover the question. Cases had been recorded in which a central scotoma resembling that seen in tobacco amblyopia existed, but in which the extension of the scotoma resulted in bitemporal hemianopia. It was not clear how pituitary tumours could press first at the anterior angle of the commissure; still, x rays were very serviceable for proving or negating the existence of bone erosion. Dr. Deyne had shown that hemianopia of the colour sense might precede that of the form sense, and give a guide to prognosis, and with that Cushing agreed. In a proportion of cases of pituitary body enlargement, homonymous hemianopia was a symptom in the earlier development of the case, but there could be no doubt that an evenly-balanced loss of the temporal field in each eye of simultaneous onset was the exception. Direct pressure on the optic chiasma, so glibly invoked, was far from being a satisfactory explanation of most of the cases. Mr. Fisher asked whether neurologists held that the anosmia present in some pituitary cases could be attributed to involvement of the uncinata gyrus. He believed the visual phenomena were explicable by traction effects on the visual pathways as the tumour extended behind the chiasma and between the optic tracts in the interpeduncular space. For operation he favoured a route through the fronto-temporal opening of the cranium. If this method were pursued the free removal of the bone and opening of the dura mater on the opposite side allowed more freedom for elevation and displacement of brain, and thus gave more ready access to the pituitary region.

The debate was adjourned to March 12th.

CLINICAL SECTION.

Friday, March 14th, 1913.

Dr. A. E. GARROD, Vice-President, in the Chair.

Exhibition of Clinical Cases.

The following cases were shown among others:—Dr. F. PARKES WEBER: "Baggy" subcutaneous fat simulating

symmetrical oedema of the legs in a woman aged 40. In similar instances the swelling had been supposed to be due to a chronic oedematous degeneration of the subcutaneous fat cells. He thought it was in some way connected with a disorder of internal secretions, especially of the thyroid gland and ovaries. Also a case of *Hypoplasia of the right limbs of cerebral origin* in a woman aged 20. The right limbs had been weak from the time she had begun to walk, but there was no history as to its cause. Dr. W. ESSEX WYNTER: *Arthritis with Baker's cysts* in a man aged 58. Wassermann's reaction was positive. The lesions did not resemble those of Charcot's disease of the joints. Dr. A. F. HERTZ and Dr. W. JOHNSON: *Progressive muscular atrophy* associated with primary muscular dystrophy in the second generation. The father, aged 41, had pure progressive muscular atrophy of rapid onset. One son, aged 17, suffered from the pseudo-hypertrophic form of muscular dystrophy. Another son, aged 5, showed early signs of the same disease. A boy aged 3, a nephew of the first patient, was possibly affected also by muscular dystrophy. Mr. T. JEFFERSON FAULDER: *Case for diagnosis*, possibly a dermoid cyst in Burns's space, in a girl aged 17. Dr. ELIP SYLVAN: Three cases of *Pulmonary tuberculosis* illustrating the value of *Gymnastic treatment*; also a case of *Myelitis*, considerably benefited by similar treatment.

SECTION OF SURGERY.

Tuesday, March 11th, 1913.

Mr. G. H. MAKINS, C.B., F.R.C.S., President, in the Chair.

Ligature of the Renal Artery as a Substitute for Nephrectomy.

Mr. T. H. KELLOCK said that the first recorded operation was done for tubercle by an army surgeon. In his own case, a man aged 30 had undergone perineal lithotomy and several operations on his loin, and a discharging sinus remained. X rays revealed a calculus and a portion of rubber tube at the bottom of the sinus. The tube was removed, but copious haemorrhage occurred when the extraction of the calculus was attempted. The excess of inflammatory tissue made the renal vessels difficult to find, so the renal artery was tied through an abdominal incision. Seventeen days later the sinus was again explored; friable portions of the kidney came away without haemorrhage, and the sinus healed up. Since this operation he had tied the renal artery in three cadavers. The peritoneum was opened 3 in. above the umbilicus; much cellular tissue was found in front of the vessels. Ligature of the right artery was the harder owing to the duodenum and the pancreas. Abnormal arteries would, Mr. Kellock added, prove a difficulty. Mr. JOCELYN SWAN thought that the operation would be chiefly required in cases of persistent sinus, when a subcapsular nephrectomy was very difficult. The PRESIDENT, Mr. KIDD, Mr. SYMONDS, and Mr. THOMPSON took part in the discussion.

Three Unusual Cases of Renal Tumour.

Mr. J. SWIFT JOLY reported these cases. In the first instance there was renal pain with haematuria, and the left kidney was found to be displaced downwards. Cystoscopic examination revealed a red mass with black spots projecting $\frac{1}{4}$ in. from the ureter into the bladder. Ureteral catheterization and examination showed that less urine and urea came from the left kidney. Nephrectomy was performed, and a hypernephroma found replacing the upper pole of the kidney. The second case was an instance of painless haematuria; the right kidney was enlarged and irregular, the urine acid, and the cystoscope showed a worm-like clot in the right ureter. Attacks of retention had occurred for three months. During nephrectomy the peritoneum was torn, and the patient died during the same night. A hypernephroma was found in the lower pole of the kidney, with secondary deposits in the kidney and perivascular fat. The third case occurred in a male, aged 44, with pain over the left kidney and haematuria. The urine was clear and acid. A hard smooth mass was felt in the left hypochondrium and lumbar region; it did not fluctuate, and the left kidney could not be felt apart from the lump; there was a small varicocele. No urine was obtained by

catheterization of the left ureter. Nephrectomy was performed, and the patient gained 4 st. in weight, and there was no sign of recurrence at the end of eighteen months. The weight of the tumour with the perirenal fat was 3½ lb. A central growth was found that cut off the substance of the kidney from the pelvis. The tumour proved to be a primary carcinoma with haemorrhagic changes. Early diagnosis and extensive operation was needed in all cases like the three he had brought forward. Partial or simple nephrectomy was contraindicated, and nephrectomy followed by dissection of the fatty capsule should not be done unless there had been an error of diagnosis. Not only the kidney with the perirenal fat but also the aortic glands should be removed. Diagnosis had to be made from a primary ureteral growth leading to a hydronephrosis. Unilateral haematuria from a large kidney with diminished secretion were useful diagnostic points. Renal tumours should first be examined and then explored, and, if possible, completely removed through a T-shaped incision. Mr. SWAN doubted, from the naked-eye appearance of the third specimen, whether it was a carcinoma. He had operated on eight cases of hypernephroma; seven of these had started with haematuria. He removed the fatty capsule, but not the aortic glands. In one case the tumour was not palpable, as it had grown upwards and pushed the liver down over it. He showed a specimen of cavernous angioma of the kidney which he had removed. Mr. KIDD thought that the cases should be cystoscoped whilst they were bleeding, as when the bleeding had ceased they were difficult to diagnose. Hypernephromata grew to a large size before they led to secondary deposits; they should be removed through a T-shaped incision. Mr. JOLY, in reply, said that the microscopic examination of the third tumour showed it to be a *clear-celled* carcinoma. The cases should be cystoscoped both while they were and while they were not bleeding.

SECTION OF PSYCHIATRY.

Tuesday, March 11th, 1913.

Sir GEORGE SAVAGE, President, in the Chair.

Clinical and Laboratory Meeting.

THROUGH the courtesy of Dr. Robert Jones, Medical Superintendent, this meeting was held at the London County Asylum, Claybry. Dr. F. W. MOTT, F.R.S., illustrated and described some recent investigations on the *Biochemistry of the neurone*. He showed by means of the ultramicroscope the living nerve cell. It was a viscous homogeneous colloidal spongoplasm containing an enormous number of minute oval or round granules, which, on a dark ground, appeared highly refractile. The nucleus with nucleoli in the centre was less refractile. When the isotonic fluid was replaced by water, endosmosis occurred, and the refractile granules escaped. They remained discrete, and exhibited a Brownian movement, but did not coalesce. Probably each granule consisted of colloidal fluid substance surrounded by a delicate membrane. Dr. Mott also demonstrated *Spirochaeta pallida* (Neguchi) in culture living; likewise changes in the central nervous system in a case of myxoedema, cachexia strumipriva and insanity, in which the thyroid was of normal size, but the gland tissue was replaced by fibrous tissue. He also demonstrated changes in the central nervous system in an English and an Egyptian case of pellagra. The English patient had not been out of this country, and the Egyptian case came from a maize district where the grain was of very poor quality. Dr. ROBERT JONES exhibited two cases for diagnosis. The first was that of a single man, aged 35, of no occupation. He had threatened to commit suicide, and occasionally showed signs of violence towards others, for which he was certified. He had now congenital imbecility with depression. His articulation was jerky, and gait ataxic. During voluntary movement he showed a coarse tremor. There was neither paresis nor wasting, and his electrical reactions were normal; no nystagmus, and pupillary reactions were sluggish; discs normal, knee-jerks increased, flexor response. His father and brother were insane; mother and sister died of consumption. The second case was that of a man, aged 44, a blacksmith, who developed suicidal melancholia. He considered that he had general paralysis and was going to die, was greatly depressed and

was irritable, and there was progressive mental weakness. There was slurring of speech, with increasing atony of voluntary muscles, fine tremor of tongue and facial muscles; no nystagmus or disc changes. Knee-jerks increased, Wassermann test and lymphocytosis negative. His mother and maternal aunt were insane. Dr. S. A. K. WILSON considered the first case was one of congenital cerebellar defect. Sir DAVID FERRIER agreed, and included the second case in the same group. Dr. C. T. EWART showed an interesting case of *Kalatoniac stupor* in a girl, aged 22. She had rigidity and mild negativism, but no stercotypy, echopraxy, or echolalia. Her habits were clean, but she had not menstruated since admission. Her answers to questions were only monosyllabic. At school she was quick, cheerful, and industrious. Her mother drank to excess during the pregnancy. Efforts are now being directed, by Turkish baths, etc., to restore the menstrual function, and the prognosis was hopeful. Dr. Ewart also brought forward a woman, aged 32, who exhibited *Washing mania*. She had melancholia with suicidal tendencies, and any soiling of her linen gave her much worry; she had also financial and other distresses. There was no evidence of an insane heredity. Dr. Ewart said the washing was a motor response to a sensory experience, just as the music of a waltz impelled certain muscular movements in the hearer. He elaborated an interesting analysis of the motives which caused women to derive pleasure from the wearing of exquisite clothing, and showed that the beautiful and the desirable standards varied with the particular society in which the person dwelt. Dr. F. PAINE showed a case of *Osteitis deformans* in a man, aged 75, who also had aural hallucinations and delusions of persecution. Also a man, aged 46, with organic disease of the nervous system presenting somewhat similar features to those of general paralysis of the insane. Wassermann's reaction was negative, and there was no lymphocytosis. He had spastic paraplegia, and well marked aortic regurgitation. He also showed a case of cerebral tumour to illustrate the value of the operation of decompression.

SECTION OF ANAESTHETICS.

Friday, March 7th, 1913.

Dr. J. BLUMFELD, President, in the Chair.

A Brief Eulogy of Mr. Clover.

Mr. BUCKSTON BROWNE expressed his pleasure that the section had accepted his portrait of Mr. Clover, whom he claimed as a surgical genius. Mechanical invention in Mr. Clover's case was hereditary. Quite apart from his valuable pioneer work in anaesthesia, his principal contributions to the art of surgery were in themselves sufficient as a title to greatness. Clover's tubes and rubber evacuator, for use after the crushing of a vesical calculus by the lithotrite, had alone rendered the modern operation of lithotomy possible. While no single man could claim the modern lithotrite as his invention, Clover's evacuating apparatus, tubes, and bottle were just as practicable in 1913 as in 1866, when he first made his invention known, and the most modern apparatus was essentially and practically Clover's. British surgeons had led the van of the army of progress during the wonderful nineteenth century, and Clover was one of those leaders, for he had left an abiding mark upon the surgical practice of his generation and probably upon that of many yet to come. Dr. DUDLEY BUXTON followed with an eloquent tribute to Mr. Clover, whose outstanding quality was a great mastery of detail and patience in the pursuit and application of knowledge. Those who in the present day were in the enjoyment of the aftermath of such labours as Clover's did well to pause sometimes and appreciate the painstaking stages by means of which permanent advances had been attained. Clover was really the scientific adviser to the Royal Medico-Chirurgical Society Committee formed in 1864 to inquire into the administration of anaesthetics, and he showed how much he was imbued with the teaching of Snow. Clover was his own mechanic, and the apparatus which he placed before the profession represented numerous stages of trial and experiment carried out by himself. Dr. Buxton congratulated the section on doing homage to so great a man. Mr. BELLAMY GARDNER, in a short communication, pointed out that Clover appeared to

have been the first man in England to apply a facepiece for the administration of nitrous oxide gas, the original demonstration of that contrivance having taken place at the London Dental Hospital in March, 1858.

Technique in General Anaesthesia for Intranasal Operations.

Mr. H. BELLAMY GARDNER read this communication. In order to obtain the ideal conditions for such work three principles were necessary for agreement between the surgeon and anaesthetist: (1) That the nasal cavities should be cut off from the upper air passages by the insertion of a captive post-nasal sponge after anaesthesia had been established; (2) that adequate ischaemia was only attained by the insertion of pledgets of cotton-wool soaked in a solution containing 2½ per cent. of cocaine and 1 in 2,000 adrenalin one hour before the operation; or (3) that it was permissible and desirable that the patient should be anaesthetized in the sitting position with the feet horizontal from the first, either with the C.E. mixture or chloroform. Mr. Bellamy Gardner gave as reasons for the adoption of these principles—(1) that all danger of invasion of blood into the lungs could be thus avoided; (2) that the surgeon's work was much facilitated by the absence both of blood spraying over the operation area during expiration, and of semi-asphyxial turgescence of the mucous membranes due to irregularities in the respiratory rhythm. The surgeon gained the additional advantage of a view of the intranasal parts in their normal relations as clearly as in the consulting-room. (3) The reduction of the total loss of blood and also of shock by the obtruding influence of the local anaesthetic solution. Chloroform anaesthesia in the sitting position by a specialist was, in Mr. Bellamy Gardner's opinion, not so productive of depression as to move a patient when he had been lying down under chloroform. Dr. G. A. H. BARRON discussed a number of details concerning the anaesthetic and the posture of the patient. Surgeons did not usually prefer the upright position for some of the operations described, including turbinectomy. He favoured abstention from giving alkaloids in cases of operations on the frontal sinus when free haemorrhage was likely to occur. Dr. W. J. McCARDIE said that the surgeons with whom he worked gave, before the general anaesthetic, an injection of six drops of adrenalin to which was added 5 per cent. solution of cocaine in 6 c.c.m. of distilled water, and for intranasal operations the lying down posture was adopted. Mr. H. E. G. BOYLE said the technique adopted in his practice was quite different from that described by Mr. Bellamy Gardner. The surgeons with whom he worked preferred to have the patient lying on the side, the head being turned well over to the side and resting on a sandbag; then any escaping blood collected in the dependent cheek, from which it could be sponged away. Post-nasal sponges were not necessary when this position was adopted. The surgeon could sit down and perform the operation in comfort.

Scopolamine-Morphine-Atropine.

Mr. A. F. MORCOM read a communication on the use of a mixture of these compounds in inhalation anaesthesia. The dose should be: Hyoscine hydrobromide $\frac{1}{15}$ grain, morphine tartrate $\frac{1}{2}$ grain, and atropine sulphate $\frac{1}{15}$ grain. The mixture should be given three-quarters of an hour before operation. When this was done, the patient, in the majority of cases, became drowsy and fell into quiet sleep, so that the anaesthetic might be given without waking him. Thus he was spared the nerve-racking preliminaries of the operation. Less anaesthetic was required when this injection had been given, and after the operation the patient continued to sleep for some hours and woke without any feeling of discomfort. Post-anaesthetic vomiting, after this preliminary injection, was almost non-existent, or at the worst reduced to about 6 per cent. It had been said that it was difficult to obtain proper relaxation of the abdominal muscles when this injection was given, but in Mr. Morcom's experience this only applied when the upper half of the abdomen was being operated upon, and did not apply to operations below the level of the umbilicus. Mr. LIONEL E. G. NORLBY followed Mr. Morcom with a paper on the same compounds given as a general anaesthetic. His experience had been limited to 6 cases, but these had been

sufficient to show that the mixture had great possibilities, especially for patients suffering from diabetes, phthisis, severe bronchitis, sepsis, and severe cardiac or arterial disease. The dose should be: Morphine tartrate, $\frac{1}{2}$ grain; hyoscine hydrobromide, $\frac{1}{15}$ grain; atropine sulphate, $\frac{1}{15}$ grain. This was administered two hours before operation, and was usually sufficient, but if not, a further injection of morphine tartrate $\frac{1}{4}$ grain was given fifteen minutes before operation. It appeared to be safer to do this than to give another injection of the mixture, which in some cases, however, was allowable. In three of the cases local infiltration of the skin with 1 per cent. solution of novocain was employed in addition. In one case it was necessary to give a little gas for the preliminary incision to be made, whilst the subsequent operative proceedings were carried out in comfort. There was no shock or pain after the operation, and the patients slept for some hours afterwards; in one case four hours after the operation the respirations dropped to eight per minute, and were "Cheyne-Stokes" in character, but the patient readily responded to a hypodermic injection of strychnine. Relaxation of the muscles was not easily obtained with the mixture alone. The injection appeared to be of most value in amputations on diabetic patients, since there was no shock and no danger of "acidosis" and coma. The President said that opinion was still divided as to the value of scopolamine in conjunction with a general anaesthetic. The dislike of it by some surgeons seemed to be based on the rigidity which it caused, and in certain instances in his experience a longer time was required to produce relaxation. He now used a mixture of $\frac{1}{2}$ grain omnipon, $\frac{1}{15}$ grain scopolamine, and $\frac{1}{15}$ grain atropine. The use of scopolamine certainly did not detract from the surgeon's and the anaesthetist's difficulties, but the patient was often grateful for its use. Dr. W. W. H. TATE did not consider that scopolamine impeded the surgeon's work, but sisters and patients were agreed that a much better period was spent after the operation in cases where it had been used. Dr. LEWELLYN POWELL remarked that nurses were of opinion that when scopolamine had been given it was more difficult to know whether the patient was in danger some hours after the operation. Dr. W. J. McCARDIE did not see the need for adding atropine to the mixture. The morphine, of course, damped down the respiration and made matters easier for the surgeon. After these alkaloids were used there seemed to be more oozing than without. When using ether he gave a fairly large dose of alkaloids. Dr. WILSON remarked on the excessive thirst of young patients who had had morphine before the general anaesthetic.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF PATHOLOGY.

At a meeting held on February 14th, Professor A. H. WHITE, President, in the chair, Mr. WILLIAM PEARSON reported a case of *Congenital tumour of the gum*. He dwelt on the rarer varieties of tumours found in connexion with the buccal cavity (odontomata, dermoids, and teratomata) and on their embryological significance. This patient was a male infant born on October 1st, 1912. Labour occurred at full term, and the child was delivered naturally. Projecting from the mouth was a large, fleshy-looking mass which gave the child a most unsightly appearance, and prevented him taking any nourishment. Two smoothly-rounded, ovoid tumours projected from the mouth. The larger lay on the right side, and was of the size of a hen's egg, the smaller was as big as a damson plum. They were bright pink in colour like mucous membrane, but the larger was congested and in parts almost black. They had appreciably increased in size since birth, and felt firm and solid in consistence like uterine fibroids. They were attached by very short slender pedicles to the free border of the gum of the upper jaw, slightly to the left of the middle line. The pedicles were transfixed and ligatured, and the tumours cut away. It was then seen that immediately to the outer side of the pedicle of the smaller growth were two other small, rounded tumours, like little berries, sprouting from the gum, and these were also removed. Examination of the child on February 12th, 1913, showed the mucous membrane of the gum to be

smooth all round, so that no evidence of the former presence of these growths could be seen. The nasal cavities and pharynx appeared normal in every way. A description of the histology of the tumours was given by Professor A. C. O'SULLIVAN, who kindly made sections and photomicrographs. Mr. Pearson was inclined to regard them as teratoid in origin. In demonstrating the photomicrographs of the sections, Professor O'SULLIVAN pointed out that the growth was covered with compound squamous epithelium, without any horny layer, and without papillae, but otherwise normal. On the deeper parts the most striking feature was the appearance of a tissue suggestive of voluntary muscle, but without striation as far as he could see, and with nuclei contained *within* the fibres. These fibres were embedded in a tissue of whose character he could not be certain. He thought it had at first been largely of one type—namely, muscle—but the fibres had atrophied. This tissue otherwise looked like oedematous connective tissue. Professor McWEENEY said that he was not inclined to reckon the new growth either a dermoid or a teratoma. This tumour was covered with epithelium, underneath which was a mass of tissue composed of cells which were much the same as were to be seen in rhabdomyoma, and, in addition, it had an element in it which he did not remember being referred to—very dilated spaces which were lined with endothelium, and appeared to him to be dilated lymphatics. This would appear to him to bring the condition into the class of lymphangiomyoma. It might have occurred by the accidental misplacement of a portion of the jaw muscles on the analogy of the mixed tumour of the parotid. Professor SCOTT said he remembered seeing a slide made by Dr. Harvey which showed striation in the muscle fibres very clearly. The section was different from the sections shown that evening, and it then struck him that there was an astonishing resemblance to cardiac muscle. This was not surprising, seeing that cardiac muscle stood midway between the imperfectly differentiated smooth and the perfectly developed striated types. The differences between sarcomata beginning in very early life and the same tumours developing after years of latent potentiality were very slight. This new growth was possibly sarcomatous. There was a strong affinity between mixed tumours such as those of the parotid and sarcomata. Mr. PEARSON, in replying to the remarks, said that his first impression was that the tumour *was* of the nature of rhabdomyosarcoma, but that clinically it did not suggest a sarcoma. After some observations on teratoma and on the increase of the tumour being partly due to venous obstruction, he admitted that the nature of the tumour was still unsettled. Professor A. C. O'SULLIVAN, replying, said he was much interested in Professor Scott's remark that he had seen striation. Professor E. J. McWEENEY showed a specimen of *Gumma of the heart*, from a man aged 36, who died suddenly without any preliminary symptom. At the autopsy (inquest case) the gumma was found to be the sole cause of death. It was of unusually large dimensions, occupying almost the entire base of the left ventricle, and completely infiltrating the posterior wall and septum with a white, fleshy mass resembling sarcoma, and consisting of confluent nodules, in the centre of which lay obliterated and necrotic areas. The new growth fungated through the septum into the right ventricle near to the attachment of one of the tricuspid segments. Microscopically, it consisted of lymphocytes, plasma cells (which were very numerous), epithelioid and fibroblastic elements, and giant cells. The latter were very numerous. Their mode of formation and differences from those of tubercle were discussed. Eosinophiles were common. Whilst the newly-formed granulation tissue was nourished by somewhat scanty capillaries, also of new formation, the pre-existing blood vessels were the seat of a most typical and intense endarteritis obliterans, as the result of which they themselves, with the surrounding tissue, became necrotic. This feature stamped the process as syphilitic, although efforts to demonstrate the treponema had not been successful. The sudden *exitus* in this case was doubtless due to interference with the conducting tracts of the heart. Dr. BOXWELL noted that he had already shown two specimens of gumma of the heart before the section. In both the condition had caused sudden death. In one the appearances were extremely like those in the heart now shown

by Professor McWeeency, except that the plasma cells were less obvious, and the gumma suppurated and had become infected, and was discharging pus into the left ventricle. Dr. W. G. HARVEY had shown a large solitary tubercle of the ventricle at the same meeting in the case of a child aged 12 years. Dr. O'FARRELL referred to a dictum of Professor McWeeency regarding tuberculous giant cells and tubercle bacilli, and suggested that the same inverse proportion might hold good in the case of syphilitic giant cells and treponemata. He thought the basophilic cytoplasm of the syphilitic giant cell was characteristic. Professor McWEENEY, in replying, said, in reference to Dr. O'Farrell's remarks, that it struck him as extraordinary that there should be so much structural change in the practically complete absence of syphilitic organisms. It might be said that it was the products of the organism that were doing the mischief, but how could its products be there if the organism was not there itself? Here was an abnormal structural change and no spirochaetes, yet the process was undoubtedly syphilitic. He thought that the precise relationship of gummata and spirochaetes was only partially understood. Dr. MERVYN CROFTON read a paper on *The theory of immunity and therapeutic immunization*. It suggested: (1) That the toxins of the microbes were ferments by which the microbe broke down the living protoplasmic molecule, and that antitoxins were antiferments just as was antitrypsin. (2) That bacteriolysis brought about by immune body and complement was an exactly similar process to the lysis of carbohydrates, fats, and proteins by the tissue cells. (3) That opsonization of a microbe could be brought about in three ways:—(a) by the attachment of heat-labile complement like opsonin; (b) by the interaction of immune body and complement; (c) by immune opsonin (probably antitoxin) by itself. (4) That Wright's technique for estimating the opsonic index did not take the last two methods into consideration, and was, therefore, an unreliable guide to the dose that must be attained in any given case. Dr. ROWLETTE said that in discussing the theory of immunization he understood Dr. Crofton to have attempted to identify the thermo-labile and thermo-stable opsonins with the complements and immune body respectively. Dr. Crofton seemed to him to leave out of count altogether any of the other protective bodies formed in the process of immunization. He (Dr. Rowlette) did not see any reason for the opsonin body being picked out and identified with immune body. There might be an extremely high opsonic index while the patient was dying, as in the case of cerebro-spinal meningitis. He considered that Dr. Crofton should bring forward more convincing arguments before this view could be accepted. Referring to the practice, he agreed with him that to a very great extent one might be guided, as regards dose and the spacing of the dose, by the clinical signs without observing the opsonic index, but he considered the opsonic index as the greatest use in cases of mixed infection. His experience had shown him that there was the greatest difficulty to be met with in cases of mixed infection. Some years ago he was much impressed by a demonstration by Dr. Crofton with regard to increasing dosage, but in every case in which he (Dr. Rowlette) had tried to increase the dose he found the local reaction so marked that he considered it would be better to increase the dose very slowly. He thought if doses could be given which just escaped focal reaction as good results could be obtained. Dr. O'KELLY considered it very hard to know how much to attribute to vaccine treatment, as, in the case of bone disease, if the diseased substance was removed the condition might improve rapidly without any vaccine treatment, and the same might be said of pyorrhoea alveolaris. Dr. O'FARRELL could not agree that opsonin could be compared with complement. He was very much impressed by the size of the doses, and considered that the cases in which the vaccine failed it was often because it was not pushed far enough. He agreed that the opsonin Wright, as the dosage at present known, was entirely due to his work and also the intervals. He agreed that the opsonic index was unnecessary now in every case. The effect of the injection of streptococcus vaccine during high temperature was very remarkable. He had experience of one case in which vaccine was given when the temperature was high, and it came down, but as a general rule his practice was to give serum instead of vaccine in cases of high temperature.

Professor COLLINGWOOD asked Dr. Crofton whether he regarded the estimation of opsonin as an estimate of the "immune body" or of the "complement," as much depended on the answer to that question. The PRESIDENT considered that in most of the cases in which a large dose was given it came at the time when the patient was well, and of course enormous doses might be given to a person who was normal, and the same with cases well or almost so. Personally, he considered every case had its own therapeutic maximum dose, and when this was reached the maximum result was produced. A start might be made with a very small dose and increased gradually with very good results. Looking back during a period of seven or eight years over a very large number of cases of surgical tuberculosis he found that the dose that he was now giving was very much less than he was wont to give in the earlier times, and comparatively better results were produced. He considered that if suitable doses of tuberculin were given 90 per cent. of all surgical cases might be cured, and the same would hold good with other infections. In cases of furunculosis, if large doses were given the boils would get worse. Such a vast amount of facts had now been accumulated in connexion with vaccines that cases could generally be dealt with on clinical grounds. For instance, even with tuberculin inoculations a very small dose might be given, and the patient might exhibit some signs by which, with a certain amount of experience, one could tell if the dose had been too large, and these signs might fall far short of any actual rise of temperature. It might be nothing more than a sense of lassitude. Dr. CROFTON, replying to the remarks, said that there was no question that antibodies could be produced by repeated small doses; but unless all the microbes had been killed off there could be no guarantee against reinfection. He disagreed with those who said that a beginning should be made with a comparatively small dose. With regard to mixed infections, good results could not be obtained if only one vaccine was used. He agreed with the use of serum in acute cases. In answer to Professor Collingwood, he believed that when Wright's technique was used the estimation made was one of the feebly specific thermo-labile opsonin—in other words, of complement—and not of a true specific immune body.

ASSOCIATION OF REGISTERED MEDICAL WOMEN.

At a meeting held on March 4th, Dr. CONSTANCE LONG President, in the chair, Dr. KATHLEEN O. VAUGHAN spoke of the *Position of medical women in India*. Dr. Vaughan first explained the position of medical men in India; they were appointed either under the L.M.S. or the R.A.M.C., or they were in charge of the mission hospitals, and a very few were in private practice. There was no prohibition against unqualified persons practising or accepting fees, and many of the so-called private practitioners, both male and female, were persons with no medical qualification whatever. Dr. Benson, at the Cama Hospital in Bombay, was the only medical woman in India acting directly under the Government, and her appointment had proved an unqualified success. The mission hospitals were also doing excellent work; they were well equipped and were entirely under the control of the fully qualified women appointed to reside there. Dr. Vaughan, after stating that the Dufferin Hospitals scheme was founded in 1884 by Lady Dufferin, with the idea of supplying fully qualified medical women to attend to the Indian women, referred to the disabilities under which medical women worked owing to the claim of the members of the Indian Medical Service always to have charge of the hospitals. There were about 150 million women in India, practically all of whom would attend either a woman doctor or no doctor at all. Although many names of women patients were found on the books of men's hospitals, hardly any of these women were actually seen by the men; they either remained closely veiled during the interview, or sent boy messengers to record their symptoms to the doctor. The sanitary officers were all men, who, on account of the purdah system, were not permitted to enter the homes, in which, of course, the diseases chiefly originate. Dr. Vaughan pleaded for: (1) The establishment of a large number of women's

hospitals in India to be under the control of properly qualified women; (2) the appointment of female sanitary officers; (3) co-operation and help from England to aid in carrying out the schemes.

Reviews.

THE PROTEIN ELEMENT IN DIET.

MAJOR D. McCAY, Professor of Physiology in the Medical College, Calcutta, has added to the series of *International Monographs* (Ed. Arnold) a very valuable volume on the *Protein Element in Nutrition*.¹ Since the publication of Chittenden's views on the protein requirements of the body controversy has been waged with unabated interest as to the level of nitrogenous interchange necessary for the maintenance of growth, health, and efficiency. Major McCay makes the following observations on this point:

No one denies the feasibility of maintaining either man or animals in a condition of nitrogenous equilibrium on quantities of protein very much below the standards set up by the old masters in the science of nutrition. If we knew exactly how much and what particular nitrogen compounds the body requires in each specific state of nutrition, it is rational to expect that it would be possible to maintain the body in health, vigor, and efficiency on quantities of protein very much less than those hitherto considered necessary; but as we do not know what form of nitrogen combination nor how much of any particular unit is required in the different states of bodily nutrition, it is surely only rational that, in order to insure a sufficiency of those elements absolutely essential, a liberal standard of dietary should be recommended.

The researches on the production of beri-beri carried out by feeding both animals and prisoners on rice deprived of its outer layers, and similar researches which show that whole meal and not white flour, black bread and not white bread, suffice with water to maintain life, have led to the conception of "vitamines"—subtle principles in the foods absolutely necessary to life. It no longer suffices to fix a diet in terms of so much protein, carbohydrates, fat, and salts. The food must contain a minimum quantity of "vitamines," and care must be taken to see that modern methods of milling and sterilizing by heat do not rob the natural food of these principles, so small in quantity and yet vital in action.

From prolonged inquiries into the habits and physique of the tribes and races of India, Professor McCay brings forward a mass of evidence which proves that a high protein ratio is necessary in childhood to produce a virile and active race of men, and that an ample protein ratio is needed to secure efficiency of the body as a working mechanism.

An absolutely dispassionate survey of the physical development and general capabilities of the races and people of India points undoubtedly to the conclusion that, other factors being eliminated, those who obtain a liberal supply of absorbable protein in their daily food are superior in every respect to those whose dietaries exhibit any marked degree of lowering of the average protein standard.

This conclusion is enforced by a series of excellent photographs which illustrate the physique of the different races and tribes investigated. The photographs are carefully selected as being as nearly as possible typical of the average development met with. Most striking is the contrast between the groups of Ooriza on page 86 with, say, the Degra or Punjab Mohammedan on page 194.

Rice is so poor in protein that in all fixed dietaries wherein it forms the main constituent the amount of it present ranges up to and over 26 oz. of the dried material. When rice is cooked it swells up to almost five times its dried bulk. The total capacity of a European stomach of ordinary size is about 1,200 grams, while the weight of a full food diet of rice exceeds 3,000 to 3,500 grams (7 or 8 lb.); the bulkiness of the diet leads to greatly increased waste of protein from non-absorption, the digestive juices fail to penetrate it, and peristalsis is enhanced. The final fate of much of this food is bacterial decomposition in the large bowel and windy evacuation.

The picture of the feebleness, laziness, lack of energy, and sleepiness of the working coolie could hardly be overdrawn.

¹ *The Protein Element in Nutrition*. By Major D. McCay, M.B., B.Ch., B.A.O., M.R.C.P., L.M.S. *International Medical Monographs*. London: Ed. Arnold. New York: Longmans, Green, and Co. 1912. (Demy 8vo, pp. 230; plates 8. 10s. 6d. net.)

We have seen three labourers, with, of course, a sirdar or overseer, take eight days to loosen the surface of a drive to the depth of 2 in.; the total surface of the drive was roughly 200 square yards. An ordinary European labourer would have finished the work in a few hours. In coal mining the physical conditions are altogether in favour of the Bengali, and the result is an out-turn barely 27 per cent. of that of the European. Between 15 and 35 years of age the expectation of life is from 36 to 38 per cent. less favourable in India for males, and from 34 to 48 per cent. for females. Eurasian students who as boys enter Calcutta colleges, and are fed on European standard of protein show development into strong, healthy men quite up to the average European standard in physique.

The lessened expectation of life, decreased resistance to disease and infection, earlier onset of the marked evidences of tissue degeneration and senility, are conditions that would be anticipated in a people who exhibit such slackness, want of vigour, tonelessness, general slowness of reaction, and other physiological attributes difficult to describe, detect, and measure, which form some of the distinguishing characteristics of the working population of Bengal. Self-absorption, introspection, want of interest in the incidents of everyday life, little power of attention, observation, and concentration of thought—these are some of the attributes of all but the better classes and better fed of the Bengalis.

"The Bengali," says Major McCay, "has never, so far as we are aware, in modern times been recruited for the fighting line," while other inhabitants of the great Gangetic Plain, stretching from the north-west in the Punjab to the sea in Bengal, exposed to and suffering from all the disabilities of climate, but on a superior dietary, are capable of exhibiting the firmest courage, determination, and endurance. Major McCay cites the observations of the Army Committee on the physiological effects of food, training, and clothing of the soldiers, and the conclusion reached that during a period of hard training 190 grams of protein a day appeared to be ample, whilst 140 grams was too low. On the other hand, the average amount of protein eaten by brain workers in the physiological laboratory at University College was found to be about 90 grams.

We must remember that a growing animal or child which receives only sufficient food to keep its body weight constant, or to allow a slight increase, is in a condition of severe starvation. The skeleton grows at the expense of the flesh, fat is consumed more or less entirely, and a great proportion of the body tissues is replaced by water; the caloric value of 1 gram of body weight taken at the extreme of such a process, may only be one-third of the normal value.

It is possible by supplying a suitable amount of food to maintain a dog for nearly one year in an emaciated condition, apparently in good health and at the weight of a puppy. If such an animal is then fed amply it fattens and rounds out, but is unable to make good the growth suspended by the long restriction of food. Hence we see the necessity of maintaining a high protein ratio in the food of the children. This is, perhaps, the most pressing of all claims on parents and educational authorities, for wise feeding is of the first importance, and this with sufficient rest may go far to ensure health in the worst kind of surroundings.

DISEASE IN CHILDHOOD.

The translation into English of the fifth volume of the first edition of the system of children's diseases, edited by Professor PFAUNDLER of Munich and Professor SCHLOSSMANN of Dusseldorf, was completed last year. The English translation² has been edited by HENRY L. K. SHAW, M.D., and LINNAEUS LA FÉTRA, M.D. The present volume is somewhat in the nature of an appendix to the general work, which in four volumes traverses the whole ground of the medical disorders of infancy and childhood with a fullness and care that has not as yet been equalled in the textbooks of other countries. The fifth volume deals with the complaints of children which are more distinctly of a surgical nature, and they are treated not from the point of view of the operative surgeon, but from that of the physician. The book aims at giving a sufficient description of the main principles of treatment in orthopaedic surgery, whether manipulative or opera-

tive, and discusses at some length the indications for and against the various operative procedures which are especially designed for the relief of disorders in infancy and childhood. Unlike the earlier volumes, the whole of the present volume is the work of one writer, Dr. Hans Spitzzy of Gratz. He opens with three essays of great value on the Child and Surgery, the Child and Operative Interference, and the Child and Anaesthesia respectively. The rest of the work is divided into six sections—congenital diseases, disturbances on post-fetal development (which deals especially with orthopaedics), surgical infectious diseases, injuries, affections of neurogenic origin, and, lastly, tumours. The book is of extreme interest throughout, and on the whole may be regarded as a very successful attempt to bridge over the very unnecessary and artificial barrier which conditions of practice have tended to erect between the practice of paediatrics and the work of the operating surgeon. The indications for surgical interference are on the whole fairly and wisely discussed. At times, perhaps, the conservative physician might object that operation is too lightly advised. For example, any one with a large experience of dyspepsia in infancy will demur to the statement that an operation is indicated when an umbilical hernia has been present for six weeks. Again, in the author's view, the opinion that strangulated hernia is rare in children is erroneous, and he uses this as an argument in favour of early routine operation. The likelihood that the hernia is merely due to the distension of the coils of intestine from dyspepsia and to increased peristalsis and colic is ignored. At times the directions as to treatment are very obscure, although whether this is the fault of the translator or of Dr. Spitzzy we have not ascertained. Thus in the treatment of rickety deformities—a subject peculiarly likely to occupy the attention of the practising physician—we are told that "circular as well as lateral traction must be avoided. I employ garters at the back and inside. The front ones very often cause extensions." Such directions are hardly explicit enough. On the whole the volume should prove a valuable addition to a system of *Diseases of Children* which has already proved its worth. The illustrations are well chosen and well executed.

A second German edition of PFAUNDLER and SCHLOSSMANN'S book³ is now in process of publication. It abounds in physiological data and doctrines, which make it interesting to those who have ample time for reading. The physiology of childhood is a recent subject of study; most of its doctrines are still open to controversy. To the student who is prepared to devote his life to the study of children's diseases the book can be confidently recommended. It teems with references to the multitudinous problems which are awaiting solution, for all the collaborators seem to take a delight in discussing theories. As an introduction to the problems of paediatrics, the work is probably unique. The present edition is certainly an improvement on the first. The editors acknowledge the aid of reviewers in their task of revision, and they have accepted some advice. For instance, the chapter on semiology was adversely criticized in the former review in these pages, and it has now completely disappeared to make way for more useful matter. English and French work, particularly the latter, has obtained more recognition than is common in German medical literature. The general sections on hygiene contain whole-hearted approval of English games and English infant clothing. In the chapter on metabolism during the first year of life, there is a rather remarkable omission of the recent work on fat metabolism in infancy. Camerer, the author of this chapter, is prepared to go to great lengths in order to obtain natural feeding for an infant, for he urges that if the supply of maternal milk be in abeyance, the child should be given nothing but a little water sweetened with saccharine, and that it be put to the breast regularly. He mentions a case where this was continued for fourteen days with ultimate success. The succeeding chapter on nutrition after the first year has been much extended. Perhaps the most remarkable sign of the times in this chapter is the insistence on the small amount of albumen actually necessary for the growing child; 2 grams of

² *The Diseases of Children. A Work for the Practising Physician.* Edited by Dr. M. Pfaundler and Dr. A. Schlossmann. Translated from the German by Henry L. K. Shaw, M.D., and Linnaeus La Fétra, M.D. In five volumes. Vol. v. Philadelphia and London: J. B. Lippincott Company, 1912. (Imp. 8vo, pp. 378; plates 90, figs. 775. 21s. net.)

³ *Handbuch der Kinderheilkunde.* Edited by M. Pfaundler and A. Schlossmann. I and II Band, 2 Auflage. In 4 vols. Leipzig: Vogel, 1910. (Demy 4to, pp. 457 and 590. Mk. 12.50 each.)

albumen a day per kilo are stated to be sufficient. This article is fully illustrated by tables and diagrams, and will be very useful to the student. The chapter on blood diseases is less ambitious than most of the others, but is very good. In discussing rickets, Stoelzner gives a short exposition of his theory that rickets is due to a functional insufficiency of the suprarenals, due primarily to lack of exercise of the striated muscles of the body. He quotes Findlay's results and refers to the fulfilment of Hanseman's prophecy that when the Japanese began to inhabit European houses rickets would appear in Japan. Although he expresses his personal belief that adrenalin is a specific remedy for rickets, Stoelzner gives no details of its application. In the chapter on diabetes insipidus there is no reference to the pituitary body as a possible factor in etiology. Pfaundler is responsible for a new chapter on the lymphatic constitution, neuro-arthritis, and the exudative diathesis. All three conditions are regarded as being approximately the same. The impression gained from a careful study of this chapter is that a child of pasty, irritable, or plethoric habit who shows certain symptoms is a subject of the diathesis. The mere list of symptoms covers more than a page, and the individual symptoms range from fever "without cause" to dysmenorrhoea. The actual causes are stated to be heredity, overfeeding, and bad hygiene. There are already numerous theories to account for the pathogenesis of the condition, and we may note that they range from larval gout to the modern fashionable anaphylaxis. The diathesis is not in itself tuberculous, but the affected individual is more liable to tuberculous infection than others, and it tends to take the form of scrofula. The treatment advised is very sensible, being largely a return to nature. The diet should be mainly vegetarian, milk should be limited even in infancy, and, above all, the child should not be treated as an invalid. The condition has been recognized and treated for years in this country by most practitioners. Was it not an English physician who described this type of fever, and advised that the doctor should accidentally break the thermometer, and supply the mother with one which would on no account register more than 99°? The succeeding sections on the acute infections are excellent although not altogether orthodox. There is a new chapter on vaccination by von Pirquet, which contains a short but clear account of the phenomena observed and their significance in relation to his conception of allergy. Theoretical discussion here predominates, rather than the neglect of vaccinal injuries. The writer on the subject of typhoid fever does not seem to accept the modern teaching of the German school on the epidemiological importance of mild atypical cases in children. The article on syphilis has been brought up to date. Modern views as to hereditary transmission are fully discussed but there is no reference to salvarsan. The section on tuberculosis is by no means so good; it is very theoretical, and too much stress is placed upon tuberculin both for diagnostic and therapeutic purposes. There is a short appendix on serum disease by von Pirquet and Schick. It is a useful statement of the views of these authors upon the subject as well as a concise summary of the facts.

