tumour could be removed by angular forceps. Mr. FAULDER also showed a *Nasal quadrilateral cartilage with a circular hole.* There was no deficiency in the mucous membrane. With such a condition during a submucous resection, perforation of the mucous membrane had to be avoided. Dr. DAN MCKENZIE considered the pressure of a crust led to destruction of the mucous membrane and cartilage. Dr. WILLIAM HILL related how, in haematoma of the septum, a perforation of the cartilage was always present. Mr. E. B. WAGGETT alluded to the destruction of mucous membrane and cartilage described by Zuckerkaudl as xanthosis of the mucous membrane. Mr. E. D. DAVIS exhibited a larynx removed *post mortem*, and a patient; in both cases the epiglottis had been amputated for *Dysphagia due to tuberculous ulceration.* Treatment in the first case had lasted over six months, and had included curetting of the arytenoids under suspension laryngoscopy. The ulceration healed, but a relapse occurred during tuberculin B.E. treatment. The pain of increased ulceration was abolished by injection of eucaine and alcohol into the internal laryngeal nerves. An exacerbation of lung trouble resulted in death, but the vigorous local treatment had relieved the pain and prolonged life. The second case, which was chronic, had derived benefit from amputation, and was receiving tuberculin B.E. Mr. H. BARWELL remarked that ulceration of the epiglottis usually indicated extensive tuberculous mischief, so that the ultimate fatal result detracted somewhat from the immediate relief of the operation. In a certain but limited number of cases, where the epiglottis only was effected, amputation gave the best results. Mr. H. L. WHALE exhibited a specimen which had been removed after laryngotomy. Dr. JOHNSON HORNE some years previously had diagnosed prolapsed laryngeal ventricle. It had caused dyspnoea and dysphagia for five weeks. Part of the lumen had remained shut off and still retained ciliated columnar cells, but the everted lumen had become covered with metaplastic squames. Mr. HAROLD BARWELL exhibited a man, aged 80, with *Infiltration of both ventricular bands anteriorly.* The rest of the cords moved fairly well, and were normal. Movable cervical glands and a small carotid aneurysm were present. The sputum contained numerous pneumococci, but no tubercle bacilli. The PRESIDENT indicated that examination of one gland would determine the nature of the disease. Mr. HAROLD BARWELL also brought forward a case of *Suppurating mucocele of the frontal sinus* in a boy, aged 12. The anterior and orbital walls projected as a hard swelling, while pus appeared in the hiatus semilunaris. Dr. DAN MCKENZIE pointed out that one view regarded the sinus opening as occluded, but many of these cases were due to occlusion of a gland in the mucous membrane lining the wall of the sinus, and such appeared to be the condition in the present case, as pus was coming away. The PRESIDENT had examined cases of mucocele and found the infundibulum open. Dr. ADOLPH BRONNER had found injection of tincture of iodine of great help in chronic empyema of the frontal sinus. Mr. FRANK ROSE exhibited a child, aged 10 months, with a *Congenital tumour of the septum*; it was pale and smooth, and caused obstruction from the first. Microscopically, it appeared to be a glioma. Mr. NORMAN PIKE exhibited an encapsuled *Spindle-celled sarcoma removed from the tonsil.* Two small cervical glands had also been dissected out. Mr. J. P. O'MALLEY brought a man, aged 54, the subject of a *Malignant growth in the antrum*, and also a woman, aged 41, with *Bilateral purulent rhinitis* of three months' standing. There was no evidence of sinus disease. A microscopical examination of the anterior end of an inferior turbinal suggested lupus. Mr. T. B. LAYTON had seen similar cases where removal of septic stumps had resulted in cure. Dr. DONELAN's case of *Congenital syphilis with sinking in of the nasal bridge* and intranasal obstruction was discussed. Mr. JEFFERSON FAULDER suggested the subcutaneous insertion of a piece of cartilage along the track made by a tenotome in preference to paraffin. Dr. DONELAN's case of *Post-diphtheritic adhesion of the soft palate* and cicatrices about the mouth was next brought forward. The PRESIDENT considered it doubtful if diphtheria gave rise to such considerable ulceration. Dr. WILLIAM HILL brought a specimen of a large *Pituitary tumour* and brain from a patient who had died after operation by the nasal route for decompression. General

signs of acromegaly were present, and enlargement of the pituitary fossa was indicated by a skiagram. Bitemporal hemianopsia was a symptom. A Killian incision was used and a burr applied to the roof of the larger right sphenoidal sinus. The passage of the burr was followed by free haemorrhage, which recurred, and was stopped by plugging the sphenoidal sinus. Death from increased intracranial pressure resulted in eight hours. After death a large pituitary tumour was found containing a haematoma and distending the pituitary fossa. The haemorrhage was due to perforation of the intercavernous veins or bleeding into the substance of the tumour. Dr. WILLIAM HILL discussed the difficulty of dealing with haemorrhage in this operation, and recommended plugging the sphenoidal sinus as entailing less risk; he considered it was a matter of chance whether the intercavernous veins were damaged. As to the form of incision, he pointed out that Ollier's—by which the soft nose is turned down by an incision at the level of the nasal bones—placed the operator $1\frac{1}{2}$ in. nearer the sphenoidal sinuses. Mr. C. I. GRAHAM brought the specimen removed after death from the patient shown at a previous meeting. Unluckily, the growth was a perithelioma growing from the third ventricle, and in spite of remarkable relief after the operation, the patient succumbed. He advocated splitting the skin over the inferior margin of the septum. At a second operation he had split the left nostril upwards, and obtained more room by removal of the middle turbinal; he had found hydrogen peroxide very uncertain in its action. Mr. E. B. WAGGETT remarked that infantilism, which follows removal of the pituitary body, should be taken into consideration when dealing with these cases. Mr. PIKE mentioned that Eisenberg operated with the head over the end of the table. Mr. O'MALLEY had noted that Hirsch used nibbling forceps. Dr. W. H. KELSON showed a section of the pedunculated growth removed from the inferior turbinal. It had the structure of a fibro-angioma, but it did not bleed. In discussing the matter with Dr. Hemington Pegler, he thought that the bleeding of these growths was a question of ulceration, to which the inferior turbinal was not exposed. The PRESIDENT, in discussing Mr. T. B. Layton's case of *Cyst of the tonsil*, advised enucleation; he considered such cysts were an explanation of certain abscesses of the tonsil. Mr. WALTER HOWARTH again brought his case of *Papilloma of the tonsil*, from which a fibroma had been removed. Mr. BARWELL and Dr. DAN MCKENZIE advised a microscopical examination in case the infiltration present denoted malignancy. Dr. LOGAN TURNER discussed the possibility of tubercle being present. Dr. BROWN KELLY related the details of a case of *Spreading papilloma*. Dr. DUNDAS GRANT brought a case of *Unilateral paralysis* affecting the palate and cord, probably due to suppuration at the apex of the petrous bone. Mr. W. M. MOLLISON exhibited a case of *Haematoma of the right side of the larynx*, consequent on a kick.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.

At a meeting on March 14th, at which the President (Professor E. W. HOPE) was in the chair, Dr. LOUIS C. PARKES read a paper on *Block dwellings for the working classes*. The necessity for accommodating the working classes in block dwellings arose from the heavy price which had to be paid for land in urban centres, for larger numbers in proportion to superficial area of land could be housed in these dwellings than in cottages or single houses, even if the latter were only provided with the minimum curtilage or open air space required by law. For many workmen engaged in regular industries it was no doubt preferable that they should reside in the purer air of the country or suburb, but there were still many for whom it was essential that they should live near to their work, and especially those who were mainly dependent on casual employment and who must be on the spot and near to the job likely to fall their way. There was no difficulty in housing men in regular employment and in making schemes remunerative, provided the tenants were not allowed to get into arrears with their rents, which should be collected in advance. During the eight years since their erection, in the Sir Thomas Nore Buildings, owned by the Chelsea Borough Council, on an average 98.4 per cent. of the gross rental had been

collected. The average weekly earnings of the occupants were about 31s., while in the Grove Buildings, belonging to the Chelsea Council, no tenant was accepted who earned over 25s. weekly. Even in the latter the loss from empties and rents uncollectable was only 0.7 per cent. of the gross rental. It paid financially to house those in regular work in block dwellings of sufficient size, with good modern arrangements, and in a neighbourhood where there was a demand for such dwellings. For the casual worker it was extremely doubtful whether any kind of housing scheme could be made self-supporting, and industrial dwellings companies would not undertake such provision. Life in block dwellings did not run smoothly unless the tenants generally were prepared to obey the rules and regulations made largely for their convenience and comfort, unless they were cleanly and tidy in their homes, civil to their neighbours, and capable of developing a certain pride in the orderliness and good character of the dwellings. In block dwellings of modern type, occupied by what might be described as a selected working-class population, the vital statistics were usually excellent, and showed that working people who had regular incomes and were above the poverty line could lead the healthiest kind of lives. Dr. Parkes emphasized the importance of employing for block dwellings a really capable resident superintendent. A good-class man was required, who would maintain order and discipline, and yet, by the exhibition of tact and discretion, earn the respect and confidence of the tenants. The PRESIDENT considered that playgrounds in connexion with block dwellings were essential. In Liverpool large areas of slum property had been cleared, and provision had been made on them for the poorest classes. Mr. JOSEPH, the architect to the Lewis and Sutton Trusts, considered that the most economical height of block dwellings was five stories, and that the width between the blocks should be equal to their height. He was of opinion that common lodging houses for women would not pay. Sir SHIRLEY MURPHY agreed as to the difficulty in providing lodging houses for women. Professor KENWOOD maintained that habits counted more than environment, and instanced certain streets occupied by Jewish families, where the lowness of the mortality-rate was quite startling if compared with adjoining streets. Dr. CHARLES PORTER regretted that medical officers of health were not more frequently consulted in connexion with the erection of industrial dwellings. Dr. HERBERT JONES emphasized the importance of having a capable superintendent of block dwellings.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

At a pathological meeting of the society, held on February 7th, the President (Dr. G. P. SHURER) in the chair, the following specimens were exhibited and discussed:—
Dr. ARTHUR SAUNDERS: *Congenital hypertrophic stenosis of the pylorus*. In addition to the usual hypertrophy, there was a sharp kink at the pyloric end of the stomach, almost sufficient in itself to obliterate the lumen of the canal. The patient was admitted to hospital at the age of 5 weeks for frequent and forcible vomiting. Visible peristalsis could be seen after feeding. The stomach was not dilated, and although it could be distinctly felt through the thin abdominal wall, no mass could be felt in the neighbourhood of the pylorus. As the symptoms improved somewhat under careful feeding, it was hoped that the child would improve sufficiently for a gastro-enterostomy to be performed, but in the ninth week of life an attack of diarrhoea occurred, to which it rapidly succumbed. Mr. ASLETT BALDWIN: (1) *Rodent ulcer of forearm* excised from a man aged 61. It started in a scar caused by lacerations from iron nails, and had been present for five years, sometimes showing signs of healing. (2) *Tumour of epididymis* from a patient aged 64. The epididymis was about four times the size of the testis, which presented no abnormality, and the central portion had broken down. Microscopically the tumour did not appear to be tuberculous or syphilitic, but merely inflammatory; various opinions, however, were given as to its nature. Hydrocele had been present for years, and a month before admission to hospital a severe pain and inflammation in the left side of the scrotum occurred. There had been no urethritis or injury. (3) *Hypernephroma*

of left kidney from a woman of 60, without urinary or other symptoms, except dragging pain in left side of abdomen. Removal about a year ago, and patient still well. MR. W. McADAM ECCLES: (1) *Mucocele of gall bladder*, removed *post mortem*. Calculus impacted in cystic duct. (2) *Mucocele of gall bladder*, removed from a woman who had for many years symptoms of dyspepsia, but never jaundice. The cystic duct was tied, and she made a very good recovery. (3) *Tuberculous salpingitis*, removed from a woman aged 25. She recovered, and is now married, but has not been pregnant. There were tubercles over the parietal peritoneum of Douglas's pouch. In reply to some remarks, Mr. McAdam Eccles said that in serous tuberculous peritonitis laparotomy was generally followed by a cure. He believed that peritonitis of a tuberculous nature in the female was caused by infection from the Fallopian tubes, and it was best to remove the tubes whenever possible. In his experience this type of case hardly ever did well if the tubes were not removed. (4) Five *Calculi from the bladder* of a woman aged 29. Since the age of 17 up to date of operation she had passed no less than 278 calculi. The stones exhibited were passed spontaneously with great pain; they proved the wonderful dilatability of the female urethra. There was no subsequent incontinence of urine. (5) *Malignant teratoma of the testis* removed from a man aged 32. It was a mixed tumour containing elements showing its teratomatous nature, and it had also sarcomatous elements. The patient died six months after operation with secondary deposits. DR. HAROLD PRITCHARD: Specimens from a case of *Banti's disease*, a late and terminal stage of splenic anaemia. Death had occurred at the age of 9 years, with all the signs of portal obstruction and marked ascites. The liver was small and contracted, with an irregular surface, and showed the changes found in typical multilobular cirrhosis. The spleen was large and tough, and contained some considerable amount of fibrous tissue. The peritoneum was thickened. MR. T. JEFFERSON FAULDER: *Guillotined tonsils* shown to illustrate that practically any kind of tonsil can be removed complete in its capsule simply with a guillotine and a short anaesthetic. The series presented included all varieties of tonsil—the common bilobed type, the flat tonsil, all grades of embedded tonsil, and tonsils reduced to the condition of mere pyogenic membranes. Many of them had been operated on previously. In reply to questions by Mr. McADAM ECCLES, MR. RICKARD LLOYD, and MR. SHUTER, all details were explained, and MR. FAULDER pointed out that the operation called "enucleation" was invented to meet the cases in which the guillotine, as used originally, had failed to cure, and the necessity for the invention of enucleation sufficiently showed that the clinical results obtained by slicing off a portion of the tonsil were often unsatisfactory. By the new method, introduced by Sluder, one could remove as much or as little of the tonsil as was thought desirable, and the operation was a much less formidable procedure than enucleation by the methods hitherto adopted. DR. H. H. SANGINETTI: *Acid-fast organisms from distilled water* closely resembling tubercle bacilli. It was important to bear in mind this possible source of contamination when investigating the presence of tubercle bacilli, especially by the anti-formin method or by the inscopie method of Jousset. DR. SANGINETTI also exhibited (for Drs. Bernstein and Elwerth) the following specimens from the pathological department of the West London Hospital: (1) *Splenomedullary leucocythaemia* showing large basophil myelocytes stained by Wright's method. (2) *Spirochaeta pallida* from a primary sore on lip. (3) *Carcinoma of appendix*. MR. McADAM ECCLES remarked on the interest of these cases, occurring so often in quite young subjects. This specimen was from a girl of 13, symptoms of chronic appendicitis were present, and when he removed the organ—a short, stumpy appendix—it showed microscopically a typical carcinoma. These cases generally recovered, and did not have any recurrence in glands or viscera. (4) *Tuberculous pneumonia*. (5) *Intussusception of ileum* into caecum discovered *post mortem* in a boy aged 1 year 10 months. There was no peritonitis. The child was brought to hospital without any definite history of abdominal symptoms, and while being examined died. The child was well developed, and in other respects healthy, and the abdomen when examined was flaccid. (6) *Interstitial nephritis*.

(7) *Melanotic sarcoma of spleen and liver*. (8) *Shirt stud abstracting larynx*. DR. H. J. F. SIMON exhibited a *Fibroid tumour of the uterus undergoing red degeneration* and necessitating hysterectomy at about four and a half months, and several other specimens of tumours of the uterus and cervix. MR. S. G. MACDONALD: *Closed renal tuberculosis*, showing the upper portion of kidney completely shut off from the ureter so that the urine was sterile and free from pus or tubercle bacilli. DR. A. K. TUOMSON took the opportunity afforded by this meeting of introducing Willard, "The Man who Grows." Willard claimed to be able to increase his height at will by $7\frac{1}{2}$ in., to increase the length of his arms from 4 to 15 in., and to elongate the neck by 2 in. without any dislocation or separation of joints. He declared that he could never be quite sure how much he would accomplish at a given demonstration, and that the $7\frac{1}{2}$ in. referred to above was his record. He then proceeded to demonstrate his power of elongating while in the standing position, and although he did not attain the figures quoted the exhibition was remarkable and interesting. On submitting himself to examination he appeared to possess, within physiological limits, an abnormal degree of spinal mobility and an unusual control over muscles rarely voluntarily exercised.

LIVERPOOL MEDICAL INSTITUTION.

At a meeting on March 6th, MR. ROBERT JONES (President) in the chair, Professor SCHÄFER gave an address on the *Physiology of milk secretion*. The mammary glands gave a secretion in which the chief organic constituents were all formed in its cells, while the salts were formed in the blood. The flow of secretion was not determined by nerve excitation. The secreting cells did not break down to form part of the secretion, but their free ends broke so as to liberate the milk constituents formed within them. Transplantation of the gland and its subsequent enlargement during pregnancy and secretion after parturition proved that nerve influences were not necessary. The secretion resembled that of the kidneys, which depended on the amount and quality of the blood circulating through its vessels, being very sensitive to an excess of those substances which, among others, formed its chief normal constituents, namely, water, urea, and common salt. The posterior lobe of the pituitary body contained a hormone which stimulated the renal and also the mammary secretion. Professor Schäfer had investigated the effect of the pituitary and several other extracts, working with Dr. Mackenzie. Fine cannulae were inserted into the incised nipples of lactating cats, and the milk was allowed to fall upon an electrical recorder. Several of these graphic records were shown by lantern screen. The effect of the injection of pituitary extract was one of the most striking experiments in physiology. The milk at first poured from the gland in a continuous stream, the flow gradually diminished, ceasing after ten to fifteen minutes. To produce a second effect it was necessary to wait for some time. Each successive dose administered at thirty minutes' interval gave a secretion well marked but diminishing in amount. The hormone was present in the pituitary body of all vertebrates examined—birds, fishes, amphibians, and reptiles, as well as mammals. Extract of corpus luteum gave a well marked galactagogue action, differing from the action of pituitary extract in not being accompanied by a rise in blood pressure. Extracts of uterus after parturition were galactagogue. Extracts of placenta and of fetus produced an inhibitory action on milk secretion. The effect of the pituitary hormones was to empty the gland as though alveoli and ducts had undergone contraction, squeezing out the milk as from a contractile sponge, yet muscle fibres had not been observed in the walls of the alveoli. Professor Schäfer exhibited slides demonstrating the electrical changes which were only found during secretion. Experiments had failed to show that the quality of the milk secreted under the influence of hormone stimuli differed from the ordinary secretion. The total yield of milk had not been influenced by the administration of pituitary extract to cows, though marked stimulation had been noted immediately after its injection. In human beings, experiment had given a large temporary increase in the secretion, but the patient had to wait a longer period before again giving the breast. The general

conclusions arrived at were: (1) The flow of the mammary secretion is induced as the result of galactagogue hormones circulating in the blood. Such hormones are produced in largest quantity in the posterior lobe of the pituitary body, but are also yielded by the corpus luteum, by the involuting uterus, by the mammary gland substance itself and perhaps by other organs. (2) Hormones which are formed during pregnancy in the tissues of the fetus and in the placenta possess the property of inhibiting the activity of the galactagogue hormones. (3) There is no distinct evidence that the mammary secretion is directly influenced by the nervous system, for it is carried on in a normal manner after the severance of all the nerves passing to the organ. Since nervous influences do undoubtedly affect the milk, this can only be either by their action on the general nutrition or by their effect on the production and pouring out of galactagogue hormones. (4) Drugs such as pilocarpine and atropine, which probably influence the secretion of glands mainly if not entirely through nerve endings, have little or no direct influence on the secretion of the mammary gland. A cordial vote of thanks to Professor Schäfer was proposed by Professor A. M. PATERSON and seconded by Mr. F. T. PAUL. Professor DE BURGH BIRCH, Professor B. MOORE, and Dr. KENNETH MACKENZIE also spoke, and Professor SCHÄFER replied.

GLASGOW MEDICO-CHIRURGICAL SOCIETY.

At a meeting on March 7th, Mr. FREELAND FERGUS, President, in the chair, Dr. J. H. NICOLL, speaking of *The avoidance of unsightly scar deformities in the operative treatment of cervical adenitis*, referred to the growth of an opinion among surgeons that complete removal of all the glands from a given region of the neck was not attainable, that by even the most mutilating incisions and dissections only a number of the more obviously affected glands could be removed, and that the same results could be obtained by less disfiguring methods. These were: (1) Evacuation of the fluid contents of a "softened" gland by a cannula or aspirator thrust through the skin and subcutaneous tissue—not a good method. (2) Evacuation by means of a small Volkmann's spoon introduced through a puncture made in one of the natural folds of the neck by a fine knife. Both these methods aimed only at removal of the gland substance from within the capsule, and were limited to cases in which one or two small glands had softened. The aim of the following two methods was the removal of the capsules with the glands, and by them in some cases large masses of glands could be "tunnelled" out. (3) The method of Treves of Margate, in which the incision was placed in the first transverse crease above the clavicle (in girls an inch higher), a tunnel made between the incision and the mass of glands, and the mass separated by digital enucleation. (4) The method of Dollinger of Budapest, in which the incision was made along the lower margin of the scalp in a line downwards and backwards from the mastoid process, and the glands similarly "tunnelled" out. The last two methods were comparatively easy in young children, but in adults were often tedious and difficult. Dr. W. R. JACK reviewed recent literature on the subject of *Vaccine-therapy in the treatment of gonococcal vulvo-vaginitis*, and stated his experience of this method in the treatment of six cases among children. In two cases, one of which was treated by an autogenous and one by a heterogenous vaccine, a clinical cure was reached after two and a half months' treatment. A third case, treated by autogenous vaccine, was free from symptoms after over three months. In the other three cases, two of which were treated by a polyvalent and one by an autogenous vaccine, the condition remained uncured after two months, five months, and over five months respectively. While these results did not appear very encouraging, it was to be noted that in all the cases a comparatively speedy improvement was attained, the irritation and discharge being much lessened, though in the unsuccessful cases it seemed to be impossible to get rid of this remainder whatever dose was used. Mr. GRANT ANDREW, speaking of *The operation for acute appendicitis—primary closure of the abdominal wound*, based his remarks on the records of 85 cases operated on by him between June, 1910, and February, 1913. In the greater proportion of the cases the appendix was gangrenous in whole or part and unprotected by adhe-

sions, and in one-third of the cases it had perforated. In a smaller proportion a localized abscess was present, completely shut off and usually very foul smelling. In almost every case the appendix was removed and the stump dusted with iodoform or treated with iodine or iodoform emulsion, and in over half the cases *Bacillus coli* vaccine was given subcutaneously. In 80 cases the wound was primarily closed without drainage, and 57 of these healed primarily. In 27 there was some infection of the wound, and in 2 cases the wound was restitched. In no case was a drainage tube necessary for the wound alone. There were 7 deaths. The list included no simple, catarrhal, or "quiescent" case, otherwise the mortality would have been under 3 per cent. The results showed that, provided the cause were removed and the caecal opening thoroughly closed, drainage either by tube or packing could be dispensed with, and primary union obtained with less risk, even under the worst possible intra-abdominal conditions.

MIDLAND OBSTETRICAL AND GYNAECOLOGICAL SOCIETY.

At a meeting at Leicester, on March 4th, Dr. MALINS, President, in the chair, Mr. J. FURNEAUX JORDAN showed a uterus containing a *Myoma the seat of necrobiotic degeneration*. The tumour had complicated pregnancy, and he had performed hysterectomy a few weeks after labour. The PRESIDENT remarked upon the small size of the uterine body. Apparently involution must have been extremely rapid. Mr. CHRISTOPHER MARTIN asked for information as to the pathology of red degeneration in fibroids. Personally he had never seen the condition apart from pregnancy. In Mr. Jordan's case, it was remarkable that the tumour had not been the cause of obstructed labour. It showed how easily a large mass will slip up out of the pelvis. Dr. PURSLOW recalled the similar specimen that he had shown before the society, where the neoplasm was cervical in position. Dr. CLARE asked if pain had been a feature of Mr. Jordan's case. Mr. MARRIOTT agreed that red degeneration was usually associated with pregnancy, but he had removed a nulliparous uterus with a very degenerated fibroid of this nature. Mr. WHITEHOUSE believed, on his own experience, that many cases of red degeneration had no relation at all to pregnancy. Mr. FURNEAUX JORDAN, in reply, stated that pain was certainly a feature of his case. In fact, a few weeks before term discomfort was so marked that the patient thought that labour had commenced. The apparent extreme involution of the uterus was due to the preservatives employed. Dr. N. J. SPRIGGS showed a new *Ligaturing forceps for pelvic surgery*. He had designed it for the easy and quick application of ligatures in inaccessible situations. It was a combination of a haemostatic forceps, designed to carry a ligature loosely knotted, with a sliding arrangement for pushing off and tightening the knot. It was rather complicated, but not more so than a tonsil guillotine, and it readily took to pieces for cleaning purposes. It had not yet been manufactured wholesale, but inquiries should be addressed to Messrs. Weiss and Son, Oxford Street, London, W. The PRESIDENT remarked upon the ingenuity of the instrument, and thought that it might certainly be useful in applying ligatures in some difficult situations. Mr. BOND said that he always had some little diffidence in employing very complicated instruments: For ligaturing superficial vessels it would be easier to use the ordinary method, but as regards deep vessels Dr. Spriggs's instrument might be of value. Dr. H. J. HICKS read a short communication upon *Localizing septic peritonitis of puerperal origin*. In the treatment of this condition he thought that simple drainage through Douglas's pouch should always be adopted when the local area of infection was within reach. Any attempt at radical removal of a pyosalpinx or an infected ovary was certain to be followed by a severe general septic condition which might be quickly fatal. The parametrium was nearly always also infected, and although the broad ligaments might not contain pus, the lymphatics were in such a state that they would pick up bacteria readily, if opened in the course of removal of the tubes or ovaries. Where simple drainage was not possible it was best to wait. The patient must be watched carefully

for any signs of extension of the infection. The longer the surgeon waited, the less virulent would be the organisms, and, further, by waiting, the natural protection against a general invasion had time to develop. In all cases Fowler's position should be adopted. The complications to be feared, if a radical operation had been undertaken, were not the ordinary complications which were familiar to all surgeons engaged in abdominal work, but septicaemia in its worst form. The PRESIDENT expressed his surprise at one remark in Dr. Hicks's paper—namely, that the "streptococcus did not cause as much permanent damage to structures as did the gonococcus." He was of the opinion that gonococcal infections as a rule produced a less severe degree of inflammation than did the streptococcus. Mr. BECKWITH WHITEHOUSE was in entire agreement with the conclusions enunciated by the author, especially as to the importance of simple drainage from below, and the value of waiting until the acute symptoms had subsided. The observance of these two facts undoubtedly saved the lives of many patients who would be lost if more radical measures were employed. With regard to the virulence of the infection, the type of streptococcus probably had some influence in this direction. Mr. FURNEAUX JORDAN had recently shown that the streptococcus which occurs in puerperal infections was frequently of a specific type, and he had named it the *Streptococcus puerperalis*. Mr. FURNEAUX JORDAN said that none of the cases brought forward by Dr. Hicks could conveniently be drained by the abdomen. Localized septic peritonitis may certainly be dealt with by the vaginal route, but if septic tubes and ovaries were to be treated, then he thought that an abdominal incision was preferable. As a rule a definite organism was present in these cases, and if possible an autogenous vaccine should be administered, but the progress of the symptoms was the index for treatment. Mr. CECIL MARRIOTT gave details of a case of *Pyosalpinx and abscess of the broad ligament* occurring twenty-one days after labour. He had attempted to reach the same extraperitoneally, but had found it necessary to perform laparotomy and drain through the abdomen. The patient recovered. Dr. PURSLOW asked what material Dr. Hicks used for ligatures and sutures in this type of case. Dr. HICKS, in reply, said that he always employed catgut sutures where the suspicion of sepsis was present. He was still firmly convinced that the best method of treating a puerperal pyosalpinx was that of simple drainage. The infected tube was frequently high up, but nevertheless the pus could be reached by this route and it was a far safer procedure than that of laparotomy and removal of the diseased appendage, at any rate during the acute stage. Mr. CECIL MARRIOTT read notes on cases of *Hysteropercy*. The operation that he preferred was a modified vaginal fixation, and this he had successfully employed for several years. Mr. CHRISTOPHER MARTIN had tried most of the various "new" operations that had been devised for the cure of retrodisplacements of the uterus, but had come to the conclusion that none were so efficient as the old "ventral fixation." If the sutures were placed below the level of insertion of the round ligament, then no fear need be entertained if pregnancy should occur. Abortion under these circumstances did not take place. In the case of complete uterine prolapse, he thought that there was no better treatment than by Simpson's "shelf pessary." Mr. BECKWITH WHITEHOUSE said that during the last two years the method of fixation that he had adopted had been the "sling" operation of Clarence Webster. It was necessary to use silk sutures and also to suture each round ligament to the uterine wall. Otherwise intestinal obstruction might occur from the passage of a coil of small intestine between the uterus and the loop formed by the round ligaments. Out of the last 30 cases treated by this operation there had been one recurrence. One patient was now three months pregnant and the pregnancy was pursuing a normal course. Dr. PURSLOW remarked, with regard to the "shelf" pessary advocated by Mr. Martin, that upon a certain occasion he had had great difficulty in removing one of these instruments from the vagina. It had, in fact, ulcerated completely through the vaginal wall and part was lying in the bladder. The PRESIDENT observed that the proper use and the abuse of a pessary were quite different things. Dr. PURSLOW's case was an

example of gross abuse of a pessary on the part of a patient, and could not be used as an argument against the proper value of the instrument. Dr. N. J. SPRIGGS read a paper upon *Congenital intestinal occlusion*, being an account of 24 unpublished cases, with remarks based thereon and upon the literature of the subject. This paper will appear in the *Transactions*. The PRESIDENT observed that the amount of work entailed in Dr. Spriggs's investigation into this little known subject must have been immense, and he heartily thanked the author for bringing it forward. Mr. BOND referred to a patient that had come under his observation upon whom a colotomy had been performed thirty years previously for occlusion of the large bowel. The lumen of the gut below the colotomy was then no more than the size of a lead pencil.

HUNTERIAN SOCIETY.

At a meeting on March 12th, Dr. ANDREW CURRIE, Vice-President, in the chair, Dr. H. LETHBRIDGE TIDY read a communication on *Myceloblastic leukaemia*, illustrated by microscopic slides. Dr. F. HOWARD HUMPHRIS, in a paper on *Non-infective inflammation*, and modern electro-therapeutic measures in its treatment, pointed out that stasis in simple inflammation was a bar to complete restitution, and that the indication in almost any stage of inflammatory process was the resolution of the local condition of infiltration; and that when a suitable electric current is used infiltration is dissipated, circulation is restored, and a healthy physiological activity displaces the former pathological torpor. Dr. Humphris pointed out that that form of electricity which stood pre eminent in producing mechanical effects was static electricity. When administered it induced successive contractions and relaxations, expressing fluid and semi-fluid debris on the mass of tissue involved. Several diseases were instanced, such as prostatitis, synovitis, neuritis, lumbago, and other forms of fibrositis, and the argument was made from the pathology of these conditions, and the mechanical action of the current, that with the removal of the stasis comes the relief of the disease, of which the stasis was either the cause or complicating concomitant. Mr. E. ROCK CARLING read a paper on *Some injuries of the fingers*, showing illustrative radiograms.

UNITED SERVICES MEDICAL SOCIETY.

At a meeting, held on March 12th, Fleet Surgeon P. W. BASSETT-SMITH, C.B., R.N., in the chair, a paper, entitled *Salvarsan in the navy*, was read by Fleet Surgeon LANGLFLOTT KILROY, who described a rapid method which he used at the Royal Naval Hospital, Plymouth, of preparing and administering the drug. By means of tabulated statements, and also by drawings and photographs, Fleet Surgeon Kilroy produced evidence of the beneficial effect of salvarsan in a large number of cases of syphilis which had come under his care. Cases of syphilis in whom the Wassermann reaction was positive, though previously treated with salvarsan and free from all active symptoms, should receive yet more salvarsan treatment as the best means of avoiding a clinical relapse. According to his experience, cases once treated by salvarsan did not fail to respond favourably to the drug when employed on subsequent occasions. Fleet Surgeon Kilroy recommended three different schemes of treatment suited, in his opinion, to primary, secondary, and tertiary cases, all of these including the administration of salvarsan and mercury, and in the cases of tertiary disease, of potassium iodide also. These methods had, in his hands, been followed by many beneficial and by no ill results. In the subsequent discussion, Major W. L. HARRISON, R.A.M.C., Staff Surgeon SCOTT, R.N., and Dr. DAVIS (Dreadnought Hospital, Greenwich), all of whom had had considerable experience of salvarsan, took part. The meeting terminated with a unanimous vote of thanks to Fleet Surgeon Kilroy for an interesting and instructive paper.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.

At a meeting on March 5th, the President, Mr. W. G. LAWS, in the chair, Dr. H. MICHIE read a memoir on *The treatment of prolapsus uteri*. He first considered the

anatomy and structure of the uterus, and explained that there were no true ligaments, but that the uterus was held up by folds of peritoneum and the round ligaments. Prolapse of the uterus was essentially a hernia, and occurred most frequently in advancing age, and after the menopause. Hard work, coughs, or strain were contributory factors. As a prophylactic, he advocated moderate exercise during pregnancy, patience during labour, and a not too early return to hard work after confinement. Hodge's pessaries or rubber rings sometimes were sufficient. Alexander-Adam's operation of ventral fixation generally cured the prolapse, but often complicated succeeding pregnancies; it was better suited for cases of retroflexion. Dr. Michie had lately devised the following operation: The abdomen was opened in the middle line by means of a small incision, the round ligaments on each side were isolated, and stout catgut was passed under the broad ligaments. These were drawn through the conjoint tendon and rectus muscle, and were stitched over the aponeurosis, just immediately below the skin. He had performed this operation twenty-five times, and all the patients had been relieved; there had been no complications in four cases of subsequent pregnancies; two patients who had incontinence of urine were relieved of this trouble.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.

At the annual pathological meeting, on March 14th, the President, Dr. DOBSON, in the chair, Dr. MYER COPLANS read a preliminary note on the *Properties of finely divided asbestos* with reference to the adsorption of bacterial toxins, antitoxins, snake poison, complement and amboceptor of a haemolytic system, specific agglutinin, diastase, and certain proteins and pigments, from watery solutions, and on the degelling phenomena exhibited towards watery agar, gelatine, and isinglass. The inhibitory action of watery agar when admixed with tetanotoxin was noted. A method of separating toxins from watery solutions by means of open gravity filtration through a layer of hydrate of alumina, its action being enhanced by the use of asbestos fibre as a binding substance, was shown. This latter experiment, when repeated with finely divided asbestos unsupported by hydrate, led to the discovery of the adsorbent properties of asbestos as detailed above. Asbestos dressings in surgical cases, especially in septic conditions, were advocated. Dr. MYER COPLANS and Mr. W. GIBBS LLOYD read a preliminary note on the *Adsorbent and catalytic properties of finely divided asbestos* as exhibited towards certain physiological substances—namely, starches, sugars, ferments, the various proteins, alkaloids, and hormones. Mr. W. C. LYONS read a paper on the various forms of "Proteose-free" tuberculin, with special reference to the enhanced diagnostic and therapeutic value of Koch's old tuberculin rendered proteose-free by treatment with ethyl alcohol—a process which was of special service in differentiating and isolating the specific from the non-specific toxins, as shown by a series of 262 cases of pulmonary and other forms of tuberculosis. The exhibits included:—Dr. COPLANS: (a) A portable apparatus for directly indicating electro-conductivity of body and other fluids; (b) a portable apparatus to be used in conjunction with the previous appliance for analysis of gases in air, carbon-dioxide being estimated by means of the fall in conductivity of a solution of baryta or lime water after absorption of the gas, carbon-monoxide, and the unsaturated olefines usually present in coal gas being estimated from the increase of conductivity of a solution of ammoniacal cuprous chloride following absorption of these gases. Dr. M. J. STEWART: (1) A *Fetus acardiacus amorphus*, the twin of a healthy male infant. It had neither head nor limbs, the umbilical cord was centrally situated on the ventral aspect, and a radiograph showed the presence of a spinal column, a rudimentary pelvis, and seven ribs on each side; a small triangular plate resembling a basi-sphenoid alone represented the cranium; the kidneys, ureters, testes, liver, and an inch of bowel were present, but the heart and lungs were absent; (2) *Teratoma of the testis and Cancer of the breast with squamous metaplasia*. Dr. J. KAY JAMIESON and Dr. J. C. BRASH demonstrated a dissection illustrating the distribution of the *Auriculo-ventricular bundle*.

Reviews.

RECTAL SURGERY.

SIX years have elapsed since the first edition of the late Sir FREDERICK WALLIS's book on the *Surgery of the Rectum*¹ was published. The second edition has been brought quite up to date, and has been presented in a practical form likely to appeal to both surgeons and practitioners. The last proofs of this work were handed in by the author just before his death; the edition was then carried through the press by a friend. The book has been largely rewritten, the print is enlarged, and the number of pages has been increased from 165 to 351. Six new chapters have been added. In the first chapter an account of the anatomy of the sigmoid and rectum is given; in the second the method of examination of patients is described, and when and how the sigmoidoscope should be used is discussed. Chapters III, IV, and V deal with the acute, subacute, and ulcerative inflammations of the colon, sigmoid, and rectum. These chapters greatly increase the importance of the book and give it a wider scope. They contain a good account of the comparatively recent pathology and treatment of these conditions without entering into points of controversy. Special attention is drawn to the treatment of intractable ulcerations by means of cataphoresis from zinc ionization. Chapter VI is devoted to venereal diseases of the rectum and anus, and Chapter VII to diseases of the perianal region. The last chapter deals with the rectal diseases of children; it includes the common developmental defects, and gives a short account of the development of the rectum and anus. The other chapters have been considerably modified and brought up to date, especially as regards treatment, accounts of many cases have been added to them, and the ease with which the book may be read is thus increased. The illustrations have been improved, and with the additions made they now number 129; they are clear and instructive.

The author ascribes the cause of intractable pruritus ani in over 90 per cent. of cases to ulceration between the sphincters; possibly this is a high percentage. A practical account is given of the operations for excision of the rectum without going into too much detail. The book is well arranged and written, and should prove of great service to practitioners.

MALE DISEASES.

IN his *Male Diseases in General Practice*² Mr. CORNER discloses an ardour and enthusiasm which lead him not only to the description of no less than ten operations for imperfect descent of the testicle—many of them with names of portentous length, such as "orchidocolioplasty"—but even to the elevation of his subject into the entity "andrology." At the same time, some of his words upon matters sexual can only be described as grandpaternal; but there is a hint in his preface that his book has been written in anticipation of a demand for such a work from women practitioners, and possibly this is the reason. It cannot explain the occurrence of such a sentence as this: "A 'pyoma' or pus tumour is an abscess"; or, again, "It is a very common assumption that just as we are born so do we remain throughout life. A minute's thought will show the fallacy of this"; nor is it quite clear from the text what is to be gained by teaching the sufferer from spermatorrhoea to make microscopic preparations of the discharges; but these are details. The best part of the book is that devoted to hydrocele, misplacement, and imperfect descent of the testicle, torsion of the testicle, and varicocele, of which the author has not only had an extensive experience but has also examined statistically large numbers of records, particularly as to late results of operations. He might perhaps have made it clearer that many so-called encysted hydroceles, though quite translucent, prove to contain spermatozoa when their clear contents are centrifuged. In expressing the opinion that

¹ *The Surgery of the Rectum for Practitioners*. By Sir Frederick Wallis, M.B., B.C. Cantab., F.R.C.S. Oxford Medical Publications. London: Henry Frowde, and Hodder and Stoughton. 1912. (Demy 8vo, pp. 370; figs. 129. 15s. net.)

² *Male Diseases in General Practice*. By E. M. Corner, M.A., M.C., F.R.C.S. Oxford Medical Publications. London: Frowde, and Hodder and Stoughton. 1912. (Demy 8vo, pp. 470; illustrations 162. 15s.)

many varicocele operations are unnecessary it would have been worth while to mention that varicoceles which have never given the slightest trouble in temperate climates sometimes do so when the patient goes to live in the tropics. There is a great deal of valuable information in the book, which has the not too common characteristic of seeming to owe very little to other textbooks and reflecting the real experience of the author.

The ninth edition of WHITE and MARTIN'S *Genito-Urinary Surgery and Venereal Diseases*³ is a bulky volume of over eleven hundred pages. Obviously it is appreciated; and yet, in spite of the large number of reissues, it is not a satisfying book. With the proportions of a book of reference it does not fulfil the promise of its appearance. The whole of the male genital organs, the urinary system, kidney, ureter, bladder, male and female urethra, and venereal diseases of both sexes are very fully dealt with; there are descriptions of cystoscopes, cystoscopy, the Wassermann reaction, the detection of spirochaetes, the investigation of renal function, and so on, with very little reference to proprietary drugs, and a large number of prescriptions that date from the time when the use of sound pharmacopoeial preparations was better understood than it is to-day. There is, of course, a section devoted to sexual phenomena of the pathological order, but it will do no more harm than turning the curious to a perusal of Krafft-Ebing. There seem to be few errors in matters of fact; it is of small moment, for example, that the pyrexia which so often accompanies syphilis of the liver is not mentioned. It is more to the point that there are numerous tables for differential diagnosis, and that the information is made accessible by a fairly good index.

We have received for review Part XXX of the *Nouveau traité de chirurgie*,⁴ published under the direction of MM. A. LE DENTU and PIERRE DELBET. It deals with the diseases of the bladder and the penis, and is written by LEGUEU and MICHON. The volume contains over 300 pages, and abounds in illustrations which adequately illuminate the text. How the publishers can publish such a volume at the price of 6 francs is difficult to understand. The text is admirably written, and sets forth methodically yet succinctly all that may be said to be known on the subject. The authors have wisely left on one side all debatable or hypothetical points and have confined themselves to facts. If we were to select one chapter beyond all others for praise we should choose Chapter VIII, on the functional disorders of the bladder, which is written in masterly fashion, and could have been written by none other than a Frenchman. The only criticism that we could offer on this work is that the references to the literature are chiefly to papers that appeared before 1900. Apart from this we can confidently recommend this work to every one interested in the subject.

BIOLOGY.

PROFESSOR ARTHUR DENDY'S *Outlines of Evolutionary Biology*⁵ is a book which is likely to be welcomed by a large number of readers. It fills a gap which has long been waiting to be filled, and the author is to be congratulated upon the success he has achieved by this work. It is well and lucidly written. Being, as it is, free from all but the most imperative technicalities, it should prove of value to all who desire to obtain a clear conception of the current views of biological thought, and not merely to students of biology in the strict sense of the term. The scope of the book may, perhaps, be best indicated by enumerating the titles of the five parts under which the twenty-seven chapters are grouped. These titles are: The structure and functions of organisms, including the cell theory; Evolution of sex; Variation and heredity;

Theory and evidence of evolution and adaptation; and Factors of organic evolution. With a programme of such magnitude it speaks well for the author's powers of concise expression when it is said that all these questions are adequately dealt with in the space of 427 pages. Though many of the subjects are still highly controversial, the author places the facts before the reader—with perhaps one or two exceptions—in a very fair and impartial manner. In discussing the phenomena of convergence, of which many interesting examples are cited, attention is rightly drawn to the pitfalls into which the observed phenomena may lead the unwary. As an instance of such, Professor Dendy refers to the fact that more than one observer has been led to "conclude that vertebrates are descended from arthropod ancestors, a conclusion which is by no means justified by the facts." A less debatable pitfall might have been cited as an example, for though the bulk of zoologists are opposed to such a theory, its supporters, though few, are by no means undistinguished, and are not all likely to have fallen into an obvious pitfall. The statement that the conclusion is "by no means" justified by the facts is, perhaps, unnecessarily strong.

Professor Dendy is clearly a believer in the inheritance of acquired characters. It is a problem of prime importance, particularly in the discussion of many of the pressing problems of eugenics. There has been a tendency for some years to regard the non-inheritance of acquired characters as proved, to accept Weismann's theory of the germ plasma as giving the final death-blow. The pendulum is beginning to swing backwards. It is to be hoped that before long some more definite conclusions may be reached upon this vexed question. A point which enhances the value of this book is the fact that the theories dealt with are applied to the vegetable as well as the animal world, and the examples given are almost as frequently botanical as zoological. There are many and good illustrations, and the index is reliable. The author is distinctly to be congratulated.

Professor TIMIRIAZEFF set before himself the very difficult task of giving a popular exposition of the physiology of plants, which has culminated in the publication of a volume entitled *The Life of the Plant*.⁶ The subject matter was originally delivered as a course of lectures during the winter of 1876 in Moscow and in a lecture given in St. Petersburg in 1875. These lectures were published in book form which has now reached a seventh edition in Russia. It is this edition that has been translated into English by Miss ANNA CHÉRÉMITEFF. That Professor Timiriazeff has achieved his aim the fact that the book has run into so many editions is evidence. The difficulty of writing a really sound and yet popular account of any science is always great, but the difficulty is considerably greater when the science is young and very progressive, as is the case with vegetable physiology. In the *Life of the Plant* the reader will find a clear and accurate account of the present state of our knowledge of the metabolism of plants, the experimental evidence being described in a plain and simple manner. As far as it is possible to judge, the translation has been well done; at any rate the English version reads well.

HEREDITY AND SOCIETY.

THE general theme of Mr. and Mrs. WHETHAM'S book entitled *Heredity and Society*⁷ is much the same as that which runs through their previous writings, notably *The Family and the Nation*. Indeed a certain proportion of the subject matter contained in the two books appears to be the same, though in a somewhat different guise. Nevertheless it makes interesting reading, and there is so much sound common sense in many of the conclusions that they bear repetition, and it will be well if the book is widely read.

It is, of course, written from the point of view of eugenics, and the first three chapters are consequently

³ *Genito-Urinary Surgery and Venereal Diseases*. By J. William White, M.D., and Edward Martin, M.D. Ninth edition. Philadelphia and London: J. B. Lippincott Company. (Roy. 8vo, pp. 1116; illustrations 300; plates 14. 21s. net.)

⁴ *Nouveau traité de chirurgie*. No. 30. Publié sous la direction de A. le Dentu et Pierre Delbet. Maladies de la Vessie et du Pénis. Par P. Legueu et E. Michon. Paris: J. B. Baillière et Fils. 1912. (Sup. roy. 8vo, pp. 324; figs. 90. Fr. 6.)

⁵ *Outlines of Evolutionary Biology*. By Arthur Dendy, D.Sc., F.R.S., Professor of Zoology, King's College, University of London. London: Constable and Co., Ltd. 1912. (Med. 8vo, pp. 468; figs. 133. 12s. 6d. net.)

⁶ *The Life of the Plant*. By C. A. Timiriazeff, Professor Emeritus, Moscow University. Translated from the revised and corrected seventh Russian edition by Miss Anna Chérémiteff. London: Longmans, Green and Co. 1912. (Med. 8vo, pp. 1-370; 83 figs. 7s. 6d. net.)

⁷ *Heredity and Society*. By William Cecil Dampier Whetham, M.A., F.R.S., and Catherine Durning Whetham. London: Longmans, Green, and Co. 1912. (Roy. 8vo, pp. 198. 6s. net.)

devoted to a brief summary of the more recent work on heredity, particularly that by the Mendelian school. The value of this work when looked at from the sociological standpoint is very great. The knowledge gained of the inheritability of such conditions as deaf-mutism, amentia and dementia, and of those extremely interesting cases of sex-limited diseases such as night blindness, is of far-reaching importance. A chapter is devoted to "Birth-rate," and once more attention is drawn to the disproportionate rate of increase between the desirable and undesirable sections of the community, leading, as it inevitably must, to a marked lowering of the average efficiency of the race. It might be supposed that the conclusions to be drawn from such facts as Mr. and Mrs. Whetlam and others have brought forward on this and previous occasions are so self-evident as to require no reiteration; but the attitude of opposition on the part of some to the recent bill dealing with the mentally defective, and indeed the very slender pretext upon which those in authority "shelved" that bill, proves how little real hold such conclusions have taken. Hence the necessity for constant repetition, in the hope that some day light may penetrate into those darkened recesses where callousness and indifference to the important problems of race betterment at present seem to reign supreme.

The two chapters on the past and present position of women are interesting, particularly at the present moment. With much that is written no doubt the more stalwart champions of women's suffrage will disagree. In the minds of some, to become a wife is sufficiently derogatory, to become a mother the greatest of calamities. This is not the view taken by the authors. Attention is very rightly drawn to the large proportion of the more highly-gifted women who are either unmarried or childless, and thus to the loss of a great national asset in the future. It is a problem of great moment to determine whether the mere fact of the greater strain on the nervous system involved by the so-called higher education of women is in itself the cause of the infertility, or whether it is due to the attitude of mind which encourages the belief that to be unmarried, or if married to be childless, are but degrees of evidence of emancipation and of sex equality.

A comparative study of the birth-rates in different sections of the community tends to the conclusion that there is some voluntary restriction of families, which, however, does not appear to occur in the cases of ministers of religion. This affords the text for an interesting chapter on the biological influence of religion. Education and politics are both dealt with in relation to heredity and to eugenics; and, lastly, there is a chapter entitled, "The Purpose of Life." In this, more philosophic and transcendental problems are touched upon. If creative evolution be intelligible, the conclusion is reached that this evolution has tended through countless aeons "to the production of the largest numbers of mankind of the highest mental and physical types." Behind all, there remains the deeper problems of the very existence of life and matter. Two possibilities seem open: Either a "blind inchoate stream of rudimentary consciousness running through the structure of the universe"; or, "the existence of a more definite consciousness, pervading and yet transcending all things." On either view the development of human personalities becomes of transcendent importance. We cannot follow the authors' discussion of questions bearing on these and cognate matters, but it is quite one of the most interesting chapters in a book which is itself full of interest.

NOTES ON BOOKS.

*Astonishing Anatomy*¹ is very good fun. On the cover, which does not correspond with the title-page—in fact, nothing in the volume corresponds with anything serious—the illustrations are described as "wood cuts, abrasions, finger prints, and thumbnail sketches," but their genius is better indicated by the statement that they are in the same vein of humour as was first worked by the author of *Wisdom While You Wait* and other skits of the like nature.

¹ *Astonishing Anatomy*. By Tingle (the rest of the title-page is too complicated to copy). London: Sir Isaac Pitman. 1913. (Cr. 8vo, 11p. 8s. 1s. net.)

Perhaps the best of them is the "simple diagram" of the fetal circulation in many colours which when held another way is seen to be something more familiar to the average Londoner. But nothing in the book is what it seems, or, at any rate, what the author says it is. There is a *réclame* in the most approved style, of pills made, it is said, entirely by hand, for "see the finger mark on every pill," a chapter on free medical advice in the manner of the Sunday paper, and an interview explaining how to keep a hospital for a second, for which the author, very properly, apologizes. These chapters, it may be objected, have nothing to do with anatomy—nor have most of the others. The author, whose portrait we do not recognize, shows by his title-page that he has some acquaintance with German literature, and that, however eccentric his views on anatomy, he has some knowledge of the proceedings of the Anatomical Association of Great Britain, Ireland, and especially Scotland.

The edition of *Truth Cautionary List*² for 1913 was issued recently. The list is a recapitulation of advice and information respecting individuals or combinations of individuals given from time to time in the columns of *Truth*. It is not designed to pillory persons as dangerous characters, but to inculcate caution in parting with money for purposes of one kind or another. That there is great need for such advice as is given cannot be doubted, and that the annual volume, which has now been issued for ten years, has proved of great use to the public is shown by the increasing demand for it. The information in the present issue is brought down to December, 1912. Notices are classified under various heads, such as religion and philanthropy, begging letter writers, medical quackery, bucket shops, and so on.

Under the title of *Coprostasis*,³ Sir JAMES SAWYER has published a reprint of a few chapters taken from his book *Contributions to Practical Medicine*. Constipation is a frequent and troublesome accompaniment of many disorders of health, but it is best considered in its relationship to the condition upon which it depends, though in the minds of some who suffer from it it becomes of itself a serious disease. The author has done well to give his professional brethren the advantage of his experience, though we could wish he had chosen a subject offering a field of greater breadth of investigation, and one affording a wider scope for the exercise of the originality he is known to possess. Is he quite sure that if defaecation be put off, "the distended rectum empties itself, if it can, backwards into the sigmoid flexure, and the returned faeces are held up there if possible"? Among details of treatment suitable daily exercises are suggested, "such as, for example, running upstairs by taking two steps of the stair at each stride, which is an excellent exercise for giving a fillip to the sluggish parts." It is also recommended "to sleep for the former portion of the night upon the right side, and for the later portion upon the left side." These are counsels of perfection which may not have occurred to every practitioner of the art of medicine, but difficulties in their fulfilment, as well as doubts regarding their universal applicability, will occur to many readers. The hints on treatment are valuable, but there is little reference to the newer medicaments, some of which have proved so successful in assisting Nature to the satisfactory re-establishment of rhythmic regularity in a normal function of the economy.

By those who are preparing for one or other of the examinations for sanitary inspectors, Mr. COWDEROY'S *Pocket Notes and Remembrancer*⁴ may be found useful as a reminder of what they have already learnt. The information given is for the most part reliable, and it is set out in a form that makes reference easy. The chapter on meat inspection, which forms nearly one-fourth of the whole book, is very well put together, and contains some practical hints which should be useful, especially to those inspectors who have not had much experience in such work. A knowledge of the contents of this chapter might save an inspector from many pitfalls.

³ *Coprostasis: Its Causes, Prevention, and Treatment*. By Sir James Sawyer, F.R.C.P. Birmingham: Cornish Bros. 1912. (Demy 8vo, pp. 74. 2s. 6d. net.)

⁴ *Pocket Notes and Remembrancer for Sanitary Inspectors and all engaged in Public Health Work*. By A. T. Cowderoy. Fourth edition. London: The Sanitary Publishing Company, Limited. 1912. (Pott 8vo, pp. 135. 2s. net.)

MILK-BORNE EPIDEMICS OF SORE THROAT.

In the early weeks of 1912 an extensive epidemic of sore throat occurred in Baltimore, and was eventually shown to be associated with the milk supply of a single dairy.

Hamburger first called attention to this outbreak in March, 1912, and a more detailed account by the same writer appeared in the *Bulletin of the Johns Hopkins Hospital* for January, 1913, together with a summary of other similar epidemics.