In his *Medical Diseases of Children*,⁴ Dr. WHIPHAM has endeavoured, within a small compass, to cover a large extent of ground. The book contains only about 400 pages, and space has had to be found for sixty-seven admirable photographs illustrating various abnormal states. Within such limits it is perhaps possible to crowd short descriptions of all the ailments to which children are prone, but it is impossible to do more. The author is debarred from introducing into the work that personal note the presence of which best justifies the repetition of descriptions which appear in many textbooks of similar scope and aim. Although the present volume can be recommended confidently as a short textbook to place in the hands of those who are starting the study of children's diseases, or who are reading for examinations in medicine, it is impossible to avoid the reflection that there already exist many works of which the same may be said. To the serious student of the diseases of children, or to the busy practitioner it

has less to offer. Much of the restricted space is occupied by passing references to or descriptions of conditions which are so rare that a man may be in practice for many years and yet meet with no example. There is not room enough for a proportionate expansion of the space allotted to the diseases that are common and of everyday occurrence. Thus, while eight pages are all that can be spared for the consideration of derangements of nutrition, including inanition, malnutrition, and marasmus, five are devoted to an account of infantile scurvy. Again, actually more space is given to the description of hypertrophic pyloric stenosis than is accorded to the consideration of the devastations of infantile diarrhoea in hot weather. Such anomalies can hardly be avoided if an attempt is made to include all disorders in a small volume, but the student will be apt to feel that there is a sharp contrast between what he reads and his experience in the out-patient department or in practice. If in practice cases presented themselves in the frequency which obtains in an exhibition of interesting clinical cases in some paediatric society, such books would be well enough, but their arrangement would better correspond with practical experience if a preponderating part of the space were devoted to the study of such common disorders as diarrhoea, bronchitis, rickets, rheumatism, and so forth. In the first chapter, entitled *The Development of the Child*, we notice some statements which seem to invite modification, as, for example, that "in the fourth or fifth month simple sounds, such as 'pa' and 'ma,' may be uttered, and the child shows some power of holding up its head"—a statement which might lead the student to suppose a very premature gift of speech and a very delayed power of controlling movements of the head. Surely, too, in well-managed nurseries, the results of training are manifested more early than would be suggested by the statement that "by the eighteenth month, if properly trained, the child should have acquired habits of cleanliness." At times the author appears too precise in his statements, as, for example, when he tells us shortly that "in the fifth year destructiveness becomes a marked feature, and in the seventh constructiveness begins." We welcome the appearance of a separate chapter entitled *Pneumococcal Infection*, dealing with its various manifestations in different parts of the body. The article on congenital syphilis is especially full and clear. Those who teach that enlargement of the epitrochlear glands is a characteristic symptom of congenital syphilis will not agree that glandular enlargement is rarely seen until after six years. Wasting, sallowness, and senility of aspect are not invariable symptoms of congenital syphilis, at any rate in breast-fed infants, as might, perhaps, be inferred from the statement on page 163. The book is well and clearly printed, and the illustrations are admirable in every way. There is a good and complete index.

Dr. HOLT'S *Diseases of Infancy and Childhood*⁵ is so largely used both in this country and in the United States that a new edition in which the author has the assistance of his former assistant, Dr. John Howland, is sure to be welcomed. The book has been brought thoroughly up to date and a considerable amount of new material has been added. The article upon tuberculosis in childhood remains one of the best descriptions which we know in the English language. The chapters upon infant feeding are very full and clear. We should have preferred to find in the article on mixed feeding a clear statement of the danger of artificial feeding during the first weeks of life, when the breast milk is slow to appear. In such circumstances the giving of two or three bottle-feeds a day is recommended, but no mention is made of the likelihood that with diminished sucking the breast secretion will decline, even if the child does not refuse the breast entirely. The book remains upon the whole one of the best of the larger textbooks. It is well and profusely illustrated by photographs, diagrams, and plates, several of which are in colour. While nothing common or of everyday occurrence is omitted, room is found for numerous succinct descriptions of disorders which are of less frequent incidence. As an example of an accurate

⁴ *The Medical Diseases of Children*. By T. Rowland C. Whipham, M.D., M.R.C.S. London: Hodder and Stoughton, and H. Frowde, 1912. (Demy 8vo, pp. 428, with 67 illustrations. 10s. 6d. net.)

⁵ *The Diseases of Infancy and Childhood*. By L. E. Holt, M.D. Sixth edition. New York; London: D. Appleton and Co., 1911. (Sup. roy. 8vo, pp. 1130; 240 illus., including 8 coloured plates. 25s. net.)

description of a condition which escapes the attention which it merits in most textbooks, we may refer to the article on perinephritis.

Dr. J. McCaw's *Aids to the Treatment of Diseases of Children* has now reached a fourth edition. We have copied the title upon the outer cover: on the title page it appears as aids to the *diagnosis* and treatment of diseases of children. This discrepancy is suggestive of the defects which this book as well as all others of its class must tend to show. It is impossible to write intelligently and wisely of treatment without referring at great length to questions of pathology and of diagnosis. Thus, if we turn the pages at random and select the article upon rickets, we find that while ten pages are devoted to this subject, only one and a half pages in reality deal with therapeutics. The book, in fact, differs little from the larger textbooks of children's diseases, save in its smaller size, in the absence of charts, diagrams, and illustrations, and in the briefness of its descriptions generally. The author in the small space at his disposal has contrived to pack a surprisingly large amount of information, and has even found room for not a few references to recent literature.

Dr. Louis Fischer's textbook of *Diseases of Infancy and Childhood* has now reached its fourth edition, and, since the first only appeared in 1907, we may congratulate the author and the publishers upon having produced a work for which a constant demand exists. Dr. Fischer's book does not differ very materially in plan or scope from a large number of other textbooks of diseases of children. Like many others, the book is rendered the more valuable because it is profusely illustrated by photographs of types of disease in childhood, as well as by numerous diagrams and charts. There are no fewer than thirty full-page half-tone and colour prints, several of which are of great excellence. Changes in the present edition are numerous. "Science," says Dr. Fischer, in his preface, "has again reversed many existing theories pertaining to gastric derangements. Clinical and microscopical observations have shown that casein, rather than being a disturbing element causing intestinal autointoxication, is really a valuable adjuvant in atrophic conditions, as it modifies intestinal putrefaction." Surely Dr. Fischer should have written not "putrefaction" but "fermentation"! The latest views upon the etiology of poliomyelitis are discussed at some length. Brudzinski's valuable sign in meningitis we find for the first time in a textbook written in English. In discussing the treatment of appendicitis the author advocates rest in bed, hot fomentations, leeches, the opening of the bowels—though whether by purgatives or enemata is not indicated—ice, and champagne for vomiting, and, lastly, cocaine administered every hour until the pain is relieved. Only if the symptoms continue in spite of the above treatment is operation advised. This advice is not a little dangerous. In the paragraph with the attractive title "When shall we Operate?" the information given by a leucocyte count is alone discussed. The book, on the whole, gives an adequate account of the diseases of children. It is well printed and bound, and the illustrations are of extreme value.

Under the title of *Occasional Papers on the Prevention of Some Common Diseases in Childhood*,⁶ Dr. J. SIM WALLACE has put together a number of essays and addresses produced during the last few years upon a variety of occasions. Their collection in a single volume has the drawback of involving a great deal of repetition, and many readers will probably experience some irritation owing to the frequent reiteration of the author's claim that by his writings and addresses he has achieved something of a revolution in the nature of our views as to

dietics in general and the cause of dental caries in particular. The main proposition for which Dr. Wallace earnestly contends is that the retention of fermenting carbohydrate foodstuffs is the cause of dental caries, and that this can be prevented by an intelligent regulation of diet, and by concluding the meal with foodstuffs which require mastication and therefore promote the flow of saliva to wash away offending particles. The important part played by faulty apposition of the teeth, whether due to mouth breathing from hypertrophy of tonsils and adenoids to rickets or to undue suction of the artificial teat is not here mentioned. It is true that the author has set aside a special chapter entitled, "Open Windows and Adenoids," to a consideration of the causation of adenoids. From certain observations which he has conducted, he believes that adenoids occur almost exclusively among children who sleep with open windows. Among 69 such cases 22 of adenoids were counted, while of 49 cases who slept with shut windows only 2 were affected. We cannot agree, despite the encouragement afforded by these figures, that a "simple investigation carried out upon these lines will prove to the medical world—as it has done to those who have already looked into the subject—that adenoids are easily preventable in nine cases out of ten." Dr. Sim Wallace is indeed a great believer in statistics. Statistics, he believes, will show that the woman who drinks milk habitually will have difficulty in nursing her infant at the breast, and again statistics will show "that the average milk-fed girl does not in womanhood develop such a womanly figure as the girl who has shown aversion to milk and a preference for more hygienic liquids throughout her life." Although we believe that the author's main contention that carbohydrate fermentation leads to dental caries is true and that the wisdom of some of the dietetic rules which he advocates is obvious, we cannot altogether share his expectation that with their universal adoption we should witness a truly stupendous decline in the incidence of disease of all sorts in childhood, any more than we agree with him that the problem of the hypertrophy of lymphoid tissue in children or of the increasing inability of women to suckle their infants hangs upon such simple issues as the shutting of windows or the drinking of milk.

SURGICAL AFTER-TREATMENT.

A SECOND edition of *Surgical After-Treatment*,⁷ by Drs. CRANDON and EHRENFRIED, has been published. We noted in reviewing the former edition how the authors turned attention to certain details which common sense ought to allow no hospital staff to overlook, though they are sometimes neglected. Sufficient care is not always given to the treatment of the patient immediately after operation and his transference to the bed in his ward. Such occurrences as vomiting after anaesthesia are not "trifles," but routine duties are too apt to be treated as trifling, and distinctions between the essential and non-essential to be confused. The authors take care that their readers should never forget such matters. The early history of modern abdominal surgery, with its fixture of the patient in the supine position and the locking of the bowels for a week, is instructive when we remember that the surgeons who insisted on it—Spencer Wells, for instance—were the strongest advocates of what they held to be systematic, scientific, and practical after-treatment. To that treatment they ascribed their successes. They did not always understand that their failures were in part due to their treatment, and still less did they comprehend what is one of the last things the surgeon succeeds in defining, namely, how patients may recover in spite of treatment which is really faulty. Drs. Crandon and Ehrenfried are to be commended for their discussion of what may be termed the systematic, scientific and practical aspects of after-treatment. They never lose sight of any one of these aspects. In one matter of detail they may provoke criticism: in some of the illustrations the essential detail is not so clear as it should be. Thus in Fig. 19, showing the technique of hypodermic injection, the face of the nurse and the patient's arm come out much more

⁶ *Aids to the Diagnosis and Treatment of Diseases in Children*. By J. McCaw, M.D. Fourth edition. London: Baillière, Tindall and Cox. 1912. (Fep. 8vo, pp. 445. Paper, 3s. net; cloth, 4s. net.)

⁷ *Diseases of Infancy and Childhood—Their Dietetic, Hygienic, and Medical Treatment*. By Louis Fischer, M.D. Fourth edition. Philadelphia: F. A. Davis Co.; London: Stanley Phillips. 1911. (Roy. 8vo, pp. 1005; figs. 308, plates 30. 27s. 6d. net.)

⁸ *Occasional Papers on the Prevention of Some Common Diseases in Childhood*. By J. Sim Wallace, D.Sc., M.D., L.D.S. London: Baillière, Tindall, and Cox. 1912. (Demy 8vo, pp. 110. 3s. 6d. net.)

⁹ *Surgical After-Treatment: A Manual of the Conduct of Surgical Convalescence*. By L. R. G. Crandon, A.M., M.D., Assistant in Surgery at Harvard Medical School, etc.; and Albert Ehrenfried, A.B., M.D., Assistant in Anatomy at Harvard Medical School, etc. Second edition, thoroughly revised. Philadelphia and London: W. B. Saunders Company. 1912. (Royal 8vo, pp. 331; illustrations 265. 25s. net.)

clearly than the skin pinched up, the fingers that are pinching it, and the needle of the syringe. A good chapter on massage has been prepared for the new edition; it is short and elementary, as fitting a work for the use of the general surgeon. The treatment by massage of certain fractures and of injuries of joints are illustrated by aid of some instructive photographs. The book is no doubt good; its main defect is the fact that its bulk apparently detracts from its simplicity, but that deficiency is unreal. Each subject is treated simply, but there are so many subjects with which after-treatment is concerned that bulk is unavoidable. The paragraphs on general preparation of the patient are specially good on account of their simplicity. After-treatment may fail, not on account of the operation, but because of errors in preliminary treatment, such as reduced diet and excessive catharsis.

PHARMACOLOGY AND THERAPEUTICS.

DR. MAX KAHANE'S book¹⁰ is an account of the newest drugs and their uses in practical medicine, compressed into a conveniently small, but not too small, bulk. The arrangement of the material is under such headings as anaesthetics, cardiac remedies, diuretics, blood tonics, organotherapy, gout remedies, antisyphilitics, serum-therapy, bacteriotherapy, and so on. Although this entails a certain amount of repetition, its convenience for clinical use is evident, as the book is primarily intended to serve as a help to the practitioner who is actually engaged in treating cases, and who is, therefore, chiefly concerned with therapeutics. In conformity with this idea the various drugs are described with special reference to taste, solubility, dosage, and the best methods of prescribing. In each section the remedies are arranged alphabetically; the list is in most cases preceded by a short but carefully written and highly interesting account of the general action of the group. These short essays lift the book out of the category of mere compilations. A general introduction reviews shortly the influence which the advances in manufacturing chemistry, physiology, and experimental pathology have exercised on therapeutics during the last twenty-five years. The volume as a whole can be highly recommended as a convenient epitome of recent efforts towards more efficient treatment by means of drugs.

Professor Wood's new volume on *Pharmacology and Therapeutics*¹¹ gives a good picture of the present state of the science of drugging, not overloaded with detail. It is founded on the requirements and prescriptions of the United States *Pharmacopœia*, so that its usefulness in other countries is to some extent limited. After an introduction of twenty-five pages, the author gives chapters to the drugs used to affect secretion, the nervous system, the circulation, the alimentary tract, metabolism, and to the causes of disease. Two final chapters treat of "extraneous remedies," by which are meant those used externally and those whose virtue depends upon some simple chemical action modifying the secretions of the body, and a selection of drugs of minor importance. The various drugs are discussed clearly enough from the points of view of materia medica, physiological action, toxicology, and therapeutic use. A few slips are to be noted in the book: the polarimeter, for example, employs Nicol prisms made of Iceland spar, and not of feldspar (or felspar) as is stated on p. 61: one litre = 1.76 pints, and not 2.113 pints (p. 4). It would be well if the many misprints and false concordances in the Latin terms and prescriptions throughout the book could be corrected by some one acquainted with the Latin tongue, unless, indeed, the butchery of a dead language is to be regarded as a matter of indifference to Professor Wood's readers.

PUBLIC HEALTH WORK IN THE TROPICS.

The bacteriology of surface waters in the tropics is ably treated by Major W. W. CLEMESHA in a small volume,¹²

which will be of the greatest value to sanitarians in other parts of the world as well as in India. The subject is one of enormous importance to India, and it is fitting that accurate scientific work should have been done upon it by a person with such attainments as the author. In 1909 Major Clemesha and his assistant published as an appendix to the annual report of the King Institute of Madras a study on the bacteriology of drinking-water supplies in Madras, and this, with studies since carried out, has now been brought up to date by the incorporation of experiences recently gained. The bacteriology of water in tropical climates is widely different from that in colder climates, therefore its special study is essential if such water is to be used for human consumption. The book deals in succession with the bacteriology of faeces; streptococci in water; the prevalence and significance of organisms which ferment glucose but not lactose in surface waters; the action of direct sunlight on common faecal organisms; the effect of sunlight on large natural lakes; the analysis of the water of lakes and rivers in India; the position of certain faecal organisms in nature, and the application of the foregoing researches to water analysis.

*Aids to Tropical Hygiene*¹³ is a little handbook by Major R. J. BLACKHAM, D.P.H., R.A.M.C., which will be found of great value by all medical men practising in the tropics. It gives a very good account of this very important subject in a short and easily understood form, and the laity might quite well also study it with advantage. As Major Blackham says, the question of the colonization of the tropics is now being seriously discussed by physicians and statesmen in every quarter of the globe, and there can be no doubt that with improved sanitation many places previously unhealthy could be transformed into places where a white population could subsist, with a death-rate somewhere about the same as that found in Europe. Though Major Blackham's book is small; nevertheless it goes into the matter in detail, and all the subjects of importance are suitably treated. As to many of these, such as clothing, soils, houses, disposal of refuse, and disposal of the dead, procedure must necessarily vary with the country, but even so, a good knowledge of conditions required in India will be a great help in devising schemes for other parts of the world. The book, therefore, may be thoroughly recommended, as it is well written and contains much valuable information, put together by a man who understands what he is writing about.

¹³ *Aids to Tropical Hygiene*. By R. J. Blackham. London: Baillière, Tindall, and Cox. 1912. (Fcap. 8vo, pp. 197; tables 2. Cloth, 3s. net; paper, 2s. 6d. net.)

MEDICAL AND SURGICAL APPLIANCES.

A Lumbar Puncture Set.

DR. J. G. PORTER PHILLIPS (Bethlem Royal Hospital) writes: The lumbar puncture apparatus which is described below is the outcome of a demand for a compact and portable set of instruments. In view of the facts that lumbar puncture is being performed with increasing frequency for diagnosis and treatment both in hospital and private practice, and that no surgical instrument maker has heretofore had a comprehensive set to offer, I have devised one which can be carried very conveniently from case to case in a hospital ward and can be used with advantage at the bedside by the general practitioner. The apparatus comprises a small nickel-plated sterilizer into which are fitted 2 c.cm. and 10 c.cm. all-glass syringes with the usual steel needles clipped on to a suitable platform, under which are fixed a pair of scissors, forceps, and two iridium-pointed platinum needles. These latter needles are somewhat longer and more strongly made than those one finds in general use, and accompanying them is a hollow silette for the injection of serums, etc., into the cerebro-spinal canal. The sterilizer is provided with a rapid-heating spirit-lamp with a circular burner on the Bunsen principle which will raise cold water to boiling-point in five minutes. In this division of the case there are small spaces for six ampoules to contain local anaesthetic, serums, etc., the former being very useful in the case of nervous and sensitive patients who may fear and object to the operation on the ground of anticipated pain. In the other division is placed a nickel-plated rack carrying four centrifuge tubes and five stoppered bottles containing lysol, ether, alcoholic solution of iodine, biniodide solution,

¹⁰ *Die Arzneimitteltherapie der Gegenwart*. Von Dr. Max Kahane. Vienna: Urban and Schwarzenberg. 1910. (Post 8vo, pp. 611 Mk. 9.)

¹¹ *Pharmacology and Therapeutics for Students and Practitioners of Medicine*. By H. C. Wood, jun., M.D. Philadelphia and London: J. B. Lippincott Company. 1912. (Royal 8vo, pp. 440; figs. 28. 18s. net.)

¹² *The Bacteriology of Surface Waters in the Tropics*. By W. W. Clemesha, M.D. (Vet.), D.P.H., Major I.M.S., Sanitary Commissioner, Bengal; Professor of Hygiene, Medical College, Calcutta. Calcutta: Thacker, Spink and Co; London: E. and F. N. Spon. 1912. (Demy 8vo, pp. 163. Rs. 7-8.)

and colloidion. There are also two small metal boxes to hold squares of sterilized lint and gauze. Each piece of apparatus is removable and can be readily cleaned or sterilized. The entire set, enclosed in a black morocco case and lined with washable batiste, only measures only 13 in. by 5 in. by 5 in., and weighs a few pounds. This apparatus, which I have found very handy and useful, has been made for me by Messrs. Maw Son and Sons, of Aldersgate Street.

Nova et Vetera.

THOMAS DOVER,

PHYSICIAN AND CIRCUMNAVIGATOR.

THOMAS DOVER, M.B., the inventor of "Dover's powder," who in his day had a notable reputation for treating many diseases by large doses of mercury until he earned the title among less successful practitioners of the "Quicksilver doctor," has been well known since the days of *Robinson Crusoe* as the discoverer of Alexander Selkirk. Information as to his private life and family connexions has only recently been forthcoming.

He was the son of Captain John Dover (one of Prince Rupert's officers), and was born at Barton-on-the-Heath, Warwickshire, in 1662. His grandfather was Robert Dover, an attorney of Barton-on-the-Heath, the son of John Dover of Norfolk. Thomas Dover matriculated at Magdalen Hall, Oxford, in 1680, at the age of 18, and migrated to Gonville and Caius College, Cambridge, in 1686. Later he became the pupil of Sydenham, by whom he was cured of small-pox. In 1696 Dover was practising medicine in Bristol, and offered his services gratuitously on behalf of the poor under the newly-appointed guardians of that city. Here, if he did not actually become a member of the memorable Society of Merchant Venturers, he certainly was closely concerned in their undertakings, and in 1708 joined with a group of members of this society in fitting out an expedition to the South Seas, which brought him and his partners much profit, and bore back to England the voluntarily exiled Alexander Selkirk. At the end of a long and prosperous career he retired to Stanway House, in the Cotswold Hills, where, with his friend Robert Tracy, he spent the closing years of his life.

In the Roll of the Royal College of Physicians it is said that Dr. Dover ended his days in London, although Munk acknowledged that this was a pure conjecture on his part. On the other hand the county historians of Gloucestershire. Rudder and Rudge, both stated that the famous Doctor Dover, who instituted the Cotswold Games, died at Stanway House in Gloucestershire, and was buried at his own request in the vault belonging to the Tracy family at Stanway. Dr. Thomas Dover, however, did not found the Cotswold Games; the real founder was his grandfather, Robert Dover, from whom Dover's Hill, near Campden, takes its name.

Local tradition in Stanway at the present day has lost all trace of the Christian name of the famous Dover who was buried there, and claims that the church contains the mortal remains of the Dover who founded the Cotswold Games and gave his name to the hill. But tradition errs, so too does the *Dictionary of National Biography* on this point. Robert Dover, the attorney of Barton-on-the-Heath, died and was buried there on July 24th, 1652, as the Barton register shows.

At Stanway the register proves the burial in April, 1742, of Thomas Dover, M.B. Stanway House, now the seat of Lord Elcho, was the residence in those times of that Robert Tracy to whom Dr. Dover dedicated *The Physician's Legacy*. It seems likely that the Tracy and Dover families were distantly related through a grandfather of Robert Tracy, who married Katherine, a daughter of Sir Anthony Keck, while Thomas Dover's maternal grandmother is described as "Joan, daughter and heiress of—Keck." The blank is regrettable; it may or may not stand for "Sir Anthony." One thing only is certain, that between Robert Tracy and Thomas Dover a firm friendship existed, which explains the death of the latter in the house of the former and his burial in the family vault of the Tracys.

In the church at Stanway no trace can now be seen of the vault, nor any memorial to any member of the Tracy family or Dr. Dover. The Tracy vault is beneath the chancel floor, where in a recent restoration the altar, which had formerly been raised on steps over the vault to an inconvenient height, was lowered to its present position. The superstructure of the vault, if any previous'y existed, has been completely destroyed, with the result that the altar is now said to stand almost upon the coffin lids.

Here underneath the altar Thomas Dover is buried, his only memorial a brief entry in the parish register. His wife Joanna (whose maiden name remains so far unknown) had predeceased him by some years, and was buried at Barton-on-the-Heath, April 27th, 1727. They had twin daughters, baptised at Barton in 1688, both of whom died young, a third daughter, Sibilla, who married John Hunt, leaving issue from whom many descendants survive, and a fourth daughter, Elizabeth, who married John Opie, and died childless.

The account given by Thomas Dover in Woodes-Rogers's *Voyage Round the World*, which redounds but little to the credit of the "Quicksilver doctor," is not corroborated by that other less well-known book dealing with the same expedition, and entitled *A Voyage to the South Sea and Round the World*, by Captain Edward Cooke, second captain of the *Dutchess*. Cooke's work was published in 1712, whereas Woodes-Rogers's book did not appear until fourteen years later, in 1726, the latter account being something in the nature of Woodes-Rogers's defence against the disagreeable figure he is made to cut in Cooke's version.

Woodes-Rogers disliked Dover, whose interest in the enterprise was commercial rather than medical, and complains of "want of sufficient medicines with which till now I thought we abounded, having a regular physician, an apothecary, and surgeons enough, with all sorts of medicines on board." Perhaps he resented the position Dover occupied as President of the Council in this expedition. Certainly they quarrelled, until Dover exchanged from the *Duke*, commanded by Rogers, to the more congenial company on board the *Dutchess*, which was commanded by Captain Courtney, with Cooke as second captain. Cooke had been a naval officer, and was twice taken prisoner by the French. His *Journal of the voyage* is the work of a better-educated and more widely-informed man than Woodes-Rogers. His historical account of South America is admirable, especially when it is borne in mind that Prescott's histories were not written until a century and more afterwards. He makes clear that the enterprise on which they were engaged was no buccaneering cruise when he describes the captains of the *Duke* and *Dutchess* as "the said Commanders having commissions from his Royal Highness Prince George of Denmark, then Lord High Admiral of Great Britain, Ireland, etc."

Both ships also had legal commissions from the same Prince "to cruise on the coasts of *Peru* and *Mexico*, in the *South Seas*, against her Majesty's enemies the *French* and *Spaniards*."

The expedition set sail with four other ships, including the *Hastings* man-of-war, under Captain Paul's orders. In the case of an engagement with the enemy the following was to be the line of battle:

| Ships. | Commanders. | Guns. |
|------------------|---------------------|-------|
| Duke | Capt. Rogers | 30 |
| Elizabeth | " Rochdale | 24 |
| Laurel | " Boshier | 18 |
| Hastings | " Paul | 42 |
| Scipio | " Edwards | 20 |
| Dutchess | " Courtney | 26 |

The *Duke* to lead with the Starboard, and the *Dutchess* with the Larboard Tack.

In the quarrel which took place when Dover claimed to be placed in command of a prize, Captain Cooke took Dover's part, and supported his claim:

At this Time we had several Differences and hot Disputes about appointing a Commander for the *Manila* ship, being a Prize of considerable Value. Capt. Dover, being an Owner, desired he might command aboard her. Capt. Rogers and several Officers of the Committee voted that myself or Capt. Fry should command her; but having a ship already, I voted against it, and proposed together with Capt. Courtney and several of our Officers that it would be for the Interest of the whole that Capt. Dover should command the said Ship.

Captain Rogers protested against this decision, which proved to be that of the majority, and appears to have intended ignoring the committee and refusing to sanction Dover's appointment. This, however, the committee, who were officers of ability and determination, strenuously opposed in a long resolution in which they state:

Now, whereas Capt. Woodes-Rogers, Commander of the Duke and several of his Officers, Members of this Committee, did refuse to sign to the agreement of the said Committee, (the like having never been refused by any before, when carried by the Majority of Voices), or to acknowledge the said Capt. Thomas Dover, Commander of the ship Batchelor Frigate: We do hereby, in Behalf of the Owners of the ships Duke and Batchelor, our selves and Company, protest against the unadvised Proceedings and Practice of the said Capt. Woodes-Rogers, and the rest of the Officers of the Committee, who refus'd to sign and agree to the same, it being contrary to the Owners Orders and Instructions, (Reference being had thereto and the Union and Peace of the Ships Companies, (by them likewise recommended).

Eventually the majority of the committee appointed Dover to the command of the *Mamila* prize (renamed the *Batchelor Frigate*) with the following limitations:

"It is agreed by a majority of this Council, that Capt. Robt. Fry, and Capt. Will. Stretton, shall both act in equal Post in the Sole Navigating, Sailing, and Engaging, if Occasion should be, under Capt. Tho. Dover, on board the Batchelor Frigate; and that the said Capt. Tho. Dover, shall not molest, hinder or contradict them in their business; and we do appoint Alexander Sil Kirk master," and so on.

This "Silkirk" was, of course, the famous Alexander Selkirk, whose lonely sojourn on the island of Juan Fernandez inspired Defoe's *Robinson Crusoe*.

The result of the firm stand taken by the majority of the committee was that Woodes Rogers yielded, but took his revenge on Dover when he wrote his own book and suppressed entirely the account of any proceedings of the committee which were favourable to Dover. Cooke gives an account of Woodes-Rogers's character, which shows him to have been an even less amiable companion than we had hitherto considered Dover.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC.

ANNUAL GENERAL MEETING.

At the annual general meeting of the Medical Graduates' College and Polyclinic on March 14th, Sir WILLIAM COLLINS, who was in the chair, described the Polyclinic as an organization for the collection of the results of medical and surgical experience and their distribution among those who had got beyond the stage of the pupil. It was rather remarkable how relatively modern was clinical instruction. Dr. John Elliotson, who died in 1868, and was said to be the first physician to discard knee breeches, was also the first to give any decided impetus to the clinical lecture. Sir William mentioned that he possessed among his treasures a stethoscope which had been presented to his father by Elliotson, who had received it from Laënnec himself. Another thing which he possessed, and which was interesting to recall at that moment, was an old volume of a medical journal containing the report of a lecture delivered by Sir Astley Cooper at St. Thomas's Hospital in 1823. The reporter prefaced his account of the proceedings with the remark that this medical audience "all appeared gentlemen with cultivated manners and of good education." They were all familiar with the *laudator temporis acti*, who would doubtless find it worthy of note that ninety years ago the profession was represented by gentlemen of such very pleasing disposition. In a reference to the comparative modernness of medical bibliography, Sir William said that Dr. Billings, whose death on March 11th had been announced, had said that although medical literature had been compared to the animal body there was one point at which the analogy failed, for in medical literature there were no means of getting rid of effete material. Dr. Billings had also expressed the fear that in time all those not engaged in writing medical works would be occupied in compiling medical bibliographies. The Polyclinic represented a return to the medical school unconnected with any particular hospital. It might be called a private venture, although, unlike some of its forerunners,

it was certainly not run for private profit. In his own early days there was a St. Bartholomew's school of thought, as well as a Guy's, and a St. Thomas's, and if such a tendency still existed it was well that there should be as a corrective an institution like the Polyclinic where different kinds of studies were brought into the common lot and stock, and where they had what might be called, to adapt a phrase of Clerk Maxwell, the cross-fertilization of the medical schools.

Dr. C. O. HAWTHORNE, in moving the adoption of the report, referred with deep regret to the death of the President, Dr. C. Theodore Williams, and said that it was hoped to arrange for some form of permanent memorial in the institution. The year had not been one of undiluted success; this he attributed to the unsettling effect of the Insurance Act, and to the setting up in various hospitals of classes which might be regarded as rivals to their own, although at the Polyclinic they regarded this development in no grudging spirit.

Dr. DRUMYD CLARK, the Treasurer, in his financial statement, referred to a certain decrease of subscriptions, and suggested that lecturers would do well to consider the special requirements for instruction which had arisen under the Insurance Act. A good start had been made with Sir John Collic's lectures on the diagnosis of malingering. A vote of thanks having been accorded to the Council, Mr. Leekhart Mummery, Dr. Purdie, and Mr. Thomson Walker were re-elected to that body, and new members were added in Dr. F. G. Crookshank and Dr. Dan McKenzie.

In moving a vote of thanks to the Chairman, Dr. FLETCHER LITTLE expressed the hope that some patriotic philanthropist might come forward to endow a post-graduate university in London.

Sir WILLIAM COLLINS, after acknowledging the compliment, said that it would be one of the greatest calamities of the Insurance Act if it had the result of diminishing clinical study by the practitioner. The author of the Act had stated, he believed, that if the voluntary hospitals were likely to suffer, it would be the business of the State either to obviate the injury or to make it good. The same thing ought to apply to the Polyclinic. Perhaps it might be possible to establish a closer relationship between the Polyclinic and the University of London, and to arrange for the delivery at the former institution of some of the courses of lectures which the university subsidized.

The committee appointed by the Royal Horticultural Society, in co-operation with the Board of Agriculture, has decided to establish a diploma in horticulture, which will be available for men and women on equal terms.

THE twenty-second annual report of the Nurses' Co-operation, 8, New Cavendish Street, W., contains a full account of the receipts and expenditure during 1912. The fees received by the nurses, which have once more considerably exceeded those earned by them in any one year since the foundation of the Co-operation in 1891, amounted during the past year to £51,081 13s. 8d.; of this amount £48,057 18s. 8d. was paid to the nurses. The income of the society derived from the commission on fees earned by the nurses was £3,023 15s., which, with the addition of £202 9s. 6d. received as interest on investments, makes a total income of £51,226 4s. 6d. The greater part of this income served to meet the expenses of the Co-operation and the nurses' home and flats; but a sum of £487 3s. 2d. still remains in excess of these charges. The money invested in the name of the society amounts at the present moment to £6,492 10s. 2d. During the past year the Co-operation has been faced with many difficult problems in connexion with the National Insurance Act, of which the most pressing was that which concerned the weekly contribution of 3d. payable by all employers under the Act. In the case of nurses, the employer, of course, is the patient; but since it was felt that to claim this sum might give rise to difficulties and might possibly place the Co-operation at a disadvantage, the nursing members have decided to pay the whole amount themselves. The insurance cards, therefore, are kept in the office and the stamps affixed there, an arrangement which is recognized by the Insurance Commissioners. The Co-operation consists at present of 455 fully trained nurses on the general staff, 34 asylum trained nurses for mental cases, and 11 nurses eligible for election who are working on probation for six months.

SCIENCE NOTES.

AN interesting addition to Professor Sylvanus Thompson's recent investigations on the physiological effect of an alternating magnetic field¹ was made by Dr. H. Lewis Jones in a communication to the Roentgen Society on March 4th. Professor Thompson perceived a faint flickering illumination over the whole region of vision when the head was inserted between two coils round which an alternating current was passed. Other workers, however, experimenting along different lines, have had negative results, and Dr. Jones believes, to the differences in duration of the induced currents set up in the various cases. The behaviour of the retina to electrical stimulation is peculiar. It is remarkably sensitive in some respects and most insensitive in others. In order to stimulate it, a current must have a considerable duration—quite a long duration as compared with what is necessary for the motor and sensory nerves. The current of a medical coil, even when sufficient to throw the muscles of the face into strong contraction, may not stimulate the retina at all. Dr. Jones said that, when experimenting with the mechanical interrupter of Leduc, he had noticed that the retinal effect varied greatly with the duration of the individual current waves. It was easy with such an apparatus to produce waves which did not stimulate the retina and to alter the duration so that they did stimulate it. He found that the retina was unable to respond to electrical impulses of a shorter duration than one two-hundred and fiftieth of a second, and that it responded much better to far slower waves than that, whereas the motor nerves responded to impulses of one twenty-five thousandth of a second. With an apparatus with everything unchanged except the duration of the individual impulses, it was possible so to regulate matters that the retinal effect could be seen to come and go. When the waves were long—say one-fiftieth of a second—a fluttering, ocular effect was produced, and when short this died out, although the muscular twitching and cutaneous sensations persisted. The retina, in fact, was very slow to respond to waves, and would not respond at all to short ones.

A startling claim was put forward by Rosenberger some time ago namely, that he was able to demonstrate tubercle bacilli in the blood in every case of tuberculosis. At the time of his latest report he had examined some 300 cases of all kinds of tuberculosis, including lupus. It is obvious that if the claim were really well founded we would have to our hands a most valuable method of diagnosis, and the technique employed by Rosenberger was simple enough. The blood, after being shaken in citrate solution, was allowed to sediment in the refrigerator for twenty-four hours; the sedimented corpuscles were thinly spread on clean glass slides, dried at a low temperature, and laked by plunging them into a jar of distilled water. The almost colourless film so obtained was dried and fixed by passing it over the Bunsen flame, and then stained in carbol-fuchsin, and decolorized and counterstained by Pappenheim's stain. Several other observers failed to corroborate the findings of Rosenberger, but Forsyth found acid-fast bacilli in 10 out of 12 cases of tuberculosis, and Petty and Mendenhall examined 7 tuberculous cases and 3 non-tuberculous, and found the former all positive and the latter negative. Hewat and Sutherland (BRITISH MEDICAL JOURNAL) examined 20 cases of tuberculosis; in one case only did they obtain even two acid-fast bacilli; after prolonged search in the same case they were unable to find any more, and they concluded that it was probably an accident. Anderson, who examined 56 cases by Rosenberger's method, came to the conclusion that Pappenheim's stain was capable of producing artefacts, which often bore such a close resemblance to tubercle bacilli that other laboratory workers were misled; after discarding Pappenheim's stain he was unable in the same cases to detect acid-fast bacilli. McFarland, at the Henry Phipps Institute, after an examination of 50 cases, only found acid-fast bacilli on one occasion, and in that particular case there were no physical signs whatever of tuberculosis, nor were the bacilli morphologically identical with the tubercle bacillus. The real source of error would seem to

be, as Brem has pointed out, the presence, in the water used as reagent, of organisms which appear to be acid-fast when the film is fixed by means of albumen, and though Rosenberger did not actually use albumen for this purpose, sufficient traces of it were bound to be present in his smears. The organisms, according to Brem, though bearing a certain morphological resemblance to tubercle bacilli, and being capable of resisting decolorization with a 25 per cent. aqueous solution of nitric acid, are, unlike the tubercle bacillus, quickly decolorized by a 25 per cent. alcoholic solution of nitric acid.

The generally accepted theory that cinematographic effect is due to persistence of vision was challenged in a lecture delivered before the Royal Photographic Society by Mr. Kasimir Proszynski, a Polish gentleman who has made a close study of cinematography for the past ten years. Hahnoltz and others have stated that a visual impression will remain for one-seventh of a second after the extinction of the light, and Professor Boll that this persistence of vision is connected with the visual purple in the retinal rods, but Mr. Proszynski maintained that the apparent continuity should be classed as a psychological, not a physiological, phenomenon. The question has its immediate practical importance, for it is upon the basis of one or other theory that the attempt must be made to suppress flicker in cinematographs. This is due to failure of continuity, and Mr. Proszynski argued that the amount of visual persistence was insignificant, and that the part it plays in securing the effect of the moving picture may be disregarded. The effect, he thinks, is really due to the limitation of vision. Exactly in the same manner as sounds which are above a certain definite frequency become individually indistinguishable, and merge into one another, like the 435 vibrations per second to which the A string of the violin is tuned, so a succession of illuminations, interrupted at and for infinitesimal intervals, appears to the eye as a continuous illumination. The illuminations become indistinguishable separately when they are projected at the rate of about 40 per second. For the last two or three years, on Mr. Proszynski's suggestion, a simple shutter with three wings has been used for the cinematograph projector, and this, making about 15 revolutions a second, secures within that second 45 separate illuminations and 45 interruptions, thus reaching a frequency at which the eye can no longer detect the variations. In spite of the adoption of the shutter, however, the theory does not seem to have been understood, and shutters in which one necessary condition has been disregarded fail to suppress the flicker. This condition is that the three wings of the projecting shutter must be of exactly uniform size, and that the distances separating them must also be uniform. The wings may be larger or smaller than the spaces between them—this will only mean a decrease or an increase of the light thrown upon the screen—but each of the three wings must be equal to the others in size, and each of the three spaces must be equal to the other spaces. A further necessity is to employ continuous current, as the interruptions in the lamp itself with the alternating current disturb the equilibrium. By observing these conditions, as Mr. Proszynski sufficiently demonstrated, flicker is entirely suppressed.

AT the German Surgical Congress, which is to meet in Berlin under the presidency of Professor v. Angerer of Munich on Wednesday, Thursday, Friday, and Saturday in Easter week, the chief subject for discussion on the first day will be the treatment of bone and joint tuberculosis. A number of papers will also be read, including one by Professor Koehler of Berne on the arrest of haemorrhage in surgical operations, and a series on plastic surgery. On Thursday the chief subject of discussion will be duodenal ulcer, and papers will be read on thoracic and abdominal surgery. On Friday there will be a discussion on the surgery of the brain and spinal cord, and papers will be read on urinary surgery and on the thyroid and thymus. On Saturday a series of papers on military surgery will be read, and others on surgery of the oesophagus, liver, gall bladder, and pancreas. Wednesday afternoon will be given up to a series of demonstrations, including one by A. Fränkel on radio-diagnosis and the prognosis after operation, and another by Schmieden on the operative treatment of severe constipation.

British Medical Journal.

SATURDAY, MARCH 22ND, 1913.

THE INSURANCE ACT AND RESEARCH.

IN dealing last week with the report of the Tuberculosis Committee we welcomed the pronouncement that in framing a scheme for the utilization of the research moneys available under the Insurance Act the object should be co-operation with existing voluntary agencies. It may now be useful to consider the lines which might be followed in materializing the recommendation that "the work of research should be carried on in places having the best facilities for the particular investigation contemplated without being limited by consideration of geographical situation, provided every part of the United Kingdom has the advantage of close association with the work of scientific investigation." While advance in knowledge is the main object of research, any scheme must obviously provide for the co-ordination of all the laboratory work required in the campaign against tuberculosis. Such work is of three kinds—first, the routine procedures required for diagnosis; next, that which requires the application of more complex methods, such as those involved in the testing of the success of a system of treatment or in studying the characters and distribution of various types of bacilli; lastly, there is research proper, whereby new ground is broken. It is important to note that at any time work in either on the two first lines may raise questions which demand the application of the most advanced methods. Simple work relating to clinical cases is best done in close proximity to the patient; but all complex questions, whether arising in connexion with clinical or administrative work, require access to a fully equipped laboratory; and here again proximity to the source is always an advantage and often a necessity. The problem is how these varied requirements are to be provided for.

The Committee recommends that the larger clinical institutions should have laboratories of their own, and that all the institutions concerned in treatment should have access to laboratories. It is in the possibility of linking up clinical with research work that the wisdom of the Committee's view of taking advantage of existing agencies becomes apparent. It will not, we believe, prove a difficult task to map out the country into areas each with a medical school in its centre. These schools at present possess adequately equipped laboratories of pathology and bacteriology. In these the higher research could be carried on, and the more difficult problems arising in subsidiary laboratories or in connexion with local administration could be dealt with, while routine work could be undertaken for institutions not themselves provided with laboratories. The heads of the departments would superintend the research and other work, and it would be with them that the Central Executive Committee would be in touch. At first the existing workers in the laboratories would be employed, but

it would be, as in fact it is at present, the business of the heads of these laboratories to be on the look-out for the young men out of whom researchers are made. These would be tried, and if successful would ultimately be given more or less permanent appointments at such salaries as would retain their services for the campaign against infection. Under such a scheme all the scientific work of a district—whether elementary or advanced, whether arising from the clinical or administrative sides—would be co-ordinated. Not only so, but the co-operation of the local representatives of sciences other than pathology, and also of clinicians, could be arranged for.

Further, and this is not less important, provision could also be made for what the Committee insists on as a necessity, namely, the more formal instruction of the medical student in tuberculosis and the training of the band of specialists required for the clinical services of the dispensaries and sanatoriums of the country. A medical school possesses the whole armamentarium for the varied post-graduate instruction the latter class would require, and the linking of sanatoriums with the school would provide the clinical material. Seeing that most medical schools are situated in large centres of population the opportunity would also be afforded to those being trained to obtain an insight into the relationships between measures dealing with tuberculosis and ordinary administrative public health work. From the contact with research workers which would necessarily take place the members of the clinical service would go out to appointments with a knowledge of the latest scientific work and an appreciation of how the laboratory could be of use to them.

The outstanding advantage of a scheme whereby existing laboratories are utilized is its elasticity and adaptability. The heads of such departments must of necessity take broad views of research, and thus not only would sidelights on tuberculosis come from investigations into cognate subjects, but, as occasion arose, inquiry into other diseases of insured persons could be undertaken. Two questions might, however, be asked. First, have the heads of laboratories time to undertake the work? And, secondly, would they be willing to co-operate? The answer is in each case easy. Practically all those occupying such positions in this country are at present directing research, most of them are actually engaged in research, and, further, it is a duty they owe to their schools to organize research whenever the means are available for doing so. It is a duty which they are anxious to perform, but hitherto they have been hampered by want of financial support. They are, we believe, as alive as their critics to the difficulty of carrying on research when the only resource is scholarships without better paid posts to which successful scholars can be promoted. The creation of such posts is at present, indeed, urgently called for. While, as we stated last week, the number of workers in the country is small, it is well to recognize that the recent development of pathological research has brought forward a number of young men who only wait the means and opportunity of bringing further credit to the schools in which they are working. It is from the ranks of these that the tuberculosis research service must at first be recruited.

We last week drew attention to a curious subsidiary recommendation of the Committee by which the Executive, if it desired to undertake research work under its own control, could approach the Government directly with such a scheme. The clause containing this proviso appears to be the only justification

a leading journal of public opinion has for relegating to a subsidiary place the view of the Committee as to the advisability of utilizing existing organizations and for reading into the report as a whole a recommendation that all the higher research should be conducted in a central institute. This appears to be contrary not only to the express words but to the whole spirit of the report, and to judge from the memorandums of the expert witnesses published in the appendix to the report, it is also contrary to the considered opinion of the majority of those at present responsible for organizing research in scientific medicine in Great Britain. The chief upholders of a central institute are Sir Almroth Wright and Dr. Simon Flexner, though their schemes differ widely in essence. The former advocates the establishment of a therapeutic research service on the lines of the R.A.M.C., the members of which would be trained in what would amount to a residential tuberculosis university situated in the country with a large staff of professors and lecturers and with an attached sanatorium. Altogether apart from the fact that the scheme would necessitate an amendment of the Insurance Act in order that local authorities should be compelled to select their officers exclusively from the new service, it is perhaps unfortunate that Sir Almroth Wright's memorandum is chiefly taken up with the training and duties of those who are actively to treat disease, and that little is said as to how the centralized research work is to be organized and manned. Though the original professoriate would of necessity be drawn from existing schools, it is recommended that the service when established should be closely guarded from "civilian" intrusion; its members would be nominated by the University Senatus, and recruited apparently chiefly on academic attainments. To many it will seem that this scheme would fail to secure that endowed research on tuberculosis should be confided to those who had had an opportunity of acquiring a broad outlook on scientific medicine.

Dr. Flexner's plan is more simple, and would aim at the establishment of an institute on the lines of the Rockefeller Institute in New York without any teaching service, and confined, we take it, to the investigation of tuberculosis. An initial objection to such a scheme is that it could not at present be established without depleting existing laboratories and making it impossible that every part of the kingdom should have the "advantage of close association with the work of scientific investigation" which the Committee considers to be of value. If the existence of a central institute meant a definite concentration of work, something might be said for it, but the actual result would be the confining of financial privileges to the research work of one centre, to the detriment of all other centres. It is easy to say that the central institute would act as an arbiter if external opinion were divergent, but the judgements of the staff would be as much open to criticism as those of any other workers, and the latter might often find themselves without resources for testing results whose validity they doubted. It is also easy to uphold concentration as a preventive of fruitless research. Frequent entrance into blind alleys is, however, an incident inseparable from research and is independent of the organization under which it is conducted. The fact is that beyond individual opinion we have little evidence in favour of centralization, and what little experience there is of special institutes devoted to tuber-

culosis is not encouraging. Furthermore, while we do not wish to appear unduly pessimistic, a central institute would not necessarily be free from failings. It is possible that its staff might not always be prepared to submit to a judicial inquiry into their results, a man of independent mind might sometimes be far from comfortable, and the workers might be committed to the views of a forceful chief.

But adverse arguments need not be pressed, for there is one piece of evidence the cogency of which cannot be gainsaid. There is one branch of scientific medicine—namely, physiology—in which England has been for many years eminent. This position has been attained by the work of the heads of the medical school laboratories, and of the pupils each has gathered round him. The progress of research has often been stimulated by the fact that the same subject has occupied the attention of different laboratories at the same time, and the frequent meetings of the Physiological Society have provided the opportunity for interchange of opinion and of criticism. This is the way in which a striking success has been achieved in Great Britain. It is by the adoption of similar means that the prospect of good results in research in tuberculosis being obtained will be most hopeful. The essential factor is the utilization of the medical schools. These are the bodies charged with medical education, in many cases they are supported in this duty by Government funds, the efforts they have already made in pathological research have been attended by success, and it is only right that their resources should be fully utilized in any scheme which is brought forward.

SURGERY IN THE BALKANS WAR.

THE French Academy of Medicine has had early opportunities of hearing the surgical experiences of its members in the war in the Balkans.¹ Professor Laurent of Brussels was in charge of a base hospital of three hundred beds at Philippopolis. Professor Monprofit of Angers, as director of the surgical organization at Salonika promoted by the Red Cross Society of Greece, enjoyed extensive facilities for personal observation in Athens, Salonika, Uskub and Belgrade, and kept in touch as well with many of his colleagues and friends in other centres.

Monprofit's story is a very human document; sympathetic with suffering, denouncing the murderous game of war, free from political partisanship. He finds that the conclusions arrived at and the knowledge of military surgery gained in the South African and Russo-Japanese wars are astonishingly confirmed in this war. Mortality from wounds is immensely lessened by three main factors: A thoroughly equipped hospital and field ambulance whose personnel is instructed precisely in its business; immediate use of the individual packet of aseptic dressing carried by every man—a more valuable content of the soldier's knapsack than a visionary field marshal's baton; and a rigid policy of non-interference and non-exploration of wounds except in the presence of a very evident call for intervention, such as a serious haemorrhage. The protection afforded by the immediate application of the individual first aid dressing on the battlefield was the means of saving an immense number of lives. Every man in the Greek and Servian armies carried this dressing, and it was applied by the man himself, only exceptionally by a surgeon or

¹ Bulletin de l'Académie de Médecine. Nos. 7 and 8 (February 25th, and March 4th). Paris: Masson et Cie. 1913.

comrade. A Servian surgeon reported to Monprofit that in an engagement near Bitolj (Monastir) he had received 800 wounded men who without exception had been dressed on the battlefield very shortly after being wounded. Tincture of iodine was universally employed with most excellent results, though we are not told definitely that it is a constituent of the packet of dressings. The first-aid dressing used in the Greek army was supplied from France, that in the Bulgarian and Servian armies from Holland.

Surgeons in the South African war were astonished to find how rapidly men recovered from bullet wounds penetrating the thorax, the abdomen, and even the head. These recoveries were credited at first to the healing qualities of the South African air. But very soon the explanation came that it was really the thin narrow bullet travelling at a high velocity which was making war more humane. In Manchuria the same experience was common. So in the Balkans the rifle bullet has done comparatively little damage. The Mannlicher bullet used by the Turks is long and narrow (6 mm. in diameter); it perforates cleanly, its track is aseptic, and the tissues close quickly and firmly. The bones, especially the expanded articular ends, were simply tunnelled. Wounds of the thorax with perforation of the lung healed generally without complication. And so complete abstention from exploration or other interference in rifle bullet wounds came to be the rule. The rule worked well too with much wider application, and M. Monprofit indulges in these *obiter dicta*: "Modern military surgery ought to be, above all, surgery of watchfulness and expectancy; '*Moins on fait, mieux on fait*'; All operations except a few of absolute urgency are contraindicated on the battlefield."

But the story is different when we consider the wounds made by shrapnel. Infantry fire is diminishing in seriousness, artillery fire is increasing. The wounds made by shrapnel were always severe; bones were pulverized, tissues torn, thorax and cranium crushed. Professor Monprofit and his colleagues are by no means hypersensitive, but they all speak of the effects of shrapnel fire as "murderous." So much harassed were the feelings of Professor Depage of Brussels, who was stationed at Constantinople, that he initiated a movement in Constantinople to induce the imperial Society of Surgery to protest against the use of the barbarous shrapnel. Monprofit gladly associates himself with Depage, but under no great illusion and with little hope of success. The artillery practice of the Allies seems to have been much more effective than that of the Turks. Professor Depage, being stationed at Constantinople, has been able to supply M. Monprofit with some statistics, which he interestingly compares with his own.

Amongst the Turks shrapnel wounds were 80 per cent. of the whole, rifle wounds 10 per cent., and bayonet and sword wounds 10 per cent.; whilst among the Allies the figures were—shrapnel wounds 15 per cent., rifle wounds 80 per cent., wounds by side arms 5 per cent. These figures show that the Turks must have had a much higher proportion of their men rendered absolutely *hors de combat* than the Balkan Allies.

Monprofit reminds us, too, of the kind of people he had to deal with. The wounded of the Balkan nations showed notable resistance to the ill effects of wounds, they tolerated operation well, they bore pain easily. Amongst his Greek mountaineers he found men who lived hardy, simple lives, vegetarians mostly, not big consumers of alcohol. His colleagues had the same reports to make of the Servians and Bulgarians; and he adds, with the

spiritual sympathy of the true Frenchman: "And then they were conquerors!—a good condition for healing."

Professor Laurent's experiences were somewhat different. Cases did not come to him till about two or three weeks after the wounds were received, so that he was called upon to deal with secondary effects—aneurysms, division of nerves, paralysis after cord injuries, cerebral conditions. Since the last great wars, surgery of the arteries has passed through a period of evolution, and arterial suture is recognized to be a feasible proceeding. Professor Laurent ventures to think that, in military surgery, reconstruction of the calibre of an artery by suture is almost always impossible, and, as a rule, does not give results superior to those of ligature. Large aneurysms, especially in the neck, were a most characteristic feature of his experience at a base hospital. Operations for traumatic aneurysm were successful as late as three weeks after the arterial injury. Section of nerves is also a condition highly amenable to treatment at a late period. Laurent thinks there is more reasonable chance of success if the nerve is sutured in a quiescent stage after all infection has been recovered from. He achieved good results by ensheathing the sutured nerve in a flap of aponeurosis taken from the immediate neighbourhood or from the fascia lata.

Serious infective conditions were found much more commonly amongst the Turks than amongst their enemies. There seems to be no doubt that the Turkish soldiers were prone to surgical disorders from wound infection chiefly from neglect of the first aseptic dressing, which they did not generally possess or did not use, and also from the slowness of transport and imperfect hospital arrangements. Repeated defeat, coupled with a poorly equipped commissariat, must have had a demoralizing effect even on such stoical fighters as the Turks.

CHINGFORD—AND AFTER.

THREE hundred years ago the "sweet waters" of the New River entered the reservoir known as the New River Head at Clerkenwell. The chief figure in this great venture of bringing sweet water to London was Sir Hugh Myddleton, who with his twenty-eight co-adventurers carried out the beneficent work, assisted financially by King James I. Last Saturday the King and Queen graced the ceremony of the inauguration of the Chingford Reservoir. Immediately His Majesty applied the key which turned on the electrical current for the five Humphrey pumps, the water obeyed the summons, and joyously dashed down the broad flight of steps into the lake below. In a few seconds the cascade was a roaring flood, and the assembled multitude burst into a loud cheer as success thus crowned the labours of the Metropolitan Water Board. When in 1613 the sluice was opened at the Clerkenwell Well Head, the poet sang:

Now for the fruits then; Flow forth precious spring,
So long and dearly sought for, and now bring
Comfort to all that love thee; loudly sing
And with thy crystal murmurs strook together
Bid all thy true well-wishers welcome hither.

He sang what the spectators felt in 1913, and then, too, "the streams ran gallantly into the cisterne drummes and trumpets sounding in a triumphal manner."

The river Lee, whose course has been diverted to fill the great Chingford lake, passes through a country

rich in historical associations. Up the Lee the Danes sailed in A.D. 879, and destroyed the ancient town of Ware. Over the Lee the first stone road bridge in England was made by Queen Matilda, and was called, from the circular form of its arches, Bow Bridge. At great risk to themselves the watermen of the Lee conveyed provisions to the inhabitants of London during the great plague of 1665, for which services they received various privileges they still enjoy. These, among others, stand out from the page of history connecting the Lee with the life of London. In the days to come the ceremony of last Saturday will take its place as a great tribute to the efforts made by the Metropolitan Water Board to give to the people of London a plentiful supply of good water. In an article in the *JOURNAL* of February 15th attention was directed to the work of the Water Board as a health authority, and we rejoice to notice that the King, in his reply to the loyal address of the Board, and in the closing words of that reply, said, "We congratulate you warmly on the success of your labours, and we shall ever follow with interest the continued progress of this important undertaking, so vital to the health and well-being of the capital of my empire." This gracious acknowledgement of the arduous labours of the Board will be prized by the members, and we feel sure will stimulate them—Mr. Barnard, their chairman, and Mr. Bryan, the chief engineer, and the other officers of the Board—to renewed efforts on behalf of the population in the water area.

The task imposed upon the water boards of the kingdom is exceedingly heavy and difficult. The serious question of the future supply is one common to London and the large towns of the provinces, and, indeed, to the whole country. Within the next twenty or thirty-five years not only London and Glasgow, but Liverpool, Manchester, and other large towns will be face to face with need for new supplies, and will be driven to the great watersheds for them. For though London is now engaged in the preliminary work prior to the construction of two reservoirs in the Thames Valley, each bigger than the Chingford one and estimated to cost £1,600,000, and although the Board has power to construct two more reservoirs, one at Staines and another in the Lee Valley, yet it realizes that in some thirty years all the possible water from the Thames, Lee, New River and Kent wells, will be day by day absorbed by the increased population and the increased amount of water used by each individual of that population. The Balfour Commission made various calculations as to growth of population in the London water area, and the number of gallons per head of population. From these estimates, which were accepted by the Llandaff Commission, it emerges that to supply 35 gallons a head for an estimated population, in 1916, of just over 8 million persons a daily supply of 281 million gallons will be requisite, and that with an estimated population of 12 million in 1941 a daily supply of 420 million gallons would be necessary.¹

Owing to the decrease in the birth-rate, the estimate of the Balfour Commission will be wrong as to

the increase in the population, but it will also be found that its estimate of thirty-five gallons a head will be below the actual figures, and as a result the two errors will probably neutralize each other and the Balfourian estimate come near the truth. As to the daily supply a head, we find in the London area in 1911-12 the average was 36½ gallons. Moreover, the total daily consumption is already 244 million gallons, which is getting perilously near the quantity estimated for 1916. In view of these conditions the Water Board looked ahead, and in 1907 passed a resolution in which it declared: "That, as the increase of population will eventually render resort to some other source than the Thames watershed imperative, the Board views with great alarm the increasing tendency of authorities throughout the Kingdom to appropriate water-supplying areas for their particular use, and in these circumstances desire to urge upon Parliament the necessity for regulating the appropriation of water-supplying areas, so that the needs of the metropolis, as well as other populous places, may receive due consideration."

Although more than five years have passed, the Government has taken no notice of this earnest appeal on behalf of the water consumers of the whole country. But surely it is time that some steps were taken to conserve and allocate the water supplies of the country, not only in the interests of the large cities which will soon be scrambling for the unappropriated watersheds in Wales and Cumberland, but in the interests of the smaller towns and villages which have not money to spend on getting supplies from a distance, and may be outside the range of the Wolverhampton clause. The Royal Commission on Sewage Disposal, in one of its many interim reports, declared in favour of doing something to save the water supplies from pollution, and of collecting information as to the available supplies and the needs of various parts of the country. This Commission is still sitting and still reporting, and nothing is being done. The Joint Select Committee which considered the Water Supplies (Protection) Bill, 1910, backed up the Sewage Commission, and strongly recommended the establishment of a central administrative authority, and the collection of information as to supplies, control, and allocation of the water in the country. Yet nothing has been done. We venture to hope, however, that before the present Parliament dies, a non-contentious bill for the nationalization of the water supplies of the country may receive the Royal assent.

THE RIGHT TO HOSPITAL ATTENDANCE.

THE claim sometimes advanced by a subscriber to a hospital to attendance in return for his subscription is an old subject of discussion to which new vitality seems to have been given by the action taken by most hospitals in consequence of the National Insurance Act. It has been brought prominently before the London public by the publication in the *Westminster Gazette* of a correspondence between Mr. H. R. Stirling, the director of a printing company, and King's College Hospital. Mr. Stirling complained that one of the employees of the firm, on applying for treatment for an injured hand, was given a first dressing and told that he must then go to his panel doctor. Mr. Stirling said that the men employed by the firm contributed from £6 to £10 annually to the Hospital Saturday Fund, and were indignant at the idea that they were not welcome at the hospital when suffering from an accident. The secretary of the hospital

¹ The full figures are as follows:

| Date. | Estimated Population. | Estimated Average Daily Supply in Gallons. |
|-------------|-----------------------|--|
| 1916 | 8,031,000 | 281,000,000 |
| 1921 | 8,703,000 | 305,000,000 |
| 1931 | 10,221,000 | 358,000,000 |
| 1941 | 12,000,000 | 420,000,000 |

stated in reply that the hospital authorities had found it necessary to make arrangements to prevent overlapping under the Insurance Act; that every insured person was entitled to the services of his panel doctor in cases covered by medical benefit; and that no injury or injustice was done to the patient suffering from a complaint within the resources of the panel doctor by referring him to that doctor after the injury had received first treatment. This did not satisfy Mr. Stirling, who, in his next letter, laid down the proposition that the employees of his company, by subscribing regularly to the Hospital Saturday Fund, were entitled, when necessary, to hospital treatment "as a right for which they have paid," and threatened that if this view was not taken by the hospital committee the men would probably discontinue their subscriptions. He wished the committee to make it clear that, quite apart from the operations of the Insurance Act, they would be willing to treat patients who come from business houses which contribute regularly to the Hospital Saturday Fund. To this the secretary to the hospital sent a reply which admirably states the case from the hospital, and, in our opinion, from the common-sense point of view. He regretted that such a misconception should prevail as that subscriptions to the hospital, whether large or small, entitle to treatment as a right. He went on to point out that the Hospital Saturday Fund gives an opportunity to the working classes to contribute to the funds of hospitals at which so many of them obtain benefit; that the hospital is instituted to give assistance only to those who cannot otherwise obtain suitable medical treatment. He then showed that all insured persons are now entitled to obtain from outside practitioners "such treatment as is of a kind which can, consistently with the best interests of the patient, be properly undertaken by a general practitioner of ordinary professional competence and skill," and that it follows that insured persons no longer require to obtain treatment for ordinary illnesses at hospitals. The hospitals will admit all cases which are beyond the skill of an ordinary practitioner just as before the Act, and the need for hospitals will remain as great as ever. The secretary very rightly pointed out that it would be improper for the committee of the hospital to use the subscriptions entrusted to it for the benefit of patients for whose ordinary medical needs ample provision is otherwise made. It might have been expected that this last argument would at once have appealed to a business man, who would denounce, and rightly denounce, as wasteful any overlapping in his own business. Mr. Stirling, however, in sending the correspondence to the *Westminster Gazette*, says that in his opinion the hospitals are making a great mistake in the attitude disclosed in these letters. He makes no attempt to meet the arguments of the King's College Hospital, which are indeed unanswerable. If the hospitals continued to allow their out-patient departments to be used for the treatment of the trivial complaints of insured persons who are amply provided for elsewhere, they would prove themselves utterly lacking in business capacity and guilty of a waste of public money, and we imagine that, generally speaking, the heads of business houses which collect subscriptions for the hospitals would be the first to complain of this waste. Mr. Stirling's view, surprising as it is in a man in his position, is one commonly held by many of the small subscribers to the hospitals, who regard their subscriptions to a charity as contributions to a provident institution from which they have a right to expect treatment. This is to misunderstand the fundamental basis of the voluntary hospital, which is an institution to which the charitable give their donations, small and great, and the medical staff give their services in order to provide emergency and special treatment to those who are unable to provide it for themselves. Its doors are open freely for all suitable cases, but to regard the subscriptions as payments

entitling the donors to treatment would be to change the whole basis of the institution. Not only would the small subscriber demand to be treated as a right, but so would the large subscriber. The inevitable result would be that the services of the hospitals would soon be confined to subscribers, and the charitable element would disappear. When that disappears the claim on the charitable services of the medical profession will disappear also. Those who claim that the hospitals should be open as a right to those who subscribe to them should clearly realize the logical consequences of their demand.

VIVISECTION ADVISORY COMMITTEE.

THE Royal Commission on Vivisection, in its Final Report published last year, recommended that the Home Secretary should have the assistance of an Advisory Committee. It recalled and endorsed the views of the Royal Commission of 1875, to the effect that the responsible Minister should be guided in the administration of the system generally by the opinion of advisers of competent knowledge and experience, but that it would be inexpedient to divide the responsibility of the Secretary of State with that of any other persons by statutory enactment; it recommended, therefore, that the advisers should be from time to time selected and nominated by himself. The Royal Commission which reported last year commended the practice, followed by various Home Secretaries for nearly thirty years, of obtaining professional advice as a guide in the exercise of their powers and the discharge of their responsibilities, but advised that the recommendations of the Commission of 1875 should be strictly followed. The Commission of 1906, reporting in 1912, accordingly recommended the Home Secretary to appoint an Advisory Committee, the members of which should, as regards Great Britain, be selected by him from a list of names submitted to him by the Royal Society and the Royal Colleges of Physicians and Surgeons in London. It was added that no person so selected should be the holder of a licence, that their names as well as the names of the scientific authorities under the Act should be published and that the present practice of reference to the Association for the Advancement of Medicine by Research should be discontinued. It was further recommended that in Ireland the Chief Secretary should be advised by a body chosen on analogous lines. On February 5th last the Home Secretary stated in the House of Commons that he was about to appoint the advisory body recommended by the Royal Commission of 1906, and it is now announced that the following have been selected from names submitted to the Royal Society and the Royal Colleges of Physicians and Surgeons: Sir Anthony Bowlby, C.M.G., F.R.C.S., Sir John Rose Bradford, K.C.M.G., M.D., D.Sc., F.R.C.P., F.R.S., Sir Horatio Bryan Doukin, M.D., F.R.C.P., Mr. George Henry Makins, C.B., F.R.C.S., the Lord Moulton of Bank, Dr. Seymour J. Sharkey, F.R.C.P., and Mr. Charters J. Symonds, M.D., M.S., F.R.C.S.

UTERINE FIBROIDS AND MALIGNANCY.

Forty years ago the surgery of uterine fibromyoma was imperfectly understood. When the growth was still small it was considered too early to operate, but when it grew large its extirpation, before aseptic principles were understood, involved very serious risks. Within the last fifteen years experience has indicated to the surgeon means by which a fibroid of moderate size can be removed with the uterus without much danger to life, and fibroid uteri of colossal size may be taken away with relatively little risk by an operator of fair experience in abdominal surgery. As for the conservative operation, myomectomy, there is much to be said in its favour; but it is not safe except in the hands of experts. The removal of a fibroid

uterus which is clearly growing larger or causing hæmorrhages or pressure symptoms is now an established operation. Small, slow-growing fibroids may safely be watched, and prophylactic extirpation is questionable surgery. A question which remains undecided is whether malignant degeneration is frequent or very rare. Even when present it may be a coincidence, the development of cancer in some glandular tissue, or of sarcoma in the connective tissue associated with the fibromyoma. Dr. Willy Hertel of Munich has analysed clinical reports of 1,100 cases of fibromyoma, excluding all examples of distinct enlargement of the uterus in which the presence of the growth in question was not absolutely certain.¹ Out of 468 of these cases, in which an operation was performed, malignant degeneration of the endometrium was detected in 16, and cancerous elements amidst the muscular tissue in 13. This group does not include any of the 8 cases of coincident carcinoma of the cervix within the entire 1,100 cases of fibroid uterus. Coincidence of two diseases that are common is only to be expected, and Dr. Hertel could trace no connexion between them in these eight instances. With carcinoma of the body the case is different; it is masked, as a rule, by the presence of a fibromyoma, and it is hardly possible to deny or affirm that the latter is directly related to the former. Hertel inclines to believe in coincidence, as in the majority of cases of the combined fibroid and cancerous disease of the body the patients were of the age when the malignant growth is most frequent. In 13 cases of operation fibromyoma of the uterus was complicated by sarcoma. This degeneration of, or within, the fibroid tumour itself—for pure coincidence of a separate fibromyoma and a sarcoma is not included in this subgroup—is a subject deserving attention. In most of the 13 cases the fibromyoma was submucous, in none subserous—that is to say, malignancy of this type usually developed in the most exposed variety. The peritoneum is a good veil or cover, but the endometrium communicating with the surface of the body, and subject to catamenial and other more disturbing influences, may involve an adjacent growth in its own troubles. Unfortunately, Hertel cannot find anything like a rule for diagnosis. Rapid growth and hæmorrhages always mean peril, and though Hertel admits that malignant degeneration is rare, according to his own statistics and those of others, nevertheless it has to be borne in mind, as fibroid uterus is a common disease. Hertel does not wish to teach "fibroid hunting," "*der Jagd auf Myome*," as he calls it, but he insists at the same time that the smallest fibroid uterus must always be kept under observation. Lastly, the x-ray treatment does not, he says, as yet render hysterectomy indispensable.

THE FUNCTIONS OF A CHEMIST IN A PHARMACEUTICAL WORKS.

On March 12th a lecture was given by Mr. C. A. Hill, B.Sc., to members of the Institute of Chemistry on The Function and Scope of the Chemist in a Pharmaceutical Works. He said the term "works" was used rather than factory or laboratory, as a pharmaceutical manufacturing establishment included both these as well as the purely commercial department, and the chemist had to exercise his functions in all the departments. It was, he said, absolutely essential nowadays that there should be adequate chemical knowledge behind all the operations of, or connected with, pharmaceutical work. The work of the chemist could be dealt with under four heads—manufacturing, analytical, investigation, and commercial. The manufacturing chemist, who must, of course, keep the question of cost constantly before his eyes, found that the cost of a manufacturing process was affected by three chief factors—time, labour, and yield, the last-named being by far the most important. Purity was, of course, an all-important consideration, but in making pharmaceutical

chemicals the relative importance of different impurities was not the same as in other cases; from a chemical standpoint, a minute trace of some given impurity might be quite negligible, but if the material was for medicinal use and the impurity toxic, even a minute trace must be removed. The same was true of some other substances, which though themselves harmless, led to changes of colour when the chemical was employed pharmaceutically; as an illustration the discoloration produced by traces of iron was mentioned. In dealing with the production or purification of chemicals on the large scale many difficulties were encountered which might not be met with when working on small quantities, and the works chemist must be able to deal with these. In making galenic preparations, processes of standardizing must be carried out in many cases; but preparations were, as a rule, standardized in regard to one constituent only; others which might also be of importance are left undetermined. The advantages of physiological standardization were, he thought, doubtful. Mr. Hill then described and illustrated by diagrams and photographs many of the pieces of apparatus in use in filtering, washing, and evaporating, in the extraction of drugs, the recovery of solvents, and in other operations of a pharmaceutical works. In the analytical laboratory all raw materials were tested to see that they corresponded to requirements as to purity and strength, and a control was exercised over the finished products from the factory. It was important that the analyst should see to the drawing of the samples as well as to the testing. It was often found that a commercial product differed greatly in purity in different parts of the bulk, and it was therefore necessary to take a sample from each cask or other container of a parcel, and even from different parts of the same container. The testing of oils, both fixed and essential, required much special knowledge; the latter in particular were adulterated with great skill, synthetic products such as glyceryl acetate or ethyl citrate being added to bring the analytical characters of an unsatisfactory sample up to the standard. The work in the investigation department of a pharmaceutical works included experiments for the improvement of manufacturing and analytical processes and the utilization of by-products; the examination of new drugs from abroad must often also be carried out, and other kinds of pure research. The principal concern of the chemist with the commercial side of the business was in the drawing up of specifications for contracts and in exercising some control in regard to the buying of materials.

MENTAL DISCIPLINE AND PRACTICAL LIFE.

An interesting address on the value of education was delivered by Sir John Byers, M.D., at the distribution of prizes in connexion with the Y.M.C.A. Education Department at Belfast on March 11th. The Chairman said that the work done in this, the largest continuation school in Ireland, which also claimed to be the largest of its kind in the United Kingdom, was unique in many respects, and showed that an attempt was being made to remedy some of the defects of the Irish system of education. It was to such classes that students could turn for those higher branches of education which would enable young men to enter the Municipal Technical Institute, the Civil Service, the banks, or the university. Sir John Byers said the object of the continuation classes was not merely the acquisition of facts, but, what was a far higher form of education, the correct use of these facts and the development of the intellectual power of perceiving the due relation and proportion between them, a faculty which really constituted what was commonly termed judgement. The present age was a wonderful period of upheaval and transition; time and space had been largely annihilated by the telephone, wireless telegraphy, the motor car, and

¹ *Monatsschr. f. Geburtsh. u. Gynäk.*, September, 1912, p. 325.

the airship. In the science of medicine the practical application of the discoveries of Pasteur, Lister, and Koch had revolutionized their ideas not only as to the causes of diseases, but as to their prevention and treatment. So, in education, the special feature of the present day was the enormous expansion of the field of study. In former times mathematics and classics largely held the field; but now science in all its varied branches, the history and literature of their own and other countries, modern languages, philosophy, economics, and technical and commercial subjects (especially in large industrial centres) all rightly claimed a position. It was a remarkable sign of the times that Oxford, the most ancient and conservative of all English universities, was arranging a site for the future engineering laboratory. A most interesting discussion had recently taken place in London on "The University Man in Business," in which some of the most distinguished educational experts of the day had taken part. A man whose mind was thoroughly trained would acquire the technical knowledge necessary for a business or a profession more rapidly than one who had not the same advantage. For centuries Oxford had nobly contended that the main function of a university was the advancement of learning; but in modern times she had begun to realize that a university must also supply that special training which would enable students to enter upon various careers after they left college. So it happened that amongst the reforms initiated by Lord Curzon, as Chancellor of the University of Oxford, in 1909, was the recommendation that a diploma specially suitable for candidates contemplating a commercial career should be created. Sir John Byers expressed the hope that in time the present confused position of educational affairs and the overloading of all school curriculums would be rectified by the proper co-ordination of primary, secondary, technical, commercial, and university education, and by establishing their inter-relationship on correct lines.

SIR GEORGE TURNER.

It is not always that a prophet hath no honour in his own country. At the last meeting of the Portsmouth Town Council, held on the 11th instant, appreciative testimony was borne to the splendid services of Sir George Turner, who is a member of an old Portsmouth family, and was the first medical officer of health for that town. His administration was both distinguished and successful. He was the pioneer in urging the necessity of the establishment of an infectious diseases hospital. Firm and resolute in action, he did what he believed to be right, not caring what the public thought of his work. The ex-Mayor, Sir Scott Foster, proposed the following resolution: "That the members of this Council desire to place on record their great appreciation of the valuable services rendered to our country and to Portsmouth by Sir George Turner, a native of the borough and late medical officer of health; and that a copy of this resolution be sent to Dr. Turner, with an expression of the hope that he may be spared for many years to continue his researches for the benefit of humanity."

ADVANCE, AUSTRALIA!

At its meeting last November the Council of the British Medical Association received an application from the Government of the Commonwealth of Australia for permission to reprint the two books *Secret Remedies*¹ and *More Secret Remedies*² as a parliamentary paper. The request was granted, but it would appear that statements had been made in Australia to the effect that the formulæ in the books had been proved to be incorrect by

Government inquiry, and that they were altered from time to time, for a further letter containing an inquiry on this head was received from the High Commissioner in London. In reply the High Commissioner's attention was directed to the proceedings before the Select Committee of the House of Commons on Proprietary Medicines, and it was indicated that the evidence had not established that the formulæ were incorrect. It was pointed out that the formulæ published in the books had not been altered, but that it was not unreasonable to suppose that the manufacturers might themselves alter the formulæ. It appears that the position, in so far as the inquiry conducted by the Select Committee was concerned, was placed fully before the Government of the Commonwealth by the High Commissioner, and from a letter recently received it is learnt that the Commonwealth Government has resolved to publish the books in pursuance of the decision arrived at by the Parliament of the Commonwealth. The two books, we have good reason to believe, did much to educate public opinion on this side of the world, and it is to be anticipated that they will be not less useful in the Antipodes.

OPHTHALMOLOGICAL CLASSES IN MANCHESTER.

THE facilities now afforded for obtaining a knowledge of the defects and diseases of the eye are vastly greater than existed five-and-twenty years ago. There were opportunities then for men who looked for them, but they were sought out mainly by those who intended to become specialists, and there was little or no organized teaching. It was at about this date, or a year or two earlier, that Dr. A. Hill Griffith began to hold classes at the Royal Eye Hospital, Manchester. They have been continued ever since, and on several occasions there have been as many as forty applicants, and it has been necessary to limit the number accepted. For some years classes have been held twice a year—in winter, on the use of the ophthalmoscope and the estimation of refraction, and in summer, on the diagnosis and treatment of the external diseases of the eye. Altogether some 600 practitioners have attended the classes, and the demand for them has continued to increase, owing, no doubt, largely to the requirements of education and other authorities. It has been arranged to extend the system, and all the members of the honorary staff of the hospital are now co-operating in a combined class. The classes are specially intended to meet the needs of general practitioners in the two divisions of the subject mentioned above, but arrangements will be made for advanced classes in operations and pathology if a demand is found to arise.

ON account of the increase of work entailed upon the Local Government Board for Scotland by the Insurance Act, the Treasury has sanctioned the appointment of an additional medical inspector. The salary offered is £500 rising to £800. The new officer will be required to have special experience in tuberculosis, but must also have a general experience of public health work. The Board is in course of considering applications for the appointment.

AT the annual general meeting of the Florence Nightingale Hospital for Gentlewomen, held at the Hospital, 19, Lisson Grove, N.W., Earl Waldegrave, who presided, in moving the adoption of the report, drew attention to the fact that 323 patients, the largest number on record, had been admitted during 1912; some had come from such widely distant places as Buenos Aires, India, Brussels, China, and South Africa. He expressed the warmest thanks to the very large number of physicians and surgeons for their generosity in attending patients gratuitously. Owing to the demand for beds, which far exceeds the accommodation, a new wing is being added, and an appeal is made for the sum of £2,500 so that the extension may be opened free of debt.

Medical Notes in Parliament.

The Ballot for private members' bills resulted in giving Mr. Ginnell the first place for a bill dealing with the housing of Irish labourers; the third place to Sir R. Baker for the Housing of the Working Classes Bill introduced last year by Sir A. Boscawen; and the eighth place to Mr. Pretymann for the Cottage Homes Bill. The second place was won by Mr. Sandys for a bill to provide for compulsory service in the Territorial Force. It is calculated that there are six Fridays between Easter and Whitsuntide on which private members' bills can be taken.

Medical Officers of Health (Superannuation) Bill. Sir Philip Magnus has introduced the Association's Bill for the Superannuation of Medical Officers of Health, and has obtained the support of Sir Henry Craik, Mr. Charles Bathurst, Mr. Godfrey Locker-Lampson, Mr. T. Lough, and Mr. W. S. Glyn-Jones. The bill was read for the first time on March 13th, and has been put down for second reading on April 18th. This bill was introduced into the House of Commons by the late Dr. Hillier on July 20th, 1911, but, owing to the congestion of parliamentary business, it never got any farther than the first reading. It includes all medical officers of health, whether part or whole time, and the scale of contributions varies from 2 to 3 per cent. of their salaries. The scale of pensions is the same as that of the Poor Law Superannuation Act of 1896. A weak point in that Act has been avoided by providing that the superannuation allowance shall be paid in proportionate parts by the several districts in which the medical officer of health has served, and not as in the Poor Law Act by the last district in which he has served. Where there is a local Superannuation Act this may remain in force as regards the medical officer of health, or the provisions of the bill may be put in force at the option of the local authority. It is estimated that the contributions of the medical officers of health will amount to about £8,000 a year, and the superannuation allowances possibly to £12,000 yearly, the differences being made up by the local authorities. Sir Philip Magnus, with his accustomed readiness to assist the medical profession, so many of whom are constituents of his own, has taken up the matter with great energy, and as the ballot has been not altogether unfavourable to him it is hoped that the bill will make good progress.

Westminster Hospital Bill.—This bill, which empowers the authorities of Westminster Hospital to acquire lands for and to erect a new hospital, to authorize the sale and disposal of the present site, and for other purposes, was read a first time on March 12th and a second time on March 17th.

Hospital Ship.—Mr. Burgoyne asked, on March 13th, whether the hospital ship sanctioned in the recent Estimates had yet been ordered. Mr. Churchill said that a suitable ship for this service had been purchased from the mercantile marine, and would be fitted out at one of His Majesty's dockyards.

Local Government (Scotland) Bill. This bill to amend the Local Government (Scotland) Act, 1894, was presented by Mr. Cathcart Wason on March 17th and directed to be read a second time on April 25th. It is supported by Mr. Ainsworth, Mr. Barnes, Sir John Dewar, Mr. Leicester Harnsworth, Mr. James Hogge, Mr. Lyell, Mr. Murray Macdonald, Mr. Macpherson, Mr. Morton, Mr. Munro, and Mr. Eugene Wason.

Care of the Feeble-minded in Scotland.—Mr. McKinnon Wood stated, on March 13th, that he proposed to introduce a separate bill for the care and control of the feeble-minded in Scotland.

Medical Treatment of School Children in Scotland.—Mr. McKinnon Wood, in replying to Dr. Chapple on March 13th, said that he had received resolutions from various school boards in Scotland regarding the recent decision of the court declaring payment for medical treatment of school children to be illegal. The matter was receiving his consideration.

Births and Deaths in Scotland. Mr. McKinnon Wood stated on March 14th, in reply to Mr. Dundas White, that the number of births and deaths registered in Scotland during 1912 had been 122,715 and 72,333 respectively. The figures for the districts of Papa Stour and St. Kilda were not yet available. The provisional figures available showed that the number of passengers recorded as of British nationality who embarked at Scottish ports for countries out of Europe during 1912 was 51,408, while the number arriving at Scottish ports from countries out of Europe had been 15,883.

The Mastership in Surgery.—In reply to Sir Philip Magnus, who addressed a question to the First Lord of the Admiralty, on March 13th, Dr. Macnamara said that instructions would be given that in future issues of the Navy List the letters "M.S." should be inserted after the names of medical officers of the Royal Naval Volunteer Reserve who held the degree of Master of Surgery.

Vaccination. In reply to Mr. William Harvey, the President of the Local Government Board said that one or two representations had been made to him to the effect that in rural districts difficulty was experienced by parents who wished to make a declaration of conscientious objection to vaccination, by reason of the fact that a magistrate or commissioner for oaths was not available without the applicant journeying many miles from his place of residence. He was not, however, prepared to propose legislation to include members of sanitary and Poor Law authorities as persons before whom such declarations might be made. In reply to Mr. James Parker, the President of the Local Government Board said that the number of declarations of conscientious objection to vaccination received by vaccination officers during the first six months of 1912 was 136,335. The approximate number for the whole year was 276,000. In reply to Mr. Pointer, Mr. Burns said that he could not undertake to recommend legislation at the present time to repeal the Vaccination Acts.

Small-pox.—In reply to Mr. Peto, the President of the Local Government Board said that 43 cases of small-pox had been notified from sixteen sanitary districts in England and Wales during the last three months. In none of the districts was there any prevalence of small-pox calling for special action by the guardians, with the exception of Newhaven (where 22 out of the 43 cases occurred).

Medical Examination for the Special Reserve.—In reply to Mr. Bennett-Goldney, the Secretary of State for War said that at all depôts the medical officer kept a register of all men medically examined for the regular army and of all men rejected on medical examination as physically unfit for the regular army; the register did not show the number of men belonging to the Special Reserve at each depôt who had, on application to join the regular army, been rejected as unfit and who were serving at present in the Special Reserve battalions.

Registration of Nurses.—A bill to regulate the qualifications of trained nurses and to provide for their registration was presented by Mr. Munro-Ferguson and read a first time on March 18th. In reply to Dr. Chapple, Mr. McKenna has expressed the opinion that registration of nurses would not prevent people from dressing as such unless this were made an offence.

The Select Committee on Patent and Proprietary Medicines has been reappointed: Mr. Norman Craig and Mr. O'Grady last session took the places of Mr. Marshall Hall and Mr. J. Hodge.

Ireland.

[FROM OUR SPECIAL CORRESPONDENTS.]

BELFAST MEMORIAL TO THE LATE LORD LISTER.

THE Lord Mayor (R. J. McMordie, M.A., M.P.) summoned a public meeting in the City Hall, on February 19th, to consider the question of commemorating the priceless services of the late Lord Lister in the cause of science and the alleviation of human suffering. The requisition to the Lord Mayor was signed by the Chancellor and Vice-Chancellor of the Queen's University, the presidents of the local medical and other societies, the chairmen of the various local hospitals, and others. The following resolutions were unanimously passed:

Proposed by the Vice-Chancellor of the Queen's University of Belfast, and seconded by Professor Sinclair, M.D.:

That this meeting strongly approves of the proposal to commemorate, by a suitable memorial, the priceless services of the late Lord Lister to the cause of science and the alleviation of human suffering; that those present and those who signed the requisition, with power to add to their number, be appointed a committee to further the object.

Proposed by Sir Alexander Dempsey, M.D., and seconded by Dr. John Campbell:

That Sir William Crawford, Sir Alexander Dempsey, Professor Symington, and Professor Sinclair be appointed honorary secretaries, and that Mr. R. J. McMordie, M.P. (Lord Mayor), be appointed honorary treasurer.

NEWCASTLE SANATORIUM CRISIS.

On March 11th a largely attended meeting of the Royal Colleges of Physicians and Surgeons was held in the Royal College of Physicians, Dublin, to consider the action of the board of the Royal National Hospital for Consumption for Ireland in reference to the medical staff of that institution. The President of the Royal College of Physicians of Ireland (Dr. Charles E. Fitzgerald) was in the chair, and the full correspondence which had passed between the board of the hospital and the medical staff was read. The President of the Royal College of Surgeons (Mr. R. Dancer Purfoy) proposed the following resolution:

That we approve of the action of the consulting and visiting staff of the Royal National Hospital for Consumption for Ireland with reference to the question regarding the appointment of an additional visiting physician to the hospital.

This resolution was seconded by the President of the Royal Academy of Medicine in Ireland, Dr. Walter G. Smith, and carried unanimously.

The Regius Professor of Physic in the University of Dublin, Dr. J. Little, proposed:

That we deprecate interference on the part of the board consisting of laymen with questions connected with the medical treatment in the hospital.

This resolution was seconded by the Regius Professor of Surgery in the university, Sir Charles Ball, Bart., and was passed unanimously. The meeting then adjourned. The position at the hospital is still unchanged.

It is stated that the extra visiting physician was appointed to attend to the insured patients in the hospital. According to the arrangements made in Dublin, the medical attendant is to receive 5s. a week for each "sanatorium benefit" patient that he attends in hospital. The board defended this arrangement on the ground that as these were a new class of patients not, technically speaking, under the charge of either of the visiting physicians, there could be no objection to their being handed over to the newly-appointed officer. The board has since said that this matter could have been rearranged so that all the visiting staff could have participated in the fees.

ROYAL VETERINARY COLLEGE.

It is announced that, as the outcome of negotiations suggested by Mr. T. W. Russell, the Royal Veterinary College in Ireland will be transferred to the control of the Irish Department of Agriculture. The department

proposes to take up about 100 acres of land, in the vicinity of Dublin, to be occupied by research laboratories for the department's own veterinary staff, where the diseases of all live stock, from cattle to fowls, will be investigated. The Royal Dublin Society and the authorities of the college have agreed to the transfer. The Development Commissioners have promised a grant of £2,500 a year, and Mr. Russell intends to ask his department to provide a similar sum, so that about £5,000 a year will be available for research. These changes will probably involve the appointment of Professor Mettam (at present Principal of the Veterinary College) to the post of the department's chief scientific officer.

DEPORTATION OF LUNATICS TO IRELAND.