EPIDEMIC AT BALTIMORE.

A sudden increase in the number of cases of sore throat was noticed in the second week of February, and the epidemic was practically over by the middle of March. In association with tonsillitis there was great enlargement of the lymphatic glands in the neck, which, however, usually subsided without suppuration. Hamburger records 92 cases of illness which occurred in 35 households. The attacks appear to have been about equally frequent in children and adults. Forty-five of the cases were in children from 4 months to 15 years of age, and 47 in persons aged from 16 to 65 years. Females were attacked twice as frequently as males in this series. There were 16 deaths, 11 in children and 5 in adults. Nine of the fatal cases ended as acute peritonitis and 1 as erysipelas. Among the other clinical complications noted were otitis media and multiple arthritis, resembling acute rheumatism.

Frost, who, after the epidemic was over, investigated all the available evidence, was able to collect notes of 600 cases of sore throat, but considered that at least 2,400 cases really occurred. He found records of 26 deaths certainly due to the epidemic disease.

The evidence inculcating a single dairy was very strong. Of 35 households investigated by Hamburger, which were all supplied by this dairy (Dairy XYZ), 33 were affected by the disease and afforded 90 cases of illness. Thirty-seven other households, which were supplied by other dairies, yielded only six cases of sore throat. Of 16 fatal cases, all but 2 had been supplied with milk from Dairy XYZ.

At this dairy the milk was usually pasteurized, though the "flash" method employed was not a satisfactory one, the milk being nominally heated to 160° F. for one to three minutes. The heating of the milk was moreover entirely omitted from January 28th till about February 5th. This period coincides with the probable dates of reception of the infection in the cases which occurred in the sudden outbreak. In the latter part of the epidemic the disease appears to have been communicated directly from one patient to another. No evidence could be obtained of any disease amongst the persons employed on the farms supplying the milk nor at the dairy, and the milch cows were stated to be healthy.

EPIDEMIC AT BOSTON.

Two similar epidemics occurred in 1911-12 in the United States—one in Boston and its neighbourhood and the other in Chicago. At Boston the main epidemic began suddenly and lasted from May 11th to 28th, 1911. The recorded cases numbered 1,043. Winslow, who reported this epidemic, found that of 304 cases of tonsillitis in Brookline 198, or 65 per cent., used milk from a certain dairy, and of the 48 fatal cases 29, or 60 per cent., had taken the same milk. No disease was found amongst the cows supplying this dairy, but attacks of sore throat like those occurring in Boston had been frequent for some time in the district from which the milk was derived. The milk was not pasteurized at this dairy. The general hygienic arrangements and the bacteriological quality of the milk were very good.

EPIDEMIC AT CHICAGO.

The number of persons who suffered in the Chicago epidemic was estimated by Capps at 10,000, and the fatal cases at 200 to 300. Inflammation of the fauces, high fever, and enlargement of the cervical lymphatic glands were the common symptoms, and skin eruptions, arthritis, nephritis, bronchopneumonia, endocarditis, and fatal peritonitis were among the complications observed. In one series of 173 cases 19 deaths occurred.

Capps and Miller investigated 622 cases in respect of their milk supply, and found that of these 539, or 87 per cent., had their milk from one dairy (Dairy X). Of 19 fatal cases investigated, 15, or 79 per cent., occurred in houses which took milk from Dairy X. The houses in three widely separated districts in Chicago were canvassed to ascertain the dairy from which they obtained their milk. It was found that the morbidity in houses served by Dairy X was fourteen times as great as that in houses served by other dairies. The cases of sore throat occurring amongst hospital nurses yielded valuable information since the nurses were under close supervision. Of 153 nurses in hospitals which used X milk, 80, or 53 per cent., were attacked, whilst of 721 nurses in other hospitals only 35, or 4.8 per cent., had similar illnesses. The experience of one children's hospital was particularly instructive, for whereas a large number of the nurses who took X milk fresh from the dairy were attacked, the occupants of the 70 children's beds, who took milk which had been pasteurized after delivery, all escaped.

Investigation showed that though the milk was nominally pasteurized at the dairy, the method in use was the inefficient "flash" method, and had moreover broken down. It was proved that the temperature to which the milk was exposed had fallen to 130° F. on several days. The days on which failure in this respect occurred were December 17th, 18th, 29th, and 30th, and January 7th and 11th. The epidemic began on December 21st, was at its height on the 25th, and attained a second maximum on January 1st. Allowing for the lapse of three to seven days from the pasteurization of the milk to cover the delay before it was consumed and the incubation of the disease, the dates of failure of pasteurization corresponded very well with the dates on which the greatest numbers of fresh cases of sore throat occurred.

An excessive prevalence of sore throat was found to have existed about this time in Batavia, the district in which the X dairy had its centre and pasteurizing station. On eleven of the farms which sent milk to the X dairy, 29 cases of sore throat were known to have occurred.

On nine of these farms cases of mastitis had occurred among the cows, and this disease was said to be unusually prevalent in the district about this time. In 84 herds, consisting of 1,848 cows, which sent milk to Dairy X, 85 cases of mastitis were known to have occurred during December, 1911, and January and February, 1912.

BACTERIOLOGICAL INVESTIGATIONS.

At Baltimore a streptococcus was isolated from the throats of patients, from the ear in cases of otitis media, and from the exudate in cases of fatal peritonitis. All the strains were of similar morphology, and gave uniform cultural reactions. The micro-organism appeared in the exudate as a diplococcus with a small capsule. On blood-agar plates a slight halo of haemolysis was formed. J. D. Davis studied forty-five strains of streptococcus which he isolated from cases of illness in Chicago, and compared them with strains from cases occurring in the Boston epidemic, and from a case of mastitis in a cow. He found that the human strains were indistinguishable, and closely resembled the bovine strain. These strains of streptococcus had the same characters as those isolated at Baltimore. Davis described an additional characteristic of his strains—namely, the production of multiple non-suppurative arthritis in rabbits when very small doses were injected intravenously. Larger doses caused the death of the animals.

E. C. Rosenow also made a careful investigation of the Chicago strains, and considered them closely related to the *Streptococcus pyogenes*, but possessing distinguishing characters. The imperfections of the methods available for the differentiation and classification of the streptococci unfortunately render the identification of members of this group of micro-organisms a matter of great difficulty and uncertainty.

EPIDEMICS IN EUROPE.

Epidemics of sore throat, in which the infection has been traced to the milk supply, have been recorded from time to time in this country. In 1912 Savage¹ was able to collect data of eighteen such epidemics in Great Britain,

¹ *Milk and Public Health*, 1912

Nine of these assumed large proportions, the cases of illness numbering from 80 to 600, and in at least three of these outbreaks deaths occurred from septic complications. In twelve or thirteen of the epidemics the infection was clearly traced to a single dairy.

Disease of the dairy cows was established in connexion with eight out of the eighteen outbreaks. On four farms cows were found to be suffering from inflammation of the udder, and on four from ulceration of the teats.

Beside the outbreaks recorded in Great Britain a large epidemic of at least 548 cases of sore throat occurred in Christiania in 1907, and was recorded by Sömmé. The milk from a certain farm was indicated as the source of infection by the distribution of the disease, and a cow with suppuration of the udder was found in the herd supplying this particular dairy.

ETIOLOGY AND PREVENTION.

The clinical features of milk-borne epidemics of sore throat are of especial interest on account of the great resemblance of the symptoms to those occurring in scarlet fever, and also because of the frequency of arthritic complications resembling acute rheumatism.

The difficult question as to the ultimate source of infection in these and similar epidemics has been thoroughly discussed by Savage. The bacteriological and experimental evidence, as far as it goes, seems to point to the infection being derived from human cases of illness. That ordinary garget or mastitis of the cow can be a source of human infection is by no means established, and such direct experimental evidence as there is tends to discredit this idea. It is, however, possible that in some instances infection may be communicated to a cow by the hands of a milker, and that inflammation of the udder may be caused in this way. Streptococci which are virulent for man may then be passed on by means of the milk to the human consumers.

In any case the lesson taught by the experience gained in these epidemics in the United States and elsewhere is that emphasized by the writers named above—namely, that besides a careful inspection of cows, milkers, and dairies, efficient pasteurization or boiling of the milk is the only means of insuring against epidemics like those which have recently occurred in America.

DIET OF THE LABOURING CLASSES.

THE Corporation of the City of Glasgow has just published an exceedingly interesting report upon the dietary conditions of the poor in the city.¹ The work was carried out in the Physiology Department of the University under the direction of Professor D. Noel Paton.

Such a report with the evidence which it contains gives much food for thought. Who is responsible for the conditions which lead to the state of poverty and bad nutrition disclosed by this report? Lies the fault with the poor themselves—is it because they are thriftless, because they lack training in cooking and in the economical spending of such income as they possess? Or is it that the actual wages which they can command are so low that it is impossible for them to purchase the actual necessities of life? Whatever the cause, the fact remains that from the evidence collected by Miss Lindsay there must be a large percentage of the people in Glasgow to-day who cannot obtain the bare minimum in the way of food.

Studies of the dietary conditions of various towns have frequently been published in America, and of York, Dublin, and Edinburgh in Britain, but so far no study of a large manufacturing city like Glasgow has been attempted in this country.

The report opens with an introduction by Professor Noel Paton who explains the reasons for undertaking the study. As he rightly points out, the significance of the truism that the prosperity of a city depends largely upon the health and vigour of its labouring classes is not always fully appreciated judging from the scant attention paid to the factors which influence the vigour of a community.

The question he asked was, "Do the working classes of this city get such a diet as will enable them to develop into strong, healthy, energetic men, and, as men, will enable them to do a strenuous day's work, or are the conditions of the labouring classes such that a suitable diet is not obtainable? Further, if a suitable diet is obtainable and is obtained, is it procured, or can it be procured, at a cost low enough to leave a margin sufficient to cover the other necessary expenses of the family life with something over for those pleasures and amenities without which the very continuance of life is of doubtful value?" He then goes on to point out how even a very small weekly contribution to insurance "for problematic benefits in future years" may so decrease the expenditure on the family diet as to give rise to imperfect physical development not only of those struggling to live but of those yet unborn. He also gives a very useful summary of the dietary requirements of a man doing hard work, and discusses briefly the nature and the composition of an ideal diet. In discussing the causes of the poor dietary conditions, he finds that ignorance of cooking and bad marketing, as well as penury, play their part.

Miss Lindsay investigated sixty families of the poorest districts in Glasgow (Cowcaddens, Anderston, Bridgeton, Gorbals, and Woodside.) These families lived in houses of one or two rooms, and had from three to ten children. The weekly wages varied between 13s. and 60s., and were in some instances regular and in others irregular. So far as could be determined the housing factor was approximately constant, so that any variations found were due to the diet.

The various families were classified in ten groups:

INCOME REGULAR.

Group A.—Children Earning, Average Wage, 39s.

This group, which consisted of seven families, was made up of decent, hard-working people. They showed, however, little foresight in their expenditure on food, and the marketing was bad. Out of the seven diets only one exceeded the standard laid down for hard work.

Group B.—Lodgers Kept, Average Wage, 43s.

In this group of eight families, one household had an income of 60s. a week. In some of the families the steadiest source of income was the lodgers' money. The value obtained for the expenditure was good on the whole. The most extravagant household in the series was found in this group, where 5 lb. of ham and seven dozen eggs were used in a single week.

Group C.—Average Wage, 27s. to 31s.

This group consisted of three families, all with a high standard of comfort. These families belonged to the artisan rather than to the labouring class. The food was good, although the expenditure was high.

Group D.—Average Wage, 20s. to 25s.

The ten families in this group belonged to the average poorer working classes. On the whole the houses were good and well cared for, and in this group the best housewife of the whole series was found. As an example of her marketing capacity the purchase of 4 lb. of halibut (in good condition) for 2d. is cited. The value obtained in the group for its expenditure was good.

Group E.—Average Wage below 20s.

In this group, which consisted of five families, the diet was poor and inadequate. The houses in which they lived were poor and dark, although they were not badly kept. Not a single diet in this group reached the minimum standard.

INCOME IRREGULAR.

Group F.—Average Wage over 20s.

In the seven families of this group days of feeding and of starvation were found more or less to alternate. Although miserably poor, these families were found to take life as a rule more hopefully and easily than those with a regular income. No thrift was attempted in the majority of cases. In this group was found the best kept house of the whole sixty visited.

Group G.—Average Wage under 20s.

This group consisted of eight families where hand-to-mouth living was the rule. Naturally, in this group the

¹ Report upon the Study of the Diet of the Labouring Classes in the City of Glasgow carried out under the auspices of the Corporation of the City. By Dorothy E. Lindsay, B.Sc., Carnegie Research Fellow, with an introduction by Professor D. Noel Paton, Physiology Laboratory, Glasgow University. (Issued by the Corporation of Glasgow.)

value of the diets showed great variation. In one, where oatmeal formed the staple, the value obtained was very good, and the children were strong and healthy. In this group, in a fourteen-day study, one household was investigated where the total income one week was 13s. and on the following between 10s. and 11s.

Group H.—Father a Drinker.

In the four families of this group the father in each case was a drinker. The diets were not excessively bad, although they were markedly deficient.

JEWISH.

The houses occupied by the five Jewish families forming Group K were larger and better furnished than the average house visited. The cost of living was in these families artificially heightened, as "kosher" meat is more expensive. Curiously enough, when compared with the preceding families, the value obtained for the expenditure was small. To a certain extent this was due to the fact that a chicken or a portion of one was a weekly purchase. Still, these families were far from extravagant, as in one case a family of two adults and ten children are reported as sitting down contentedly to a dinner where half a chicken was the chief item.

ITALIAN.

Group L consisted of three Italian families. The studies in these cases were difficult to carry out and required very careful supervision. Although these families did not live in the true Italian style, macaroni was freely used. The value obtained for their expenditure was not very good.

NATURE OF DIETS.

Viewing the various diets as a whole, it was found that they were characterized by a lack of variety. Bread, butter, sugar, tea, and beef were found in all without exception. Fish was little used by the British families. Cheese was only used in small amounts in forty-one families. Butter was always used in preference to margarine, as those who used the latter product were looked down upon by their neighbours. Oatmeal was used in forty-six families only, and the average amount per man per day was less than 1 oz.

WAGES AND FOOD.

In discussing the relation of wages to food, it is pointed out that 28.5 per cent. of the families whose weekly income is over 20s., and of those whose weekly income is under 20s., or irregular, 62.5 per cent. have a diet the energy value of which is less than 3,000 calories, a value which is too low for the purposes of ordinary hard work. Miss Lindsay concludes this section of her report by definitely stating that the figures which she has obtained "show conclusively that while the labouring classes with a regular income of over 20s. a week generally manage to secure a diet approaching the proper standard for active life, those with a smaller income and those with an irregular income entirely fail to get a supply of food sufficient for the proper development and growth of the body or for the maintenance of a capacity for active work."

GENERAL CONCLUSIONS.

In the second part of her report Miss Lindsay deals with certain individual problems arising out of her investigation.

1. The Method in which the Income is Expended.

She has examined the expenditure on rent and food and the surplus available for other expenses, and has compiled the following table:

| | Percentage of Income Expended. | | |
|----------------------------------|--------------------------------|----------|----------|
| | On Rent. | On Food. | Surplus. |
| A, B, C, regular, above 25s. ... | 11.0 | 61.9 | 27.1 |
| D, E, regular, under 25s. ... | 15.3 | 67.3 | 17.4 |
| F, G, irregular ... | 16.0 | 75.5 | 8.5 |
| H, irregular, drinkers... .. | 17.9 | 85.9 | -4.8 |

It is clear that even with a regular income the amount of money left over—some three or four shillings—for clothing,

fuel, taxes, amusements, etc., cannot be said to err on the side of abundance.

2. Comparison of Urban and Rural Diets.

In this section she shows that the energy value obtained by the rural classes is distinctly higher than that obtained by the town dweller. She finds that the figures for Edinburgh and Glasgow agree very closely, and she compares with the two Scottish cities the figures obtained for New York and for York (England):

| | New York. | York. | Edinburgh | Glasgow. |
|----------------------------|-----------|-------|-----------|----------|
| Rent, percentage of income | 15 | 18 | 13 | 13 |
| Food | 35 | 51 | 62 | 65 |
| Other expenses .. | 50 | 31 | 25 | 22 |
| Cost per man per diem ... | 10.05 | 5.93 | 7.29 | 7.07 |

3. Relation of the Physique of the Children to the Diet.

This section of the report was carried out with the cooperation of Dr. Chalmers, Medical Officer of Health to the City of Glasgow, and Dr. Roberts, Chief Medical Officer to the Glasgow School Board.

Miss Lindsay finds that when the weight of the child at a given age is much below the average for that age it is found, almost without exception, that the diet is inadequate. An attempt was made also to determine the part which an inadequate diet played in the genesis of rickets, but the data obtained were not sufficient to enable her to draw any very satisfactory conclusions. One fact was determined, however, and that was in those families in which overcrowding took place rickets was found.

RECOMMENDATIONS.

In bringing her very interesting report to a conclusion Miss Lindsay states that in her opinion bad marketing is one of the main contributing factors to the poor dietary conditions, and advocates proper school training in cooking and marketing as the best corrective. She maintains that greater use should be made of cheese and the vegetable foods like oatmeal, peas, beans, etc., which are rich in protein. She admits that there is a difficulty in preparing these foods, but rightly states that "if the diet of the labouring classes is to be improved, without increasing the cost, time and labour must be expended on properly cooking these more nutritive vegetable foods."

ROYAL MEDICAL BENEVOLENT FUND.

At the March meeting of the Committee, thirty cases were considered, and grants amounting to £264 made to twenty-five of the applicants. Appended is an abstract of the cases relieved.

1. Daughter, aged 69, of late M.R.C.S. Used to be a matron of a private asylum, but had a serious accident a few years ago, and is now practically dependent on her friends. Voted £10.
2. Daughter, aged 74, of late M.R.C.S. Maintained herself for many years as a governess, but is now incapacitated by chronic arthritis. Only income £11 a year. Voted £10.
3. Daughter, aged 66, of late M.R.C.S. Was formerly a governess or companion, but had to undergo two serious operations, and now finds regular occupation impossible. Voted £12.
4. M.R.C.S., aged 78. Has practised near London for many years, but had a serious accident six months ago, and has in consequence lost most of his patients. Voted £10.
5. Widow, aged 34, of M.R.C.S. Lost her husband a few weeks ago, and finds that when his affairs are settled there will be very little left out of the sum for which he was insured. Voted £5.
6. Daughter, aged 45, of late M.R.C.S. Kept house for her father for some years after old age compelled him to retire from practice, and at his death, when nearly 90, was quite unprovided for, as his savings had been unavoidably spent. Has been trying to support herself, but is at present in very bad health, and entirely dependent on her friends. Voted £10.
7. Widow, aged 47, of L.R.C.P., L.R.C.S.I. Since husband's death has supported herself as governess or companion, but at present has no post, and is in temporary difficulties. Voted £10.
8. Daughter, aged 61, of late M.R.C.S. No income, and maintains herself and an elder invalid sister by making blouses. Relieved twice, £24. Voted £12.

9. Daughter, aged 57, of late M.R.C.S. Has been a chronic invalid for many years, and is consequently entirely dependent on this fund and a sister who allows her 7s.6d. a week. Relieved fifteen times, £173. Voted £12.

10. Daughter, aged 62, of late L.S.A. Has maintained herself for several years by letting lodgings, but is in ill health and finds increasing difficulty in doing the necessary house work. Relieved four times, £48. Voted £12.

11. Widow, aged 68, of M.D., C.M.Glasg. Is allowed £14 a year by the Working Ladies' Guild, and receives a little help from a son earning 25s. a week. Health very feeble for many years past. Relieved thirteen times, £148. Voted £12.

12. Widow, aged 68, of L.R.C.P. Edin. No income, and practically dependent on a daughter earning £1 a week as a cashier; health indifferent. Relieved eight times, £84. Voted £12.

13. Widow, aged 63, of M.R.C.S. Health feeble, and consequently finds the help given by her sons, who only earn small weekly wages, insufficient for unavoidable expenses. Relieved fourteen times, £159. Voted £12.

14. Widow, aged 59, of L.R.C.P., L.R.C.S.J. Lost her husband fifteen months ago from new growth, and endeavours to support herself by taking boarders. Two children, aged 8 and 7, the elder a candidate for an institution. Relieved once, £10. Voted £10.

15. Widow, aged 89, of M.R.C.S. Income about £32 a year. Children unable to help. Relieved eight times, £61. Voted £12.

16. Widow, aged 56, of M.R.C.S. No income and so crippled by rheumatism that self-maintenance is impossible. No children. Relieved ten times, £94. Voted £12.

17. Daughter, aged 64, of late M.R.C.S. Takes boarders and receives a little help from relations, but is unable to meet her unavoidable expenses without the assistance of this fund. Relieved six times, £72. Voted £12.

18. Widow, aged 72, of M.R.C.S. Left quite unprovided for at husband's death and supported herself for several years by massage, but is now dependent on an old age pension and a son-in-law, who can ill afford to help. Relieved three times, £30. Voted £10.

19. Widow, aged 55, of L.S.A. Endeavours to maintain herself by taking boarders; health indifferent. Relieved seven times, £76. Voted £12.

20. Daughter, aged 49, of late M.R.C.S. No income and finds great difficulty in obtaining suitable occupation. Relieved twice, £15. Voted £12.

21. Widow, aged 55, of L.R.C.P., L.R.C.S. Edin. No income; no children; health too feeble to allow regular occupation. Relieved nine times, £94. Voted £12.

22. Widow, aged 67, of M.D. Edin. Supplements help given by friends by taking a boarder, but at present is without one. Relieved three times, £18. Voted £6.

23. Daughter, aged 65, of late M.D. Edin. Maintained herself for several years, but is now dependent on friends. Relieved twice, £20. Voted £10.

24. Daughter, aged 54, of late M.R.C.S. Is obliged to live with and nurse an invalid mother, whose income is less than £13 a year. Relieved once, £12. Voted £12.

25. Widow, aged 72, of M.R.C.S. Only income, £21 a year, which is insufficient for expenses necessitated by applicant's age and infirmities. Relieved twice, £10. Voted £5.

Contributions may be sent to the honorary treasurer, Dr. Samuel West, 15, Wimpole Street, London, W.

LITERARY NOTES.

Dionis, who was surgeon-in-chief to the Dauphiness of France in the early part of the eighteenth century, left an amusing account of some of the principal quacks who preyed on the Parisians of the day. In *Paris médical* M. René Le Roy gives a long extract from the *Neuvième démonstration du cours d'opérations de chirurgie de Dionis* (2e édition, 1714), from which we take a few particulars. The chief place in the fraternity of quacks is assigned to Caretto, an Italian who called himself a marquis. He sold a wonderful remedy of his own invention at the rate of two louis d'or a drop. He was taken up for a time by the court, but the death of the Marshal de Luxembourg under his hands brought his vogue to an end. Then there was an "apothicaire du Comtat d'Avignon," who advertised a pastille which no disease could resist. It was composed of sugar and arsenic, the poison being unequally distributed, so that there was only a small amount in some of the pastilles while others contained 2 grains or more. The alarming effects of the stronger one brought the panacea into discredit. Frère Ange, a Capuchin, had been servant to an apothecary, from whom he learnt to compound a few medicines. His own specific was a syrup which he called "mesenteric." This he gave to all who sought counsel of him, as he attributed to it a selective action whereby it purged the body of whatever might be the peccant humour. He also vaunted a "vegetable salt"

of his own preparation as possessing greater virtues than all the drugs used by the doctors. With these two remedies he drove a thriving trade. His fame reached the Court, and he was called in to the Dauphiness. Dionis says he was an honest man, and readily disclosed the composition of his remedies to the physicians in attendance, who consented to their being tried. It would seem they had little choice in the matter, as the royal patient had made up her mind to take them. She did so for a fortnight, when finding they did her no good she dismissed the Capuchin. Another clerical quack in whose hands the same princess placed herself was the Abbé de Belzé, a Norman priest, who purged her twenty-two times within the space of two months. After four months of this treatment she was worse than when she began it. He in his turn was dismissed. Two of the Dauphiness's women, wishing to please their mistress, put themselves under his treatment, to the violent effects of which they both succumbed. A third quack who was recommended to the Dauphiness was one du Cerf, whose nostrum was an oil or essence of guaiacum; this, he boasted, would make those who used it, externally or internally, immortal, as it cured all diseases. This man was not admitted to the princess till the day of her death. After feeling her pulse and palpating her abdomen he declared that he could cure her with an enema containing his essence, which would clear the belly of all impurities. He went off to prepare the enema, but the poor lady escaped his ministrations by dying before he came back. Naturally he attributed her death to the fact that she had not had the benefit of his treatment. The reputation of his elixir of immortality received a mortal blow by his own death, which occurred soon afterwards. Later there came on the scene at Versailles one Bouret, who professed to cure every kind of disease by means of certain marvellous pills. He was presented to Louis XIV. who was sufficiently interested in the matter to suggest that the composition of the pills should be disclosed to his physician Fagon, on the understanding that a considerable sum should be paid for the secret if the remedy seemed likely to be useful. Bouret at first declined the offer, but, changing his mind, was intriguing to obtain a renewal of it when he was attacked by an inflammatory affection of the abdomen. He would take no remedy but his own pills, which, according to Dionis, so much aggravated the inflammation of his bowels that he died on the fourth day. These are only a few among the quacks who in the early years of the eighteenth century found ample scope for the exercise of their peculiar talents in Paris. Dionis, after warning the public against ignorant pretenders, gives an interesting view of the regular profession in Paris at the time he wrote. He says:

The Paris Faculty of Medicine is composed of more than 100 doctors, all very skilful, while the company of Saint Côme consists of more than 200 Master surgeons who all have given proofs of their skill by a "master-piece" of twenty-five acts, both on the theory of their art and on the practice which they have had before their incorporation into that celebrated company. These two bodies, fertile in learned and experienced persons, have always surpassed all others in Europe, and all those who in a spirit of presumption have ventured to measure themselves against them have been forced to acknowledge their superiority.

Dionis evidently felt, and wished others to feel, that he was a citizen of no mean city.

In an article on David Livingstone, by the Rev. Dr. Norman Maclean, in the *Scotsman* newspaper for March 15th, it is pointed out that the Livingstones came originally from Ulva, one of the Argyllshire Hebrides, and were Gaelic speaking. Dr. Livingstone himself thought that his name in Gaelic was *Mac an leath*, "son of the grey-headed"; but Dr. Maclean says that it is *Mac an leigh*, "son of the physician," or, as they might say, Doctorson or Leechson. This question may be left to Gaelic-speaking medical men to decide, but any one can convince himself that *leigh* means a doctor, for the Gaelic Bible gives the well-known proverb "Physician heal thyself" as *A leigh leighis thu seòin*. There is, however, a matter which suggests itself for inquiry at the present time when the Livingstone centenary is being celebrated: it is the question why on the tombstone to the great explorer in Westminster Abbey there is no word to indicate that he was a medical man. He is called "missionary, traveller, philanthropist," but not physician.

British Medical Journal.

SATURDAY, MARCH 29TH, 1913.

SUPERANNUATION FOR MEDICAL OFFICERS OF HEALTH.

IN our Parliamentary Notes last week it was mentioned that the bill of the British Medical Association for the superannuation of medical officers of health had been introduced into the House of Commons by Sir Philip Magnus, and had been put down for second reading on April 18th. This is not the first attempt the Association has made to secure for public health officers a much-needed reform. In the session of 1903 Sir Francis Sharp Powell introduced for the Association a bill with a like purpose, which was supported, as is Sir Philip Magnus's bill, by members of both political parties. Of those members who backed the earlier measure, Mr. Henry Hobhouse and Sir C. A. Cripps are still in the House of Commons. In the session of 1911 Dr. Hillier introduced a superannuation bill which was backed by Mr. Henry Forster, Sir Clement Hill, Colonel Hickman, Mr. John Robertson, and Mr. Barnes. It will be seen, therefore, that the principle of superannuation for medical officers of health is supported by a large number of prominent members of the present House of Commons, including two members of the Government. The principle was also strongly advocated by the Royal Sanitary Commission of 1869, of which Sir Charles Adderley was chairman. In a memorandum on duties of medical officers of public health, prepared by some members of that commission, it is stated that "to a provision for superannuation, or any other which might put public medical health officers on an equal footing with other branches of the Civil Service, we attach great importance."¹

The present bill would enable fixed contributions to be made by medical officers of health towards a fund from which superannuation allowances would be drawn. As it is impossible to say whether these contributions will make the fund self-supporting, it is proposed to provide that any deficit shall be made up out of moneys provided by local authorities. In any case the deficiency cannot be very great, as the number of officials concerned is under 2,000, and any deficiency that did occur would be more apparent than real, for a newly appointed officer rarely receives at the beginning of his career as large a salary as his retiring predecessor, and the difference between the two salaries would in many instances more than compensate for any contribution that had to be made towards a superannuation allowance from local funds. The position taken up by some local authorities may be gathered from a report adopted by the County Councils Association on July 25th, 1911, in which it was pointed out that a superannuation scheme could not be regarded as solely for the benefit of the employees, for the question of retirement, upon which superannuation depended, was at least as important for the employer, and it might fairly be said that the primary object

and effect of such a scheme was to secure efficient service even more than to benefit the employees.

Many other reasons might be adduced in favour of superannuation, including the increased flow of promotion, carrying with it greater popularity of the service among younger men, and the greater contentment among those already in the service through the removal of anxiety as to the future. These and other considerations no doubt largely account for the readiness with which many employers of labour deem it prudent to make provision for the superannuation of their employees, and for the recognition by successive Governments of the importance of establishing suitable superannuation schemes for State officials.

If it is asked why medical officers of health should be subject to superannuation more than other public officials, it may be replied that the majority of other officials can already claim superannuation. Medical officers connected directly with the civil service, Poor Law medical officers, and medical officers of asylums have all their superannuation schemes, some on a contributory basis, but all in the nature of deferred pay. One of the principal arguments in favour of the superannuation of asylum officials, which no doubt weighed with Parliament when the Asylums Officers' Superannuation Act, 1909, was under consideration, was that these officers held positions of great responsibility and were subjected in consequence to considerable mental strain. The same applies equally to medical officers of health, whose responsibilities are increasing year by year, and who are required to give advice which must be of the highest quality, for upon it may depend the well-being and indeed the very existence of their fellow men. A further important circumstance must also not be forgotten. It is that during the past few years an increasing number of medical officers of health have been appointed who are debarred from private practice, and whose incomes, as well as being non-elastic, are in many instances so meagre that it is impossible for them to make suitable provision for the time of their retirement. Unless they are compelled, as the bill seeks to compel them, to contribute to such provision, they will be obliged to cling to their posts long after, as they would be the first to admit, they ought to give place to younger men. The passing of the bill into law is thus eminently in the public interest, and we have every confidence that those members of Parliament who give to it serious consideration will support Sir Philip Magnus and his colleagues in seeking to pass into law a measure which, though primarily affecting only a few hundred public officials, in reality is of the greatest concern to the inhabitants of the whole country.

BIOLOGICAL REACTIONS IN PREGNANCY.

It is good for our modesty to realize that the improved recovery rates shown in reports on puerperal eclampsia have been reached by methods founded mainly on empirical grounds, and that on this field is being fought out the movement at present evident from more active measures towards conservative systems such as that associated on the Continent with the name of Stroganoff. A scientific basis for treatment is still in the crucible, and the keenness of controversy shows no signs of approaching solidification.

Opinions are not yet agreed as to whether normal pregnancy is to be deemed an exhibition of parasitism or a mutually advantageous symbiosis.

¹ Second Report of the Royal Sanitary Commission, vol. ii, p. 354, 1871. (C. -281. -1.)

Possibly these should be taken as the terms of a continuous scale of association where the point of transition is not well marked, and where an associate—such, for example, as the *Bacillus coli*—may shift from the safety to the danger side. Possibly, too, we are misled by the nearness of our standpoint to consider pregnancy as a continuing condition, whereas it is biologically a transitory but recurrent one. It is certainly the rule that offspring is biologically a sacrifice to the race and not a source of profit to the parent.

The tools which in recent years the physiological chemist and the parasitologist have developed for the attainment of knowledge have been as yet but sparingly used for the investigation of pregnancy. Seven years ago¹ we gave a systematic account of the investigations that had been carried on with regard to metabolism during pregnancy, showing that, though there was some evidence of nitrogenous loss in the early months, there was evident nitrogen retention during the later months. Dr. Leith Murray of Liverpool has in a recent article² given a review of the work done during the last few years, especially on the parasitological side. As Dr. Murray points out, the work is very new and largely unconfirmed. As yet general conclusions cannot be drawn with safety, but some attempt may be made to indicate the direction in which the evidence is leading us.

The desire to explain the startling phenomena of eclampsia readily led to a consideration of the also startling condition of anaphylactic shock, and yet, as Dr. Murray insists, the two conditions are contrasted rather than analogous. The asthma, the depression of blood pressure, and the lowering of temperature seen in anaphylaxis are not characteristic of eclampsia. It is, however, practicable to produce experimental anaphylaxis to placental extract, and in the early part of pregnancy there seems to be already some sensitization to it. Eclampsia is typically an event of later pregnancy. The difference between early and late pregnancy shows itself again both in the complement fixation experiments, which give positive results only about the second and third months, and in the antitoxin reaction in Weichardt's diffusimeter, which is best marked towards the end of pregnancy. In the complement fixation experiments the antigen is prepared from the villi of early pregnancy. The result of some precipitin experiments with liquor amnii showed no evident difference between pregnant and non-pregnant serum.

Serological methods may be applied to the diagnosis of pregnancy, and in this connexion the power of the serum of pregnancy to break up placental albumen has given Abderhalden two reactions of value. A polarimetric reading gave correct results in 75 cases, and a reaction by dialysis, best marked in early pregnancy, had been detected as early as the second week. The serum of pregnancy shows, especially during the first half, an increased antitryptic power, as do fevers, carcinoma, and a few other conditions, and, except at the early part, there is an increase in the lipid content and a definite cholesterol reaction.

There is some evidence that cases of eclampsia give transiently a positive Wassermann reaction, but more interest is probably due to the comparison which Dr. Murray has already made in the Obstetrical Section of the Annual Meeting of the British Medical Association at Liverpool and elsewhere between eclampsia and cobra venom poisoning. Analysing

the lesions of eclampsia Murray argues for haemolysis, haemoagglutination, fibrinous thrombosis and endotheliolysis, and adds on clinical evidence a neurotoxic element. We may recall how far Dienst made thrombosis go in explaining the phenomena of eclampsia.³ In the lesions as well as in the clinical characters of cobra poisoning Murray finds analogies to eclampsia. He obtained a positive reaction to cobra venom in 80 per cent. of primiparous and 66 per cent. of multiparous normal pregnancies and only in 22.5 per cent. of non-pregnant persons. In his eclamptic cases a positive result was found in 28 per cent., and Murray argues that the reaction, though not essential, shows a difference in pregnant and non-pregnant persons and that this difference is lost in eclampsia.

The whole of the evidence as marshalled seems to show analogies between the processes of pregnancy and infection and though much work will be needed before we reach finality it seems as if we might be able to explain why the intoxication of the early period gives hyperemesis and that of the later period eclampsia.

MIND CURES.

THE article on mind cures from the scientific point of view in the current number of the *Quarterly Review*, though addressed primarily to the intelligent layman, is founded on a wealth of clinical experience which gives it a particular interest to members of the medical profession. The influence of the body on the mind is very well known to every man who is at all observant of human nature in himself and others, and every one admits, as a general proposition, that the mind has a great influence on the bodily functions. But Sir Thomas Clouston, from the nature of his life's occupation, has a more vivid impression of this influence, for good and evil, than most of us.

As a rule, when there is mention of the influence of mind on body, the implication is that the effect is for the benefit of the body—for the cure of disease. But the author of this very striking article reminds us that the effect is often—perhaps quite as often—in the opposite direction, and the aberration or decay of the mind, inextricably linked as it is with the derangement or decay of the brain, is attended by disorder of the bodily functions, evidenced by malnutrition; the brain has ceased to exercise its function of direction or sends out perverted influences. The lowering effect of mental depression on the nutrition of brain and body is well known. "I had a patient once," Sir Thomas Clouston says, "who, being intensely depressed, took the idea he would and should die, and was determined to die; and die he did, in spite of all that could be done for him. A mental cause undoubtedly killed him, but it was through the brain arresting his nutritive energy, for he got thinner and thinner in body until he was utterly emaciated, though he was taking plenty of food." To complete the picture the author adds: "I have had many other patients who fought against their morbid mental depression, and determined to recover and did so, chiefly through the strength of their wills acting through the brain." Every medical man knows in a general way that this is true, but it is well to be reminded of it, and it is useful when reflecting on the many modern systems of faith healing, of Christian Science, and of the New Mysticism, to

¹ BRITISH MEDICAL JOURNAL, June 30th, 1906.

³ BRITISH MEDICAL JOURNAL, 1912, ii, 650.

bear in mind this converse picture, since it will serve to impress the essential facts which underlie the successes which all these systems can with more or less justice claim. It is, we confess, a little irritating to find each exponent and critic of some new-old system of mind cure reproaching medicine with not paying sufficient attention to the influence of mind over body. As Sir Thomas Clouston very justly points out, medicine at the beginning, and in primitive races to-day, knew almost no other means of cure. The medicine man of the savage tribe, with his grotesque costume and horrid ceremonies, the priest-physicians of ancient Egypt and early Greece, with their ritual, reinforced no doubt by change of climate and diet, the charms and amulets of Roman and early Christian times, and the religious ceremonies and pilgrimages of the middle centuries which have been continued to modern times—all these curers and ways of curing acted through the mind and its organ, the brain, on the body. The aim of the application of scientific method to medicine has been to distinguish, to proceed from the general to the particular, and to adapt the means to the end.

The article contains an admirable analysis of the innate qualities of the mind of man which render possible the gigantic success of the obscurantist in medicine and the modern nostrum seller. They are seen to be the powerful fascination for the mysterious, the mystical, the miraculous, and the occult in medicine which still exists, though diminishing as civilization advances, and the tendency in "the undeveloped and semi-irrational mind of man" to believe any statement authoritatively made. Various systems of treatment, nowadays more or less popular, which invoke the mind to cure bodily ills, are reviewed. There thus come under notice hypnotism, Christian Science, theosophy, Professor Freud's system of psycho-analysis, the Emmanuel Movement, and the psychic treatment of Dr. Dubois of Berne. The list, with a digression on hysteria, is, it will be seen, comprehensive, including the regular and the irregular, the old and the very new, in a net whose only fault is that it is not sufficiently capacious to give the fisher full scope for his remarkable powers of popular but yet clear and adequate exposition. In some of them dogmatism, in some expectancy, plays the largest part; in others suggestion, though in most all three methods of influencing the mind, and so causing it to influence the body, are combined. Modern science, as he says, claims to study and explain the occurrence of so-called mind cures. It admits their existence, but calls in the brain as the direct agent through which they are brought about. For the present the parallelism of mind and brain action must be accepted as best fitting the facts. In the cure "the mind comes in by setting the brain to work." Science includes mind as well as life and matter in the scope of its investigations, and "emphatically repudiates the mystical, miraculous, and superstitious views of such mind cures as being unreasonable and often degrading."

Sir Thomas Clouston thinks—and the opinion is one which we have often ventured to express—that the medical profession is not free from blame for the present backwardness of rational views of medicine, nor even for the atmosphere of mystery that pervades physic in the public mind. But we are not sure that we can follow him all the way when he says that medicine has not been candid enough in explaining the general purpose of treatment to patients and to the public, in the hope that thus it may be put on a rational basis in the patient's mind. It may be

retorted that we are not always very sure of the rational basis, and that this is particularly true of "mind cures," although Sir Thomas is ready to maintain that scientific and rational explanations can be given of most such cures. He does not deny their existence, but that they are due to occult, mystical, or unexplainable causes, and protests against their irrational misinterpretations. "We may be ignorant," he says; "we need not be credulous."

THE POLICY OF IMPORTATION.

It is asserted by its friends that the desire of the Government is now to pursue a policy of conciliation towards the medical profession in respect of the administration of medical benefit under the Insurance Act. If this information be correct, we venture to think that there is occasion for the exercise of the soothing influence of the central authority to mitigate the rather rough manners of local bodies at various points of the compass. In several districts criticisms by the medical profession of the schemes proposed for providing medical attendance have been met by attempts to introduce whole-time practitioners willing to accept such appointments in such circumstances. We may take Swansea and the surrounding district as an example; there the endeavour of the medical practitioners to secure more adequate remuneration for contract practice than has hitherto obtained has been met by an attempt to establish a medical aid association in the town. The local Division of the British Medical Association appealed to the honorary medical staff of the Swansea Hospital for its support, and at a meeting of that staff a resolution was adopted expressing surprise and indignation that the just and moderate demands of the medical profession had been met in this manner; the resolution concluded with the following declaration: "Recognizing that underpaid medical work is equally as bad for the patient as for the doctor, the hon. medical staff have decided that in the event of the establishment of any society or association having for its object the employment of medical men under conditions not approved of by the medical profession, they will under no circumstances meet in consultation or have any professional dealings with any medical man holding office under such society or association in connexion with a patient either privately or at the hospital, and, moreover, they will decline, except in cases of the gravest emergency, to treat in hospital any member of such society; also that the staff adopt the same attitude towards medical men undertaking contract work at terms below those decided upon by the medical profession of any district." At a special meeting of the board of management, Dr. Lancaster, the senior physician of the hospital, who is also chairman of the board, vacated the chair and presented the resolution in a very forcible speech. He was, he said, the mouthpiece of a unanimous and determined staff, loyal to itself, and loyal to its brethren in the town and district; they knew that the contract system was being more and more abused, and that doctors were underpaid and overworked in conditions which a working man would not tolerate. The wages of the working classes had increased by leaps and bounds, and the only thing which had not gone up was the remuneration of medical practitioners in contract practice, though the expenses had practically doubled in twenty-five years. In its attempt to put matters on a better footing, the profession had been met with discourtesy; it would not tolerate the formation of medical aid societies in the town, and the medical staff of the hospital would not allow itself to be used as a tool to crush their brethren outside. The Mayor, who had taken Dr. Lancaster's place in the chair, protested that he knew from experience that

no body of men appreciated the work of the hospital medical staff more than members of friendly societies, and eventually, on his suggestion, it was arranged that a conference should be held between six medical men, six trade unionists, and six representatives of friendly societies. In Gillingham, Kent, the difficulty to which we referred a few weeks ago has not been abated. The first plan of the Insurance Committee would seem to have been to bring eight men into a town which is already somewhat overdoctored. When the threat in this form failed to produce the expected panic, the committee is reported to have reduced the number to six. Advertisements were put out, and it was asserted that a whole flock of men were tumbling over one another to get an opening in the new El Dorado; it was announced with a flourish of trumpets that six men had been chosen. It was rumoured that three of these were to be dumped at once, and the other three held over as a sort of reserve force to be hurled into the breach in case the first three were overwhelmed by the amount of work. Those local practitioners who had joined the panel could not regard this with complete equanimity. Their lists, it was stated, were not full, and they probably felt apprehensive that they might be sacrificed to establish the imported men. Their anxiety may have been allayed by an announcement that one of the newcomers had not found the conditions of service sufficiently agreeable or promising to induce him to stay, and by the belief that only one of the three was as yet in residence. However this may be, there are some who ask the question, Who will be left in the lurch, if the promised 2,000 patients apiece be not forthcoming—the local men or the newcomers? What the insured are thinking about it all is also a subject of speculation. Gillingham appears to be one of the places where the threat to "close the panel" has been carried out. It is reported that the door is, in fact, so well banged, barred, and bolted that the committee has refused to readmit to the panel one repentant soul who, after entering, had passed out from it again; the legality of this proceeding is questioned. In Scotland, as will be seen by the report in the SUPPLEMENT of the discussion at the meeting of the South-Eastern Division of the Edinburgh Branch last week, a protest is being made against the new form of agreement issued to medical practitioners by the Commissioners in that country. In Ireland matters appear to be at present in a good deal of confusion, to avoid the more picturesque terms commonly used by our correspondents in that island. Altogether, then, there seems to be a good deal of work in the way of co-ordination and conciliation for the Joint Committee of Insurance Commissioners to do.

THE PLEASANTER SIDE OF THE INSURANCE CAMPAIGN.

It is an agreeable duty to record two recent instances in which the enormous amount of voluntary work done by honorary officers of Divisions of the British Medical Association has received recognition at the hands of members. At a luncheon in the Guildhall, Winchester, on March 13th, attended by a large gathering both of members of the Winchester Division and of members of other Divisions of the Southern Branch, Mr. H. J. Godwin, M.B., F.R.C.S., Surgeon to the Royal Hampshire County Hospital, Winchester, was presented with a testimonial from the members of the Division and medical friends beyond its borders. The Chairman (Dr. H. Maturin of Winchfield), in making the presentation, said that the Division desired to honour Mr. Godwin for his very valuable services to the British Medical Association in Hampshire, and for the skill, tact, judgement, and common sense he had displayed during the momentous period of the insurance controversy. The energy he had expended on this labour of love and the nature of his vexatious

and herculean task could only be realized by those who had been in touch with the secretarial work. The presentation consisted of a testimonial containing the signatures of all the subscribers, accompanied by a large silver tray bearing a suitable inscription, and a silver tea kettle. Dr. Fuller England (Winchester) then handed to Mr. Godwin for presentation to Mrs. Godwin a gold bracelet set in jewels. Mr. Godwin briefly acknowledged the presentation and accepted the gift for his wife, who, he confessed, was his right hand. A vote of thanks to Dr. Maturin was proposed by Dr. J. G. Frere, of Fleet, the Representative of the Division, and supported by Dr. J. F. Briscoe, of Alton, a past chairman. Dr. Maturin having briefly replied, the members present went on to the spring meeting of the Division. The number of subscribers to the testimonial was seventy-three, an evidence of the widespread respect and regard felt for Mr. Godwin. The second instance is afforded by a gathering of medical men on March 20th, at Dr. Laslett's house at Gillingham, to make a presentation to Dr. C. Courtenay Lord, Honorary Secretary of the Rochester and Chatham Division of the British Medical Association, in recognition of services rendered by him to the profession during the insurance campaign. Many members of the profession were present from all parts of the Division. Dr. Fairweather, in making the presentation, spoke very highly of Dr. Lord's work on behalf of the profession generally. Dr. Lord, in acknowledging the gift, thanked the subscribers very sincerely for the very tangible recognition they had made him. He also thanked members for the splendid support they had given him throughout the fight—a fact which had made his task much less arduous. The testimonial took the shape of a handsome silver cigar case containing a cheque of substantial proportions. The case bore the simple but eloquent legend, "The Campaign, 1912-1913."

A TRANSITION STAGE.

On March 14th Sir James Barr delivered to the Sunderland Division of the British Medical Association an address on rheumatoid arthritis, which it is hoped shortly to publish in full. The annual dinner of the Division took place on the same evening under the chairmanship of Mr. D. F. Todd, who took the opportunity of proposing the health of Sir James Barr. The Division, Mr. Todd said, had had three Irish chairmen in succession, and it was thought a fitting occasion to ask another Irishman to give an address to it. The profession had been going through strenuous times, but it had produced men to meet them, and in the struggle Sir James Barr had taken a prominent and a manly part. No President of the British Medical Association had given greater attention to the duties of that office, and every effort was indeed needed, for while it was true that the Association was great and strong, it had to take care that no Government should tread upon the profession as the present one had attempted. Sir James Barr, in reply, said that the great fault of Irishmen was that they thought too much of their own country. He had once heard of an Irishman who, when asked what he would have been if he had not been born an Irishman, replied that he would have been ashamed of himself. The medical profession was in a transitional state. He had anticipated something higher than the tendency he saw in the country at the present time. Instead of recommending young men to join the profession, he now advised them to step out of it. Those who were in it, of course, had to make the best of it. The reason why he had looked forward to a better time for the medical profession was because he had looked forward to a better and healthier race. He had thought, and still had hopes, that surgical craft would be soon a thing of the past, and that there would be less surgical work necessary than there had been. He had always believed in individualism, for trade

unionism to his mind had always meant a levelling down and not a raising up of the standard. The more individualism was encouraged the better it would be for the nation. If medicine went on as it ought the nation would be as it ought to be—the greatest nation and the greatest people, with not so many decrepit people, lunatics, and mentally deficient, and a quarter of the population to be kept. If things went on as they were, the working man would have to support not a quarter of the people, but far more. But there was a good deal of vitality in the nation yet, and he hoped that the transition stage would soon be past. Medical men should make it their duty to see that they were properly respected and properly remunerated. Dr. Farquharson, in proposing the toast of “The Division,” said that no words of his could express adequately the debt the Division, and indeed the whole medical profession, owed to Mr. D. F. Todd. Dr. Modlin, Honorary Secretary of the Division, said that it had already done its fair share of work for the profession, but still had much to do. Among other matters it was giving attention to the treatment generally of school children and to their dental treatment, but every man in the Division and in the Association must realize his own responsibilities.

CHOLIN IN INOPERABLE CANCER.

A REPORT of the address delivered by Professor Czerny of Heidelberg at the meeting of German Scientists and Physicians on the various non-operative methods of treating cancer was published in the *JOURNAL* of September 21st, 1912, p. 727. Professor E. Werner, who is also working at the Samariterhaus in Heidelberg, has recently in part gone over the same ground. After referring to radio-therapy he goes on to maintain that a chemical imitation of radio-activity is involved in the use of cholin. Of the cholin salts he has tried he prefers the borate, which he administers by intravenous injections, using at first 2 to 3 c.cm. of a 10 per cent. solution diluted to 20 c.cm. Later the dose is increased to 4 to 5 c.cm. For injection into the tumour or into the gluteal muscles he uses undiluted 10 per cent. solutions in doses of 2 to 5 c.cm. He usually gives 4 or 5 injections each week, but special precautions have to be taken to prevent a disturbing sensitization of the skin. He has treated 171 patients, including inoperable or recurrent cases of various kinds. All were advanced and apparently hopeless cases. Marked improvement was observed in 21 of the cases, including 1 carcinoma of the fauces, 1 rectal carcinoma, 1 round-cell sarcoma, 2 lymphosarcomata, 1 carcinoma of the parotid gland, 7 mammary carcinomata, 2 uterine carcinomata, 2 carcinomata of the stomach, 1 bladder cancer, and 1 carcinoma of the gall bladder. In 28 cases a considerable improvement and decrease in the tumour was observed, while the remaining 122 patients did not derive material advantage from the treatment. This may partly have been due, he thinks, to the fact that they did not remain under treatment for a sufficiently long period. In a series of 56 cases, in which thorium X and Roentgen rays were used as well as the cholin, he found that the dose of the latter was of importance. When between 3 and 5 grams of cholin in solution were used, only 1 out of 25 cases was materially improved, while in 20 the result was negative; when between 5 and 8 grams were used, 2 out of 18 were improved markedly, and in 10 the result was negative; while, when over 8 grams were injected, 7 out of 14 showed marked improvement, 5 showed considerable improvement, and only 2 did not respond to the treatment. He has gathered from other cases not included in the series, in which the treatment supplemented operation, that the tumours soften and become fluid under the influence of cholin, in a manner similar to the changes seen in mice cancers under chemo-therapeutic remedies. It is, he states, too early to speak of the best

method of applying the treatment, since he has only used it for about a year. He gives some details of two apparently hopeless cases of stomach and gall-bladder cancer, in which the result was most striking. He, however, warns the reader that these non-operative means of treating cancer should only be applied in cases in which an operation cannot be carried out, or in order to prevent recurrence after an operation has been performed. In no instance has it been proved that cancer can be cured by these means.

STATISTICS OF NOTIFICATION.

A REPORT on the incidence of notifiable infectious diseases in England and Wales during 1912 has been presented to the Local Government Board by the medical officer, Dr. Newsholme, and is issued as a separate publication.¹ The report contains statistics showing the number of cases and the incidence in relation to population of each of the notifiable acute infectious diseases in every sanitary area of England and Wales and in certain grouped areas. The issue for the year 1911 was the first full record of the kind. The newly-issued report contains a brief history, by Dr. Bruce Low, of the occurrences of plague, cholera, and small-pox abroad during the year 1912. The information as to small-pox has been added in view of the increased importance which attaches to imported small-pox as the chief source of the disease in this country in recent years, and it is hoped that the information will be helpful in drawing attention to some of the likely sources of imported infection. The report also contains for the first time complete statistics of cases of pulmonary tuberculosis notified during the year. This has been rendered possible by the Board's general order which came into force on January 1st, 1912. In this issue the number of cases of pulmonary tuberculosis notified in each sanitary district is not shown, because it is felt that for several years comparisons, especially for small areas, will be liable to a number of errors, and because, speaking generally, such comparisons, if unchecked by corrected death-rates, are, it is rightly considered, to be deprecated. In the report for 1913, however, it is intended to give tables showing the number of cases of both pulmonary and non-pulmonary tuberculosis in certain large areas and the age and sex of the patient. In 1912 the total number of notifications was 110,706; the number notified in London was 33,392; in England, excluding London, 72,193; in Wales and Monmouthshire, 4,966; and in ports, 155. The notification of acute poliomyelitis only became compulsory on September 1st, 1912, and subsequently 421 cases were notified, but prior to the general order nearly 900 sanitary authorities had made the disease notifiable, and the total number recorded was 824. The same observations apply to the notification of cerebro-spinal fever; the number of cases notified after the order came into operation was 104, while the total number for the year was 272. The number of cases of small-pox notified in England and Wales in 1912 was 111, as compared with 265 in 1911; of typhus fever 31; of enteric fever 8,262, as compared with 13,730 in 1911; of erysipelas 22,865, as compared with 24,939; of diphtheria 44,687, as compared with 47,747; and of scarlet fever 107,477, as compared with 104,617. The total number of cases of puerperal fever was 2,184, as compared with 2,029 in 1911. The highest rates from puerperal fever occurred in Fulham and Manchester (0.19), Bermondsey and Warrington (0.17), Finsbury, Birkenhead, and Stoke-on-Trent (0.14), and Sheffield (0.12). The lowest rates in London were in St. Marylebone (0.03) and Woolwich (0.02), and in Holborn (none), and among the county boroughs in Gateshead and Halifax (0.01); in Canterbury, Derby, Eastbourne, Lincoln, and Norwich no cases were notified. The administrative counties showed a curious variation, the highest being 0.12 in Carmarthen.