At the last meeting of the Clonmel Asylum Committee, the resident medical superintendent, who was asked to explain the cause of the recent increase in the number of insane in the asylums, stated that it was partly due to the fact that insane people were being deported from America. It was also stated that the unions were troubled with paupers deported from England. In one case a patient who had been fifty years in America was deported and put in a train at Queenstown and left to find his own way. In another case a young man was landed at Queenstown, and a telegram was sent to his brother in Queen's County. In yet another case the parents went out in their yard in the morning to find their daughter, insane, back from America; they had had no notice of her coming. Two patients had been fourteen and twelve years respectively in American asylums, and were then deported. It was understood that agents accompany the patients back to Ireland and then turn them loose. It was decided to draw up a list of the cases and lay it before members of Parliament.

FULL CENSUS RETURNS.

According to the complete Census returns for Ireland, which were published last week, the total population was 4,390,219, compared with 4,458,775 in 1901. This decrease of 68,556 is the smallest recorded at any Census since 1841, being 1.54 per cent. of the population in 1901, as compared with a decrease of 5.23 per cent. in the preceding decennial period. The general figures show an increase in the town population, accompanied by a decrease in the rural. During the decade there has been an improvement in the housing of the poor town dwellers, as shown by a decline in the number of one-room tenements. Of the 1,531,821 males over 15 years of age, 55.52 per cent. were unmarried, whereas of the 1,557,759 females of corresponding ages 48.26 per cent. were unmarried. A striking feature of the present Census as compared with previous ones is the great increase in the number of people returned as being over 65 years of age. Since the last Census their number has increased from 234,506 to 440,898. The total number of people who were returned as able to speak Irish has again fallen; the proportion per cent. of the population in 1891 was 14.5, in 1901 14.4, and in 1911 13.3. In 1901 over 20,000 were returned as speaking Irish only, but in the last Census there were 4,000 fewer. There was an increase in the number of speakers of Irish under 18 years old, which was more than counteracted by the reduction in the number of Irish speakers over this age.

Scotland.

[FROM OUR SPECIAL CORRESPONDENTS.]

THE WORK OF THE EDINBURGH ROYAL INFIRMARY.

MORE than ordinary interest attaches to the illustrated lecture on the work of the Edinburgh Royal Infirmary given on the evening of March 12th, in the Synod Hall, to a large audience, consisting mainly of industrial workers. Mr. W. B. Blaikie, one of the managers of the infirmary, presided, and in his opening remarks he said that he believed that there had arisen some misunderstanding as to the arrangements of the infirmary, owing to the National Insurance Act; consequently the managers had thought that the simplest plan to remove any such misunderstanding would be to take the citizens of

Edinburgh, and particularly those by whom the infirmary was chiefly used, into their confidence and show them exactly how matters stood. He touched upon the inception of the institution in 1725, and upon one or two events in its history.

Mr. Paton, the organizing secretary, then gave his lecture. Although the institution did not bear a national name, it was, he said, truly national in the sense that there was not a county and scarcely a parish in Scotland from which at one time or another patients had not come to the Edinburgh Royal Infirmary. It began in a hired house, with six beds, at the top of Robertson's Close, the first patient being a Caithness woman, and in its first year thirty-five patients were treated, of whom one died. Last year there were 12,600 in-patients, in addition to 39,500 who were treated in the out-patient department. The total expenditure, including that of the Convalescent House, was in round figures £60,000 per annum. In 1741, when the first part of the first permanent infirmary was opened, the managers resolved that the sick poor should be admitted from whatever place or country they came without restriction. It was open to all. Other interesting details were given, views illustrating the working of the various departments were shown, and the procedure adopted in respect of insured persons under the Act was explained. The managers are to be congratulated on the action they have so promptly taken in this matter, and on the success of the lecture; and it is not unlikely that the example they have set will be followed by the directors or managers of similar institutions. The invitations to the lecture were issued through the public works, the friendly societies, the trade unions, and other organizations of the same kind.

ODONTO-CHIRURGICAL SOCIETY OF SCOTLAND.

The annual meeting, followed by the annual dinner, of the Odonto-Chirurgical Society of Scotland was held on March 14th in Edinburgh. The office-bearers for the session 1913-14 were elected, Dr. G. J. Goldie being made President in place of Mr. Douglas Logan. A lecture on the influence of the buccal cavity on primary digestion was delivered by Dr. Francis Boyd, C.M.G., F.R.C.P.E., who also proposed the toast of the Society at the dinner. Dr. Boyd laid considerable emphasis on the fact that the successful progress of patients suffering from pneumonia or typhoid fever depended largely on the condition in which the mouth was kept.

ANTHRAX IN MAN.

The daily press takes notice of the fact that two men from the Haddington district, the one a butcher and the other a shepherd, are at present under treatment in the Edinburgh Royal Infirmary suffering from anthrax. The source of infection seems to have been a bullock.

MEDICAL ARRANGEMENTS AT CRAIGLOCKHART AND CRAIGLEITH POORHOUSES.

At the Edinburgh Parish Council on March 17th some important changes in the medical arrangements at Craiglockhart and Craighleith Poorhouses were discussed and adopted. At the former it was decided to have in future a medical officer to assume entire charge and responsibility for the medical work; he is to devote his whole time to the duties, and he is to receive an initial salary of £350 per annum, with an allowance meantime at the rate of £50 per annum in lieu of house accommodation. At the latter (Craighleith) it was arranged to appoint a consulting physician, whose duties should be to visit and examine the sick inmates at least twice a week, and also when specially required to do so by the resident medical officer or the governors; the salary attaching to this post is to be at the rate of £105 per annum. The third suggestion, which was also adopted, was that for both poorhouses a consulting surgeon be appointed at an annual fee of £105, namely, 70 guineas for Craiglockhart and 30 guineas for Craighleith. The change here about to be effected shows how markedly the poorhouses are being hospitalized. At the same meeting Dr. A. Hill Buchan was appointed certifying medical officer, to attend daily at the inspector's office; the salary is £100 per annum.

England and Wales.

FROM OUR SPECIAL CORRESPONDENTS.

LEEDS.

THE GENERAL INFIRMARY.

The statistical tables for the year ending December 31st, 1912, which are included in the annual report for the corresponding period, show that 781 more patients were admitted to the wards than during 1911, the numbers being respectively 7,905 and 7,124. Adding the number of patients remaining under treatment at the end of the year 1911 at the main building as well as at the two semi-convalescent hospitals, the total number of patients dealt with in the in-patient department amounts to 8,346. Of the admissions, 1,430 were to the medical wards, 3,819 to the surgical wards, exclusive of 743 accident cases which for statistical purposes are separately classified; 1,078 were admitted to the eye wards, 451 to the department for ear and throat, and 404 to the wards devoted to diseases peculiar to women. The daily average number of in-patients at the infirmary was 398, the number of available beds being 432; at the two convalescent hospitals the daily average was 87, the total number of available beds being 88. There was therefore an average number of 485 patients in the wards of the infirmary and of its two semi-convalescent hospitals throughout the year. At the semi-convalescent hospitals it is to be expected that, as all the patients who are admitted there pass in the first instance through the wards of the main institution, the number of patients may closely approximate to the total available number of beds; but every one who is familiar, especially from practical experience, with the working of a large hospital will feel that a daily average of 485 patients, with a total available number of beds amounting to not more than 520, indicates a condition of high pressure, especially when it is considered that some of these beds may be regarded as emergency beds. On at least one occasion the total number of patients did, in fact, correspond with the total number of beds at the disposal of the three institutions, and the total number never fell below 428. Taking the main building, the average number of days each patient was resident was 17.6, and the average number of in-patients to each occupied bed was 20.7.

The number of deaths was 558, giving a percentage of 6.7. If the number of patients dying within forty-eight hours of admission are deducted, the percentage works out at 4.6. In the extern maternity department there were 410 confinements. The figures representing the work in the out-patient department, which will be watched with interest during the coming year in respect of the effect which it is believed the operation of the Insurance Act will have upon their number, showed an increase in the number of patients, but some decrease in the number of attendances. During the year 4,221 operations were performed on in-patients and 3,696 in the operating theatres of the out-patient department.

The board in the annual report make an earnest appeal for more generous financial support. The infirmary is efficiently but economically managed, but the annual expenditure is always markedly in excess of the regular income. In consequence it has for many years been the custom to use legacies almost entirely to meet current expenses, and during the year the board have thought it wise to dispose of £17,857 worth of stock to reduce the large overdraft on the treasurer's account. Reference is made to the work of the lady almoners which has gone on in association with the similar work of the Hospital for Women and Children and the Leeds Public Dispensary. As a further instalment of the improvement of the infirmary to be carried out under the King Edward VII memorial extension scheme, wards No. 1 and 2 have been renovated and the sanitary blocks attached to the wards reorganized.

During the year Dr. Barrs has joined the consulting staff at the end of his twenty years' service as full physician. Though the event does not fall within the period dealt with in the report, mention is made of the

impending departure from the infirmary of Miss Fisher, the Lady Superintendent of Nurses. Miss Fisher entered into the service of the infirmary some twenty-seven years ago as assistant to Miss Gordon. When Miss Gordon became head of the nursing department of St. Thomas's Hospital, Miss Fisher succeeded her, and for a period of about twenty-three years she has carried on the work with efficiency and with zeal, earning the confidence of the board as well as the respect and regard of all with whom she has come in relation. Miss Fisher is to be succeeded by Miss Innes, who was previously Assistant Superintendent and who was some time ago appointed matron of the Halifax Royal Infirmary.

In contemplation of the National Insurance Act coming into force in January, the weekly board, on the recommendation of the Faculty, agreed to the following regulations, which have been posted in the out-patient rooms and elsewhere as well as published in the local press.

On and after January 15th, 1913, all persons applying for treatment at the General Infirmary at Leeds will be required to state whether they are insured persons or not.

Insured persons who on examination are found to be suffering from *slight* ailments will be referred to their own doctor outside the infirmary.

Insured persons with *slight* accidents will receive immediate attention and must afterwards obtain treatment by a medical practitioner outside the infirmary.

These regulations have been in operation since the date mentioned and appear to have acted smoothly with all concerned.

The King Edward VII Memorial Fund now stands at £111,000, and it is hoped during the coming year to make a further appeal to the public to complete the minimum amount which was aimed at; namely, £150,000. The scheme, which involves the diversion of certain thoroughfares and the acquisition of some property by the Corporation, has been sanctioned by that body, and a bill is being promoted which it is hoped will be approved by Parliament during the present session.

HOSPITAL SUNDAY.

The Hospital Sunday Fund is administered by a committee representative of the different charities of the city. A feeling has been prevalent for some time that the amounts obtained at the various congregational collections is smaller than it should be when regard is had to the magnitude of the work which it is intended to promote and to the size of the city. On the suggestion and invitation of the Lord Mayor of Leeds (Mr. A. W. Bain) a meeting of the clergy and ministers interested in the movement was held at the infirmary some time ago, the object being that those who wished it might be able to say something at first hand as to the character of the work carried on at the infirmary. It is gratifying to be able to record that this seems to have been attended with some benefit to the collections. The amount from 194 collections is £1,189 11s. 7d., as compared with £983 5s. 6d. from the same collections last year. From collections from areas outside the city the amount from the same number of offertories—namely, 128—was £348 17s. 6d., as compared with £256 7s. 9d.

LIVERPOOL.

SIR ALFRED JONES'S BEQUESTS.

THE Chancery Court of Lancaster has sanctioned a scheme prepared for carrying out the provisions of the will of the late Sir Alfred Jones, which disposed of £227,100 for charitable and educational purposes. The Liverpool School of Tropical Medicine will at once receive £40,000 to form a fund to be called the "Sir Alfred Lewis Jones Bequest." It is to be devoted: (a) To defraying the cost of a new wing or ward to the Liverpool Royal Infirmary for the reception of persons suffering from tropical diseases, to be called the "Sir Alfred Lewis Jones Tropical Ward"; (b) to the erection of new premises in Liverpool for the study of tropical medicine, to be permanently associated with the name of the testator; (c) to the erection and equipment of a laboratory in Sierra Leone, to be called the "Sir Alfred Lewis Jones Tropical Laboratory"; (d) the residue of the gift is to be used

as a permanent endowment. Eventually, when certain annuities cease, the school will receive a further sum of £40,000. Further bequests are those of £1,000 to Liverpool University, £10,000 for a hospital at Garston, and £3,000 each to the Liverpool Hospital for Women and the Home for Epileptics at Maghull.

EUGENICS.

Sir James Barr is the centre of activity in matters of eugenics in Liverpool. Under his chairmanship Major Darwin recently delivered a very outspoken address on the subject of large families and small. The lecture was attended by many members of the medical profession. The eugenical idea is making steady progress, and there is a strong body of medical opinion in favour of legislation to prevent reproduction in the most obvious cases of unfitness.

THE INSURANCE ACT.

The Local Medical Committee has been recognized, and has contributed its representatives to the Insurance Committee. Many matters have been referred to the Medical Committee for advice, and the relations between the lay and medical bodies promise to be harmonious as far as Liverpool is concerned. No decision has yet been reached as to the allocation of persons who have failed to place their name on a doctor's list—about 25,000 out of a total of 250,000 insured persons; it is expected that the allocation will eventually be made on a territorial basis. The Insurance Committee still continues hostile to contracting out in any shape.

LONDON.

IRISH MEDICAL GRADUATES' DINNER.

THE annual festival of the Irish Medical Schools' and Graduates' Association passed off very successfully on St. Patrick's Day, with a dinner and social evening at the Trocadero Restaurant. The President, Dr. W. Douglas, was in the chair, and the guest of the evening was His Honour Judge Rentoul, K.C. As usual the guests included many ladies.

The loyal toasts having been proposed by the President, Dr. J. G. Fitzgerald, in a felicitous speech, submitted the toast of "Our Defenders," to which Captain Clarke, R.N., replied.

Dr. H. Macnaughton Jones, in proposing "Our Guests," referred to the distinguished career of Judge Rentoul.

His Honour Judge Rentoul, in reply, humorously referred to his connexion with the medical profession. His only brother was a medical man; he had eight nephews, of whom four were medical men; of his five sisters, three were married to medical men; the fourth was married to a medical student, and the fifth was unmarried because no medical man had turned up. He was proud to be the guest of a profession that was the most humane and charitable of all the callings in the world.

Dr. Alfred Cox, who proposed "The Association and the President," mentioned that the Association could now claim thirty-six years of uninterrupted success. Dr. Douglas had rendered yeoman service to his fellow members, and was to be congratulated on having been elected President. This was not the only association for which Dr. Douglas had worked strenuously; he had done much valuable work for the British Medical Association.

Dr. Douglas, in responding, remarked that the Association watched over the interests of Irish medical men in this country, and endeavoured by social meetings to foster good fellowship amongst them.

The proceedings terminated with the singing of "Auld Lang Syne." During the evening an excellent programme of music was carried through.

METROPOLITAN EAR, NOSE, AND THROAT HOSPITAL.

AT the annual general meeting of the Metropolitan Ear, Nose, and Throat Hospital it was reported that the more commodious premises the hospital now possessed at 2, Fitzroy Square, had been acquired, fitted, and furnished largely through the liberality and support of the president and chairman, the late Earl of Crawford, K.T. It was announced that his successor in the title had accepted the

office of president. It was also reported that the expenditure for the year 1912 amounted to £1,479, a sum which exceeded the income by £57. Eventually the hospital will benefit by a reversionary bequest.

PATIENTS' CONTRIBUTIONS TO VOLUNTARY HOSPITALS.

Mr. Richard Kershaw has published a short pamphlet, to which he has given the title *Provident Principles in Voluntary Hospitals*, which, as will be seen, is something of a misnomer. His object is to advocate the system adopted by some special hospitals of calling for contributions from patients during the time they are receiving medical treatment at the hospitals. He admits that "in some quarters an indefinable scant respect is meted out to some of those hospitals which have made this contributing system a part of their organization," and he complains that grants made by the Metropolitan Hospital Sunday Fund towards these hospitals are less than those made to other hospitals, which seems to him to be "a penalizing of sound, healthy, provident principles." He also quotes the report of the Committee of King Edward's Hospital Fund, which says: "On the whole we are of opinion that the system of payments might advantageously be abolished." He denies that hospital abuse exists to any noteworthy extent, but admits that the middle classes, feeling that they cannot obtain the highest medical skill which the rich can afford to provide for themselves and which is provided freely for the very poor, seek relief at the voluntary hospital and accept the services of the surgeons gratuitously, often against their inclinations. Some interesting figures are given from the analysis book of the Central London Throat and Ear Hospital, which show that in 1911 the in-patients numbered 826, of whom 42 per cent. gave a contribution, 28 per cent. were admitted free on subscribers' letters, and 30 per cent. were admitted free without letters. The total contributions amounted to £362, or an average of £1 0s. 9d. for an average of eleven days' residence in the wards. This is about 1s. 10½d. per day, or 9½d. if the whole number of in-patients be taken into account. As to the new out-patients, the number was 11,303, of whom 75 per cent. gave contributions on their first visit, 11 per cent. were free on subscribers' letters, and 16 per cent. free without letters or other passport except suitability for treatment. The aggregate contributions received from these new out-patients on their first visit was £504, or an average of 1s. 2d. per contributing patient. The subsequent attendances of these 11,303 new out-patients numbered 35,312, and 54 per cent. gave contributions, the total amounting to £1,584, which equals 1s. 4½d. per contributing patient, these payments extending over periods varying from a week to a month.

To meet the objection that the wrong class of patients were admitted, it is shown that of the 826 in-patients, 520, or 63 per cent., were sent by their private medical attendant, 25 per cent. came of their own accord, and were admitted free as being too poor to pay for medical attendance of any kind, and 12 per cent. were urgent cases calling for immediate operative treatment, and admitted by the surgeons direct from the out-patient department. Of the out-patients, 40 per cent. were recommended by their private medical attendant, 5 per cent. were sent by other hospitals for special treatment, 11 per cent. came with subscribers' letters, 16 per cent. were obviously of the poorest class and were admitted free without letters, while 5 per cent. came because they evidently thought that they would secure the best advice, but their eligibility being doubted, they were referred to their own doctor to speak as to suitability, and only on the very rarest occasion has an unfavourable reply been received. It is noticeable that these figures only account for 97 per cent. of the total. It is understood that no distinction is made between free and contributing patients, and there are no private wards. Mr. Kershaw holds that there is a great difference between converting a charitable hospital into a commercial undertaking, which some fear this contributing system would lead to, and simply asking a patient to make some small contribution towards the expenses, and he claims that such a system as this is charity conducted on business-like lines, and ought to be more systematically adopted.

India.

[FROM OUR SPECIAL CORRESPONDENT.]

PHOSPHORUS LEGISLATION IN INDIA.

THE Member for Commerce had little difficulty at the last meeting of the Viceroy's Legislative Council in making out a strong case in favour of the white phosphorus matches bill. It was introduced in March, 1912, and the postponement has served the useful purpose of allowing fuller and more convincing proof of the need for the measure to be collected, and the fact that the American Congress has passed a law imposing prohibitory taxation on matches made with white phosphorus and forbidding their importation has been duly noted. Even in England before prohibition was enforced, difficulty was experienced in obtaining evidence of the occurrence of necrosis, and in India, among a floating and very ignorant factory population, this difficulty is enormously increased. Sir C. P. Lukis, Director-General of the Indian Medical Service, has pointed out that 8 cases of necrosis of the jaw had been discovered last year in districts in which match factories were working, though there was no evidence to connect these cases with the match industry, but the Indian labourer would not associate his disease with his occupation, and as the match industry is still in its infancy in this country, medical officers would be unlikely to make inquiries on this point. An additional argument is the fact that the present market in India for foreign phosphorus matches helps to bolster up the industry in other countries. As regards the inconvenience and loss to which the Indian villager would be subjected by being deprived of his favourite "strike-anywhere" match, it is sufficient to state that out of 271 brands of "strike-anywhere" matches tested at the English Customs Houses, only 11 were found to contain white phosphorus. The argument that white phosphorus matches are a practical necessity in damp climates is disproved by the fact that since 1890 their importation into Burma has been prohibited and no inconvenience has been felt in that province. It is also significant that in Calcutta, which serves such damp districts as Assam and Eastern Bengal, the proportion of white phosphorus matches imported is only 25 per cent., as against 75 per cent. at Madras, 60 per cent. at Bombay, and 50 per cent. at Karachi. There is little reason to doubt that as soon as the bill is passed a "strike-anywhere" match manufactured without white phosphorus will be placed on the Indian market, and will remove any temporary inconvenience to which the bill may lead.

FAMINE RELIEF IN BOMBAY PRESIDENCY.

The committee appointed recently in connexion with famine relief in the Ahmednagar district has issued an appeal for one lakh of rupees for special relief. This is the third year in succession in which the rainfall has been deficient, and the gravity of the situation in the famine area is greatly increased by the absence of drinking water. Ordinary relief works are rendered impossible on this account. Later reports are that the cattle that were taken out of the district for grazing elsewhere are returning, the plan of emigration having failed.

MINTO OPHTHALMIC HOSPITAL, BANGALORE.

Considerable progress is being made in the founding of hospitals in India. The Maharajah of Mysore takes very great interest in the development of these institutions, and in June, 1897, the Maharani-Regent, the mother of the present ruler, laid the foundation stone of the Victoria Hospital, and in December, 1910, the Maharajah laid the foundation stone of the Minto Ophthalmic Hospital. Much of the credit of this is due to the senior surgeon, Colonel Smyth, who used his influence to get a special hospital for treatment of diseases of the eye. Colonel Smyth had studied recent improvements in hospital arrangements in England, and reproduced many of these in the designs of the new hospital.

On January 31st, 1913, the new building, which was called the Minto Ophthalmic Hospital, was opened by His Highness the Maharajah of Mysore, G.C.S.I. It is a handsome building, which affords in-patient accommodation for 34 males, 34 females, and 12 children. There are two

operating theatres, and the building covers 20,190 sq. ft. To the regret of all, Colonel Smyth had left by this time, and Dr. Iyenjar is the superintendent. The Maharajah, after expressing his gratification that such an institution should have been built and the pleasure with which he declared it open, said that a third hospital was about to be constructed, and suggested that after that the turn of the Maternity Hospital might come. He impressed upon his hearers the medical needs of the outlying districts, especially in Malnad, where the steady decrease in the population was a matter of great concern to his Government. He expressed his confidence in the officers of his own medical service, many of whom possessed English and other European qualifications. He hoped the number of private medical practitioners in his State would quickly increase, as he was anxious that his people, both in matters sanitary and medical, should rely more and more on themselves. He trusted that those responsible for the management of the hospital would strive to make it a worthy memorial of Lord Minto's friendship to the State and of his eminent services to the people of India.

THE HINDU UNIVERSITY FOR ALL INDIA.

His Highness the Maharaja Sir Pratap Singh announces, on behalf of the Marwar Darbar, a donation of two lakhs in a lump sum and Rs.24,000 annually to found a chair bearing the name of the Viceroy, Lord Hardinge. The lump sum and the permanent annual donation capitalized amount to Rs.8,70,000. This is the largest individual contribution hitherto made to the funds of the university.

Malta.

REPORT ON PUBLIC HEALTH FOR 1911-12.

The annual report of the Public Health Department of Malta states that the population at the census of 1912 showed an increase of 1,911 on the estimate for the previous year. The birth-rate was 33.49; in the previous year it was 36.12, and the average for the last twelve years was 37.97. The death-rate for the year was 24.42; in the previous year it was 21.42, and the increase is accounted for by the increased infant mortality due to a severe epidemic of measles. The percentage of deaths under 5 years to the total was 54.12, against 52.85 for the previous year. Infantile mortality is very high, the death-rate of children under 1 year to 1,000 births was 267.21, against 236.93 in the previous year. The deaths from infectious diseases numbered 495, against 269 in the previous year, measles and cholera being responsible for this increase. Dr. Scieluna states that the incidence of Mediterranean fever, gauged by the notifications in the year, was lower than in any one of the last ten years. In 1905-6 there were 822 cases with 117 deaths, while in 1911-12 there were 273 cases and 26 deaths. The examination of 221 herds affords evidence of infection in goats in 112 instances. Altogether, 15,341 goats and sheep were examined; of these, 386 were found infected and destroyed. Since the enforcement of these regulations the milk or blood from 30,188 goats and 5,571 sheep has been examined. As a result of observations made in connexion with these periodical examinations, the following conclusions have been arrived at:

- The incidence of Mediterranean fever infection is considerably more frequent in goats than in sheep. The proportion of goats giving a positive milk and blood reaction was 3.48 per cent., and the same proportion in sheep 0.71 per cent.
- When more than one happen to be infected in the same pen, they are generally found to be tethered one near the other.
- When on successive examination of the same herd one or more goats are found infected, the goats found infected in the last examination are often found to have been fastened on a spot where goats declared infected on previous examinations were tethered.
- Goats, of which the milk but not the blood reacts against *Micrococcus melitensis* on a given round, when examined later on during a successive round or rounds were found to give a positive reaction in both milk and blood.
- The organs in goats found to yield positive bacteriological evidence of infection—namely, the organs from which *Micrococcus melitensis* can be isolated—were in the majority of cases the mammary glands; if these are found infected, the organism may be recovered also from the inguinal glands, less frequently also from the mesenteric glands and exceptionally from the spleen and kidneys.

These *post-mortem* findings appear to be consistent with the theory that Mediterranean fever infection in the goat is at first purely local, the organ in which the specific organism effects initial settlement being the udder. It travels upwards to the lymphatics, and may finally give rise to a generalized infection. Though cholera had been prevalent in neighbouring countries for several years, the measures taken to prevent its introduction were so successful that until October, 1911, the islands were free from infection. In 1911, with the immigration of nearly 2,000 refugees from Tripoli and Cyrenaica, owing to hostilities between Turkey and Italy, cholera was introduced. Altogether 116 cases were reported, with eighty-five deaths. The outbreak was of short duration and limited extent; but the case mortality was 73.2 per cent.

The number of deaths from tubercle under 1 year and under 5 years is gradually decreasing, and a similar tendency is observed in the case of tuberculosis of all ages.

Compared with other Mediterranean countries the island is specially favoured, the death-rate from pulmonary tuberculosis for the year under consideration was the smallest since 1901-02, 0.72 in 1911-12. The meteorological returns show a mean temperature for the year of 63.2° F., with a rainfall of 24 in.

Special Correspondence.

PARIS.

Emetine Treatment of Amoebic Dysentery and Abscess.— Expectation of Life after Nephrectomy.

DRS. FLANDIN AND DUMAS have reported to the Hospital Medical Society a case of hepatic abscess treated by emetine, which affords a parallel to the remarkable case recorded by Professor Chauffard in the *JOURNAL* of March 15th, p. 574. In the second case the patient was a woman who began to suffer from what was taken to be phthisis in December, 1910; a diagnosis of amoebic abscess of the liver, opening into the lung, was made in July, 1912. In December, 1912, the emetine treatment was begun, and in an extremely short time the purulent discharge ceased and the patient was completely cured. Dr. Dopter mentioned a case which he had treated under very similar conditions with equally satisfactory results. Professor Chauffard has since communicated to the same society another serious case of abscess of the liver which recovered very rapidly. It was operated upon, and the patient was also given emetine. Professor Chauffard informs us that he has reason to hope that Rogers's method will be employed in the French army as well as in the French colonies.

M. Bazy, at a recent meeting of the Academy of Medicine, discussed the expectation of life after nephrectomy. The prognosis was in general so favourable that he was inclined to think that a man with one kidney had the same expectation of life as a man with two. He had followed up patients who, after removal of one kidney for tumour, were living after fourteen, eleven, eight, five, and three years, and appeared to be in perfect health. In tuberculosis of the kidney the prognosis, he thought, depended upon the state of the bladder; patients in whom it was healthy had an extremely good chance of escaping secondary complications in the other kidney. In cases of simple suppurating kidney the cure was complete; once the kidney was removed, the albumen entirely disappeared. He drew the conclusion that nephrectomy should be performed in all cases of suppuration in the kidney.

A SPECIAL commission which has been sitting in Paris has presented a report proposing certain alterations in the examination for the rank of *agrégé*, which is the stepping stone to the professorship. Its most important recommendation would tend to allow successful candidates to specialize with a view of improving the teaching in special subjects in the various faculties and schools of medicine. The commission has also made representations as to the need for more liberal contributions from the State to the maintenance of laboratories.

Correspondence.

TRADES UNIONISM AND MEDICINE.

SIR,—I have read Dr. Bateman's letter on this subject with considerable interest and some amazement. That men of Dr. Bateman's mental bias exist has been painfully shown in the events of the past eighteen months, but it is rare that they expose the workings of their minds in the press. I do not know Dr. Bateman personally, but I have met his type frequently at Divisional and Representative Meetings. He seems unable either to grasp facts as they are or intelligently to anticipate the logical outcome of such facts in the future.

Dr. Bateman commits his first error in attributing to trades unionism as essentials the actions of certain trades unionists, as men judge socialism by the actions of socialists. A society registered as a trades union is enabled *ipso facto*, as Mr. Verrall would say, to do acts which otherwise would be unlawful. That is all. The law of conspiracy had been invoked to prevent organization; legislation thus became necessary.

I suppose Dr. Bateman is aware that a certain enactment known as the National Insurance Act has interfered in a very autocratic way with the liberties which were enjoyed by the medical profession. He must also be aware that the excellent Association in whose JOURNAL this letter appears is *not* a trades union, and incidentally has failed in its fight on behalf of our common liberties. Primarily it has failed because it has not and never has had any effective control over its members, and also because of the large leaven of men of Dr. Bateman's stamp who confuse ethics with sentimentality and *esprit de corps* with politics.

A trades union, with its closer grip on its members and its more businesslike methods, is necessary, in order that future struggles—and they will be plenty—may result in victory and not defeat.

I suppose Dr. Bateman is serious when he prophesies a general order to down stethoscopes and thermometers and "boo" any practitioner seen entering a patient's house. Apart from the uselessness of such a procedure, I should have thought that by now he would have realized that our fight in the future is with a Government department and not with mankind in general. If France were to declare war on Germany, it is inconceivable that she would commence operations by an onslaught on England, America, and Portugal.

In theory the ideals of our profession are such that there should be no difficulty in restraining individuals from doing acts which are contrary to the expressed wishes of the majority. In practice we see that even in things that are not vital considerable variety of action inevitably results, while in matters which touch the bed rock of existence every man becomes a law unto himself. The old laws lacked sanction and were obeyed just so long as obedience was consonant with personal taste. We must have something new and strong, and for my own part I can see nothing for it but trades unionism.

I should like to remind Dr. Bateman that in certain areas where the co-operation of practitioners was completely assured the whole gamut of rampant trades unionism, including picketing, has been successfully gone through under the protection of the British Medical Association. All we want is a machine that will ensure that such action shall be general and not local: something that will give the Warning Notice and the action of divisional secretaries a real and potent force.—I am, etc.,

Salford, March 15th.

STANLEY HODGSON.

SIR,—I have read with interest Dr. Bateman's letter published in the last issue of the JOURNAL. While in full agreement as to the impropriety of the trades union methods instanced by him for professional usage, I cannot help thinking he has missed the practical point in the controversy on this subject.

Very few members of the profession, if any, have seriously considered that under any circumstances such methods as "down tools" or "peaceful picketing" could be employed to further professional objects; and the

proposal that came before the British Medical Association at Liverpool last year, and which is adjourned to the Brighton meeting this year, is that the Association should, if possible, become registered as a trades union. Such registration would not necessitate the use of all so-called trades union methods.

In my opinion, there is one object that can be thereby attained of such transcendent importance that it would be cheaply purchased, even if it cost considerable labour and expense, namely, the protection of the funds of the Association from claims arising from damages awarded against us in carrying out our professional policy. As in the future, if professional union is to be of any practical assistance, much highly controversial work will have to be done, the true merits of which it is not easy for the public to comprehend, it will not be difficult for skilled advocates to stir up the indignation of juries against our methods.

Nothing is easier, where funds are available, than to bring actions. Already the financial resources of the Association have been embarrassed by adverse verdicts in such actions, which are not likely to be less in the future, if an active policy is to be carried on. So that if by means of the Trades Disputes Act it is possible for us to safeguard our funds against so obvious a danger, it seems to me only wise and provident on our part to avail ourselves of that enactment.

I do not think there is any important section of the profession that is in favour of trades unionism, except on some such grounds as I have indicated, and Dr. Bateman's letter does not touch upon this side of the question. In conclusion, I cannot agree with his dictum as expressed in the following passage of his letter:

Any unity founded upon trades union lines would be degrading and derogatory to professional men in the extreme, and I hope that the suggestion will be scouted and dismissed as utterly untenable.

The unity of trades unionism is precisely the same as ours and its object to promote the true welfare of the workers in the particular trade or profession it represents. Because some of the lines followed by trades unionism are "degrading and derogatory," it is not logical to assume that all trades union lines are such.—I am, etc.,

London, N.E., March 15th.

MAJOR GREENWOOD.

SIR, In your last issue you print a letter from Dr. Bateman against trade unions for the medical profession. That letter is calculated to do harm to a movement in which I, amongst others, feel very interested. Perhaps I may be permitted to make a few remarks as to what we hope to gain by forming a trade union? In the first place, we hope to show the public that some, at least, of us realize that the welfare of the health of the nation is in the hands of the medical profession, and that it is in the nature of a trust which we have of late most scandalously betrayed. The man in the street knows well enough all about the betrayal, and some of the better educated are looking to see whether we shall fall back into our selfish but "dignified" attitude of aloofness from all public affairs, or whether we shall shoulder our increased responsibilities like men and recreate the dignity which we have lost.

Now, since politicians have publicly laughed at us and our assumption that we knew what sort of medicine was best for the people (whereon we trembled and fell down), it is obvious that we have fighting before us if we are not to be similarly scorned in the future. It is also obvious that, if we are not prepared to fight, fresh extensions of contract practice await us, fresh obstacles to medical progress will prevail against our "dignified" resolutions.

Then comes the question as to whether a trade union is or is not the best fighting body available. Here Dr. Bateman does us an injustice, for he omits to mention the chief advantages of trade unionism, but instead puts up certain untenable hypotheses, advanced by no one but himself, and then with righteous anger at the creatures of his own creation, knocks them down again. It may first be noted that a trade union is not some strango and barbarous weapon for the furtherance of antisocial interests, but the instrument of self-defence elaborated by the State after some hundreds of years of experience. Even in the days

of the barber-surgeons and other guilds it was realized that those who followed the same calling had some right to exist in a corporate capacity for the protection of their own interests and the prosecution of their legitimate aims. Since that time successive statutes modified and enlarged the rights and immunities of such corporations until, at the present time, we have as their lineal descendant the more or less modern trade union. The rights include the right to operate in restraint of trade (and we are undoubtedly a trade technically) without being subject to legal action, and the immunities include the all-important immunity of funds from attack under the conspiracy and libel laws. When it is remembered that perhaps half of the profession are at this moment under some form of contract with insurance, Poor Law, and other authorities, and that concerted interference with these contracts is probably conspiracy if done by any other body than a trade union, it is surely obvious that we must have a trade union as soon as possible. It may be noted that the State does not give these powers to such bodies as limited companies, so that it is futile to suppose that any existing body could acquire them if it was formed and collected subscriptions for scientific purposes and is registered as a company. It is obvious that in making these last remarks I have the British Medical Association in mind, and I may, in order to avoid misconception, say that I am quite aware that the British Medical Association has a special fighting fund not subscribed for scientific purposes. At the same time, if it were sought to put that fund on any safe basis it would have to cease to be managed by the present organization of the British Medical Association—that is, the whole-time officials, the JOURNAL, the Branch Councils, etc.—for all of these are supported by funds subscribed for scientific purposes under the Articles of Association and cannot be alienated to other work until it has been made clear to each member for what fresh purpose he is subscribing. In other words, the Association would have first to cease as a company, except the JOURNAL, which would be equally obliged to continue as a company or cease altogether, since a scientific journal is probably no legitimate activity for a fighting fund; the present assets—for example, 429, Strand, etc.—would presumably have to be given away or else left with the JOURNAL, and then the members might form themselves into a fighting body with nothing of the old Association except the name. All these things were set forth by the Solicitor to the Association, and can be found in the BRITISH MEDICAL JOURNAL SUPPLEMENT, 1912, ii, p. 138.

I have digressed thus far for a good purpose and in order to show that if the members of the British Medical Association are to acquire real fighting powers it must be through some independent association and that this latter must be a trade union. Now it would be the object of a trade union to provide such a body, and it should work in unison with the British Medical Association for the good of the profession at large. The British Medical Association as an organizer of social and medical meetings all over the country is unique; as a fighting body it lacks the proper fighting basis which can alone secure immunities for its funds, nor can it assume that basis.

In conclusion, may I state those strong activities of a trade union which Dr. Bateman omits?—namely, (1) it has over its members ties of interest as well as of honour, for it provides all sorts of insurance, and failure to comply with the policy of the union implies expulsion and loss of all premiums paid; but lest this should seem unduly harsh, it has (2) statutory powers of compensating those who suffer from adherence to the policy of the union; moreover, (3) it of course gives its members legal support whether as individuals or collectively, whether attacking or attacked; and (4) it can represent its members in Parliament or by any other political means—what a difference it would have made if we had had one or two real representatives of the profession in Parliament in recent years—and (5) it cannot fail to be a sign to the public that the profession has realized its responsibilities and is again worthy of the respect it used to have until it fell down before the words alone of a politician ignorant of the very essentials of the healing art.—I am, etc.,

London, W., March 17th.

GORDON R. WARD.

SIR,—It is apparent from Dr. Bateman's views on the above subject in your issue of the 15th inst. that he has

not outlived his earlier ideals—ideals which most of us started with, but which we have gradually shed in the course of our struggles as general practitioners.

When I qualified some twenty years ago I never expected that a Government, however socialistic, could bend a proud profession to its will as in the recent conflict through which we have emerged—vanquished. Twenty years ago the adoption of trades union methods would have been as repellent to me as it is now to Dr. Bateman. But times have changed; the working masses have gained the control of the country. Their cry is for more and yet more from the classes, and in the present Government they have a pliant tool to gratify their demands. Their chief, Mr. Lloyd George, has spared us no abuse, no indignity, to place us under the yoke. Our humiliation is complete. We have become not general practitioners, but general dispensers. Our leisure for professional self-improvement is given over to filling up returns as useful for purposes of vital statistics as the death certificates emanating from the old sixpenny dispensaries.

To take effective measures for mutual protection through trades unionism is as necessary for the profession now as for the honest man to protect himself from burglary by arming himself with the weapons of the burglar.—I am, etc.,

Hanley, March 16th.

S. WESLEY WILSON.

SIR,—As one of the oldest members of the British Medical Association, in the good name of which I once was proud, I hope you will allow me to thank Dr. Bateman for his letter in the JOURNAL of March 15th. His facts make his logic irresistible, and I hope there are many members who agree with him. This Association was formed in the interests of science, as well as in the honourable interests of the medical profession; but, since this unfortunate Insurance Act frightened the profession and made some fear financial disaster, its aim has been altered; and the sooner that aim, which is in the direction of trades unionism, is given up by the Association, the better it will be not only for the interests of science, but for the honour which is the highest interest of the medical profession.—I am, etc.,

Hawick, Scotland, March 15th.

JOHN HADDON, M.D.

THE NEGLECT OF VACCINATION.

SIR,—I am obliged to Dr. Maude for his reply, but must confess it is rather disappointing. He evidently confuses the terms *fatality* and *mortality*; speaks as though I had only had experience of a single outbreak of small-pox in Leicester (as a matter of fact I have had to deal with some nineteen distinct outbreaks, including two major epidemics); suggests that 700 cases of small-pox are not enough to found new generalizations upon (ignoring the fact that the "Leicester experiment" had been going on long before I came to Leicester); and makes the old erroneous assumption that in Leicester, when an epidemic of small-pox occurs, "the population is so alarmed that they all rush to be vaccinated."

I quite agree with Dr. Maude that the country as a whole is not so well organized for dealing with small-pox by modern methods as it should be, but when we come to realize that we can no longer depend upon infantile vaccination, it is reasonable to hope that increased attention will be paid to strengthening the weak spots in what we shall then regard as our chief line of defence.

As regards Dr. Rice, I am very glad to find that others are beginning to feel the desirability of speaking out on this question. His analogy—to soaking buildings and their contents with water to prevent them taking fire—is excellent.

As regards Dr. J. W. Papillon's letter (in your issue of March 8th), he asks me to explain how the future of small-pox prevention in this country can lie with the medical officer of health rather than with the public vaccinator, seeing that even in Leicester we advocate the vaccination of medical attendants, nurses, and contacts.

The obvious answer is that the public vaccinator, in any case, has no part in the vaccination of medical attendants and nurses; whilst as regards the vaccination of contacts, although it is true that in Leicester hitherto it has

been thought expedient to utilize the services of the public vaccinator for this purpose (and I take this opportunity of publicly acknowledging the ready and willing co-operation which I have always received from the public vaccinators in Leicester), yet surely Dr. Papillon will not seriously suggest that it is necessary that the country should maintain an army of public vaccinators, vaccination officers, medical inspectors, and all the expensive machinery of public vaccination for the sake of vaccinating a few contacts in the rare event of an outbreak of small-pox! Even at present some medical officers of health prefer to vaccinate their own contacts, as being simpler and more expeditious. In my experience the chief trouble is to convince contacts of the need for vaccination, and this is already the work of the medical officer of health.

Dr. Papillon quotes Germany as a country where infantile vaccination followed by revaccination—and, I may add, by a second revaccination—has practically abolished small-pox. But how much better if we in this country can do the same without either infantile vaccination or revaccination! Be that as it may, Dr. Papillon must be aware that there is not the slightest prospect of any Government attempting to introduce a measure making revaccination compulsory, still less of their being able to enforce it if such a measure succeeded in getting on to the Statute Book. Therefore, as practical men, we may as well leave compulsory revaccination entirely out of our calculations, and confine our attention to the really important question of how far infantile vaccination is really helping us to-day in our efforts to prevent the spread of small-pox.

I would point out that small-pox is not now an endemic disease in this country. It is not now so much a question of reducing the mortality from small-pox, which has sunk to insignificant proportions, in spite of the increasing neglect of vaccination; the real question at the present day is *how to prevent the disease from spreading* when isolated cases are imported from abroad. If we could do this, then without doubt small-pox in this country would virtually become extinct. This is no Utopian dream; the indications all point to its being one day an accomplished fact.

As regards Dr. W. Hardman, I fear from the tone of his letter I must not expect much sympathy from him. I can only suggest to him that, as deep truths are sometimes hidden from the wise and prudent yet revealed unto babes, so perhaps time will show that the conscientious objector, ignorant and illiterate though he often may be, is not so very far wrong after all when he asserts that it is not necessary, in order to save from small-pox, to introduce "disease matter" into the body of his healthy child.

In conclusion, may I be allowed to submit a few ideas on this question which, for the sake of economizing space, I have endeavoured to crystallize out in the form of aphorisms, each of which I am quite prepared, if necessary, to justify and substantiate? They only apply, of course, to the problem as affecting our own country.

Vaccination Aphorisms.

1. It is the vaccinated persons whose vaccination has "lapsed," rather than the unvaccinated, who really spread small-pox.

2. Infantile vaccination alone, however efficiently enforced, will never save a country from small-pox.

3. Small-pox does not "spread like wildfire" in an unvaccinated community where modern methods of prevention are efficiently carried out.

4. There is no fact more firmly established in the whole field of science than that variola and vaccinia confer reciprocal immunity.

5. Modern methods of small-pox prevention are superseding infantile vaccination just as the latter superseded small-pox inoculation.

6. It seems probable that, in spite of increasing neglect of vaccination, small-pox (in this country) will ere long become virtually extinct.

7. A system of infantile vaccination which is not followed by revaccination is only a half-measure. Half-measures often do as much harm as good.

8. The effect of vaccination in masking small-pox, and thereby thwarting modern preventive measures, is a serious drawback, which has not yet been sufficiently considered.

9. As a *dernier ressort*, unvaccinated communities can always fall back upon universal vaccination, should the need for it ever really arise.

10. It is the hostility to vaccination (engendered by compulsion), rather than the neglect of it, which constitutes the real danger to unvaccinated communities.

11. The injuries to health caused by vaccination have not been so carefully recorded as they might have been. The debit side of the balance sheet has not always been filled in.

12. Vaccination, as a scientific operation for conferring complete but temporary immunity against small-pox, was never in a stronger position than it is to-day. It is justly regarded as one of the most striking discoveries in the history of medicine.

Vaccination, as a State system for the compulsory inoculation of infants, is no longer really necessary; it is largely discredited with that section of the community which it is specially intended to serve, and it is becoming obsolete.—I am, etc.,

Leicester, March 17th.

THE DISSEMINATION OF RECTAL CANCER.

SIR,—In the JOURNAL of March 15th Mr. Sampson Handley takes exception to certain comments made by your reviewer in discussing a paper by me entitled "Intramural Spread of Cancer of the Rectum."

So far as I am concerned there is no question as to the accuracy of Mr. Handley's observations, but, in defending his theory of mucous permeation, he endeavours to fortify his own position by exposing what your readers may assume to be a weak point in mine. Mr. Handley maintains that, inasmuch as he is disinclined to discredit the existence of intermuscular permeation because he has not himself observed it, so is it unjustifiable to doubt the occurrence of mucous permeation because no evidence was found to support it in my series of cases. This argument would be valid if the case in favour of intermuscular permeation were strictly comparable to that in favour of mucous permeation. That they are not comparable may easily be shown by a consideration of the microscopical evidence only, and the position is briefly this: Mr. Handley has described and figured cells in the mucous layer of the bowel wall at a distance from the margin of the growth, but the nature of these cells is still open to question. On the other hand, I have demonstrated, in the intermuscular lymphatic plexus, cells the cancerous nature of which cannot be denied.—I am, etc.,

PERCIVAL P. COLE.

IMMEDIATE OPERATION IN APPENDICITIS.

SIR,—For some time prior to the discussion which Mr. Edmund Owen's article has reawakened, my partner, Dr. Ralph Norman, had been trying to convert me to his own conclusion, that immediate or very early operation is the only bridge across the chasm of all-too-frequent disaster in appendicitis. Every case I have encountered since my conversion (the completeness of which I cheerfully admit) has but strengthened our now joint conviction, and three object lessons especially that we have had within three months confirm all that Mr. Owen and his school maintain.

The first, a schoolboy of 12 at a local preparatory school, to whom I was called fifteen hours after nocturnal onset of pain, I found to be in but slight discomfort, wanting to get up. Pulse 100, temperature 99°, with moderate resistance over the lower right rectus. I had some difficulty in getting consent for operation, the parents being in India; but, fifteen hours later, the earliest possible time we could arrange, Mr. Sherren found a zone of commencing gangrene of the middle third of the appendix.

My second case, a little girl of 7, I operated on thirty-eight hours after onset, the symptoms having been of the mildest to within six hours previously. She had a "flaming" appendix 5 in. long, a fearsome spectacle of disaster impending a few hours later.

The third case occurred this evening. A young man of 21 walked into Dr. Norman's surgery at 7 o'clock saying that a pain for which he had sought relief yesterday was no better. There was well-marked resistance over the usual area, temperature 99°, pulse under 100. He consented to go into hospital at once, and at 9 o'clock I removed an appendix already the colour of a mulberry, with a stercolith at the extremity, and on the point of gangrene.

All three cases were caught before abscess formation, each—if left a few hours later—would have required extensive drainage, there being practically no "walling off" in any, and the sequel would have been at best a ventral

hernia or a weakened abdominal wall. Who would have dared prophesy no worse ending even than this had the "wait and watch" policy been adopted?—I am, etc.,

Westcliff-on-Sea, March 15th.

CHARLES FORSTH.

SIR.—It may be of interest to indicate the results of operative treatment of appendicitis by one who has been guided in dealing with these cases by one rule and one rule only—"operate immediately"—and who, moreover, cannot lay claim to any special experience or operative ability, in that he only commenced to operate independently on these cases just over two years ago. The cases, taken from hospital practice, were all acute cases of varying duration, and represented all stages of the disease. Operation was never refused even when the chance of recovery seemed almost hopeless. It must be common knowledge that in hospital practice such cases are of all too frequent occurrence.

I have in the past two years operated on 58 cases with 6 deaths. Analysing the deaths, it is found that 3 had general suppurative peritonitis at the time of operation, one such case being that of a female, aged 74, who, however, lived ten days. One patient had concurrent pneumonia which proved fatal. In one case, with an abdominal tumour, operation was delayed owing to the doubtful nature of the mass, but was rendered urgently necessary by a sudden rise of temperature and rapid increase in the size of the swelling. The sixth case, an early one, died from general peritonitis.

In many cases delay was responsible for conditions which seriously endangered the lives of the patients and rendered their recovery prolonged and anxious. It will be noted, however, that in 4 cases the patient's chance of recovery was practically hopeless, and the fatal result must be directly attributed to the fact that operation was performed too late.

If these 4 deaths be eliminated the mortality is 3.7 per cent., and it is thus seen that the adoption of the fatal policy of procrastination has raised the death-rate from this figure to 10 per cent., which represents the total mortality in this series.—I am, etc.,

London, W., March 15th.

PERCIVAL P. COLE.

PHYSICAL SIGNS OF MYOCARDIAL INVOLVEMENT.

SIR.—The point which Dr. Carey Coombs raises in your last issue interests me very greatly. If I mistake not, Dr. Coombs does not disagree that the presence of heart-block is of value in the diagnosis of myocardial involvement; on the other hand, he questions whether heart-block is as frequent as my paper would infer. Dr. Coombs says the disturbance is comparatively rare; my own belief has been that it is not uncommon. Dr. Coombs's conception of its incidence may in the end prove the more justifiable; the personal observations, to which he makes reference in his letter, are evidently extensive, and in the light of this, his valuable experience, I am unwilling to emphasize my own view. Whether the cases which have come my way are or are not a fair sample, may be left for Dr. Coombs and other observers in the same field finally to decide; confining my remarks to the patients of a single hospital, I have certainly been impressed by the number of those in whom transient heart-block has been observed. I have also a strong conviction that many such cases pass unnoticed. They pass unnoticed, I believe, for several reasons. The heart-block may be very transient; it may produce no irregularity of the pulse, and when pulse irregularity is present (from missed responses) it may, on account of its partial correction, by changing A-S intervals, be slight enough to escape observation; and, finally, a little acceleration of heart-rate, such as is produced by examination, may abolish all actual irregularity. Dr. Coombs will not misunderstand me. These arguments are not premature criticisms of his own work, but I am sceptical of the usual bedside method of pulse examination in this connexion. Moreover, I am unwilling to take refuge behind so special a method as the electro-cardiographic: it seems to me that the polygraphic is in most cases quite sufficient for the purpose; and, as Dr. Coombs has utilized it, I look forward with interest to the report of his observations, and shall not hesitate to revise my view, should these newer observations prove adverse to it.

In conclusion, may I say that although when heart-block is present I regard it as a valuable sign of myocarditis, I am quite of Dr. Coombs's opinion that myocarditis is often present and the conducting structures are often involved in the process, while heart-block fails to appear? It is perfectly clear that a histological examination of the special junctional tissues often conveys but an imperfect notion of the manner in which these tissues have performed their chief function during life.—I am, etc.,

London, W., March 15th.

THOMAS LEWIS.

RECENT ADVANCES IN THE DIAGNOSIS, PROGNOSIS, AND TREATMENT OF HEART DISEASE.

SIR.—It was with the utmost surprise that I read the contents of the extraordinary letter of Dr. Thomas Lewis in your issue of last week regarding the address on recent advances in the diagnosis, prognosis, and treatment of heart disease which I had the honour of giving at the opening meeting of the session of the Toronto Academy of Medicine.

The following are the facts: The whole of the passages quoted by Dr. Lewis, which he insinuates were copied bodily by me from his book, appeared verbatim and in the same order in an address which I gave before the Brighton and Sussex Medico-Chirurgical Society on October 5th, 1911, and repeated at the Folkestone Division of the British Medical Association on November 2nd, 1911, and again (as two lectures) at the Polyclinic in February, 1912.

Dr. Lewis states that his handbook on *Clinical Disorders of the Heart Beat* appeared in the spring of 1912.

I have never read Dr. Lewis's handbook on *Clinical Disorders of the Heart Beat*; it was never in my hands until late in the summer of 1912, when, owing to some of my pupils at the Polyclinic questioning me in regard to it, I glanced through it in order to see what were its nature and scope.

About April of 1911 I was asked by the council of the Medical Graduates' College and Polyclinic to start a practical class on the recent developments of cardiology. I accepted, and chose for the title, "Clinical Studies of the Heart by the Newer Methods, including the Polygraph." The first class was arranged for June. Unfortunately, owing to illness, I was reluctantly compelled to go away for a few weeks. Dr. Davenport Windle was appointed in my place. In order that he might see the ground which I had intended to cover, I handed some notes to him containing many of the very phrases which Dr. Lewis has quoted from my address, and Dr. Windle had them in his possession for some time. After my return I conducted classes in August and October of 1911, as well as others, before Dr. Lewis's book appeared.

Over three years ago Dr. James Mackenzie kindly asked me to become associated with him in his cardiac research work, and since then I have devoted most of my time to a close study of the subject. During this time I have seen scores of patients who have been the subjects of extra-systoles. Among the sensations of which they have complained to me are "gripping in the throat," "the heart stops," "a thud or shock" in the region of the heart following the pause, and "fluttering." When I was a smoker (long before Dr. Lewis's book appeared), I suffered from them myself, and they were certainly worse after I had gone to bed at night, and caused me "worry and anxiety," until I learnt what was their significance. Am I to be debarred from using these common expressions of common phenomena simply because Dr. Lewis may have used them or may at some future date use them? In what better way can I describe subjective phenomena than by using the patient's own words? Some patients with extra-systoles are quite unconscious of their presence. Am I not to be allowed to say so? Or may I not make use of such commonly used expressions as "worry and anxiety" without Dr. Lewis coming to the conclusion that my doing so is the result of my reading some of his writings? Has he never heard of bromides being used to "mask or modify symptoms, especially in nervous subjects"? Does he think he is the only physician who has proved the value of

bromides for the subjective symptoms of which patients the subjects of extra-systoles complain? (See Dr. Mackenzie's book published in 1910.) Am I not to be allowed to enumerate the conditions under which extra-systoles may occur—conditions which are well known to every student of the subject? In regard to the spelling of one of the drugs, I have always rendered it "phlyostygmine," and unless my attention had been drawn to the matter I should have continued to do so. Evidently I am not the only one who uses a "y" instead of an "i" in spelling the word.

In regard to the remarks on heart-block of mild degree, I hope Dr. Lewis and myself are not the only physicians who know that it may occur during the course of infective diseases and what its significance is. On page 186 of his book, Dr. Mackenzie states that in acute affections of the heart the presence of the irregularity due to the milder degree of depression of conductivity indicates that the muscle is being invaded by the disease. Again, on page 189 he states that the milder cases of heart-block warn us that myocardial changes are involved.

Again, in regard to pulsus alternans, I should have thought that every student of the subject knows that in the vast majority of cases it is necessary to take a tracing of the radial artery in order to recognize it, and that very rarely in cases in which it affects the pulse continuously it is perceptible by the finger. Apparently I should not be allowed to state these facts as I have done without Dr. Lewis's permission.

In regard to my remarks about the intravenous injection of strophanthin, in my address I stated, "Strophanthin may be administered intravenously, either two or three doses of $\frac{1}{32}$ th of a grain at an interval of two hours, or a single dose of $\frac{1}{16}$ th of a grain." Dr. Lewis in his book writes: "The intravenous injection of strophanthin is also valuable at such times. Two or three doses of $\frac{1}{32}$ th of a grain, each in 40 to 60 minims of saline, are given at an interval of two hours." For about two years I was associated with Dr. James Mackenzie and Professor Cushtny and other workers in conducting at the Mount Vernon Hospital a series of investigations regarding the efficacy of drugs in different affections of the heart. Some of the investigations were joint investigations. Others were conducted by individual workers, by myself for example on aconite, and by Drs. Marris and Linnell—I understand at the suggestion of Professor Cushtny—on the intravenous injection of strophanthin, all of which I followed, and with the results of which I was thoroughly conversant before I gave my address at Brighton (on October 5th, 1911). The result of these researches went to show that $\frac{1}{32}$ th grain of strophanthin is useful in the most acute cases of cardiac failure, and I mentioned this fact at the above meeting, and in the rough minute book this is stated and the above dose given. Until I read Dr. Lewis's letter I did not know that he had ever written a line or spoken a word on the subject. Am I to be precluded from stating facts which I have learnt from personal observation simply because Dr. Lewis may have at some date, or in the future will make mention of the same facts and in similar language?

In my future writings is it incumbent upon me to previously read everything Dr. Lewis has written in order to be quite sure that I do not employ similar language in describing common phenomena?

Owing to the limited phraseology of the subject every writer must of necessity use similar language in describing certain phenomena. If other people cared to look at the matter in the same spirit as, apparently, Dr. Lewis does, it would be easy to point to phrases used by him in his small handbook published in 1912 very similar to some employed by Dr. Mackenzie in his well-known work published in 1910 (see p. 66), when, referring to heart affections and a hypersensitive nervous system, the latter states that "by the judicious administration of the bromides patients can be *tided over* trying periods"; and the former, on p. 54, says: "The bromides . . . and these drugs are especially useful in *tiding* a nervous or excitable patient *over* a period of disturbances." (The italics are my own.) It is also very interesting to compare the phrases used by Dr. Mackenzie in describing auricular fibrillation, in his Oliver-Sharpney Lectures in April, 1911, with those used by Dr. Lewis in his various writings.

(Of course I am not suggesting that either quoted from any writings of the other.)

It is obvious to any one reading my address that I aimed at giving a simple, practical, comprehensive, and bird's-eye view of recent advances in cardiology. I submit that it is certainly not the custom, nor does courtesy require it, as Dr. Lewis apparently suggests, nor would it be practicable, to make specific reference to the sources of the innumerable points dealt with in a lecture like mine. In this respect I shall be quite content to be classed with Dr. Mackenzie, who, in the Oliver-Sharpney lectures on heart failure before the Royal College of Physicians, described auricular fibrillation in full without mentioning Dr. Lewis's name. (Of course, I am not for a moment suggesting that he should have done.) Also, other lectures of a similar nature have been published in the journals without reference to individual workers. But let us turn to Dr. Lewis himself. In a book—namely, his small handbook on *Clinical Disorders of the Heart Beat*—the classification and differentiation of cardiac irregularities are founded upon the magnificent work of Mackenzie, Wenckebach, and Cushtny; but I cannot find a single reference made by him to these workers.—I am, etc.,

London, W., Mar. 17th.

FREDERICK W. PRICE.

Medico-Legal.

IMPROPER USE OF A MEDICAL CERTIFICATE.

LATHAM v. STEVENS.

THE following report of this case, heard in the Chancery Division before Mr. Justice Sargant on March 14th, is quoted from the *Times* of the following day.

This action was brought by Dr. Arthur Latham, of 38, Portland Place, London, the well-known physician and authority on the subject of tuberculosis, against Mr. Charles H. Stevens and C. H. Stevens and Co., Limited.

The plaintiff now moved for an interlocutory injunction restraining the defendants from publishing, printing, circulating, divulging, or parting with, otherwise than to the plaintiff or by deposit in court, and from allowing to be printed, circulated, or published a document or certificate, dated January 1st, 1912, relating to one A. G. Hodgson, and signed by the plaintiff, or the effect thereof, or copies thereof, or extracts therefrom, and from representing, either by advertisement or otherwise, that the plaintiff had given any certificate in relation to or expressed approval of an alleged cure for consumption, the property of the defendants or one of them.

Mr. Mark Romer, K.C., and Mr. J. Fischer Williams were for the plaintiff; and Mr. T. J. C. Tomlin for the defendants.

THE PLAINTIFF'S CASE.

Mr. Romer, in opening the plaintiff's case, said that Mr. Stevens claimed to be the discoverer of a cure of consumption of which the defendant company were now the proprietors, Mr. Stevens being the managing director of the company. The certificate, which related to Hodgson, had been obtained from Dr. Latham by a fraudulent trick under the following circumstances: In December, 1911, Hodgson wrote to Dr. Latham stating that some time ago he had had a very bad cough, that a doctor had considered him consumptive, and that in consequence he had been somewhat shunned by his friends and business acquaintances; that the cough had left him for twelve months, but that his friends still held aloof; and that the writer thought that if Dr. Latham examined him and gave him a certificate which he could show to his friends it would remove the unpleasantness. The writer then made an appointment for his examination. Hodgson was examined by Dr. Latham, and after Hodgson's sputum had been examined the doctor had given him a certificate, which in its final form had been inserted in *Lloyd's Weekly News*, the *Weekly Dispatch*, and *Reynolds's Newspaper*, all of February 23rd, 1913, in advertisements relating to Mr. Stevens's alleged consumption cure.

The certificate in its final form was as follows:

38, Portland Place, W.,
January 1st, 1912.

I have recently examined Mr. A. G. Hodgson, and came to the conclusion that he is not now suffering from consumption, and is, therefore, not a source of danger to other people. In order to make quite certain I had his expectoration examined

on two occasions; on both occasions with complete absence, in spite of very careful examination, of tubercle bacilli, or, in other words, the seeds of consumption. I therefore have no hesitation in saying that Mr. Hodgson cannot infect other people, and that there is no danger to others who may happen to be in his company. (Signed) ARTHUR LATHAM, M.D., F.R.C.P., Physician to St. George's Hospital.

In his affidavit the plaintiff said that he saw Hodgson on December 20th, 1911. He then told the plaintiff that his age was 53, and that he was following the occupation of an ironmonger. He stated that he had been ill with consumption for eighteen months, that he was very anxious to know whether he was well, but more especially whether he was a source of infection to those with whom he was brought in contact. He did not tell the plaintiff anything about any particular form of treatment which he had undergone; in fact, he came to plaintiff, as he said, to obtain a certificate to enable him to have a more comfortable time with the people with whom he associated. Plaintiff instructed him to keep his temperature record for a week, and meantime had his expectation carefully examined by the bacteriologist to His Majesty's Household. On December 28th, 1911, Hodgson sent the plaintiff particulars of his temperature enclosed in a second letter expressing an urgent hope for a certificate that he was free from consumption.

THE BACTERIOLOGIST'S REPORT.

It appeared, said the affidavit, that his temperature was normal, and the bacteriologist reported to plaintiff that no tubercle bacilli were present in the sputum. So far as the plaintiff's own examination went, he had found very slight evidence of fibrosis of the lungs, probably due to healed tubercle. Consequently, on December 29th he sent Hodgson a certificate to the effect that he was free from infection and not a source of danger to other people. On December 30th Hodgson wrote in answer thanking the plaintiff for the certificate, but suggesting for the reasons given in such letter that it might state more clearly that he was not now consumptive, and he set out in the fold of his letter a copy of plaintiff's certificate showing in brackets the words he wished to have added.

In answer to this appeal, on January 1st, 1912, the plaintiff sent him a new certificate altered slightly from the first certificate, and saying in so many words that he was not suffering from consumption. Plaintiff gave this for the particular purpose of allaying the fears of those with whom Hodgson was working, and in no way as any certificate for the benefit of or relating to any line of treatment which he might have had.

The affidavit then referred to the evidence given by Hodgson in an action for libel brought by Stevens against the British Medical Association, and tried in October, 1912, in the King's Bench Division. The learned counsel also read the letter from Hodgson to Dr. Latham, dated December 28th, 1911, in which the former said:

I beg to hand you herewith particulars of my temperature morning and evening for the past week as desired. The expectation I forwarded to Dr. Spitta on Friday last. I trust the result will be favourable to me, and that you will be able to give me the certificate that I am free from consumption, or at any rate that there is no danger of infection through being in my company. To those who have not experienced it, it can hardly be possible to realize the feeling of being shunned and suspected, especially when feeling so well, and I look forward anxiously for your reply, and trust that if it is favourable to me you will so word your letter that upon my casually showing it my friends cannot fail to understand it.

The learned counsel said that the suggestion of the advertisements was that Hodgson had been cured by Stevens. The insertion of a medical man's certificate in such an advertisement was detrimental to him, and the British Medical Council would not regard such an advertisement in a favourable manner. There were ample grounds for the present application in the reported cases as to restraining the publication of private letters, and, alternatively, the case might be rested on the law of copyright, there being no necessity under the present law to register the copyright before suing in respect of it.

THE DEFENCE.

Mr. Tomlin, for the defendants, read an affidavit by Mr. Stevens, stating that he was the discoverer of the cure for consumption, the property of the defendant company. He also said that it was correct that he paid the fees for the consultation, certificate, and examination of the sputum of Hodgson, whom he had previously treated for consumption, and had cured.

Mr. Stevens, in his affidavit, further said that he had never intended by any advertisement to convey, and submitted that upon its fair construction no such advertisement was capable of being read so as to

convey, to any reader the suggestion that Dr. Latham certified the condition of Hodgson as being the result of Stevens's treatment, or gave any certificate with reference to his cure, and he submitted that the use which he had made of the letter was not a breach of confidence; that none of the advertisements were intended to suggest or did in fact suggest that Dr. Latham had certified that the restoration to health of Hodgson had been effected by the use of Stevens's cure, and he denied that any of the advertisements were or could be damaging to the plaintiff's reputation. He further said that he had acted perfectly bona fide in the matter without any intention of doing anything more than showing that Hodgson was in fact free from consumption at the date when he was seen by the plaintiff.

After some discussion the learned counsel said that his clients could, he thought, submit to what was asked for in the notice of motion.

Mr. Justice Sargant said the defendants had very wisely submitted to the injunction, to treat the motion as the trial of the action, and to pay the costs.

Solicitors.—Hempsons; Barton and Pearman.

INSURANCE ACT.

Medical Certificates for Members of Approved Society: Validity of Rule requiring such to be given by Panel Doctor.

In the case of *Heard v. Pickthorne* and others, heard in the King's Bench Division before Mr. Justice Bailhache, the plaintiff, a member of a Court of the Ancient Order of Foresters Friendly Society, sued for a declaration that a certain resolution passed by the society purporting to prevent the society from accepting as evidence of the incapacity of its members within the meaning of the National Insurance Act, 1911, certificates of medical practitioners other than those who were upon the list specified in the Act was illegal, *ultra vires*, and unenforceable. The action was dismissed with costs. The judge said that in his opinion the resolution passed by the society was not such an illegal act on the part of the Ancient Order of Foresters as would justify an action being brought in respect of it. The matter was one which in his judgement ought to be decided under Section 67 of the National Insurance Act, by arbitration between the plaintiff and the officers of the society, and ought not to come before the courts.

Universities and Colleges.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

A COMITIA was held on Monday, March 17th, Sir Thomas Barlow, Bart., K.C.V.O., the President, being in the chair.

President's Address.

The President delivered the annual address, in the course of which he reviewed the present condition of the College and the more important events which had occurred during the past year. He referred to the honours which had been conferred on Fellows, Members, and Licentiates of the College, and to the awards of medals and other distinctions. After drawing attention to the lectures which had been delivered during the year, he mentioned the various gifts which had been made, including the valuable collection of stethoscopes which had been presented by Mrs. Theodore Williams. The President reminded the College of the alteration in certain by-laws which had been effected, especially the alteration which now permits licentiates to assume the courtesy title of "doctor." After mentioning that the examination buildings had been completed, he gave a brief outline of the steps and recommendations made by the College in relation to the National Insurance Act.

The President then referred in appropriate terms to the eighteen Fellows who had died during the year: John Dixon Mann, William Ogle, Augustus Drake, Thomas Houghton Waters, William Murrell, Reginald Edward Thompson, John Ebenezer Rankin, Andrew Duacan, Frank Montague Pope, Frederic Bagshawe, Edward Alfred Birch, Charles Theodore Williams, James Lewis Stordet, James Barclay Montgomery, Lord Ikeston, William Carter, Alfred Baynard Duffin, and William Hewshp Dickinson.

Sir William S. Church, on behalf of the College, thanked the President for his address, and for the way in which he had conducted the very arduous business of the College during the past year. The President expressed his thanks to the College and vacated the chair.

Election of President.

The election of President then took place, and Sir Thomas Barlow was re-elected by a large majority.

The Senior Censor (Dr. S. J. Sharkey) delivered the insignia of office to the President, who gave his faith to the College, and thanked the Fellows.

Thanks of the College.

The thanks of the College were returned to Mrs. Theodore Williams for the gift of stethoscopes mentioned in the President's address.

After further business the President dissolved the Comitia.

Obituary.

JOHN S. BILLINGS, M.D.,

FORMERLY LIBRARIAN OF THE SURGEON-GENERAL'S OFFICE,
WASHINGTON, AND FOUNDER OF THE "INDEX MEDICUS."

WITH the death of Dr. John Billings on March 11th there has passed away a striking figure in the profession whose name will always be associated with three great achievements—the Surgeon-General's Library, Washington, the *Index Catalogue*, and the New York Public Library. Few men have had such a capacity for work, and he died, as he would have wished, in harness.

He was born in 1839, and graduated from the Medical College of Ohio in 1860; after a session as demonstrator of anatomy he joined the Northern army and served throughout the civil war, at the conclusion of which he was Medical Inspector of the army of the Potomac. He then became attached to the Surgeon-General's Office in Washington. After determining to utilize the enormous clinical and statistical material of the war, a serious difficulty arose in the absence of the necessary works of reference. Surgeon-General Hammond had already started a library in connexion with his office, and this formed the beginning of the now famous collection. Dr. Billings was put in charge of the few hundred volumes and given a free hand. With a large annual appropriation, Europe was ransacked for books and files of journals, and the library grew with extraordinary rapidity. In connexion with this work Dr. Billings paid several visits to this country and laid the foundation of his warm friendship with many distinguished members of the profession, particularly Sir Henry Acland, Dr. Ord, and Mr. Pridgin Teale. In this bibliographical work the late Dr. Windsor of Manchester acted as his friend and adviser. In the last report, October, 1912, the library is said to contain 178,741 bound volumes and 317,740 pamphlets. The collection is extraordinarily rich in old fifteenth and sixteenth century works, and particularly in the journal literature of the world. Owing to the liberality and freedom with which successive Surgeons-General have allowed its treasures to be utilized, the library has had an important influence upon the medical profession in the United States.

In 1876, as the library began to grow, the question of a printed catalogue was discussed, and a specimen fasciculus was distributed for purposes of criticism. The work progressed slowly, but in 1880 Volume I of an *Index Catalogue*

was printed, containing nearly a thousand pages. As subject and author catalogue it was immediately recognized that such a publication would be of the greatest help, but few at the time thought that a work on so vast a scale could be kept up. The literature of every subject was given with extraordinary fullness, though representing only the material available in the library; thus in Volume I, under Aneurysm, there were some 70 pages of references. Year by year the work progressed, and the first series of sixteen volumes was completed in 1895. Dr. Billings had a happy faculty for choosing able assistants, and he early had the good fortune to associate with him Dr. Robert Fletcher, whose death was noticed in the *JOURNAL* a couple of months ago. The first volume of the second series was published in 1896

and Volume XVII of Series II has just been issued. The remarkable growth of medical literature is well illustrated by comparing the references on Syphilis in Vol. XIV of the first series and in Vol. XVII of the second; in the one there were 109 pages, and in the other 207.

It was always a marvel to Dr. Billings's friends how year by year he kept up the publication of the *Index Catalogue*, but he used laughingly to say that it was only a matter of organization; he read every page of the proofs, and the singular accuracy which characterizes the work is due to Dr. Fletcher and himself. As an outgrowth of this library work the *Index Medicus* of current medical literature was started by Dr. Billings, and continued, after his retirement, by Dr. Fletcher.

Early in his career Dr. Billings became interested in public health and in hospital organization, and was in charge of the preparation of the vital statistics for both the tenth and eleventh census of the United States. Of the Johns Hopkins Hospital Trust Dr. Billings was appointed adviser,

and drew up the plans for the hospital, and was active in getting it organized. An important interview I had with him illustrates the man and his methods. Early in the spring of 1889 he came to my rooms, Walnut Street, Philadelphia. We had heard a great deal about the Johns Hopkins Hospital, and knowing that he was virtually in charge, it at once flashed across my mind that he had come in connexion with it. Without sitting down, he asked me abruptly, "Will you take charge of the Medical Department of the Johns Hopkins Hospital?" Without a moment's hesitation I answered, "Yes." "See Welch about the details: we are to open very soon. I am very busy to-day; good morning;" and he was off, having been in my room not more than a couple of minutes. In the early days of the hospital Dr. Billings's counsel was

Sincerely yours

J S Billings

always sought, and the growth of the school was a matter of pride to him. For years he lectured on the history of medicine. In 1891 he accepted the professorship of hygiene at the University of Pennsylvania, and became director of its new laboratory of hygiene. In 1896 he became director of the New York Public Library under the Astor, Lenox, and Tilden foundations, and the crowning work of his life has been to consolidate these collections, and to see them housed in the magnificent building that was opened two years ago. The extent of the library may be gathered from the fact that it has more than 2,000,000 volumes and upwards of fifty branch libraries, with a staff of 1,002 persons.

In the foundation of the Carnegie Institution in Washington Dr. Billings took an active share, and for years he was chairman of its board.

Dr. Billings was the author of many works on vital and social statistics, on bibliography and on hygiene. Honorary degrees were conferred on him by Edinburgh, Oxford, Dublin, Munich, Harvard, Yale, and other universities. His two strong qualities were a capacity for work and for organization. He worked easily, without fuss or effort, but incessantly. He had an equable temperament, and took the accidents and worries of life in a philosophic spirit. Of late years he was often in the hands of the surgeons, on several occasions for very serious operations, which he bore with his characteristic equanimity. He leaves a son, Dr. John S. Billings, whose work in connexion with the Public Health Department of the city of New York is well known; one of his daughters married Dr. W. W. Ord, of Salisbury.

WILLIAM OSLER.

[We are indebted to Dr. W. W. Ord for the opportunity of reproducing the portrait with which this biography is illustrated, and to Sir LAUDER BRUNTON for the following personal appreciation:]

It is only when one meets with a man like the late Dr. Billings that it is possible to realize the meaning of the phrase "Rare Ben Jonson," for a combination of good qualities such as that possessed by Billings is so rare indeed that one only meets with a few examples of it in a lifetime. He was a splendid specimen of what Oliver Wendell Holmes in *Elsie Venner* calls "the Brahmin caste of New England." As his name shows, he was of Scandinavian ancestry, and he retained the overpowering strength and energy by which his Berserker forefathers carried everything before them. But he concealed them under such a quiet, unassuming, courtly exterior that those who had only a casual acquaintance with him could hardly suspect the enormous latent energy he possessed. Though his learning was stupendous he never obtruded it, but, along with an easy flow of language and a quiet vein of humour, it made him an excellent speaker and an agreeable companion, while his strong nature, affectionate disposition, and kindly ways rendered him at the same time beloved and trusted by those whom he honoured with his friendship.

Although he was one of the greatest living authorities on hospital construction, yet it will be as a librarian that his name will go down to posterity. His formation of the *Index Catalogue* of the Surgeon-General's Library marks an epoch in medical literature. It was a herculean task which very few men would have dared to attempt, and fewer still would have had the power to carry through successfully. But he did it, and has earned the gratitude of every worker in medical science for all time to come. Not satisfied with the success of this gigantic work, he undertook, when past middle age, a task almost greater still—that of making for America a library which should rank with the British Museum, the Vatican, and others as one of the seven or eight great libraries of the world. This work he has got fairly under way, and, although much still remains to be done, he has had the satisfaction of seeing before his death that the great aims which he had set before him have been effectually carried out, and that his work will remain to a grateful posterity as an evidence of his energy and power. But, to those who knew him intimately as a friend, the blank left by his death will never be filled up, for his rare combination of qualities was such that we have good cause for saying that we shall never look upon his like again.

Mr. J. Y. W. MACALISTER, Secretary of the Royal Society of Medicine, has kindly responded to our request by writing the following personal tribute:

In Billings has passed away the kind of man who makes epochs. He was a *great* man in every sense of the word. Big in body, big in mind, and almost superman in his power of work, he impressed all with whom he came in contact with the conviction that, whatever walk in life he chose, he would be easily first. He undertook tasks, and carried them through, which ordinary men attempt only by means of committees, institutions, societies, "co-operations," and a vast amount of fuss and noise. His plan was simplicity itself. If the thing were worth doing, he simply did it. I saw him once "resting" in the evening after a long and arduous official day. He was lying on a couch, almost hidden by two mountains of medical periodicals in every language, one on either side of him. He was slowly, but without pause, steadily working through the mountain on his right, marking the items to be indexed, and transferring each journal, as finished, to the mountain on his left. This was when he was, almost single-handed, producing month by month the *Index Medicus*, and the still greater task of the *Surgeon-General's Catalogue*—two pieces of work without which the rapid advance of medicine in the last thirty years would have been impossible.

I remember his saying to me once when I said something in praise of what he was doing, "I'll let you into the secret—there's nothing really difficult if you only *begin*—some people contemplate a task until it looms so big, it seems impossible, but I *just begin* and it gets done somehow. There would be no coral islands if the first bug sat down and began to wonder how the job was to be done."

He had done a big life's work when he was called to plan and administer the great New York Public Library, and he tackled it on his own principle—without fuss or unnecessary publicity; he just "began," and each day's herculean "chore" saw him miles on his way to triumphant success.

He was quite simply and sincerely modest, although this did not prevent an amused but quite magnanimous contempt for mere talkers. As an illustration of his modesty and simplicity (at the risk of appearing vain) I recall that when he was planning the New York Public Library, he sent me a copy of the plans with a detailed memorandum on the specification with a request that I would "help him" (!) with criticisms or advice. I am prouder that *he* asked me this and prouder still that he thanked me for and adopted some humble suggestions than if I had been consulted by a Government.

His interests were as broad as his mind. One happy day I went with him and his lifelong friend, Justin Winsor, to Stratford-on-Avon. With us went Sam Timmins, the creator of the Memorial, and while Timmins did the honours of the place in his own inimitable way, Billings showed us—introduced us—to the *man*, Shakespeare. They might have been school-mates, so vivid was the living imagination with which his slow, almost solemn periods discoursed of the living Shakespeare and his immortal creations.

Take him for all in all, Billings was a *man*, and *we* are not likely to look upon his like again.

JOHN BLYGH, M.D., M.Ch.,
LIVERPOOL.

It is with deep regret that we have to announce the death of Dr. John Blygh, J.P., of Liverpool, which took place at his residence, 109, Mount Pleasant, on Saturday, March 8th, after a brief but very acute attack of double pneumonia.

John Blygh was born at Castle Lackett, Ireland, in 1840. He was educated at Queen's College, Galway, where he had as fellow students Lord MacDonnell, Mr. T. P. O'Connor, M.P., Lord Atkinson, Sir Andrew Reed, Dr. John Conway, and the late Sir W. Thompson. He graduated M.D.R.U.I. in 1865, and was the first man in Ireland upon whom the degree of Master in Surgery was conferred. There was an interval in his college career when, in 1862, he went to Liverpool for one year as assistant to Dr. Parsons. This was when the old custom of medical apprenticeship was in vogue. In 1865

he took up his residence in Mount Pleasant, Liverpool where he remained until his death.

Dr. Bligh was married in 1876 to the daughter of the late Mr. Frederick Harris, of Liverpool, and his wife, a daughter, and two sons survive him.

Dr. Bligh was one of the best known and esteemed members of the medical profession in Liverpool. He had a very wide circle of friends, while among the poorer section of the community there will be many who will feel they have lost a true and generous friend. His generosity and sympathetic disposition were principal traits in his character. Many an Irish peasant stranded in Liverpool, many a poor Irish working man or woman who had fallen on evil days, and many a struggling priest, had good reasons to be grateful to Dr. Bligh for medical and other services freely rendered. He was, indeed, a Good Samaritan to a multitude of sufferers, but his work was unostentatious, and he never claimed credit for his beneficence. Allied to great professional skill was a bright and genial disposition; he was an optimist in his practice, and always influenced those whom he treated by his buoyancy of manner.

This was to have been his jubilee year of practice, and a movement was recently set on foot to take advantage of the occasion to make some recognition of his generosity to his less fortunate Roman Catholic co-religionists in Liverpool. It was intended to make him a presentation, but unfortunately he did not live to receive it. As a politician Dr. Bligh always felt a just pride in his Irish nationality, and was devoted to the interests of his native country and its people; he actively assisted in promoting the Irish cause in Liverpool from a very low ebb to the influential position it now holds. In this he was assisted by his brother, Dr. Alexander Bligh of Shaw Street, and by Dr. Andrew Commins, barrister. Whilst holding strong views on Irish affairs, he always respected the opinions of those who differed from him. His political recollections included much that was interesting as to Parnell, and the circumstance in which the Irish leader, while a guest of Dr. Bligh in Mount Pleasant, aided in prevailing upon Dr. Commins to become the Nationalist candidate for Rosecommon, where he was elected in opposition to The O'Connor Don.

Dr. Bligh was a great lover of music, and many years

ago was closely associated with the late Mr. Carl Rosa and the leading members of his renowned opera company, who were always his welcome guests. A strong friendship existed between Dr. Bligh and the late Mr. Eugene Goossens, the distinguished musical director of the Carl Rosa Company.

Dr. Bligh became a justice of the peace in 1892, but beyond attendance on the Bench he rarely took part in public life.

Dr. Bligh had a large practice, and for many years acted as medical adviser to the priests of the Roman Catholic Church in Liverpool, who about twenty years ago, to show their appreciation of his services, entertained him at a public dinner, when he was presented with an illuminated address. A fully attended meeting of all the branches of the Liverpool and District Committee of the United Irish League and all the National public representatives was held on March 10th, when Mr. Austin Harford, J.P., who presided, expressed the sense of loss that Irishmen and Catholics in Liverpool felt at the demise of Dr. Bligh; the poor had lost a true friend, the Catholic Church an exemplary member, and the Irish cause a patriot to the core.

The funeral took place on March 12th in the churchyard of SS. Peter and Paul, Crosby; prior to the interment Requiem Mass was sung at the Roman Catholic Pro-Cathedral, Copperas Hill, which was crowded to its utmost capacity. All classes of people had gathered to pay their last respects to the man who was so generally respected and to whom so many had had reason to be grateful. The paucity of the departed doctor. "It was no matter of wonderment," he said, "that Dr. John Bligh had been not only esteemed but loved by many to whom the principal medicine he prescribed was compounded in the pharmacy of his simple and loving soul." Father O'Connell, administrator at the Pro-Cathedral, officiated at the graveside. Telegrams of sympathy and condolence were received from the following members of the House of Commons: John Redmond, P. O'Brien, T. P. O'Connor, John P. Hayden, Clancy, John O'Connor, from Colonel Seely, M.P., from Sir William and Lady Nelson, and many others.

DR. JOHN BLIGH.
(Photograph by Elliott and Fry.)

J. G. E. COLBY, M.A., M.B., B.Ch., Oxon., F.R.C.S. Eng.,
MALTON, YORKS.

It is with deep regret we have to announce the death of Dr. J. G. E. Colby, at Colwyn Bay, after a long and trying illness.

He was born in 1861, and was educated at King Edward VI Grammar School at Old Malton. From there, in 1880, he went to Wadham College, Oxford, where he gained an Exhibition in Science. From Oxford he went to St. Bartholomew's Hospital, where he gained the Open Entrance Scholarship in Science and afterwards the Junior Scholarship in Anatomy and Physiology and the Brackenbury Scholarship in Surgery, and subsequently held the appointments of house-surgeon and ophthalmic house-surgeon.

He took the degrees of M.A., M.B., B.Ch. at Oxford in 1888 and the diploma of F.R.C.S. Eng. in 1890. In 1894 he took the D.P.H. Camb.

In 1890 he joined his father in practice at Malton, and soon acquired a wide reputation in the district as an able practitioner and skilful surgeon. The successful establishment of the Cottage Hospital at Malton was largely due to his initiative, and as surgeon to that institution his skill was much appreciated. He was appointed Medical Officer of Health to the Malton Union Sanitary Authority, in which capacity his work was characterized by his usual thoroughness.

He never spared himself, and his constitution, undermined by constant hard work, was unable to withstand the inroads of an attack of septicaemia, from which he suffered last August. After treatment at Leeds, his health seemed to improve for a time, and he was removed to Colwyn Bay, where he was seen by several well known members of the profession, but all their efforts proved unavailing.

He was the eldest surviving son of the late Dr. W. T. Colby, J.P.

In 1899 he married a daughter of the Rev. J. H. Mandell, vicar of Haydon Bridge, Northumberland, who survives him, together with a young family of two sons and three daughters.

Dr. CHARLES GEORGE LEE of Liverpool, who died a short time ago at the age of 61, was born in Chester on September 16th, 1852. He was educated at Wesley College, Sheffield, and pursued his medical studies at Guy's Hospital. He settled in Liverpool in 1877, and was appointed assistant surgeon to the Eye and Ear Infirmary in 1878. In 1885 he was appointed full surgeon to that institution and retained that position until 1911, when he was appointed consulting surgeon. He also held the positions of honorary ophthalmic and aural surgeon to the School for the Deaf and Dumb, to the Home for Epileptics, Maghull, and honorary aural surgeon to the Royal Southern

Hospital, Liverpool. He was a gentleman of kind, genial, and sympathetic disposition and upright character. He was greatly esteemed and respected by his colleagues, and enjoyed the confidence and admiration of his patients. He was regarded as an expert operator, and his work on cataract extraction was well known.

Medical News.

AT the meeting of the Hunterian Society of London, which will be held in the library of St. Bartholomew's Hospital on Wednesday next, at 9 p.m., Dr. Arthur Latham will open a discussion on the uses of tuberculin. It will be adjourned for a fortnight, when Dr. Nathan Raw will reopen it.

THE third International Congress of Neurology and Psychiatry will be held at Ghent on August 20th to 26th. The congress has the support of the Belgian Government as well as of the leading practitioners of neurology and psychiatry in the country. The secretary of the congress is Dr. F. D'Hollander, 110, boulevard Dolez, Mons, from whom further information may be obtained. The subscription to the congress is for members Fr. 20, for associates Fr. 10. The international exhibition will be open in Ghent at the period mentioned.

THE *Times* reports that at the North London Police Court a dairyman who pleaded guilty, and against whom several previous convictions were recorded, was fined the maximum penalty of £100 (with 5 guineas costs) for having sold by his servant milk containing 6 per cent. of added water. A man formerly in the employment of the defendant explained that separated milk was mixed with new milk, water coloured with annatto added, and the mixture sent out to the branches as new milk. The prosecution was instituted by the Islington Borough Council.

THE first meeting of the British Sectional Committee for the furtherance of the International First-Aid Congress to be held in Vienna from October 9th to 13th next, was held in London on March 11th, under the chairmanship of the Earl of Londesborough, President of the Committee. It was resolved to invite the contribution of papers to be read in Vienna, and it was arranged that the papers of authors unable to be present should be read for them and should subsequently appear in the *Transactions*. It was also arranged to invite firms dealing with first-aid appliances to send exhibits so that the space allotted to Great Britain might be worthily filled. The committee decided that Great Britain should not take part in the International Congress to be held at Ghent in August next, as that date was announced after the date of the Vienna congress had been fixed. The holding of a congress in Ghent so soon before that to be held in Vienna would, it was felt, tend to diminish the importance of the latter. The Secretary of the British Committee is Mr. Samuel Osborn, Constitutional Club, Charing Cross, London, W.C.