¹ Reports to the Local Government Board on Public Health and Medical Subjects. New series, No. 78. London: Wyman (through any bookseller). 9d.

while in Merioneth, Radnor, Rutland, and Westmorland no cases were notified; the East and North Ridings of Yorkshire also showed well with a rate of 0.01.

EPIDEMIC INFANTILE PARALYSIS.

THE State Medical Institute of Sweden made a report of its investigations on epidemic infantile paralysis to the Fifteenth International Congress on Hygiene and Demography at Washington in 1912, and this is now published in English.¹ It contains six accounts of experimental and pathological investigations by Kling, Pettersson, Wernstedt, and Josefsen, and an epidemiological report of the great Swedish epidemic of 1911 by Wernstedt. Both interesting and valuable results were obtained by the investigators; they found that the virus of the disease is in all probability always present on the mucous membranes of the nose, mouth, pharynx, and intestine of the patients during the acute stage, and they also found it in abortive cases, and in healthy persons who might or might not have come in contact with patients severely or fatally affected. Cases that recovered might still be carrying a virulent form of the infection nearly seven months after the onset of the illness; the authors think that the success of their experiments in so many cases may have been due to the fact that they had to deal with a virus of exceptionally intense virulence. Josefsen found the virus in two handkerchiefs and some needlework handled for a week by children severely affected by acute infantile paralysis, but not in flies caught by the patients in the wards; nor could it be found in fleas taken from patients or monkeys similarly affected. In monkeys the mortality was high—96.6 per cent.; 44 out of 120 died within the first twenty-four hours of the onset, and four main paralytic types of the disease were distinguished in them—an upper, a lower, a mixed, and a type showing a general muscular weakness (the marasmic type of Leimer and von Wiesner). The great Swedish epidemic of 1911 began in the early spring; in July there were 179 cases, in August 893, in September 1,067, in October 423, in November 235, out of a total of 3,840 cases; and the epidemic had not ceased to spread early in 1912. Town and country were about equally affected; no common source of infection could be found, and Wernstedt believes that the origin of the epidemic of 1911 was intimately connected with and to be sought for in the previous epidemic of 1905 (over 1,000 cases). Topographical studies show that the local centres of the epidemics in 1905 and 1911 were generally immediately adjacent to one another, though only a few cases in 1911 occurred actually in the 1905 centres, and vice versa. Hence it is concluded that the epidemic of 1905 produced a general and widespread immunity to epidemic infantile paralysis in 1911. The papers forming this report contain a great deal of interesting and important matter; its illustrations are good, its English does great credit to its writers, and the whole should be in the hand of every neurologist.

POOR ECONOMIES.

THE guardians of the West Ham Union have decided to advertise for a whole-time district medical officer at a salary of £350 per annum, rising by annual increments of £20 to a maximum of £450. The terms of the advertisement, the publication of which in the BRITISH MEDICAL JOURNAL has been declined, should be carefully examined by any medical man who might be disposed to make application for the post. At first sight the salary might seem attractive to a newly qualified practitioner, but he should bear in mind that when in five years the maximum of £450 a year has been attained, any prospect of financial improvement is ended, and for the rest of his life, should he retain the post, that will be sum on

which he must maintain his home and family and educate his children. He must also remember that he will be on duty twenty-four hours a day for seven days a week, with the probable or possible exception of a summer holiday. Should he give up the post at the end of five years he will lose the amount that he has paid towards his superannuation, probably about £40, and will have to make a fresh start. The scheme appears to involve a combination of three districts, now staffed by three medical officers, whose combined salaries would appear to have started at about £390 a year rising to £540. In addition the present holders of these separate appointments have time to devote to more remunerative private work; moreover, they can retain the payments made to them for extra services, which, according to the terms of the advertisement, the whole-time medical officer would, if appointed, have to pay over to the guardians. The advertisement is not explicit with regard to the amount of work, but states that the average number of persons in receipt of outdoor relief is 1,423. It does not state whether medical relief is meant, but the total probably refers to those persons who have been granted permanent relief tickets, and only includes the aged, those permanently sick, and widows and children. If this be so, the advertisement contains no mention of at least half the work. Nothing is said in it of those cases of illness among the poor treated under the medical orders issued by the relieving officer in each case as required. We believe that we are right in saying that the number of such orders issued annually in the three districts now proposed to be combined has been about 2,000 a year. If we make an allowance for the change which is being brought about by the Insurance Act, we shall still be well within the mark in saying that the number of such orders issued in future will be at least 1,000. This, again, on a very moderate estimate, will apply to a population of at least double that number—that is to say, of 2,000 persons—but probably to a considerably larger number. All these 2,000 persons must be reckoned among the potential patients of the whole-time district medical officer proposed to be appointed. Adding to these the 1,423 patients at present in receipt of outdoor relief, we get a population of 3,423 persons, any of whom he may be called upon to attend. This, as we have said, is a very moderate estimate. The latest State capitation rate for medical attendance is 7s. per annum, and presumably this rate is considered by the authorities to be neither too much nor too little. At this rate the medical list of the new district medical officer would give him a salary of about £1,200 per annum, but the West Ham guardians offer a salary of £350. Panel practice has many disadvantages, but within the last three weeks both an infirmary superintendent and a chief medical officer in East London have, it is reported, resigned their posts under their guardians to take on insurance work. This goes to show that even panel work is preferable to the Poor Law Medical Service as it is at present controlled and remunerated.

THE announcement that Dr. A. L. Galabin died on the evening of March 25th will be received with much regret by old Guy's men and by many who knew medical London twenty or thirty years ago. Dr. Galabin had been in Sicily from the beginning of the year until a few weeks ago. He returned to his residence at Bishopsteignton on March 19th, and was taken ill with lobar pneumonia on the following day. In spite of the attention of Dr. Morton Palmer of Teignmouth, who had the advantage of consultation with Sir James Goodhart, death ensued after five days' illness.

A BILL has been introduced into the Nebraska Legislature to provide that English shall be used in the writing of all prescriptions, and to forbid the use of any other language. A similar bill is now before the North Dakota Legislature.

Medical Notes in Parliament.

Vivisection Advisory Committee.—In Supply, on Tuesday of last week, Colonel Lockwood criticized the appointment of Sir John Rose Bradford to be a member of the Advisory Committee appointed by the Home Secretary to advise him as to the administration of the Vivisection Act. Colonel Lockwood's criticism appeared to be based on the grounds that Sir J. Rose Bradford had at one time performed certain experiments on dogs, and that it was only by a narrow majority that the Royal Commission on Vivisection had failed to pass a recommendation in favour of excluding dogs altogether. Mr. George Greenwood, who supported the contention, said that although Sir J. Rose Bradford did not now hold a licence, he had held one not long ago, and he believed that the Commissioners intended that a man who had held a licence and who was well known as a vivisector should not be among the advisory body. While admitting that the appointment was technically right since Sir J. Rose Bradford no longer held a licence, he asked the Home Secretary to reconsider the matter. Mr. Butcher thought it was a strange thing to put on an Advisory Committee appointed for the purpose of seeing that the Vivisection Acts were properly administered a man who had made experiments on dogs. Sir Philip Magnus pointed out that the fact that Sir J. Rose Bradford had performed experiments of this nature really rendered him a very suitable person to be an adviser, since the advice of a person quite unacquainted with the nature of these experiments would not be useful. —Mr. McKenna, in his reply, said that the Royal Commission had recommended that the Royal Society and the Royal Colleges of Physicians and Surgeons should be invited to suggest names to the Home Secretary for appointment to the Advisory Committee, and that Sir J. Rose Bradford had been suggested by the Royal Society. He was aware that charges of cruelty had been made by certain witnesses, but the Commission had not given any countenance to them, and he thought that no one who read the evidence of the charges and Sir J. Rose Bradford's reply could doubt that he had completely vindicated himself; Sir J. Rose Bradford had not held a licence for nine years. In reply to a question on March 24th Mr. McKenna said that Sir A. A. Bowlby and Sir J. Rose Bradford were the only members of the Advisory Committee who had ever held licences to perform experiments on living animals, the former twenty-six years ago, and the latter nine years ago.

The Army Estimates seem to increase in bulk and detail year by year, so that every pound of the millions voted can easily be traced. In the estimates for medical services the money for officers and men is in separate votes. Vote I, "Regimental Pay, etc." includes the warrant, non-commissioned officers and men of the Royal Army Medical Corps, numbering 3,797, at a charge of £112,500. In Vote II, "Medical Establishments, etc.," the estimate for 1913-14 is £440,000, an increase of £4,000 on 1912-13, entirely due to greater cost of medicines and appliances of all kinds, including medicines for the Special Reserve, for there is an actual decrease in the pay of medical officers owing to their smaller numbers. The establishment of medical officers for the year is 1,069, against 1,085 last year. The total is made up of 735 on the British and 334 on the Indian Establishment, the reduction being entirely in the former. There are 64 retired officers still employed. On the non-effective rate there are 538 medical officers, 49 quartermasters, and 26 lady nurses, but this list has not shown any tendency to increase in recent years; indeed, its highest point was reached about twenty years ago, when the retirement of the Crimean and Mutiny officers took effect. The great reform in the status and efficiency of the Army Medical Service in these last decades has undoubtedly repaid the State a hundred-fold in the remarkable improvement in the health of the troops, to which the Secretary of State for War bore generous testimony when he said, on introducing these Estimates on March 20th: "We have reduced the number of men under (medical) treatment (since 1898) almost exactly by half. Of course this means a great increase in fighting strength. This wonderful change, due in great

measure to the Royal Army Medical Corps, and on invaliding being lower than it has ever been before since statistics were taken, reflects credit on the Royal Army Medical Corps, and in great degree on the troops themselves."

Eyesight and Colour Blindness Tests. Mr. Lynch asked the President of the Board of Trade, on March 20th, whether, in regard to the mercantile marine tests for eyesight and colour blindness, they were carried out by non-medical men; and, if so, whether this practice prevailed in any other country. —Mr. Robertson said that the local examiners in form and colour vision were not medical men, but an ophthalmic surgeon had been added to the body of examiners to whom candidates who had failed locally could appeal. A return published in 1910 contained information with regard to the examiners who conducted the test in certain of the principal maritime countries. Mr. Lynch also asked what means, if any, were adopted to test the form vision and colour vision of the look-out men in the mercantile marine. Mr. Robertson replied that the Board of Trade had provided facilities for any person serving or intending to serve at sea to undergo the same examination in vision as that prescribed for candidates for certificates of competency, but under the Merchant Shipping Acts there was no power to compel a man who was employed as a "look out" on board ship to have passed the sight test. It rested with the owner or master of a ship to satisfy himself as to the competence of a seaman appointed to perform the duty, and the attention of owners had recently been called to the matter, by means of a notice.

Hospitals and Legacy Duty.—In reply to a question addressed by Sir John Barran to the Chancellor of the Exchequer on March 25th, Mr. Masterton stated that the appeal made on behalf of voluntary hospitals to remit the legacy duty had been carefully considered, but that the Chancellor of the Exchequer was unable to see his way to make the suggested alteration, even in view of the present and prospective difficulties and the responsibilities devolving on voluntary hospitals through the Insurance Act. The amount of duty involved was, he said, approximately £100,600 per annum. Attention was called to the fact that hospitals in Ireland were already exempt from this duty, but Mr. Masterton would not commit himself to defending this discrepancy further than to point out that it had existed for sixty years.

Calf Lymph. Mr. Keir Hardie asked the President of the Local Government Board, on March 25th, whether his attention had been called to a memorandum on the manufacture of glycerinated calf lymph, by Captain W. A. Justice, of the Indian Medical Service, in Progress of Sanitary Measures in India (Cd. 6538), describing visits to the vaccine institutes at Hong Kong, Tokio, and the Dépôt at Hendon, whether he sanctioned for use as the best stock lymph that which was derivable by the cultivation of small-pox virus through four to five calves and continued without admixture; whether small-pox virus was now in use at the Hendon dépôt for the purpose of propagating lymph supplies or setting up any fresh strain of lymph required; and whether bull calves were preferred at Hendon because the lymph collected from the surface of the serotum was of greater activity than other lymph. —Mr. Burns said he was aware of the memorandum referred to. As regards the source of lymph used at the Government lymph establishment, the usual method of renewing lymph was by vaccinating calves with vaccine lymph obtained from children, but in some instances the lymph had been obtained from abroad, and in such cases it would usually not be practicable to give its original sources. He might, however, state that in no case was lymph used at the establishment unless it had been passed through a series of calves. The answer to the last two parts of the question was in the negative.

The Mental Deficiency Bill was introduced by the Home Secretary on March 25th. It contains a new provision to the effect that the decision to treat a person as mentally defective should be revised at the end of the first and second years, at the end of every subsequent five years, and also when the person reached the age of 21 years.

Leprosy.—In reply to Colonel Yate, the President of the Local Government Board said that there were only a few cases of leprosy in this country, and, so far as he was aware, the disease was not spreading. He was advised that measures for the compulsory segregation of persons suffering from leprosy in this country would not be justified at present, but the whole question was under the careful consideration of the Local Government Board.

Mines Rescue and Aid Order, Scotland.—Mr. McKenna said, in reply to Mr. Duncan Millar, that the returns called for from the Scottish mine-owners, under the Mines (Rescue and Aid) Order, had been tabulated, and showed that in some counties the progress made was far from satisfactory. The Order had been in force for nearly a year, giving the owners ample time to make arrangements, and unless he received an assurance that energetic steps were being taken at once it would be necessary to take legal proceedings to enforce the Order.

Scottish Universities Additional Grants.—Mr. Masterman informed Mr. Munro-Ferguson, on March 20th, that the payment of the additional grants to the three Scottish Universities which had agreed to fulfil the necessary conditions would be made immediately.

Irish Milk Commission.—Mr. Birrell informed Mr. T. M. Healy, on March 20th, that the report of the Irish Milk Commission was in course of preparation, and would, it was expected, be ready in about six weeks.

THE TUBERCULOSIS PROBLEM.

ON March 18th Dr. J. C. McVail, Deputy Chairman of the Scottish Insurance Commission, gave a lecture in the Synod Hall, Edinburgh, on the relation of the tuberculosis problem to the Insurance Act. Fifty years ago, he said, there was no tuberculosis problem, not because nobody died of the disease, but because no one supposed that it was preventable. Some far-sighted people, amongst whom was Professor Hughes Bennett, believed that by abundance of fresh air night and day it might be cured; but beyond this point medicine had not progressed. Now there were three lines along which the disease could be treated—the attack by the bacillus could be prevented, the individual powers of resistance could be fostered, and recovery from the attack could be aided. The Insurance Act helped in all these three directions. It provided the insured person unfit for work with 10s. weekly for six months, and 5s. weekly afterwards as long as he remained unfit. It provided him with medical attendance and medicine throughout his illness, even if he were not recommended for sanatorium benefit. It provided a fund (about £87,000 annually in Scotland) for the treatment of tuberculous insured persons recommended for sanatorium benefit. It allocated a capital sum of about £158,000 as Scotland's share in a parliamentary grant to aid the provision of institutions for tuberculous persons in the population generally, whether insured or not. Finally, it provided a sum of about £57,000 a year for the United Kingdom for the purpose of scientific research into all that relates to the spread and treatment and prevention of this and any other diseases which might seem to call for it. Further, the Imperial Treasury had recently promised to pay one half of all expenditure for the extension of sanatorium benefit to the dependants of the insured and to the uninsured. These things would make a vast difference to the public health of the community, and they would still do this even if there were no tuberculosis to fight against.

THE INCLUSIVE FEE IN MEDICINE.

The question of the inclusive fee in medicine in Edinburgh University is likely to prove a troublesome one to settle. At the meeting of the University Court on March 18th a letter was read from the Treasury asking whether any steps had been taken to surmount the difficulties. The Court, in its reply, submitted that as the

adoption of the inclusive fee in the Faculties of Arts and Law and in Pure Science was to be regarded as tentative and provisional; it was of opinion that experience had not yet been gained to justify its adoption in the Faculty of Medicine and in Applied Science. The question, however, is being raised in extramural circles whether some light on a dark subject might not be gained by a full discussion of the matter by representatives of the university and of the school of medicine of the Royal Colleges. Admittedly the difficulties are great, but no statement has yet been made to show that they are insurmountable; farther, when the problem of the adoption of the inclusive fee in medicine does come up for settlement it will be well to have prepared the way for arrangement between the two great teaching bodies inside and outside the university. Some steps have already been taken towards solving this problem as it presents itself in Glasgow, where there is also an extramural school. Further, on March 22nd there was a conference at Perth between delegates from the Business Committees of Edinburgh and Glasgow Universities' General Councils, to consider the question of the applicability of the inclusive fee to the faculties of Medicine in the Scottish Universities. Some progress was made, for it was remitted to a subcommittee to prepare a reasoned statement showing in detail the financial and administrative difficulties which have been urged against the adoption of the inclusive fee in medicine, the probable ultimate effect of such an inclusive fee on the extramural schools, and of the uniformity of the inclusive fee on the progress of the individual universities. The time, therefore, seems to have come for making a conjoint effort to settle this matter or to show good reasons for no longer attempting its settlement.

TREATMENT OF TUBERCULOSIS.

A SCHEME has been suggested under which the Public Health Committee of the Corporation would be responsible for the treatment of tuberculosis patients in Dublin. The money, half of which will be supplied by the Treasury, is to be handed over to the Corporation, and the Public Health Committee agrees to provide treatment for all persons whose claims are sanctioned by the Insurance Committee. In the Crooksling Sanatorium and the Collier Dispensary the Corporation is, of course, equipped to meet immediate demands, and it is not unlikely that the Allan Ryan Home may eventually be included in the scheme. It is stated that a second special dispensary, with separate staff, will be provided for the south side of the city. Specially qualified practitioners, it is said, will be entrusted with the home treatment of patients, and it is believed that one of the orders of visiting sisters will co-operate in this phase of the work, while the Samaritan Committee will also continue its work. Wards for the treatment of suitable cases of tuberculosis will, by arrangement, be provided in many of the general hospitals. It is also hoped that after a time one or two hospices for the treatment of children may be established. At present the greatest need is for suitable places for advanced cases, and it would appear from inquiries that are being addressed by the county councils to the Dublin hospitals which have been recognized for "sanatorium treatment," that an attempt will be made to dump these hopeless cases in the Dublin hospitals. Included in the above outlined scheme is the appointment of a tuberculosis officer, but here a cheese-paring economy is shown, since the salary to be offered for a whole-time officer is £300 per annum, the smallest offered for such a post by any county council in Ireland; it is absurd to expect that a man who would inspire the medical profession in Dublin with confidence would accept such an arduous post for this remuneration. The scheme has still to be sanctioned by the borough Insurance Committee at a special meeting, and it is to be hoped that this defect will be rectified. At a meeting of the Tyrone County Council held last week, twenty applications for the appointment of tuberculosis medical officer for the county at a salary of £400, increasing to £500 per annum, with £100 travelling allowances, were considered. Dr. Arthur Langan O'Keefe was elected.

NEWCASTLE SANATORIUM CRISIS.

The position at Newcastle Sanatorium remains unchanged. The daily press has been flooded with letters, and, as might have been expected, the primary question of lay control of the medical treatment of the patients has been largely pushed aside by the entirely secondary one of the merits of the particular treatment. Numerous letters have appeared from former patients of the doctor in question. The essential part of the treatment in question is stated to be the intravenous injection of iodoform in ether. The method has, we believe, been tried both on the Continent and in Great Britain, but does not seem to have become established. From inquiries made and from the examination of the published reports, it would appear that the results obtained at the Newcastle Sanatorium compare very favourably with those of other sanatoriums in the United Kingdom. The excuse offered by the board of governors that the appointment of another visiting physician was necessitated by the large increase in the number of patients—from 24 to over 100—falls to the ground when it is understood that this increase occurred so long ago as 1905, and that since then a second resident physician has been appointed. Numerous methods of treatment have been tried from time to time by the visiting staff, including tuberculin with opsonic control, garlic, and dioradin, but in every instance it appeared that the control cases, treated merely by the open air method, did quite as well.

ANTIVACCINATION IN IRELAND.

In the seventeenth annual report of the National Antivaccination League, reference is made to Ireland, showing the serious state of affairs that has arisen. Though the Belfast and other boards of guardians have refused to stop prosecutions, over twenty unions, including both the North and South Dublin, have refused to enforce the Vaccination Act. The Local Government Board has done its best to persuade the various boards that it is their duty to enforce the law, but without avail. In Waterford the parents were fined 1d. for vaccination offences under the Public Health Act. The report indicates that attempts made to arouse the interest of Irish members of Parliament have not been very successful.

(FROM OUR SPECIAL CORRESPONDENTS.)

MANCHESTER AND DISTRICT.

THE RECOMMEND SYSTEM AT THE MANCHESTER INFIRMARY.

The pressure on the available accommodation for indoor patients at the Manchester Royal Infirmary and the necessity that there should be a substantial increase in the donations and subscriptions if the institution is to meet its annual liabilities, led the Board of Management, at a meeting last week, to confirm a resolution submitted by the House Committee in the following terms:

That persons resident elsewhere than in Manchester and Salford applying for admission as in-patients must lodge with the general superintendent a recommend signed by a trustee resident or carrying on business in the town or district within which the applicant resides, but the recommend may be dispensed with in exceptional cases with the consent of the general superintendent. This resolution shall not apply to cases of accident or emergency, which will be treated as heretofore.

The Chairman of the Board, Sir W. Cobbett, explained that the recommend system was formerly used as a means of ascertaining the opinion of the local medical men as to the physical state and the means of the applicants for admission as in-patients, but of late years it had been found better to rely on the examinations of the infirmary doctors and the investigations of the District Provident Society, and though the recommend system had not been entirely abandoned, it had practically been little used. But it was now found that a very considerable number of applicants for admission were coming from neighbouring or even distant towns, costing the infirmary a large amount for treatment, though in many cases little

or nothing was contributed from those towns towards the cost. As an example, one neighbouring town sent patients whose treatment cost something like £400, though the total subscriptions from the town were only £14. In another case, 14 employees of a large firm in a distant town were received as in-patients last year, but the firm on being applied to for a subscription definitely refused. At the same time there were often as many as 160 to 200 persons waiting for admission, and the Board thought it was not right that the number of waiting persons in the home district should be increased while the beds were being occupied by people from distant places which contributed little or nothing to the infirmary. Owing to the ability of its medical and surgical staff, the infirmary had obtained a reputation which induced medical practitioners at a distance to send difficult cases for special treatment, and it was realized that exceptional cases would occur which ought to be met with proper consideration, but it was thought that these cases were sufficiently provided for in the resolution by giving the general superintendent discretion to dispense with recommends.

It has long been a matter of complaint that the beds at the infirmary were often occupied by patients from towns even as far as 100 miles away, while there were no vacancies for Manchester and Salford patients, and the introduction of the recommend system, against which there are so many objections on other grounds, appears to the Board to be the only practical method of meeting the difficulty. At the same time it must be acknowledged that it is a dangerous weapon to employ.

A UNIFIED HEALTH SERVICE.

At the third session of the Labour Elected Persons' Conference in Manchester on March 22nd, Dr. Alfred Salter, of Bermondsey, gave an address on a unified local public health service. There was, he said, a lamentable lack of co-ordination between the various agencies for the prevention and treatment of disease. As an illustration he quoted a case of a family afflicted with tuberculosis where the father, having been ill for some months, was not eligible to come under the Insurance Act, and was being treated as a pauper by the board of guardians; the wife, being at work, was being dealt with by the London Insurance Committee, and would soon be sent to a sanatorium; one of the children had been confined and had a baby, and the local health officer was attending at intervals to give advice as to the care of children; another child was being dealt with at a school clinic, another was attending for treatment at Gny's Hospital, and another was being dealt with at a local tuberculosis dispensary run by private charity. Such overlapping and inco-ordination, Dr. Salter thought, was wasteful and deplorable, and there ought to be some correlation between the various agencies for prevention and treatment. There were about 26,000 doctors occupied in private practice, but they were very unevenly distributed, being too numerous in some places and insufficient in others. In Bermondsey, for example, it would take four times as many doctors as there were at present to do the work satisfactorily without being overworked. On the other hand, in residential districts the doctors had not enough work to do. He suggested that the State should see that the local panel doctors had not too many patients, and that doctors should be called from districts where there were now too many and planted in industrial centres where they would be of use and better off financially. He called attention to the ease with which people who were generally considered to be outside the Insurance Act might enjoy its benefits. Dependants of the insured were not now entitled to medical treatment, but they could obtain it in a very simple way. For example, any working woman could take in a little sewing for a week, or do a little washing for a neighbour. She thereby became an employed person, could get a card from the post office, stick one stamp on it, and she was thereby entitled to free medical attendance for the rest of the year. He laid emphasis on the point that every insured person is entitled to adequate medical attendance and treatment, and he submitted that this meant that he was entitled to be sent to a hospital or operated on when necessary at his own home by an expert or sent to a convalescent home free of charge. Allusion was made to the falling off in the number of medical students and the shortage of doctors,

and to remedy this he suggested that labour-elected persons should use all their influence to get scholarships set apart for the clever sons of working people to enable them to become doctors. Above all, he pleaded for the linking up of the chain of medical service, with full correlation from top to bottom between all the curative and preventive services, which should all be brought under one authority. A short discussion followed the address, in which a number of delegates took part.

BOVINE TUBERCULOSIS.

Mr. J. W. Brittlebank, chief veterinary inspector of the Manchester Corporation, in an address to the Nantwich Farmers' Club last week on bovine tuberculosis, said that he found from the statistics of the Board of Agriculture that there were about 3,000,000 dairy cows in Great Britain, and it was an accepted fact that 33 per cent. of the cows were affected with tuberculosis in some form, not taking account of feeding cattle or cows of that class. Assuming that the depreciation in value of an affected cow amounted to £1 a year, he concluded that each year there was a loss of £1,000,000. Of the 33 per cent. of cows which reacted to the tuberculosis test the percentage of cows which had the disease in a dangerous form was from 2 to 7 per cent. He hoped that the dairying industry would bring pressure on the Government to compel an adequate advance and a liberal grant of money to enable them to check the disease.

Correspondence.

TRADE UNIONISM AND MEDICINE.

SIR.—The discussion aroused by Dr. Bateman's letter anent trade unionism and its advantages or disadvantages for the medical profession is one that, at all events, indicates the general sense of a need for some effective means of co-operation between the members of the medical profession, and at the same time seems to me to show how widespread are the differences of opinion as to what should constitute the objects of union in the profession.

Would it not be wiser—more scientific, in fact—if we first endeavoured to arrive at some guiding principle as to what the proposed union should be designed to do? Is it to deal with rates of pay only, and terms and conditions of medical labour, or is it to regulate the work and social relations of the profession with the public generally? If the former be the main objects of the proposed combination then certainly the trade union would at first glance seem to be the sort of thing we want. The functions of a trade union as exemplified in the industrial organizations are to obtain for its members fair pay—that is, such a rate as will enable a condition of reasonable comfort to be obtained, and also such hours and conditions of labour as will not undesirably strain the human organisms concerned. Its main weapons are the strike and the boycott. To a more limited extent so far it has also made use of political agitation, and the subsidy of representatives in the various governing bodies. To some extent the trade union has succeeded in attaining its objects, but the results of the recent general strikes seem, on dispassionate consideration, to be incommensurate with the amount of the effort and sacrifice entailed on its members. Also the strike is coming increasingly to be considered as an anti-social proceeding because of the suffering it entails on the mass of the community.

Now there is a real need in the medical profession for some sort of assurance of fair pay and still more of fair conditions of work, but in view of the fact that its members are conducting their work on the lines of individual and competing craftsmen rather than in the masses in which the members of existing trade unions are employed it is difficult to apply the methods which may be suitable for another class. The vast proportion of medical work is done by men who are ploughing a lonely furrow, and who in but the most infinitesimal part of that work ever come into relations of co-operation with any of their fellows.

On the face of things this would not appear to be the most likely method of attaining success as to results in such a highly specialized profession as that of medicine, yet from the views that have been expressed during the

fight over the Insurance Act it would appear that this system of "free competition" is very dear to the majority of doctors. "Free choice of doctor" is the battle cry of this large and influential section of the profession, and must remain so as long as the commercialized form of practice at present existent continues. It follows, therefore, that our relations with the public are rather those of shopkeepers than of artisans; hence it is obvious that under present conditions any true union is exceedingly difficult of realization. In any case, as all Dr. Bateman's critics admit, the strike is a difficult weapon for us to wield. Its use by us corresponds to the declaring of a strike against the public by the purveyors of bread rather than to a strike by the working bakers against their employers.

Unless and until a combine of producing or distributing agencies virtually resulted in a practical amalgamation of their businesses it would have but little chance of success. That is to say that it could only succeed by the abolition of competition among its members. Moreover, it is probable that if successful it would, unless strictly moderate in its demands and highly efficient in its action, have to be taken over by the State.

Furthermore, as this individual method of working is much more marked in medical work among the less financially endowed members of the community, there is the further difficulty that it is impossible to raise the price of our labour to what it needs must be to allow of the practice of a really scientific form of medicine. And without State help it is difficult to see how co-operation in the poorer classes of practice is to be secured.

This may seem to be a digression from the main subject of trade unionism, but as there is a widespread feeling of irritation in the profession because of the recent incursion of the State into what we are pleased to consider as our preserves, it is reasonable to presume that many desire this proposed medical combination in order to keep the State from further "interference," and it is, I think, necessary to consider this point.

A closer study of political methods would, I am sure, result in a different conception of the effects of party politics on national control of the Government than seems to exist in the mind of one of your correspondents. The difficulty rather is that, by reason of the apathy of men of our own and similar professions, control is in the hands of a professional Government, let what party there may be in power. I think it probable, therefore, that reform of political methods would remove the objection to State help to medicine. Such a reform would unquestionably be greatly forwarded by the entry into political life of representatives of the medical profession, not as party politicians, but as independent representatives of a great medical union.

To return to the main purpose of this attempt of mine to deal with the question of professional union, I would suggest as the basis of such a union the following points:

1. The securing for the practitioners of medicine of such rates of remuneration and hours of labour as shall leave them time to keep abreast of progress.
2. The replacement of mere commercialized competition in the profession by a real professional and scientific competition, which, by encouraging mutual help and co-operation, will promote efficiency.
3. The advancement of medicine as a science. This, to my mind, embraces the other points.

To obtain these results something different from trade unionism is necessary. For, surely, the main recommendation of the medical provisions of the Insurance Act was that it provided some form of medical attendance, as a certainty, for the industrial classes at what was at all events a higher rate of remuneration than had been secured in the past by any medical organization. And the fact that the union in the medical profession that followed the introduction of the Insurance Bill was practically the first movement of the kind in its history, and was principally directed to a manifestation of opposition to outside interference, not unnaturally laid the profession open to a charge of being simply "out for fees." Had we put our house in order previously, and devised a union for purposes of mutual help in our work, and for giving adequate voice to the opinion of the profession on medical questions of public importance, we should have had a much greater degree of public sympathy.

Even at the risk of being accused of what one of your

correspondents is pleased to call "confusing ethics with sentimentality" I venture to say that the sort of union we want is one that will promote good-fellowship amongst us, not by coercive methods, but by organizing the work of the profession so as to secure to it more leisure through arrangements for taking emergency night and Sunday work in rotation, possibly also by a sickness and pension fund, etc. Time was when I thought coercive measures were the only useful ones, but a short personal experience of organizing work has taught me the superiority of more suave methods.

A union that will offer advantages to its members in times of peace will have a far greater influence with its members than one which pursues a policy of dragooning them into obedience.

When offensive action is necessary it will also take greater pains to secure that its policy is in accordance with its members' views and powers, and rely less on the rights of majorities to coerce minorities. As a consequence its fighting powers will be immeasurably enhanced.—I am, etc.,

Devonport, March 23rd.

EDWARD McCULLOCH.

SIR,—I am astonished at the inconsistent letter from Dr. A. G. Bateman, published in the BRITISH MEDICAL JOURNAL of March 15th. If any man in the medical profession should know the value of co-operation, surely it is the secretary of the Medical Defence Union. Those of us who advocate trade unionism do so, among other reasons, because Parliament has granted certain great privileges to trade unionists that we do not at present enjoy, and we are seeking to obtain these privileges, and at the same time to adopt all that is good, and reject all that experience has proved to be bad, in these organizations. If, in our conflict with the Government last year, we had been united in a strong trade union, with paid whole-time officials and ample reserve funds, we should have won easily without neglecting a single patient; in fact, in the case of a medical trade union, the threat to "down tools" would be out of the question and unnecessary.

Dr. Bateman hopes we shall never "descend to the level of dockers." Personally, after the *débâcle* of last year, I should be ashamed to talk to a docker on the subject of trade unionism. The docker, out of his 18s. a week, pays what is to him quite a large sum to his union, and when a strike occurs, whether he approves of it or not, he stands by his fellows as long as there is a penny in the war chest and as long as he has a garment or a piece of furniture to sell or pawn. We, on the other hand, pay the magnificent sum of 4d. a week to the British Medical Association, apart from the price of the JOURNAL, and when the Chancellor offered his bribe last autumn quite enough men deserted our ranks to enable him to coerce almost all the rest who were engaged in working class practice. Whatever one may think about those who accepted the bribe, one cannot blame those who were coerced. Having no union with adequate funds to fall back on, and no chance of ever regaining their work, how could they be expected to court certain ruin for themselves and their families? The British Medical Association, with its amateur leaders, did wonders with our 4d. a week till it came to close fighting, but

We was rotten 'fore we started—was never disciplin'd;

We made it out a favour if an order was obeyed;

Yes, every little drummer 'ad 'is rights an' wrongs to mind,
So we had to pay for teachin'—an' we paid."

Again, the Medical Defence Union has done most excellent work for many years, although our subscription is only 2½d. a week; but I should imagine that Dr. Bateman would be the last to deny that with the subscription doubled or trebled we might calmly face any legal proceedings under its protection without the latent fear that even if we won our case we might still be heavy losers. Yet Dr. Bateman says that "unity founded on trades union lines would be degrading and derogatory to professional men," and Sir James Barr is reported to have said yesterday at Sunderland that, in his opinion, "trades unionism meant a levelling down and not a raising up of the standard, and the more they encouraged individualism the better for the country." I remember as a boy seeing large brass plates on imposing houses in some of the

principal thoroughfares of London, and on these plates, beneath the doctor's name, was the following notice: "Advice gratis." Since then, in a fairly long experience, I have seen keen competition between individualistic medical men to give their advice and visits for nothing in order to sell their medicine for any sum between 2s. and 3d. a bottle. I have known well-qualified men competing eagerly for friendly society appointments where the annual payment per member was only 2s. 6d. Since this is the result of individualism it is high time we tried something else.

A trade union would fix a minimum fee for professional visits and advice, and there would no longer exist in our ranks the peripatetic pharmacist. No maximum charge would be fixed, and thus the man who valued his services at a higher rate might charge what he thought right. Men who felt secure by reason of private means or permanent appointments, and who had so little *esprit de corps* or so much false pride as to stand outside a union of their fellow workers need fear no peaceful picketing, but would certainly be "sent to Coventry" if they accepted a less fee than the trade union minimum. If the British Medical Association does not rise to the occasion we must make up our minds at once to form a proper trade union, though I hope we shall still retain our membership of the old Association, which will then revert to its original form as a scientific body.—I am, etc.,

North Shields, March 15th.

F. C. MEARS.

SIR,—Dr. Bateman, in his letter on the subject of trade unionism and medicine, propounds a number of questions based on the assumed action of a medical trade union in a dispute, and supplies the answer, "The idea is monstrous." Every medical trade unionist will agree that any such action as he suggests would indeed be monstrous. But has the possibility of any such action ever entered the minds of medical trade unionists? I have no hesitation in saying, Certainly not! The idea of a medical strike against the general public is inconceivable: it holds no place in practical medical politics. On a very different footing stands a strike against a public body, such as the Government. Has Dr. Bateman forgotten the methods by means of which we successfully extorted a large increase of remuneration and many other valuable concessions from the Government? Were not these concessions obtained by the threat that the profession would refuse to do the Government work under the conditions then offered? Had these concessions not been granted Dr. Bateman would have seen the profession "on strike" against the Government.

Dr. Bateman is confusing the aims of trade unionism with the methods employed by certain trade unions—methods which are eminently suitable to the class of men with which they have to deal, but entirely unsuited to the medical profession. Nobody expects that the mere fact of registration as a trade union will, *ipso facto*, mean the future safety of the medical profession. Admittedly, we must have the "unionism" first; having achieved that, we had far better take advantage of the protection and privileges granted by the Trade Union Acts than remain without such protection. I venture to think that only one thing can assure that much desired unity—namely, community of interest, which already exists and is already threatened with attack—I refer to our women and children patients. Already attempts are being made to bring them into the net of contract practice at a most unremunerative fee. The medical profession must see to it that it is not again found unprepared; that in the coming fight (which is nearer, perhaps, than many imagine) we have an organization the sole duty of which shall be to safeguard our professional interests, and the constitution of which shall be suited to the work which it will have to perform. If this organization takes advantage of the degree of protection afforded by registration as a trade union it will, at the least, be the more efficient by that protection than it would be without it.—I am, etc.,

London, E., March 25th.

HENRY J. CARDALE, M.B.

SIR,—Dr. A. G. Bateman entirely misapprehends the aims and objects, as the means to an end, proposed by an increasing number of general practitioners who see no

possible way of uniting their fellows for the legitimate objects of mutual protection other than agitating for obtaining statutory powers to govern themselves and to compel minorities to submit to the desire of the majority for the common weal. The legal profession possesses such statutory "protection," to wit, the "Incorporated Law Society." Why, then, should we doctors be denied the similar right of an "Incorporated Medical Society," based on such similar lines as will pertain to the profession of medicine?

There are, no doubt, great difficulties in the way, but I decline to regard them as insurmountable; and if we will take to heart the lesson of our recent ignominious surrender it cannot fail to determine us to close up our broken ranks for the final and successful effort to obtain our professional rights.—I am, etc.,

C. STENNETT REDMOND.

Late Chairman, Manchester West Division.

London, N., March 17th.

SIR,—May I, as one of the originators of this discussion, be allowed a few words more? That the doctors who have had to go on the panels will now need to form some sort of trade union is, it seems to me, self-evident; the latter step is a natural corollary of the first. The only subject which we really need dispute about is whether the British Medical Association is, as I say, to be "commandeered" for this purpose. Now, even if the Articles of Association permitted of this—and it was made quite clear at last year's Liverpool meeting that they did not—we must surely all agree as to the desirability of there being in our midst some big national body whose primary *raison d'être* shall be the advancement of the science and art of medicine.

It is nonsense to suggest that this supreme aim will be brought about by "fighting" anybody. A trade union is certainly based on the assumption that "what is your gain is my loss," and, therefore, fighting is of its very essence; but trade union methods at the present time are only justified as a purely temporary expedient, to keep the profession from complete disintegration. I say boldly that but for our own shortcomings in the past the employment of such artifices would never have become necessary. The cynicism with which certain of our claims have recently been met comes from our so far having failed to impress the public with the fact that we, as a profession at least, are better qualified to heal their aches and pains than are certain other competing bodies. Further, they have grounds for thinking that some of us are moved more by a desire for pecuniary gain than by a pure love of our art. The reinstatement of the profession in the public esteem will certainly not be hastened by the most rigid methods of "organization," nor even by our arming ourselves, in the simile of Dr. S. Wesley Wilson, "with the weapons of the burglar." It can only be brought about by our throwing ourselves—each one of us individually—with more zeal into our work and proving to the people our indispensability, not by words, but by deeds. To attain this end we will be the better of having some common platform on which we can voluntarily meet for mutual encouragement, advice, and help. This platform has been afforded in the past by the British Medical Association, and it is very much to be desired that it will not, at this crisis in our affairs, renounce such a highly important function. Any temporarily necessary trade union activities will be very much better carried out by a body formed *ad hoc*. Two or three such organizations are already springing up in London and elsewhere.—I am, etc.,

Edinburgh, March 23rd.

ARTHUR J. BROCK.

OPERATIONS ON CHILDREN IN THE OUT-PATIENT DEPARTMENT.

SIR.—The sphere of usefulness of a children's hospital can be very materially increased by performing major operations in the out-patient department.

The paper by Mr. Nicoll in the JOURNAL on February 22nd, and the subsequent letters of Mr. Andrew Fullerton and Mr. Stanley Green, show to what extent this can be carried out successfully. By so doing, not only is the waiting list kept within reasonable limits, but the wards can be reserved for those cases needing some more serious

operation, or where prolonged investigation or rest in bed is required.

In addition, I have found that in the case of infants, admission to the wards may cause serious nutritional disturbance, especially to those who are being breast-fed. For these cases, where the operation is not urgent, one must wait till they are weaned; or as a better alternative operate on them as out-patients.

During a recent week, in addition to the usual in-patient list, I operated on cases of hernia, hydrocele, depressed fracture of the skull, and meningo-myelocele as out-patients, and I have followed this custom for some time. Local anaesthesia also conduces to the success of this method, and all the above cases except the herniae were operated on under cocaine infiltration. The absence of a general anaesthetic still further diminishes any risk, while the children are able to take nourishment immediately the operation is completed.

The preparation of the skin by iodine and the sealing of wounds by collodion has greatly simplified this method of treatment.—I am, etc.,

Newcastle-upon-Tyne, March 11th.

FREDERICK C. PYBUS.

THE AFTER-EFFECTS OF GASTRO-ENTEROSTOMY.

SIR.—Dr. A. F. Hertz has certain very definite opinions regarding the anatomy and motor functions of the stomach, and they differ greatly from mine. I regret that I was not present at last year's British Medical Association's Meeting to hear his "opening address on the anatomy of the normal stomach." On reading over again the report of the proceedings in the BRITISH MEDICAL JOURNAL of September 28th, 1912, I fail to appreciate that "practically unanimous agreement" was accorded to him by the subsequent speakers.

Many years ago I felt that the anatomy and motor functions of the stomach were not as had been described, and, on reading the late Professor D. J. Cunningham's treatise¹ on the subject, I was convinced that he had come very near the truth as far as the pure anatomy was concerned. I carried out *then*, as Dr. Hertz recommends me to do *now*, a series of observations on what I took to be normal stomachs, and, having consideration to Cunningham's work, came, shortly stated, to the following conclusions:

1. That the stomach shows a more or less dilated, saccular, feebly motile cardiac portion, and a more or less contracted, tubular, strongly motile pyloric portion.
2. That the pyloric portion begins at the incisura angularis of His; its commencement is marked on the greater curvature during, at least, the earlier part of gastric digestion, by a well-marked notch; and that this notch is caused by action of what, for the sake of brevity, I called the "middle sphincter."
3. That, as indicated by Cunningham, there exists along the lesser curvature of the cardiac portion well marked remains of the original alimentary tube, one side of which has "blown out" to form the fundus and large part of the cardiac portion of the stomach; that the action of this rudimentary tube carries food to the lower part of the cardiac portion of the stomach, and, in doing so, sometimes shows modified segmentation.
4. That the pylorus is situated just internal to the gall-bladder, well above and to the right of the umbilicus, and may practically be regarded as fixed.
5. That certain radiographers and others were, therefore, wrong in their ideas as to the position of the pylorus, and therefore in much of their interpretation of what occurred during digestion.

In the course of Dr. Hertz's criticism of my views, during December, 1910, he invited me to go to see Dr. A. C. Jordan's work at Guy's Hospital. This I have been unable to do, but I may refer to the *Archives of the Roentgen Ray* published in January, 1911 (Dr. Hertz collaborated then with the editor of that journal, in which, embellished by numerous illustrations, are two articles, which to my mind confirm my conclusions. What other explanation than that which I give in conclusion 3 can Dr. Hertz give of figures 15, 16, 17, 19, 20, 23, which

¹ Transactions of the Royal Society of Edinburgh, vol. xlv, Part I, No. 2.

illustrate the paper of Dr. E. Ribas y Ribas, of Barcelona? In figure 1, illustrating Dr. A. C. Jordan's paper, the pylorus of what he states to be a normal stomach is "situated behind the umbilicus (marked by a metallic disc)," and the shadow of the metallic disc is well to the left of the middle line as shown by the shadow of the vertebral bodies. Such a position must mean that the first portion of the duodenum had been lengthened by at least 4 in., because there does not seem to be any displacement of the second (fixed) part of the duodenum. I wish that the plate of this excellent skiagram by Dr. A. C. Jordan could be published in the BRITISH MEDICAL JOURNAL, so that unbiassed opinions might be formed. Drs. Maclaren and Daugherty, in the *Annals of Surgery*, September, 1911, state that normally the pylorus is "practically a pelvic organ"! I cannot in the majority of cases, even in abnormal stomachs, displace the pylorus to the level and left of the umbilicus, much less into the pelvis. How many surgeons have found it possible to pull down the pylorus for examination in a mid-line incision which does not reach higher than the umbilicus?

In face of such diversity of view and discrepancy of interpretation on the part of the skilled skiagraphers, I fail to see how Dr. Hertz has arrived at such finality in the matter.

Dr. Hertz's recent paper might be far more convincing and valuable if it did not, as he admits, concern a collection of bad results from a conglomerate of surgeons, in the discussion of which no mention is made of the conditions for which the operation was done, the kind of operation done, or the complications which were present.

One would like to know the number of cases on which Dr. Hertz based his paper and formed his recommendations as regards surgical procedure, because, considering the results stated respectively by Messrs. Collinson and Bourne recently in the BRITISH MEDICAL JOURNAL, these recommendations can carry no weight unless backed by a full knowledge of the surgical procedure which preceded the failures which came under his notice.

In advocating drainage of the lowest part of the stomach and the making of a small stoma Dr. Hertz would have us go back to the early days of the operation. Like Dr. Hertz, I am not yet satisfied with my results, but I ascribe such good results as I do have greatly to the avoidance of these points which Dr. Hertz advocates.—I am, etc.,

Aberdeen, March 17th.

H. M. W. GRAY.

IMMEDIATE OPERATION IN APPENDICITIS.

SIR,—Mr. Edmund Owen has been good enough, after quoting several extracts from my letter in the JOURNAL of March 1st, in which I deprecated the policy of "look and see," to put a pointed question as to what treatment I advocate in cases of early appendicitis. I thought that I had clearly indicated my views in general terms with regard to that matter in the following statement in my letter: "We are all agreed that definite appendicitis is a surgical disease for several hours after its onset," but now I feel that it is necessary to explain that by "surgical disease" in that phrase is meant "a disease to be treated by manual operations" and that by "we" is meant surgeons.

In other words I am, like every surgeon, an advocate of appendicectomy in early cases of appendicitis. Unfortunately for sufferers, the great majority of the medical profession in every country that I have so far visited for the purpose of learning surgery have not yet got into the habit of dealing with appendicitis as a surgical disease from my point of view. Consequently surgeons, when they are called in, have to decide whether an "immediate operation" should be performed upon the individual case of appendicitis from evidence of the existing conditions, the history of the past treatment, and the circumstances and surroundings under which such cases are found.

The vast majority of cases I see have been ill for some days. These have passed the period of the "surgical opportunity" during which an operation would have given the best chance of saving life.

I think the expression "immediate operation" in the interesting discussion Mr. Edmund Owen raised by its use in his valuable paper has led to confusion.

In one case the term seems to be applied in the sense that the expression "early operation" is used by American

surgeons with regard to the onset of the disease, and in the other it bears relation to the time which elapses between the advent of the surgeon on the scene and the performance of the operation, irrespective of the duration or age of the disease.

With the above explanation I would add that I am a firm believer in "early operations," but not in "immediate operations" except when they are early.

The following case well illustrates the point I desire to make. Last year, on a Friday evening, Dr. G. R. Sparrow asked me to see a girl, aged 10 years, who was suffering from a virulent type of early appendicitis. She had vomiting, marked meteorism, pulse 156, temperature 102° F., and was gravely ill. She was the only child, and as her mother's uterus had been removed recently our responsibility was the greater.

Two trained nurses were immediately put in charge of the case, and "the greatest vigilance, the strictest observance of proper non-surgical treatment" were adopted—namely, Fowler position, rigid Ochsner's treatment, drop saline per rectum, morphine gr. $\frac{1}{4}$ hypodermically, the abdomen splinted, to report by telephone every two hours the condition of pulse and temperature, and instantly to call one if any new symptoms supervened. On the second day the pulse and temperature came below 100°, meteorism disappeared, and the patient was nearly ready for a safe operation. On the Sunday morning a fresh attack of acute perforative appendicitis suddenly set in about 10 a.m. I saw her midday and did appendicectomy within six hours of the recrudescence of disease. The patient got well and was up and about in a few days.

I learnt the value of early operation long ago, but I did not fully realize the many details involved in the life-saving value of "the strictest observance of proper non-surgical treatment" until I had the privilege of spending a few days in Chicago in 1906 and visiting Dr. A. J. Ochsner's surgical clinic.

The importance of this subject impels me to quote facts which speak for themselves. Dr. Ochsner operated upon one thousand (1,000) cases of appendicitis in thirty-three consecutive months, terminating on April 1st, 1904. Out of this enormous experience "fifty-five cases were of the acute perforative or gangrenous type without abscess. Five of them entered the hospital within forty-eight hours after the beginning of the attack and were operated at once. Sixteen of the remaining cases seemed in a condition making an immediate operation safe and were operated at once." The remaining thirty-four were piloted through the storm until they were placed in what I call dry dock for repairs. "This occurred in most cases within four days after admission, while in others the interval was longer." *These fifty-five cases were all cured.*

The mortality of the total (1,000) was 2.2 per cent., notwithstanding that it included "33 cases entering the Augustana Hospital with diffuse peritonitis resulting from perforative or gangrenous appendicitis," and "of this class a number were in a dying condition."

I must ask to be excused trying to solve the riddle suggested by Mr. Owen in "the case of a boy seized in the night with acute abdominal pains, with tenderness in the iliac fossa and rigid muscles over it, the temperature and pulse being about a hundred," because it is only an assemblage of symptoms, and is not a complete picture of a case upon which I could give an answer without qualifications. If it were an undoubted case of appendicitis, I would not hesitate in certain circumstances to delay the performance of an "early operation" at the patient's home, and would advise his removal to a place where the necessary conditions for safe performance of operations existed. On the other hand, if a doubt existed about the nature of the disease, I would advocate the policy of "wait and see," under certain conditions, rather than adopt that of "look and see," as advocated by Mr. Edmund Owen.

By the adoption of the former policy in my practice very suspicious cases have turned out to be affections of other organs, such as the bile channels, psoas muscle, or right kidney, and the right Fallopian tube in females.

Let us hope that Mr. Edmund Owen's paper will be of use in diminishing the avoidable mortality which now exists through ignoring the fact that appendicitis is a surgical disease.—I am, etc.,

Cardiff, March 24th.

J. LYNN THOMAS, C.B., F.R.C.S.

ALIMENTARY TOXAEMIA.

SIR,—I have been interested in the discussion at the Royal Society of Medicine on alimentary toxæmia, but, notwithstanding the number of workers, it will be obvious to every one that the field is yet quite unexplored. Intestinal stasis is a disease of civilization, and is seen at its worst in cities, where the mode of living is largely artificial. As doctors we meet the condition only in human beings, but it is equally common in house pets, such as dogs, cats, etc. It is already a chronic state when noticed by the sufferer, who tries all the advertised cures before he consults his physician. I do not doubt the latter's power to better the condition, but in many cases, owing to carelessness or forgetfulness on the part of the patient, the stasis is soon as bad as ever. But I can hardly follow Mr. Lane in attributing so many other diseases to intestinal toxæmia. Even were the connexion beyond what he calls quibbling, the cure would have to be safe and absolute, for it is an operation of convenience. The mortality would have to be as small as, say, "interval appendicectomy," and the after-results as satisfactory. Ileo-sigmoidostomy is fairly safe, but the after-results are not always satisfactory. Mr. Lane has had to do a colectomy later. Colectomy, as a primary operation, has too big an immediate death-rate, and Mr. Lane admits the usual after-effects of abdominal operations—adhesions, etc. These are often avoidable, unless the strain is too great for both patient and surgeon. At present that is the trouble. The surgeon cannot get the perfect closure of the peritoneum all round that is theoretically desirable. The size of the abdominal wound, and the lengthy exposure of the abdominal contents make an ideal operation impossible for the average surgeon. And it is the average surgeon who will supply the registrar with statistics, not the Lanes.

I am not quite convinced that intestinal stasis is due to Lane's kinks. Jackson's membranes, *et hoc genus omne* of recent discoverers, but there is a large consensus of opinion pointing to the ascending and transverse colon as the part in which stagnation mostly takes place, and from which toxins are absorbed. To remove this area is well within the power of the average surgeon who has experience in abdominal work. It is a safe proceeding, almost as safe as removing the appendix. My own method is to put the patient on the left side as for a nephrectomy. The incision goes from the tip of the twelfth rib to the rectus, midway between the umbilicus and pubis. The peritoneum is incised all along the outer border of the ascending colon, which is freed forward till it is quite outside the abdominal cavity from appendix to beyond the hepatic flexure. This point is easily recognized, as the whole transverse colon will then pull out. The bowel is crushed at the end of the ileum by a broad-bladed enterotome (a broad ligament clamp, with a tubing cover, does quite well), two ligatures are applied, one of thin, easily absorbed catgut on the side to be left, and the other of strong silk on the side to be removed. The same is done at the transverse colon at a point about its middle. Both crushed parts are now divided between the ligatures. The silk ends are brought together and covered up, while the catgut ends are sewn together with a fine gut suture. Two rows of continuous Lemberts invaginate the ileum into the transverse colon in a complete serous covering. The lumen, it will be observed, has never been open, so that the escape of intestinal contents is impossible; and it is this escape usually, and not errors of technique, that is the danger. The excluded portion is now removed, and the area opened up, as well as the end of the mesentery and transverse mesocolon, are brought together. There is left no hole for strangulation and no points for adhesions, and during the whole operation the abdominal contents have not been exposed for a moment, in fact need hardly be seen. Drainage is unnecessary. The catgut ligatures give way without any signs of obstruction, and before any real union has taken place; in fact, they serve the part of the Murphy button without its dangers. The kidney can be dealt with if desirable. I have done this operation on eight occasions—three for malignant disease and five for stasis. There has been no shock, no local trouble, and perfect movement of the bowels. There has been no need to wear a bib at the wrong end, as one of my ileo-sigmoidostomy patients suggested.—I am, etc.,

Dundee, March 16th,

ALEX. DON.

PHYSICAL SIGNS OF MYOCARDIAL INVOLVEMENT.