THE report presented to the annual meeting of the Governors of the Cancer Hospital, Brompton, stated that 690 patients had been admitted to the wards during the year; there were 1,033 new out-patient cases with a total attendance of 14,968. The number of operations performed was 535, with a mortality of 4.48 per cent. Lord Northbrook, the President, intimated that Sir David Salomons had kindly offered £500 worth of radium to the hospital to increase the amount already in its possession. The new Radiotherapeutic Department under Dr. Knox was now in complete working order and a separate report showed the great value that the hospital derived from it not only in the treatment of inoperable cases, some of which were brought within the sphere of successful operation, but also as a routine adjunct after surgical operations. In replying to the vote of thanks to the staff, Mr. Ryall, the senior surgeon, pointed out that there was much need of education of the public as to the nature of cancer if the best advantage was to be taken of modern operative treatment. In particular, he referred to two popular fallacies that stood in the way—first, that cancer was essentially a painful malady, and secondly, that operative measures only temporarily arrested the disease. He held that by the application of the knowledge derived from investigations in surgical pathology to operative treatment fully 40 per cent. of all cases were permanently cured, a percentage which would increase if earlier diagnosis were established. The series of lectures to practitioners that were recently started had been most successful and were well attended.

Letters, Notes, and Answers.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the BRITISH MEDICAL JOURNAL alone unless the contrary be stated.

COMMUNICATIONS respecting Editorial matters should be addressed to the Editor, 429, Strand, London, W.C.; those concerning business matters, advertisements, non-delivery of the JOURNAL, etc., should be addressed to the Office, 429, Strand, London, W.C.

MANUSCRIPTS FORWARDED TO THE OFFICE OF THIS JOURNAL CANNOT UNDER ANY CIRCUMSTANCES BE RETURNED.

CORRESPONDENTS not answered are requested to look at the Notices to Correspondents of the following week.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Office, 429, Strand, W.C., on receipt of proof.

TELEGRAPHIC ADDRESS.—The telegraphic address of the EDITOR of the BRITISH MEDICAL JOURNAL is *Articology, Westrand, London*. The telegraphic address of the BRITISH MEDICAL JOURNAL is *Articulate, Westrand, London*.

TELEPHONE (National):—
2631, Gerrard, EDITOR, BRITISH MEDICAL JOURNAL.
2630, Gerrard, BRITISH MEDICAL ASSOCIATION.
2634, Gerrard, MEDICAL SECRETARY.

Queries, answers, and communications relating to subjects to which special departments of the BRITISH MEDICAL JOURNAL are devoted will be found under their respective headings.

ANSWERS.

DYSPEPSIA.

DR. H. J. THORP (Ipswich) writes to suggest that "A. E." should try gr. $\frac{1}{2}$ calomel three times a day.

LETTERS, NOTES, ETC.

IN PRAISE OF THE PHYSICIAN.

ANOTHER correspondent sends us the following, said by a Norfolk labourer on his death-bed: "The first thing I shall dew when I gets to heaven will be to tell God A'mighty how kind yew and Dr. A. hev bin to me."

FUNGI AS STYPTICS.

DR. J. R. HICKINBOTHAM (West Bergholt, Colchester) writes: The article by Dr. Edward Knight on "The Application of Fungi as Styptics," and especially the case he quotes of the woman with the open cancer of the breast, recalls to me the fact that puff-ball powder is used by some of the aborigines of North-West Australia in the treatment of venereal ulcers and soft chancres. In some cases of ulcerative granuloma of the pendulum, a very common malady in North-Western Australia, I have used it made into a paste with water and applied on lint. In cases in which the glans penis was studded with granulomatous nodules, the nodules disappeared after the puff-ball paste has been applied for twenty-four hours, and sharp-cut ulcers remain in their place. Thinking that the action was possibly due to some digestive ferment, I tried peptonizing powders in the same way, but the pain produced was so severe that I abandoned the experiment and went back to the puff-balls. I afterwards reverted to the sharp spoon, which was quicker. It has, moreover, struck me that the puff-ball powder can be used when the sharp spoon cannot, and certainly the sharp spoon is not a styptic. There is no doubt in my mind that the puff-ball powder I got in Western Australia was capable of destroying morbid tissue of low vitality while leaving the healthy tissues intact.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

| | £ | s. | d. |

| A page | ... | ... | 8 0 0 |

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Wednesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *postes restante* letters addressed either in initials or numbers.

A Lecture

ON

THE MUCOUS CHANNELS AND THE
BLOOD STREAM AS ALTERNATIVE
ROUTES OF INFECTION.*

[WITH SPECIAL PLATE.]

By CHARLES J. BOND, F.R.C.S.,

SENIOR SURGEON TO THE LEICESTER INFIRMARY.

LEAVING on one side wounds and the abraded skin, it is recognized on all hands that the mucous membranes provide the usual channels by which the micro-organisms of disease gain access to the human body.

The problem now before us, however, represents only a small part of this larger question of the route of infection. It relates to the manner in which organisms reach epithelial secreting and excreting organs through their mucous ducts, and the manner in which organisms, introduced into one portion of a mucous canal, like the intestine, find their way to other portions of the tube at a higher level. In other words, we propose to inquire whether the organisms which bring about infective diseases of the liver, the kidney, the gall bladder, the urinary bladder, the mammary, salivary, and other glands, reach these structures by the blood stream, or by the mucous canals through which these organs communicate with the surface of the body.

There are three recognized ways by which the disease organism gains access to the recesses of a secreting gland, apart from the agency of the blood and lymph channels: (1) It may, if a motile organism, transport itself by its own movements as the spermatozoon traverses the oviduct. (2) It may be passively transported by muscular or peristaltic movement, or by the ciliary action of the epithelium lining the canal, as the ovum is carried to the uterus. (3) It may spread over the surface of the mucous membrane by a process of continuous growth, as the diphtheria bacillus spreads over the fauces. But in addition to these three recognized methods there is a fourth, which in my opinion is more frequent than many pathologists and clinicians are inclined to think. In the Address in Surgery to the British Medical Association in 1905 I brought forward evidence to show that small particles of an inert substance like indigo, which is insoluble in the bodily secretions, may under certain circumstances be carried along mucous canals and gland ducts in a direction opposite to that taken by the normal secretion. If non-motile particles of indigo can travel in this manner along mucous surfaces, then it is reasonable to suppose that the organisms of disease can be also transported from the mucous orifices of the body up the intestinal canal and urinary canals to the recesses of organs like the kidney and gall bladder. I also stated, as the result of clinical and pathological observation, that three conditions were necessary for this transportation of foreign particles in a direction opposite to that of the flow of secretion:

1. There must be a reversed mucous current along the channel.
2. There must be some stasis of the normal secretion or excretion in the duct.
3. Or a fistulous communication must exist at the proximal end of the canal by which the contents can reach the surface of the body without passing down the duct.

Since that time further evidence has accumulated which goes to show that active absorption of contents at one part of a mucous tube or canal can play the part of the fistula at the upper end or the stricture at the lower end, and can bring about a backward flow of mucus to take the place of the mucus or secretion which is undergoing absorption or removal at the upper end.

Let us consider for a moment what occurs in the intestinal canal. Rapid absorption of the watery content of the fluid faecal material pouring through the

ileo-caecal valve goes on in the caecum and along the whole length of the large bowel. It is probable that, though the muscular movements may vary in activity and possibly in direction at different levels, and at different times, absorption of fluid takes place along the whole canal. It is practically certain also that in diseased states of the bowel absorption may go on at one level and secretion of mucus at another. The occurrence of accelerated absorption in the caecal end and delayed absorption at the rectal end of the tube will provide the necessary conditions for a reversed mucous current along the canal without the necessity for a reverse peristalsis, or the existence of a fistulous opening.

We already know from experiment that indigo granules are present in the mucus which flows from a caecal fistula in twenty-four to forty-eight hours after they have been introduced into the rectum; this occurs independently of muscular contraction or the flow of faecal material; indeed, it takes place more quickly in an empty and contracted than in a loaded and distended bowel. A fistulous opening probably acts by removing the mucus or fluid at the upper end, and thus causes a flow of mucus along the tube to replace that which has escaped; the suggestion is, therefore, that unequal and rapid absorption in one portion of the tube will act in the same way as a fistula.

There are some points about these ascending mucous currents in the bowel which are of interest in connexion with the subject of malignant and other strictures. It has been pointed out by Messrs. Makins, Wallace, and Sargent,¹ and other observers, that the mucous membrane above and below a malignant ulcer of the lower bowel is often studded with mucous polypi. These may be situated at some distance from, or in close proximity to, the seat of cancer (Figs. 1 and 2). Histologically they are adenomata, generally of a benign type, and even when they grow close to the site of ulceration they often show no infiltration of the mucous or submucous tissues by epithelial cancer cells (Fig. 4). The relation of these benign growths to the primary cancer is one of much interest.

Besides these adenomatous overgrowths the epithelium for some distance above a malignant ulcer often shows a roughened whitish appearance, a leucoplakia visible to the naked eye. The numerous openings of the glands can be seen, and in some cases minute ulcers dot the surface of the mucous membrane. (Fig. 3.) The fact that these changes are generally more marked above than below the stricture no doubt depends upon the presence of some degree of obstruction or faecal stasis, even where no actual constriction of the lumen of the bowel exists. The upward mucous currents probably distribute the infective material or cancer cells over the surface of the mucous membrane. It is at any rate interesting to note the comparative infrequency of these changes below the ulcer, although the cancerous discharges pass through this portion of the bowel to reach the surface. The sharp division between large and small intestine at the ileo-caecal valve probably prevents the flooding, under normal conditions, of the ileum by regurgitating faecal fluid; the mucous currents, however, are probably not wholly arrested at this point. Small foreign particles and organisms are thus carried up from the large to the small bowel without the necessity for any reversed peristalsis or regurgitation of faeces. Organisms may also be carried into the appendix by the same means.

The recent debate at the Medical Society of London included some important problems in regard to intestinal stasis.² The beneficial results of short-circuiting operations by Lane and other surgeons in many cases have now established the fact that an intimate association does exist between the delayed passage of intestinal contents and a condition of chronic poisoning, and the question arises as to the nature of the poisons, and the part of the intestinal tract in which absorption occurs.

Some observers, notably Daniel, regard the symptoms as the result of repeated infections and reinfections of the intestinal mucous membrane rather than as the result of absorption of the products of food decomposition. This is important in view of the fact that ascending mucous currents occur in the intestinal canal which are capable (apart from stagnation of contents and reversed peristalsis) of transporting organisms from one part of the tube in which they normally occur, to other parts in which they are not normally found.

* Revised since its delivery at the Medical Graduates' College and Polyclinic, London.

Although several speakers drew attention to the frequent association between intestinal stasis and urinary infection, very few facts were brought out which bear crucially on the question of the alternative routes of invasion, namely, the mucous channels or the blood stream. Dr. Eyre has found coliform organisms in considerable numbers in the contents of the small bowel in cases of intestinal stasis; this fact is important in view of the possible transference of organisms by ascending mucous currents in the absence of faecal regurgitation through the ileo-colic valve.

STASIS IN THE SMALL INTESTINE AND DUODENAL ULCERATION.

These ascending mucous currents also have an important bearing on morbid conditions of the upper bowel. Moynihan, the Mayos, Paterson, and other surgeons have pointed out the frequent association between appendicitis and duodenal ulcer, and it has been suggested that haematemesis and other gastric and duodenal symptoms, when not associated with oral or naso-pharyngeal sepsis, are due to an ileo-colic sepsis, of which the primary focus is situated in the appendix, and from which organisms are carried to the gastric and duodenal mucous membrane by the blood stream. Dr. Wilkie³ has recorded a number of cases which suggest that one important pathological factor predisposing to duodenal ulceration is faecal stasis in the colon or ileum. In some of his cases duodenal ulceration was associated with partial obstruction the result of pericolic adhesions, the appendix itself being normal. Arbuthnot Lane also speaks of the importance and frequent occurrence of absorption of toxins (the result of stasis) in the small intestine following obstruction in the colon.⁴

In view of the mucous currents now described, we must, I think, consider the possibility that these organisms reach the duodenum by way of the intestinal canal. We have already seen that there need not necessarily be any faecal regurgitation or reversed peristalsis in a distended canal. The currents will carry foreign particles and organisms up a contracted bowel provided that some stasis exists below, or that a fistula or some irregular reabsorption of contents causing mucus suction exists at some higher point in the channel. It will be objected that if the infecting material travels up the intestine it should leave its effects along the whole length of the small bowel. It may be that minute ulcerative foci do often exist, but, even if no pathological effects are produced, we know that organisms can travel along the urethra without causing urethritis, and only cause symptoms when they reach the bladder. Moreover, the gastric and duodenal epithelium may be less resistant than that of the ileum or jejunum to organisms whose usual habitat is in the caecum.⁵

INFECTIONS OF THE GALL BLADDER AND BILIARY AND PANCREATIC DUCTS.

From duodenal ulcer we pass naturally to a consideration of the etiology of gall stones and infections of the pancreatic and biliary ducts. Naumyn, Lartigau,⁶ and others have suggested that gall stones arise in a deposition of biliary salts and cholesterol round a nucleus of attenuated bacteria. It is supposed that organisms gain an entrance into the blood or lymph stream through some abraded mucous or intestinal surface and thus reach the liver, that they are excreted by the liver cells in a state of reduced virulence in which they can set up chemical and physical changes in the bile, but are unable to produce acute infection in the mucous membrane of the gall bladder or the biliary ducts. No doubt organisms—for example, the *Bacillus typhosus* and bacteria of the *coli* group—do under certain conditions reach the liver by way of the portal circulation and are excreted by the liver cells, just as organisms brought to the kidney by the renal circulation are excreted in the urine. The immediate question is, however, whether the organisms around which gall stones are deposited reach the gall bladder from the liver above, or whether they reach it from the duodenum below, by passing along the common and cystic ducts.

Stress has been laid on the fact that infection of the gall bladder (but not gall stones) has been experimentally produced by the injection of organisms into the blood stream

in animals in which the cystic duct has previously been tied. Of course it is possible that the epithelium of the gall bladder, like that of the kidney, may excrete pathogenic organisms brought to it by the blood (and if the ligature has been placed on the cystic and not the common duct this must have taken place); but, bearing in mind the rapidity with which infection passes through any constriction of a mucous canal, we can hardly regard this experiment as conclusive proof of the haematogenous origin of all gall bladder infections.

It is an undoubted fact, as shown by W. Mayo⁷ and others, that the primary and probably exclusive seat of the formation of gall stones is the gall bladder, and even when they occur in the biliary ducts they occur primarily in the gall bladder. Neither are biliary salts usually deposited from the bile which remains stagnant in the biliary ducts in cases of obstructive jaundice.

Now the gall bladder is a hollow viscus of very slight muscular development; every surgeon must have noticed that when squeezed and partly emptied of its contents during life it remains flabby, and does not contract on the bile which it contains. It is, however, a somewhat elastic organ; it undergoes alternate emptyings and fillings, and thus provides ideal conditions for the origination of to-and-fro mucous currents in the cystic duct.

Experiment shows that when, for surgical reasons, a fistula has been established between the fundus of the gall bladder and the surface of the body, indigo granules taken by the mouth can be recovered from the mucus and bile which flows from the fistulous opening.⁸ The question is whether foreign particles, and presumably organisms, are ever carried to the gall bladder from the duodenum by way of the cystic duct when no fistula is present—whether, in fact, the alternate filling and emptying of the gall bladder does not act in the same way as the fistulous opening in producing a to-and-fro mucous current.

Even if we suppose that the organisms which produce gall stones, as well as others, reach the gall bladder after excretion by the liver cells the question still arises whether the more acute infections of the gall bladder are produced in the same way.

If they are so caused, it is difficult to understand why organisms which have passed through the blood stream and have been excreted by the liver without causing any violent reaction, retain sufficient activity and virulence to bring about acute infections of the gall bladder. This difficulty does not arise if we assume, as I think there are grounds for doing, that the virulent organisms, together with the mucus and other materials in which they are growing, reach the gall bladder from the duodenum. We must remember that when, as happens in cases of pyelophlebitis, virulent organisms do gain access to the portal circulation they produce very marked effects on the liver and cause multiple centres of suppuration. Now it is a significant fact that under such conditions the gall bladder is often free from any acute inflammation. On the other hand, acute infections of the gall bladder (either with or without gall stones) often occur without any other evidence of liver infection. Taken together the clinical facts suggest that organisms may reach the gall bladder by way of the portal circulation after excretion by the liver cells, but that under such circumstances they undergo a reduction in virulence, and while they may possibly serve as the starting point for gall stones they are not apparently able to set up acute infections of the gall bladder. On the other hand, organisms which cause acute cholangitis reach the gall bladder from the duodenum by way of the common and cystic ducts, and we have experimental evidence to show that they can be carried there by ascending mucous currents.

In view of the contradictory results of Doerr (negative) and Chirolanza (positive) with the intravenous injection of organisms after ligature of the cystic duct, the size of the indigo particles which are found in the bile flowing from the gall bladder fistula in the indigo experiments affords some evidence of the route by which these particles have reached the gall bladder. It is common to find large irregular-shaped indigo particles larger than leucocytes, and these retain their blue-black colour, while the much smaller granules which have been ingested by phagocytes are generally of a sky-blue colour. Further, it is important to remember that along with pathogenic organisms carried

up the cystic duct the mucus in which these organisms are growing is carried up with them.

The objection has been made that the contents of the duodenum are normally sterile, but we must remember that some degree of intestinal stasis and intestinal catarrh is present in most of these cases of gall bladder trouble, and the duodenal contents are probably not sterile under such conditions. Gall stones are more common in females than in males in the proportion of 3 to 1. Among married women 90 per cent. date their gall bladder trouble from some particular pregnancy (W. Mayo). Pregnancy predisposes to constipation, and constipation means intestinal stasis, and while intestinal stasis no doubt forms one of the conditions under which organisms are apt to pass through the intestinal epithelium into the blood stream, intestinal stasis, with irregular absorption in the upper reaches of the bowel, also favours the origin of to-and-fro mucous currents by which organisms which normally inhabit the lower bowel are carried to the upper.

There are grounds for thinking that if the condition of the whole intestinal tract were fully investigated in cases of gall stones and gall-bladder disease, not only would appendicular and ileo-colic complications be found in many cases, but in some the whole lining mucous membrane would show signs of widespread catarrh of infective origin.

Typhoid Carriers.

The facts concerning typhoid carriers are of interest in this connexion. Lenz, and later Forster, showed that the gall bladder is the hiding place and breeding ground of the typhoid bacillus in these persons. Moreover, as Schottmüller has shown,⁹ typhoid carriers are nearly always of the female sex. In fact, there seems to be a greater chance of organisms (whether excreted by the liver and gall bladder epithelium, or carried up from the bowel) finding their way into the gall bladder in the female than the male. We do not know what the peculiar conditions are which cause this peculiarity, but it is difficult to explain it by differences in the blood stream of men and women. The typhoid bacillus from a typhoid carrier can produce a typical attack of typhoid fever in another susceptible person; it cannot, therefore, have undergone any reduction in virulence in the body of its host; hence the absence of symptoms in the carrier must be attributed to an acquired immunity in the carrier and not to any attenuation of the organism. This means that the typhoid organism is leading a sort of extra-corporeal existence in the gall bladder of the carrier. It lives in the superficial epithelium, and has become acclimatized to the mucus and bile just as it flourishes in the sewage of a contaminated water supply. This acclimatization to a mucus-secreting epithelium environment fits in better with a mucous channel route of entry into the gall bladder than with a haematogenous origin, together with liver or gall-bladder excretion.

The clearing up of two bacteriological points would probably add materially to our knowledge of typhoid fever and typhoid carriers. The first is whether typhoid bacilli in an active and virulent state are present in the vomit and therefore presumably in the duodenal contents of typhoid fever patients. And the second is whether typhoid bacilli from the urine of typhoid fever patients which have presumably been excreted by the renal epithelium after passage through the blood stream, are as virulent as the typhoid bacilli which are present in the stools of the same patients.

The difficulty of permanently getting rid of the typhoid bacillus from the gall bladder is well known; even cholecystotomy and drainage are not always successful. It is interesting to compare the behaviour of the *Bacillus typhosus* which has become adapted to a gall-bladder environment with the behaviour of the *Bacillus coli* which has become adapted to the environment of the urinary bladder or the pelvis of the kidney. In both cases the organism lives and multiplies among secretory epithelial cells, and in a secretion, and not in the deeper tissues of the body, and in both cases it successfully resists the bactericidal action of vaccines and drugs. The difficulty of getting rid of organisms which have become adapted to a secretory epithelial environment is well shown in the case of dysentery. Shiga's and Keuse's bacillus and Flexner's bacillus grow and multiply in the intestinal mucous membrane, and in the mucus and faecal contents of the large

bowel; they are not found in the spleen or gall bladder or urine.¹⁰ In dysentery the organism can be recovered from the stools in many cases for some time after the patient has recovered clinically, and in the case of dysentery carriers they may persist in the evacuations for years. The question arises. Why is not the *Bacillus dysentericus* found in the urine and in the gall bladder like the *Bacillus typhosus*, since the persistent diarrhoea gives frequent opportunities for infection of the urinary tract, especially in women, and we should expect, therefore, to encounter some cases of dysenteric pyelitis on the supposition of an ascending infection? The reason that this does not occur may be that the *Bacillus dysentericus*, unlike the *Bacillus typhosus* or the *Bacillus coli*, cannot adapt itself to a urinary or biliary environment. On the haematogenous theory of infection we must suppose that the organism cannot maintain its vitality after running the gauntlet of the blood stream and the renal or hepatic epithelium.

THE INFLUENCE OF MUCUS ON THE GROWTH OF MICRO-ORGANISMS AND THE PART PLAYED BY MUCUS IN THE PROTECTION OF EPITHELIAL CELLS.

One, perhaps the most important, function of the gall bladder is to secrete mucus. It has been shown experimentally by Opie¹¹ and clinically by Halstead¹² that pure bile injected into the pancreatic duct produces acute pancreatitis, but Flexner has also shown¹³ that bile, when previously mixed with mucus, does not cause this pancreatic change. We know that the presence of high percentages of bile in the blood supplied to the pancreas in jaundice does not set up acute pancreatitis. These facts suggest that some inflammatory affections of the pancreas are caused by a regurgitation of bile along the pancreatic duct rather than by organisms which reach the pancreas by way of the blood, and pancreatic calculi may be due to the same cause. Even where no massive regurgitation of bile takes place a reversed mucous current may occur, and organisms may thus reach the pancreas.

The influence of different kinds of mucus—that is, mucus secreted by different kinds of epithelium on different kinds of pathogenic organisms is a subject which would well repay investigation. Observations carried out for me in the Leicester Infirmary in 1909 show that some samples of freshly obtained mucoid fluid from ovarian cysts form an excellent culture medium for the *Bacillus coli*, while other samples do not form a suitable medium. Observations on a sample of clear mucus obtained under strict aseptic precautions from a distended gall bladder seemed to show that this material exercised some inhibiting influence on the growth of bacilli of the colon group. It would be of interest to know whether organisms which normally inhabit the bowel and can grow in intestinal mucus grow equally well in mucus derived from the urinary tract, and whether the *Micrococcus ureae* will grow in mucus secreted by intestinal epithelium. The gonococcus grows well in urethral mucus, but we do not know—at any rate, observations have not been recorded—to what extent it will grow on rectal mucus; at all events, it does not tend usually to invade the rectum.

The influence of a layer of mucus in protecting the epithelial cells from mechanical and chemical irritation is probably very important. One part of the effect of repeated mechanical irritation in producing cancer may depend on the absence of mucus due to the removal of the mucus-secreting cells. Mucus also differs in its physical characters when secreted under different conditions. Thus the mucus which is poured out by the epithelium lining the bronchial tubes during an attack of acute bronchitis, is very viscid; it adheres to the sides of the vessel even when expectorated into water, while the mucus which is secreted during recovery consists of masses of phlegm which do not stick to each other or adhere to the sides of the vessel. The same is true of the mucus secreted by the bladder during the height and the decline of an attack of cystitis. It is quite possible to judge clinically of the progress of a patient with cystitis by observation of the mucus at the bottom of the vessel in which it has been collected. The difference in viscosity may depend on some difference in fibrin content, but the actual physical difference must itself have an important effect on the flow of mucus

currents and on the spread of the organism over the surface of the membrane by continuous growth.

If I may be allowed a digression in the field of comparative anatomy and physiology, I should like to draw attention to two very different kinds of mucus secreted by the salivary glands in some birds. The green woodpecker obtains its food by inserting its long, barbed, whip-like tongue into crevices in the bark of trees and into anthills, and withdrawing it with the insects adhering to it. Now it is interesting to find that in the green woodpecker the salivary glands are enormously developed (Fig. 5). Each is formed of two parts, a larger white portion having the appearance of a salivary gland and a thinner strip of red tissue, like lymph gland, lying alongside the first (Fig. 6). Each gland opens by a separate duct on the floor of the mouth. The secretion of the white gland is an extremely viscid mucus, and serves to stick the insects to the whip-like tongue just like bird-lime. The secretion of the red gland is ordinary non-viscid lubricating mucus; it no doubt helps to clear the tongue of the insects when withdrawn into the mouth, and also aids the passage of the food into the pharynx. Here we find two kinds of mucus secreted by the salivary glands of the same bird; one kind resembles the sticky mucus secreted during acute inflammation, and the other the lubricating mucus secreted during recovery.

These adhesive and lubricating properties seem to be present in varying degrees in all kinds of mucus. Where the contents of the mucous canal are solid or semisolid, as in the large bowel, one important function of mucus is to bind the faeces together (cohesion mucus of Nothnagel),¹⁴ while another and even more important function is to lubricate and render easier the passage of faecal material over the surface of the mucous membrane. In the oviduct in birds it is necessary for the albuminous secretion to adhere to the ovum and not to adhere to the epithelial lining over which the whole mass must glide, and it is interesting to note that indigo granules inserted into the cloaca of the bowel have been found in the lining membrane of the egg laid by the same bird a few days later.

INFECTION OF THE GENITO-URINARY TRACT.

In view of the frequent passage of the gonococci along the genital canal to the fimbriated openings of the Fallopian tubes and the pelvic peritoneum in women, it may seem unnecessary to refer to the occurrence of ascending mucous currents in these organs. Owing, however, to the frequency of surgical operations on the genital canal in the female, it is important to remember that non-motile foreign particles, such as indigo granules, can be carried along the whole length of the canal from the os uteri to the pelvic peritoneum in less than forty-eight hours, even when no gross disease of the uterus is present. When we recall the very frequent occurrence of displacements, of tumours, of stenosis, and of other pathological conditions which tend to produce stasis in the contents of the uterus, we can realize the ease with which ascending infections of the genital organs take place in women (Figs. 7 and 8).

We do not know the conditions under which absorption takes place by the pelvic peritoneum, or to what extent absorption in this situation originates a retrograde flow of mucus along the Fallopian tubes, just as the presence of a fistulous opening in the pelvis of the kidney or in the gall bladder sets up a reversed mucous current in the ureter and the cystic duct. It is, however, clearly established that many of the infections of the genital canal in women are mucous and not blood infections, and this has an important bearing on the well-known fact that the female pelvic peritoneum is more tolerant of surgical

interference and more capable of resisting infection than the male peritoneum. There is no reason to suppose that organisms pass more freely through the coats of the bowel into the blood stream in women than in men, hence the greater resisting power of the female pelvic peritoneum is probably due to an acquired immunity, the result of the repeated introduction of small doses of infection through the peritoneal openings of the Fallopian tubes.

In a paper on the occurrence of menstrual secretion in the Fallopian tubes in the human subject¹⁵ I drew attention to the frequent occurrence of menstrual fluid in the lumen of healthy Fallopian tubes which had been removed for surgical reasons during the menstrual period (Figs. 12 and 13). At that time I was inclined to entertain the possibility of a true Fallopian tube menstruation; since, however, I ascertained the fact that reversed mucous currents do occur in the Fallopian tubes, I am inclined to regard the occurrence of blood-stained fluid in this situation during menstruation (apart from tubal conception) as the result of regurgitation from the uterine cavity (Figs. 9 and 11). Experiment shows that particles of indigo or carmine inserted within the os uteri reach the Fallopian tubes within twenty-four to forty-eight hours, and under certain conditions they are carried through the fimbriated openings and are deposited on the surface and in the superficial layers of the pelvic peritoneum (Fig. 10). Where non-motile inert particles are carried micro-organisms can be carried also.

Sippel¹⁶ and Wildbolz¹⁷ both draw attention to the fairly frequent occurrence of infections of the bladder and urinary tract in newly-married women the result of coitus. It has been supposed by some that the organism gains an entrance into the blood or lymph stream through some wound of the hymen or abrasion of the mucous membrane of the vagina, but this does not explain the fact that the infection starts in many cases in the bladder and only reaches the kidney later, and it is especially liable to do so if pregnancy supervenes. The strong probability is, therefore, that the organism enters through the meatus

uriarius and travels up the urinary tract, the pressure of the enlarging pregnant uterus in pregnant cases brings about that degree of urinary stasis, especially in the right ureter, which favours an ascending mucous current, and so provides for the transference of the organism to the pelvis of the kidney. Now if the *Bacillus coli* can be rubbed into the meatus during coitus it is difficult to suppose that it cannot be introduced by contact and in other ways in the case of patients who are wanting in personal cleanliness, or who are suffering from nervous and other diseases which predispose to contamination.

Pneumococcal peritonitis is certainly commoner in female than in male children; some authorities place the ratio as 2 to 1. At the Toronto meeting of the British Medical Association¹⁸ I pointed out that it is not necessary that evidence of metritis or salpingitis should be present in the cases of female children in whom the absence of any other focus makes it probable that the pneumococcus has reached the peritoneum through the vagina. In a case of this kind in a child of 3 we found the Gram-staining capsulated diplococci lying on and between the columnar epithelial cells which line the Fallopian tubes, without any signs of invasion of the deeper layers or evidence of inflammation in the mucous membrane. Every surgeon must have operated on early cases of pneumococcal peritonitis in women in which the fibrinous and purulent exudation was confined to the pelvic peritoneum, and in which no other centre of invasion could be found. In such cases it is difficult to resist the conclusion that the organism gained access to the peritoneal cavity by way of the genital canal.

ureter in the bowel wall. A case of my own reported in the BRITISH MEDICAL JOURNAL of May 19th, 1906,²⁷ is of interest in this connexion. A youth, aged 16, the subject of ectopia vesicae had both ureters transplanted into the rectum below the peritoneal fold. He lived two years and died eventually from kidney infection. At the necropsy it was found that the opening of the left ureter into the rectum had undergone some cicatricial contraction, the ureteral dilatation and pyelitis were much more marked on this side owing to the urinary stasis. On the right side a freely patent ureteral opening had prevented to a considerable extent the ascending infection (Fig. 14).

The position, then, seems to be that pathogenic organisms reach the urine by way of the blood stream and by way of the urinary tract, but local symptoms of urinary infection do not occur unless there be some temporary arrest of the normal flow of urine, and this occurs more quickly in the case of ascending than in descending infections. The real question is as to the relative frequency of these two routes of invasion, and whether it is possible to determine the actual route followed by the organisms in any particular case. It is, of course, obvious that when organisms like the pneumococcus or *Staphylococcus aureus* (which are not likely to cause urethral contamination) are being excreted in the urine in cases of generalized infection the route is probably the blood stream, but when the infection is due to the *Bacillus coli*, then the question of the route of the invasion becomes one of practical importance.

It will, I think, be found that when organisms are found in the urine which have been excreted by the kidneys they produce symptoms and effects which differ from those produced by organisms which reach the renal pelvis by way of the urinary tract. In the former case urinary symptoms are often absent, and if the kidney is affected, it is affected, in common with other organs, as part of a blood change, of which some other evidence may often be found, or some other primary focus may be detected in some other part of the body; but in the latter case the local urinary symptoms afford the first indications in many cases of any departure from health. The effect of an autogenous vaccine is more marked in relieving symptoms than in removing the organism from the urine in ascending than in descending infections of the urinary tract. It is, for instance, well known that it is much easier to relieve the symptoms in a case of pyelitis of *coli* origin than to remove all the bacilli from the urine. If the *Bacillus coli* persists in the urine in spite of the influence of a vaccine, this must mean that the organism has become adapted to its environment, that it is able to multiply in the renal epithelium or in the urine or the mucus which fills the ureter and the pelvis of the kidney. The fact that the organism is able to grow and multiply outside the tissues of the body itself suggests a mucous rather than a haematogenous origin for the infection. If vaccine treatment rapidly and permanently removes any organism from the urine, this fact affords a presumption, but not a certainty, that some primary focus of infection exists in another mucous membrane, or in some other part of the body, and consequently that the organism is reaching the urine by way of the kidney and the blood stream. The clinical differences in the two cases depend on the fact that in ascending infections the organism is primarily adapted to a urinous environment, while in descending infections it is primarily adapted to a blood

stream or a mucous environment of another kind. We do not know fully the extent to which the increased resistance acquired by the blood and tissues as the result of infection are handed over to the secretions, how far, that is to say, the mucus, the urine, or the milk of a patient suffering from typhoid fever contain the bactericidal and immunizing substances specific to that disease.

Dr. Eyre²⁸ states that the *Bacillus coli* in the urine undergoes changes in fermentation-producing capacity after a patient has been treated by vaccine. The extent of this adaptive capacity may prove to be greater in the case of bacilli which are living and multiplying in the urine than in bacilli which are being excreted by the kidney from the blood.

I have already alluded to the great importance of mucus as a secretion. The rôle played by mucus as a first line of defence against invasion of the body by micro-organisms has not, I think, been sufficiently recognized

by pathologists. There are, as far as I am aware, no recorded observations showing to what extent, if any, the mucus secreted by the epithelium of the urinary tract of patients who have undergone a course of autogenous vaccination against *coli* infection is capable of inhibiting the growth of the *Bacillus coli* in various culture media. Neither do we know whether mucus secreted by intestinal epithelium is injurious to the epithelial cells which line the bladder, nor do we know whether salivary mucus (which, as we have seen, is of two kinds in some birds) has any cytolytic action on the epithelium which lines other cavities beside the mouth and gullet.

Before leaving the subject of genital urinary infection, we may draw attention to the fact that veterinary surgeons seem to attach considerable importance to the mucous channels as the chief route of infection in pyelitis in animals. The infectious disease known as pyelonephritis of horses and cattle is more frequent in female than in male animals; moreover the organism can apparently traverse the bladder without causing symptoms of cystitis (Moussu and Dolan).²⁹

EPITHELIAL SECRETING ORGANS.

The Mammary Gland.

Infective diseases of the mammary gland are well known in animals and in the human subject. They are for the most part localized and affect one or more lobules of the same gland; this is the case in the infective disease of the udder in cows known as "Garget" and in the abscesses which accompany lactation in women. The probability is that these localized infections of the mammary glands are due to the passage of micro-organisms up the lacteal ducts. If we can show that foreign particles are conveyed from the orifices of the ducts which open on the nipple to the deeper recesses of the gland, a case is made out for the transference of pathogenic organisms along the same route. One such experiment on the cow's udder is of interest in this connexion. Some powdered indigo was inserted into the opening of the main lacteal ducts in the teat of a nulliparous heifer; a microscopical examination of the mammary gland, when the cow was killed a few days later, showed a few indigo granules in two or three acini and in one small lacteal duct. It is quite true that most of the ducts were clear of foreign particles and only a very few indigo granules were present in the whole

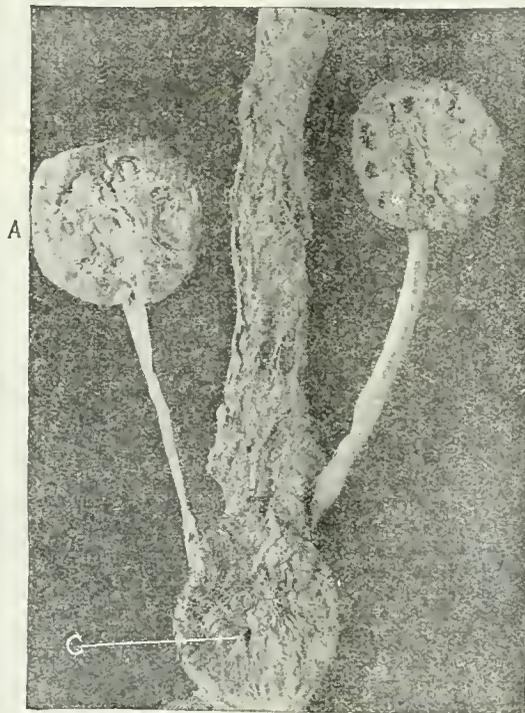

Fig. 14.—Rectum (laid open from behind). Kidneys and transplanted ureters from a case of extroverted bladder. Operation two years before. A, Right kidney healthy. B, Left kidney cystic; strictured opening of ureter. C, Patent opening of ureter.

gland, but the resting quiescent gland is very different from the lactating gland; the conditions are far more favourable in the lactating gland for the establishment of to and fro secretion of mucous currents.

The two common diseases of milking cows—garget and milk fever—are both of interest from our present point of view. Both occur almost entirely in animals in which the udder is physiologically active; milk fever frequently occurs within a day or two of calving. Both are more common in the hot summer months. It is possible that besides infection from the hands of milkmen and dirty litter, flies may take some share in conveying to the orifices of the lacteal ducts the streptococcus which has been shown by Nocard and others to be the cause of contagious mammitis in cows. The first effect of infection of the udder by this organism is to bring about coagulation of the milk in the teats and larger ducts, milk stasis thus occurs, and the conditions arise which favour backward currents and the transference of the organism to the recesses of the gland.

Milk fever, or *post-partum* paralysis, or parturient apoplexy in cows is generally regarded (since Schmidt's work) as due to a toxæmia having its origin in the mammary gland. The fact that the local injection of solution of potassium iodide and air, or of oxygen alone, into the galactophorous ducts frequently produces rapid recovery affords some confirmation of this view, and it is quite possible that this serious disease of the dairy farm may eventually be traced to an infection which reaches the mammary gland through the mucous channels of the lacteal ducts.

In the human subject I have found indigo granules on a plug of white sterile gauze introduced into the cavity of a mammary abscess after the application of indigo to the nipple. In this case a fistula had resulted from the opening of the abscess, and thus a reversed mucous current up the lacteal duct had probably been established (Fig. 15).

The question arises whether reabsorption of milk occurs in the deeper recesses of the mammary gland during the quiescent periods between the flow of milk, and, if reabsorption does occur, whether it occurs through the medium of the epithelial cells or through the lymphatics of the gland. It seems probable that in cases of biliary obstruction the bile is reabsorbed into the blood through the biliary lymphatics and not through the epithelial liver cells.

If reabsorption of normal secretion does occur in glandular organs during the intervals between periods of activity, then such reabsorption taking place in the acini of the gland would act like a fistula and produce reversed currents along the ducts, and that transference of non-motile particles which we know from experiment does occur in cases in which no fistulous communication exists.

Supposing, however, that reabsorption of secretion does not usually or normally occur, there are many abnormal conditions apart from actual disease which bring about arrest of secretory activity in glands. The influence of strong emotion, and many chemical substances, foods, and drugs, will produce this result. The influence of these sudden arrests of secretion in causing stasis and back currents in the mucous canal system of any large secreting organ must have very considerable influence in favouring the entry of micro-organisms, and in bringing about infections which are hard to account for in any other way.

Before leaving the subject of the breast we may notice in passing the widespread habit in the young of many animals to stimulate the mammary secretion in the mother by mechanical means. Lambs and calves violently punch the udder with their noses, kittens knead the mammae with their paws, and infants knead the breast with their hands. No doubt the object of these movements is to stimulate or increase the flow of milk, but in addition to this their physiological effect they may also cause back eddies in the flow of secretion which may have some influence in bringing about infection. The facts about mucous currents and mucous infection which concern the mammary gland apply also to other epithelial secreting organs, such as the pancreas and the salivary glands, and, indeed, to any collection of glandular epithelial cells which communicate with the exterior by means of a mucous duct. It is a

significant fact that apart from the specific form of parotitis or mumps, suppurative infections of the parotid seem to occur chiefly in such illnesses as are associated with partial or complete arrest of salivary secretion and with a dry and septic condition of the mouth.

Salivary stasis and the presence of pathogenic organisms in the vicinity of the buccal orifice of Stenson's duct provide the two conditions which favour the upward passage of infecting material along this mucous canal. I have recovered indigo granules from the orifice of a salivary fistula after previously placing some indigo powder in the mouth. It is difficult to understand why the parotid glands should suffer from infection more than the submaxillary if we suppose that the infection reaches the gland by way of the blood stream. If, however, the infection travels up the duct, then the fact that the parotid ducts open high up on the inside of the cheek and the submaxillary ducts low down on the floor of the mouth beneath the tongue may have something to do with the greater liability to infection of the parotid glands, for drying of the mucous membrane in the neighbourhood of the opening of the duct and blocking of secretion is more liable to occur in the former than in the latter. Other interesting questions also arise in the case of mumps. Is the orchitis which sometimes occurs as a sequela the result of a blood infection or is the specific organism excreted by the kidney, and does it reach the testis by way of the vas deferens? The body and not the epididymis is the part of the organ attacked, and this suggests that the infection travels by way of the blood stream, and the same may be true in those rarer cases in which the pancreas shares in the specific infection.

CONCLUSION.

In bringing to a close these remarks on the mucous channels and the blood stream as alternative routes of invasion, I wish to emphasize the fact that, apart from the importance of obtaining clinical and bacteriological information concerning the path traversed by pathogenic organisms when they infect the tissues of the body, certain problems in immunity are also intimately related to this question of the route of invasion.

I have given reasons for thinking that, when an organism like the *Bacillus coli* reaches the pelvis of the kidney by ascending the urinary tract, it produces symptoms and effects which differ from those produced by the same organism when it reaches the kidney by way of the blood stream. I have also suggested that these differences depend on the fact that the organism is undergoing adaptation to a mucous and urinary environment in the one case and a blood or lymphatic stream environment in the other.

In many ways, therefore, this subject of the route of invasion by disease organisms is one of considerable interest.

The Arris and Gale Lectures

ON

THE GENITAL FUNCTIONS OF THE DUCTLESS GLANDS IN THE FEMALE.

DELIVERED AT THE ROYAL COLLEGE OF SURGEONS ON MARCH 10TH AND 12TH, 1913,

BY

W. BLAIR BELL, B.S., M.D.LOND., M.R.C.S.ENG.,
L.R.C.P.LOND.,

GYNAECOLOGICAL SURGEON TO OUT-PATIENTS, ROYAL INFIRMARY,
LIVERPOOL; EXAMINER IN GYNAECOLOGY AND OBSTETRICS
TO THE ROYAL COLLEGES OF SURGEONS AND
PHYSICIANS, LONDON; AND TO THE
UNIVERSITY OF DURHAM.

[Abstract.]

LECTURE I.

INTRODUCTION.

ANY attempt to describe the special correlated functions of the ductless glands, or, to be more exact, of the internal secretions, appears to be avoided by those who have worked most at the subject. Correlations are admitted; points in support of them are produced, and the matter is then dropped. In many ways this is much to be deplored, for, to some extent, it is accountable for the present disordered condition of our knowledge.

I do not wish it to be inferred from these remarks that I am in any way prepared to give in these lectures a complete explanation of the interactions of the ductless glands in regard to the genital functions. It would be impossible in the time at my disposal, even had I the knowledge, which I certainly have not. I do, however, wish to call attention to the fact that the genital functions in the female must be considered from a very wide standpoint in view of our accumulated knowledge concerning them. I shall deal most fully with those parts of the subject on which I have myself worked, and I shall bring forward experimental results to clear up some of the points at issue.