SIR,—Although not attaching so much importance to cardiac graphology as some who contribute to your pages, I venture to make a few remarks on the interesting subject dealt with in your recent issues by Dr. Lewis and Dr. Coombs under the above heading.¹ In the first place, I am glad to note that Dr. Lewis now confidently regards the auriculo-ventricular bundle as a "neuro-muscular strand," a view which he probably would not have expressed with so much assurance not very long ago. I should have imagined it reasonable to suppose that such a conception of the nodal structures which invade the myocardium might have suggested the possibility of such irregularities of action as he describes being at times due to disturbances of cardiac innervation, more especially as it is acknowledged that such cases need present no evidence of anatomical lesions in the "sensitive tract," as Dr. Lewis terms it, while in yet others lesions may be present which have not been associated with dropped beats or delayed ventricular response during life. "The bundle belongs to the myocardium," Dr. Lewis remarks,² and an invasion of the bundle, especially when, as is usual, it happens through vascular channels, can hardly occur without the exposure of the remaining muscle." It is remarkable, indeed, that it does not more frequently manifest the anatomical evidences of invasion, being so accessible to injury, as it apparently is, from its subendocardial situation in rheumatic endocarditis. This, however, is no more remarkable a fact than the comparative immunity from valvulitis and endocarditis of the right as compared with the left chambers of the heart in rheumatic infection. As Dr. Lewis's quotation from Professor Aschoff shows, however, invasion of the nodal system does occur not infrequently, although the graphological evidences of such are not always noticeable. This may, of course, be explained from the partial involvement of the structure, just as considerable portions of the larger mass of the myocardium—Dr. Lewis's silent area—may be affected by various conditions without disabling the heart as a whole.

But, while the bundle is a differentiation of mesoblast which originates in the embryo and penetrates the myocardium, as the nerves and blood vessels do, it no more "belongs to the myocardium" than do the latter structures. It is in as intimate relation to the nervous as it is to the muscular system of the heart, and, with all due respect to those who think otherwise—and I willingly concede they are in a majority at present—I hope I may without presumption be permitted to remark that I think its functions even now are not so clear as some would have us believe. As we are now quite certain that it is a "neuro-muscular strand," and were not in a position to be so comparatively recently, is it not just possible that we may in time modify our conceptions of the functions at present assigned to it? Not only do I believe this to be possible, but even probable, for even its anatomy requires further investigation.

Both Dr. Lewis and Dr. Coombs are disposed to regard chronic myocardial disease as due to a series of what our Teutonic brethren would term bacterial "insults." That is, that the heart, as Dr. Coombs puts it,³ is "reinvaded from without by new batches of micro-organisms." As Dr. Lewis truly remarks:

How many young girls come to us with advanced mitral stenosis and degenerate heart muscle, and relate the story of a single mild attack of chorea or rheumatic fever! Yet mitral stenosis does not develop during one attack of either; the advanced lesion is one which has evidently taken a long while making.

Does Dr. Lewis, then, suggest that repeated attacks of mitral valvulitis are necessary to the production of an ultimate stenosis? If this be his intention, I think it will be difficult for him to adduce proof to maintain his thesis. I should go even farther than he does, and state that both men and women appear before us in the condition he refers to, who have no knowledge of having ever suffered either from chorea or rheumatic fever. Nevertheless, since the date of such an attack "a long while" ago, and proved on necropsy to have occurred, the subject has lived, and the heart worked at some mechanical disadvantage, the products of a distant inflammatory lesion

¹ BRITISH MEDICAL JOURNAL, March 8th and 15th.

² BRITISH MEDICAL JOURNAL, March 8th, p. 438.

³ BRITISH MEDICAL JOURNAL, March 15th, p. 535.

ciatrizing and muscular texture degenerating from altered nutrition and perpetual labour effected with a handicap. I do not require to be informed that such a view has not the sanction of a new "school" of thought in such matters, the views of which *should*, if they do not obtain permanent acceptance, when regard is had to its vigorous propagandism and ingenious advocacy by crisp and confident exponents.

By these remarks I in no way desire to rob the myocardium of its long acknowledged importance in the mechanism of the circulation, but I hope I do Dr. Lewis no injustice when I state that he appears to me unduly to depreciate the consequences of inflammatory disease and deformity both of the valves and pericardium. May not his admittedly transient "block" signs of myocardial involvement be neural interferences with conductivity which do not necessarily indicate myocardial lesion of even a fleeting nature? We know how difficult it is experimentally to induce heart-block without complete division of the common stem of the so-called auriculo-ventricular bundle, and how insistent some myogenists have been that undisturbed ventricular action, in the presence of disease of the bundle, merely indicates that the structure has not been completely involved. Under these circumstances it is difficult to accept a little congestion of the bundle, even in the presence of dropped beats and other clinical evidence of heart-block, as the essential cause of the phenomenon. The value, therefore, of such a sign in itself, as an indication of myocardial involvement in infectious disease, seems at least questionable.—I am, etc.,

London, W., March 24th.

ALEXANDER MORISON.

RECENT ADVANCES IN THE DIAGNOSIS, PROGNOSIS, AND TREATMENT OF HEART DISEASE.

SIR,—In 1911, as Chairman for the year of the Folkestone Division of the British Medical Association and Folkestone Medical Society, I invited Dr. Price to give an address on cardiac disease to the members. He kindly came down on November 2nd of that year and gave us an address. I was in the chair on that occasion, and in his discourse Dr. Price enunciated the theory and practice of modern heart therapy and described very carefully and defined the extra-systole, etc. Dr. Price explained that he could not publish his lecture then as he was going to give it in other places.

This lecture is the only one I have heard, and Dr. Mackenzie's work on the heart is the only medical work I have read on modern heart theories. When I read Dr. Price's Toronto address¹ it was at once apparent to me that it was the same address he had delivered to us at Folkestone.

I remember quite well some of the phrases Dr. T. Lewis quotes out of this address. If I looked at these things in Dr. Lewis's way I should certainly have considered, had I read his book published in the spring of last year, that his information was derived from these two sources named. I cannot suggest that Dr. Price about a year and a half ago copied information from a book only published about twelve months ago.

It is sufficient for any one reading Dr. Mackenzie's works to judge how very many similar phrases occur in Dr. T. Lewis's book. I take it one must use correct definitions, symptoms, and terminology in describing the same set of ailments, and naturally the same things occur to all accurate observers and must be stated in similar terms. The affinity of great minds is proverbial.—I am, etc.,

Folkestone, March 22nd.

LENNOX WAINWRIGHT.

SIR,—In his letter appearing in the last issue of your JOURNAL, Dr. Price mentions that so long ago as early in 1911 I was cognizant of the text of the address he delivered before the Toronto Academy of Medicine in October of last year. This statement I confirm.

I feel some explanation of the circumstances under which the paper came under my notice is called for from me. Some time about the end of May, 1911, I was asked by Dr. Hawthorne, the Chairman of the Polyclinic, to

give a course of instruction there on modern methods in heart disease. I understood Dr. Mackenzie had mentioned me as one likely for the work. At the time I was not aware Dr. Price was the appointed lecturer for this course, but was unable to act because of illness.

Subsequently Dr. Price wrote to me on the matter, and forwarded for my guidance the typescript of the lectures he had purposed giving. I made no use of the paper, as I considered it better to adhere to the syllabus of my previous classes.

I read Dr. Price's paper carefully, and I can vouch that the subject was dealt with substantially in the same manner and order as in his recent address, but at greater length. I cannot, however, remember particular phrases, niceties of diction, or the order of words used in describing facts. The only paragraph of the paper I recall is that relating to *pulsus alternans*, in which I am greatly interested. I noticed that this pulse rhythm was described as being often difficult or impossible to detect by the finger, except at times when alternation was continuous.

I was under the impression that this was my copyright, and flattered myself Dr. Price had probably troubled to read a paper of mine in the *Lancet* incidentally dealing with this subject; but I found this was unlikely, and concluded that, perhaps after all, this and most other statements of fact in the paper were derived from the source from which all writers so far have had to draw so freely. No one has yet worked long enough to revise from his own experience all the observations in Dr. Mackenzie's classical writings.—I am, etc.,

Southall, W., March 21st.

J. D. WINDLE.

SIR,—I am glad to confirm Dr. Price's letter of March 17th. I had the pleasure of listening to his lecture at Brighton in October, 1911, and when I read his Toronto address I was surprised to find nothing which I had not heard before. To refresh my memory, I have looked up the notes made by the honorary secretary of our society; they begin with a mention of aconite and finish with $\frac{1}{25}$ of a grain of strophanthin intravenously. It is more than probable that Dr. Lewis and Dr. Price have both unconsciously adopted the phraseology of Dr. Mackenzie, the one great master of modern cardiology.—I am, etc.,

Brighton, March 23rd.

WALTER BROADBENT.

SIR,—I have read the correspondence in your JOURNAL concerning Dr. Price's address at Toronto last year. Dr. Lewis appears to think it was written after his book was published. I do not know the exact date of the publication of Dr. Lewis's work, but on reading Dr. Price's address in the JOURNAL of March 8th I at once recognized it as having been delivered at the Polyclinic on February 28th and 29th, 1912. More than twelve months having now elapsed, I cannot remember all the words and phrases to which Dr. Lewis has drawn attention. However, I distinctly remember some of the passages which Dr. Lewis has italicized—not every word, though very nearly so—and of course the meaning conveyed was identical.

It appears to me only right, under the circumstances, to state those facts.—I am, etc.,

London, W., March 22nd.

JAMES CHUTE.

MEDICAL ILLUSTRATORS.

SIR,—I have nearly finished a volume on *Medical Men as Illustrators*, for I found that scanty credit had been given to many such either in the early folios or in the modern works—indeed, very often no mention was made at all.

I am giving a short life of each man, also his portrait and a specimen or two of his work. This was easy with regard to the earlier writers, as I have been a collector of first editions of medical works for the past thirty years, but I have some difficulty in getting portraits of such men as McClise, H. V. Carter, J. Hewslip, etc.

I would be most grateful for new names for my list, also sources where the human side of the man is given in biographical or autographical form. Curiously, near relations seem the least able to supply such details.—I am, etc.,

HOWARD A. KELLY, M.D.

Baltimore, Maryland, U.S.A., March 14th.

Obituary.

ARTHUR JOHN WALLACE, M.D. EDIN.,

ASSISTANT LECTURER ON GYNAECOLOGY AND OBSTETRICS,
UNIVERSITY COLLEGE, LIVERPOOL.

We regret to announce the death of Dr. Arthur J. Wallace, of Liverpool, which took place, after a short illness, at St. Annes-on-Sea on March 16th.

He was the eldest son of the late Professor John Wallace, and was born at Dalston in 1867. He was educated at the Liverpool Institute, and pursued his medical curriculum partly in Liverpool and partly in Edinburgh, at which latter University he graduated in 1889. He was then appointed on the resident staff of the Liverpool Royal Infirmary, and later to the Holt Scholarship in Anatomy and Surgery at University College, Liverpool. At the close of his term of office he proceeded to Paris and Berlin to study gynaecology in those cities. On his return he was appointed to the post of demonstrator, and later to that of assistant lecturer in gynaecology and obstetrics at University College, Liverpool.

For the last fifteen years he had held the post of honorary surgeon to the Hospital for Women in Shaw Street, Liverpool, and for the same period had served on the honorary staff of the Maternity Hospital in Brownlow Hill, Liverpool. He was one of the Honorary Secretaries of the Section of Gynaecology and Obstetrics at the annual meeting of the British Medical Association in

Liverpool last year. He was a member of many learned societies, and in 1908 was elected president of the North of England Obstetrical and Gynaecological Society. A few weeks ago he was appointed honorary consulting gynaecologist to the Royal Southern Hospital.

He contributed several papers to the *Transactions* of that society, to the *Journal of Obstetrics and Gynaecology*, and to the *Lancet*. He was the author of an essay on the *Treatment of Pregnancy complicated by Operable Carcinoma Uteri*, and of a *Syllabus of Midwifery for Midwives*. He had a wide reputation in his speciality both in this country and on the Continent. His work was sound and scientific, his judgement and opinion of the highest, and, combined with his skill as an operator, gained for him a distinguished position in his profession.

His unexpected decease in the prime of life and professional career came as a sad surprise to all who knew him. His loss will be keenly felt by a large circle of friends and professional brethren, to whom he had greatly endeared himself. Dr. Wallace leaves a widow but no family.

Prior to private cremation at Anfield, a service was held on March 20th at St. Mary's Chapel for the Blind, Hardman Street, conducted by the chaplain, the Rev. T. W. M. Lund. In addition to the chief mourners, there was a numerous assemblage, including representatives from many hospitals and

societies, members of the medical profession, and other friends, which manifested the high esteem in which Dr. Wallace was held by all in the city.

ARTHUR JOHN WALLACE.

J. J. KIRK DUNCANSON, M.D., F.R.C.P.E., F.R.S.E.,

LATE SURGEON, EYE, EAR, AND THROAT INFIRMARY,
EDINBURGH.

By the death of Dr. Kirk Duncanson at Gullane, on March 12th, a familiar and much respected figure has been removed from the medical profession in Edinburgh.

He was born near Dunfermline, and educated at Dollar Academy and the Edinburgh Institution. He spent a short time at engineering after leaving school, but soon turned his attention to medicine, and his advent as a student was welcomed by former schoolfellows and friends. Among the latter, his most intimate associate was David Ferrier, now Sir David Ferrier, who had just returned from Heidelberg, whither he had gone with two double firsts in arts after a brilliant career at Aberdeen, and completed his medical curriculum in Edinburgh. The present writer was often in their company, and can recall many happy evenings spent in their society. Duncanson was an enthusiastic botanist and Ferrier was a keen physiologist, and even then, with deep philosophical knowledge, discussed with profound criticism Professor Hughes Bennett's views on localization of function in the brain. It is interesting to remember that Ferrier treated his first case of rheumatic fever with half-drachm doses of bicarbonate of potash—sound therapeutics even in these advanced days. Space forbids the writer to enlarge too much, but the temptation to picture Duncanson's environment as a student is irresistible: Balfour, Playfair and Allman, Hughes Bennett, Goodsir and Spence, Christison, Laycock, Simpson, MacLagan and Henderson in the university; Sanders, Begbie, Haldane, Crum Brown, Grainger Stewart, and

Littlejohn, in the extra-mural school. Sir William Turner became Professor of Anatomy in 1867, the year before Duncanson graduated, but he had practical charge of the department for some time before that. Among the juniors, T. R. Fraser, Dyce Duckworth, W. Ruthertford, Annandale, Joseph Bell, John Chiene, John Wyllie, and Lauder Brunton, were at the commencement of brilliant careers. Prominent men of his year were Ferrier, Russell, Halliday Croom, and Byrom Bramwell.

Duncanson graduated in 1868, and spent some time in Heidelberg studying gynaecology, and then went on to Vienna, where he made a special study of the ear. Returning to Edinburgh, he graduated M.D. in 1871 and became a Fellow of the Royal College of Physicians in 1874. He was also a Fellow of the Royal Society, Edinburgh. He acquired a good general practice, but afterwards devoted himself to diseases of the ear and throat, and after acting as Assistant Surgeon to the Eye and Ear Infirmary, under Mr. Benjamin and Dr. Joseph Bell, for some years, he became Surgeon to that institution. He did not make many contributions to medical literature.

Dr. Duncanson was a man of very retiring and unassuming habits. His hobbies were chiefly golf, long country walks, and botanical excursions. He was often to be met on the Queensferry Road or Ravelstone Dykes in the afternoons, with a Skye terrier and spaniel who were his faithful companions. He was a staunch friend, and did many kindnesses to his poor patients. He had been in bad health for several years before his death. He leaves a widow but no family. *Requiescat in pace.*

PHILIP FRANK, M.D. BERLIN, F.R.C.P. LOND..

FORMERLY OF CANNES.

THE death of Dr. Philip Frank in his 83rd year has not only terminated the career of one of the most distinguished physicians of the last generation, but has stirred very deep feelings of personal loss among countless friends in all walks of life. His experience of life was unusually varied, and, combined with very high ideals, served to enlarge its horizons in all directions. In his earlier experiences in Berlin, where he studied and graduated M.D. in 1853, he was intimately associated with the great spirits of the time who played the most important part in that renaissance of German medical and surgical science which has brought it to its present proud position. While assistant to B. v. Langenbeck at the Berlin University Klinik, he became intimately acquainted with Billroth, Volckmann, Guilt, Virchow, and others of that galaxy of talent who banded together to reform the then deplorable conditions which obtained in medical and surgical practice, and who, reaching out in all directions for fresh inspirations, were at a later date among the first to recognize and acknowledge the great genius of our own Lister and what his teaching meant for humanity. He became a Member of the Royal College of Surgeons of England in 1856, and that year he entered the Army Medical Service. In it he still further enlarged his knowledge of men and disease in Malta, South Africa, and India, whence he was invalided home in 1859. In that year he became a Member of the Royal College of Physicians and was elected a Fellow in 1871. After 1859, he worked again in Berlin, and later was assistant to Professor Longmore in the Army Medical School. He then spent three winters in Madeira and two in Mentone as medical attendant on Lord Brownlow, and practised in the last place until the spring of 1868; then in Cannes. From August, 1870, to the spring of 1871 he served with the Anglo-American Ambulance in the Franco-German war and took a very active share in treating the sick and wounded in and around Sedan. From 1871 to 1898 Dr. Frank practised in Cannes, where he enjoyed a really great reputation and became the close and valued friend of many notable personages of all nationalities.

Throughout his career Dr. Frank was carried along by a wide sympathy and the realization of the necessity, not only of keeping himself abreast of the times in medical and surgical science, but also of studying men of all conditions and of every nationality. In all this he was aided by his linguistic powers, which were of a high order, and by an intelligence which he cultivated in every way. He was early influenced by the fresh impetus given to science by the men of the Continental schools among whom he worked, and seemed to experience a generous exultation in the achievements of every honest worker, no matter what his nationality. His broad and cultivated mind, with its tender reverence for all goodness, recognized the brotherhood of medical men even in lands sundered politically, and the respect that was due from each to all. This spirit was kept fresh up to the very last. After he retired from practice in 1898, and went to live in Kensington, he was a constant attendant on the medical and surgical practice of our hospitals, and year after year, until quite recently, was a most inspiring visitor in the wards and operating theatres to many of the younger teachers. Nothing could exceed the modesty of his quiet comments and inquiries, but they constantly opened up new lines of thought and stimulated increased effort.

Those of us who were privileged to know Dr. Frank intimately were favoured by the friendship of a most retiring and high-minded gentleman of wide culture and the largest sympathies, "who spoke no slander, nay, nor listened to it," who was generous by nature, generous of his acquired knowledge and experience, and also in more material ways, of which he would be the last to wish any one to speak. The keynote of his being was duty in its widest meaning, and his cheerful life and end seem to answer Coleridge's question very fully:

What would'st thou have the good great man obtain?
Riches or honour or a gilded name,
Or throne of corpses which his sword hath slain?
Hath he not always treasures, always friends?
Three treasures—Love and Light
And Calm Thoughts, regular as infant's breath;
And three firm friends, more sure than day or night—
Himself, his Maker, and the Angel Death.

For, indeed, Death was kind to Dr. Frank, and came swiftly and without pain to body or mind while he still thought clearly and felt warmly.

HENRY W. COLEMAN, M.R.C.S. L.R.C.P. EDIN.;

LEEDS.

IT is with great regret that we have to record the death of Mr. Henry Coleman, which took place at his residence in Leeds on March 18th. Mr. Coleman was born at Pontefract, where his father was town clerk and registrar of the county court and where the position of town clerk was also held by his brother and by his grandfather. He was educated at the Pontefract Grammar School and at Cheltenham. He afterwards entered as a student of the Leeds Medical School, being a pupil of the late Mr. Whellhouse, and took the diplomas of M.R.C.S. Eng. in 1870 and of L.R.C.P. Edin. in 1874. He became one of the residents at the General Infirmary, and was on the resident staff at the time that the work of the institution was being transferred from the old building in Infirmary Street to the present building, and the writer has often heard him refer to the fact that it fell to him to admit the first patient to the wards. He then became associated with the late Mr. Rickards, of Armley, whom he succeeded in practice in that part of the town. For many years there was no better known practitioner in Leeds than Mr. Coleman.

He was a strenuous worker, and a great favourite with his patients, among whom he was able to number many personal friends. Some years ago he retired from practice, and was succeeded by one of his former assistants, Dr. Alexander. At this time he gave up most of his public appointments, including those of Medical Officer of the Bramley Workhouse, and Medical Officer and Public Vaccinator for the Armley and Wortley District of the Bramley Union. The position of Certifying Factory Surgeon of the West Leeds District he retained till quite recently. A strong churchman and a keen politician, he took a great interest in public affairs, and was for some time chairman of the West Leeds Conservative Association. He was on the Commission of the Peace for the city of Leeds, and in this capacity was a very regular attendant on the Bench. By all who knew him Mr. Coleman will long be remembered as a man of great geniality and of true kindness of heart. He was always ready to help his juniors in the profession, and the writer can call to mind many acts of true kindness to himself and to others. He was full of amusing reminiscences of the older days of the infirmary and school, and his good-natured mimicry was a source of entertainment to the principals themselves and to those who knew them.

He was laid to rest at Pontefract, and the funeral was attended by a large number of those who were associated with him in his professional life, and who desired to pay the last tribute of respect to one who was regarded with affection by all. He was 66 years of age, and is survived by his widow and daughter.

SURGEON-GENERAL H. SKEY MUIR, C.B.

THE older officers of the Army Medical Service will realize with regret that they have lost another old friend in Surgeon-General H. Skey Muir, C.B., who died at his residence in London on March 6th in his 72nd year.

Henry Skey Muir, having first matriculated in 1859 at the London University, proceeded to Glasgow, where he passed two medical sessions. He entered Guy's Hospital in 1861, and these two schools therefore share the education of this distinguished medical officer. He took the M.D. degree at Glasgow in 1863, and later the diploma of M.R.C.S. Eng.

He entered the Army Medical School at Netley in 1864 shortly after the removal of that school from Fort Pitt, Chatham. On completion of the probationary period there he was posted to Nova Scotia, and subsequently was gazetted assistant surgeon to the 6th Foot (now the Royal Warwickshire Regiment), in which he served until 1877. Promotion to surgeon-major came in 1876, and the next year he proceeded to India. This tour of service included the second Afghan war, in which he served. One of his experiences in this campaign was the march of the Kaudahar column under Sir Donald Stewart up to Kabul.

His services gained him the distinction of a mention in dispatches.

He passed afterwards a sufficiently varied career, during which he visited the West Indies and the Cape, performed a second tour of Indian service, holding charge of the important military hospitals at Lucknow and Aldershot and the appointments of Principal Medical Officer of the North-Western District and of a district in India during a third tour in that country. In 1897 he became Principal Medical Officer in Egypt, where, although he did not accompany Lord Kitchener's expedition up the Nile, he was responsible for the medical organization and arrangements of the British troops engaged. After thirty-four years of service he was selected for the appointment of Deputy Director-General of the Army Medical Service at the War Office. He held this post during the strenuous times of the late war in South Africa, and, although he reached the age limit on October 4th, 1901, he was retained in his appointment until the end of that year, when he was succeeded by Sir Alfred Keogh. At that time he was also a member of the Central British Red Cross Committee, which rendered such valuable aid to the sick and wounded in the Boer war. In 1900 he was created a C.B.

Besides his military services Surgeon-General Skey Muir devoted much of his spare time to the study of a branch of science other than his immediate profession, and became a Fellow of the Zoological Society. Like many of his brother officers, he found relaxation by diverting his mental activities into another channel.

Thus was passed a long career of usefulness, which, though it did not culminate in the highest office open to the army medical officer, yet illustrates the varied experiences and responsibilities successfully carried out by a highly capable, courteous gentleman.

ON March 8th the death occurred of Dr. JOSEPH BRADLEY, Medical Officer of Gortin Dispensary District of Omagh Union. While out on a sick call a short time ago Dr. Bradley became suddenly ill, and was found to be suffering from appendicitis. He was removed to the Tyrone County Hospital in his motor car and an operation was performed, but unfortunately complications set in which proved fatal. He was much respected in the district, and only a few months ago, on the occasion of his marriage, was presented with an illuminated address by the people of Gortin and Greencastle.

It is with feelings of deep regret that we record the sudden death of Dr. F. G. GRAVES on March 2nd. Dr. Graves received his medical training at the London Hospital, where he held the post of resident medical officer. In 1857 he took the diploma of M.R.C.S., in 1858 that of L.S.A., and in 1859 the degree of M.D. St. Andrews. For over fifty years Dr. Graves had practised in Paddington, where he was a well-known figure, and by his genial and kindly manner, together with his professional skill, had endeared himself to all with whom he came in contact. His sudden death will be keenly felt by his many friends and patients. He leaves his eldest son to carry on his practice.

THE late Dr. PETER ANDERSON, who died at Rose Villa, Stanley, Perthshire, on March 12th, was known amongst his friends as "Anderson of Formosa." He deserved the name, for he worked as a medical missionary for thirty-one years in that far-off island, for twenty-five years in the capital, Tainan, and for six in Takow. He was born more than sixty years ago in Perth. He began his medical studies in Edinburgh, under the aegis of the Edinburgh Medical Missionary Society, in 1874. He took the diploma of L.R.C.P. and L.R.C.S. Edin. in 1878, and sailed for Formosa as a missionary of the English Presbyterian Church in the same year. His chief work was done in Tainan before the Japanese occupation of the island; after that event Tainan so increased in size that, to use Dr. Anderson's own words (in a letter to a friend) he was glad when an opportunity came to exchange his responsibilities there for the smaller sphere at Takow. In 1906 Dr. Anderson brought his wife home to Scotland, but she was then suffering from a fatal affection, and died soon afterwards. He himself came home in 1910, and had lived since then in Stanley. He married a second time,

and leaves a widow and several children. He was buried in Redgorton Churchyard on March 15th. Always a modest man about his own achievements, Dr. Anderson has left his mark upon the natives of Formosa, and the Japanese were among the first to acknowledge the beneficial effects of the medical missionary work accomplished by him in Tainan.

Universities and Colleges.

UNIVERSITY OF OXFORD.

Course for the Diploma in Ophthalmology.

THE annual course for the Diploma in Ophthalmology begins on April 21st. There will be a series of lectures on diseases of the eye and on medical ophthalmology, as well as clinical instruction at the Eye Hospital. Courses on bacteriology of the eye and pathology will also be held. Instruction in physiological optics is given at the Physiological Laboratory, and on the anatomy of the eye in the Anatomical Department at the Museum. For information apply to the Assistant Registrar, Oxford University, or to Mr. P. H. Adams, M.A., Margaret Ogilvie Reader in Ophthalmology, 53, Broad Street, Oxford.

UNIVERSITY OF GLASGOW.

INCLUSIVE FEES.

At the meeting of the Glasgow University Court on March 13th, a report was submitted by the committee recommending that the inclusive fee for the specified courses of instruction for the M.B. and Ch.B. degrees be 90 guineas payable in four annual instalments of 20 guineas and one instalment of 10 guineas. The inclusive fee would admit to thirty of the specified graduating courses. A candidate who had paid one or more of the annual statements of the inclusive fee at one Scottish university, and completed his curriculum in another, would pay the remainder of the annual instalments to the latter university, and would be entitled to attend such further graduating courses therein as with those already attended in the former university would make up the stated number. It would be necessary that the amount of at least two annual instalments should be paid to the university in which he completed his curriculum, and that before he received his degree therein he should present evidence that he had paid in all an amount equal to the inclusive fee. A candidate whose attendance elsewhere than at a Scottish university on courses of instruction in all the subjects of the first division of the professional examination had been accepted by the Senate as qualifying for graduation would be entitled to a deduction of 25 guineas from the inclusive fee; and a candidate whose attendance on courses of instruction in all the subjects of the first and second divisions of the professional examination had been so accepted would be entitled to a deduction of 50 guineas from the inclusive fee.

Principal Sir Donald MacAlister explained that, owing to the clinical courses being under the control of other bodies than the university, it was impossible meantime to suggest a uniform clinical inclusive fee. The present aggregate was one of 27½ courses for 90 guineas, so that by giving 30 courses for this sum the university gave a bonus of 2½ courses, and the student stood to gain this. The extramural students were as free as the intramural students to take advantage of the educational bonus, and therefore nothing was done to interfere with the present freedom.

After a discussion during which Sir David McVail objected to the principle of a medical inclusive fee, a motion was carried instructing the committee to confer with the authorities of the extramural schools in Glasgow on the scheme now laid before the court, and to report.

VICTORIA UNIVERSITY OF MANCHESTER.

THE following candidates have been approved at the examinations indicated:

FIRST M.B., Ch.B. (*Part I. Inorganic Chemistry and Physics*)—
F. H. Anderson, Mercy D. Barber, W. T. G. Boul, C. F. J. Carruthers, C. G. Carson, Ruth E. Conway, G. E. Hayward, N. Kletz, E. N. P. Martland, A. B. Platt, J. Shlosberg, H. Taylor, H. Tomlinson, F. White. (*Part II. Biology*).—J. H. Albinson, R. J. Allison, F. H. Anderson, Mercy D. Barber, W. T. G. Boul, C. F. J. Carruthers, C. G. Carson, B. W. Conway, Ruth E. Conway, G. E. Hayward, N. Kletz, E. N. P. Martland, F. H. Moor, R. S. Peterson, A. B. Platt, J. Shlosberg, D. M. Sutherland, H. Taylor, H. Tomlinson, F. White.

SECOND M.B., Ch.B.—M. C. Peterson

THIRD M.B., Ch.B. (*General Pathology and Morbid Anatomy*).—
W. S. Booth, J. E. Brooks, F. Gladwick, F. S. Charnoek, J. W. Craw, N. H. Davison, J. Fielding, W. Halliwell, E. A. Linell, Cheri A. Lomas.

Passed with distinction.

D.P.H.—P. Bevington, D. E. Connolly, W. G. Evans, N. Gebbie, G. Jessel, R. C. Hutchinson, R. Proudfoot.

Ashby Memorial Scholarship.

The Ashby Memorial research scholarship in the diseases of children has been awarded to Mr. John Morley, M.B., Ch.M., F.R.C.S., who will carry out researches with regard to certain congenital abnormalities and their clinical significance. Mr. Morley, who received a scholarship when he graduated in 1908,

afterwards held the Professor Tom Jones memorial surgical scholarship.

Appointments.

Dr. E. B. Leech has been appointed assistant lecturer and demonstrator in materia medica and therapeutics, and Mr. T. Graham Brown, M.B., B.S., a Carnegie Fellow who has recently been working under Professor Sherrington at the University of Liverpool, has been appointed lecturer in experimental physiology.

UNIVERSITY OF LIVERPOOL.

A CHAIR of Regional Surgery has been established, and Mr. W. Thelwall Thomas has been appointed professor.

UNIVERSITY OF BRISTOL.

THE following candidates have been approved at the examination indicated:

M.B., CH.B. (*Second Examination*).—Hilda Kate Ewins, William George McKenzie, Cedric Norman Vaisey, Guy Richard Penny Wooley.

UNIVERSITY OF BIRMINGHAM.

DR. ALFRED H. CARTER has resigned his Professorship of Medicine after being connected with the Birmingham Medical School for about thirty-five years.

Dr. Henry Whitehead, M.D., D.P.H., Medical Superintendent of the City Hospital, Lodge Road, has been appointed Clinical Teacher in Fevers and in Hospital Administration.

Dr. John T. Hewetson, M.D., Ch.M., F.R.C.S., has been appointed Assistant to the Chair of Midwifery and Diseases of Women.

In connexion with the meeting of the British Association in Birmingham in September next, the council will hold a reception and degree congregation in the Great Hall of the Edgbaston buildings on Thursday, September 11th.

SOCIETY OF APOTHECARIES OF LONDON.

THE following candidates have been approved in the subjects indicated:

SURGERY.—E. C. Banks, *A. C. Dickson, *R. G. Maglione, †H. Rimington.

MEDICINE.—E. C. Banks, O. W. D. Steel, †S. Zarchi.

FORENSIC MEDICINE.—F. C. M. Gabites, G. F. Malden, C. E. Reckitt.

MIDWIFERY.—S. H. Andrews, L. B. Clarke, T. H. Cresswell, P. R. Cross, H. Dudley, T. B. Paul.

* Section I. † Section II.

The diploma of the Society has been granted to Messrs. E. C. Banks, R. G. Maglione, H. Rimington, and O. W. D. Steel.

Public Health

AND

POOR LAW MEDICAL SERVICES.

OUTBREAK OF TYPHOID FEVER AT RINGWOOD.

IN THE BRITISH MEDICAL JOURNAL for March 15th reference was made to the report to the Local Government Board by Dr. Hugh A. Macewen, upon an outbreak of typhoid fever which occurred in the town of Ringwood in the autumn of last year, in which seventy-seven persons were attacked and five died. We have received a communication from Mr. Howard Tozer, vice-chairman of the Ringwood Rural District Council, in the area of which the town of Ringwood is situated, enclosing a long report from the medical officer of health, Dr. Charles E. Blackstone. In both of these documents certain statements made by Dr. Macewen are traversed, and objection is taken to the conclusions he has drawn. The main points at issue appear to be as to the cause of the outbreak, as to the attitude of the district council with regard to it, and as to the sanitary administration of the district generally. Dr. Macewen stated in his report that it was suggested that locally manufactured ice-cream might have been the infective agent, and that there was a certain amount of evidence to give colour to the suggestion. He seems to have made careful investigations into the possibility of this being the case, but eventually came to the conclusion that ice-cream was not so likely a cause as the drinking of water from the Cockstone stream which courses through the town. Dr. Blackstone, on the other hand, gives some very good reasons for concluding that a particular supply of ice-cream was the main factor in causing the outbreak. On the question of sanitary administration of the district, Dr. Macewen stated he had been informed on good authority that privy buckets had been washed by the district council's men in Cockstone stream on August 1st, and that the contents were on at least one occasion thrown into the stream instead of being taken to the cart and removed in a proper manner. He referred also to the absence of any hospital accommodation for infectious diseases, though Dr. Blackstone is able to show that a temporary hospital was opened in a disused

farmhouse within a fortnight of the receipt by him of the first notification of any case. In this connexion, Mr. Tozer states that very considerable efforts had been made in the past by the district council to provide an isolation hospital. Plans had been drawn and a site selected, but the residents near the site protested so strongly that another site had to be sought, only with a like result. The council, he says, then undoubtedly weakened in its purpose because of local opposition, and allowed the matter to stand over for a time. We are glad to learn from Mr. Tozer that Dr. Macewen was mistaken in his impression that the members of the district council were reluctant to realize the gravity of the outbreak. He assures us that from the very first moment it was reported to the district council they took a serious view of it and neglected no step recommended by their advisers.

Medical News.

A MEETING of the newly-formed British Oto-Laryngological Society will be held at the rooms of the Medical Society of London, Chandos Street, W., on Thursday next, at 5 p.m.

THE Harveian Society of London has arranged for its annual Harveian lecture to be delivered on April 10th, at 8.30 p.m., by Dr. A. P. Luff, who will deal with the various forms of fibrositis and their treatment. All members of the medical profession interested in the subject are invited to be present. The society's home is at the Stafford Rooms, Titchborne Street, Edgware Road, W.

By an Order in Council dated March 14th the term "sulphonal" in Part II of the Schedule to the Poisons and Pharmacy Act has been replaced by "sulphonol and its homologues whether described as trional, tetronal, or by any other trade name, mark, or designation." In the same order diethyl-barbituric acid and allied bodies whether described as veronal, preponal, medial, or by any other trade name or designation, and all poisonous urethanes and urecides, are added to the schedule.

ON March 22nd Dr. Church, who has been in practice in Minchinhampton for nineteen years, and is shortly leaving for British Columbia, was presented with two silver entrée dishes bearing the inscription, "Presented to Dr. B. E. Church by the people of Minchinhampton, Gloucestershire, in remembrance of their affection for him, March 22nd, 1913." The gift was accompanied by an illuminated album containing the names of the subscribers.

THE sixth and last of the Galton Laboratory lectures on national eugenics was delivered by Professor Karl Pearson at University College, London, on March 18th. He gave an interesting account of some recent studies of heredity in dogs, which, he said, proved once more the fallacy of Mendelian theories. Experiments in breeding and interbreeding different types of dogs showed that no hard and fast rules could as yet be laid down to account for the laws of heredity. The fact was that the study of eugenics was still in its infancy; eugenists at present could only echo the words of the soothsayer in *Antony and Cleopatra*, "In Nature's infinite book of secrecy a little I can read."

MR. WILLIAM BROWN, M.A., D.Sc., lecturer on psychology in the King's College of the University of London, will during next term give a course of lectures on psychology for medical students and practitioners adapted to the syllabus of the examination for the Cambridge diploma on psychological medicine. The fee for the course, which includes twenty lectures each followed by practical work, is five guineas, and those who intend to join are requested to send their names to Dr. Brown or the Secretary at King's College. An introductory lecture will be given on Wednesday, April 23rd, at 4 p.m., to which admission will be free.

IT must be confessed that, of the thousands who die in the prime of life, most are roughly and prematurely wrenched from the tree of life, before coming, "like as a shock of corn cometh in his season," to that fruition when they would have been gathered full of years if not of honours. Doctors aim at prolonging life by entrenching mankind behind the defences of remedial measures during the fight with the arch destroyer, but also by spreading the principles of right living. The time to prepare for war is during peace. The time to ward off disease and death is during health. Every doctor is an evangelist of the gospel of preventive medicine. One of the latest is Dr. Lachlan Grant, who in a brightly written, optimistic contribution to the *Caledonian Medical Journal*, points out the conditions of health. Dr. Grant's suggestions on the subjects of sleep, food, work, exercise, recreation, social intercourse, and worry, will be endorsed by his fellow practitioners, although it is disconcerting to be told that tea and coffee as frequently made are "deadly poisons."

THE advantages of gas as a domestic fuel have lately been made the subject of two Cantor lectures, delivered at the house of the Royal Society of Arts by Mr. F. W. Goodenough, who claimed that the undoubted diminution of fog in London was due to the fact that during the last twenty years the number of gas-heated cooking and hot-water appliances sold, hired, or loaned in the metropolis had increased from a few thousands to nearly a million and a half, with a consequent reduction in the number of kitchen fires. He also pointed to the physical and moral value of the gas-cooker to the working-classes. It had a physical value because it insured for the working man a well-cooked and nourishing breakfast, and prevented the necessity which often arose with a slow and refractory kitchen grate, of beginning hard work without hot food. It had a moral value, for it gave to the working man the certain prospect of a hot and punctual supper, and thus conduced to evening sobriety. Although houses were still erected on the supposition that gas was at best only a second string to the kitchen bow, yet this cleanly and ideal domestic fuel had established itself. Mr. Goodenough claimed, from end to end of the social scale, from Mayfair kitchens with their multiple ovens and special roasting chambers, to the single all round stove of the artisan's scullery. As to its economy compared with coal, he thought that the answer was forthcoming from the 750,000 housewives in London who used gas-cookers although compelled to prudence by means so scanty that they had to buy gas a penny a time through automatic meters. The complaint of the wastefulness of gas in larger houses was rarely heard when the mistress of the house did her own cooking, and never when she had learnt how to use her stove. Some small prejudice still existed against gas-cooked food, but Mr. Goodenough maintained that the juices of the meat were retained, while the excess of fat was eliminated. It was proved that meat while being cooked in the gas-oven was emissive and not absorptive. Mr. Goodenough showed some forms of distillers and porous water sterilizers for purifying drinking water by a gas-heating arrangement. The purpose of the sterilizer was to bring the water just to the boiling point without entailing the insipidity which was characteristic of water boiled for a long time.

PRINCESS CHRISTIAN OF SCHLESWIG-HOLSTEIN presided over the ninth annual meeting of the Association for Promoting the Training and Supply of Midwives, which was held in Central Buildings, Westminster, on March 14th. The annual report for the year 1912 stated that twenty women had been entered for training, and the standard of general efficiency had been well maintained, so that the association might rest assured that its primary object of promoting the supply of midwives and furthering the purposes of the Midwives Act was being steadily carried out. This Act, however, was but feebly administered in some districts, and there was still a tendency in many places to ignore the fact that untrained women are at work, so that in this direction the association had still abundant work lying to its hand. The work at the East Ham Home continued to increase from year to year. The number of midwifery cases received there during the past year amounted to 843, and the monthly cases to 243, making a total of 1,086 confinements. The average number of deliveries by each pupil was 42, that is, 22 more than the minimum number required by the Act. The care exercised by the Committee in the selection of candidates for training at the Home could be judged from the fact that out of the 390 women who applied for training in 1912 only 18 were accepted. The balance sheet for 1912 showed a decrease in subscriptions, and a slight increase in donations. The raising of further funds would therefore soon be necessary if the work of the association was to be properly carried out. As it was, the future, even apart from money matters, was far from reassuring. The Insurance Act had created an entirely new and most difficult situation in the medical and midwifery world; and though the association was not an employing body, and had, therefore, no direct responsibility laid upon it by the Act, the position demanded the most careful thought and action if the future of the midwifery profession was to be assured. The report and balance sheet having been adopted, a short address was delivered by Dr. Christopher Addison, M.P., on "Midwifery and the Maternity Benefit," in the course of which he pointed out that a woman was entitled to the benefit even when attended only by a midwife and a pupil. At his suggestion it was unanimously decided that a deputation should be sent from the association to the Insurance Commissioners to point out the numerous difficulties which at present arise in connexion with the payment of the maternity benefit under the Act.

Letters, Notes, and Answers.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Office, 429, Strand, W.C., on receipt of proof.

Queries, answers, and communications relating to subjects to which special departments of the BRITISH MEDICAL JOURNAL are devoted will be found under their respective headings.

QUERIES.

MAJOR C. B. LAWSON, R.A.M.C., asks for references to literature relating to the treatment of goitre by iodine cataphoresis.

SOUTH WALIAN asks to be recommended a suitable portable battery for cautery work in general practice. He has found a dry cell battery unsatisfactory, inasmuch as after being left unused for a couple of months, it failed to give a sufficient current. A wet battery is inconvenient, as it must be filled with fluid every time it is used, and may then not give a sufficient current.

H. E. J. would be glad to hear of comparative results obtained in the treatment of rheumatoid arthritis with (a) continuous counter-irritation, and (b) oral administration of radioactive drinking water.

With regard to the internal administration of radioactive (emanation) water, our correspondent might consult the report of the Radium Institute (BRITISH MEDICAL JOURNAL, January 25th, 1913).

CARIES OF THE MILK TEETH.

A. M. W. writes: As a school inspector I find in the course of my examination of a very large number of children during the year that a high percentage are suffering from decayed teeth. In the district in which I work there is no dentist employed to attend to these children, and so all I can do is advise all parents to obtain treatment, and I usually advocate it on these grounds: (1) In order to prevent dyspepsia and other troubles connected with the digestive organs, and consequent malnutrition due to the swallowing of septic organisms from the bad teeth. (2) To avoid the absorption into the system by the lymphatics of the septic material in the cavities, and also the possible entrance of tubercle bacilli. (3) To prevent the imperfect development of the jaw caused by deficient mastication owing to the tenderness of the gums consequent on the inflamed condition of the sockets. One may also mention the occurrence of alveolar abscess and the loss of good looks later in life due to absence of teeth, etc.

In spite of my efforts I find that a great many parents will not take the trouble to have anything done; they usually do not realize the necessity, and sometimes cannot pay for treatment, but those who do take their children to a doctor or dentist are often told (and this is the point of my letter) that they had better leave the teeth alone, especially if they are first teeth. Now this is very unfortunate, and puts me in rather an awkward position with the parents, school teachers, and school nurses, and I cannot understand the reason, unless it be that doctors and dentists do not like the trouble of treating children's teeth, or else that they think by extracting a carious primary tooth they will interfere with the growth of a secondary one. There may be some ground for this latter opinion, and it is in order to find out if such be the case that I am writing to you.

ANSWERS.

MAJOR R. MCCARRISON, I.M.S. (Kasauli, Punjab) writes: In answer to "Country Doctor," who asks for advice on the treatment of a case of goitre in a girl of 18 (BRITISH MEDICAL JOURNAL, February 8th, p. 320), I would suggest the use of a *coli* vaccine made from the patient's own strain of *coli* (from the faeces). Inoculations should be made at intervals of seven to ten days—an initial dose of 75 million gradually increased to 150 million. For particulars of this treatment "Country Doctor" might refer to my Milroy Lectures on the Etiology of Endemic Goitre for this year.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

| | £ | s. | d. |
|-----------------------|-----|-----|-----|
| Eight lines and under | ... | ... | ... |
| Each additional line | ... | ... | ... |
| A whole column | ... | ... | ... |
| A page | ... | ... | ... |

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Wednesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *postes restantes* letters addressed either in initials or numbers.

A Lecture ON CANCER OF THE TONGUE.

DELIVERED AT THE CANCER HOSPITAL, BROMPTON,
ON FEBRUARY 12TH, 1913.

BY

CHARLES RYALL, F.R.C.S.,

SENIOR SURGEON TO THE CANCER HOSPITAL; SURGEON TO THE LOCK
HOSPITAL; SURGEON TO THE BOLINGBROKE HOSPITAL, ETC.

Laboratory research has so far failed to discover the immediate cause of cancer, though it is generally agreed that some form of irritation is an important factor in starting the changes that evolve in malignancy. These sources of irritation, often obscure, vary from ease to ease and from organ to organ. But in cancer of the tongue we have a definite group of mediate factors that arrest attention, and these consist primarily in syphilis, and secondarily in the superadded effects of minor irritants. Various figures are given by clinical observers regarding the frequency of syphilitic histories in cases of lingual cancer. To obtain a history or admission of syphilis is not always an easy matter, and the closest inquiry and most tactful cross-examination are often required. Too much reliance must not, therefore, be placed in the correctness of the routine hospital notes, for in many cases the patient has either forgotten the past trouble or has attached no importance to it, and one is apt to overlook the fact that not infrequently the primary sore and concurrent symptoms may disappear after a comparatively short course of treatment, and the disease may lie dormant only to break out in less tractable forms many years afterwards.

Histories obtained from women, too, are often most unreliable, for they may have been unaware of the nature of the disease, although they have been treated for actual manifestations. Here the tale of repeated miscarriages may be the only suspicious information available. Some years ago I collected figures of the history of syphilis in cases of cancer of the tongue under my care. It worked out at over 80 per cent., and seems to be conclusive as to the intimate association of the two diseases. It was held by neurologists—an opinion that in view of recent investigations has almost become a certainty—that without syphilis there would be no tabes. I should not care to go so far as to say that without syphilis there would be no cancer of the tongue; but certainly if there were no syphilis the numbers of the latter would be vastly diminished. This opinion has been forced on me as the outcome of clinical observation on the cases I have seen during several years at the Cancer and the Lock Hospitals.

Lingual cancer is a common sequela of syphilis, more common than locomotor ataxia and much more selective than the latter of the male sex. Its frequency with regard to sex is as 8 to 1, whilst the incidence of syphilis alone, judging from our experience at the Lock Hospital, might roughly be considered as ten times more common in males than in females.

How is it that there is such a striking relationship between syphilis and cancer of the tongue? Syphilitic lesions of the tongue are of very frequent occurrence, and they lower the resisting power of the organ, rendering it vulnerable to irritation of all kinds. The primary sore may occasionally be found there, mucous plaques of the secondary stage are by no means uncommon, but it is specially to the later or tertiary lesions that dangerous

sequelae ensue. These tertiary lesions occur not only in cases of neglected or insufficient treatment, but also where the most rigid mercurial treatment has been carried out. By no means do all cases of syphilis even obstinate or very chronic, exhibit tongue lesions, and women appear to be particularly exempt from them. Why should this be so? There must be some connecting link between the primary infection and such lesions, and that connecting link is long-continued irritation. Correlated with the high percentage of syphilis in the histories you will find that an equally large number have been smokers and very heavy smokers. To a person in normal health tobacco smoking is not a source of irritation of the tongue, and much as I should sympathize with a patient deprived of the solace of "my Lady Nicotine," I am convinced that were the use of tobacco discontinued from the onset of symptoms of syphilis until when, after thorough treatment, the Wassermann reaction is and remains negative, tertiary manifestations in the tongue would almost cease to exist, and cancer of the tongue would be amongst the rarities of our experience. Alcohol has come in for a good deal of abuse (and I use the word "abuse" in all its senses), and though when taken to excess it intensifies the evils of syphilis yet it is of little moment in determining these chronic lesions. Thus we have syphilis as the primary factor in producing vulnerability of the tongue, and tobacco further acting as an irritant on the abnormal organ, with the resulting production of chronic lesions that in themselves are to be regarded as, and indeed are generally nothing else than, precancerous conditions.

As the result of long-continued irritation there is first a thickening of the surface epithelium, perhaps in more places than one, producing the white patches that characterize "smoker's tongue." At first pearly grey in colour, they become denser and more pronounced as the result of further irritation. The cornification of the epithelium progresses. In the course of time it spreads over the tongue, the epithelium and papillae at some parts concentrically atrophying

Fig. 1.—Small ulcer of tongue, showing proliferation of epithelium down into fissure. Enormous round-cell infiltration. Islets of epithelium on base of ulcer.

and giving rise to bald, smooth areas amidst the thickening epithelium. Deeper in the tongue other changes are going on. There is round-cell infiltration beneath the mucous membrane, and the accompanying or subsequent cicatrization interferes with the vascular supply, producing the bald areas, and leads to puckering and fissuring of the surface. We see the surface of the tongue irregularly broken up with these fissures. Debris collects here and ulceration ensues. Unlike the normal organ, such a tongue is very irritable—irritable to the roughness of tartar or the edge of a dental plate. Smoking, spirit drinking, and hot condiments add to the irritation. Such a tongue is a source of danger, but the patient, becoming accustomed to minor annoyances, grows callous on the onset of ulceration, ready to endure, as best he can, his unfortunate lot. When fresh trouble breaks out—trouble which may be very serious—he pays little attention to it at first. If it be cancer, as it may quite well be, the cancerous ulcer, for some considerable time after its onset, not infrequently produces less pain and inconvenience than an ulcerated fissure or some other non-malignant lesion associated with chronic syphilitic glositis. It is the old tale—familiarity breeds contempt.

Growing into the fissures, the epithelium digs down into a tissue robbed of resisting power, where it may take on malignant proliferating character (Fig. 1). Cancer once started tends quickly to extend to the deeper parts of the tongue, spreading out as it penetrates, its surface extent hiding its wider prolongations beneath (Fig. 2). The lymphatic glands become early infected, and, owing to the free anastomosis of lymphatic channels in the substance of the tongue, the lymph glands on both sides

of the neck are apt to be involved. It often happens that enlarged glands are found on the side opposite to the primary lesion. As the lingual growth advances, the tongue becomes more and more fixed, the loss of mobility renders articulation painful and difficult, swallowing is a matter of great difficulty, and saliva dribbles from the mouth. The increase in the size of the tongue may interfere with mastication and even with the closing of the mouth. The foul cancerous mass cannot

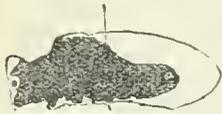

Fig. 2.—Cross section through a cancer of tongue to show small superficial ulcer and deep-spreading involvement of the muscles.

be kept clean and the teeth cannot be brushed. Usually there is very considerable pain and the necessity of taking nourishment becomes a penance. The condition of such a patient is harrowing; not only is he a pitiable object to his friends, but he is an offensive nuisance to those called upon to attend him.

DIAGNOSIS.

An early diagnosis of all forms of malignant disease is important, and in no situation more so than in the tongue, because of the great rapidity with which it spreads. When any doubt exists as to a particular lesion, the part ought promptly to be excised and examined microscopically. Valuable time should not be wasted in attempting to solve the nature of the trouble by the Wassermann reaction or by therapeutic tests. A positive Wassermann reaction proves only the presence of the syphilitic taint, and does not exclude carcinoma; and as most cases of cancer of the tongue supervene on syphilis, we find, as a matter of fact, that where there is an indubitable cancer the reaction is very frequently positive. It is, therefore, valueless in this case. Unfortunately, too, antisyphilitic treatment is too often resorted to in order to settle the diagnosis. The practitioner coming across a suspicious lesion, and perhaps influenced by the admission of previous syphilis, is apt to conclude that it may, after all, be only a tertiary manifestation; and if it does show signs of improvement, his conclusion is fortified. He loses sight of the fact that both syphilis and carcinoma not infrequently coexist in the tongue. The patient may probably express the opinion that the treatment is improving the condition, and his medical attendant, noticing himself the unmistakable change for the better, is apt to conclude that with perseverance a cure is in sight. Alas for fond hopes! I have been led astray myself by seeing a large lesion of the tongue apparently clearing up under iodides, only to wake up to the fact that it was a case of epithelioma grafted on to a large syphilitic ulcer, and that while the latter was cicatrizing and healing the former had been growing apace. My experience is that practically all epitheliomas of the tongue become clearer and appear to undergo a change for the better under iodides, and more especially so after an injection of salvarsan.

Whether we shall have a sero-diagnostic method for cancer is a question for the future, but until it arrives and proves to be reliable my advice is, waste not a day, but have a portion excised and submitted to a pathologist. It cannot be resorted to too early. If the suspicious lesion is small, it can be wholly excised, but where it is comparatively large a portion from the edge of the most suspicious part should be removed, but it must be of sufficient size and, above all, of a good depth. Shavings are useless to the pathologist.

Cancer of the tongue is generally developed after the age of 40. The most common situation is the margin of the tongue, sometimes the dorsum, and occasionally the tip. Most of the lesions are in the anterior two-thirds. Sometimes the frenum and floor of the mouth are the sites of the origin. Usually there is concurrent evidence of syphilitic glossitis. When epithelioma occurs on the dorsum it arises frequently in a breaking-down gumma.

Epithelioma commences in a variety of abnormal conditions, such as in a wart, a fissure, a chronic ulcer, no lule, etc., and it is obvious that under these conditions it has no definite characteristic feature. Only the microscope will reveal the malignant change. But when well established, there are two main forms in which it manifests itself, the ulcerating form and the pseudo-papillomatous form. The ulcer is an indurated infiltrating sore

with raised and sometimes undermined edges and very hard base; in its early stages, when it occurs in a fissure, it has no peculiar characteristics beyond that of an ulcer that refuses to heal, with perhaps a slight suspicion of infiltration. The pseudo-papillomatous form is characterized by the appearance of a slight raised flat patch of crowded warts; and though in its early stages, at least, it may be less infiltrating than the ulcerating type, yet it is hard and indurated. The lesions that may cause difficulty in diagnosis are simple ulcers and breaking down gummata. In the case of the former there will be evidence of irritation from the sharp edge of a tooth or a stump, and the induration and infiltration that characterize a carcinoma will be absent. A breaking down gumma is generally found in the dorsum of the tongue, and is characterized by a very deep, almost punched out, ulcer with marked induration but with a septic, sloughing base. Great stress is laid on the tuberculous ulcer in the textbooks. It is, as a matter of fact, exceedingly rare, is generally far back on the tongue, and is invariably secondary to tuberculosis elsewhere.

TREATMENT.

(a) *Preventive.*—As I have already pointed out, tobacco is dangerous in all cases of syphilis, and its use ought to be prohibited, in my opinion, in every case of syphilis, and certainly on the slightest appearance of leucoplakia of the tongue. Syphilitic lesions of the tongue should have thorough treatment, and are most successfully dealt with by the combined administration of calomel and salvarsan injections. Treatment should be continued until the Wassermann reaction is negative and remains so after six months. Leucoplakia is not amenable to treatment, and is, perhaps, best left alone. All chronic tertiary lesions should be kept under observation and all sources of irritation should be removed. This entails the removal of carious stumps and rough edges of teeth, careful brushing of the teeth, and attention to the general hygiene of the mouth. The prolonged use of strong, stimulating applications is a mistake. The frequent application of some bland antiseptic is indicated, and boroglyceride is as good as anything else. It is advisable to excise any chronic ulcer or papilloma that refuses to yield to treatment. I should not hesitate to recommend excision of the tongue in the case of a very extensive chronic syphilitic lesion that remains unamenable to antisyphilitic remedies. It is important to keep cases under observation, as early malignant disease may thus be detected. I have watched several cases of syphilis in which malignancy has supervened and has been discovered at an early stage.

(b) *Radical.*—The spread of the disease is always more extensive than clinical examination would lead one to believe. The glands are early involved. The situation of the primary focus does not determine the particular chain of glands or even the particular side that may first be involved. Deviation of the tongue on protrusion or impaired mobility is a sign of the spread of the disease, though unimpaired mobility is no guide as to the extent. My last case, for example, had no impairment of mobility, yet the spread was very extensive. Enlargement of the glands in the neck always adds seriously to the outlook, but I do not regard the enlargement of the submental glands with the same amount of gravity as I do those of the carotid group. In all cases it is necessary to remove the lymphatics, fat, and fascia in the anterior triangle on both sides of the neck. The complete removal of the tongue, together with the dissection of the neck on both sides, entails a very serious operation, attended by shock, and we are compelled, much against our ideas, to do the operation at two sittings, removal of the tongue and dissection of one side of the neck being done on the first occasion, and the other side of the neck being cleared out at a subsequent operation. It is a matter of difficulty to obtain a patient's consent to subsequent removal of glands from the side of the neck not apparently involved, but I have seen patients who refused the double operation return later with involved glands on the untouched side.

I always advise complete excision of the tongue. Where the lesion is very minute a very wide removal might suffice, but the larger operation even then would be more ideal. With an incision carried from behind the angle of the jaw along the anterior border of the sternomastoid to opposite the sterno-clavicular articulation, and

another from beneath the tip of the chin to meet this at right angles, the anterior triangle is first cleared of the fascia, fat, and lymphatic glands belonging to the submental, submaxillary, inferior parotid, and carotid groups, taking care to prevent tearing of these glands, as otherwise cancer implantation followed by recurrent nodules, or, more frequently, widespread and rapid malignant induration of the whole side of the neck, might result. Drainage tubes are inserted before closing this wound, to remove blood-stained exudation or secretion from any of the salivary glands, or in case a communication be accidentally made with the oral cavity. Thereafter the mucous membrane of the floor of the mouth and the frænum is divided, allowing of the tongue being pulled forward and the lingual arteries ligatured. The tongue is divided transversely as far back as possible and the mucous membrane of the floor of the mouth sutured over the stump. Preliminary laryngotomy is quite unnecessary, and is not adopted by us. The modified Trendelenburg position in which the patient is put at operation prevents blood entering the trachea. The patient is propped up in bed as soon as is possible; mucus is removed by swabbing; and nourishment is given by means of a rubber tube placed on the spout of a feeding cup and passed well into the pharynx, where swallowing is entirely a reflex action. As the healing of the wound progresses the patient is able to drink out of a cup. He is supplied with a writing block, and is forbidden to make attempts at speech. Gradually the scar tissue disappears and mobility of the floor of the mouth and the stump becomes restored, so that after the lapse of a fortnight articulation is possible and improves with time, finally approaching so near the normal that the uninitiated might not detect the loss of the tongue. You will hear from one of the patients here to-day, whose tongue I removed for cancer fifteen years ago, how perfect is this articulation. For the first week after excision of the tongue, partly as a result of the operation and partly from the enforced silence, the patient is apt to become very depressed, and I always advise getting him out of bed as soon as possible to sit in an armchair, as this cheers him up.

(c) *Palliative*.—In those cases which are beyond the stage of operation, where their life becomes a burden to them and their sufferings grow more acute, can nothing be done? I strongly advise removal of the tongue where it is possible, even when there is no hope of cure owing to the widespread glandular involvement. In many cases it may be removed even when the disease is far advanced, and with the aid of the cautery any suspicious foci of recrudescence can be attacked and the condition rendered vastly more satisfactory than if the disease had been allowed to pursue its course unchecked. Unless something is done to alleviate the patient's condition terrible suffering has to be endured. For a considerable time I have been endeavouring to carry out some sort of starvation treatment of the growth by avascularizing the part. The fact that the tongue is a fairly well isolated organ with a definite blood supply coming from the two lingual arteries seemed to hold out the hope that by ligation of these vessels avascularization would result, but I found that, owing to the free anastomosis between the various branches of the external carotid arteries, such a proceeding was attended with but little success. Further attempts by tying the external carotids did not give any better results, and it is, in fact, impossible by mere ligation to cut off the blood supply anywhere in the carotid area. Dawhan suggested the injection of the vessels with a paraffin preparation of a melting point somewhat higher than body temperature. This I have adopted on several occasions. The method indubitably accomplishes more complete avascularization than ordinary ligation. It causes shrinking of the part, the ulceration becomes less foul, contrary to what one would expect, but the great benefit derived from it is the marked alleviation of pain. In one case, where there was extensive recurrence in the stump of the tongue and the floor of the mouth and where the disease had spread to the anterior pillar of the fauces and the right side of the pharynx, the whole affected area cicatrized over and the disease seemed to have disappeared. It, however, recurred on the side of the pharynx a year afterwards. I cannot recommend paraffin injections as a routine method, as they appear to be not wholly free from risk.

CONCLUSIONS.

The lessons to be learnt are: Wide removal in definite epithelioma; microscopic examination of suspicious lesions; the avoidance of tobacco by those who have syphilitic lesions of the tongue; and radical treatment of all syphilitics till serologically they are pronounced free.

The thorough treatment of syphilis would wellnigh abolish cancer of the tongue.

ENUCLEATION OF TONSILS AND REMOVAL OF ADENOIDS UNDER GAS ANAESTHESIA.*

By JOHN F. O'MALLEY, F.R.C.S.

AURAL SURGEON, EVELINA HOSPITAL FOR SICK CHILDREN; ASSISTANT SURGEON, ROYAL EAR HOSPITAL; CHIEF ASSISTANT, AURAL DEPARTMENT, ST. BARTHOLOMEW'S HOSPITAL.

By enucleation of the tonsil I mean the complete removal of the circumscribed mass of lymphatic tissue lying between the anterior and posterior faucial pillars, together with its capsule.

The earlier operations on the tonsils were directed chiefly towards the removal of the redundant mass of tissue which projected beyond the pillars of the fauces, leaving the tonsillar base and capsule *in situ*. Such tonsils gave rise to some mechanical obstruction, associated with occasional inflammatory attacks, and these constituted the indications for their amputation.

With the evolution of the view, as to the part played by the tonsils as a path of entry for local and systemic infections, came more vigorous attempts at their removal as a whole, greater importance being attached to septicity than to size. These attempts were more or less successful, but no surgeon could state with any degree of tolerable certainty, when about to operate, that he would be able to remove the gland with its capsule completely, except in a limited number of medium-sized, compact, and firm tonsils, until the method of enucleation by dissection was introduced.

This method is a certain and efficient one, and in the hands of its advocates has been used frequently to enucleate the portion of the glands which the older method failed to remove, and with decided benefit to the patients.

Any operator with a fair degree of dexterity can soon master either or all of the various types of technique used in this method, but there are certain essentials of the operation which stand in the way of its popularity. This applies particularly to the depth of chloroform anaesthesia required, which is always a source of anxiety to surgeon and anaesthetist; and, indeed, many of the latter dislike pushing the anaesthetic to such a degree. Partly on account of this difficulty with the anaesthetic, and at the same time recognizing the value of complete removal, surgeons have latterly turned their attention to perfecting some method of enucleation by tonsillotomes.

To Greenfield Sluder of St. Louis belongs, I believe, the credit of having first originated the idea of applying the tonsillotome by its outer aspect to the tonsil, whilst laying special emphasis on the sliding of the tonsil on to the alveolar projection of the lower jaw, to facilitate pushing the gland through the ring of the instrument. Sluder's idea has been considerably modified by some surgeons in this country, notably Iybus and Willis of Newcastle and Peters of London. The points which, in my opinion, are of most importance, and my reasons for specially emphasizing some of them, will probably be best conveyed by giving a description of the whole of the method and the technique which I adopt at the Evelina Hospital for Children, where an average of about thirty cases in a morning have to be operated on.

1. Preparation of the Patient.

If the patient has any decayed teeth the help of the dentist is sought to get the mouth into good condition. It is obviously bad surgery to operate in the presence of manifest sepsis, in the absence of urgency. The bowels are cleared out the day previous to operation, and on the

* Read before the Dartford Division of the British Medical Association.

morning of the operation no solid food is given—in fact, the usual preparation for a general anaesthetic. The following mixture is given one day before the operation and continued for six days after:

| | | | | | |
|-------------------------|---|-----|-----|-----|-------|
| R. Sodae salicyl. | } | ... | ... | āā | gr. x |
| Potass. bicarb. | | | | | |
| Potass. chlor. | } | ... | ... | ... | m̄ xx |
| Elixir aromat. (B.P.C.) | | | | | |
| Aq. chlorof. | | | | | |

This is the strength of a stock mixture. The dose is as follows: Under 6 years of age, 1 drachm; from 6 to 12 years, 2 drachms. It is given for its local and general antiseptic action, and to counteract any septic absorption from the raw tonsillar bed and naso-pharynx. This treatment has arisen out of the view that acute rheumatism is a type of systemic infection of tonsillar origin. Potassium chlorate enjoys a wide reputation as an excellent drug in the treatment of unhealthy conditions of mucous membranes. When taken internally it is said to be excreted by the saliva, and in this way can exert its local action on the throat after operation. For the idea of this useful combination I am indebted to my friend Mr. Somerville Hastings.

2. Position of the Operating Table.

This is of considerable importance to ensure good light. I have tried the various forms of head lights, and discarded them one after the other as unsatisfactory, and only to be used in the absence of daylight. The table is placed lengthwise, parallel to the window, and the operator stands between the two. A good light and full view of both tonsils are absolutely essential to enable the surgeon to enucleate completely, and avoid injuring the uvula and faucial pillars. The table shown in Fig. 1 has two hinged

Fig. 1.

basins, fitted one on either side near the top, and when not in use they swing under the table. The basin next to the operator is for the purpose of receiving the blood. It also receives the water used in cleaning the patient's face. The basin on the opposite side contains ice-cold water and sponges to apply to the patient's face when the operation is completed.

This simple device limits the range of blood-splashing so common during these operations, and is far more effective and cleanly than a pail or tray of sawdust placed on the floor. The table should not be higher than the tip of the great trochanter of the surgeon, or he will find his movements restrained during the operation.

3. Position of the Patient.

The patient is placed on his back on the table with his right side to the window, and resting on the specially constructed sand pillow seen in Fig. 1. This pillow, though not an essential, as any pillow measuring about 12 to 14 in. square by 1½ in. thick will do quite well, enables the operation to be done with greater comfort and speed, as it guides the nurse who assists to the exact position in which to keep the patient. It is, therefore, especially useful when doing a large series of cases.

The shoulders rest on s, the occiput at o, and the right cheek against the process a, with the face partially turned to the window and the operator. When the tonsils are removed the patient is turned on to the right side for the removal of the adenoids. The right cheek now rests flat on the process a, and the right shoulder fits into the notch x. This gives fixity and stability to the position of the patient, and enables the operator to manipulate with

a greater degree of precision when removing the adenoids. The nurse must hold the patient's arms well down along the sides to depress the shoulders below the level of the chin.

4. Gag.

I use a modified Doyen's gag, made for me by the Holborn Surgical Company; it answers the purpose well. Its flanges are applied to the lateral teeth and not to the incisors. This enables the operator to bring the adenoid curette out in an abrupt curve, and sweep the growths cleanly away. There is less risk of slipping down the naso-pharynx with the cutting edge, and consequently less danger of leaving tags or removing mucous membrane than if the blade of a gag is resting against the upper incisor teeth.

5. Anaesthesia.

At the Evelina Hospital I use nitrous oxide gas anaesthesia with air in all cases of enucleation of tonsils and removal of adenoids. When skilfully administered it gives ample time to complete the operation efficiently. The enucleation of each tonsil takes four to five seconds, and the removal of adenoids fifteen to twenty seconds—in all less than half a minute.

I do not propose to discuss the merits of the various anaesthetics in use for this operation, and therefore desire at this point to remove any impression which the title of this article may convey as to my being an advocate of gas anaesthesia exclusively. My purpose is merely to state that, in my opinion, with a properly modified tonsillotomy and careful technique, tonsils can be enucleated as completely as it is possible by any other method, even under such short anaesthesia as gas affords.

I do, however, wish to add that, personally, I like a longer anaesthetic than gas, and particularly when doing isolated cases and working with strange assistants. A hypodermic injection of morphine and atropine given three-quarters of an hour to an hour before the operation adds considerably to the after comfort of the patient. In children $\frac{1}{16}$ grain of morphine and $\frac{1}{32}$ grain of atropine is sufficient to ensure a good night's rest following the removal of tonsils and adenoids. In private I find that it is an excellent addition to the general anaesthetic and can be used to advantage, but in a large out-patient department at a hospital it is difficult to carry out.

6. Tonsillectome.

As this instrument is used exclusively for enucleation, I propose in future to refer to it as the *tonsillectome*. The instrument which I find most satisfactory is a modification of one designed by Ballenger of Chicago for Sluder's method, made for me by the Holborn Surgical Company (Fig. 2). In the original instrument the handle was set at a very acute angle to the shaft and blade, and was chiefly intended for use on patients in the sitting position. Owing to this close proximity of the handle and shaft, it was almost impossible to enucleate tonsils with the patient lying down, hence the open angle in the present instrument. The shaft and blade are 1 in. longer than Ballenger's, and there are several other points of difference. The essential features are:

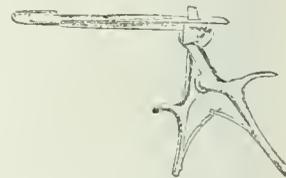

Fig. 2.

(a) A thin ring, not bevelled (like the usual type of tonsillotomy), but square-edged around the margin of the opening.

(b) A small opening. The transverse diameter of the opening is eleven-sixteenths of an inch. The transverse diameter, including opening and ring, is fourteen-sixteenths of an inch. The antero-posterior diameter of the opening is ten-sixteenths of an inch. The two diameters of the opening can be increased up to thirteen-sixteenths of an inch with advantage, as this size will take any tonsil, and one instrument will suffice for all cases, but with the smaller opening the beginner can operate on the vast majority of cases with far less risk of including and damaging the faucial pillars, uvula, etc. It is therefore better to have the two sizes.

(c) Dull edged blade and long, stout shaft.

(d) No slot to receive the blade when the latter is driven home. The slot recess is filled with lead and the blade cuts on to this.

The thin ring, not bevelled, enables one to thread it on to any tonsil, no matter how flat, with very little risk of slipping when the gland is being raised forwards to the anterior pillar of the fauces. The small opening fits tightly around the base of the tonsil when the latter is squeezed through it and the capsule is inverted in this manoeuvre. The thin ring and small opening have the further combined advantage of keeping the size of the instrument such that it will fit any fauces and remove any type of tonsil in one bite (if the larger opening is used). The stout shaft is necessary to prevent bending when pressure is exerted in raising the tonsil forwards. The shaft being long, the handle clears the patient's cheek and chin and facilitates movements. The dull-edged blade, entering between the anterior faucial pillar and the tonsil, strikes the anterior border of the capsule, and the leaded slot of the ring rests against the posterior border.

7. Removal of the Tonsils.

The patient's shoulders rest at s on the pillow shown in Fig. 1, the occiput at o, and the face looks towards the operator and the window. In this position the chin is thrown forwards from the chest and the head is partially extended. This position of the chin enables the operator to move the handle of his instrument freely from side to side, without any obstruction from the patient's chest or shoulders. When the facepiece of the gas apparatus is removed the fauces are full in the light of the window, as the mouth is already opened by the gag. Opening the mouth to its fullest extent is undesirable, as it tightens the faucial pillars and diminishes the mobility of the tonsils. Partial opening, just wide enough to give a good view and easy access to the tonsils when the tongue is depressed, is quite sufficient. Observance of this small point will obviate the dislocation of the lower jaw, which one hears of occasionally.

The right or lower tonsil is removed first. This enables the operator to seize the left or upper, and extract it before his view is obscured by blood from the lower. The right hand holds the instrument for both tonsils.

The tonsillectome is inserted with the outer aspect of the ring towards the tonsil to be removed, and the edge of the shaft is used as a tongue depressor, to bring the whole tonsil into view. The lower part of the ring is threaded under the lower pole of the tonsil, pressed firmly outwards, and the latter is then raised forwards as far as its mobility will allow. This movement is aided and slipping of the ring on the tonsil controlled by hooking the left thumb under the centre of the shaft.

The handle and outer end of the shaft are next carried to the opposite angle of the mouth, and a quarter turn given to the shaft, which is now lying obliquely across the oral cavity with its outer aspect upwards. This causes the tonsil to lie over the tonsillectome opening, bulging the anterior pillar, as it does when seized by a blunted conchotome in dissection enucleation. The handle is now slightly depressed, the ring still more firmly pressed up behind the tonsil, and the whole instrument withdrawn a little way. This movement has the effect of rolling the tonsil better into view, and its junction with the anterior pillar is more readily seen, for the insertion of the blade at the margin of the capsule. It also facilitates the inversion of the latter, when the left index finger is applied outside the border of the anterior pillar, on the prominence of the tonsil, to push it through the opening of the instrument. When the tonsil is slightly larger than the opening, and some pressure is required to squeeze it through, a peculiar sensation of "dislocation" is felt by the left index finger. This is due to the fact that the margins of the tonsillectome ring are firmly applied to the periphery of the tonsil, and offer resistance, so that when the latter is pushed through the opening the capsule is inverted, and gives a sensation of slipping, like that felt when a dislocated shoulder-joint slides into place on reduction.

The blade is now closed, and includes the whole periphery of the tonsil capsule between its dull edge and the leaded face of the ring. Both hands momentarily grasp the handle of the instrument and drive the blade more firmly home. Another half-turn is now given to the tonsillectome in the long axis of the shaft towards the uvula, and withdrawn, bearing the tonsil and capsule on the inner or under aspect of the instrument. In this way the capsule is stripped off its bed completely, and its

vessels are first crushed and then torn across. For this reason the haemorrhage is far less than when a sharp blade cutting into a slot is used, as the latter type of instrument cuts through the margins of the capsule. All the tonsils removed are carefully examined, and in several long series done recently enucleation was quite as complete in every case as that by the dissection method. I have used this method exclusively for over twelve months—in nearly 1,000 cases—with very satisfactory results.

8. Removal of Adenoids.

After removal of the tonsils the patient is promptly turned on to the right side, and the anaesthetist empties the throat of blood by momentarily holding the face partly downwards over the side of the table and basin, and shaking the head. This obviates swabbing and much of the after-sickness due to swallowed blood or the risk of any of the latter entering the bronchi.

The patient's right cheek is now placed firmly on the process a of the pillow, with right shoulder in the notch n (Fig. 1). The curette which I find most useful is one which Krohne and Sesemann have made for me (Fig. 3).

Fig. 3.

It is practically the same size as Lake's No. 2, but shaped like the German-made modification of Gottstein's (a smaller size is used for children under 4 or 5 years of age). The cage somewhat resembles that in common use, but it is controlled by a spring which is exerting constant pressure on any mass of adenoids which enter it, and prevents their slipping out when the instrument is withdrawn. By using it as described below the main mass of adenoids is always withdrawn in the instrument, and where the mass is a compact growth it is removed so completely in one sweep as rarely to need any further curettage. This helps to obviate the risk of leaving a separated mass to be swallowed or inspired, or that of a hanging mass falling over the laryngeal opening and causing respiratory distress.

The operator's left hand is placed on the parietal and occipital region of the patient's head, to control the resistance to the pressure exerted by the curette, and to flex the head, as the instrument is being swept over the nasopharynx. This flexion diminishes the prominence of the body of the axis, and makes the naso-pharyngeal curve more even. The curette is inserted in the middle line, using it as a tongue-depressor to enable the point to clear the uvula and avoid injuring it, and is pushed backwards until it strikes the pharynx. The point is then carried upwards, firmly pressed against the posterior wall, and still in the middle line, until it is stopped by the posterior border of the septum. It is now drawn forwards to pull on the soft palate to ensure its proper relationship to the latter before starting to cut. The point is again carried upwards along the septum and pushed backwards, downwards, and outwards, still in the middle line, with firm pressure and gradual, easy movement, whilst the patient's head is partially flexed and steadied by the operator's left hand. With a small unaged Kirstein or Stubbs curette any remaining adenoid irregularities are removed by a series of short scrapes, and the forefinger is finally introduced to verify this.

9. After-Treatment.

The patients are placed in bed in an airy room for two days at least. It is always wise to keep them in bed for two days to recover from whatever degree of shock they may have suffered as a result of the operation. After this period they should be allowed to get up if they show a desire to do so. The diet should be cool liquids for the first two days, and then semi-solids and solids.

The sodium salicylate mixture is continued for six days and then followed by syrup of the iodide of iron or syrup of ferri phos. co. for a fortnight.

Breathing Exercises.

When healing is complete, a short, easy, daily course of breathing exercises, with the mouth shut, is insisted upon. This should be persisted in for at least six months.

Conclusion.

Let me enter a plea for raising the standard of this branch of surgery, by making it an operation of precision, and removing some of the reproach of doubtful value and inefficiency attached to it. In this connexion I should like to quote the following extracts from Dr. Still's excellent book on *Common Disorders of Childhood*:

"I would lay stress upon the importance of complete removal of adenoids and tonsils by whatever method is found to be most practicable." "I will venture to insist that the operation for removal of adenoids and tonsils is not so simple that anybody and everybody who happens to have a surgical qualification and a guillotine can do it as it ought to be done; it is one which, if done, ought to be done by the most expert skill attainable."

A CASE OF VAQUEZ'S DISEASE

(POLYCYTHAEMIA WITH PLETHORA, AND SPLENOMEGALY).

BY

H. L. WATSON-WEMYSS, M.D., M.R.C.P. EDIN.,
ASSISTANT PHYSICIAN TO THE LEITH HOSPITAL.

It is now just over twenty years since Vaquez first described the syndrome of polycythaemia with true plethora, cyanosis, and splenomegaly, with which his name is associated. A full description of the condition, with the literature, was given by Parkes Weber¹ in 1908, and by myself² in 1911, while Senator's³ monograph published in the latter year contains much of the most recent work on the subject. This observer then paid special attention to the condition of the gaseous exchange in the lungs. He found in several cases not only a greatly increased exchange of both oxygen and carbon dioxide, but also a great increase in the volume of air respired. Further observations are required with regard to these points. Since that date considerable additions have been made to the literature, and cases have been recorded by Hale White,⁴ Emanuel,⁵ Isaacs Coke,⁶ and Parkinson⁷ in this country, by Kuttner⁸ in Germany, while Hamilton and Morse⁹ have published a case in America with a full report of the *post-mortem* findings.

The fact that so many fresh cases have been published in so short a period shows that the condition is by no means so rare as was at one time believed. But while so much advance has been made in the recognition of the disease, it cannot be said that equal advance has been made in the elucidation of its etiology. The case which it is the purpose of the present paper to record merely confirms previous observations; it is, perhaps, of special interest because the bone-marrow was examined during life, a procedure which, so far as I am aware, has only been adopted before on one occasion, namely, in the case described by Gibson¹⁰ and later published by myself.

A man aged 52, a gamekeeper, was admitted to the Royal Infirmary in August, 1912, under the care of the late Dr. G. A. Gibson. He complained of pain in the upper part of the abdomen. The family history is of little importance, his mother having reached the age of 92, while his father was the victim of an accident at the age of 54. He is married and has three children living, three others dying in infancy. With the exception of a slight attack of influenza fifteen years ago he has never had a day's illness. He is a non-smoker and practically a teetotaler, and from the nature of his occupation he leads a healthy open-air life. The pain of which he now complains first troubled him a month before admission. It is sharp and lancinating in character, is almost constantly present, and is felt in the left hypochondriac region. For some months his wife has told him that his face was becoming very florid. The patient states that he has had several attacks of epistaxis. He has lost fully a stone in weight during the last two or three years.

General Appearance.—His height is 5 ft. 8½ in., and his weight is 9 st. 2½ lb. The face, lips, and ears show a striking degree of cyanosis. The tongue and mucous membranes are of a dark bluish-red tinge. The conjunctivae are markedly injected. He is thin, but not emaciated.

Alimentary System.—The tongue is clean and moist. The teeth in the upper jaw are artificial, the others having become loose and dropped out; those in the lower jaw are fairly good. He complains of some loss of appetite, and he also suffers to a slight extent from a sensation of distension and discomfort after meals. There is no sickness, thirst, or constipation. His breath is rather foul. The stomach is not dilated, and the vertical dullness of the liver is not greater than normal.

Abdomen.—The most striking feature of the examination of the abdomen is the presence of an enlarged spleen, which

extends downwards and forwards three fingerbreadths beyond the left costal margin. It is firm, and very slightly tender to the touch. On auscultation distinct friction is heard over it.

Circulatory System.—The heart is not enlarged; the apex beat is in the fifth interspace, 3½ in. from mid-sternum. The sounds are closed and pure. The vessels are healthy and the systolic pressure 108 mm. Hg.

The examination of the respiratory system was negative.

Urine.—Acid; specific gravity 1016; deposit of urates and uric acid; no albumen or sugar. The centrifugized deposit shows no tube-casts.

Nervous System.—The patient has occasionally slight headache. He states that he is unable to read for long at a time. The pupils react briskly to light and on convergence. The examination of the fundus oculi shows that the vessels are engorged with very dark blood.

The Blood.

| | | | |
|------------------------|-----|-----|--------------------|
| Red blood corpuscles | ... | ... | 8,420,000 |
| Haemoglobin | ... | ... | 100% + (Tallqvist) |
| White blood corpuscles | ... | ... | 39,000 |

Differential count of 400 leucocytes:

| | | | |
|--------------------|-----|-----|------|
| Polymorphs | ... | ... | 87% |
| Lymphocytes | ... | ... | 6% |
| Large mononuclears | ... | ... | 3% |
| Eosinophiles | ... | ... | 2.5% |
| Mast cells | ... | ... | 1.5% |

Further observations:

| | | | |
|--------------------------|-----|-----|--------------------|
| (1) Red blood corpuscles | ... | ... | 9,248,000 |
| Haemoglobin | ... | ... | 100% + (Tallqvist) |
| White blood corpuscles | ... | ... | 24,000 |
| Polymorphs | ... | ... | 81% |
| Lymphocytes | ... | ... | 8% |
| Large mononuclears | ... | ... | 2% |
| Eosinophiles | ... | ... | 4% |
| Mast cells | ... | ... | 5% |
| (2) Red blood corpuscles | ... | ... | 9,240,000 |
| Haemoglobin | ... | ... | 110% (Haldane) |
| White blood corpuscles | ... | ... | 28,200 |
| Polymorphs | ... | ... | 77% |
| Lymphocytes | ... | ... | 12% |
| Large mononuclears | ... | ... | 1% |
| Eosinophiles | ... | ... | 6% |
| Mast cells | ... | ... | 4% |
| (3) Red blood corpuscles | ... | ... | 9,760,000 |
| Haemoglobin | ... | ... | 110% (Haldane) |
| White blood corpuscles | ... | ... | 31,600 |
| Polymorphs | ... | ... | 81% |
| Lymphocytes | ... | ... | 9% |
| Large mononuclears | ... | ... | 3% |
| Eosinophiles | ... | ... | 5% |
| Mast cells | ... | ... | 2% |

The specific gravity of the blood, estimated by Hammerschlag's method, was 1062. The viscosity, estimated by Denning and Watson's clinical viscosimeter, was 26.4, that is, 2½ times the normal.

The coagulation time, estimated by Wright's coagulometer, was slow, 6 min. 25 sec. This is in accordance with the observations of Bence¹¹ and Pethybridge.¹²

The red cells were unaltered in size and shape; abnormal cells were exceedingly scanty, for though a large number of films were examined only two megaloblasts, one neutrophilic myelocyte, and one eosinophilic myelocyte were seen.

On September 20th Mr. Alexis Thomson kindly trephined the right tibia, and from the bone marrow thins obtained films and sections were made. Two days after the operation there was considerable bleeding from the wound, necessitating frequent dressing, and a haematoma formed. In order to determine whether the haemorrhage had caused any marked change in the blood count, the following observations were made:

| | | | |
|------------------------|-----|-----|----------------|
| Red blood corpuscles | ... | ... | 9,216,000 |
| Haemoglobin | ... | ... | 110% (Haldane) |
| White blood corpuscles | ... | ... | 40,000 |
| Polymorphs | ... | ... | 86% |
| Lymphocytes | ... | ... | 4% |
| Large mononuclears | ... | ... | 6% |
| Eosinophiles | ... | ... | 3% |
| Mast cells | ... | ... | 1% |

It was also noted that the spleen had become much smaller since the previous day, and now only just reached below the costal margin, a fact which tends to confirm the usual view that, while the spleen in this condition enlarges partly on account of increased functional activity, it also acts partly as a reservoir to compensate for the greatly increased total volume of the blood.

The bone marrow from the centre of the shaft of the tibia was deep red in colour. The microscopical appearances were not nearly so well marked as in the case published two years ago. There was marked congestion, a few small haemorrhages were present, and the blood vessels were crowded with non-nucleated erythrocytes. The films did not show any great departure from the normal, but the sections revealed distinct though slight evidence both of erythroblastic and leucoblastic reaction. The fatty tissue of the marrow was encroached upon only to a slight extent; but when one remembers that all the long bones share in the erythroblastic and leucoblastic reaction, although it is only slight in degree, there is no difficulty in explaining the high counts of the red and white corpuscles.

Judging from the appearances of the bone marrow, the case must be considered a fairly early one. The patient was also singularly free from many of the usual symptoms associated with the condition. Pain in the left hypo-

chondrium due to perisplenitis (of which the patient complained) is, apart from cyanosis and splenomegaly, one of the commonest symptoms of the disease. Three years ago I investigated¹⁵ the relative frequency of the signs and symptoms of erythraemia in 58 cases, and found pain in the left side present in 50 per cent. Albuminuria, which I found in 60.3 per cent. of cases, was never present in the patient under consideration. Vertigo and obstinate constipation are usually marked features, yet this patient was free from them.

The blood in this case was extremely typical. Notable features were the high degree of leucocytosis and the high percentage of mast cells. The absolute increase in the polynuclears and in the eosinophiles is, of course, present in nearly all cases. The great increase in the blood viscosity in the presence of what is, after all, when we consider the extremely high counts found in this condition, only a moderate polycythaemia, must be partly explained by the large number of white cells present. I have found in a case of myelogenous leukaemia with a red count of 3,300,000, and a leucocyte count of 388,000, a viscosity value which, if the leucocytes were normal in number, would be equivalent to about five and a half million erythrocytes. An analogous case is reported by Denning and Watson¹⁴ which makes it clear that the leucocytes have relatively a greater effect on the viscosity than on the erythrocytes.

No factor could be ascertained in the case here described which seemed to throw any light on the etiology of the condition.

The occurrence of influenza (which Saundby¹⁵ considers important) was, even if one accepts his views, too remote to have any bearing on the case. Symptoms referable to the intestinal tract were vague and ill-defined, and were only mentioned by the patient when leading questions were asked. It certainly cannot be said that there was any definite evidence of the absorption of toxins from the bowel, although this possibility cannot be ignored. From the experience gained in this case, it would appear that operation in order to obtain bone marrow ought not to be lightly undertaken. True, moderate haemorrhage may be actually beneficial; but it seems that, as occurred in this case, the healing of the wound may be greatly delayed, owing perhaps to the sluggish circulation in the peripheral vessels.

My best thanks are due to Dr. John Eason, who was at the time in temporary charge of the ward, for giving me every facility for examining the patient and for permission to publish the case.

A LABORATORY for cancer research is to be erected at Columbia University. The endowment is provided by the George Croker research fund of about £300,000, the income of which must be used solely for research.

THE personal estate of the late Dr. Edward Henderson, who died at his residence in Kensington on February 27th, has been declared at a net value of £44,241. Dr. Henderson, who became M.D. Edin. in 1864, passed most of his life in China, where he was medical officer of health and Surgeon-General of the European Hospital, and held an appointment also in connexion with the British Consulate.

THE Internationale Komitee für das ärztliche Fortbildungswesen (International Committee for Post-Graduate Medical Education) desires it to be known that it has no connexion with the Association Internationale de Perfectionnement Scientifique et Médical. The next meeting of the Internationale Komitee für das ärztliche Fortbildungswesen will be held during the International Medical Congress in London in August next. The International Committee is composed of delegates appointed by national organizations or by the Governments of the participating countries, and its object is the furtherance of medical education and mutual instruction based on experience reaped in different countries.

TUBERCULOMA OF THE LARYNX.

BY

WILLIAM SANDERSON, M.B., CH.B. EDIN.,

SURGEON TO THE LIVERPOOL EAR, NOSE, AND THROAT CLINIC.

TUBERCULOUS growths in the larynx were suspected as far back as the Sixties of last century by Tobold, and again in the Seventies by Ariza and E. F. Ingals. J. N. Mackenzie, however, claims to have been the first to demonstrate, in 1882, the existence of tuberculous disease as a definite tumour occurring in the windpipe. His two first cases were observed *post mortem*, and were proved to be tuberculous by histological examination. A number of cases have been collected and published since then by Avellis, and Payson Clark, and others.

Mackenzie classifies tuberculous outgrowths in this region in three groups: (1) Granular hyperplasiae in connexion with tuberculous ulcers; (2) papillomatous excrescences, vegetations, and tumours, probably papillomatous tissue infected with tubercle, and sometimes the only visible sign of tuberculosis for a considerable period; (3) true tuberculous tumours—extremely rare—composed of masses of closely aggregated miliary tuberculous nodules, and occurring independently of infiltration and ulceration of the mucous membrane. The majority of reported cases are considered to belong to the first two groups.

In an examination of recorded cases I find that true tuberculous tumours are situated as a rule in the larynx, the usual sites being the ventricular bands, vocal cords, and ventricles, but they may also be found on the arytenoids, aryepiglottic folds, epiglottis, and in the trachea.

An interesting case was shown a few years ago by P. H. Abercrombie of tuberculoma of the naso-pharynx in a man, which resembled clinically an adenoid mass or lympho-adenoma. Microscopic examination demonstrated its real nature. As a rule, lung changes are present or show themselves sooner or later; but in this case, as also in some of those in which the larynx has been involved, there were no other apparent symptoms of tuberculous disease. The fact, however, that such symptoms are not discoverable during life does not negative the existence of tuberculous lesions in the lungs, such being frequently found in a quiescent or healed state *post mortem*. One is therefore chary in regarding these growths as primary, and particularly so when it is known that they are usually covered with intact mucous membrane. Apart from the fact that tuberculoma of the larynx is rare, the following case is of interest in that the site was unusual and the disease had developed in a man of advanced years.

S. C., aged 69, was first seen by Mr. Bark and myself in September, 1908. He complained of a feeling of chokiness, especially on lying down at night, and of difficulty in swallowing food. These symptoms had lasted for a period of over three years and were becoming more aggravated in spite of the treatment that he had already undergone. There was nothing to note in his own or his family history with regard to tubercle. He was well nourished, had led a healthy outdoor life, and only of late years had been treated by his medical attendant for some "heart weakness." There was occasional cough but no expectoration. Owing to irritability of the throat examination was not easy, but the laryngoscope showed a pale greyish growth with a broad base and irregular surface extending from the posterior surface of the right arytenoid cartilage downwards into the hypopharynx towards the oesophagus. The right vocal cord and the right arytenoid cartilage were somewhat impeded in their movements. There was no ulceration in the larynx and no enlarged glands were to be felt in the neck. A portion of the growth was removed. Microscopical examination of a section showed a considerable number of giant cells, epithelioid cells, and lymphocytes, and a diagnosis of tuberculoma was made. This was confirmed by an opinion from Sir Felix Semon and Mr. Shattock, who later examined both the patient and the tumour section. There were no signs of tubercle elsewhere.

Removal of the growth was attempted with the wire snare, but the manipulation caused so severe and distressing a cough with spasms of the glottis that a more rapidly-acting instrument had to be used—namely, laryngeal cutting forceps. With this as much of the growth was removed as possible. Several remaining fragments were punctured with the galvano-cautery and the raw surface rubbed with lactic acid. The patient was practically relieved from his dysphagia for five months (October, 1908, to March, 1909), when there was some recurrence and the punch was again used, but, owing to the severe spasmodic cough, with less effect than on the first occasion. So acute was the distress from coughing caused by the introduction of the forceps that the attempt had to be abandoned. Two months later the tumour had grown to its former size and dysphagia

was troublesome. The introduction of forceps again brought on symptoms as described above, so severe that the patient dreaded any further attempts at removal, but he was able to tolerate galvano-cautery puncture.

Repeated and frequent applications of the cautery brought about alleviation of the dysphagic symptoms for the next twelve months. Swallowing then became painful as well as difficult, and the patient died from exhaustion some three months later (September, 1910).

As stated above, a tuberculoma is generally covered with smooth intact mucous membrane of a pale grey to a dark red colour. The surface was irregular and scarred in this case when we saw it, but this may have been due to some attempts at removal that had already been made. The disease is usually found between the ages of 20 and 45, and, as in this case, is of slow growth. As is the case with other forms of laryngeal tubercle it is more frequent in males, and is generally associated with a primary focus in the lungs. The results of treatment in a few cases of true tuberculous intralaryngeal tumour in the absence of any demonstrable lung changes have been excellent; this was no doubt due to the fact that operative interference and topical applications could be followed by more or less complete rest of the parts. The latter factor is of the greatest value in tuberculous lesions of the larynx, and as an example of this the following case may be cited:

A young lady, aged 23, was seen twelve months ago for hoarseness; the right ventricular band was found to be swollen and infiltrated and to cover the right cord, the left ventricular band to a less extent, but two months later the left cord was also hidden from view, and the epiglottis was slightly affected. Clinically the appearances were tuberculous. Von Pirquet's test was negative, lung changes were absent, and there was no cough or expectoration. Tubercle bacilli were discovered some months later. Besides using an antiseptic spray and attending to her general bodily health the patient carried out the somewhat depressing treatment of absolute voice rest for ten months. The right cord was the first to appear, and was slightly ulcerated, but gradually the larynx assumed its normal state, a certain amount of paresis of the adductors remaining.

Complete rest was the main object of this long silence, and, as in ordinary tuberculous laryngeal lesions, so in other forms, rest is essential. This is obviously what could not be obtained in the case of tuberculoma I have described, as the situation of the growth on the posterior aspect of the arytenoid and cricoid cartilages rendered the prognosis as regards cure unfavourable on account of the irritation produced by the passage of food and saliva.

AN ACCOUNT OF A TERATOMA OF UNUSUAL SIZE AFFECTING THE TESTICLE OF A HORSE.

By H. BLAKEWAY, M.S. LOND., F.R.C.S. ENG.,

DEMONSTRATOR OF ANATOMY, ST. BARTHOLOMEW'S HOSPITAL;
ASSISTANT SURGEON TO THE CITY OF LONDON TRUSS
SOCIETY.

THE following case appears to me to throw some light upon the nature of certain tumours of the testicle which occur in man, and to be worth recording on that account.

On September 22nd, 1910, there was removed *post-mortem* from the abdomen of a bay cart-colt 2½ years old a tumour of the left testicle, which was imperfectly descended; the tumour had caused no symptoms during life. The right testicle, normally descended, had been removed when the colt was a yearling, and the animal died during an operation performed with the object of removing the gland on the left side.

Description.

The specimen removed consisted of the testicle, epididymis, and part of the spermatic cord (Fig. 1).

The pampiniform plexus was very large and the epididymis widely separated from the tumour, which appeared at first sight to have originated in the body of the testicle; but careful inspection showed, at the point where the epididymis joined the tumour, a flattened structure of a reddish colour, and about 1 in. thick at its middle, spread out over an area of 6 in. by 4 in. Microscopic examination proved this to be the testicle; its deep surface was separated from the tumour by a well-marked capsule of fibrous tissue, but its superficial aspect was invested by a grey shining membrane absolutely continuous with that covering the surface of the tumour in its neighbourhood. I think it probable, therefore, that the tumour arose in the

mediastinum testis, that is, within the tunica albuginea, but not in connexion with the seminiferous portion of the testicle.

The dimensions of the tumour were: Length, 16½ in.; breadth, 10½ in.; thickness, 8½ in. It weighed, in the fresh

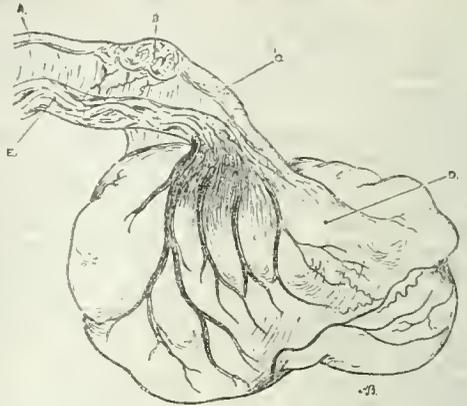

Fig. 1.—External appearance of tumour. A, Vas deferens; B, coiled portion of vas; C, epididymis; D, position of flattened testis proper; E, pampiniform plexus.

state, exactly 30 lb. The surface showed a division by a shallow groove into two approximately equal lobes, each of which was nodular, grey or pink in colour, with large veins running over it.

On section there was a much more obvious division into two lobes, separated from one another by a fibrous septum (Fig. 2). Each half consisted, for the most part, of a collection of cysts varying from a microscopic size to that of an orange. Most of the cysts were filled with a yellow mucinoid fluid, but some contained brown jelly; each cyst had a firm, shining lining membrane, and the walls of some of them contained tissue resembling cartilage; there were numerous intracystic growths which were themselves cystic.

Two of the smaller cysts, however, contained sebaceous material and numerous stiff, curly hairs (Fig. 2, A and B). In

Fig. 2.—Photograph of a section through the tumour. A and B, Cysts containing sebaceous material and hair; C, masses of solid vascular growth.

the cyst marked A the hairs were white; in that labelled B they were black. This point is of interest in view of the statement which is usually made, that the hair contained in a dermoid cyst is of the same colour as the hair of the individual bearing the cyst.

The stroma consisted largely of fat, with, in addition, fibrous tissue, numerous deposits of calcareous material, and a few small masses of cartilage. Scattered in this stroma were several circumscribed masses of soft, solid, vascular growth (Fig. 2, C).

The microscopic examination of the tumour revealed a structure even more complex than the naked-eye appearance had suggested.

The cysts were not all of the same nature. Those which contained sebaceous material and hair were lined by stratified squamous epithelium, and contained in their walls numerous sebaceous glands and hair follicles (Fig. 3); but others in addition were lined by stratified epithelium, with neither hair follicles nor sebaceous glands. The cysts which contained mucinoid fluid showed a lining of tall columnar cells, with very numerous goblet cells; these cysts were of very variable size, and all stages in the formation of the larger cysts from the smaller ones could easily be traced. Even in the large cysts the columnar epithelial lining was usually well marked (Fig. 4). A third variety of cyst, also numerous, contained granular

material, and possessed a lining of cubical cells, in some cases more than one layer in thickness; whatever their origin may have been, they cannot have resulted from cysts originally lined by columnar epithelium which became flattened as a result of the pressure of the cyst contents, for even very small cysts of this variety showed the same structure.

The stroma consisted, in addition to the masses of fat above mentioned, of connective tissue, in some parts densely fibrous

doubt: the first section through the tumour showed a typical specimen of "cystic disease"; a further slice revealed the presence of the two hair-containing cysts, and microscopic examination showed clear evidence of tissues derived from all three embryonic layers, the ectoderm being represented by stratified squamous epithelium, hairs, and sebaceous glands; the entoderm by the cysts

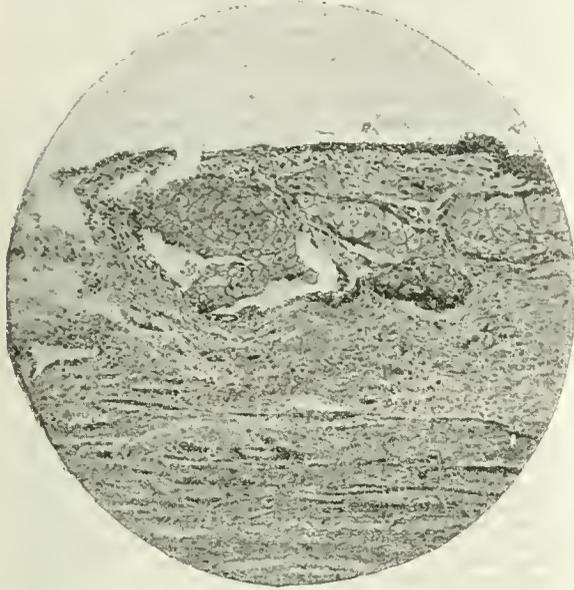

Fig. 3.—Section through the wall of one of the dermoid cysts labelled A and B in Fig. 2. Sebaceous glands are well seen lying beneath stratified squamous epithelium which forms the lining of the cyst. $\times 130$.

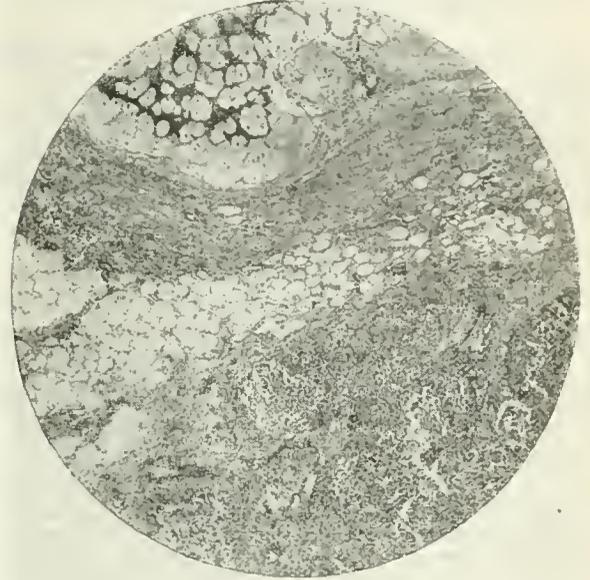

Fig. 5.—Section through part of the connective-tissue stroma of the tumour. The section shows a nodule of cartilage, the matrix of which has stained much more deeply in the central part of the nodule, owing to calcification having occurred. The dense round-celled infiltration of some parts of the stroma is also well seen. $\times 80$.

with but few cells, in other cases myxomatous, and here and there densely infiltrated with small round cells. Nodules of well-developed cartilage were seen, the matrix of which showed evidence of calcification (Fig. 5). Calcification was also proceeding here and there in the fibrous stroma of the tumour. The masses of soft vascular growth shown at C in Fig. 2 consisted of a loose fibrous tissue basis, densely infiltrated with a columnar-celled growth, in some places forming regular

lined with columnar epithelium, and the masses of columnar celled carcinoma; and the mesoderm by the stroma of the tumour and the masses of cartilage.

Dermoid cysts are not uncommon affections of the imperfectly descended equine testicle. In man such tumours are excessively rare. Microscopic examination of cases of

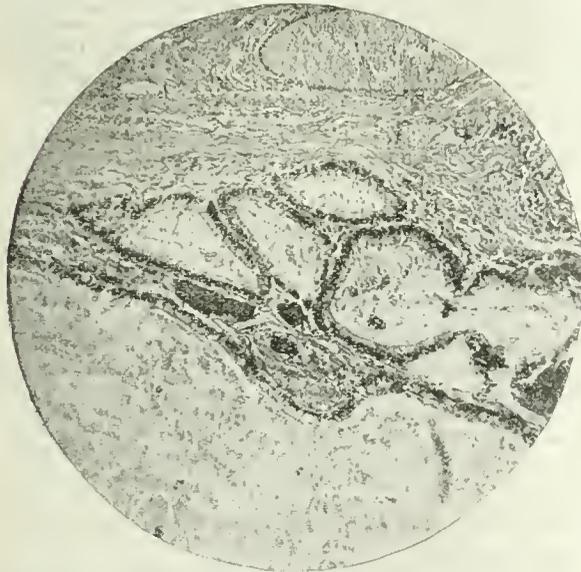

Fig. 4.—Section showing stages in the formation of the mucus-containing cysts. The cysts, both large and small, are lined by tall columnar epithelial cells, with many goblet cells. Calcification is proceeding in three spots in the stroma between the cysts. $\times 130$.

acini which were grouped together into lobules, in other spots quite irregular and definitely carcinomatous (Fig. 6).

It is becoming generally recognized that the affection of the human testicle often known as "cystic disease" is in reality a teratoma, though the exact place and mode of origin of the growth is still a matter of dispute. In this case the teratomatous nature of the tumour is beyond

Fig. 6.—Section of some of the soft solid growth seen at C in Fig. 2. It shows the structure of columnar-celled carcinoma. $\times 130$.

cystic disease of the human testis frequently reveals their teratomatous nature, but it is uncommon for the epiblastic part of the tumour to be represented by cysts, containing hair and sebaceous material, large enough to be evident to the naked eye.

The great size of the tumour is worthy of note. I am informed that even in the horse a testicle of such dimensions is very uncommonly met with.

DISTILLED WATER VERSUS SALVARSAN IN THE TREATMENT OF SYPHILIS.

BY

G. ARBOUR STEPHENS, M.D., B.S., B.Sc.LOND.,

HONORARY PHYSICIAN, ROYAL CAMBRIAN INSTITUTION FOR THE DEAF;
APPOINTED SURGEON UNDER THE FACTORY ACT.

THE simple treatment for syphilis herein recommended consists of the hypodermic injection of 6 to 10 c.cm. of distilled water every three days for two to four weeks.

I was induced to give this treatment a trial as the result of some research work I had done on surface tension, the results of which I published privately some fifteen months ago. I had previously published in the *Practitioner* an article on the Part Played by Colloids in Physiology and Pathology, in which I drew attention to the value of a consideration of surface tension. An experiment that I carried out to show the effect of the calcium salts on surface tension is rather interesting:

When pure hydrogen peroxide is added to pure mercury in a clean test tube, catalytic action occurs and oxygen is given off, the mercury remaining unaltered. This reaction is due to an extremely fine film that forms on the surface of the mercury, but, on account of the tension, breaks almost as soon as formed, the making and breaking being rhythmic. On adding a small quantity of a 10 per cent. solution of pure calcium chloride to the mercury, shaking well and draining it off, the mercury itself behaved peculiarly, its surface tension having been modified to such an extent that it could be induced to take up all sorts of shapes instead of the usual globular one. When the hydrogen peroxide was added the mercury was immediately changed into a grey colour and was then broken up into minute grey masses, many of which passed, as in the colloidal form, through filter paper; meanwhile the ebullition of oxygen was exceedingly great, and the heat generated sufficient to make the test tube very hot.

This experiment has been given at such length in order to show the marked effect of a slight alteration of surface tension.

The value of mercury in the colloidal form as an antiseptic is due to its possessing the powers of both classes of antiseptics—namely, the power of the heavy metals to combine with protein matter, and the power of chloroform, toluol, and the like to interfere with the surface tension of all living cells. It seemed to me, therefore, that it would be of interest to find out the surface tension of individual substances, and with that object I instituted some experiments.

In some of the experiments it was found that colloid mercury as well as mercury perchloride and carbolic acid have a tendency to reduce the surface tension existing between mercury and potassium chloride, and the fall is not complete at once, but is progressive. This fact is important, for with such a varying surface tension around a living cell the latter finds it very difficult to accommodate itself to its surroundings; in fact it fails, and its life ends.

The water soluble contents of coal-tar pitch, which no doubt are responsible for pitchworkers' cancer, have surface tensions that tend to drop considerably, whereas the soluble contents of blast furnace pitch have not this tendency, at least not to the same extent.

In the *Dublin Journal of Medical Science* for June, 1911, I gave the results of some experiments in which boiled yeast had been added to living yeast in a suitable growing medium, and I there showed that the effect of this addition was to stimulate the living yeast to marked activity, to a rapid life, and consequently to an early death. My experiments on the surface tension of boiled and unboiled yeast showed that whereas the surface tension of the latter was 70.62 dynes per centimetre, the surface tension of boiled yeast solution fell in twenty-four minutes from 70.96 dynes per centimetre, to 66.31, and in five hours to 61.02 dynes per centimetre.

I have previously shown that fertilizing with boiled bacteria stimulates the living ones to rapid growth and an early death. Boiled bacteria being vaccines, we can conclude that vaccines lower the surface tension, and by so doing produce their good results.

This lowering of surface tension is associated with a more rapid production of catalytic products in the cells, but the injection of vaccines is associated with the production of antibodies; therefore it seems but right to

infer that the production of antibodies is closely associated with a lowering of the surface tension.

The addition of distilled water to blood corpuscles so affects the osmotic pressure as to cause a passage of water into the cell, which gets larger and eventually scatters its contents. In disease the rapid catalytic changes and the rapid production of antibodies are interdependent, and if one can induce these marked catalytic changes with or without a vaccine, one stands the chance of setting free a number of very useful and remedial antibodies.