My endeavour will be to emphasize, if I can, the importance of all the internal secretions in the special economy of the female. So that those who are interested in gynaecology may come, if they have not already done so, to look upon all the ductless glands as genital glands—not, of course, exclusively so, nor all in the same way in a metabolic sense, but rather that each is absolutely indispensable to the harmony of the genital functions, which are, therefore, not solely dependent on the functional activity of the special genital gland.

Until recent years attention centred round the ovary, as if it were the only controlling factor in the genital processes. I shall, therefore, first consider the functions of this organ.

THE FUNCTIONS OF THE OVARY.

These are: To provide ova, and to produce an internal secretion or secretions. We need not consider further the liberation of the ova.

The internal secretion of the ovary has never been isolated. Indeed, it is still a matter of considerable dispute as to how and where it is produced. The only evidence that there is an internal secretion rests upon the results of extirpation and destruction experiments, and, to a lesser degree, on clinical observations. The resulting atrophy of the uterus is taken to indicate the loss of some secretion which normally activates this organ.

Some believe that there is more than one secretion, and various authorities have considered that different secretions are produced by the lutein cells of the corpus luteum, by the interstitial cells of the stroma of the ovary and by the membrana granulosa cells; but that they differ in the degree of importance to be ascribed to each.

Prénant, and later Bern and Fränkel, were probably the first to call attention to the importance of the lutein cells; and the last named showed that destruction of these cells led to abortion in pregnant rabbits. Hick and I, and many others, invariably produced abortion by the removal of both ovaries in these animals.

It has been supposed that the corpus luteum provides a secretion which assists in maintaining the position of the embedded ovum intact. Experiments on animals seem to support this view; but cases in the human subject are on record in which both ovaries have been removed during the first few weeks of pregnancy for such discrete tumours as fibromata, without interrupting the course of gestation. And herein lies one of the great difficulties in the study of our subject; different orders of mammals have organs of internal secretion which are structurally and even functionally different, although perhaps in degree only. Individuals in the same species may vary, both in animals and in man. Consequently, some of the contradictory statements made by different experimenters may be explained on the ground of these variations.

The interstitial cells of the ovary also are believed to possess a special internal secretion. Limon first compared the ovaries of many species of mammals, and found an enormous difference in the preponderance of interstitial cells in the different ovaries.

Every one is familiar with the structure of the human ovary and the obvious scarcity of secretory cells—apart from those connected with the follicles. But if we examine the ovary of an adult rabbit, or any other rodent, we see a most remarkable structure. The whole organ is composed of a mass of cells which are epithelioid in character. And still more remarkable is the appearance of the corpora lutea, the cells of which can only be distinguished, if at all, from the cells of the stroma by their larger size. The Graafian follicles are crowded round the periphery of the ovary as though pushed outwards.

From very close observation of the corpora lutea in all the stages of development I have come to the conclusion that they do not undergo involution in rodents as in the higher mammals, but that they ultimately form the so-called interstitial stroma cells. Often one can see the cells of the corpus luteum merging into the similar cells in the stroma of the ovary.

If we examine the ovaries of rabbits a few weeks old, we find them composed entirely of primordial ova and a few follicles, separated by bundles of connective tissue. There is an entire absence of interstitial cells. This also indicates the probability of the origin of these cells from corpora lutea, although it is possible that in the human ovary, and in the ovaries of animals which contain very few interstitial cells, these arise from the capsular epithelium, or possibly from special stroma cells. Thirdly, there are the Graafian follicles with their linings of membrana granulosa cells to which some attribute an internal secretion. In favour of this view I shall adduce some evidence later.

The question now arises whether we are justified in assuming that there is only one type of secretory cell in the ovary. If we were to put aside the liquor folliculi as an internal secretion, I do not think we should be wrong in assuming that the interstitial cells and the corpus luteum have the same function, especially if we believe that they are derived from the same source. In experimental investigations of the ovarian functions we have no means of separating the various parts of the ovary, and can, therefore, only estimate the total function.

My own experiments have been carried out on dogs, cats, and rabbits. As already stated, the ovaries of the carnivora resemble in structure the human ovary more closely than is the case with the ovaries of rodents. The methods of investigation have consisted in noting the effects of oöphorectomy on the pregnant and non-pregnant uterus, on the other ductless glands, and on the general metabolism of the body.

Effects of Oöphorectomy on the Genital Functions.

Hick and I pointed out some years ago that the effect of oöphorectomy on the non-pregnant uterus was to produce, first of all, atrophy of the muscular coats.

We concluded that the normal muscular contractions were abolished and atrophy supervened in the manner usual to muscles that are not utilized. This has been confirmed and accepted by Marshall and others. The total ovarian secretion exercises a somewhat remarkable experimental effect on the uterus. Hick and I found that when injected intravenously it caused contractions in the oestrous uterus of the rabbit, but inhibited the

contractions of the pregnant uterus. We were, however, not always been able to produce the latter result.

Recently I have investigated the important question whether the metabolic conditions of the body are materially altered by oöphorectomy, or not.

Effects of Oöphorectomy on the General Metabolism.

In the early part of last year I removed the ovaries of six cats which were kept for periods ranging from 139 to 251 days. The urine was collected and fully examined at frequent intervals both before and after operation.

It was found that the specific gravity was higher after operation than before in half the cases. This, of course, would lead us to expect a larger proportion of solids in the latter period of observation, and this was more or less borne out except in the case of one cat. Since there was some irregularity in the individual results, and we had a sufficient number of animals, an average estimation of all six cases was worked out. From this we drew our conclusions.

The calcium excretion was diminished by one half. The chlorides were slightly diminished. The phosphorus excretion was much increased, as was the total nitrogen and urea percentages. The ammonia was slightly increased. There was no real change in the ammonia coefficient.

Knowing as we do the marked changes in the nitrogen metabolism which normal animals undergo, we cannot look upon the changes recorded in regard to the nitrogen as of much importance.

The increased phosphorus excretion was somewhat curious in view of the definite decrease in the excretion of calcium.

I may, perhaps, be allowed to recapitulate a few other facts which afford evidence contributory to the view that the ovaries are concerned in promoting calcium excretion. During pregnancy and lactation the function of the ovaries is in abeyance in regard to menstruation, and at these times first the fetus and then the breasts utilize all the available calcium—indeed, the mother's tissues are sometimes drawn upon to her detriment.

With regard to the mammary secretion, although it is so intimately connected with the genital functions, I look upon it as of subsidiary importance. That is to say, the secretion of milk is produced by a special arrangement of the general metabolism in response to various hormones connected with the necessities of the occasion. In women there is sometimes no response.

I do not propose to discuss lactation in these lectures, since it is one of the side issues, and the metabolic processes connected with the production of milk are comparable with those which provide for the building up of the fetus in the uterus. It is a process with which all the ductless glands are directly or indirectly concerned.

Osteomalacia, about which I shall have more to say in the next lecture, has often been cured by the removal of the ovaries, and this result indicates a condition of calcium retention in the tissues. My experiments are therefore supported by clinical observations.

We know quite well, of course, that from a casual inspection of animals which have undergone oöphorectomy we can detect no outward change, except some degree of adiposity, yet apparently there is a constant metabolic disturbance in regard to the calcium retention and increased phosphorus excretion as shown by the urinary analyses.

On the other hand, we know well from our clinical experience that outward changes of a marked character may occur in women in whom an artificial menopause has been induced by oöphorectomy. At the same time it has been a matter of very lively speculation why one woman should suffer all manner of evils when her ovaries are removed, and another suffer very little.

And this is another reason why experimentation on animals has to be very carefully considered. The metabolism of women is much more easily disturbed than is that of the lower animals; and psychoses and neuroses which are not observed after oöphorectomy in the latter are often the source of the greatest distress in women.

But we shall see that, in addition to certain constant and positive results which are always reliable in regard to the metabolism, experimentation provides us with other

most useful information, and this information is just that which we cannot obtain in our clinical work, although it may be at the bottom of many obscure phenomena. I refer to the effects produced on the other ductless glands by removal of the ovaries. No doubt the differences in the effects of oöphorectomy in women, just alluded to, are largely dependent upon the individual variations that we know exist with regard to the adjustments of the internal secretions, and are evidenced by the outward characteristics of adiposity and thinness, lethargy and brightness, and many other physical and psychical attributes. So that it is clear that if one woman be better adjusted than another against the removal of the ovarian secretion, she will show less signs of the menopause. Animals do not vary in the same way. They all seem to have a remarkable power of readjustment. But with the higher psychical evolution of woman it is not surprising that removal of the ovaries often causes a severe alteration of temperament.

It has been supposed that the changes that occur in other members of the ductless gland system after removal of one of their number are in some cases compensatory, and consequently that disturbances in the body metabolism may thus be made good or prevented.

Effects of Oöphorectomy on the Thyroid.

If one were to select any other order of mammal than the rodent one would come to the conclusion that any alteration in the functional activity of the thyroid after oöphorectomy was of little or no importance in so far as histological evidence was concerned. For instance, in the cat I have been unable to detect any material difference after oöphorectomy in the thyroid itself or in the parathyroid.

But if one compares the thyroid of a normal female rabbit with the thyroid of the same animal after removal of the ovaries, one sees a very different picture. The thyroid of the normal non-ovestrous and non-pregnant female rabbit is not a very active organ in so far as the production of colloid is concerned. But after removal of the ovaries there is great distension of the vesicles, which are filled with colloid. Further, the colloid is seen to be basophile in character, staining blue with haematoxylin instead of pink with eosin, whereas the normal thyroid colloid is, of course, acidophile and stains with eosin.

Before attempting any explanation of the changes in the thyroid after oöphorectomy we must not forget that this organ in the pregnant rabbit shows a relatively great increase in the amount of colloid, but that it is then eosinophile in character.

It may safely be asserted that there is a considerable increase in functional activity of the thyroid of rodents after oöphorectomy.

Why the colloid should be basophile instead of eosinophile we can only conjecture. I have carefully considered the question of an artefact, but I think this must be rejected for many reasons, into which I need not enter here. We are, however, assisted in our attempt to arrive at a conclusion by observations made on the pituitary body, some of which will be referred to more fully later.

The normal colloidal secretion of the anterior lobe and pars intermedia of the pituitary is basophile, but under conditions of increased activity it is eosinophile. Further, like the thyroid, in a condition of greater hypophysial activity no colloid is formed, but the secretion is abstracted directly from eosinophile cells. In conditions of the greatest activity of all, as I shall show later, the secretion is directly abstracted by the blood or lymph from faintly staining basophile cells, that is, from the so-called chromophobe cells. There is, in fact, a cycle of events to be demonstrated in the hypophysis according to the needs of the moment.

It is probable, then, that the basophile colloid found in the rabbit's thyroid after oöphorectomy represents a storage secretion, which is formed to meet the altered conditions of metabolism, but which is not of a great degree of activity in this order of mammals.

As I have previously suggested, the inactive thyroid which is found in rodents is probably related to the very marked development of the interstitial cells in the ovaries of these animals; and, as a consequence, a marked reaction is produced in the thyroid of rodents by

oöphorectomy, and not to the same degree in other mammals, such as the carnivora.

Effects of Oöphorectomy on the Thymus.

Calzolari first showed that castration produced hypertrophy of the thymus. His experiments were carried out on rabbits.

No work has been done in regard to women, but eunuchs have been found to possess thymuses which have not undergone involution. It has also been noted by Marrasini and by Gellin that castration, after genital activity has been established, gives rise to enlargement of the thymus.

In my experiments on cats we found the thymus much larger after oöphorectomy than in the normal adult animal, and on section it appeared to resemble the normal gland in the active stage before puberty.

Effects of Oöphorectomy on the Pineal Gland.

I have personally made no observations of the pineal gland after oöphorectomy; indeed, very little physiological work has been done in this connexion.

Biach and Hülles published a paper last year, in which they gave the results of castration of male and female kittens a few weeks old. The animals were kept from seven to eight months. These investigators arrived at the conclusion that atrophy of the pineal gland occurred in all cases. Other observers have been able to find no changes in this organ.

Later on I shall consider the effect of pathological changes in the pineal on the genital functions.

Effects of Oöphorectomy on the Suprarenals.

I have examined many suprarenals after oöphorectomy in rabbits and cats, and have found that there appears to be a definite increase in the reticulated portion of the cortex, at the expense of the zona fasciculata. What the interpretation of this is I cannot say.

Clinical Observations of the Effects produced on the Thyroid by Ovarian Insufficiency in Women.

No experimental finding in regard to the interrelationship of the internal secretions can be considered of real or practical value unless it be supported by clinical evidence.

Indeed, it may be considered that experimental evidence concerning the functions of the ductless glands, which, as I have already pointed out, are subject to individual variations, is most useful in giving us a lead in the interpretation of those difficult cases with which we may be confronted, but are now beginning to understand more fully. This understanding has been brought about by dovetailing our experimental results into our clinical experiences. A brilliant example of what may be accomplished along these lines is afforded by Harvey Cushing's recent work on the pituitary body.

What evidence have we, then, of a clinical nature concerning the correlation of the thyroid and ovary, in the circumstances under discussion—that is, with ovarian insufficiency?

I have many times alluded, as have other writers, to the well-known enlargement of the thyroid in pregnancy. It is probable that normally this enlargement corresponds with that found after oöphorectomy, for in certain respects the ovary is quiescent during pregnancy. We know that this enlargement normally does not produce the signs associated with exophthalmic goitre, but is, as I have already shown, due to excess of colloid material. At the same time I have known more than one case of Graves's disease commence during pregnancy.

It is probable, also, that the enlargement of the thyroid seen in girls during menstruation about puberty is due to the incomplete state of development of the ovaries, and histologically is the same in character as that occurring during pregnancy. I am not aware, however, that such a thyroid has ever been examined microscopically, for obvious reasons.

In addition to this we have other evidence of a pathological nature. No doubt many gynaecologists have had experiences similar to mine.

In one case, Mrs. J., aged 46, I removed both ovaries for cystic adenomata; on histological examination adenocarcinoma was found in a portion of one of the cysts, as is frequently the case when the patient is over 40 years of age. All went well for two months; then the patient developed slight enlargement

of the thyroid. The condition passed rapidly into one of acute exophthalmic goitre, from which the patient actually died within a year of the operation.

I have recently seen a most remarkable case which I believe to be unique.

G. R., aged 25, was referred to me by one of my medical colleagues at the Liverpool Royal Infirmary. She had been married for three years, and had had one child eleven months before she came under observation. The delivery was difficult and was effected with forceps. She was able to nurse the baby for a few weeks only, owing to deficient secretion of milk.

The patient presented herself with typical symptoms of early exophthalmic goitre, and her pulse-rate was 150 per minute. She had never menstruated since her confinement, but had always been regular before she became pregnant—three to four days per mensem.

I found she had the somewhat rare condition of superinvolution of the uterus. The length of the uterine cavity measured under 2 in. The left ovary was palpable and apparently not atrophied.

Now, the pathology of superinvolution is not completely understood, but I think that there must sometimes be an insufficiency of ovarian secretion, even if it be not possible to recognize histological changes in the ovary by our present methods of investigation. At the same time, as we shall see later, insufficiency of other ductless glands may lead to the same condition.

In view of the facts recorded, I think it is amply proved that ovarian insufficiency leads to changes in the thyroid, which may either be of the type seen after experimental oöphorectomy—namely, colloid accumulation—or, more rarely, that represented by exophthalmic goitre.

Until we know a little more of the relation of colloid secretion to the excessive secretion without colloid formation that occurs in exophthalmic goitre, we cannot go into details concerning the exact pathological reactions that occur in the general metabolism. My own view is that it is the regulation of the calcium metabolism that is concerned in these changes. We have seen that oöphorectomy diminishes the output; and we know that the excretion is much increased in Graves's disease, so that this condition may represent a counter-effect to ovarian insufficiency. This at least seems obvious, although I am fully aware that the changes in the thyroid may be merely the gross representation of a number of most intricate changes connected with growth, reproduction, and the life of the individual in which all the ductless glands are concerned.

Effects of Oöphorectomy on the Pituitary Body.

The close relationship between the pituitary body and the genital system has long been recognized, and I have made a number of observations of the effect of oöphorectomy on this intracranial organ.

The interpretation of these observations necessitates the formulation of definite ideas as to what the changes observed may mean. We read of "hyperplasia" or of "increased activity" of the anterior lobe, which can convey little meaning to any one until we have decided what are the appearances associated with increased activity and the reverse in the pituitary body. So far as I know, tentative views only have been put forward, and no very decided statements have been given concerning this complex and interesting organ.

As every one knows, the pituitary consists of three parts: the pars anterior, the pars intermedia, and the pars nervosa.

To each of these various portions, or perhaps more especially to the pars anterior and to the pars posterior—which consists of the pars intermedia and pars nervosa—have been assigned different functions. Authorities are still very much in disagreement concerning them.

Thus we find that Harvey Cushing arrived at the definite conclusion, as the result of his experiments, that the anterior portion was largely concerned in the well-being of the genital organs and in the metabolism of the carbohydrates and of the bony skeleton. As the result of some, if I may say so, rather insufficient clinical observations, he completely changed his opinion, and now asserts that it is the posterior lobe which is responsible for the integrity of the genitalia, and for carbohydrate metabolism. Bernhard Fischer had previously propounded this view.

After careful consideration and observation I have come to the conclusion that we must look upon the pituitary body as *one organ*, and not two. In this way only can we

reconcile all the facts of experimentation and clinical observation.

The secretion of the active chromophobe cells of the anterior lobe, such as are seen in pregnancy, is probably not different from that of the pars intermedia. And I believe that the secretion of the cells of the pars intermedia, which are developmentally the same as those of the pars anterior, may be regarded as pro-infundibulin, and that when it passes into the pars nervosa it becomes modified and acquires pressor qualities. In connexion with this passage of secretion into the pars nervosa there are many very important and interesting facts which are not actually concerned with our subject, so I refrain from discussing them here.

Next we must come to some definite conclusion concerning the interpretation to be placed upon the remarkable differences in staining properties possessed by the cells of the anterior lobe.

Although these variations in staining affinities are well known, I must recapitulate them in order to explain my views concerning their meaning. The cells, then, of the anterior portion are chromophobe or chromophile—they stain indifferently or well. The chromophile cells are either eosinophile (acidophile) or haematoxylinophile (basophile). With eosin they stain red, and with haematoxylin blue. The chromophobe cells stain lightly with haematoxylin.

There are two opinions held concerning this extraordinary grouping. The one, first put forward by Saint Rémy and Benda, finds expression in the belief that these appearances represent different phases of secretory activity. While the other opinion, propounded by Gemelli, represents the idea that each type of cell has a special secretion. My own view coincides with the first suggestion, and after careful investigation I have come to the following conclusions regarding the cycle of events.

First, the eosinophile cells represent the actively secreting cells, which ordinarily discharge their secretion into the blood vessels or lymphatics. If there be no great demand for the secretion the cells may become basophile and enlarge. They gradually become darker until finally they discharge basophile colloid among the neighbouring cells, which may form a vesicle-like wall around it.

After the discharge of colloid we see the small shrunken chromophobe cells all with large nuclei in which a network of chromatin fibres can be seen.

In certain circumstances, as in pregnancy or after removal of the thyroid, there is a great and immediate demand for secretion. Under these conditions the small chromophobe cells regenerate into large chromophobe cells, and eosinophilia—a more leisurely process—does not occur to the usual extent. These chromophobe cells have been called "pregnancy cells," owing to their constant appearance in the pars anterior during pregnancy.

Finally, it must be mentioned that the pars intermedia secretes colloid—normally basophile in reaction, but in some circumstances, to be mentioned directly, eosinophile. The colloid, which is formed in the pars anterior and pars intermedia, is probably a storage secretion, like the colloid seen in the thyroid.

The more active method of secretion in both parts of the pituitary is intracellular. In the pars intermedia the cells swell up and become fused, and the secretion is, I believe, taken up straight away by the blood or lymph. Some of the secretion of the pars intermedia, and even the actual cells, pass directly into the pars nervosa, whence absorption occurs; and it is in the pars nervosa, in my opinion, that the pressor qualities of infundibulin are acquired.

To return from this digression. Removal of the ovaries appears to exert a certain influence over the secretory functions of the pituitary body on the lines indicated. But in my experience the change is moderate and not quite constant. Thus, in one experiment—Cat No. 6 of my ovarian removal series—after an interval of 210 days, there was no divergence from the normal to be recognized histologically.

I believe the effect is more or less temporary, and in no way comparable to the genital lesions seen after partial extirpation of the pituitary. In most of my cats, however, definite changes were found as long as 245 days after oöphorectomy. There was a large preponderance of

eosinophile cells in the anterior portion. This shows activity, but not the great activity seen after thyroidectomy. In the pars intermedia the cells are fused, and there are colloid vesicles, and sometimes colloid cysts. This colloid stains with eosin, in contradistinction to the normal condition of basophilia.

It is interesting to note that the changes which occur in the pituitary with ovarian insufficiency are not comparable with those found in pregnancy; so that the relation of the pituitary body to the genital glands differs in this respect at least from the ovarian-thyroid relationship in similar circumstances.

Fiehera, however, believes that the "hyperplasia and hypertrophy" that follows oöphorectomy resembles that seen in pregnancy. Accordingly he believes that the change in the anterior lobe in pregnancy is due to ovarian insufficiency. As already stated, I have seen nothing to lead me to adopt this view.

Clinical Observations of the Effects produced on the Pituitary by Ovarian Insufficiency in Women.

There is extremely little evidence of any absolute value in regard to this, partly owing to the inaccessible position of the pituitary body and partly owing to the few attempts that have been made to investigate any possible changes present.

As we have seen, there is a peculiar and active stato produced in the pars anterior and pars intermedia in pregnancy, but our evidence does not lead us to suppose that this is due to ovarian insufficiency. It is probably concerned with the fetal metabolism, for, unlike thyroid enlargement, it appears to become more pronounced late in pregnancy.

The hemianopia that is sometimes seen during gestation has been attributed to the pressure produced by the enlargement of the pars anterior. And, in the increased secretion of this portion of the pituitary some have sought to find an explanation of the enlargement of the hands and lower part of the face, also sometimes noticed during the period of pregnancy. But there is no evidence I know of that goes to show that the enlargement is skeletal. Indeed it is usually merely a temporary thickening of the soft tissues, such as may be seen after oöphorectomy.

Again, because atrophy of the genital organs is associated with lesions of the pituitary, especially in the condition known as dystrophia adiposo-genitalis (Fröhlich), some authorities (Tandler, Gross, and others) have endeavoured to attribute the primary cause of the pituitary affection to the atrophy of the genital glands. But this is hardly to be believed on the present evidence at our disposal, and it is much more likely that the genital atrophy is subsequent to the pituitary lesion.

The facts I have brought forward in this lecture illustrate the influence of the ovaries on the uterus, on the general metabolism, and on the rest of the principal organs of internal secretion.

With regard to the influence of the ovary on the uterus, we have seen that to some extent the implantation of the fertilized ovum is assisted, possibly by the secretion of the corpus luteum. Further, the activity of the uterus is maintained and regular contractions promoted, probably by the secretion of the interstitial cells.

In the general metabolism the total ovarian secretion appears to promote the excretion of calcium and the retention of phosphorus. And lastly, total ovarian insufficiency arouses increased activity in all the remaining ductless glands.

THE third biennial congress of the Far Eastern Association of Tropical Medicine will be held in Saigon from November 8th to 15th next, under the presidency of Dr. Clarac, inspector of the sanitary and medical services of Indo-China. Papers offered will be classified for reading by a scientific committee, and it is hoped to receive contributions on protozoology and helminthology, on cholera, plague, leprosy and tuberculosis, on malarial and other tropical fevers, on beri-beri and dysentery, on obstetrical surgery and infantile diseases, and on climate and sanitation. Dr. M. L. R. Montel, medical officer to the Saigon municipality, is acting as secretary to the congress; the official language will be English, but papers may be read also in French or German. The subscription is 10s. 6d. (6 dollars, Saigon currency).

THE AESTHETICS OF MEDICINE.*

BY

CHARLES J. MACALISTER, M.D. EDIN.,
F.R.C.P. LOND.,PHYSICIAN, LIVERPOOL ROYAL SOUTHERN HOSPITAL AND ROYAL
COUNTRY HOSPITAL FOR CHILDREN.

It is curious to note how short-lived the memory of some evil things may be. When we suffer bereavement, time softens our sorrows and we come to look back with equanimity upon the anguish which we suffered at the time of disease or disaster and death, and only the happy memories associated with life remain. In the case of nations which have been at war the tragedies and calamities and anxieties incidental to the period of hostility after a time become mere matters of talk. The sense of reality which surrounded them at the time of their occurrence is lost and they are looked back upon without emotion. As in the case of all friendships which have been seriously broken and patched up again, scars of mistrust and of enmity remain on either side, and it is doubtful whether they can be effaced, at all events in the lifetime of a generation. Fortunately, however, these scars are not necessarily transmitted to the descendants of the previously hostile races; just as the children of disfigured parents are born without blemish, the old animosities become smoothed away and, an *entente cordiale* being established, nations which were formerly enemies may become fast friends. It is common knowledge that the lessons of a war are soon forgotten, all the enthusiasm which existed at the time of the war about having territorial regiments up to strength disappears, and instead of having to reject men because there is no room for them—the young manhood of the country lapses into its old condition of indifference and carelessness, and all kinds of schemes and projects have to be formulated and employed to encourage recruiting and to impress the necessity for training and readiness in case of emergency. Just as in the case of a war, the memory of a scourge which, passing over a country, kills thousands of people, soon goes; a decade passes, and the remembrances of the sore experiences become softened, and people having resumed their normal cheerfulness and optimism, think, if they do not say, "Sufficient unto the day is the evil thereof." A generation passes, and the new one regards the story of woe as a matter of historic interest, worrying no doubt to their ancestors, but why trouble about a set of people whom they only knew by hearsay, or about a disease which is little likely to become epidemic again in view of all the precautions which the health authorities undertake to keep it in check? A nation's gratitude is often periodically revived by the celebration of the anniversaries of great historic battles and military events—for instance, by the keeping of Trafalgar days and Ladysmith days, and by the decoration of the statues of heroes and of regimental memorials, but I wonder how many people ever dream of what they owe to medicine, to the great generals who have come out victorious in the battles against disease and against the scourges to which I have referred. We never hear of any national or international rejoicings to celebrate the victories of men like Jenner and Lister, or of the numerous lesser lights, who have done more for this country and for humanity in general, and have covered themselves with more glory and honour than could have been attained by the carrying out of any great military operations. The one type of glory is always associated with destruction of life and health and with misery, privation, and international jealousy; the other is inseparable from what is universally benign and from factors which have to do with the salvation of life and health, and they are also inseparable from those bearing upon the subject which more immediately interests me at the moment, namely, the preservation of physical good looks and beauty. Just as disease has a destroying effect upon beauty, so medicine has exerted its influence in the way of its preservation. Deformity, using the word in its broadest sense, is almost invariably the result of disease, and when a person is deformed, whether in mind, feature, body or limb, his or her chances in life are lessened, sometimes on grounds of diminished physical

utility, but not infrequently simply because beauty is an important asset, the admiration and appreciation of the beautiful being an inborn attribute of humanity. Medicine has done a great deal in the past to preserve good looks. Nowadays, for instance, we regard with some curiosity the face of a man or woman which is pitted by small-pox, and we truthfully ascribe it to some careless or foolish neglect of vaccination. Some of us, however, remember the time when a large proportion of the older people whom we knew in the days of our childhood were more or less scarred by that disease—those who were children in the early vaccination or prevaccination days, and who had run the gauntlet of the small-pox in their childhood. Everybody had to run the risk of it then, just as the children of to-day almost invariably get measles. After the Vaccination Acts small-pox became rare among children, and the scarred faces were mainly seen among the adults who had had it in the prevaccination days. That generation having passed away, their protected children grew up and took their places with unblemished faces, and we, the great-grandchildren of that scarred and pitted ancestry, are hardly able to realize the state of affairs which existed in the former days. The whole human world owes much of its retained facial beauty to Jenner, and we little appreciate to-day the number of people whose features have been saved and their good looks preserved through vaccination.

Disease has always taken an important place in history, fiction, philosophy, and poetry, and it is not surprising that the small-pox which raged periodically in the country should have figured largely in these branches. It was a factor which entered into everybody's calculations, because it spared no class of society, and was an important cause of death as well as of deformity. It was sometimes spoken of as a murderous disease. You will recollect that Mary, the wife of William of Orange, succumbed to it, and its importance on account of its fatality may be estimated by the fact that in comparatively recent times nobody would have been accepted for life insurance who had not either had the small-pox or been vaccinated, and to-day every insurance inquiry form requires information on this point.

We have an example of its introduction into fiction in Esther's narrative in *Bleak House*, where Dickens so graphically describes Esther's recovery from small-pox—her gradual restoration to health and the returning sight and strength; then the pathetic recognition that the room had been changed; the looking-glass gone; how Charley, when Esther asked about it, "making as if she had forgotten something, went into the next room and was heard to sob there." Then the bravery of Esther when she realized that her beauty had gone for ever, and that the course of her life was thereby possibly changed for ever.

This change from beauty has been the almost invariable theme of the novelist and of the philosopher in connexion with small-pox; the latter, at all events, has made it the circumstance whereby some finer qualities of mind were eventually developed or brought out. This is exemplified in the "Consolation Offered to a Beauty Destroyed by the Small-pox," written by Steele in the *Spectator* dated Wednesday, February 20th, 1711—just over two hundred years ago. Parthenissa has written a letter in which she says "This face which (according to many epistles which I have by me) was the seat of all that was beautiful in woman, is now disfigured with scars." Steele first of all reproves her for having thought so much of her beauty, and then proceeds to comfort her by saying that beauties generally speaking are the most impertinent and disagreeable of women. He says:

Ask any of the husbands of great beauties, and they will tell you that they hate their wives nine hours out of every day they pass together. . . . They pray at public devotions as they are beauties—they converse on ordinary occasions as they are beauties. Ask Belinda what it is o'clock, and she is at a stand whether so great a beauty should answer you. In a word, I think, instead of offering to administer consolation to Parthenissa, I should congratulate her on her metamorphosis; and, however she may think she was not the least insolent in the prosperity of her charms, she was enough so to find she may make herself a much more agreeable person in her present adversity. . . . Good nature will always supply the absence of beauty, but beauty cannot long supply the absence of good nature.

Steele's consolation was very well in its way for one

* Read at the Liverpool Medical Institution, May 2nd, 1912.

who, having possessed beauty, had lost it, but I am sure that all will agree that beauty and insolence are not so inseparable, and that good qualities are sufficiently often associated with goodly appearances to make their retention well worth while. I doubt very much whether loss of beauty would always have the effect of removing or abating disagreeable points in character: indeed, it is probable that it might sour the temper. It is proverbial, for instance, that the hunchback tends to be an ill-tempered and disagreeable type of person.

So much for the small-pox. Let us be thankful that it no longer disfigures us as a nation, and let us pray and hope that no foolhardy measures will ever make it optional whether our children be protected from it or not. There is no greater danger to the people than the anti-vaccination agitator, for we owe it to our children that their good looks as well as their lives be preserved, even if the law insists upon it.

Apart altogether from epidemic diseases such as the one just referred to, there are a large number of other conditions which affect the child and lead to lasting structural defects of one kind or another. These, if they do not give rise to actual physical deformity, occasion more or less chronic ill health which, in itself, detracts from what would have been normal physical and mental character. Beauty is a corollary of health, and health is the expression of physiological perfection and fitness. During the past thirty years public opinion has undergone a most extraordinary change with reference to the importance which is to be attached to the proper care of the child. The time was when the young and inexperienced doctor was thought to be good enough to look after the children of a household, and they were also sent to less expensive dentists than those employed for the grown-ups. By degrees it has become realized that many of the chronic troubles of men and women—indeed, one may say a great deal of their lack of capacity for undertaking the duties of life—have resulted from ignorance concerning the care which might have been accorded to them during their childhood. It was an appreciation of this fact among others which led to the establishment of the Royal Liverpool Country Hospital for Children, which has done and is doing so much to grapple with those troubles which give rise to permanent crippling and ill health, and the same principle has, no doubt, led to the establishment of all of those school clinics and medical inspections which are becoming an essential part of the administration of every child's life. Every one will agree that a person who is normally good looking, whether child or adult, loses his or her attractiveness when the normal curves and lines of beauty are disturbed by disease. I shall presently refer to some of the ways in which nutritional disturbances and the misuse or disuse of physiological function give rise to changes which detract from beauty; but, in addition to these, there are a large number of ailments more especially affecting children which not only immediately influence their appearances but give rise to lasting defects and deformities. Apart altogether from its aesthetic aspects, there are in this connexion few questions in social economics which are more worthy of attention than the care and treatment of the child. If taken early enough, its disease may be arrested before much damage has been effected; and, on the other hand, even if organic changes have taken place, by suitable treatment crippling and deformity may be minimized, and the less the amount of crippling the greater will be the wage-earning capacity of the future man or woman, and the less will he or she be likely to drift into the workhouse, or to become indigent and dependent upon charity. On this account, if for no other reason, the subject is important. At the moment, however, I cannot deal with this aspect of the question, my purpose being simply to speak of the influences which have to do with the preservation of beauty.

Civilization is a factor which is no doubt responsible for some of the defects and deformities to which I shall presently refer. In the lower animals instinct forms a guide which leads them to functionate naturally, but in our case instinct has been lost, and our methods of bringing up the child are so artificial that structural changes take place simply from want of proper regard for the carrying out of physiological principles. Nature, while resenting overwork, requires, nevertheless, the

exercise of function for the maintenance of physiological soundness, and habitual desuetude engenders atrophy, and atrophy may in its turn lead to loss of vitality and consequent disease.

For many years I have been interested in the condition of the teeth of children, and there is no part of the body to which the above statements are more apposite, and since the teeth are so essential to goodly appearance and to the well-being of the individual, I propose to say a few words concerning them.

When visiting the museum of the Royal College of Surgeons in London a year ago, I was privileged to attend a demonstration by Professor Keith, who, among other things, showed us the celebrated Gibraltar skull, which is said to be 500,000 years old. One of the points which struck me concerning it was the regularity of the teeth and the straightness with which they were set up in the jaws. This is a characteristic which is noticeable in most of the skulls of primitive people whether they be those of children or of adults, and if we examine the teeth of the uncivilized races of to-day, those who live on more or less primitive lines, we find that the same principle holds good—namely, that they have good and regular teeth just as in the case of the lower animals whose teeth so comparatively seldom depart from the normal. They are squarely set in the jaws, the molars meeting crown to crown and articulating well when the jaws are closed. How does this compare with what we find in our modern civilization? Why, in nearly every child which has completed its second dentition we find that the molars, and especially the lower ones, have tumbled in towards the middle line, so that when the jaws are closed the outer edges of the crowns alone come in contact and the grinding surfaces never come near each other. It is not uncommon to find this deformity so excessive that the crowns of the upper teeth actually overlap and articulate with the outer surfaces of the lower ones, in which event decay is nearly always very marked.

I will guarantee that nine out of every ten children whom we examine present this deformity to a greater or less extent, and in many cases the incisors are similarly affected. Professor Keith has been kind enough to confirm what I have said as to the regularity and straightness of the teeth in the Gibraltar skull, and he has also informed me that this "edge to edge" or "overlapping bite . . . only became common some centuries after the arrival of the Anglo-Saxons." Associated with this deformity in the teeth is a loss of vitality in them and the consequent infective necrosis which so often begins in the six-year-old molar and then spreads to other teeth. When a person has a beautiful set of teeth free from decay, you will nearly always find that they are squarely set and with regularly opposing crowns. In old people who have retained their teeth this characteristic is almost invariably present; for instance, in an old lady of my acquaintance aged 94 who has never lost a tooth in her life, every upper molar articulates perfectly with its opposing fellow, and the axes of the teeth are quite perpendicular. Now, what is the meaning of this deformity? It is not due to rickets—of this I am satisfied because I have so often seen it in children who have never had a sign of that disease. It does not generally occur in the milk teeth, which are often quite good and regular as compared with the permanent ones which succeed them, and it would, therefore, seem to have something to do with the permanent ones or with the alveolar structures in which they grow during their period of development. Desuetude, atrophy, deformity, decay; that is the order of events, and why does it occur so commonly in the civilized child? Simply, I believe, because we do not give its grinders anything to do. Endless trouble is taken to educate mothers and those having the care of infants as to how babies should be fed. Our corporations introduce milk dispensaries, and there are other private philanthropies which take pains to teach mothers all about the feeding of their infants in such a way as not to violate physiological principles, and during the period of infancy, if these instructions are carried out, we get corresponding health, peace, and quietness. Then comes the period of early childhood, and we straightway forget that there are principles equally important to be observed then. A perverted instinct leads us in our mistaken kindness to forget the necessity for the exercise of physiological function, and we provide the child with every description

of softened starch, ground-up oatmeal, and other easily swallowed products (many of them even patented as being easily taken by a child) which go down with a gulp. We are under the impression, perhaps, that they are rendered more digestible by the softening process; the teeth are saved all trouble, no mastication is required of them, and correspondingly little salivation takes place, which incidentally accounts in a measure for the common amyloid dyspepsias of children. What wonder is there that the jaws atrophy and that the coming and developing teeth, which are no doubt influenced by the treatment accorded to their predecessors, as well as that to which they are themselves subjected, atrophy from disuse, topple over, and become easy victims to caries? Thus it will be observed that I associate this dental deformity and subsequent decay, and the starch indigestions, too, which are so common during childhood, with lack of function, and would advocate for its prevention the use of starchy foods which require to be thoroughly chewed and masticated if we are to preserve the teeth in a condition of beauty and soundness. These observations are not based upon mere theoretical grounds, but upon lessons learnt in connexion with inspections of industrial and reformatory schools which I have carried out from time to time. It is a notable circumstance that on the school ships, where the boys are fed upon the traditional ship's biscuits, this type of deformity is not nearly so prevalent as it is among children of the shore schools who are fed on soft starches. For many years, at one of the latter institutions, by my advice, the boys have had these biscuits added to their rations, and there is not the slightest doubt that both the tooth troubles and the dyspepsias have diminished; and, furthermore, there seems to be some evidence that dental deformities which had already taken place have to some extent become corrected since the harder food has been given. I am quite enthusiastic as to this (in my opinion) essential factor in the feeding of children, if we are to preserve their teeth and their digestions.

This disuse is not the only predisposing factor which has to do with the destruction of dental beauty, but it is one with which we are capable of dealing; and if people would only observe the necessity for exercising this common physiological function of the teeth, I feel convinced that not only the present health of the child would be preserved, but that many of those later troubles which are now known to result from dental caries, especially with reference to the digestive functions, might be prevented or mitigated.

Any nutritive disturbances in early childhood will interfere with the regular formation of the teeth, and will cause them to have a deficiency of enamel with thinning of the dentine. The bases of the teeth near to the gums may in such a case be thick and covered with enamel, whereas their bodies are thinned, discoloured, and deeply striated in a longitudinal direction with thickened transverse ridges, giving a very unwholesome and anything but beautiful appearance, more especially to the incisors. This type of trouble is often seen in cases of backward development or where there are congenital arrests of development, such as congenital heart disease, but they may also result from any prolonged illness, and even acute diseases such as pneumonia cause minor dental deformities. It is difficult to deal with this kind of trouble, but the possibility of an interference with the beauty of the teeth should act as an incentive to all parties concerned to shorten the course of chronic disease in early childhood with a view to the preservation of future good looks.

Endless trouble is taken by parents to avoid facial blemishes in their children, and medical men will adopt every measure to avoid operations on the face and neck which may leave ugly scars and marks; but we seldom regard constitutional disease in the young child from an aesthetic point of view, or think about the effects it may have upon its appearance in later life. In a disease like rickets, which causes immediate bony deformities of the limbs, the matter may be considered, but I doubt whether the remote effects are greatly thought about. Just think of the damage done to the features by this disease; how it deforms the brow and beaks the jaws, causing lasting changes in these visible parts, not to speak of the stunting of growth and other nutritional disturbances in the bones and muscles which it occasions. The lesson to be derived

from all of these troubles is that not nearly enough attention is directed towards the education of mothers as to how their children should be fed and dealt with after as well as during the period of infancy. A war should be waged against rickets and against all the faults in hygiene to which I have referred, not only on account of their immediate effects, but also because they are destroyers of the beauty of our childhood and of that of the after manhood and womanhood.

While thus advocating a careful education concerning diet and hygiene with reference to their importance in maintaining normal structure, it is just a question whether in some respects we do not overdo the hunting out of congenital defects some of which might with advantage be left alone if we regard them from an aesthetic point of view. I was present at a meeting last winter at which a large number of girls from 8 to 17 years of age were present and took part in some drill and other kindred displays. I could not help wondering whether all of the large proportion of them which wore spectacles really required them. I confess that I dislike to see children in spectacles and would personally prefer that they should tolerate some of the minor degrees of ocular defect, providing they cause no inconvenience, rather than have their faces disfigured with glasses, and it is not only the face but the whole attitude of the child which becomes altered by them. It walks differently and it runs differently when it wears these correctors of visual defect. I imagine that some of the deformities of the eye may be something like those of the feet inasmuch that every case may not need active attention. I regard with remorse the number of useful men and boys who are kept out of the services on account of flat feet, for instance, which is in many cases static and harmless, but which through being a technical flaw disqualifies the candidates. My experience of Volunteer and Territorial work has taught me this lesson, for one knows of plenty of men whose feet were flat as flat could be who have done long and trying marches without experiencing any inconvenience. So, with the eye, there are surely physiological or anatomical defects which cause little trouble and are compensated for by nature. I would go so far as to say that there are certain types of short-sightedness which rather add to the attractiveness of a girl, and if they cause no practical inconvenience or nervous disturbances, why interfere with them, and by mounting her in spectacles constitute a life-long disfigurement? On this account, I do hope that the enthusiasm of the school medical officers will not lead them to attempt to deal with every case which does not come up to a standard of visual perfection.

During a meeting of the workers of the Invalid Children's Association in Liverpool a number of the members visited the Royal Liverpool Country Hospital for Children at Heswall, an institution in which the patients are treated entirely in the open air. A lady whom I was talking round the wards exclaimed, "What handsome children you have in this part of the world!" and these children, although they are all of them suffering from diseases of one kind or another, certainly do look handsome, but this is not because they are more beautiful than other children, it is simply due to the fact that they are living in conditions which tend to bring out their good looks. The beauty of the child depends, like many other things appertaining to it, upon its environment. It fades when in unwholesome surroundings, where worry, improper feeding, unrest, and uncleanness influence it on the one hand, and the unrefining influences of clamour, filth and degrading language, drunkenness and vice, exist on the other hand. I do not say that these conditions prevail in every case, but every sick child which is in poor circumstances is in an environment of unrest, using that term in a broad sense, which tells upon its nutrition and upon its nervous system, and the secret of the good looks of the children to which this lady referred is the fact that in the hospital these conditions of unrest are absent, and that the nutritional conditions are at their highest; the sunlight and the constant fresh air stimulate metabolism, with the result that they put on weight in an extraordinary way, the normal curves of beauty take the place of pinched and hard lines and of the bony prominences and angles which exist in any condition of wasting; the proportions which the various parts of the body normally bear to one another, so essential to grace

and perfection of conformity, become restored, with the result that many a child which appears to be plain when it comes to the hospital becomes positively good-looking in a very short time. Any painful disease or any condition of chronic disease alters the features perhaps permanently, and so do any conditions which cause irritability of temper, in itself a common enough symptom of disease, and the handsomeness of the children which was noted simply depended upon the fact that with improved health comes grace of posture and of action and of movement; beauty of expression and of colour; brightness of the eyes and alertness of mind—all characteristics of a well-conditioned and attractive child.