In such a chronic disease as cancer it seemed to me that the process was allowed to continue owing to the absence of sufficient antibodies, or at least a sufficient number to act together at the same time, and if one could set free any catalytic antibodies in sufficient numbers one might get a good result.

Knowing of no vaccine to induce this antibody effect, it occurred to me that the injection of distilled water might so affect the surface tension as to bring about the osmotic effects, and with this object I determined to try the effect at the first opportunity, which I owe to Dr. Lloyd Edwards, Medical Officer of the Swansea Union, and to whom I desire to express my thanks.

CASE I.

A man (in the infirmary), aged 62, who was suffering from immensely enlarged glands of the neck, secondary to an epithelioma of the lip. The glands were suppurating profusely, and the smell was so bad that the room had to be fumigated continuously. I injected 8 c.cm. of distilled water into the skin of the back, having previously rubbed it with alcohol to remove the grease (for the introduction of grease has a marked effect on surface tension). I did this every other day, and after the third injection the smell had disappeared almost entirely and the fumigation was discontinued. The surface of the sore seemed to be much cleaner, and the suppuration became more profuse, but otherwise the disease was not checked.

CASE II.

A man who had previously been operated on for epithelioma of the lower jaw by Mr. Bilton Pollard, and soon after for clearing out the glands of the neck. This latter was an extensive operation, but the wound eventually healed up well and firmly. Within three weeks of his discharge from University College Hospital there was a return of the growth, and I thought that if injections of distilled water were started early enough one might be able to do some good. At this time the wounds were quite sound and firm, but after three injections, to my great surprise an abscess headed and burst about the middle of the scar. I continued the injections in the hope that this marked activity presaged a favourable catalytic change in the cells, but the growth increased rapidly and the suppuration came to a head in two other openings. Closely following the suppuration appeared a mass of granulation tissue arising out of the part where the wound had quite healed, which spread rapidly. During all this time the pus was inoffensive, and the nursing of the patient was never objectionable to the least extent.

The marked effect produced by the injections of distilled water made me feel certain that in any similar disease of less malignancy their effect ought to be still better, so with that object I undertook, with Dr. Lloyd Edwards's permission, the treatment of the syphilitic patients under his charge. Both he and his assistant, Dr. Dunbar, were rather inclined to treat my mission as somewhat harebrained, but at the end of a week's treatment of my first patient I was able to prove to their satisfaction that the effect was excellent. The Wassermann reaction is, in my opinion, nothing but a very roundabout way of determining the surface tension at which haemolysis occurs, and if this view is correct, the time ought not to be far distant when a simpler and more scientific method is introduced, and one that is not open to so many pitfalls.

It is easily understandable from the point of view of surface tension that in several diseases the haemolytic point may be the same although the antibodies may be different.

CASE I.

An alcoholic prostitute, aged 26, had been in the infirmary since June, 1912, suffering from ulcers on the face and a large ulcer on the left shin. She was first admitted in August, 1910, having been infected a few months previously.

The area covered by the inflammation and ulcers was wing-shaped, covering both cheeks, upper lip, and a good part of the nose, and over the whole of this area there was considerable thickening. The ulcer on the leg looked indolent and unhealthy. She had not menstruated for two years.

I started treatment on October 25th, and continued it every other day until November 4th, but discontinued it on November 6th, as she had started to menstruate. I restarted treatment on November 8th, and continued it every third day till November 23rd, when the ulcer on the leg had healed. By November 9th the ulceration on the face had cleared, although there was still some thickness, as well as dilated venules to be seen.

Her general health improved greatly, and she looked better and felt in better spirits than she had done for a long time.

The readiness with which the edges of the ulcer took on a healthy appearance was extraordinary, especially as she had ceased to respond to the ordinary methods of syphilitic treatment.

After each injection there was a marked reaction, the face becoming very flushed, and the temperature rising in a short time afterwards as indicated by the two-hourly chart. The four-hourly chart shows it still better.

Her general improvement was a matter of comment by all the others in the ward, and both Dr. Edwards and Dr. Duibar were surprised.

CASE II.

T. A., aged 35, had been in the navy, but after leaving was employed at some works in the neighbourhood, where he received a blow on the arm, as the result of which there was a thickness which persisted longer than the usual bruise. With a history of syphilis, I naturally concluded that this was a syphilitic thickening of the periosteum, and gave him the injections of distilled water every other day. At the end of the fortnight the swelling and pain had disappeared, and he returned to work.

CASE III.

T. J., aged 46, was admitted to the infirmary on March 6th suffering from multiple ulcers of the left leg and foot. There was the brownish scar on the right shin, which confirmed the diagnosis of syphilis. The ulcers on the left leg and foot would nearly heal and then again break down, but never assumed a healthy appearance. I started injecting distilled water on October 31st, and continued the treatment every other day until November 16th, when I did it every third day. By the end of the first week the edges of the ulcers had taken on a very healthy appearance, and the pain from which the man suffered had practically disappeared.

There were ten ulcers altogether, and by November 23rd seven of them had healed over, and the two largest were two-thirds covered with new tissue. The man appeared healthier, and some colour had returned to his face. He said he felt much better, and looked forward to the time for each injection.

A reference to his temperature chart shows that there was a reaction after each injection, but the temperature did not rise nearly so high as in Case I.

CASE IV.

B. T., aged 24, had a hard chancre $\frac{1}{2}$ in. in diameter on the dorsum penis, which appeared a fortnight before I saw him.

I started injecting him with distilled water on November 2nd, and injected him every third day, and by the 14th it had practically disappeared, as well as the enlargement of the glands in the groin. His general health improved rapidly, and he looked much better after a fortnight's treatment.

CASE V.

M. S., aged 20, single, was admitted in November, 1911, as she was pregnant and infected with syphilis. After confinement and some treatment she was discharged, to be readmitted on November 11th, 1912, suffering from tertiary ulcers in different parts of the body. There was a small sore on the right ear and one on the right eye, whilst one seemed to be forming on the forehead.

Treatment was started on November 12th, and by November 19th there was considerable improvement, the ear and eye being practically well, and the swelling on the forehead had subsided.

All the other ulcers had taken on a healthy appearance, so that by November 25th they were all covered over.

Her general health improved greatly, she seemed brighter, looked healthier, and had colour in her cheeks, whilst the appetite improved. She much appreciated the treatment, although she cried on the first occasion.

The temperature reactions in this case were very marked, as in Case I, rising a few hours after each injection to 100° F.

CASE VI.

W. E., aged 26, admitted October 10th for sores on the right leg. Was infected with syphilis in the army.

Treatment was started on November 10th, and, after injections every third day, the gummata on thigh and leg were all covered over by healthy tissue on November 25th. A sore inside the right cheek also subsided, whilst his general appearance became more healthy.

The Arris and Gale Lectures

ON

THE GENITAL FUNCTIONS OF THE DUCTLESS GLANDS IN THE FEMALE.

DELIVERED AT THE ROYAL COLLEGE OF SURGEONS ON
MARCH 10TH AND 12TH, 1913,

BY

W. BLAIR BELL, B.S., M.D.LOND., M.R.C.S.ENG.,
L.R.C.P.LOND.,

GYNAECOLOGICAL SURGEON TO OUT-PATIENTS, ROYAL INFIRMARY,
LIVERPOOL; EXAMINER IN GYNAECOLOGY AND OBSTETRICS
TO THE ROYAL COLLEGE OF SURGEONS AND
PHYSICIANS LONDON; AND TO THE
UNIVERSITY OF DURHAM.

[Abstract.]

LECTURE II.

IN the last lecture I endeavoured to estimate the direct and indirect influences of the ovaries in regard to the genital functions. In considering the indirect influences I discussed the effects of ovarian insufficiency, both in physiological and pathological circumstances, on what I may, perhaps, describe as the rest of the genital system of ductless glands; and I also demonstrated the effects produced on the general metabolism by this condition.

In this lecture I shall reverse the process and endeavour to trace as far as possible in the time at my disposal the influence of the rest of the ductless glands upon the ovaries and the reproductive functions generally.

THE RELATION OF THE THYROID TO THE GENITAL SYSTEM.

We shall, perhaps, be in a better position to consider the changes that occur in the rest of the genital system if we first discuss the effect on the general metabolism of removal of this organ.

Effects of Thyroidectomy on the General Metabolism.

Different mammals vary very much in their power of withstanding the disastrous results which may follow complete removal. I have never observed any grave effects supervene on the removal of the thyroid in rabbits. This has been explained on the ground that the parathyroids are relatively large, and lie well away from the thyroid itself, and consequently cannot be removed without a careful search—in other words, they escape removal during the operation of thyroidectomy.

Swale Vincent and Jolly have shown that after thyroidectomy the parathyroids actually secrete colloid, and, in fact, perform the functions of the thyroid, just as they resemble it in structure after this operation. But I do not believe that this question of the remaining parathyroids is the whole truth.

I think rodents have less need of the thyroid than other mammals, such as the carnivora. It may be because the diet is different, but also I feel sure it is due in some measure to the variations in the structure and function (or degrees of function) seen in the other ductless glands. I have already alluded to the differences in structure between the ovaries of rodents and the higher mammals. If we take cats and remove their thyroids many die in a few days, usually with convulsions. In these cases it is probable that the immediate result is due to the removal of the whole thyroid apparatus (thyro-parathyroid). Some, however, survive the operation for a long period of time. In all these cases one can demonstrate the removal of the whole thyroid together with the internal parathyroids, which are embedded in the two lobes of the thyroid. So that one gets in these animals the true effects of thyroid insufficiency. The number in which the metabolism was investigated fully was small, for, as already stated, many died too soon for the metabolism, as represented by the urinary excretion, to be estimated. The record of one non-pregnant cat, which was destroyed two and a half months after operation, has been selected as typical. Other cases were complicated by the cats having had kittens shortly before operation, and in consequence did not appear to be suitable for averaging.

In this animal acetone was present three times in twenty estimations after operation. The calcium excreted

The fourth International Congress of School Hygiene will be held at Buffalo, New York, in August next (25th to 30th), under the honorary presidency of Dr. Woodrow Wilson, President of the United States. The actual president is Dr. Charles W. Eliot, formerly president of Harvard University. The general secretary is Dr. Thomas A. Stoney, Professor of Hygiene, College of the City of New York.

after operation was the same in quantity as before operation. There was a drop in the phosphorus excretion, in spite of the increase in the post-operation specific gravity; and the total nitrogen and urea were increased out of proportion to this rise in the specific gravity. The ammonia coefficient also was slightly increased.

Before considering the effect of thyroidectomy on the rest of the ductless glands I will bring forward a rather important series of experiments in which thyroidectomy was performed on three pregnant cats, which survived the operation for some time. They were carried out in order to observe the influence of the thyroid on the metabolism during pregnancy, especially with reference to the possible production of the symptoms of eclampsia with marked alterations in the ammonia coefficient.

Acetone, albumen, and sugar were found a good many times after operation in one cat, and more frequently after parturition than before, without any real disturbance of the ammonia coefficient.

We found that so long as the cats remained pregnant the calcium excretion remained constant, but that after parturition it was increased to three times the quantity. The phosphates after the birth of kittens showed a remarkable increase, and there was a drop in the urea excreted. There was no real disturbance of the ammonia coefficient.

It does not appear probable, therefore, that the thyroid is in any way specifically connected with the production of eclampsia, as was originally suggested by Nicholson. It is true that two of our cats, which were in the first half of pregnancy, died with convulsions in a few days, but the manner of death was similar in every respect to that seen in non-pregnant animals in similar circumstances.

Effect of Thyroidectomy on the Ovaries and Uterus.

The normal ovary of the cat, with which we are concerned in these experiments, shows certain affinities for eosin in some of its elements. The zona pellucida, the liquor folliculi, the interstitial cells, and the cells of the corpora lutea, all stain faintly with eosin. After thyroidectomy all these elements show an increased avidity for this stain. This is especially true of zona pellucida and the liquor folliculi, and appears to be a matter of some importance.

It seems that removal of the thyroid calls for a response from the ovary, just as oophorectomy did from the thyroid. And the nature of the response, if my observations are correct, is one of considerable interest, for it brings forward evidence that the granulosa cells of the Graafian follicle form an organ of internal secretion. But this secretion is not connected with the integrity of the uterus, for the effect of thyroidectomy on this organ is remarkable. The uterus of the thyroidectomized cat shows very considerable muscular atrophy, quite as much as occurs after oophorectomy. But the same effect is obtained in the non-pregnant animal. The importance of this intense atrophy will be considered directly; for before drawing our final conclusions of these results it will be advisable to consider the clinical observations that have been made in regard to insufficiency of the thyroid.

Clinical Observations of the Effect of Thyroid Insufficiency on the Genital Functions in Women.

These are quite well known. We frequently see young girls with adiposity suffering from amenorrhoea, or we see the more marked insufficiency which produces myxoedema, and is also invariably associated with suppression of the menstrual function.

Now, both the minor and the major state of thyroid insufficiency are readily amenable to thyroid treatment, with one reservation: if the girl has suffered from thyroid insufficiency for some years past the period of puberty, and has never menstruated, then it may be impossible to relieve her genital condition, and the uterus may remain under-developed. If, on the other hand, the insufficiency has arisen later, after the subject has possessed full genital activity, then the uterus may, even after a long period of inactivity, resume its normal functions.

Further, the full and increased activity—if my interpretation of the staining properties be correct—of the secretion of the membrana granulosa cells, with inactivity of the uterus, puts out of court the hypothesis that the cyclic changes in the uterus are due to this secretion. On

the other hand, it is possible that the secretion of the interstitial cells is rendered insufficient in the absence of thyroid secretion.

Effect of Thyroidectomy on the Suprarenals.

The normal suprarenal structure is well known, but I shall briefly refer to it in order better to illustrate the changes that occur—physiologically and pathologically—in the cat.

The suprarenal is divided into two parts, the cortex and the medulla. These have different physiological properties when examined experimentally. The medulla produces the well-known pressor effect of adrenin, while the cortex is inactive.

Now the changes that seem to indicate excessive activity of the suprarenals occur in the cortex. They may be seen normally in pregnancy and, so far as we know, in ordinary circumstances. The normal appearances differ, however, from those associated with the activity which follows thyroidectomy.

In three of my animals an actual calcareous deposit was found in the zona fasciculata subsequent to thyroidectomy. I have not seen this condition in a normal suprarenal gland.

Effect of Thyroidectomy on the Pituitary.

The changes that occur seem to be an increase in active eosinophile cells of the pars anterior at the expense of the large basophiles. And both in the pregnant and non-pregnant animal there is an increase of large active chromophobe cells, such as occurs normally in pregnancy. The latter are, of course, most pronounced in an animal in which thyroidectomy has been performed during pregnancy.

The condition was well seen in Cat X of my series. Forty-eight hours after operation two premature kittens were born. After a further interval of 120 days the animal was destroyed with chloroform. In this length of time all the chromophobe "pregnancy" cells would have disappeared in the ordinary course of events. But as the result of thyroidectomy they not only persisted but showed an increase in secretory activity. The secretion appeared to form vacuoles among the cells. In this case the pars nervosa showed no abnormal invasion of pars intermedia cells.

In the case of a non-pregnant cat (No. 9) killed 79 days after thyroidectomy again many active chromophobe cells were to be seen in the pars anterior, and an increase in active eosinophile cells at the expense of the basophiles.

We learn, then, from these observations that thyroidectomy causes an increase in the secretory activity of all parts of the pituitary body.

THE RELATION OF THE PINEAL TO THE GENITAL SYSTEM.

The pineal gland has never been successfully removed from mammals; and, owing to its inaccessible position in the brain, there seems to be little likelihood of experimental extirpation ever giving satisfactory results.

The effects of castration on the pineal have already been mentioned.

Clinical Effects of Pineal Disease on the Genital System.

Comparatively few observations have been made, but in most cases where a tumour has been observed it has been a teratoma, and somewhat remarkable symptoms have been seen. When the patient was a child, as was usually the case, there was a precocious development of the skeletal structures and also of the genital organs. According to L. Kidd, who has recently reviewed the literature of the pineal body, all the cases recorded occurred in boys. In a few instances obesity has been seen, but apparently unaccompanied by genital atrophy.

THE RELATION OF THE PITUITARY TO THE GENITAL SYSTEM.

Some of the normal physiological changes in the pituitary which occur are well known. But there is much need for a systematic investigation into the age changes in this organ. So far as I know, only a few isolated observations have been recorded.

There is reason to believe that the secretions of the pituitary determine many of the metabolic functions necessary for the establishment of puberty, or sexual maturity.

We fully recognize the remarkable enlargement and the histological changes that occur in this gland as the result of pregnancy. The eosinophilia disappears and a large majority of the cells of the pars anterior become chromophobe, and, as already mentioned, have been called "pregnancy" cells.

A few years ago Dale and also Hick and I showed that an extract of the posterior lobe produces powerful uterine contractions. This effect may be produced physiologically in labour by the infundibular extract.

Ott and Scott first showed that the same extract is a galactagogue. It is probable that there is an expressor effect. It would be interesting if it were a fact—of which we have no proof—that the pituitary normally promotes the secretion of milk. It is, however, certain, in my opinion, that after the birth of the child the stream of metabolic products directed to its maintenance and growth in the womb are diverted to the mammary secretion which is to supply its post-natal necessities.

Effects of Removal of the Pituitary (Partial or Complete).

Most of the early work on the extirpation of the pituitary was absolutely unreliable, and it was not until Paulesco improved the technique, which Harvey Cushing and Biedl subsequently adopted, that results worthy of consideration were obtained.

Cushing's conclusions may be summed up as follows: Complete extirpation caused death in a short time. The same effect was obtained by complete extirpation of the pars anterior. Partial removal of the anterior lobe led to the condition known as dystrophia adiposo-genitalis; that is to say, there was great obesity, with atrophy of the genital organs and undergrowth in young animals.

Biedl confirmed these findings, and also stated that the posterior lobe (pars intermedia and pars nervosa) might be removed without producing symptoms.

It is difficult to believe in the results of experiments in which the anterior or posterior lobe are said to have been removed separately. But there can be no doubt that partial removal of the anterior lobe is not difficult to accomplish; and the results following this procedure should be reliable.

Effects of Removal of the Pars Anterior.

On the Ovaries and Uterus.—There is no good description of the histological appearances found, but Cushing states that the Graafian follicles disappear while the interstitial cells persist. The uterus also undergoes atrophy. I have had no opportunity of examining ovaries after this operation, but, in view of the genital atrophy, would have expected the same changes as those which follow thyroidectomy—that is to say, the reverse of what has been found by Cushing.

On the Thyroid.—It has been noted by Cushing and others that there is a remarkable degree of hyperplasia in the thyroid after partial removal of the anterior lobe. This condition eventually subsides, and is superseded, it is said, by a considerable colloid formation, with apparent disappearance of epithelial activity.

On the Thymus.—This leads to hypertrophy of the thymus, just as the condition of hypopituitarism is often associated with thymus enlargement.

On the Suprarenals.—The operation, according to Cushing, is followed by hyperplasia and lipoid vacuolation of the cells of the zona fasciculata.

Clinical Observations of the Effect of Pituitary Insufficiency on the Genital Functions in Women.

These have been made chiefly in regard to acromegaly and the condition already described as dystrophia adiposo-genitalis. The former disease is supposed to be due to excess of secretion, and the latter to deficiency.

The relationship of these two conditions, however, is not quite so simple as the above statement would seem to imply. It is usual to find amenorrhoea both with acromegaly and with the condition which is supposed to represent the opposite in regard to secretory activity.

With acromegaly the excessive thickening of bones indicates calcium retention—a condition which appears associated with masculinity, as we shall see when dealing with the suprarenals.

In cases of dystrophia adiposo-genitalis genital atrophy is invariable, yet there is no doubt that, if the individual

has had functional activity before the onset of the disease, this activity may return on relief of the condition by decompression or by administration of pituitary extract. I have observed this result follow injections of anterior lobe extract in dystrophia adiposo-genitalis. Similarly I have seen good results after the administration of this preparation in cases in which the patient was very obese and suffered from amenorrhoea, without showing the signs of intracranial pressure which are usual when the condition has reached the stage of dystrophia adiposo-genitalis.

Success is more likely when the patient has had some functional activity previously; but it is possible that delayed menstruation with obesity might be successfully treated if the patient has not long passed the usual age of puberty.

THE RELATION OF THE THYMUS GLAND TO THE GENITAL SYSTEM.

The thymus has been shown to have a very important relation to the development of the individual and of her reproductive functions. It is probable that once the genital functions are established the thymus rapidly undergoes atrophy, and plays no further part in the metabolism of reproduction. We have already seen that the thymus undergoes hyperplasia after removal of the ovaries.

Effects of Thymectomy on the Ovaries and on the Calcium Metabolism.

Paton found that if the operation be performed before puberty there is a rapid development of the genital glands. It appears, therefore, as if the thymus either inhibits the development of the ovaries (Biedl), or that their development follows the withdrawal of the thymus secretion.

It is highly probable that the thymus is intimately connected with the calcium metabolism; but it can hardly be, as Biedl suggests, that the effect of its secretion is to cause calcium retention in the bones—although several investigators (Basch, Cozzolino, Tarulli, and Lo Monaco) have found that rickets follows thymectomy in young animals, an effect not confirmed by Paton—for the skeletal structures become much more heavily laden with calcium phosphate after puberty when the gland atrophies.

Effects of Thymectomy on the Other Ductless Glands.

No reliable work appears to have been done on these lines. It is urgently needed, in order to clear up many of the difficulties concerning the relation of the thymus to the general metabolism.

THE RELATION OF THE SUPRARENALS TO THE GENITAL SYSTEM.

These glands may be studied in the same way that we have already adopted—that is, from a physiological and pathological standpoint.

In pregnancy certain changes occur normally in the suprarenals. So far as my own observations go these are confined to the cortex. The cells of the zona fasciculata appear swollen and cloudy.

Some observers (Guéysse and Gottschau) have found that in pregnancy the zona fasciculata increases in thickness at the expense of the zona reticularis and medulla. My own observations are in accord with this.

Effects of Removal of the Suprarenals.

In most mammals complete removal of the suprarenals causes death in from a few hours to a few days.

Many rats, owing to the fact that a large percentage of them have accessory interrenals, consisting of cortical substance, are said to be able to survive extirpation of the main organs. I have had no experience of extirpation experiments on these animals. My investigations have been carried out on rabbits and cats. Those from which both suprarenals were removed, either at one or at two sittings, died within forty-eight hours. I tried, therefore, the effect of the removal of one suprarenal in the hope of being able to produce insufficiency, since we know the other suprarenal hypertrophies in these circumstances, and shows a condition somewhat comparable with the hyperplasia of pregnancy. Two cats gave negative results in

regard to the metabolism; but with regard to two rabbits I obtained definite results. One of the animals was destroyed at the end of thirty days, as it was obviously dying. It was much emaciated, its weight having dropped from 2,000 to 1,400 grams.

The other rabbit died at the end of 127 days. It also was greatly emaciated, its weight having decreased from 1,710 to 1,020 grams. At first it gained weight after the operation, and then it steadily lost ground.

No cause for death was found in either case.

These results are apparently of some value, for, according to most recent authorities, unilateral extirpation in rabbits produces no symptoms.

With regard to the metabolism, we obtained very interesting results. In each case a considerable increase in the excretion of calcium was observed.

In one case the average quantity excreted after operation was seven times as much as that excreted before operation. In the other case it was sixteen times as much. The average for the two cases was, of course, between these figures. The excretion of phosphorus was not increased in proportion, as one might have expected.

The urea excretion was increased out of proportion to the differences between the specific gravities before and after operation.

Now this increase of the calcium excretion is of very considerable interest. It is well known that the view has been advanced that osteomalacia is due to insufficiency of suprarenal secretion, and Bossi first called attention to the beneficial results to be obtained by the injection of adrenin in these cases. Unfortunately I have not met with a case of osteomalacia in recent years. So I have had no experience of this treatment. But these experiments give very strong support to this view of Bossi, not only in the metabolism results, but in a most striking way in regard to the bones of one of these animals.

The bones of the forelegs—which I presume a good deal of weight would fall—were found to be markedly bent. The bones of the back legs, which are thicker, were only slightly curved. But owing to the manner in which a rabbit sits very little weight would fall on these bones.

Effects of Suprarenal Removal upon the Pituitary Body.

The changes that occur seem to be much the same whether the insufficiency be acute or chronic; thus in cat No. 1 of my series of suprarenal removals, the glands from both sides were removed at the same time. There was an interval of thirty-six hours between operation and death.

The cells of the pars anterior show a marked degree of chromophobia with a moderate degree of faint eosinophilia. In many places the nuclei are very deeply stained with haematoxylin.

In the pars intermedia the cells are discrete—that is to say, they are not fused, and show no special activity; the nuclei stand out prominently.

The pars nervosa is freely invaded by the cells of the pars intermedia, but the nuclei only are prominent, as though they were left stranded after the disappearance of the cell cytoplasm.

We cannot, therefore, come to any conclusion other than that the anterior lobe shows increased activity. The pars intermedia is certainly not in an actively secreting condition, but the extensive invasion of the pars nervosa by pars intermedia cells, and the rapid disappearance of the cell cytoplasm, appear to indicate that an attempt is being made to counterbalance the loss of adrenin by the rapid production of infundibulin.

Effect of Removal of the Suprarenals upon the Thyroid.

I have been unable to trace any histological change either in acute or chronic suprarenal insufficiency.

Effects of Removal of Suprarenals on the Ovaries and Uterus.

There appears to be no histological change of importance in the ovary; but it is worthy of note that the normal eosinophilia of the zona pellucida is not decreased—rather, if anything, is it increased. After removal of one suprarenal, if insufficiency be produced, the uterus appears to undergo changes comparable with those that are seen

after thyroidectomy, but the muscular atrophy appears to be less in extent; probably this is due to the state of incomplete insufficiency.

Clinical Observations of the Effect of Pathological Lesions of the Suprarenals on the Genital System.

We meet with conditions in the human subject which represent both an under-secretion and an over-secretion of the suprarenals. This is decided on clinical and histological evidence. At the same time, we are still in the dark as to the exact relationship of the cortex to the medulla.

In Addison's disease we have what are apparently the symptoms of insufficiency of medullary secretion, as is shown by the low blood pressure and general muscular weakness. But in this disease the cortex also is destroyed.

It is doubtful if sufficient pathological observations have been made with a view of observing changes in the ovary and uterus to enable us to give any definite statements regarding them.

Amenorrhoea is, I believe, usually associated with Addison's disease, but this may be due solely to the effects of a condition which produces general progressive enfeeblement. On the other hand, our experimental evidence indicates that atrophy of the uterus, and presumably insufficiency of the function of the interstitial cells, occurs in these circumstances.

The other pathological lesions which have been subjected to a good deal of attention lately are hyperplasia and tumour formation in the suprarenal cortex. For some years these lesions have been known to be associated with extraordinary changes in the primary and secondary sex characteristics. Attention was first called to these interesting phenomena by Woolley, Bulloch and Sequeira, and Neugebauer.

Last year my colleague, Professor Ernest Glynn, reviewed exhaustively the whole subject and added 5 fresh cases in children to those already collected by Bulloch. Out of 17 cases in children 14 were females. In these there was usually skeletal overgrowth, hair on the face and pubes, and sometimes hypertrophy of the clitoris. Further, Glynn collected 6 cases occurring in young adult females, in all of whom there was growth of hair on the face, shrinkage of the breasts, amenorrhoea, and sometimes a masculine voice.

Pathologically the suprarenal enlargement in the children and young adult females was unilateral and neoplastic in character, and directly or indirectly caused death. Metastases were sometimes found.

In a second group of cases there were 13 pseudo-hermaphrodites—12 being females—and in these the suprarenal enlargement was bilateral, hyperplastic in character, and there were no metastases.

Glynn suggested that in these cases hyperplasia of the suprarenal cortex occurred in fetal life before the differentiation of the genital ducts, and led to the persistence of the Wolffian derivatives, thus causing female pseudo-hermaphroditism.

No sex changes are associated with tumours of the suprarenal cortex when they occur in adult males or in women after the menopause.

THE CORRELATION OF THE INTERNAL SECRETIONS IN REGARD TO THEIR GENITAL FUNCTIONS.

I have endeavoured to trace, for the most part from my own observations, the disjointed facts concerning the influences exerted by the different members of the ductless gland system upon one another and on the metabolism generally, in so far as the genital system is concerned. And in so doing I have sometimes shown clearly the nature of the associations between the different organs. But it is absolutely impossible at the present time to correlate fully all their functions, so that perhaps the less said now the less there will be to withdraw at some future date.

In view, however, of what I said at the commencement as to the necessity for a lead in this intricate matter, I cannot refrain from enunciating what I believe to be the general principles. I shall not have time further to analyze the details.

It appears, from the evidence at our disposal, that, in spite of great variations in the structure of the ductless

glands in different mammals, the *total functional result* is the same so far as the genital processes are concerned. The variations in function that depend on the differences of structure are probably related to differences in the food and habits of life.

In adapting our knowledge to the requirements of human physiology and pathology we must take into account *both* the essential functions I have already referred to—the individual metabolism of the mother and the metabolism of her reproductive functions—for they are completely interdependent.

We have seen as the result of our studies that the ovaries, on the one hand, have as their share of these dual functions the onus of ensuring the reproduction of the species, by furnishing the ova and by keeping active the rest of the genital structures and functions. And, further, the secretions of the ovary are concerned in keeping the other members of the ductless gland system in touch with the necessities of the reproductive situation. The latter function is of the deepest importance, and is one which explains much that would otherwise be obscure.

When the reproductive functions cease and the ovaries atrophy at the menopause the harmony that previously existed between the general and the genital metabolism is temporarily deranged, and various disturbances may ensue. And it is only by the careful investigation of each menopausal case that one can arrive at a determination of the manner in which the balance has been upset. It is impossible always to alleviate the symptoms, but the basis of treatment rests on the regulation of the existing disarrangement by the administration of the necessary secretions. Some patients react to thyroid extract, some to pituitary, others again to combinations, so great are the individual variations. In most cases a natural readjustment takes place in the course of time. So that, strictly speaking, the ovary is only concerned in the temporary function of reproducing the species, and, by its hormones or internal secretions, of bending the metabolism of the body to its purpose. As accessory to these functions the ovary has been supposed to be responsible for the beauty of the vessel by means of which its ends are to be attained. But to-day we are beginning to wonder how far the ovary does influence secondary sex characteristics, and whether full individual secondary characteristics can be obtained by the influence of the ovary alone.

We have evidence that hyperplasia of the suprarenal cortex can upset any influence the female genital gland may be supposed to possess, and can produce in a female some of the secondary characteristics of the male, and even partially change the genitalia to complete the picture.

I well remember seeing a case under the care of Dr. Russell Andrews. The subject possessed every female characteristic except for the absence of uterus, Fallopian tubes, and ovaries; instead there were testes within the abdominal cavity. This individual was a male pseudo-hermaphrodite with the pure secondary characteristics of a female, and a prepossessing one at that. Such a condition could not have existed with hyperplasia of the suprarenal cortex.

Any influence the ovary has over the general metabolism is, then, related to and dependent on its primary reproductive function. I do not believe that it influences the metabolism except in so far as this special function is concerned. Of course, removal of the ovaries may produce a temporary disturbance, but this has already been explained, and does not invalidate the view just mentioned.

On the other hand, the rest of the ductless gland system is related to the genital function in various ways.

First, some of the members—the thyroid, pituitary, and suprarenals—influence the development and subsequently preserve the integrity and activity of the genitalia, as I have already demonstrated. Others—the thymus and possibly the pineal—appear to prevent sexual precocity.

Secondly, all the ductless glands control the metabolism in response to the necessities of the genital functions; but, in addition, they adapt the whole organism to the possibility of the situation and regulate the secondary characteristics, both physical and psychical, to suit the needs of the individual. Once, however, the reproductive organs

are removed or undergo atrophy, the primary genital functions of the rest of the ductless glands cease, and the rearrangement of the metabolism that follows produces what are known as the symptoms of the menopause. Contrariwise insufficiency of the thyroid, pituitary, or suprarenals causes the cessation of the genital functions with atrophy of the uterus.

As to the more particular parts played in the metabolism by each member of the ductless gland system, these have already been specified.

In spite, therefore, of the reluctance to correlate our knowledge shown by most investigators, the matter is not one of very great complexity if my views be correct in a general way, although there remains much detail to fill in.

As soon as possible we must come to a conclusion as to what are the facts. So much work that has been done is contradictory. There is therefore so much more the need for further efforts.

In concluding, I would again insist that in order to solve completely the problems surrounding the genital functions we must focus at one and the same time the two essential processes of life—the individual metabolism and the reproductive metabolism. They are absolutely interdependent. Indeed, the individual metabolism is the reproductive metabolism. It is the neglect of this point of view that has brought about much of the confusion that exists.

Weismann and Ray Lankester describe the relation between the reproductive cells and those of the soma in still more striking terms. The latter says: "Among the multicellular animals, certain cells are separated from the rest of the constituent units of the body, as egg cells and sperm cells; these conjugate and continue to live, whilst the remaining cells, the mere carriers as it were of the immortal reproductive cells, die and disintegrate. The bodies of the higher animals which die may from this point of view be regarded as something temporary and non-essential, destined merely to carry for a time, to nurse and to nourish the more important and deathless fission products of the unicellular egg."

Whatever views we may hold as to details, I question whether this philosophical statement is open to contradiction.

The function of reproduction in all its preparations and performances commences in the early stages of segmentation, and may be said to continue in man until the care of the offspring is completed.

In many insects, male and female, the act of reproduction is also the cause of death. Evolution and the pressing necessities of individual life have led men to look upon the function of reproduction as of vastly inferior importance to their own individual metabolism. No doubt women will soon come to think so too, for they seem to be changing. Whether this change be due to an increasing hyperplasia of the female suprarenal cortex I do not know. But just as we are beginning to think that our knowledge of their special functions is becoming well defined they invite us to follow their further evolution, which apparently they think will not involve them in the joys of motherhood.

Helmont said "*Propter solum uterum mulier est quod est*"; Chéreau changed this to "*Propter ovarium solum mulier est quod est*."

Virehow reiterated this statement and, according to Biedl, added that "All the peculiarities of her body and mind . . . everything, in fact, which in the true woman we admire and revere as womanly, is dependent on the ovary."

In the light of our present knowledge I venture to think that the following aphorism more nearly describes the cause and effect:

Propter secretiones internas totas mulier est quod est.

The original work detailed in these lectures, which were illustrated with many photomicrographs and colour photomicrographs, was carried out in the Biochemical and Pathological Laboratories in the University of Liverpool; and I am much indebted to Professor Benjamin Moore and Professor Ernest Glynn for help in various directions, and especially for the facilities accorded to my assistants, and for the superintendence of their work.

The entire expenses were defrayed out of the J. Arthur Smith Research Fund.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

UNDEVELOPED LARGE INTESTINE.

DR. CLIFFORD MAYER reports (JOURNAL, March 8th, p. 498) a case of undeveloped large intestine in an infant. The following is another instance: I operated on a child last month as a last resource, explaining to the parents that it would most certainly die if left alone, and probably even if operated on. A soft catheter could be passed 4 in. up the rectum, and I diagnosed absence of part of the gut. I made an incision in the middle line, and rapidly stitched the caecum to a small opening in the right iliac region. The large intestine from the caecum to the sigmoid flexure was represented by a white thin, cord-like band, having about the appearance of a rather narrow white shoe-lace. The small intestine was greatly distended, and completely hid the large gut. The appendix was well developed, and the caecum was distended. The lack of patency in the large gut appeared to begin about 1 in. from the colic end of the caecum. The operation was undertaken later than I would have wished—about the third day after birth—and the child died shortly after. The mother stated that her first child had "no back passage."

A case I had last year, evidently of the same nature—lack of development of the large bowel—died without operation a week after birth. In this a bougie was passed about 4 in. up the rectum. The mother of this case also said that she had had an infant with "no back passage," which had died soon after birth.

Gillingham, Kent.

IAN JEFFERISS.

HAEMORRHAGE FROM A CORPUS LUTEUM CYST.

On May 15th, 1912, Mrs. F., aged 18, nullipara, was suffering from acute abdominal pain and vomiting and diarrhoea. She had been ill two days. The temperature was 102°. The abdomen was rigid, and there was tenderness in each iliac fossa, but particularly on the right side, the rectus on that side being on guard. She was expecting to menstruate at any time. On vaginal examination there was nothing palpable in either fornix, but there was tenderness on the right side. Menstruation began next day, May 16th; it lasted five days and was normal.

On May 22nd an operation was undertaken to remove the appendix. On opening the peritoneum the abdominal cavity was found to contain free blood. The appendix was inflamed and was removed. The right ovary and broad ligament were normal. As the left ovary and tube could not be reached through the appendicectomy incision, the patient was placed in the Trendelenburg position and an abdominal section made in the middle line. The left ovary, on being brought up into the wound, was found enlarged and cystic, and adhering to it was a small mass of dark clotted blood about the size of a filbert. When this was removed blood oozed freely from a small sharply cut puncture. The peritoneum contained about three pints of blood-stained fluid and clots. Microscopically, the cyst showed the characters of a corpus luteum and no sign of an ovarian pregnancy.

F. ADAMS, M.B. Sydney.

SCARLATINIFORM RASH DUE TO VENICE TURPENTINE.

A MAN of 22 was first seen on February 6th, having been sent by his medical man as a probable case of scarlet fever.

The history given was that he had felt warm and flushed on the previous afternoon, and by evening the skin all over the body was red. There had been no sickness, and no sore throat. A typical vivid scarlet punctate rash was found all over the body, and on the fauces there was marked redness and mottling. There was only a slight white coating on the tongue, but the temperature in the mouth was 99.2 F. I inquired whether the patient had been taking any unusual article of diet, or copaiba, or other drug, but the only suspicious circumstance was that he had taken a few doses of what he called "Veno's turps" for a cold. In view of the typical scarlatiniform rash, the appearance of the fauces, and the slight rise of temperature,

it was decided to isolate the case for observation. The rash faded quickly, there were no further symptoms of illness, and no sign of desquamation after fourteen days.

As the case was so suggestive of a drug rash, I made inquiries, and found that the remedy the patient had been taking was really Venice turpentine, a thick resinous preparation, with a bitter acrid taste, not infrequently taken for pains in the back supposed to be due to the kidneys. The man had taken of this drug a piece the size of a pea twice on February 4th, and three times on the 5th, before I saw him on February 6th.

Venice turpentine is an oleo-resin obtained from the larch. In its composition, physical characters, and action on the body, it is very similar to copaiba, and the oil it contains is isomeric with oil of copaiba.

From these facts I think it highly probable that the rash in this case was due to the Venice turpentine, and that the rash invaded the fauces. The slight rise of temperature may have been due to the cold for which the patient had been treating himself.

I have been unable to find mentioned anywhere the possibility of a rash from this particular cause being mistaken for scarlatina, and in view of the importance and frequent difficulty of diagnosing scarlet fever, I think it may be of interest to record the case.

WILLIAM ANGUS, M.D., D.P.H.,
Assistant M.O.H., Ipswich.

FETAL GOITRE.

ON January 11th, 1913, I delivered a primipara, aged 31, at full term of a male stillborn fetus with a large goitre. Labour commenced at 9 p.m. on January 10th; at 5 a.m. on January 11th, when I was called by the midwife, the membranes had ruptured, the os was dilated, and the face presenting, the lower maxilla being anterior and slightly to the left about one inch from the perineum.

I administered chloroform and tried to apply Neville's axis traction forceps, but the upper blade would not lock with the lower. I then introduced my left hand to ascertain the cause of obstruction, and found that the head was greatly elongated, and that it was quite impossible to apply forceps. I turned the fetus and brought down the right leg; the patient then, with the help of traction with a towel around the foot, delivered herself. The occiput was greatly elongated, and extended to about the fourth dorsal vertebra. A goitre occupied about two thirds of the left side of the neck. It measured 10½ in. at its greatest circumference. The mother has had a large goitre since she was 14. Her mother is free; her sister and her two brothers have goitre. The case, I believe, is rare. The elongation of the occiput on the right side is probably to be accounted for by the goitre being larger on the left side of the neck and so pushing the lower maxilla to the left of the symphysis pubis during delivery.

Reports

ON MEDICAL AND SURGICAL PRACTICE IN HOSPITALS AND ASYLUMS.

ROYAL NAVAL HOSPITAL, PLYMOUTH.

CURE OF LIVER: RECOVERY WITHOUT OPERATION.

(By W. EAMES, Deputy Surgeon-General, R.N.)

A STOREN, aged 21, was admitted at 10 p.m. on December 10th, 1912, suffering from abdominal injury, caused by falling side-ways from a ladder on his ship, a distance of 5 to 6 ft., and alighting across his epigastrium on the steel edge of the coaming of a hatchway beneath.

I found the patient blanched, and in an extreme state of collapse; the pulse was imperceptible at each wrist, the lower extremities cold, and respiration shallow and sighing. He was conscious, and complained of great abdominal pain.

On examination, the patient lying on his right side, the whole of the right half of the abdomen was found to be markedly dull and slightly bulging, with a marked senso

of fluctuation, evidently due to blood in the peritoneal cavity from ruptured liver; there was no vomiting. Prior to my arrival Surgeon Wilson had administered ether and strychnine hypodermically, and a rectal injection of saline solution (20 oz.). The patient was well packed round with hot water bottles, and no improvement having followed the before-mentioned treatment, I ordered a hypodermic solution of ergotinine citras $\frac{1}{10}$ gr. in the right flank; this was followed in a few minutes by an apparent improvement in the patient's pulse, which was just perceptible; a further injection of the same dose of ergotinine was given, followed after a brief interval by morphine hydrochlor. $\frac{1}{2}$ gr. hypodermically; the paroxysms of abdominal pain, which had been present since admission, now became less frequent; the pulse was only occasionally perceptible at the wrist, and the extremities remained cold. The patient was moved on the anaesthetic table on which he was lying to the operation ward, and placed in front of the ward stove.

Next day the pulse volume had improved, and there was no increase in the abdominal dullness; some retention of urine was relieved by catheter; the urine was clear; the tongue was inclined to dryness; there had been no vomiting, the abdominal pain was less, and the colour had improved. With the patient now lying on his back there was marked dullness in both flanks.

I administered morphine hydrochlor. $\frac{1}{4}$ gr. hypodermically, directed that no food should be given by the mouth, ordered nutrient enemata, and rectal injections of saline (6 oz.) every four hours. At 6 p.m. the patient was drowsy, and had occasional bouts of pain in the abdomen; retention of urine was relieved by catheter. He had retained rectal salines and the greater part of the nutrient enemata. He slept well, and urinated normally.

On December 12th the pulse was of fair volume, the pain in the abdomen slight, the dullness was less marked in the left flank, well marked in the right; rectal salines were given every two hours, and the nutrient enemata continued. At 6 p.m. it was reported that he passed two loose, dark-coloured stools. Morphine hydrochlor. $\frac{1}{4}$ gr. was given hypodermically.

On December 13th he was doing well; the abdominal dullness was confined to the right hypogastric and lumbar regions. Small quantities of fluid nourishment were allowed by the mouth. The volume of the pulse had improved. At 6 p.m. he was comfortable; an injection of morphine $\frac{1}{4}$ gr. was given at 9 p.m.

On December 14th his local and general condition much improved; but on December 15th, after transfer to a general ward, he was seized suddenly with considerable pain referred to the upper half of the abdomen. He became faint and somewhat blanched, and was evidently the subject of a secondary haemorrhage due to the breaking down of a portion of the already formed blood clot, caused by excessive body movement. Morphine $\frac{1}{2}$ gr. was immediately given hypodermically, followed shortly after by ergotinine citras $\frac{1}{10}$ gr., and ice was applied to the abdomen. Next day he was markedly jaundiced, and there was some haemoglobinuria; the pulse was 50, and of good volume; there was no abdominal pain, but dullness in the right flank had somewhat increased. On December 17th the jaundice was very marked, as also the haemoglobinuria; there was no abdominal pain, and the pulse was 42, and of good volume. On December 18th the jaundice and haemoglobinuria were less marked, and his general state was otherwise good; the bowels were acting well; the pulse was 48, and its volume good.

From this date the patient, both locally and generally, steadily improved. On December 29th there was slight dullness in the right loin and hypogastric region, but he was taking full dietary without any distress or inconvenience, and his colour was quite good.

I think this case is interesting from the point of view of recovery from what appeared to be an impending fatal condition, which latter prevented one dealing with it operatively without producing an immediate fatal issue.

UNDER the will of the late Miss Mary Bone, of Lancing, the Worthing Hospital receives a bequest of £500, other sums of £300 and £200 respectively going to the Chichester Infirmary and the Sussex Eye Hospital.

Reports of Societies.

ROYAL SOCIETY OF MEDICINE.

SECTION OF GYNAECOLOGY AND OBSTETRICS.

Ventri-fication.

At a meeting on March 6th, Dr. AMAND ROUTH, President, in the chair. Dr. W. S. A. GRIFFITH, in opening a discussion on ventri-fication of the uterus, said that the operation was adapted for the relief of certain cases of displacement of the uterus, where there was a failure on the part of the supports of the uterus to maintain that position necessary for the comfort of the patient, and to enable her to perform ordinary laborious duties. These cases fell into two classes: (1) Those in which the supports of the uterus were sufficient to maintain it at, or nearly at, its proper level in the pelvis, but in which retroversion or retroflexion of the body of the uterus and adjacent broad ligaments, leading to prolapse of the ovaries, was the cause of the serious discomfort. (2) The cases in which prolapse of the uterus, broad ligaments, and ovaries was considerable and associated with varying degrees and forms of vaginal, vesical, and rectal protrusion. Many cases in both these groups were sufficiently relieved by pessaries, though some women, for various reasons, preferred the relief to be obtained by operation to the prolonged use of pessaries and the medical attendance and frequent douchings which were the necessary alternative. The following appeared to be clear indications for the operation: Class 1: The uterus is retroverted and more or less fixed by adhesions. The uterus is pressed down in the position of retroversion by a tumour, commonly ovarian. After enucleation of a fibroid from a retroverted uterus. The retroversion is complicated by prolapse and enlargement of the ovaries, a constant source of pain, unrelieved, and in some cases increased, by the pressure of the pessary. The retroversion or retroflexion is not kept in position by a pessary owing to the small size of the vaginal cervix or the dilated condition of the vagina. Class 2: In the second class the operation was often needed, the prolapse of the uterus being accompanied by prolapse of the vagina, and in most cases great enlargement of the vaginal orifice. The large rings so frequently used did much harm by the greater dilatation of the vagina which they caused. The support which the operation gave to the uterus in this class was only a part of that needed for their complete relief, and the speaker usually performed it at the end of the vaginal operation—namely, after curetting, partial excision, or repair of the cervix, if these were needed, and after the repair of the posterior vaginal wall and perineum, with anterior colporrhaphy if the cystocele was considerable. An examination of the patients twelve months or longer after operation was essential for a correct opinion as to the result. Some surgeons were in the habit of performing this operation in cases of retroversion in women of poor general health, who had no local symptoms, with the idea that retroversion was a cause of the general feeble state of health. The condition of the uterus in these cases was merely a symptom, and in no sense a cause of the ill health, and it was undesirable to subject such patients to this operation.

The next speaker, Professor H. BRIGGS, discussing the technique of the operation, advocated a purely peritoneal direct ventral fixation over a limited and appropriately chosen area, that is, over a site immediately adjacent to the pelvic floor. As a low-level fixation by silk suture of the lower portion of the body of the uterus to the parietal peritoneum adjacent to the summit of the bladder, its peritoneal bands were harmlessly and effectively situated above the usual cervical site of the retroflexion. This method of ventral fixation further ensured complete freedom to the greater part of the body of the uterus during the child-bearing period of life when the operation was at its best. Only in a relatively small number of cases was ventri-fication alone adequate treatment.

Dr. A. E. GILES dealt with after-results, but premised that his remarks referred not to "ventri-fication" or "ventrosuspension" of the uterus, but to a specific operation to which the speaker restricted the term "hysteropexy." The

features of this operation were described. In his previous recorded after-results of abdominal operations down to July, 1909, there were 309 cases of hysteropexy, 248 of which were traced. From August, 1909, to July, 1912, 199 additional cases were done, making a total of 508 hysteropexy operations. An endeavour had been made to complete the after-histories of the additional cases; about 120 of them had been traced. An analysis of these cases confirmed the conclusions previously arrived at—namely, that the general health was improved and symptoms relieved in over 90 per cent.; that the position of the uterus remained permanently good in over 95 per cent.; that hysteropexy when followed by pregnancy caused no subsequent complications of labour; and that pregnancy following hysteropexy did not disturb the position of the uterus. Of the 199 additional cases, 92 were operated upon for retroversion, 40 for prolapse, and 67 for procidentia. To get the best results in the last two groups, it was usually necessary to combine plastic operations on the vagina and perineum with the hysteropexy. It was desirable that operators should record the results of a large number of cases of other operations for uterine displacements.

Dr. HERBERT SPENCER was surprised at the frequency with which other gynaecologists performed ventrifixation, as he himself had only done it twenty-seven times in 1,000 abdominal sections. The reason why he had performed so few of these operations was that it was an unscientific operation by no means free from danger. Giles had had 4 deaths in 220 cases, Zweifel 5 deaths in 336 cases, 4 of the latter being deaths from septic peritonitis. Another reason which influenced him was that he had seen so many cases in which the operation had failed to relieve the symptoms. He noticed in Dr. Giles's valuable investigation into the after-history of these cases that 42.2 per cent. of those inquired into had pain after the operation, although in 32.5 per cent. it was stated that the pain was less than before. In his opinion both ventrosuspension and ventrifixation, as ordinarily performed, were unscientific and dangerous operations, giving rise to peritoneal bands, which on many occasions had caused strangulation of intestine. For procidentia in women beyond the menopause he considered ventrifixation a useful adjunct to colporrhaphy and perineorrhaphy, but care should be taken completely to close the peritoneum over the bladder.

Dr. ARTHUR DONALD remarked that Dr. Griffith had said that the operation should not be performed for retroversion when there were no local symptoms, but he did not state what he considered the symptoms of retroversion to be. The symptoms usually associated with retroversion were menorrhagia, metrorrhagia, and dysmenorrhoea, and many operations for retroversion were done in the hope of curing these symptoms, which were attributed to congestion induced by the displacement. There was, however, no reliable evidence that retroversion caused congestion, or that congestion could lead to changes in the endometrium causing menorrhagia, metrorrhagia, and leucorrhoea. The practice of stitching up the uterus for the cure of these symptoms was therefore unscientific. The speaker believed that in these cases there was an abnormal condition of the endometrium (endometritis), which was often the cause, but never the result, of the retroversion, and his own practice was to cure these cases and disregard the position of the uterus.

Dr. MCKENNAUGHON-JONES said he had never performed hysteropexy as advocated by Dr. Giles. Since 1905 the operation he had performed was as follows: A strong catgut suture, to last eighteen days, was passed on each side so as to include a loop of the round ligament, the parietal peritoneum, and the peritoneal fascia. The ligaments were then crossed so as to bring the ligature out at the opposite side; the ligatures were tied after closing the peritoneum. He did not think that fixation of the uterus should be practised during the child-bearing period of life.

Miss IVES said that her operative experience was confined to 150 cases of Gilliam's operation. In the last 50 cases she had adopted Mayo's modification, the round ligament being drawn through the peritoneum at the internal inguinal ring, so that no abnormal slit was left, as in Gilliam's procedure. There had been one fatality, in a case complicated by chronic appendicitis. About 93 per cent. of the cases had been followed up, and the results were very satisfactory.

Dr. HANDFIELD JONES did not consider that cases in which the ovaries and tubes were removed for disease and the uterus then stitched forwards should be regarded as cases of ventrifixation, as in the vast majority there was no need to suture the uterus at all. He had found the operation of most use in women of middle age, who found relief from wearing a pessary, but after a reasonable time were unable to do without this support. He had seen much distress caused by the uterus being fixed at too high a level, and in these cases he had given the patients immediate relief by setting the organ free again. The patient should be prepared for the operation by ten days' treatment in bed with hot douches and glycerine tampons.

Dr. ARNOLD LEV said he had done the operation seventy-five times in 500 abdominal sections; the greater number of the cases were for backward displacement. He was opposed to treating these cases with pessaries, as the pessaries rarely had any curative effect, except in cases of simple retroflexion following confinement.

Dr. HERBERT ROBEARS believed that the greater number of cases of backward displacement did not require operative treatment. He considered that retroversion was often the first stage of prolapse, and if an operation was required at all it should be directed to repairing the pelvic floor. He had done the operation in a few cases, selecting Gilliam's operation in young women and ventrifixation in women who had passed the child-bearing period.

Mr. BUCKWILL WHITTHORSE expressed the opinion that in some centres there was a growing tendency to fix the uterus for inadequate causes. In his experience fixation often failed to relieve pain in the case of patients suffering from simple displacements, and care should be exercised in the choice of cases. He had seen a case of intestinal obstruction which was caused by a band of adhesions resulting from fixation of the uterus to the abdominal wall, and he did not regard this method with favour. His own preference was for the "sling" operation of Clarence Webster, in which a loop of the round ligament was drawn through the broad ligament on each side and stitched to the posterior uterine wall. He described in detail the technique he had himself been led to adopt.

Dr. J. S. FAIRBAIRN said that with regard to cases of simple backward displacement he agreed with a previous speaker that the operation should only be done when absolutely necessary. The difficulty was to decide what made it necessary, and he considered that those who did these operations by the hundred were still living in the mid-Victorian period of gynaecology when displacements were regarded as of supreme importance.

Dr. FARQUHAR MURRAY reported some clinical observations made by Mr. Bryden Glendining and himself upon the capacity of the bladder before and after ventrifixation. In the result half the cases showed an increased and half a decreased capacity after the operation.

Dr. WALTER TATE said that he had performed the operation of ventrifixation in 44 cases between the years 1900 and 1910 at St. Thomas's Hospital. In 25 the after-history had been followed, showing that seven had borne one or more children since the operation without any complication occurring during either pregnancy or labour. This good result he attributed to the fact that the fixing sutures were passed through the lower part of the uterus leaving the fundus free. In contradistinction to a previous speaker, he considered that the operation was specially called for in women in the prime of life who had to earn their living. But he only advised the operation in cases where pessaries and other methods of treatment had failed to relieve. He had also found the operation of use in some distressing cases of incontinence of urine from weakness of the bladder sphincter. By fixing the uterus the neck of the bladder was also supported, and in this way the relief of the trouble might be explained.