As I have already said, beauty is a corollary of health, and the restoration to health with the minimum amount of crippling or deformity—whether it be of lung, heart, abdominal organ, or of the limbs—involves an economy not only respecting the future wage-earning capacity of the individual, but it also enhances his chances of obtaining, as well as of retaining work. On this account, the early recognition and treatment of disease means not only a great advantage to the patients inasmuch that they recover with less detriment to their appearances and capabilities, but also to the public, who provide the funds for maintaining the hospitals, and to the associations and institutions which undertake the care of invalid children, because, by getting the cases early the periods of treatment can often be shortened and the amount of expense in any given case is consequently lessened; last, but not least, it is an advantage to the taxpayer, who will certainly have to look after the child when it grows up if it is badly damaged. When the advanced cases present themselves, of course we have to look after them just as carefully, but they take longer to mend and the amount of deformity and of crippling which they sustain is likely to be correspondingly marked. Never, therefore, should we pass lightly over the case of a child which is showing early signs of invalidism, or because it does not appear to be seriously ill. If we could only get hold of these cases early and train such organizations as the Invalid Children's Associations to recognize them, and by bringing them under suitable treatment prevent the advance of their disorders, we might save an immense amount of suffering and of anxiety and of money, too, not to speak of the preservation of goodly appearance, which is such a valuable asset to the individual mainly concerned.

Much experience has now been gained by the treatment of diseased children in open-air wards, and there is not the slightest doubt that the processes of repair are greatly aided by the therapeutic influence of fresh air which is one of the most powerful allies of the doctor. It is remarkable that, like the processes of repair, those of growth are correspondingly stimulated by it. The cellular environment (which I have referred to in another paper) is improved, with the result that children who have been backward brighten up, and their mental activities improve *pari passu* with the restoration of their bodies. This fact indicates that it is not only the diseased child who should have this kind of treatment in the open air. There are thousands of children whose cellular environment is indifferent. The vitality of their cells is consequently lowered, and they are on the verge of disease. Advantage should be taken of these open-air methods of raising the cellular vitality and resistance for all of these. Every school should be a sanatorium, or, using the word in its proper sense, a preventorium, and with proper appliances such open-air class-rooms could be used both summer and winter with great advantage to the children both physically and mentally. At one of the industrial schools in Liverpool this system has, by my desire, been experimented with, and the teachers themselves have become convinced of the benefits which accrue from taking the children out of the closed schoolroom.

Do not let us regard the actually diseased child as the only one who is to reap the benefit of this beneficent measure. Liverpool has pioneered the method of treating diseased children in the splendid open-air hospital at Heswall, and it is earnestly to be hoped that other towns will follow her example, and that the principle of giving healthy children, and especially the indifferently healthy ones, the advantages of open-air education will become generally accepted. The results will manifest themselves not only in the improvement and maintenance of their

healths and sharpening of their wits, but it will also be found that the spread of tuberculosis and of infectious diseases will be minimized, so that as a preventive measure it is to be recommended, if for no other reason.

The idea of open-air schools comes in very timely association with the improved sanitary conditions which have been carried out by our health authorities with reference to insanitary dwellings, and in connexion with it should come a vigorous educational campaign having for its object the teaching of the people that open air is as necessary for the child at home as it is elsewhere. The child is the most valuable possession of the nation. Much money is expended upon it, which is wasted if it becomes diseased or crippled, or if it dies, as so often happens just at the period when childhood terminates. Its educational birthright is recognized and provided for; but that equal claim which it has—to be brought up decently, to be protected from disease and deformity, and taught how to protect itself in the future, also needs to be regarded; and the factors which influence the cellular environment, of which fresh air is one of prime importance, must be remembered and duly utilized.

In conclusion, let me once more direct attention to the fact that beauty is a corollary of health, and just as the wiping out of small-pox has done so much to preserve the beauty of the race, in like manner attention to the treatment of those diseases which tend to promote permanent organic changes and deformities and crippings, added to appropriate measures being taken for their prevention, will do much to further this aesthetic aspect of the work of the medical man, and of the work of those organizations which are doing such magnificent service in the way of helping suffering childhood.

HENOCH'S PURPURA WITH INTUSSUSCEPTION: LAPAROTOMY: RECOVERY.

BY

SEYMOUR BARLING, M.S., F.R.C.S.,
ASSISTANT SURGEON, GENERAL HOSPITAL, BIRMINGHAM.

THE occasional complication of a case of Henoch's purpura by the occurrence of an intussusception has been recognized for some years, yet the cases are of sufficient rarity to make the following worthy of record:

The patient, a boy aged 4, was brought to the out-patient department of the General Hospital by his mother; she stated that he had always been rather a delicate child with a poor appetite, and that for the last twelve months he had suffered from stomach-ache and frequent attacks of sickness. Three weeks before admission the attacks of abdominal pain and sickness became more noticeable, and were accompanied by a rash which appeared on the buttocks, and then spread to the limbs; the rash at first was definitely urticarial, the spots being raised above the surface and about the size of a shilling; these spots soon became haemorrhagic. On one occasion the mother noticed a small amount of blood in the motion. The rash faded, but fresh crops came out of a similar nature, the spots, however, being smaller. The child gradually improved, but at the end of three weeks, on the evening before admission, he had a sudden violent attack of abdominal pain, worse than anything he had ever experienced previously; he was sick, and almost immediately dark fluid blood was passed from the bowel. These symptoms of violent pain, sickness, and haemorrhage from the bowel continued intermittently throughout the night, but abated somewhat on the morning of admission. He was seen by his doctor six hours after the attack had started; examination of the abdomen, on the suspicion of an intussusception being present, failed to reveal a tumour.

On admission, twenty hours after the onset of pain, the child was pale and quiet, pulse 128, temperature normal; the belly was soft, and an irregular trilobed tumour could be felt lying somewhat transversely in the epigastrium, and apparently somewhat movable on respiration. Per rectum nothing could be felt; dark fluid blood, however, escaped on removing the finger from the bowel. The urine contained a light cloud of albumen, but gave no reaction to guaiacum. On the knees and ankles, and on the forearms, especially in the neighbourhood of the elbows, there was a slightly raised papular rash, some of the papules showing old haemorrhage.

Operation Immediately after Admission.

A median incision above the umbilicus revealed a large dark tumour lying more or less transversely across the abdomen; owing to the force with which the invaginated bowel had been thrust into the lumen of the colon, the latter had become bent on itself, giving the trilobed appearance which had been noticed on examination. The tumour was about 10 in. in length, and

the apex of the intussusception was in the upper part of the descending colon. The distal half of the swelling reduced quite easily; the proximal 4 in., however, required some twenty minutes' manipulation before the invaginated bowel could be freed, and in effecting this reduction the peritoneal coat of the ascending colon tore. This residual part of the tumour consisted of the ascending colon, containing the caput caeci, the appendix, and some 18 in. of the lower end of the ileum—these were expressed in turn. The appendix, caecum, and the ileum that had been involved in the intussusception showed extensive interstitial haemorrhage, and some inches of small bowel were black and apparently gangrenous. The part of the ileum above the obstructed portion was distended for some distance by dark blood-stained fluid lying in its lumen. The gangrenous portion of bowel, together with some inches on the proximal and distal sides of it, was excised, about 12 in. in all being removed, the open ends of the bowel crushed and tarred in, and the continuity of the gut established by a lateral anastomosis between the ileum and the lower part of the ascending colon.

The patient suffered much from shock, and was very restless for the first forty-eight hours, but after that made satisfactory progress with the exception of some superficial suppuration in the wound.

The piece of bowel removed was the lowest 12 in. of the ileum; the portion next the ileo-caecal valve was gangrenous for some 4 or 5 in.; above this were two short segments, each about 2 in. long, with thickened walls, and separated by a portion of bowel quite normal in appearance. On section through the thickened segments it is seen that the bowel wall is infiltrated with blood, and measures nearly a quarter of an inch from the peritoneal to the mucous surface. Such interstitial haemorrhages are common in Henoch's purpura, and the lowest part of the ileum is a frequent site of election; it is probable that these localized haemorrhages are the usual cause of the intussusception that sometimes arises in the course of the disease.

Henoch¹ in 1874 collected a number of cases of purpura associated with vomiting, colic, and intestinal haemorrhage, and sometimes accompanied by effusion into and around the joints. Since his description this symptom group has been generally known by his name. Osler,² however, refers these cases into a larger class under the name of "erythema exudativum multiforme," including under this name cases presenting widely different manifestations in the skin, the viscera, and occasionally the joints. The skin lesions are polymorphic, and urticaria and purpura of all degrees of severity may be found. The visceral manifestations may take the form of gastrointestinal crises, endocarditis, pericarditis, or acute nephritis; bleeding is common from the mucous surfaces of the nose, mouth, stomach, and bowel.

A feature of the disease is recurrence, and successive attacks may occur at intervals for many years. In these attacks one or other type of symptoms may predominate; thus, skin symptoms may be very slight or absent, with the presence of severe visceral manifestations. Such cases often present great diagnostic difficulties, until the onset of some skin or joint lesion or the history of their presence in previous attacks throws light on the deeper trouble.

Henoch's purpura presents a double problem to the surgeon. In the first place the attack often simulates an intussusception closely, and secondly, an intussusception may arise in the course of an attack of purpura.

The numerous operations that have been performed in cases of Henoch's purpura in the belief that an intussusception was present amply testify to the difficulties of a differential diagnosis. Such cases, for instance, are recorded by Burrows,³ Sutherland,⁴ and Fitzwilliams.⁵

The difficulty is especially likely to occur in those cases presenting little or no external manifestation of the purpuric condition. Such cases are by no means uncommon. In some a few purpuric spots may be found after careful search; in other cases, such as the one recorded by Theodore Fisher,⁶ no skin lesion appeared from the beginning to the end of the case, which ended fatally.

Arthritis is frequently but not invariably found; it takes the form of an intra- or peri-articular effusion, and especially affects the tendon sheaths around the joints; the affected joint is swollen and tender, but may be but little painful on movement.

The symptoms of intermittent colicky pain—vomiting and blood per anum—are met with in both intussusception and Henoch's purpura, and there is really nothing distinctive about them which will help to differentiate the

two conditions. The presence, however, of blood in the vomit is very suggestive, being very commonly present in Henoch's purpura, and never in my experience in intussusception.

The age of the patient may help to distinguish between the two conditions. Henoch's purpura may occur at all ages, but seems commonest in childhood; I can find no case recorded under the age of 3. Intussusception, on the other hand, in something like 70 per cent. of cases occurs in infants of under 12 months. In suspicious cases careful inquiry may elicit a past history of joint pains or swellings, of slight outbreaks of purpuric or urticarial eruption, the tendency to recurrence in one or other of its manifold forms being a most marked characteristic of Henoch's purpura.

An examination of the urine should not be omitted, and may show the presence of casts or a few red blood corpuscles in the purpuric cases. Out of eleven cases recorded by Osler, five showed evidence of nephritis of greater or less extent.

The local signs in the abdomen are of great importance in making a differential diagnosis. In intussusception during the first twenty-four hours the belly wall is commonly flaccid, mobile, and not tender in the intervals between the attacks of pain, becoming hard and fixed when the child writhes under an attack of colic. In Henoch's purpura the condition of the abdominal wall often presents exactly similar features; not infrequently, however, the belly is distended, tender, or rigid from the onset of the illness, a condition almost unknown in intussusception. Amongst the local signs of intussusception the presence of the characteristic sausage-shaped tumour, lying usually on the arc of a circle with its centre at the umbilicus, can generally be found. Cases in which an intussusception is suspected, but in which no tumour is felt, should always be examined with anaesthesia; under these circumstances, in my own experience, not more than one in twenty will fail to exhibit the typical tumour. A tumour may be present in Henoch's purpura, being caused by haemorrhage into the mesentery (Lett⁷), a coagulum lying in the lumen of the bowel (Fitzwilliams⁵), or a massive interstitial haemorrhage into the bowel wall (Grieg⁸); and though such tumours will usually lack the characteristic shape and feel of an intussusception tumour, yet it is evident that occasionally the similarity may be so great as to lead to laparotomy being performed, as in Grieg's case. To sum up: When purpuric manifestations in the skin or joints are absent, the most important points in making a differential diagnosis between the two conditions are a reliable history, a careful examination of the urine, and the presence or absence of the characteristic lump in the abdomen when examined, if necessary, under anaesthesia.

With regard to the second point, the onset of an intussusception in the course of an attack of Henoch's purpura such as occurred in the above case, several instances have been recorded, of which Lett's⁷ is one of the most interesting. Here, after the successful reduction of one intussusception by operation, a second occurred four days later, leading to death of the patient. In numbers of cases haemorrhage has been demonstrated as present in the bowel wall in Henoch's purpura, usually in the lower end of the ileum. Whether this is always the cause of the intense colic is uncertain, but it seems probable. That it is the exciting cause of the intussusception in these cases there is little doubt—the tumour thus formed and the nodal interruption of the peristaltic wave that must be produced by the local paresis of the bowel wall would form just the conditions likely to produce an intussusception.

In the case I record above it is probable that the intussusception occurred with the onset of the violent pain twenty hours before operation; it is not likely that the bowel would have become so badly damaged in a shorter space of time, and although no lump was felt six hours after the onset of the pain I think it probable that invagination had already commenced, but the tumour could not be detected until it had reached a larger size. In this case the diagnosis was made easier, as the purpuric symptoms had subsided somewhat, so that the sudden access of pain followed by the presence of a lump when I saw the child, made diagnosis easy.

When, however, the acute colic of Henoch's purpura causes an intussusception to arise in the middle of an

attack, it is on the characteristic appearance of the tumour alone that a provisional diagnosis can be made, and Lett's dietum is that the appearance of this lump during an attack of Henoch's purpura resembling an intussusception justifies exploration. The discovery of an intussusception after death is a disaster, but it must not be forgotten, in considering the question of exploratory operation during an attack of purpura, that it is not without its especial risks; the wound may show a tendency to slough, or uncontrollable oozing may occur from it, and ultimately prove fatal, as in the case mentioned by Fitzwilliams.⁵ The recognition of this liability to intussusception, the careful and frequent examination of the abdomen, and, if necessary, the administration of an anaesthetic if rigidity or distension of the abdomen make proper examination otherwise impossible, are the only means by which the condition will be recognized sufficiently early to render operation effectual.

I have to thank Mr. Gilbert Barling, into whose ward the patient was admitted, for permission to publish this case.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

HYSTERIA IN A LAD.

At 11 a.m. one day a lad, aged 17, cut a piece of flesh (the size of a threepenny-piece) out of the inner side of the terminal phalanx of his left index finger when cutting off the leaves of a mangold with his pocket knife. The daughter of his employer washed the wound and dressed it with boracic ointment. He went on with his work, and appeared in his normal health during the afternoon. At 5 o'clock his employer found him leaning against the wall of his yard in a "fainting" condition. He helped him indoors and laid him on a couch.

I saw him at 7.30 p.m., and found him unconscious and very restless; the pulse was rapid and very weak; his extremities were cold. I could not get a clear history, and, thinking that he was suffering from loss of blood, I gave him a hypodermic injection of strychnine ($\frac{1}{10}$ grain) and applied hot bricks to his feet and axillae. His restlessness soon increased, and there began some violent clonic movements of his arms and legs, and twice he got into a position of slight opisthotonos. I then gave him a hypodermic injection of morphine ($\frac{1}{8}$ grain) and atropine ($\frac{1}{10}$ grain). The rigor-like movements continued, sometimes in one limb, sometimes in all. He would twist his body from one side to the other, so that he had to be prevented from falling off the couch. At no time did he have any tonic spasms. The pupils were rather dilated and reacted readily. Breathing was normal. He had not vomited, nor passed urine nor faeces, nor bitten his tongue. The temperature was 98.2°; the knee-jerks appeared normal. There was no mark nor contusion on his head nor was there any history of his having fallen down. The extremities soon became warm and the pulse full and strong.

At 11.30 p.m. he seemed much better and asked for a glass of milk, which he drank. In answer to inquiries, he said he felt quite well; his finger did not pain him, and he remembered nothing of his attack. At 2 a.m. he relapsed again and was, I am told, more violent in his movements. At 6 a.m. he became quite normal for twenty minutes, after which he relapsed again. At 10 a.m. he again became normal and walked across the room to the night-stool, where he passed about one pint of high coloured urine.

When I saw him at 11 a.m. he was again unconscious, with occasional clonic movements of the limbs and restless movements of the body. He often clutched his injured finger with the other hand. The lungs, heart, and abdomen appeared normal; the temperature was

98° F. and pulse 64. I dressed his finger again. It was looking very healthy.

For the next four days he was, for the most part, in this unconscious state, but woke up from time to time to ask for food. His bowels were open after castor oil, and he passed his urine only once a day. After the first day he could be partially roused if shouted at. The temperature varied from the first between 98° F. and 98.4° F., and the pulse never quickened above 80. Each attack grew less severe. On the fourth day of his illness, when his attendant was asleep in a chair, he got up and went into the next room to the night-stool. In his lucid moments he talked rationally, complained of nothing, and remembered nothing of his attacks. His finger healed rapidly, and on the sixth day he walked outside to a van and was driven home.

In appearance he was a healthy looking fellow. He had had no previous severe illness. His younger brother, however, I am told, is very nervous and faints if he cuts or scratches his finger. His parents are healthy, but quick tempered.

From the second day I considered his attacks to be functional and treated him by suggestion. I think the family history of nervous instability, the history of the case, and the absence of signs of any organic disease confirm my diagnosis.

RICHARD C. C. CLAY, M.R.C.S., L.R.C.P.

Fovani, Salisbury.

A CASE OF PETROL INTOXICATION.

The minor effects of petrol fumes are well known—headache, sickness, giddiness, etc. These pass off quickly, and no bad result follows, but the following case nearly proved fatal.

P. S., aged 16, apprentice to a firm of electrical and motor engineers, was sent to clean out the pit of a private garage, the car being outside. He was called for to do something, and, not answering, was found crouched up in an angle of the pit. He was lifted out and laid in the open air, and shortly afterwards vomited violently, staggered up, seized the brush he had been using to sweep the pit, and was with difficulty prevented from continuing his work. He then became unconscious again, and was taken home (about two miles) in the car.

When I saw him, immediately on arrival, he was unconscious with shallow breathing, a weak, thready pulse, marked inward strabismus, and contracted pupils. No light reflex was present. His lips were a bright red and his cheeks flushed. He was cold and his teeth chattered, but there was no distinct rigor. The knee-jerks and other reactions were absent, nor had he any sensory reactions. His clothing smelt very strongly of petrol and his general condition was bad. The respirations, though shallow, were regular, and, as it was noticed that his pulse was slowly improving, artificial respiration was not used.

Three hours after being found he answered questions if aroused; he complained of intense headache and of a pain in his stomach. The reflexes were still absent, but the strabismus was not quite so marked. He also began to turn over and to adopt a sleepy expression and attitude. Throughout the night he slept well and quietly.

Next morning he could not remember much. He said something made him cough badly directly he stooped down in the pit. Then he thought he slipped and fell. He remembered being sick. I do not doubt that very little more of "the gas" would have been fatal. The time which elapsed between his going into the pit and being found cannot be accurately fixed, but, so far as can be judged, it was not more than about three minutes and a half at the outside.

MEDICAL AND SURGICAL PRACTICE IN HOSPITALS AND ASYLUMS.

WEST SUFFOLK GENERAL HOSPITAL, BURY ST. EDMUNDS.

A CASE OF KAPOSI'S DISEASE.

(By J. R. HAYMAN, M.R.C.S., L.R.C.P., Resident Medical Officer.)

Kaposi's disease, or xeroderma pigmentosum, was first described by Kaposi in 1870. Since then about eighty cases have been recorded. The present instance of the disease was in a man, aged 27, who had worked as a farm labourer. His family history was good, and there was no consanguinity of his parents.

His brother, aged 30, suffered from freckles on the face for the last twenty years, but there was no tendency to ulceration.

The history given by the patient of his illness is as follows:

When 2 years old he had several fits, after which it was noticed that his skin became dark. Freckles then appeared on his face and the back of his hands. No further change took place until he was 10 years old, when he developed a cutaneous ulcer over the left lower eyelid and a second over the infraorbital region. He was taken to the West Suffolk General Hospital. The ulcers were curetted, and the one over the eyelid healed up completely but the other only slightly improved.

Since then he has been in this hospital on seven different occasions for periods varying from five weeks to three months. Ulceration occurred over the bridge of the nose, the right lower eyelid, the right tragus, and the depression between the angle of the jaw and right mastoid process and the lower lip. The treatment on each occasion was by curetting. In addition he was treated in 1907 with Finsen light and x rays. All the ulcers healed except one over the left maxilla, one over the right tragus, and one over the right half of the lower lip.

The patient was last admitted in October, 1912. Previous to this he had not been treated for five years. His condition on admission was as follows: There were freckles and deep pigmentation over the face, scalp, neck, back, the front of the legs, the outer side of the upper arms, the forearms, and the back of the hands. The freckles varied in colour from light brown to very dark. At places they were confluent. The skin over the back of the hands was warty and nodular, and that over the face gave a dry parchment-like sensation. A few scattered telangiectases were present in the pigmented area. There were three ulcers on the face, one over the left maxilla measuring $1\frac{1}{2}$ by $1\frac{1}{2}$ in. Part of this was raised and fungating, and part of it excavated; the edges were not everted. It was fixed to the maxilla, and could be felt on the inner side of the cheek. It had been present for twelve years. The second ulcer was situated on the right side of the lower lip, and had been present for nine years. It measured $1\frac{1}{2}$ by $1\frac{1}{2}$ in., and was excavated. The third ulcer was situated on the right tragus, and had been present for many years. It measured $\frac{3}{4}$ in. across, and was covered by a scab; it discharged a little clear serous fluid. None of the ulcers showed any tendency to bleed, and only the infraorbital wound gave rise to any pain. The ulcers appear to have commenced as small warts, which broke down and ulcerated. There was ectropion of the lower eyelids. The conjunctivae were deeply congested, and adhesions were present between the ocular and palpebral portions at the lower fornices. Sight was not affected. The general health was good, and the patient took his food well. There was no evidence of any secondary infection. A simple blood count gave the following result: Erythrocytes 5,500,000, leucocytes 10,500, haemoglobin 95 per cent., haemoglobin index 1.1.

For the first two months after his last admission the patient was treated with x rays twice a week. Three minutes at each sitting was given to each of the three

ulcers; a simple dressing was applied. Arsenic was given internally. The ulcer over the left maxilla decreased slightly, but neither of the other two were affected.

On December 14th, 1912, the patient was anaesthetized and the ulcers of the cheek and lip curetted. Three weeks later the ulcers had become much reduced in size, that on the cheek measuring $\frac{3}{8}$ by $\frac{3}{8}$ in. and that on the lip $\frac{3}{8}$ by $\frac{3}{8}$ in., but ulceration had commenced on the upper lip and was rapidly extending.

On February 9th, 1913, the patient was again operated on. The ulcers of the cheek, upper and lower lips, and on the tragus were thoroughly curetted. The ulcer on the tragus was found to extend $\frac{1}{4}$ in. deep and that of the lower lip to have perforated the cheek.

At the present time all the wounds have much improved. The ulcers of the tragus and of the upper lip have entirely healed. That over the left maxilla has become reduced in size to $\frac{3}{8}$ by $\frac{1}{4}$ in. and that on the lower lip to $\frac{7}{8}$ by $\frac{1}{4}$ in. Unfortunately a fresh ulcer has commenced on the right side of the upper lip, and this will be curetted later. At present there is every prospect of the ulcers healing, but the ultimate prognosis of the case is unfavourable.

I am indebted to Dr. Hinnell for kindly permitting me to report this case.

British Medical Association.

CLINICAL AND SCIENTIFIC PROCEEDINGS.

SOUTHERN BRANCH: PORTSMOUTH DIVISION.

A CLINICAL meeting was held on March 5th, when Mr. BOSWORTH WRIGHT (Chairman) and twenty-one members were present.

Clinical Cases.

Dr. COLE-BAKER showed two cases of restoration of the nose by plastic operation, and also a case of dislocation of the scapula upwards and forwards, the origin of which was unknown. Dr. CRAWLEY showed a case of spastic nervous disease for diagnosis, a case of skin disease involving one side of the face, and a case of congenital total absence of the eyes, attributed by the mother to maternal impression. Dr. LEON showed a case of heart disease with multiple exostoses. Mr. RIBOUT showed three cases of frontal sinus empyema treated by a modification of Killian's operation.

Pathological Specimens.

Dr. BANKART showed hairs from a case of monilethrix, and read a communication on the pathology of the disease. Dr. KEY and Dr. LISTER WRIGHT showed specimens of salivary calculus. Mr. CHILDE showed a specimen of myeloid sarcoma of the left parietal bone, in which the gap in the dura mater left after removal of the tumour was filled by fascia lata taken from the thigh; he showed also a prostate removed from a patient aged 81 after thirty years of catheter life without aseptic precautions and without cystitis.

GLOUCESTERSHIRE BRANCH.

A GENERAL meeting of the Gloucestershire Branch was held at the Royal Infirmary, Gloucester, on March 20th, when the PRESIDENT was in the chair and sixteen members were present.

Cases.

Mr. FIRMIN CUTHBERT showed two cases after operation for talipes and acute osteomyelitis of the tibia respectively. Dr. FINLAY showed a case of progressive muscular dystrophy in a boy aged 9 years. Dr. GOSS gave the history of a case of malignant disease of the pancreas, and showed the specimen. Dr. WAYLAND ANCRUM read notes of the following cases: (1) Malignant disease of the ileo-caecal valve; (2) extreme dilatation of the caecum; (3) adhesion of bowel to the anterior abdominal wall, forming a false sac; it had caused periodic attacks of intestinal obstruction. Dr. KNIGHT showed a woman after partial removal of the lower jaw for osteo-sarcoma, and the growth removed.

Reports of Societies.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF MEDICINE.

Friday, February 28th, 1913.

Dr. J. O'CARROLL, President, in the Chair.

An Unusual Nervous Case.

Dr. PURSER showed a patient of Dr. O'Carroll for diagnosis, a male, 40, single, a harness-maker. He had suffered from gonorrhoea twenty years ago, but syphilis was denied, and Wassermann (blood) negative. Two years previously he had been attacked by sudden weakness and stiffness in the right thigh, recovering after hospital treatment. Six weeks later a similar condition occurred in the left thigh. Improvement was slow and incomplete. There was a gradual relapse to the weak condition of the right thigh. Now, he could only walk with the help of two sticks or a crutch. Five or six years ago he had pain, described as lumbago, lasting a few months. For two years or more he had pains in the legs, like the "lightning pains" of tabes. The cranial nerves were in all respects normal; no Argyll Robertson pupil; no optic atrophy. The upper extremities were normal; trunk showed zone of anaesthesia fifth to ninth dorsal segments, not absolutely complete; relative analgesia to pin-prick in a slightly wider band. Weakness and wasting in the muscles supplied by third and fourth lumbar roots were marked most especially in the right quadriceps, which two months ago appeared quite paralysed, but now showed some slight contraction. The muscular condition showed a tendency to improve. Besides the "lightning pains" referred to, there was slight anaesthesia to cotton-wool in both thighs and down inner aspect of legs. There was relative analgesia to pin-prick all over the lower extremities up to Poupart's ligament. Thermal sensation was normal, except in that "cold" was felt occasionally after stimulus had ceased. Muscle-pain sense was absolutely lost. Sense of position and of passive movement in toes and ankles less acute than normal. Compass test—4.5 cm. on soles. Knee-jerks and ankle-jerks were lost, but abdominal and plantar reflexes were normal. There was no splinter trouble at any time. Lumbar puncture repeatedly failed (and further attempts were not allowed), on account of deformity in the spine. X ray showed that the fourth lumbar vertebra was rotated around a vertical axis, so that the spine looked rather towards the right, and it was rotated also, so that the lower articular process on the right was on the same level as the upper articular process on the left. The intervertebral discs between the third and fifth lumbar vertebrae were apparently gone. The body of the fourth lumbar vertebra was small. There was no evidence of traumatism or tuberculosis. Dr. Purser submitted that though most of the motor symptoms could be explained by the spinal lesion, that lesion, being apparently mechanical in its action on the nerve roots, could not explain the sensory disturbances in the legs nor the anaesthesia around the trunk. He suggested a diagnosis of tabes dorsalis with spinal lesion (giving rise to the motor trouble) analogous to Charcot's disease in other joints, but admitted that it was not convincing. Dr. FINN said it was very hard to grasp the whole case with sufficient accuracy to be able to recognize the importance of the different phenomena presented. It seemed to be very compound, beginning with the motor paralysis of one muscle, partial or complete recovery from which was followed on the left side by a repetition from which the recovery was imperfect. The area of anaesthesia and analgesia were peculiar. The anaesthesia seemed to be in areas other than those supplied by the third and fourth lumbar roots. The physical deformity from which the patient suffered in the absence of an accident was unusual. The small amount of loss of tone shown in the case was against the tabes dorsalis diagnosis. He also suggested that the patient had not got the typical gait of locomotor ataxy. Dr. KIRKPATRICK referred to the fact that Dr. Purser explained the weakness in his patient's legs by a lesion in his anterior nerve roots (third and

fourth), and attributed his sensory phenomena to another disease altogether, but it seemed to him (Dr. Kirkpatrick) difficult to understand that he should have a lesion of his anterior nerve roots and no lesion of his posterior nerve roots. He was not in a position, however, to offer any other diagnosis, but in the absence of a specific history and of Argyll Robertson pupil there appeared to be a great deal of difficulty in accepting the diagnosis of locomotor ataxy. As to whether any such condition of the spinal column was found similar to Charcot's disease he could not say, but he pointed out that in Charcot's disease there was always considerable destruction of the joint, and he thought if the patient suffered from any such condition in his spinal column within recent years there would be some more evidence of it than a mere pain like lumbago. The explanation of the condition he considered very ingenious, but there seemed to him to be very much, if not more, against the acceptance of it than there was for it. The President endeavoured to give an easy explanation of the case. The man had a spinal disease with neuritis of his motor nerves and possibly ascending degeneration in the posterior column—pseudo-tabes dorsalis. The other mischief would be sufficiently accounted for by the compression of the sensory nerves.

The Coeliac Affection.

Dr. DRURY read a paper on a case of "the coeliac affection," the title under which Gee described the condition in 1888. A girl, aged 3½ years, had an apparently ordinary attack of diarrhoea, which, however, persisted and then three or four very bulky motions were passed in the twenty-four hours. These were like porridge, but white, sometimes frothy, and extremely fetid. There was no fever, but great lassitude, emaciation, and distension of the abdomen. No treatment was of any avail until the child was put on an almost pure meat diet, small pieces of thin, well-toasted bread being the only other food allowed her. Under this the stools soon became normal, and in a few weeks she began to regain her spirits and put on weight. The etiology of the condition was not known. Dr. FINN said that coeliac disease was so far free from all pathological definition, but the idea that it was a catarrh of the duodenum and upper ileum seemed to be the most likely. The condition was very rare, and in his long experience he had only a record of three cases. The first patient was a fine boy about 3 years old, said to be sweet-tempered, but more probably apathetic. His abdomen was doughy, his motions were as large as those of an adult, and he had several of them in the day. He would sit in whatever position he was put, and never ask to be removed, and he appeared to have difficulty in moving his lower limbs, but he was in no way paralysed. Smith's method of treatment was adopted, all milk was stopped, and a meat diet substituted. Recovery was very rapid, as it was only two or three months before the child got back to ordinary diet. Two other cases similarly treated also made satisfactory recoveries. He never met with a case in his hospital practice, and he wondered if the disease was peculiar to well-fed children. Dr. O'KELLY related the case of a fellow student. Whenever this young man took milk he invariably had a tendency to diarrhoea; the stools became white, and there was loss of flesh. When milk was discontinued the condition disappeared. Dr. CROFTON said the case was one of much interest to him, as he had come across others where the stools were white, and the treatment he adopted was to make a vaccine for the catarrh, and this generally cured it. He suggested that all cases of indigestion were due to micro-organisms, and reacted well to vaccine treatment. He inquired if any micro-organisms were discovered in Dr. Drury's case. Dr. CHILL agreed with Dr. Crofton that a vaccine would have done some good. Dr. NESBITT said that the character of the motions implied that the trouble was the defective digestion of the carbohydrates and fats, and treatment with pure protein would bear out this view. There might have been an absence of pancreatic secretions. Very full examination of the stools was absolutely essential, and not only would fat have to be looked for, but fatty acids. In regard to vaccine treatment he referred to the multiplicity of bacteria in the intestinal tract, and asked how the microbe that would cure this condition was going to be isolated. The President related an instance where a boy

aged 2½ years was not confined to bed, but presented a very curious picture, with a pink and white complexioned face, little thin legs supporting a huge, almost spherical body. At that age, and with a history of having been brought up on artificial food, he thought it was a case of rickets, but eventually the idea of getting a name for the condition was given up, and no information could be ascertained. The little patient was, however, put on a minced meat diet, much the same as that indicated by Dr. Finny, the meat being rubbed down and given on extremely thin toast and agreeably flavoured with currant jelly. On this treatment the child got well, but the treatment had to be renewed from time to time, as he took farinaceous food. He was afterwards called on to treat the child for tapeworm. This was the second case that he had seen of tapeworm following raw-meat treatment.

EDINBURGH OBSTETRICAL SOCIETY.

Wednesday, March 12th, 1913.

Dr. HAIG FERGUSON, President, in the Chair.

Intraperitoneal Haemorrhage from Ovary.

PROFESSOR KYNOCII (Dundee) read notes on an instance of this condition in a 5-para, aged 38. There had been irregular and painful menstruation ever since the birth of the last child, five and a half years ago, but amenorrhoea between September and December, 1912, then a show appeared for seven days, and a fortnight later a sanguineous discharge was noted; it lasted until January, 1913. There had been six attacks of abdominal pain, and when the patient was seen, symptoms of intraperitoneal haemorrhage were marked. The abdomen was opened and found full of blood which issued from a small ovarian blood cyst. There was no microscopic evidence of ovarian pregnancy. The patient recovered.

Subinvolution due to Persistent Corpus Luteum.

Dr. F. W. N. HAULTAIN showed an ovary with a large corpus luteum removed from a patient four months after labour. During pregnancy there had been severe pain on the corresponding side, and it continued after labour. Before the operation the uterus was markedly subinvolved and the blood showed 5,800,000 red and 19,200 white cells. Within a week after operation the reds were 4,875,000 and the whites 16,000. A few months later the uterus was of normal size. It was suggested that the subinvolution was dependent upon a non-disappearance of the corpus luteum of pregnancy.

Rare Uterine New Growths.

Dr. HAULTAIN reported three cases. In the first, a patient of 59 had a child at 30 and ceased menstruating at 45. Two years later bleeding returned and reappeared at intervals of eight to ten weeks. It was never severe till recently, when after curettage the mucous membrane was found to show a simple papillomatous change. As the bleeding continued hysterectomy was performed, when a diffuse hypertrophy of the mucosa was found. There was no malignancy. The second patient, 35 years old, was unmarried and virginal. On examination the cervix was seen to be the seat of a swelling in colour and shape like a large bramble. Examination of a small piece showed tubercle, and the cervix was removed by amputation. The patient was well sixteen years later. The third patient, 21 years old, had severe dysmenorrhoea, and, after removal, the uterus was found to be beset by a large number of fibrous nodules towards the mucous aspect. The author has called this condition "diffuse nodular fibrosis."

Perithelioma and Necrobiosis in Fibroids.

Dr. BARBOUR recorded two cases of fibroid where degeneration caused difficulty in diagnosis. A patient 62 years old underwent removal of a large sloughing fibroid polypus at the age of 55. Five years later the abdomen began to swell, ultimately reaching the size of a seven months pregnancy. On removal the uterus was found transformed into a cyst, on the wall of which a mass was present. It was, as the microscope showed, a fibroid undergoing peritheliomatous degeneration. In the second patient, 51 years old, a rapidly growing fibroid the size of an eight months pregnancy was removed for severe pain. The patient was gravely ill at the operation and died six days after. The tumour was necrobiotic and showed advanced red degeneration.

ROYAL SOCIETY OF MEDICINE.

SECTIONS OF OPHTHALMOLOGY AND NEUROLOGY.

Wednesday, March 12th, 1913.

Sir ANDERSON CRITCHETT, C.V.O., President, in the Chair.

Resumed Discussion on Disease of the Pituitary Body.

Dr. TURNEY discussed a case which he had shown at the last meeting. The symptoms referred mainly to the posterior lobe. The patient was a lady, aged 25, who, until 1907, showed no abnormality. Menstruation, previously regular, then ceased entirely. Her friends noted her increasing stoutness, and during the last two years bruises readily appeared, especially on the legs. There was also pain in the back, starting from a kyphotic curve in the upper dorsal region and travelling round the ribs. Mentally she seemed unaffected, and her sight remained good, except for the slight error of refraction to which she had always been subject. Thyroid extract had been administered repeatedly, but was given up as it caused palpitation. In spite of the obesity now present, her weight was now less than formerly; her face had become fat and florid, but there was no puffiness about the eyes. The hair was dry and somewhat scanty, but the eyebrows were present. The expression was bright, and the manner alert. The skin was not pigmented; the pubic and axillary hair was scanty. The upper limbs were of normal size, whilst the lower limbs and buttocks were thin. The thyroid was normal in size and consistency. No evidence of enlarged thymus, lymphatic glands, or spleen could be detected. X-ray examination showed absorption of posterior clinoid processes. There had never been increased intracranial pressure or involvement of the nervous system. In July, 1912, Mr. J. H. FISHER reported that the white, blue, and red fields were not transposed, and there was no certain evidence pointing to the probable development of temporal hemianopia. On recent examination, surrounding four-fifths of the right disc there was now a subretinal exudation of glistening character and ill-defined limits; no blood there except two or three very fine spots on the white area; otherwise each fundus was normal. The blood pressure on admission was 200 mm. of mercury, and it had remained at about that level ever since. There was a tendency to polycythaemia, without other blood changes. At one examination the red cells reached 8 million. A spontaneous fracture of the sternum, between the manubrium and the gladiolus occurred. The urine was normal, and there was no polyuria. The sugar tolerance limit was normal at about 120 grams of laevulose. Professor DIXON had examined the urine, and found it to contain a pressor substance in considerable quantity: 10 c.c.m. of the urine injected into a cat raised the blood pressure 70 or 80 mm., whereas a similar injection of normal urine would lower the blood pressure nearly to the base-line. Dr. Dixon added that this patient's urine contained one hundred times the pressor substance found in normal urine, and that it corresponded closely with the urines of cases he had examined of acromegaly. Extract of posterior lobe was given, at first subcutaneously, but this method had to be abandoned owing to the tendency to superficial necrosis. The patient showed no increased tolerance to carbohydrates. The presence of the pressor substance showed that the pituitary secretion was in excess. Dr. TURNEY discussed the case fully, his conclusion being that the patient had a pituitary-sexual-gland syndrome, the lesion being in the posterior lobe of the pituitary. A possible alternative was that there was a temporary failure of the element controlling carbohydrate metabolism. Professor DIXON reported his investigations in the case of a man subject to acromegaly for ten years. The patient had an enormous heart, without any rise of blood pressure. On injecting 1 c.c.m. of the urine into the cat, the blood pressure went up, and the injection of 5 c.c.m. caused it to rise to 80 mm. The active substance was urohypertensin. The man died suddenly as a result of some extra exertion. The pituitary body was as large as a walnut, and the heart weighed about 3 lb. Dr. A. E. GARROD gave a description of a case in which myxodema and acromegaly probably coexisted. The improvement under thyroid treatment left no doubt as to the thyroid defect. The evidence of acromegaly was less conclusive; a skiagram showed

enlargement of the sella turcica. Dr. WILLIAM HILL discussed the best route for operative treatment of pituitary tumour. He did not favour Cushing's method, preferring that used in submucous resection, followed by the short, though dangerous, further step. The chief danger was that of wounding the optic chiasma. Hirsch's operation was simpler than that of Cushing, and Dr. Hill, like Mr. Graham, found that it gave good access to the tumour. He gave a word of warning as to the dangers of the operation, especially without exhaustive preliminary study. Dr. LANGDON BROWN discussed the subject, and showed photographs of a case. Mr. RICHARDSON CROSS (Clifton) drew attention to the importance of the interrelation of the various glands of the body in the economy, particularly the ovaries, the testes, the pituitary, perineal, suprarenal, and thyroid bodies, and the thymus. He had found great benefit from the administration of thyroid and pituitary extracts. Dr. F. E. BATTEN and Dr. GRAINGER STEWART also took part in the debate.

SECTION OF LARYNGOLOGY.

AT the meeting on March 7th, the President (Mr. HERBERT TILLEY), who was in the chair, showed a larynx removed after death from *A patient aged 58, who had worn a tracheotomy tube for eighteen years.* The operation had been performed for dyspnoea due to the cords remaining in a position of adduction. Mr. T. W. P. LAWRENCE described the cricoid as congenitally deficient in the transverse diameter, and split by a gap filled in with a membrane continuous with that of the trachea. The rima was reduced by the consequent approach of the thyroid alae and the close apposition of the mesial surfaces of the arytenoids. The PRESIDENT considered that some inflammatory condition must have determined the late onset of dyspnoea at the age of 40. Sir FELIX SEMON read notes of a somewhat similar case. Mr. W. HOWARTH demonstrated *Killian's apparatus for suspension laryngoscopy*, with a thyroid depressor calculated to bring the anterior commissure into view. Mr. T. B. LAYTON suggested that it was more convenient to attach the "gallows" on the left side of the patient, as on one occasion he was compelled to perform tracheotomy during a "suspension" operation. Mr. E. B. WAGGETT commented on the fact that the important pyriform fossa came into excellent view by this method, which was also praised by Sir FELIX SEMON and the PRESIDENT in that both hands were freed from the irksome task of holding the laryngoscope in position. Dr. DAN MCKENZIE showed a man aged 56 in whom a *Laryngectomy had been performed fourteen days after tracheotomy.* The upper end of the trachea was closed with catgut sutures, and attached to the skin flaps. The transverse incision was left partly open and packed with gauze to absorb discharges. The tracheal sutures cut through in ten days; the patient now breathed through the gaping end of the trachea, which by this time was separated from the upper wound. All diseased teeth were previously extracted, and a feeding tube retained in the oesophagus for sixteen days. Sir ST. LAIR THOMSON commended the excellent result, but advised laryngotomy as a prelude to laryngectomies. Dr. D. R. PATERSON considered that the above operation was excellent for patients with a short neck, as the trachea was thereby anchored to the skin before laryngectomy was performed. Dr. DAN MCKENZIE exhibited a case in which *West's operation for obstructed nasal duct*, consequent on a previous operation for ethmoiditis, had been performed. A flap of mucous membrane was turned back from the middle nasal fossa. The lacrymal canal was then opened by a gouge and a communication made so that the lacrymal probe passed through the sac into the middle fossa. Dr. D. R. PATERSON stated that after West's operation patients could not conveniently use a handkerchief without pressure on the lacrymal sac. Von Eicken had opened the naso-lacrymal canal into the antrum. He had found that excision of the sac gave better results. Mr. T. JEFFERSON FAULDER exhibited a man, aged 21, with *Recurrent loss of voice.* The interarytenoid space was occupied by a papillomatous mass, yet it was uncertain if adduction of the cords was prevented by the presence of this growth or infiltration. The trouble was probably tuberculous. Mr. H. BARWELL considered that the tuberculous