The PRESIDENT (Dr. Amand Routh) hoped that the speakers in their replies would more closely define the indications for those cases where ventrifixation was done for retroversion where the uterus was mobile. Accessory ventrifixation was in many cases a recognized and useful addition to a laparotomy performed for removal of appendages, etc., but he doubted if it was often a necessity apart from those cases. His primary ventrifixations did not amount to more than 3 per cent. of the abdominal sections, and they were almost entirely cases

where in addition to the retroversion one or both ovaries were also prolapsed. Here ventrifixation had its most useful application. Plastic operations, curettage, etc., had each their special indication in these cases of retroversion, and these minor operations often relieved the patient better than a ventrifixation. If these failed, then let ventrifixation be performed. It then became an operation of necessity. Drs. GRIFFITH, BRIGGS, and GILES briefly replied.

PATHOLOGICAL SECTION.

At a meeting on March 18th, Dr. R. T. HEWLETT, President, in the chair, Dr. H. H. DALE read a paper on *Anaphylactic reaction in the guinea-pig and its modification by strong salt solution*. In the investigation the reaction of the rabbit's uterus was utilized, the part being kept in a water bath whilst its contractions were graphically recorded. Dr. H. R. DEAN recounted an *Attempt to preserve haemolytic complement in a permanent form*. It was only partially successful. One method already devised was to absorb it with filter paper and dry; another to salt the serum and keep it cold. The author's method was to cool fresh guinea-pig serum to 0° C., and add cooled absolute alcohol. The flocculent precipitate resulting was then dried; it was soluble in water or salt solution. The solution had but a slight haemolytic action on sensitized blood. It was the mid-piece of the complement factor only that was so obtained. It was not of use for haemolytic observation. Dr. J. A. BRAXTON HICKS described an *Unusual organism from a case of septicaemia* which he had isolated from the blood during life: it was a bacillus of the *proteus* group. The patient was suffering from septicaemia following the removal of a pelvic cyst. It was virulent to the guinea-pig. Mr. S. G. SHARROCK exhibited a histological lesion which he named *Pseudotuberculosis hyalina*.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

At an ordinary meeting of the society, held on March 7th, Dr. G. P. SHUTER, President, in the chair, Mr. OSWALD L. ADDISON read a paper on *Syphilitic disease of bones and joints in children*. It seemed possible, and even probable, that many cases of syphilitic disease in children were acquired and not congenital. A confirmatory history of the disease in the parents could not be obtained in many cases, and the classical signs of congenital syphilis were conspicuous by their absence. This teaching of typical signs accounted for false diagnoses of a large number of cases, but within the last few years diagnosis, where there was suspicion, could be settled by a Wassermann reaction. The condition termed "syphilitic epiphysitis" appeared at first sight most marked about the joints, but in reality was most advanced at the ends of the diaphysis. It occurred at any time from birth up to the end of the first year—most frequently in the third month—and was seldom strictly monoarticular. It was nearly always present in a syphilitic stillborn fetus, and, when observed in a living infant at birth, commonly affected all the long bones. In an older child it appeared at first in one joint only—most often the shoulder—but on careful examination more if not all the bones of the same or both arms were found affected. The lower limbs were much less frequently involved. A mother frequently stated that her baby was quite well until a few days previously, when it screamed on being washed or when the arm was moved. It was often quite healthy in appearance, except that one arm was limp and motionless—pseudo-paralysis. A further examination revealed some tenderness and slight swelling about the shoulder-joint, and not infrequently in a less marked degree about the arm, elbow, and forearm. Rapid recovery took place under suitable treatment—namely, complete rest of the affected limb for about a fortnight and with mercurial inunctions. The usual syphilitic bone affections seen in these children after the age of infancy were periostitis and osteomyelitis. The former led to the formation of nodes on the skull or long bones, and, if extensive, to a general thickening. Periostitis was uncommon under 4 or 5 years of age, but might occur up to 25, or even later. Although the

subcutaneous bones, especially the tibiae, appeared to be affected most commonly, it seemed probable that this distribution was more apparent than real, for unsuspected nodes on the other long bones were frequently detected on x-ray examination. Tenderness and pain became severe in the later stages only. In the diffuse form affecting the tibia an apparent bending of the bone was produced from a deposit of new bone along the anterior border and on the subcutaneous surface. The diagnosis from new growth was not, as a rule, difficult, but from other chronic inflammations a correct diagnosis might be clinically impossible until a bacteriological culture or a Wassermann reaction had been obtained. Inunction and the administration of potassium iodide were necessary, but with great thickening and severe pain operative procedures gave the best relief. Osteomyelitis affected chiefly the long bones, and again the changes were most marked at the ends of the diaphysis. It was uncommon before the age of 9 or 10, and was often singularly painless, medical advice being sought on account of chronic sinuses or abscesses about the limb. As the most advanced disease was immediately beneath the epiphysal cartilage, interference with the growth of the bone was usual; sometimes overgrowth, but more often shortening resulted. Treatment by drugs was efficacious in the early stages, though where sinuses were present, vigorous operative treatment was necessary. Healing of the wounds was very slow on account of the secondary infection always present. The only two forms of syphilitic joint disease at all frequent in children were symmetrical serous synovitis (Clutton's joints) and gummatous synovitis. The former was not in his experience so common in children as the gummatous type, which was so often taken to be tuberculous. Gummatous synovitis, usually monoarticular, sometimes multiple, mostly attacked one of the larger joints. The synovial membrane and peri-articular tissues were swollen in a varying degree, there was no effusion into the joint, and muscular spasm and wasting were marked. In fact, all the signs associated with tuberculous disease were present. The x-ray appearances might be useful, but were not diagnostic. A rarefaction of the epiphysis was generally seen, and a superficial layer of new bone was often present at the end or ends of the adjacent diaphysis, while the focus of absorption frequently present in tuberculous disease was absent. This condition was not common under the age of 4, and, in the absence of the other signs of syphilis, a certain diagnosis could only be made by the Wassermann reaction. In the unusual event of several joints being affected, the diagnosis from rheumatoid arthritis had to be kept in mind. Under treatment perfect recovery of function was the rule, though overgrowth of the bones was not unusual. Symmetrical serous synovitis was commonly seen in the knee-joints. There was considerable effusion, with a varying amount of synovial thickening. The condition was always much more obvious in one joint than the other, and the symptoms were slight. X-rays showed nothing characteristic, and the diagnosis was, as a rule, clear. Treatment was the same in both types of arthritis—namely, a splint, Scott's dressing, inunction, and iodide. Absorption of fluid and recovery of the synovial membrane were often slow, and relapses were apt to occur, but ultimately a normal joint was obtained. Dr. SYDNEY A. OWEN, in discussing Mr. Addison's paper, urged the employment of the Wassermann test, and pointed out that treatment with mercury was of less avail in converting a positive into a negative reaction in congenital syphilis than in the acquired disease. In infants under 1 year of age an atypical case of infantile scurvy might cause confusion, but the condition usually occurred at a later date than the so-called epiphysitis of congenital syphilis. In children over 1 year the hyperaesthesia, subjective pains, and pseudoparesis of rickets had to be kept in mind. Acute poliomyelitis, prior to the onset of definite palsy and loss of deep reflexes, might cause doubt for a short time. In considering acute rheumatism in childhood, commencing with the involvement of a single large joint, the diagnosis might be difficult in the absence of co-existing endocarditis, nodules, etc. Gonorrhoeal arthritis in infants, with co-existing ophthalmia, did not present difficulties. Dr. Owen also referred to Still's disease, haemophilia, erythema nodosum, and a case he had seen of Charcot's joint in a patient aged 16 years. In

some cases of acute leucæmia tender oedematous swellings at the lower ends of the long bones, especially the tibiae, occurred. Mr. McADAM ECCLES remarked that a syphilitic joint in child life was present more frequently than was generally suspected, hence errors in diagnosis and faulty treatment. As the joint lesion might be the only manifestation of syphilis the true origin of the synovitis was easily overlooked. A skiagram always revealed some diaphysial mischief, and this mischief was usually primary, the joint lesion being subsequent. Dr. HUGH THURSFIELD found that epiphysitis of syphilitic origin was rare in babies over 3 months of age, and usually accompanied by enlargement of the spleen. Laryngitis was another, not rare, complication, sometimes sufficiently marked to render the baby aphonic. This combination of laryngitis and epiphysitis seemed pathognomonic. Clutton's serous synovitis was a distinct and fairly common lesion accompanying interstitial keratitis after the age of the second dentition. Another manifestation in congenital syphilis was enlargement of the lymphatic glands. Mr. DENEXAN C. L. FITZWILLIAMS insisted that the cause of the disease was a spirochæte, always acquired, either before birth, at birth, shortly after birth, or in later life. In the mature subject the disease passed through certain stages known as secondary and tertiary, while in the immature state the two stages were inextricably mixed. The incidence of epiphysitis was not so rigidly limited as Dr. Thursfield appeared to believe. Infantile senry Mr. Fitzwilliams had never seen under the age of 6 months. Craniotabes and Parrot's nodes were sometimes well marked in children who did not suffer from syphilis. Syphilitic diseases of bone were rarely found associated with the textbook signs of congenital syphilis, and if only one bone happened to be affected and the condition advanced, it might be difficult to exclude sarcoma without the aid of the Wassermann test. Gummatus changes in bones were by far the commonest cause of spontaneous fracture in children. Many "bone cysts" were really areas of gummatus destruction. Of the joint conditions, the joints full of fluid were the most striking, and being so characteristic were easily diagnosed. They were painless, and gave rise to no symptoms, hence their frequency was difficult to gauge with certainty. In the gummatus joint the synovial membrane was very thickened, as in tubercle, from which it was most difficult to distinguish it before the Wassermann reaction was introduced, but the presence of fluid in the early stages was diagnostic of syphilis. These joints were among the most resistant to treatment of all syphilitic manifestations. Mercury in these cases was more satisfactory than salvarsan. The Wassermann reaction should be regarded much in the same light as Widal's in typhoid, for it was an indication that the system had been infected previously, and apart from symptoms it was no evidence of active disease. Mr. N. BISHOP HARMAN contributed some interesting statistics he had worked out on a large number of children between the ages of 5 and 16 years of age, who were more or less blind, owing to the inheriting of syphilis. The majority showed typical symptoms. Bone disease and joint affections of some kind or other were very frequent amongst them. In several the bone lesions appeared while the children were undergoing vigorous antisyphilitic treatment for relapsing eye symptoms. Mr. RICHARD W. LLOYD, referring to Dr. Thursfield's remarks on the association of synovitis with interstitial keratitis, said he had observed it often enough in connexion with the knee-joints to cause him to seek for it whenever a case of interstitial keratitis came under his notice. The synovitis was not so painful as in ordinary cases of that disease, and as it existed only during part of the course of the keratitis Mr. Bishop Harman's important statistics minimized the frequency of the association of these two symptoms. He had also observed the association of synovitis and corneal inflammation in the course of gonorrhæal rheumatism sometimes. Mr. MAYNARD HEALTH drew attention to the fact that in cases of syphilis where one of two parallel bones were obviously affected, an x-ray photograph generally showed some affection of the neighbouring bone, and he regarded this as strong evidence in favour of syphilis in doubtful cases. In conclusion, Mr. ADDISON replied to the various questions raised during the discussion.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF OBSTETRICS.

At a meeting on March 7th the Chairman, Dr. H. J. J. J. J., exhibited specimens from two cases of *Genital tuberculosis*, one of them showing tuberculosis of the tubes associated with carcinoma of the ovaries. In connexion with these cases he invited opinion as to whether tuberculous disease of the tubes was commonly accompanied by tuberculous disease of the uterus and whether such cases got well after removal of the tubes. Some authors stated that this was usual, but he had never found tuberculous disease of the uterus that did not eventually lead to serious complications. Dr. TWEEDY said that, whether the uterus was or was not involved, he had known patients to get well after resection of the tubes. He instanced the case of a lady of good position who, after being six weeks married, was found to be suffering from very extensive tuberculous disease of the tubes, and to be exuding a thick, caseous material from the cervix, but whether the substance came from the tubes or the uterus he did not know. He removed the diseased tubes, and left the uterus and a small portion of the ovary, and for the last four years she had been in perfect health, and in no way suffered from tuberculous disease. Tuberculous disease of the tubes was frequently seen, but disease of the uterus was rarely met with. Dr. SHEILL said that he had seen a pretty considerable number of cases of disease of the tubes of tuberculous origin, but he had seen but one case of definite tuberculous disease of the uterus. Dr. J. J. J. in reply, thought that Dr. Tweedy's case did not throw any further light on the point raised, as it was not definitely known whether there was tuberculosis of the uterus in the case or not. He suggested, with a view to throwing further light on this important subject, that all operators should examine scrapings from the uterus in all cases of tuberculous salpinx. Dr. SHEILL having recorded two cases of *Uterine rupture*, Dr. GIBBON FITZGIBBON read a paper on six cases of *Gonorrhæal vaginitis treated by vaccine*, five with good results. The sixth appeared cured, but relapsed or else had been reinfectcd. He considered that vaccines, to be effective, should be made from cultures grown fresh from the human host, but that they need not be autogenous. Local treatment, in combination with vaccine, was advisable, and probably necessary, certainly in the chronic cases with mixed infection. Dr. SHEILL said he considered the paper of extreme importance from the point of view of treatment of gonorrhæal infection in young children, as in such cases they were confronted with many difficulties in local treatment, and therefore if there was another means of treatment it should be pushed. He did not think local treatment should be done away with, but he considered vaccines a very useful adjunct. Dr. TWEEDY considered Dr. FitzGibbon fortunate in having seen so much gonorrhæal vaginitis. He had always found it very hard to be sure of the infection. Dr. MABILL said he had seen a good deal of gonorrhæal infection at the extern department of the Rotunda Hospital, and he had tried many varieties of local treatment. He thought the best results were produced by protargol. He was struck with the chronicity and difficulty of diagnosis in these cases. He pointed out that Professor Bumm had described five kidney shaped intracellular diplococci, one of which was Gram positive and the other four negative to this stain, and the only difference he knew between these was by culture. He thought gonococcus was very difficult to grow. He went on to describe the methods adopted at Worthen's clinic for making this vaccine, and said that the dosage given was rather smaller than that indicated by Dr. FitzGibbon, the dose being 5 million of a mixed vaccine every forty-eight hours, followed by autogenous gonorrhæal vaccine. In most cases good results were obtained, and in cases where the results did not materialize they were controlled by estimation of the opsonic index. No case was considered cured until the microscope failed to find anything of the nature of gonococcus in the secretions. Dr. ROWLETT said that in the present state of our knowledge of vaccines it was of importance that full details should be given in all cases reported, and he therefore considered that Dr. FitzGibbon's paper was of great assistance as a guide to treatment. There was great difficulty in treating cases of gonorrhœa in the

female owing to the ease with which the infection became mixed. He did not think that the gonococcus disappeared for a considerable time, but it became crowded out by other organisms, and was not easily found. In some cases of gonorrhoea in the male that came under his notice it was found necessary to treat with staphylococcus after treating with gonococcus vaccine. A point of importance was that the vaccine should be made from a fresh culture. This he considered of more importance than that the vaccine itself should be fresh, although vaccine kept for a long time did lose in efficacy. He believed that the slide shown by Dr. FitzGibbon was undoubtedly one of gonococcal infection. Dr. O'KELLY said that in some cases it was very questionable whether the infection was really gonococcal. He never succeeded in getting gonococci to grow. Dr. HENRY MOORE said that in the cases in which vaccine was most useful—namely, at the very beginning of an attack, or in old-standing cases of gleet—an autogenous vaccine was impossible. His method of obtaining serum was to get a vaccine once a month from a male case on the second day of the urethritis. It is doubtful as to the cause of an old-standing discharge or the cure of a patient who has suffered from gonorrhoea, he gave from 15 million to 30 million, and examined the resulting discharge, if any, twenty-four hours after. In old-standing cases of posterior urethritis no local treatment was effective without vaccine, and the serum should not be more than four weeks old.

LIVERPOOL MEDICAL INSTITUTION.

At a meeting on March 13th, Mr. ROBERT JONES, President, in the chair, Professor ERNEST GLYNN, Dr. LISSAET COX, and Miss POWELL, in a paper on *Methods of standardizing vaccines*, summed up their conclusions as follows: (1) Wright's method frequently underestimates the strength of bacterial vaccines by 100 per cent. or more. This is undoubtedly mainly due to the unequal distribution of the bacteria and red blood corpuscles in different parts of the smear. (2) The plate culture method is cumbersome and underestimates the strength of bacterial emulsion by 100 per cent. or more when prepared from cultures twenty-four hours old, as many of the bacteria are dead; and also because it is impossible to obtain an absolutely homogeneous emulsion with every bacterium separated from its fellow. (3) The haemocytometer chamber method, using an oil-immersion lens and some weak stain, is the most satisfactory; and is more accurate than either Wright's or the plate culture method. (4) The ordinary coverslip used in microscopical preparations is inadmissible for the ordinary haemocytometer chamber, which is 0.1 mm. deep, as it is neither rigid nor optically plane. A reinforced coverslip, however, 0.13 mm. thick, would be both rigid and optically plane and suitable for all ordinary achromatic oil-immersion lenses when employed with chambers 0.1 mm. deep. (5) A counting chamber 0.04 or 0.02 mm. deep, however, is superior to the one usually employed, for three reasons: (a) The greater ease with which the bacteria adhering to the under surface of the coverslip may be counted; (b) the rapidity with which the bacteria settle; (c) the improved definition of the bacteria. (6) Weak carbol thionin is the cleanest and most satisfactory staining solution. The authors added that they were unable at present to express any opinion with regard to the value of the gravimetric method. Dr. BLAIR BELL gave a lantern demonstration of colour photomicrographs illustrating experimental work in which he had been engaged in connexion with the genital functions of the ductless glands. The specimens shown by various members included one of cirrhosis of the liver in a cart-horse, by Professor GLYNN.

BRISTOL MEDICO-CHIRURGICAL SOCIETY.

At a meeting on March 14th, Dr. WALTER SWAYNE, President, in the chair, Dr. CAREY COOMBS, in a paper on *Adventitious pericardiac sounds*, pointed out the frequent occurrence in cases of cardiac valvular lesions of pulmonary crepitations over the third left interspace in front, particularly in cases of mitral stenosis. They were probably due to collapse of the lung margin, owing to pressure of the enlarged conus arteriosus, together with hyperaemia, and were of interest in that they not uncommonly led to a mistaken diagnosis of

pulmonary tuberculosis. The stationary condition of the signs, together with the absence of tubercle bacilli in the sputum, were sufficient to negative the presence of tuberculosis. Dr. MICHELL CLARKE remarked that the limitation of these expirations to the first deep inspiration during auscultation pointed to their being due to a condition of atelectasis. Dr. J. R. CHARLES said that, in an examination of some thousands of *post mortem* records, he had found the coexistence of pulmonary tuberculosis and mitral stenosis to be a rare occurrence. Dr. CHARLES also, in a paper on the *Etiology of migraine*, propounded the theory that the symptoms of migraine were due to a transient swelling of the pituitary gland. Such swelling was known during pregnancy, and from the anatomical position of the gland it was conceivable that if swollen it might show effects on the optic nerves and those in the walls of the cavernous sinus. The vasomotor effects might be explained by an increased secretion from the posterior lobe. Mr. ELWIN HARRIS did not think that the theory could explain in his own case the occurrence of hemianopsia half an hour before the headache. Dr. CAREY COOMBS did not see how the association of migraine and epilepsy could be explained by this theory. The following were among the exhibits:—Dr. WATSON-WILLIAMS: (1) A specimen from a case of *Cerebro-spinal rhinorrhoea*, in which there was an opening found in the dura and bone of the anterior fossa *post mortem*, death occurring from meningitis from a complicating frontal sinusitis. During life the cerebro-spinal fluid had caused a fluctuating swelling at the inner orbital margin, thus simulating an ethmoidal mucocele. (2) A case in which an extensive *Epithelioma of the larynx* had been removed a year previously. There had been no recurrence, but there was some stridor from cicatricial contraction. Mr. HUBERT CURRY: An infant aged six weeks, with *Congenital absence of the ulna*, of two digits and their metacarpals on the left side, while on the right one digit and its metacarpal were absent.

NORTH OF ENGLAND OBSTETRICAL AND GYNAECOLOGICAL SOCIETY.

At a meeting in Sheffield on March 14th, Dr. FOTHERGILL (Manchester), President, in the chair, Dr. CATHERINE CHISHOLM (Manchester), in a paper on a comparison of *Menstrual disturbances in adolescence and adult life*, showed that more of the latter suffered discomfort during menstruation. Constipation, sedentary employment, lack of exercise, overwork, and great mental strain appeared to produce menstrual discomfort. In very few instances did the menstrual discomfort interfere with the working capacity. The appearance of pain indicated a pathological condition which ought to be investigated and treated as soon as it developed. Dr. ARNOLD W. W. LEA (Manchester) described three cases of *Kyphotic pelvis* which he had treated by Caesarean section. Skiagrams of the three pelvis were shown. All had very narrow outlets, 2 in. to 2½ in. All the patients and children recovered. A pelvimeter for measuring the outlet of the pelvis was also shown and described. The following were among the exhibits: Dr. HELLER (Leeds): (1) Two specimens of *Ruptured ectopic gestation*, one of them of the interstitial variety; (2) a specimen from a case of septic miscarriage infected by *B. aerogenes capsulatus*. Dr. BARBER (Sheffield): A case of *Torsion of the pedicle of a subperitoneal myoma*. Dr. ARNOLD W. W. LEA (Manchester) reported (1) a case of Caesarean section for *Concealed accidental haemorrhage*; the uterus was not removed and the patient made a good recovery. (2) A case of *Pan-hysterectomy for interligamentous myoma*. Mr. CURRY (Sheffield) reported a case of *Severe metrorrhagia* in a young woman. Mr. MILLS H. PHILLIPS (Sheffield) showed a case of *Ruptured uterus* treated by vaginal hysterectomy. The vaginal route and clamps were used, as the uterus was infected and the patient collapsed. The patient made a good recovery and had no further rise of temperature.

ON March 5th a bill was submitted to the General Assembly of the State of New York providing that all artificial or patented infant foods shall be approved by the State Health Commissioner. It is further required that every certificate of death of an infant under 1 year of age shall be supplemented by a statement signed by the attending doctor as to the method of feeding employed.

Reviews.

FOOD AND DIETS.

THIS is a revolutionary age in which use and wont have lost their authority, long-standing custom and the experience of countless generations are set at naught, and the most extravagant doctrine gets an attentive hearing if it adopt the livery of the "new age" and professes to instruct the modern generation how to suck eggs in a better fashion than that known to its grandmothers. In his work, *Modern Theories of Diet*,¹ Dr. ALEXANDER BRYCE reviews these doctrines critically with good sense and in the light of recent science, writing in a style so plain and vigorous as to make the book not only a valuable source of information to medical practitioners, but useful, instructive, and intelligible to the public too apt to accept the guidance of lay persons whose qualifications for such a task exist solely in their own conceit. The author has been so wise as to seek and so fortunate as to obtain the assistance of experts in the presentment of the difficult and ever-changing theories of metabolism, this portion of the book having been revised by Dr. Fraser Harris, Professor of Physiology in the University of Halifax, Nova Scotia, while Dr. E. P. Cathcart, Lecturer on Physiological Chemistry in the University of Glasgow, has looked over the whole manuscript, so that in these important respects the accuracy and soundness of the book is sufficiently guaranteed. Dr. Bryce has been for many years a student of dietetics and has personally investigated the dietetic theories of America, the birthplace of most of the heterodoxies which form his subject matter, so that he has a special claim to be heard. His first two chapters discuss theories of metabolism so clearly as to enable the educated reader to appreciate the subsequent argument. Chapters III and IV deal with vegetarianism and the low protein diet. In spite of his respect for Professor Chittenden, to whom he dedicates the book, and his acceptance of the conclusion that the Voit standard is unduly high, he uses Major McCay's observations to emphasize the dietetic importance of animal protein, and the danger to the race as well as to the individual of allowing sentimental or other arguments to prevail against experience. His conclusion here, as throughout the book, is in favour of moderation. While admitting individual differences, he leans on the whole to the opinion that in England and America a reduction in the quantity of flesh food tends towards better health and greater efficiency. He is, however, unsparing in his exposure of the fallacies and inconsistencies of the current vegetarian and lacto-vegetarian arguments, and disposes most effectively of the claim that flesh eaters are more prone to disease or possess diminished power of resistance to morbid influences than those who abstain. He states from personal observation of the vegetarians of Battle Creek that they are in nowise less prone to "colds" than are flesh eaters, but he expresses surprise that Americans, with their habit of three meat meals a day, can adapt themselves so easily to a vegetarian regimen. While recognizing the practical value of Haig's teaching, he rejects his theory. Hare's and Salisbury's diets are classed as partial starving cures, and the value of these under adequate medical supervision is allowed. He shows the same discrimination in considering the claims of "Fletcherism," while very properly emphasizing the extreme importance of mastication as the starting point of good digestion. A whole chapter is devoted to the "Fasting Cure," and its dangerous side is plainly exposed. The last chapter is written to expand and impress upon his readers the principle of moderation in dietetics as containing the whole root of the matter. Those who are engaged in family practice frequently encounter faddists primed with arguments derived from pamphlets or periodicals published for the purpose of propagating peculiar doctrines, and Dr. Bryce's book forms an arsenal from which suitable and overwhelming answers may be drawn. His attentive readers will acquire the knowledge upon which to found themselves; they will learn what

should be admitted as true and what denounced as false in doctrine or dangerous in practice. While the healthy may err by eating too much, many of the ailing go further wrong in the opposite direction by eating too little.

We noticed Part I of Dr. CRAIK TAYLOR'S *Diet Charts*² a few months ago (see *JOURNAL*, December 28th, 1912, p. 1751), pointing out the absence of any adequate space for indicating quantity and the excessive recommendation of proprietary articles. This second part is open to the same criticism—for example, six kinds of patent bread are named, but ordinary bread is omitted; while other things are suggested that are unfamiliar, and in some instances are given undue prominence. The principles on which the author constructs his tables is not quite easy to understand. In the dietary for acute nephritis he says "that it is not good practice, nor is it suitable, to feed your patient on milk alone." We would not quarrel with this statement if the author meant to prefer milk diluted with barley water or soda water, or to give arrowroot or bread and milk, and the like, but he goes on to say: "Add cream, plasmon or sanotogen, one of the proprietary 'milk foods' or 'malted milk,'" thus introducing needlessly expensive specialities into the diet. His direction for making imperial drink does not agree with the classical formula, which is half an ounce instead of a teaspoonful of cream of tartar to a pint of water. The dietary for subacute and chronic nephritis might aim at excluding purins, but tea, coffee, oat flour, or oatmeal, meat, and fish are allowed. Alcohol is suggested, cheese is forbidden, and potatoes and eggs are omitted altogether. The medical attendant is told to regulate the amount of meat by the output of albumen, although in advanced contracting kidney this may be a mere haze, and nothing is said about the output of urea. Under diabetes, von Noorden's practice with regard to his oatmeal diet is to be followed by "two days of carbohydrate-free food" instead of by two vegetarian days. Why is chutney, which is often very sweet, allowed, and Burgundy and sherry, which always contain a good deal of sugar? Why omit codfish? Why allow grapes, which are full of sugar? Why exclude potatoes when agreeing that carbohydrates may be allowed? Why not mention cream with tea and coffee, as milk is omitted? And why exclude cheese? Why not point out that it is absolutely essential to fix the quantities? Finally, under the diet of school children, why recommend "sweet potatoes," which are not often seen in this country? We have said enough to show that in our opinion these tables require a good deal of revision before they can fulfil their purpose of guiding practitioners in the construction of dietaries.

Dr. W. STERNBERG'S book, *Diät und Küche*,³ is a strange medley of ancient Grecian philosophy and metaphysics with the physiology of taste and cooking. The author disbelieves in the modern physiological researches which have demonstrated the worth of foodstuffs in terms of energy. He will have nothing to do with computations of diets in calories. Taste and mental effects of foods are for him the only side of the subject worth considering. It is true that the most recent researches have demonstrated that it does not suffice to measure a diet singly in caloric value and in the proportionate worth of carbohydrate, fat, protein, and salt. There must be considered in addition the vitamins, the subtle substances which exist in fresh food, outer layers of wheat and rice berries, milk, etc., destroyed by modern methods of milling and by the high sterilization temperatures often used in canning. Dr. Sternberg, however, does not deal with them—for him the psychic effect derived from good cooking is the factor of supreme importance. Flavour promotes digestion and appetite, but in modern civilized states it also often promotes over-eating and consequent ill health. But bad cooking also causes ill health and is moreover wasteful. So that the only wise course must be to make the psychic effort necessary to practise moderation.

¹ *Modern Theories of Diet and their Bearing upon Practical Dietetics*. By Alexander Bryce, M.D., D.P.H.Camb. London: Edward Arnold. 1912. (Demy 8vo, pp. 383. 7s. 6d. net.)

Dr. DONALD STEWART has written a little book in simple language concerning *The Essentials of Food*.¹ He intends it to be "a correct summary of present-day knowledge about food." He neither writes as a first-hand expert nor as one who has deeply read in his subject, but draws largely on the writings of the late Dr. Pavy and on Dr. Robert Hutchison's well-known book on food and dietetics. From the latter he has borrowed many tables representing the percentage composition of the foodstuffs. In the attempt which the author makes to deal with the chemical nature of foods he is not particularly happy. "An element in chemistry," he says, "is the first principle beyond which or lower than which it is not possible to go." "In recent years the elements arsen (sic) and radium were discovered." "Fat is made up of carbon, hydrogen, and oxygen, and written thus in chemistry: C₁₈H₃₆O₂." In regard to the composition of water, H₂O, "the figure 2 under the H means not two atoms of the hydrogen, but two elements have to be taken with one of oxygen to form water." On page 25, he says, "gelatine contains about 84 per cent. of albumen." He frequently uses the word "salines" in place of "salts" in dealing with the composition of foods. He speaks of the production in the intestine "of the evil-smelling gases, skatole, indole, and phenol" (sic). We are told that proteid signifies "the highest value as a food; perhaps albumen comes next to proteid in value." He gives an antiquated classification of the nitrogenous substances in foodstuffs—"fibrine in the albumen in cereal seeds," etc.—and he says that protein is chemically regarded as the base and chief of them all. "Protein contains the elements C₁₂H₁₀N₂O₂ and sulphur, but not phosphorus." Dr. Stewart seems unaware of the fact that "protein" is the term now used in place of "proteid." On page 138 he writes: "Our object ought to be to apply such heat that the starch of the cereals shall be turned into gelatine." Again the reader would be led to understand from the text that the 118 grams of protein of the Voit diet is contained in about 118 grams or 4 oz. of meat, in place of five times that amount. Apart from these errors, the little book is written in such a way as to inculcate the valuable doctrine of moderation in eating, plain living, and simple life—a doctrine much wanted nowadays when a large part of the wealthier people daily over-eat, while the very poor are badly nourished. The author cites from Dr. Pavy's writings the miller of Billericay, who in the eighteenth century lived for sixteen years on 16 oz. of flour per diem, made into a pudding with water, no other food or liquid being taken. This diet contained half of the protein, one-sixth of the fat, and two-thirds of the carbohydrate in Voit's diet. The miller could not have lived on white flour, for this lacks the essential active principles found in the germ and outer layers of the wheat-berry. Dr. Stewart does not mention these subtle active bodies, and implies that protein, carbohydrate, fat, and salts include everything necessary in a diet. The causation of beri-beri by a diet of polished rice, and its cure by extract of rice polishings, show that there is far more to be considered in food than he dreams of. The author supports Clittenden's conclusions, and wisely urges moderation in animal food, especially after youth is past. The most interesting tables in the book are those in which he contrasts the diets of the inmates and the attendants at the Aylesbury Union, Borough Asylum (Derby), and Bucks Asylum (Stone). At the Aylesbury Union the ordinary diet of the inmate is: Bread 18 oz., meat 4½ oz., vegetables 12 oz., milk 20 oz., gruel 1 pint, oatmeal 1½ oz., with a calculated value of protein 98 grams, fat 38 grams, carbohydrates 364 grams; while that of the attendant is: Bread 16 oz., flour 2½ oz., meat 16 oz., potatoes 16 oz., tea ½ oz., butter 1½ oz., sugar 2½ oz., cheese 1½ oz., beer 2 pints, giving protein 168 grams, fat 146 grams, and carbohydrates 536 grams. We have not the least doubt that the former diet would keep the attendants in better health than the latter if it is really eaten—and that 16 oz. of meat as well as 1½ oz. of cheese is a most unnecessary and extravagant allowance. We believe that it would be found at all public institutions the attendants are over-fed. An allowance of beer nowadays is quite unnecessary. We know of the case of a most capable cook who lost her situation at an important

institution from drunkenness. Her two kitchenmaids did not take their allowance of beer, and she had the six pints a day.

A SYSTEM OF SURGERY.

Mr. C. C. CHOYCE promises a *System of Surgery*² in three volumes of moderate dimensions, and, if we may take the first and second volumes as an earnest of the whole, we have reason to congratulate ourselves that British teachers and writers are behind no other nation in the production of high-grade finished work. The contributors are carefully selected for well-tried qualities in teaching and in practice. The list contains the names of many of the younger generation of surgeons, metropolitan and provincial, who have established both local and general reputations.

Volume I is devoted chiefly to the consideration of general surgery and surgical pathology. The latter subject, in which Professor J. M. Beattie has collaborated as pathological editor with Mr. Choyce, is presented in the most thorough business-like manner, with no dreary over-elaboration of detail and no uncalculated speculative wandering. Every subject is dealt with by authors "whose special knowledge and experience entitle them to write with authority." For example, the four articles on syphilis and venereal diseases are from the pens of Colonel Lambkin, Major Gibbard and Major Lawrence Harrison, Mr. J. E. R. McDonagh, and Mr. C. A. Leedham-Green; general anaesthesia is by Dr. J. Blumfeld; hydrophobia, by Professor Calmette, of the Pasteur Institute, Lille.

We make no attempt to differentiate in merit here all is of the best, but the article on tumours, by Mr. Raymond Johnson and Mr. T. W. P. Lawrence, is among the most satisfying work in this department of surgery we have met with. The authors have preserved the only classification—the clinical—which appeals alike to surgeons and patients. Amongst benign tumours they have unhesitatingly placed myeloma or so-called giant-celled sarcoma. There can be now little doubt that these tumours do not conform to most of our ideas of malignancy, in particular in the absence of metastasis. Giant cells may be found in sarcomatous tumours of bone, and these are malignant enough, but the comparatively common medullary giant-celled sarcoma is properly removed from amongst the sarcomata. In their description we should have liked a little more discussion on the relation to osteitis fibrosa and "aneurysm" in bone, and also as to the possibility of the whole three being different stages of one pathological process, as suggested by Bloodgood.

The paper on x-ray examination is by Dr. W. Ironside Bruce. The series of skiagraphs reproduced is exceedingly neat and compact. A few representative pictures of the bismuth meal in the intestinal tract might usefully have been added. Dr. Bruce reminds his readers that x-ray examination must not displace the older and well-tried clinical methods of investigation, but must be regarded as supplementary.

In the paper on "Constitutional Disturbances associated with Trauma," Mr. Russell Howard makes no attempt to define shock, and for practical purposes will not distinguish shock and collapse. His paper is a study of the causes of shock and its clinical phenomena. It is a well-informed article, and follows closely the experimental work of Crile and other very recent writers.

The second volume of the *System* deals with regional surgery, and here again we find that the contributors are mostly all well-known surgeons who have high reputations as teachers in their own schools. It is a decided advantage that the authors should be widely distributed geographically, and the specimens lavishly and beautifully illustrated in the text are selected from so many museums. The breast and its surgery is in the able charge of Mr. Sampson Handley. Readers have, therefore, at first hand the theory of spread of cancer by permeation fully and lucidly stated. It is of interest to note how the permeation

¹ *The Essentials of Food*. By Donald Stewart, M.D. London: Bale, Sons, and Danielsson. (Cr. 8vo, pp. 190. 3s. 6d. net.)

² *A System of Surgery*. Edited by C. C. Choyce, B.Sc., M.D., F.R.C.S., Dean of and Teacher of Operative Surgery in the London School of Clinical Medicine; Assistant Surgeon to the Seamen's Hospital, Greenwich. Pathological Editor, J. Martin Beattie, M.A., M.D., C.M., Professor of Pathology and Bacteriology in the University of Sheffield. In three volumes. Volume I, *Surgical Pathology, Tumours, General Surgery*. Volume II, *Surgery of Regions*. London and New York: Cassell and Company, Limited, 1912. (Med. 8vo, vol. i, pp. 979, plates 84, figs. 250; vol. ii, pp. 1105, plates 20, figs. 375. 21s. net each volume.)

theory may explain much that has not been understood. For example, Paget's disease is to be regarded as an eczema following blocking and fibrosis of lymph vessels of the skin and areola, and is comparable to the sodden eczematous skin in varicose eczema and to the eczema of elephantiasis.

Mr. A. Miles writes the chapter on the intestine, hernia is by Mr. Lawrie McGavin. "The Upper and Lower Urinary Tract" by Mr. J. W. Thomson Walker, and "The Female Genital Tract" by Mr. Victor Bonney. In Mr. Cyril A. R. Nitch's paper on "Malformations of the Face, Lips, and Palate" too much space has perhaps been allotted to description of the Brophy and Lane operations for cleft palate, and correspondingly too little to the Langenbeck operation. This is the more noticeable that the writer's opinion is that the Langenbeck operation performed between two and three years gives the best result in the majority of cases. A thorough and minutely detailed description of the operation, noting all the little things which make for success, would have rounded off very nicely an otherwise good article. The admirable work of Mr. James Berry on this subject is not referred to.

The general appearance of these volumes is substantial but not heavy. Reading is greatly assisted by free use of bold type to indicate new paragraphs and subjects. The pictures are of uniform excellence; they are mostly original—the coloured plates in both volumes are worthy of special praise. We have found only two typographic errors, and these are in the illustrations: in Fig. 2 of plate opposite page 638, vol. i, "tarsus" should be "carpus," and on page 334, vol. i, the picture is inverted.

One sometimes feels that too many surgical books are being published, but there is room for an "All British" System of Surgery. Mr. Choyce's work will soon make a place for itself, not on patriotic grounds only, but because of its real merit.

DISEASES OF THE MENINGES.

THE French have always devoted much study to diseases of the meninges, particularly since Quincke's application of lumbar puncture in 1890 placed at their disposal a fluid well adapted for cytological examination. The latest discoveries and views are summarized in a recent volume⁶ of Gilbert and Thoinot's new edition of Bronardel and Gilbert's well-known *Traité de médecine et de thérapeutique*. Acute meningitis, by Hutinel and Voisin, covers the first 273 pages, or more than two-thirds of the whole. It begins with a general account of the condition; then follow chapters dealing with tuberculous meningitis, epidemic cerebro-spinal meningitis, acute suppurative meningitis, serous meningitis and meningism, the etiology of meningitis (some two and twenty different bacteria are enumerated as being capable of causing it), and a general discussion of its diagnosis. Chronic meningitis is described in fifty pages by Klippel, with meningeal hæmorrhage; and the last sections, by Claude and Lévy-Valensi, describe the disorders of the spinal meninges, including the rare syndrome of massive coagulation of the cerebro-spinal fluid first described in 1903 by Lépine. No mention of the meningitis seen in acute infantile paralysis seems to be made. The book is very readable, as French scientific works so generally are; it is fully up to date in its references to the French literature, and has a number of useful figures. A certain tendency to overstatement may be noted, as when, for example, we read that an inherited neuropathic tendency is the chief factor in predisposing children to die of tuberculous meningitis (p. 65), that the parents are often very intelligent and have used their brains to excess, that the children are often very wide awake, precocious, with large heads and highly developed cranial circulations but slender bodies, children whose intelligence has been too soon fatigued. Such paragraphs would come better from the pen of a speculative sentimentalist like Maeterlinck; they strike a false note in a scientific discussion of the etiology of tuberculous meningitis. No index is given and no list of figures; the book is well arranged, full of interesting facts and details, and should find a place in all medical libraries and on the bookshelves of neurologists.

⁶ *Maladies des méninges*. Par Hutinel, Klippel, H. Claude, R. Voisin, et Lévy-Valensi. Fasc. xxxv. Du nouveau traité de médecine et de thérapeutique, de Gilbert et Thoinot. Paris: J. B. Baillière et Fils, 1913. (Roy. 8vo, pp. 384; 49 figs. Price 8 fr. paper, 9 fr. 50 bound.)

NOTES ON BOOKS.

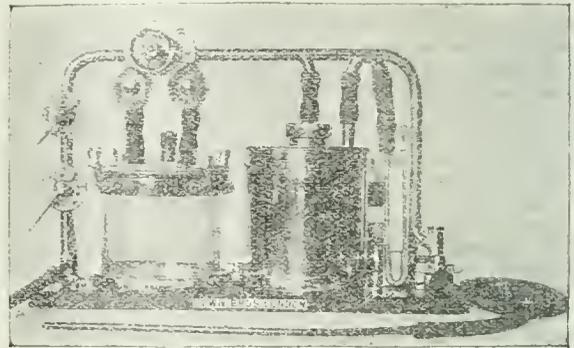

PROFESSOR PASTRE is the general editor of a series on *Questions biologiques actuelles*, published by A. Hermann et Fils, and the first volume which has come before our notice is one on the *Parathyroïdes*, by LEWIS MOREL.⁷ The author concludes that the experimental removal of these glands causes an auto-intoxication, the most usual but by no means inevitable result of which is tetany, that acidosis is a constant and fatal condition of parathyreo-priva, an acidosis characterized by excessive elimination of nitrogen, mineral salts, and organic acids, such as diacetic and lactic, an increase in the ammonia contents of the blood, and diminution in the power to use dextrose. The antitoxic functions of the liver are gravely disturbed by removal of the parathyroids. All this is rendered difficult of acceptance by the fact that removal of the parathyroids in some animals has no grave effect. We think the English reader will find the whole question treated in a clearer and more convincing manner by Professor Swale Vincent in his recent volume on the internal secretions.

⁷ *Les Parathyroïdes*. By Dr. Lewis Morel. Paris: A. Hermann et Fils, 1912. (Roy. 8vo, pp. 344. Fr. 10.)

MEDICAL AND SURGICAL APPLIANCES.

Portable Apparatus for the Intratracheal Administration of Ether.

DR. R. E. KELLY (Liverpool) writes: The principle of the intratracheal administration of ether is now well known. Warm, moist, and etherized air is supplied to the patient at the bifurcation of the trachea by means of a catheter passed through the glottis. The air is under pressure, and as the catheter is only half the size of the glottis, the excess of air escapes easily between the catheter and the glottis. It remains, however, under sufficient pressure to expand the lungs, and being constantly renewed suffices for respiration. Though primarily designed for the performance of surgical operations on the

A B C D E
Fig. 1.—Etherization apparatus.

thorax, the apparatus here illustrated possesses further advantages in general surgery.

1. By its means thoracic surgery is rendered possible without resorting to the cumbersome and costly positive and negative cabinets.
2. In mouth, nose, and throat operations there is no danger of the inspiration of blood, mucus, or pus.
3. In goitre operations air is supplied below the tracheal obstruction.
4. In head and neck operations the anaesthetist is well out of the way of the surgeon.
5. It renders easy, from the slight respiratory movements, many operations on the upper part of the abdomen; and
6. It is a most efficient artificial respiratory apparatus.

The apparatus consists of two parts. The first part is for the production of the current of air. Where the electric current is available, this current of air is produced by a rotary blower actuated by an electric motor. The motor is $\frac{1}{2}$ h.p., and is made to run for the particular voltage obtainable. The blower runs at from 50 to 1,000 revolutions a minute, the usual rate being about 500. Both are enclosed in a box measuring $16 \times 10\frac{1}{2} \times 10\frac{1}{2}$ in. Where the electric current is not available, its place is taken by a foot bellows which will give the pressure of air required, with very little effort.

The second part of the apparatus is that which etherizes, warms, and moistens this current of air. It consists of, first, the ether chamber A—a glass jar with a metal lid screwed airtight over a leather washer. The

lid has two openings, the entry dipping into the chamber for about an inch and the exit flush with the lid. By a simple arrangement of taps gearing into one another, the current of air may cutfully run over the surface of the other or miss the other altogether. When the taps are turned to any intermediate position, then a part only of the air is etherized. In this way a graduated dose of ether is obtained. This etherized air is now warmed by passing

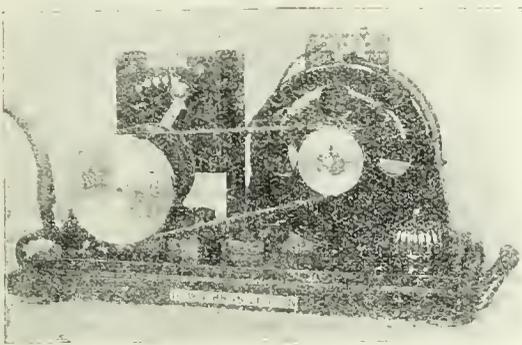

Fig. 2.

through a coil of piping immersed in hot water in the chamber B, after first passing over a moistened piece of gauze in a little container standing in it. Before the air reaches the manometer D, it has in its circuit a safety valve C. This merely consists of a bottle of mercury into which dips a glass tube in circuit. According to the depth to which the glass tube is immersed this safety valve will blow off at any pressure. Just before the air leaves the apparatus there is also inserted in its circuit a thermometer E. In the circuit are placed three taps. The first two are placed before the ether chamber. The first one is to reduce the pressure if it is too high, and the second is for the purpose of putting oxygen into the circuit should it be desired. Before the air passes to the patient there is a third tap which will reduce the pressure instantly to zero. This manœuvre is done every few seconds or so in order to allow the large veins in the thorax to fill. The whole of the second part of the apparatus consists of plated metal tubing with no constrictions, and with as few bends as possible: it is constructed on a board measuring 18 x 7 in. The apparatus is made by Messrs. Down Brothers, St. Thomas's Street, S.E.

Nova et Vetera.

THE WATER CURE OF HYDROPHOBIA.

For many centuries water applied externally and internally was regarded as a specific for hydrophobia. It is related that the poet Euripides, having been bitten by a mad dog, the Egyptian priests cured him by plunging him into the sea. The fear of water being a symptom of rabies, it was argued that the way to overcome this dread was the application of water or its introduction into the system. A surprise bath was recommended by Celsus, who says: "When the illness has reached this point (coming of the symptom hydrophobia) there is scarcely any hope. The only remedy that can be tried is suddenly to throw the patient when he does not expect it into a piscina, and let him go to the bottom if he cannot swim, so that he may drink. Then he should be taken out." Dr. Koshem, in an article on the subject which appeared in a recent number of *Paris Medical*, says the Arab Jahiah-Ebn-Serapion, who lived at the beginning of the ninth century, devised several methods of introducing water into the patient's system. A favourite plan was to take a little block of honey hollowed out in the middle: this hollow was filled with water, and the opening closed with honey. This sweetmeat the patient swallowed without knowing that he was taking water. Intravenous injections of water were recommended even in the nineteenth century, and seem to be based on this theory of surprise. The bath was long fashionable. Sea baths are mentioned from the thirteenth century in almost all works which deal with hydrophobia. During the first six years of the seventeenth century there appears to have been an epidemic of hydrophobia in Paris. It was very

severe at the beginning of May, 1604. At that time sea bathing was considered the best cure. Police orders against stray dogs were issued and they were killed without mercy. Dog owners had to keep their animals shut up, infraction of the law being punished by a heavy fine. Yet there were many cases of the disease, and Dieppe was the fashionable resort for the cure. In the early years of the seventeenth century Henry IV's dog Fanor, which was supposed to be suffering from rabies, was sent to Dieppe to be treated by sea bathing. The event was made the occasion of great festivities given by the Sieur de Sigogne as long as the dog was at Dieppe. It is a pity that history does not tell us whether the illustrious patient got well. In 1671 Madame de Sévigné wrote thus of certain ladies of the Court of Louis XIV:

"For the rest, if you believe that the Queen's maids of honour are mad you will believe rightly. A week ago Madame de Ludres, Coëtlognon, and the little Rouvroy were bitten by a little bitch belonging to Théobon. This little bitch died rabid, and so Ludres, Coëtlognon, and Rouvroy started this morning for Dieppe to be thrown three times into the sea. The journey is sad. Benserade was in despair about it. Théobon did not wish to go, though she had been slightly bitten. The Queen does not wish to have her about her until it is known what is going to happen. Don't you think, my dear, that Ludres resembles Andromeda? As for me, I see her tied to a rock and Prévile on a winged horse killing the monster. *Ah! Zéu, tantôt le Grigou, l'étrange rose l'étre zébe toute nue tous la mer!*"

Gui Patin, writing to Falconnet on September 17th, 1670, expressed disbelief in the water cure of hydrophobia, but he could do nothing against the fashion, which still prevailed in the middle of the following century. In the eighteenth century mention is made in the municipal archives of subventions to enable poor persons to go and bathe in the sea after they had been bitten. The surprise bath was applied either by throwing the patient into the sea or by giving him shower baths of the most primitive kind. Van Helmont once saw an old man dripping with water and fastened to the mast of a ship. He asked what crime he had committed, and was told that he was a hydrophobic patient who was being thrown into the sea from time to time. In Italy Morgagni prescribed three successive immersions. Boerhaave thought sea water had a specific action and neutralized the poison. According to him salt was the active ingredient. Acting on this idea, some doctors applied herrings to the wound.

According to Desault the following was the method adopted in the South of France in the eighteenth century. The patient, with nothing on but a shirt, was placed on his knees at the edge of the sea. When a wave came two strong men ducked his head, so that the wave went all over him. This was repeated up to nine times. He was then wiped dry and clothed. Then he was believed to be safe. In 1775 Sabatier, whose name is well known in medicine, took to Dieppe a non-commissioned officer and a soldier of the Invalides who had been bitten by a rabid animal. When they arrived there the mistress of the inn told him that immersion in the sea was very frequent, and that many patients came for the purpose. The treatment was then a monopoly of six persons, who obtained the privilege from the municipality. Some of these were accordingly summoned, and the patient was made to go into the sea entirely naked, being held firmly by the elbows and under the armpits. The bathers walked face outwards, the patient going backwards. When a wave came in the bathers suddenly threw their victim backwards, repeating this manœuvre five or six times.

The reputation of the treatment declined rapidly in the last years of the eighteenth century and in the nineteenth it was almost an extinct tradition, though, as late as 1864, there was at least one French doctor who believed in it. It is to be noted that many of those who claim cures by this method forget to mention that before having recourse to it they had at once cauterized the wound. This was done very often. Again, it has to be remembered that many of the dogs were unjustly accused. There was then no means of establishing that they were rabid. In genuine cases of hydrophobia the sea-water cure was useless: when people were the victims of a false alarm, suggestion had the largest share in the cure. In the seventeenth century, when it was most fashionable, there were notorious cases of failure, many people having died of the disease after they came back from the seaside.

THE NUTRITIONAL IMPORTANCE OF THE PRESENCE IN DIETARIES OF MINUTE AMOUNTS OF CERTAIN ACCESSORY SUBSTANCES.

THE importance of minute amounts of substances as accessory factors in dietaries has recently received a good deal of attention. The most notable example of the effect of such substances is afforded by the numerous investigations into the causation of beri-beri. Other examples are afforded by the discoveries concerning the conditions that induce scurvy, and concerning the inability of certain dietaries to promote the growth of young animals, although they can maintain adults in weight and health. It is the more important results of the investigations of these three problems that will be briefly considered in this review.

Beri-beri is prevalent in rice-eating communities, and the conclusion that the disease resulted from the continuous consumption of a diet consisting too largely of polished rice was first reached by Eykman (1897), and afterwards by Braddon as the result of epidemiological investigations extending over ten years. Braddon's work brought out the further important point that natives consuming rice which had been parboiled before the removal of the pericarp did not contract the disease. As the result of the substitution of parboiled for polished rice based on his recommendations, the case mortality of beri-beri in the hospitals of the Malay States was greatly diminished.

Various theories have been held in regard to the causation of beri-beri. The epidemiology of the disease strongly simulates that of an infective malady, and numerous micro-organisms have been held responsible for it. Beri-beri has also been regarded as arising from the presence in the rice of a poison, formed either by a fungus, as in the case of ergotism, or by some fermentation change during storage. The disease has also been ascribed to a deficiency of proteins in the diet.

An important step in the investigation of beri-beri was the discovery by Eykman (1897) that birds, when fed on polished rice, developed an analogous disease with extensive polyneuritis, and that this disease was not induced by diets of unpolished rice. Eykman also showed (1906) that the aqueous extract of rice polishings cured polyneuritis and that the active constituent was dialysable and soluble in alcohol. These observations have been confirmed by many other workers (Schaumann, 1908-11; Fraser and Stanton, 1910-11; Terruchi, 1910; Chamberlain and Vedder, 1911).

Grijns (1901, 1909) showed that foodstuffs other than unpolished rice could prevent polyneuritis, but he found that their protective properties were destroyed by heating to 120 C. He put forward the view that beri-beri results from a deficiency in polished rice of a substance necessary for the metabolism of the nervous system. This view has been borne out by the results of subsequent investigations.

Fraser and Stanton (1911) ascertained that polished rice contained less phosphorus than unpolished rice, and that the content of phosphorus was a useful indication as to whether the rice was an adequate diet or not. These results supported Schaumann's theory (1908) that beri-beri was caused through a deficiency in the dietaries of organic phosphorus compounds. He found (1910), however, that many phosphorus-containing substances were ineffective in preventing and curing polyneuritis; and Chamberlain and Vedder (1911) subsequently showed that a curative extract of rice polishings contained only a minute proportion of the total content of phosphorus in the original polishings. Schaumann (1911) therefore modified his theory and suggested that the curative substance was an activator in metabolism, favouring the assimilation of certain nutrients, probably phosphorus compounds.

Braddon, and later Cooper and Funk (1911), found that exclusive diets of various pure carbohydrates induced polyneuritis in birds, thus disproving any intoxication hypothesis concerning the causation of beri-beri; and Cooper and Funk also showed that the curative substance was entirely precipitated by phosphotungstic acid from an aqueous solution of an alcoholic extract of rice

polishings. The active fraction contained no phosphorus, protein, or carbohydrate.

Funk (1911-12) by a complex fractionation of the phosphotungstic precipitate, involving the use of the salts of heavy metals, succeeded in isolating a small amount of a substance melting at 233° C. Of this 0.02 to 0.04 gram cured neuritic pigeons. He ascribed to it the provisional formula $C_{17}H_{20}N_2O_4$. Subsequently he isolated curative substances melting at a similar temperature from ox brain, yeast, and milk. The active substance was precipitated by silver nitrate and mercuric acetate, but not by mercuric sulphate or nitrate; its aqueous solution was of neutral reaction, and did not react with acids. These properties suggested to Funk that the substance was probably a pyrimidine base, analogous to thymine and uracyl and a constituent of nucleic acid. He has in a recent paper (1911) shown furthermore that certain purin and pyrimidine substances exert a marked action on pigeons affected with polyneuritis, in some cases prolonging the lives of the birds, but in others actually ameliorating the symptoms. Cooper (1913) also found that strychnine prolonged the lives of neuritic pigeons.

B. Moore and his collaborators (1912) have also obtained from yeast a curative substance to which they ascribed the formula $C_7H_{17}N_2O_4$, and Suzuki, Shimamura, and Odaki (1912) have prepared an active substance containing nitrogen from rice-polishings by forming its picrate, but they have not published results of its analysis.

The difficulty encountered by all these workers is that the active substance seems to be largely destroyed during the chemical manipulations, so that it has not yet been possible to prepare sufficient to study its chemical constitution and properties. For some time the prevention of beri-beri must therefore depend upon the addition to the polished rice of foodstuffs known to contain the antineuritic substance, and accordingly Cooper (1913) has investigated the distribution of this substance amongst various foodstuffs by a series of dietetic experiments upon birds. The results indicated that while voluntary muscle was deficient in the antineuritic substance, heart muscle, egg yolk, lentils, and barley were very effective in preventing polyneuritis; of these lentils and barley will probably be the most suitable substances with which to supplement the polished rice diet.

It was also shown by Cooper that the loss in body weight resulting from the polished rice diet was not necessarily prevented by the addition of an amount of a foodstuff sufficient to prevent polyneuritis, and that brain was very effective in maintaining body weight, but was of relatively small antineuritic value. These results indicated that in polished rice there exists a secondary deficiency of substances essential for the maintenance of body weight, as was believed by Schaumann (1911).

The conclusion to be drawn from the numerous investigations is that beri-beri is caused by the deficiency in polished rice of a nitrogenous substance, small amounts of which are essential in the metabolism of the nervous system. The substance appears to be a pyrimidine base, but its exact nature is not yet discovered. Little is known concerning the part this substance plays in metabolism. It would appear not to be firmly combined with the lipoids of the nervous system, because it can be almost entirely removed from lipoids by simple treatment with acetone (Maclean, 1912) or water (Cooper, 1913). As has been already stated, Schaumann considers that the antineuritic substance behaves as an activator or catalyst in metabolism, thereby rendering possible the assimilation of certain nutrients, probably phosphorus compounds. The rapid curative action of the substance in small amount certainly suggests that by some stimulating effect it can quickly readjust the nutrition of the nerve cells to its normal state, but there is no evidence at present that it is especially related to phosphorus metabolism.

Ship beri-beri sometimes develops amongst crews of sailing ships during long voyages, and symptomatically somewhat resembles tropical beri-beri. The disease was rare on Norwegian ships before 1894, but since this date has been of frequent occurrence. Till 1894 the diet of the crews consisted of salt meat, peas, and biscuits made with rye flour, but subsequently, with the idea of improving the conditions of the sailors, shipowners were required by law to provide bread made from wheat flour, and at the same time the rations of salt meat and peas were reduced

and supplemented with tinned meat and fish which had been heated above 100° C. during preparation.

Holst (1907) found that birds fed on rye bread or peas remained healthy, but developed polynneuritis when fed on wheat bread, or on salt meat boiled for an hour at 100° C. Grijs (1901) had previously found that polynneuritis resulted from diets consisting of meat which had been heated above 100° C. These experimental results strongly suggested that ship beri-beri became prevalent in consequence of the replacement in the dietaries of white flour bread for rye bread and the reduction of the ration of peas, and not apparently in consequence of the substitution of tinned for salted meats.

During the last few years scurvy—another disease occasioned by the continuous consumption of diets which, although adequate as regards proteins, carbohydrates, and fats, are deficient in some unknown constituent minute quantities of which are essential—has been investigated principally by Holst and Fröhlich, Fürst, and Funk. Scurvy is particularly liable to result from diets of cereals and preserved foodstuffs, especially if they have been sterilized by heat. The disease can be prevented and cured by the addition of an adequate amount of lime juice, fresh vegetables and fruits to the diet, but, as has been pointed out by Jackson and Harley (1900), it has sometimes occurred in expeditions, notwithstanding the inclusion of these foodstuffs in the diets. Possibly the rations consumed were insufficient to supply the necessary amount of antiscorbutic substance.

Just as the investigation of beri-beri was facilitated by the experimental production in birds of a polynneuritis (Eykmann), similarly our knowledge of the nature of scurvy has been greatly advanced by the discoveries of Holst and Fröhlich (1907-12) and Fürst (1909-12) that symptoms resembling those of scurvy could be induced in guinea-pigs and rabbits by exclusive diets of barley, oats, rice, and bread, and prevented by the addition to these diets of sufficient amounts of various antiscorbutic foodstuffs such as green vegetables, fruit, etc.

Fürst (1909) also made the interesting observations that yeast, which was very effective in preventing beri-beri, possessed no protective properties against scurvy, and that whereas grain was lacking in the essential principle, it developed an antiscorbutic substance during germination. He suggested that this substance is produced in the plant by the agency of enzymes.

No information has yet been obtained in regard to the nature of the active substance. It appears to be even more labile than the antineuritic substance, and the methods of fractionation adopted for the separation of the latter which involve the use of heat and alkali appear to be even more unsuitable for the isolation of the antiscorbutic agent. Holst and Fröhlich (1911, 1912), however, have found that the substance is soluble in acid, insoluble in petrol-ether, and dialysable; and Funk (1913; 2) has found that milk retains its antiscorbutic properties after the elimination of the proteins, and that the active constituent is carried out of solution by kaolin, but not by dialysed iron.

The fact that foodstuffs effective in preventing beri-beri are not necessarily antiscorbutic indicates that beri-beri and scurvy are caused by the deficiency of different substances in the diets. It was shown, however, by Holst (1911) that although a diet of polished rice induced polynneuritis in birds, it gave rise to both scorbutic and neuritic symptoms in pigs, and to scorbutic symptoms only in guinea-pigs. It has been concluded from these observations that a very close relationship exists between beri-beri and scurvy. The facts do not, however, necessitate this conclusion, and it is possible that the antineuritic and antiscorbutic substances participate in distinct metabolic processes, and that the relative amounts of the two agents required for the maintenance of health are not identical for different animals. If this be the case, then in animals placed on diets deficient in both the antiscorbutic and antineuritic substances the relative rate of utilization of the active substances stored in the tissues will be specific for each animal, and scorbutic or neuritic symptoms will therefore appear according as to which protective substance is consumed first. On the other hand, if the rates of consumption of the two substances are nearly identical, neuritic and scorbutic symptoms will develop simultaneously.

The conclusion, then, to which we are brought is that scurvy results from the deficiency in the diets of a specific accessory substance, and in this resembles beri-beri, but as yet no information has been obtained in regard to the nature of the antiscorbutic agent.

Infantile scurvy has been ascribed on clinical evidence by several investigators since Barlow (by Meyer in 1901, Neumann in 1902, Henbner in 1903, and Brachi and Carr in 1911) to the consumption of diets consisting of boiled milk with or without carbohydrate foodstuffs. The disease can be cured by raw milk, lime juice and grape juice. It resembles scurvy symptomatically and in being apparently caused by the deficiency in the diet of some necessary substance.

Fröhlich (1909, 1912) has shown that pasteurized milk (that is, milk heated to 70° C.) prevented the development of scorbutic symptoms in guinea-pigs fed on oats, while milk heated at 98° C. for ten minutes did not obviate the development of scurvy, because it may be assumed it did not contain enough of the essential substance. Exclusive diets of either raw or boiled milk, however, did not induce scurvy. This suggests that in boiled milk there is a sufficient amount of the antiscorbutic agent to supply the needs of the guinea-pig's organism when milk is the sole food, but when cereals are added to the diet, owing either to the increased requirements of the organism or to a reduction in the ration of milk, the supply of active substance is inadequate. Somewhat analogous results have been obtained by Cooper (1913), who found that birds fed on large rations of polished rice developed polynneuritis in a shorter time than underfed birds, the supply of the antineuritic substance stored in the tissues thus appearing to be more rapidly utilized in the former than in the latter. These facts are of fundamental importance to dietetics, and a further investigation of the question will be of value.

The clinical evidence obtained by Dr. Janet Lane-Clayton (1912-13) indicates that raising milk to the temperature of boiling water has no deleterious effect upon its nutritive value. It would appear that the amount of antiscorbutic substance normally present in an average sample of milk is such that, although some is destroyed by heating to the above extent, there is still sufficient left to supply the needs of the infant's organism. The fact that infantile scurvy does occasionally result from diets of boiled milk may be due to the particular milk being poor in the active substance, or to the requirements of the children being greater than usual, or possibly, as suggested by Fröhlich's researches, to the addition of starchy foodstuffs to the diet.

The particular importance of small amounts of substances of unknown composition in the metabolism of growing animals appears from the interesting researches of Osborne and Mendel (1911) and Hopkins (1912). These investigators have shown that when dietaries consisting of the requisite proteins, fats, carbohydrates, and salts capable of maintaining adult rats in weight and health were administered to young animals, although they might keep them healthy, they totally failed to promote their growth. When, however, very small amounts of milk from which the proteins had been eliminated were added to the diet, growth proceeded normally. The nature of the substances present in the protein-free milk so essential for growth is unknown.

Of the three substances respectively necessary for the prevention of beri-beri and of scurvy and the promotion of growth, we at present possess some knowledge of only one—namely, the antineuritic agent. These substances exist only in small amount in food materials, but they are so extremely active that minute quantities are sufficient to supply the needs of the organism. The presence of the substances in such low concentration, however, is the great obstacle to their isolation on a large scale, and this is accentuated by the considerable loss in active material incurred during the necessary chemical manipulations. Thus 0.001 gram a day of the anti-beri-beri substance seems adequate for the pigeon's organism, and this is contained in about 5 grams of barley (the daily amount required to prevent polynneuritis in pigeons fed on polished rice), so that to obtain a sufficient amount of the active substance for chemical and physiological experiments a large quantity of material must be utilized. A considerable amount of work must therefore be

carried out before these substances can be isolated and their chemical composition determined. Such discoveries, however, will be of great importance not only as a contribution to our knowledge of metabolism, but also on account of their practical value in the prevention of the respective types of malnutrition resulting from the deficiencies of the substances in diets.

The nutrition of an animal is thus seen to depend not only upon the supply of proteins, carbohydrates, fats, and inorganic material, but also upon the presence in the diet of certain accessory substances, small amounts of which are sufficient to supply the needs of the organism. As the active substances are distributed most irregularly amongst foodstuffs (this is true at any rate in the case of the antineuritic and antiscorbutic agents), the nutritive value of food material cannot be accurately expressed in terms of its composition and potential energy, unless the content of the accessory substances is taken into consideration. The experience of agricuturists that expectations based on the results of chemical analysis as to the nutritive and fattening values of food materials are frequently not justified in practice may find an explanation in facts of the order of those detailed in this article.

E. A. COOPER,

Beit Memorial Fellow, Lister Institute.

THE PARLIAMENTARY COMMITTEE ON PROPRIETARY MEDICINES.

HAVING been reappointed this session, the Parliamentary Committee which is inquiring into the sale and advertisement of proprietary medicines resumed its sittings at the House of Commons on March 27th. Sir Henry Norman again presided.

THE ANALYSES IN "SECRET REMEDIES."

Evidence was given by Mr. Arthur E. Barclay, of Messrs. Barclay and Son, Limited, wholesale chemists, London. The witness endorsed the views expressed to the Committee on behalf of the Proprietary Articles Section of the London Chamber of Commerce. He mentioned that of the 235 preparations referred to in *Secret Remedies* and *More Secret Remedies*, his firm only knew of 120, about 115 being entirely unknown to them. The preparation known as "Mrs. Johnson's American Soothing Syrup" was the only article manufactured by his firm mentioned in the volumes. The analysis given stated that the preparation contained a considerable proportion of free hydrochloric acid, but, as a matter of fact, no hydrochloric acid was introduced in manufacture. Such a large proportion as the analysis mentioned could not be introduced accidentally, because it would amount to 1½ gallons of the

quantity of 50 gallons made at one time. The analysis also omitted two important ingredients; the names of these the witness supplied to the Committee privately. The witness expressed himself in favour of the registration of proprietary articles in order that the manufacturers might be more easily identified. He said that Mrs. Johnson, whose name is associated with the soothing syrup manufactured by his firm, was a real person; the rights in the medicine were purchased in 1831 for £1,950.

Mr. Glyn Jones called the attention of the witness to an editorial in the BRITISH MEDICAL JOURNAL of March 23rd, 1912, alluding to the soothing syrup as a preparation consisting of hydrochloric acid, common salt, saffron, and honey, to be rubbed on the gums.

The witness said that possibly owing to the difficulty of analysis in this particular case, the citric acid, which the preparation did contain, had been wrongly described as hydrochloric acid.

Mr. Glyn Jones: When your firm saw this misdescription, as you say, in the BRITISH MEDICAL JOURNAL, why did you not take some action?

The Witness: One reason was that we thought if an action was brought we should have to disclose the formula, which we did not wish to do. In reply to a further question, the witness said that 160 pages of a catalogue issued by his firm were devoted to proprietary articles. There were 80 on a page, so that the number of articles referred to would be about 12,000. He did not think it was possible for a profitable business to be done in a proprietary medicine which had no real merit.

Mr. Glyn Jones: Is it your experience that articles obviously of a fraudulent character have to be put on the market at a comparatively high price?—Yes.

And the business is done by direct sale to the public?—The greater part of it is done by direct sale and by canvassing from place to place.

And they have to catch a fresh dupe every time?—Yes; they cannot rely on repeat orders. The witness added, in reply to another question, that his firm constantly received requests to place new proprietary preparations on the market, but he did not recollect ever having received such a request from a medical man. They came principally from members of the public.

Mr. Glyn Jones: How do the retail trade generally regard the business in proprietary medicines—favourably or not?—They regard it favourably, as one they can make a profit out of, but the competition is so great and the prices have been cut so much that a great many articles are sold without any profit at all.

The Chairman called the attention of the witness to the differences in the wording which appeared on the labels of the soothing syrup as sold in this country and Australia. He asked if the following statement did not suggest a Government guarantee of the preparation: "Mrs. Johnson having sold this preparation to them, Messrs. Barclay and Co. beg to refer purchasers to the Government stamp with their name thereon as a security to the public."

The witness said he did not read the phrase in the sense suggested by the Chairman. The reference was to the name of the firm, and not to the Government stamp.

The Chairman: Can you suggest that any ignorant person would not regard it as meaning that the Government stamp constituted a certain security, and was not this form of words devised to give that impression?

The Witness: I believe that form has been used ever since we sold the medicine.

The Chairman: If there is any offence in the form of words—I am not saying there is—the fact of using them for so many years would only make the offence greater. I notice that although the law permits that to be stated to the British public, the Australian law causes the statement to read: "Mrs. Johnson having disposed of the recipe to Messrs. Barclay and Co., they guarantee that the syrup is made of pure ingredients and beg to refer the public to their signature, without which the contents of the packet cannot be genuine."

The witness remarked that in Australia a Government stamp was not required, so that the wording could not be the same. He considered the effect of the two statements was practically identical.

The Chairman also called attention to variations in Australia and this country in the directions accompanying the packet. The British public were informed, "As soon

as the syrup is rubbed on the gums the child will recover, being as innocent as it is efficacious." The Australian authorities seemed to be a little more particular as to the grammar, for on the Australian labels the statement was merely, "The syrup is rubbed on the gums." Another statement made to the British public was that "by opening the pores at that early age no child will have fits." That statement was omitted from Australian labels. The witness admitted that this was a rather sweeping statement, but the firm adhered as much as possible to the old style of label used when they bought the remedy.

"WINCARNIS."

Mr. W. Rudderham, general manager of Messrs. Colman and Co., Limited, proprietors of Wincarnis, was the next witness. He dealt with the evidence given before the Committee by Dr. Mary Sturge, with reference to medicated wines. He denied that any one could take the preparation without knowing it was a wine. The ingredients were stated on the bottle, and consisted of a high class foreign wine, meat extract, and extract of malt. The quantity instructed to be taken would not have any intoxicating effects. Before intoxication could result a very unpleasant and nauseating feeling would be produced by the meat and malt extracts contained in the wine; these were calculated to prevent any misuse of the preparation. The witness said there was a substantial difficulty, in making a satisfactory mixture out of the ingredients he had mentioned, to secure a preparation which would be stable and clear in appearance. The method of doing this was an important trade secret, which it would be injurious to the company to be compelled to disclose. Wincarnis was not advertised as a cure for any specific disease, but as a restorative, and as being beneficial for various ailments. He could prove that the preparation had been recommended by 10,000 medical men. Since 1909 the company had received 4,700 testimonials and recommendations from doctors to send bottles to patients. Documents of this kind prior to that date were destroyed in the flood which overtook Norwich last August. The only adverse criticism of the preparation had come from extreme total abstainers.

ONE HUNDRED YEARS AGO.

AN ENCYCLOPAEDIA OF MEDICINE IN 1813.

IN April, 1813, the subscribers to the *Dictionnaire des sciences médicales* were reading or glancing over the contents of the fourth volume of that great work. The first volume had appeared in 1812, and the last (the sixtieth) did not come until 1822, so that for ten years at intervals of about two months the individual parts were being published in Paris and were making their way all over Europe. The publisher was C. L. F. Panckoucke, and how widely the work was being distributed may be learnt from the list of booksellers given on the page facing the title in each volume. Not only were there firms in Paris and in all the leading towns of France from whom the *Dictionnaire* could be obtained, but also in various other countries there were booksellers ready to supply it. Thus there were agencies in Aix-la-Chapelle, Alexandria, Amsterdam, Brussels, Colmar, Florence, Ghent, Geneva, Hamburg, London, Leipzig, Lausanne, Madrid, Maestricht, Mannheim, Milan, Naples, Turin, Warsaw, and Venice; whilst the fact that in Moscow there was a bookshop from which the work could be got must not pass unnoted.

It was a gigantic undertaking. But France had been astonishing the world by several vast enterprises. To the amazement of Europe the troops of the Republic had withstood and got the better of the seasoned armies of Austria and Prussia. In 1812 fighting was still going on in many places; the French forces in the Peninsula were strong enough to hold Wellington at bay, and yet Napoleon was able to lead an army of nearly half a million men into Russia; there seemed to be nothing too great or too hard for the soldiers of either the Republic or the Empire to accomplish. Even the disastrous retreat from Moscow was a gigantic event; Bonaparte had nothing that was mediocre in his affairs; his victories were magnificent and his failures were stupendous.

Now whilst the troops of France were pouring in disorder and defeat across the frozen plains of Russia French medical men were launching an undertaking which, in its way, was also huge and impressive. They were beginning to invade Europe with their *Dictionnaire des sciences médicales*. When the army of Napoleon was in retreat from Moscow the first volumes of the *Dictionnaire* were being issued from the press in Paris, and, astonishing to relate, Messrs. Ricce and Saucet, the booksellers, were apparently receiving orders for the work near by the charred walls of the Kremlin. This medicoliterary invasion had a happier result than any of the military achievements of the Emperor, and under the orders of "une société de médecins et de chirurgiens" the *Dictionnaire* was destined to carry the evidence of the greatness of French medicine to the most remote corners of Europe. It is also no small honour to their country that the doctors made no retreat during all these tempestuous times, but continued to send forth, even during the Hundred Days before Waterloo, the bi-monthly volumes of their *Dictionnaire*.

They are not small books, these bi-monthly volumes. The one which was being read in April, 1813, contained 572 pages, and carried the alphabetical rubrics from *Can* to *Cha*; it was the fourth, and there were to be fifty-six more of that size before "Fin" could be printed. Neither were the writers small men, although there may be some justification for the criticism offered by the *Journal de bibliographie médicale* for April, 1813, that they were all of one school. Seventy-five names appear on the title-page, and amongst them are to be found Alibert, Bayle, Breschet, Cadet de Gassicourt, Chanssier, Cloquet, Coste, Cuvier, Dubois, Fournier, Gall, Geoffroy, Kergardec, Laënnec, Larrey, Pelletan, Pinel, Royer-Colliard, Spurzheim, and Tollard—all of them men who had made or were making a reputation.

Our English word "dictionary" does not at all convey the idea worked out in this set of sixty volumes. "Encyclopaedia" comes nearer to it, "encyclopaedia and dictionary" nearest of all, perhaps. There are long articles, such as one meets with in modern encyclopaedias; but between these, there are also short ones, which may be, and in many cases are, hardly more than definitions. There are illustrations, but they are not numerous: there are two in the fourth volume, there is one in the third, and four each in the first and second volumes. It need hardly be said that in the early part of the nineteenth century illustrations were much more expensive than now, and, for the time, one may call the work well supplied. The articles are all signed, and some of them are provided with good bibliographies.

Some idea may be gained of the matters dealt with in this work from a simple enumeration of the headings in the first fifty pages of the fourth volume. The first article is on *canelle* (cinnamon), with a short separate note on *canelle blanche*. Then follows a paragraph on *canepin* (lambskin), and an interesting note on *canicule et jours caniculaires* (Sirius and the dog days) in which Hippocrates and Aristotle are quoted. *Canin* (canine) is referred to in its various medical combinations, such as *faim canin* (canine hunger), "une faim tres-considerable et que rien ne peut apaiser"; *dents canines* (canine teeth); *fosse canine* (canine fossa), and *muscle canin* (commonly called "risorius muscle" by the anatomists of to-day). Then comes an article on *canitie* (canities or greyness) with curious observations of exceptional cases and some recommendations for the prevention of this sign of old age, for, says the writer, "although grey hair is no disgrace, and though a white head inspires respect, there are women and even men vain enough insistently to demand that grey hairs shall be caused to disappear," human nature being the same always. The headings *canne aromatique* and *canne à sucre* are mere cross references, but the article on cantharides covers twelve pages, and is provided with a long list of books and papers which have been written on that coleopteral product; "one could make a book out of the titles alone of the writings which have dealt with cantharides and their preparations," is the comment of Chaumeton, who is responsible for this article. Then there are papers on *canthus*, on *canule* (a canula), on *caout-chouc* (vulgairement gomme élastique), on *capeline* (a sort of bandage), on *capillaire* (in its botanical, physical, and anatomical

meanings), on *capillament* (the hair of the head and of other parts of the body), on *capillation* (a slight fracture of the cranium), on *capistation* (with its cross reference to plimosis), on *capistre* (a sort of trismus), on *capitale* (a stermatory powder), on *capituluve* (a head bath), on *capreolaire* (an old descriptive term applied to the spermatic vessels), on *caprier* (the caper tree), on *caprisant* (uneven, as applied to the pulse), on *capsulaire* and *capsule* (with their anatomical, botanical, and chemical significations), on *capucine* (the *Tropocolum majus*, one of the Geraniaceae), on *caput mortuum* (the residue after distillation), on *carabe* (one of the coleoptera). Articles on *caractère*, *caractéristique*, *caramel* ("c'est le nom qu'on donne au sucre qui a été soumis à l'action du feu"), and *carbonate* bring to an end the list of subjects dealt with in the first fifty pages of this volume.

Perhaps the most interesting, and certainly the most entertaining, article of this instalment of the *Dictionnaire* is that of more than 120 pages on *cas rares* by Fournier. It is a sort of scrapbook of all kinds of wonderful things—monstrosities, deformities, minor malformations, abstinence from food, catalepsy, slow pulse, spontaneous combustion, anomalies of conception, constipation, third dentition, ruination, voluntary vomiting, sweating blood, haemophilia, longevity, ventriloquism, etc.; and at the end the author writes: "The article will seem very long to persons who do no more than count its pages; those who will read it through will be of opinion that it falls far short of saying all that might be said on a subject so interesting as that of rare cases." We do not believe the readers of 1813 found it too long; those of 1913 may easily spend an interested half hour in its perusal and not grudge the time.

Such was the *Dictionnaire* which Panckoucke was publishing in the second decade of the nineteenth century. It was not, of course, the first encyclopaedia to appear; there had been Chambers's *Cyclopaedia* in 1728, Diderot's *Encyclopédie* in twenty-eight volumes (1751-72), and the first edition of the *Encyclopaedia Britannica*, which was published in Edinburgh between 1768 and 1771; but it was the first medical encyclopaedia of considerable dimensions. A *Diccionario de medicina y cirugía*, in seven volumes, had been published at Madrid in 1805-7, but this was a small thing compared with the sixty volumes of Panckoucke's venture. It was soon followed by many others, and there has hardly been a pause since in the succession of encyclopaedias which have poured from the press of France, Germany, and our own land. There was the *Dictionnaire abrégé des sciences médicales* in fifteen volumes (1821-6), the *Encyclopädisches Wörterbuch der medicinischen Wissenschaften* in thirty-seven volumes (1828-49), the *Dictionnaire de médecine et de chirurgie pratiques* in fifteen volumes (1829-36), the *Dictionnaire de médecine ou répertoire général des sciences médicales* in thirty volumes (1832-45), Forbes's *Cyclopaedia of Practical Medicine* in four volumes (1833), the *Encyclopédie des sciences médicales* in forty-one volumes (1834-46), Copland's *Dictionary of Practical Medicine* in three volumes (1834-59), the *Dictionnaire des dictionnaires de médecine française et étrangers* in eight volumes (1840-50), the *Encyklopädie der gesammten Medecin* in ten volumes (1841-5), the *Nouveau dictionnaire* in forty volumes (1864-86), and the huge *Dictionnaire encyclopédique des sciences médicales* in eighty-one volumes (1869-86), not to name many of more recent date, and not to refer at all to those which were truly dictionaries rather than encyclopaedias. Perhaps, however, a sentence should be found for the *Medicinal Dictionary* of Dr. Robert James, published in three volumes in 1743 and translated into French by Diderot and others in 1746; this was Samuel Johnson's Dr. James, also the Dr. James of James's powder. Boswell states that Dr. Johnson wrote parts of the dictionary himself, but what parts he leaves to medical men to discover.

THE personal estate of the late Dr. Peter Redfern, formerly Regius Professor of Anatomy and Physiology at Queen's College, Belfast, has been sworn at £96,279.

THE sixth Pan-American Medical Congress will be held in Lima, Peru, in August (3rd to 10th). In connexion with the congress there will be an international exposition of hygiene, which will be opened on November 2nd and closed on December 31st.

TRADE UNIONISM AND MEDICINE.

At the Annual Representative Meeting at Liverpool last year an interesting discussion took place on the advantages which might accrue from the establishment of a medical union registered under the Trade Union Acts, and on the part which it might be possible and desirable for the British Medical Association to take in any such scheme. During that discussion the Solicitor made a statement as to the legal position of the Association and as to the legal difficulties which would attend action by it in this direction. He made it clear that the difficulties in the way of converting the British Medical Association into a body which came within the definition of a union capable of registration under the Trade Union Acts were very considerable, and the Representative Meeting adjourned the discussion to the annual meeting at Brighton next July.

UNIONS REGISTERED OR FORMED.

Meanwhile a medical union recently formed in Leicester has been recognized under the Trade Union Acts, and is in the enjoyment of such powers and immunities as the Acts confer; and another body called the National Medical Guild has been constituted, and has applied for registration under the Trade Union Acts. The fourteen members of its first council, who will hold office until October, 1914, are, with three exceptions, resident in London.

A brisk discussion on trade unionism and medicine has been occupying a considerable amount of space in our correspondence columns for some weeks, and it has seemed worth while to look carefully at the Trade Union Acts—the most recent only received the Royal assent a few weeks ago—in order to see what exactly are the powers and immunities enjoyed by a body registered under these Acts as compared with those possessed by a body such as the British Medical Association, which is registered under the Companies Acts (as a company not for profit).

OBJECTS OF A TRADE UNION.

The primary object of a trade union is to make the terms of service, including the remuneration of all the persons employed in the calling with which it is concerned, reasonably good, and so to maintain them. This implies either that the existing terms of service are not reasonably good, or that there is a risk of their becoming bad.

An ancillary object of a trade union is to assist its individual members to defend their rights as individuals, and to help them to make better provision by provident methods against the changes and chances of this mortal life. But as some common measure must be used, and as men are to be found to take practically any risk for money, with its promise of future luxury or ease, most disputes in which trade unions have engaged have turned on the question of pay, but not all, as recent railway difficulties may remind us.

The medical profession already has experience enough amply to prove that a medical union must be prepared to deal with both kinds of encroachment, unreasonable or improper demands unduly increasing its labours and responsibilities, and attempts to refuse just pecuniary remuneration. It must have power to defend its members individually, and it must have powers of collective defence. Defence in both cases comprises both the legal right to defend and the pecuniary resources for effective defence, including the compensation of members who suffer by reason of adhering to the union.

There is this difference: that collective defence means collective action, which can only come about through a solid unity which has some efficient sanction in professional sentiment and in common material interests, with, if possible, legal power of enforcement.

UNION AND TRADE UNIONS.

The fault found with the British Medical Association appears to be that its powers and resources for collective defence and for individual defence and support are inadequate, and that its influence and control over its members are insufficient to ensure effective collective action. Its most loyal members may admit all this—nay, they have been proclaiming it from the housetops—and have striven for years to bring about the changes in its constitution and the extension of its powers needed to effect this reform. But from this to the conclusion

that a Medical Union registrable under the Trade Union Acts should be formed, or the British Medical Association wound up and its assets used for the foundation of such a union, is a long step, and cool-headed members of the profession and of the Association will desire to be quite convinced that the step is not over a precipice into a quagmire.

The syllogism appears to be—"an effective union of the profession is desirable: a union registered under the Trade Union Acts is an effective union: therefore registration of a Medical Union under the Trade Union Acts is desirable." The syllogism would be watertight if the middle term were "a union registered under the Trade Union Acts is the only effective union." Put in either way, the crux is the definition of "effective union." The assumption seems to be that registration under the Trade Union Acts constitutes an effective union, while registration under the Companies Acts does not.

How is a trade union made effective, and what are its powers and immunities as compared with those which are possessed or may be acquired by an association registered under the Companies Act, or, as the British Medical Association has been advised would be the better alternative—a body possessed of a royal charter?

The Acts of Parliament making and amending the law relating to trade unions and trade disputes have to be read with and into one another, which is an obscure and perplexing process.

THE TRADE UNION ACT, 1871.

The Act of 1871, known as "The Trade Union Act," clearly indicates its objects in its opening sections.

(2) The purposes of any trade union shall not by reason merely that they are in restraint of trade be deemed to be unlawful, so as to render any member of such trade union liable to criminal prosecution for conspiracy or otherwise.

(3) The purposes of any trade union shall not, by reason merely that they are in restraint of trade, be unlawful so as to render void or voidable any agreement or trust.

Ever since the reign of Henry V it had been held that a contract in general restraint of trade was void. A learned judge, speaking of a trade union, said, "It appears to me that without the Act it is clearly an unlawful association; it is an association by which men are not only restrained in trade, but they are bound to do certain acts under a penalty."

Section 4 of this Act disclaims interference, and whilst taking away no jurisdiction it does not confer any. In fact, it leaves matters in this respect just where they were *in statu quo ante* the passing of this Act. This is not always realized, and many people who read about the funds and levies of trade unions believe that a trade union has extra legal powers to raise money from the members.

This section expressly states that there is no legal power. But, of course, the forces of coercion and picketing permitted by the Acts might be used for the purpose of enforcing the levies. The section is as follows:

(4) Nothing in this Act shall enable any court to entertain any legal proceedings instituted with the object of directly enforcing or recovering damages for the breach of any of the following agreements, namely:

1. Any agreement between members of a trade union as such, concerning the conditions on which any members for the time being of such trade union shall or shall not sell their goods, transact business, employ or be employed.

2. Any agreement for the payment by any person of any subscription or penalty to a trade union.

3. Any agreement for the application of the funds of a trade union—

(a) To provide benefits to members; or

(b) To furnish contributions to any employer or workman not a member of such trade union, in consideration of such employer or workman acting in conformity with the rules or resolutions of such trade union; or

(c) To discharge any fine imposed upon any person by sentence of a court of justice; or

4. Any agreement made between one trade union and another; or

5. Any bond to secure the performance of any of the above-mentioned agreements.

But nothing in this section shall be deemed to constitute any of the above-mentioned agreements unlawful.

Therefore, if a member of a trade union refuses to pay his subscription or levies he cannot be sued; if he is willing to sacrifice what he has paid into the union and drop his membership he can do so.

Definition of Trade Union.

In the Trade Union Amendment Act, 1876, we get a definition:

The term "trade union" means any combination whether temporary or permanent for regulating the relations between workmen and masters, or between workmen and workmen or between masters and masters, or for imposing restrictive conditions on the conduct of any trade or business, whether such combination would or would not, if the principal Act had not been passed, have been deemed to have been an unlawful combination by reason of some one or more of its purposes being in restraint of trade.

The words "any combination . . . for regulating relations . . . or for imposing restrictive conditions on the conduct of any trade or business" led the courts to hold that societies actually proposing to carry on trade cannot be registered as trade unions, and in a leading case the Board of Trade had refused to register a union as the proprietors of a newspaper. A learned judge has held that a union may carry on a newspaper in the interests of the members but not for profit or as a trading venture. In the present state of the law a trade union is in its legal aspects a negative combination for the purpose of imposing restrictive conditions and has no powers to carry on any trade or business of a positive nature.

CONSPIRACY AND PROTECTION OF PROPERTY ACT.

Four years after the passing of the Act of 1871 came the Conspiracy and Protection of Property Act, 1875, a most important section of which enacts:

7. Every person who with a view to compel any other person to abstain from doing, or to do any act which such other person has a legal right to do or abstain from doing, wrongfully and without legal authority:

1. Uses violence to or intimidates such other person or his wife or children or injures his property; or

2. Persistently follows such other person about from place to place; or

3. Hides any tools, clothes, or other property owned or used by such other person, or deprives him of or hinders him in the use thereof; or

4. Watches or besets the house or other place where such other person resides or works or carries on business, or happens to be, or the approach to such house or place; or

5. Follows such other person with two or more other persons in a disorderly manner in or through any street or road

shall on conviction thereof . . . be liable to pay a penalty not exceeding twenty pounds or be imprisoned for a term not exceeding three months with or without hard labour.

TRADE DISPUTES ACT, 1906.

The Trade Disputes Act, 1906, is to be read with the Conspiracy and Protection of Property Act. It deals with peaceful picketing as follows:

2. (1) It shall be lawful for one or more persons acting on their own behalf or on behalf of a trade union or of an individual employer or firm in contemplation or furtherance of a trade dispute, to attend at or near a house or place where a person resides, or works, or carries on business or happens to be if they so attend merely for the purpose of peacefully obtaining or communicating information or of peacefully persuading any person to work or to abstain from working.

The Trade Disputes Act was framed to alter the law as laid down in a variety of judgements of recent years. There had been complaints of "judge-made laws."

The Act alters the law of conspiracy, practically abrogating it in the case of unions, actions for tort are limited, and the law of picketing relaxed. Section 1 deals with conspiracy. A paragraph is added as a new paragraph after the first paragraph of Section 3 of the Conspiracy and Protection of Property Act, 1875, which enacted:

(Conspiracy and Protection of Property Act.)

3. An agreement or combination by two or more persons to do or procure to be done any act in

contemplation or furtherance of a trade dispute . . . shall not be indictable as a conspiracy if such Act committed by one person would not be punishable as a crime.

Nothing in this section shall exempt from punishment any person guilty of a conspiracy for which a punishment is awarded by any Act of Parliament. . . . A crime for the purposes of this section means an offence punishable on indictment or on summary conviction punishable by imprisonment.

The additional paragraph reads:

(Trade Disputes Act.)

(1) An act done in pursuance of an agreement or combination by one or more persons shall, if done in contemplation or furtherance of a trade dispute, not be actionable unless the act, if done without any such agreement or combination, would be actionable.

The right of action against individuals who conspire survives in this addition, and a plaintiff may proceed against his opponents singly for a tort, or jointly for conspiracy to commit that tort.

But Section 4 of the Trade Disputes Act, 1906, protects unions from the charge by which before the passing of the Act they had often been brought down—that of conspiracy to injure.

4. (1) An action against a trade union, whether of workmen or masters, or against any members or officials thereof, on behalf of themselves and all other members of the trade union in respect of any tortious act alleged to have been committed by or on behalf of the trade union, shall not be entertained by any court.

(2) Nothing in this section shall affect the liability of the trustees of a trade union to be sued in the events provided for by the Trades Union Act, 1871, Section 9, except in respect of any tortious act committed by or on behalf of the union in contemplation or in furtherance of a trade dispute.

A tort may roughly be defined as an injury to a private individual for which the wrongdoer has to compensate the injured party.

Libel is a tort, and the trustees of a trade union cannot be sued for libel or slander published or uttered in contemplation or furtherance of a trade dispute.

TRADE UNION ACT, 1913.

The Trade Union Act, 1913, which became law on March 7th last, empowers a trade union to raise and manage a "Political Fund" for the purpose of promoting the election of a person to Parliament, or to any public office, and of his maintenance after such election. Any member may claim to be exempted from payment to the political fund, and must not on that account be excluded from any benefits of the union (Section 3).

Section 1 of the Act distinguishes between statutory objects and political objects:

1. (1) The fact that a combination has under its constitution objects and powers other than statutory objects within the meaning of the Act shall not prevent the combination being a trade union for the purposes of the Trade Union Acts, 1871 to 1906, so long as the combination is a trade union as defined by this Act, and, subject to the provisions of this Act as to the furtherance of political objects, any such trade union shall have power to apply the funds of the union for any lawful objects or purposes for the time being authorized under its constitution.

(2) For the purposes of this Act the expression "statutory objects" means the objects mentioned in section sixteen of the Trade Union Act Amendment Act, 1876, namely, the regulation of the relations between workmen and masters, or between workmen and workmen, or between masters and masters, or the imposing of restrictive conditions on the conduct of any trade or business, and also the provision of benefits to members.

2. (1) The expression "trade union" for the purpose of the Trade Union Acts, 1871 to 1906, and this Act, means any combination, whether temporary or permanent, the principal objects of which are under its constitution statutory objects: provided that any combination which is for the time being registered as a trade union shall be deemed to be a trade union as defined by this Act so long as it continues to be so registered.

The right of a member to claim exemption from any

contribution to the political fund of the union is defined in Sections 5 and 6.

5. (1) A member of a trade union may at any time give notice, in the form set out in the Schedule to this Act or in a form to the like effect, that he objects to contribute to the political fund of the union, and, on the adoption of a resolution of the union approving the furtherance of political objects as an object of the union, notice shall be given to the members of the union acquainting them that each member has a right to be exempt from contributing to the political fund of the union, and that a form of exemption notice can be obtained by or on behalf of a member either by application at or by post from the head office or any branch office of the union or the office of the Registrar of Friendly Societies.

Any such notice to members of the union shall be given in accordance with rules of the union approved for the purpose by the Registrar of Friendly Societies, having regard in each case to the existing practice and to the character of the union.

(2) On giving notice in accordance with this Act of his objection to contribute, a member of the union shall be exempt, so long as his notice is not withdrawn, from contributing to the political fund of the union as from the first day of January next after the notice is given, or, in the case of a notice given within one month after the notice given to members under this section on the adoption of a resolution approving the furtherance of political objects, as from the date on which the member's notice is given.

6. Effect may be given to the exemption of members to contribute to the political fund of a union either by a separate levy of contributions to that fund from the members of the union who are not exempt, and in that case the rules shall provide that no moneys of the union other than the amount raised by such separate levy shall be carried to that fund, or by relieving any members who are exempt from the payment of the whole or any part of any periodical contributions required from the members of the union towards the expenses of the union, and in that case the rules shall provide that the relief shall be given as far as possible to all members who are exempt on the occasion of the same periodical payment, and for enabling each member of the union to know, as respects any such periodical contribution, what portion, if any, of the sum payable by him is a contribution to the political fund of the union.

THE LEICESTER UNION.

The first "Union of Medical Practitioners" has been registered at Leicester. Its objects are:

To regulate the relations and conduct of medical practitioners as between themselves, and between medical practitioners and their employers.

To regulate the rates of payment and conditions of service of club, friendly society, dispensary, and other forms of contributory contract practice, and the terms and conditions upon which medical service shall be given to persons of limited income.

To impose any other restrictive conditions which may be considered desirable on the conduct, by members of the union, of the trade or business of medical practitioners carried on by them.

In furtherance of these objects the union adopts the following methods and means:

- (i) The establishment of a fund or funds.
- (ii) The promotion of a system of medical service regulating medical attendance and provision of medicines for persons unable to pay ordinary medical charges (Public Medical Service).
- (iii) The promotion of a system or systems of school clinics for the treatment of necessitous children.
- (iv) The giving of legal assistance to members in connexion with the above objects.
- (v) The promotion of legislation for the protection of the union and for the general and material welfare of its members or the support of or opposition to alterations.
- (vi) The advising of members in ethical matters.
- (vii) The watching over, protection, and promotion of the interests of members and medical practitioners generally.
- (viii) The federation or amalgamation with other bodies having similar objects.
- (ix) The establishment of branches, subdivisions or districts.
- (x) "Any other lawful method which may be decided to be advisable in the general interests of the members as declared by a majority of two-thirds of those of the members present and voting at a general meeting."

There is an entrance fee of £1 ls., and an annual subscription not to exceed £1 ls.

The Central Committee has the power from time to time to make a levy of a sum not exceeding £5 per member, provided that an interval of not less than three months has elapsed since the laying of a previous levy.

The duties of members are as follows:

Rule 16. Duties of Members.

(b) No member of the Union shall consult with or meet a medical practitioner who carries on any form of contract or contributory contract practice within the sphere of operations of the Union and who does not conform to the working rules for the time being in force regulating the Public Medical Service and the Bye-laws of the Sub-division within which any patient so treated by him resides.

(c) No member shall take or treat on contract or contributory contract terms any patient at a lower rate than that prescribed by the working rules for the time being in force regulating the Public Medical Service or any patient who is to his knowledge in receipt of an income exceeding the income limit laid down by such working rules or by the Bye-laws of the Sub-division in which such patient resides.

(d) No member shall act for an Insurance Committee, Friendly Society, or combination of lay persons for the provision of medical treatment or medicines which does not conform to the working rules, etc.

(e) No member shall canvass or advertise for patients or influence or attempt to influence any persons to do so on his behalf.

(f) If any member is found by the Central Committee to be guilty of any act forbidden by paragraphs (b), (c), (d), or (e) of this Rule, his conduct shall be deemed to be detrimental to the honour and interests of the Union."

Rule 17.

The effect of this rule is that any member found guilty of conduct detrimental to the honour and interests of the Union as calculated to bring the business trade and profession of a medical practitioner into disrepute shall *ipso facto* cease to be a member of the Union.

The penalty for non-payment of subscription, levy, fine, or other sum payable is expulsion by resolution of the Central Committee.

THE NATIONAL MEDICAL GUILD.

The objects of the National Medical Guild are generally similar to those of the Leicester Union, but the following are in addition set out:

. . . to employ the funds of the Guild for the political objects defined in Section 3, subsection 2 of the Trade Union Act, 1912. . .

. . . to provide for the insurance of Members, either directly or by arrangement with insurance companies against death, illness, third party liability and (or) damage caused to and by motor cars or other vehicles; to publish books, papers, and literature in furtherance of the ends of the Guild. . .

to acquire, lease or build premises for the purposes of the Guild.

These concrete instances of the powers to be obtained by way of registration under the Trade Union Acts may usefully be compared with the powers possessed or sought by the British Medical Association.

THE POSITION OF THE BRITISH MEDICAL ASSOCIATION.

In the draft charter submitted to the Privy Council (as amended by the Representative Meeting of 1909) the Association among other powers sought the following: To publish the **BRITISH MEDICAL JOURNAL**, or any other journal of a character specially adapted to the needs of the medical profession; to originate, support, promote, and oppose alterations in the law of the United Kingdom or any British colony or dependency affecting the public health or the medical profession, and to promote the candidature of any member of the Association for Parliament or for any British legislative assembly; to take or defend and assist persons in taking or defending legal proceedings, civil or criminal, including proceedings before the General Medical Council in which the honour or interests of the medical profession, or any member of the Association in his professional capacity or any question of professional principle should be involved, and for this purpose to establish, contribute to, organize, and manage a fund, or funds, for the purpose; to provide facilities for the sale or transfer of practices, and for the engagement of assistants or locumtenents; to establish, endow, contribute to, organize, and manage, provident, or benevolent funds, for the benefit of members of the Association; to manage any trusts, directly or indirectly conducive to the interests of the Association or of the pro-

fession, or any branch thereof; and to take such other means as might be incidental or conducive to the promotion or carrying on of these objects.

These points may be compared with paragraphs iv, v, vii, and x, of the methods and means of the Leicester Union. With regard to the methods ii and iii of the Leicester Union, the Association has already taken action by way of a central scheme, or schemes, administered locally. Many of the powers sought by the charter are already exercised by the Association. For example, it has always taken a part in the promotion of legislation and the amendment of the law; it has frequently defended or given legal assistance in cases of professional interest, that is, in cases of more than merely personal interest; it regularly takes cases before the General Medical Council; it has recently improved its organization for advising members on ethical matters; and it has set up trusts for purposes ancillary to those of the Association, it has, for example, established a Central Emergency Fund and the Central Insurance Defence Fund. It grew in its early days by amalgamation with other bodies having similar objects, and its organization is based on a system of Branches and Divisions.

The granting of the charter was opposed by certain medical corporations and by certain medical benevolent organizations, but the weight of the opposition undoubtedly lay in the objections advanced by certain branches and members of the Association who objected to certain of the ordinances and by-laws, but expressed their desire that, if the regulations were modified so as to meet these objections, the charter should be granted to the Association, giving it all the powers specified in the draft. The wish of the members, therefore, that the Association should possess the additional powers enumerated above would seem to be practically unanimous.

After the granting of the charter had been refused by the Privy Council, the Association sought to proceed by way of establishing a new association registered with extended powers under the Companies Act, which would take over the work of the British Medical Association as a going concern. It was ascertained that the Board of Trade would sanction the registration of a new company possessing the following powers not definitely included in the present articles of Association, though, as regards (1) and (2), already exercised by it:

(1) Power to promote and oppose legislation affecting the public health or the profession.

(2) Power to take part in certain legal proceedings affecting the profession.

(3) Power to establish, endow, and manage benevolent funds (with the restriction that no grant may be made directly to a member of the Association; a member may, if indigent, be benefited indirectly by a grant to his relatives or dependants).

(4) Power to borrow and mortgage.

And that, in addition, certain other matters which had been held to come within the scope of the objects of the existing Association, but are not clearly provided in the existing memorandum, would be clearly defined, namely:

Power to provide libraries and places for social intercourse.

Power to undertake trusts for the benefit of the profession.

General powers of management of and dealing with property.

The Board of Trade, however, required that the following should be added to the draft memorandum:

Provided that the Association shall not support with its funds or endeavour to impose on or procure to be observed by its members or others any regulation, restriction, or condition which, if an object of the Association, would make it a trade union.

On looking into the matter further it appeared that the powers which could be obtained in this way were all, with the exception of (a) the establishment of a medical benevolent fund, and (b) the borrowing of moneys, powers already exercised by the Association, and, in view of the considerable expenditure necessarily attending the transfer of the work and assets of the Association to a new company, the Council resolved to advise the Representative Meeting not at present to proceed further in this way, but to apply to the High Court for an extension of the

memorandum to include only the power of borrowing money on mortgage or otherwise—a power which would result in considerable economy.

SOME DEDUCTIONS AND CONCLUSIONS.

To the question—What can a trade union do for medical men that a voluntary association cannot do? the answer is, from the legal point of view, not very conclusive.

It would appear that a medical union registered under the Trade Union Acts would have the power to defend its members in the courts. It would also have power to provide for them in sickness, in old age, in unemployment, or in pecuniary distress due to acts done in accordance with the policy of the union. But provision for these matters could be made by a voluntary association out of a trust fund raised for the purpose.

The union would be immune from action for injuries to private individuals if committed in contemplation or in furtherance of a trade dispute. It could also, it would appear, issue a libel in a publication published by it if such publication be issued *in the interests of the members*, but not as a trading adventure.

It would be exempt from the law of conspiracy (except in respect of a conspiracy for which a punishment is awarded by statute) in doing any act in furtherance of a trade dispute if such act committed by one person would not be punishable as a crime.

It would have the power to form a political fund, but not to compel its members to subscribe.

It would have the power to make levies, but would not have power to enforce them at law.

The real power of a trade union would seem to depend:

- (1) On its being made to include so large a majority of the persons engaged in the calling that the minority, having regard to the procedure, for example a strike, proposed to be taken is negligible.
- (2) On the constancy of its members in abiding by the decision of the majority, properly ascertained according to the regulations of the union.
- (3) On the power, in the event of the union failing to come to an amicable arrangement with the employers, to induce its members to strike, that is, to refuse to work.

As to the first point (1), it seems clear *a priori*, and the history of trade unionism fully confirms the conclusion, that the power of a trade union is the same as that of any other voluntary association, such as an association registered under the Companies Acts—neither greater nor less.

As to the second point (2), the advantage which a trade union possesses over an organization such as the British Medical Association as at present constituted, resides in the benefits which it provides for members. A member who leaves his trade union at a pinch forfeits his right to benefits. This is a very real and tangible hold on members which ceases only when the reserve funds of the union have been eaten up by paying compensation to members who are unemployed owing to their loyalty in adhering to the decisions of the union (strike pay). This advantage is reinforced by the power to make a levy, of an amount assessed by the committee, but not exceeding an amount fixed by the rules of the union. Such a levy may be made in anticipation of a trade difficulty, during a strike, when it can, as a rule, only be made on those members who are continuing to work, or after it is over to reinstate the reserve funds of the union.

The power a trade union has in order to induce an individual member to strike (3), over and above a sense of loyalty to his fellows, is, in the first place, the fear of the loss of benefits to which he has become entitled by his contributions, should he, owing to failure to obey the decisions of the union, incur the penalty of expulsion; and, in the second, "peaceful picketing."

Those who have spoken or written in favour of the establishment of a medical union registered under the Trade Union Acts do not contemplate a strike—that is to say, they do not contemplate what manual labour calls the policy of "down tools." They realize, as every one realizes, that the Insurance Act will have the effect of increasing, rather than diminishing, the need for an effective system of professional defence against encroach-

ments by the Government, by friendly societies, and other forms of contract practice, and by individuals, and they believe that while the old system lacked sanction and was obeyed just so long as obedience was consonant with personal taste, trade unionism would afford the desired sanction for rules and would ensure their observance.

We have endeavoured without prejudice to set out the effect of the law with regard to trade unions, and to indicate the powers and immunities which bodies registered under the Trade Union Acts possess, and we have avoided any reference to what may be called sentimental objections, but objections of this order would have to be taken into consideration if one of the propositions advanced above be correct, namely, that the first necessity for a successful trade union is that it shall include so large a majority of the persons engaged in the calling that the minority, having regard to the action proposed to be taken, is negligible.

THE MENTAL DEFICIENCY BILL.

It will be remembered that shortly after the opening of the autumn session last year the Government announced that it could not find time to press the Mental Deficiency Bill (1912) through all its stages. It decided to complete the consideration in Committee of those portions of the bill which had already been dealt with by the Standing Committee at great length and taking these clauses as a foundation to introduce a new measure this year. This decision had the immediate effect of relieving the Committee from the somewhat obstructive tactics of certain members of the Committee who were strongly opposed to certain aspects of the bill. Accordingly the Committee on December 2nd presented to the House of Commons the torso of a measure consisting of seven clauses dealing with (1) central and local authorities and (2) the method of dealing with mentally defective persons. The sacrifice of the bill called forth outcries of disapproval from those interested and pleas that some attenuated measure should be pressed through without delay.

In these columns the view was expressed that on the whole the delay involved in the withdrawal would be amply compensated by the opportunity afforded for re-drafting it in view of the fundamental alterations that had been made, the fuller knowledge of the subject which had been gained as a result of the discussions in Committee, and not least in order to have the advantage of the expert assistance of the Commissioners in Lunacy in framing the machinery of such an Act.

The new bill was issued on March 31st, and it is clear, from even a cursory survey of its provisions, that the Government and its advisers have made good use of the time and opportunities thus put at their disposal.

In comparing the bill of 1913 with that of 1912 it must be borne in mind that the latter as amended differed essentially from the bill as originally introduced both in regard to the central authority, the categories of defectives subject to be dealt with, and the definition of defectives in general. In all these respects great improvements were made, and with certain subsidiary changes these improvements are retained in the present draft.

Apart from this, the principal points of importance in the present bill may be summarized under a few main heads.

1. *The General Attitude towards the Problem of the Mentally Deficient.*

In regard to this it may be said in general terms that the note now is more definitely and exclusively the interests and needs of the defective for his own welfare; this note was not wanting in last year's bill, but it was not made so dominating, and it was accompanied by the refrain of the interest of society.

We are fortunate in regard to this problem in that what is desirable in the interest of the individual tends also to be largely in the interest of society also, but it became evident during the debates on this matter last year that what Parliament would readily concede if satisfied that any restraints imposed are in the interest of the individual concerned, it would be less ready to sanction solely in the interest of society. This may not be a very far-seeing attitude, but it is one which has to be reckoned with, and it seems likely that the note struck in the present bill will help to facilitate its passage through the Legislature.

As an illustration of this attitude one may refer to the change in the full title of the bill; it is, to make further and better provision for the care of (instead of as before merely "with respect to") feeble-minded and other mentally defective persons, and to amend the Lunacy Acts. Incidentally attention may be called to these last six words which are new. They are clearly required in view of the amendments made last year, but they may be important as allowing an opportunity for further amendments which could hardly have been incorporated under the bill as previously entitled. Indications of the same spirit may be seen in Subclause 6 (3), where the judicial authority is empowered to make an order "if he thinks it desirable to do so in the interests of such person"; and, again, in the omission from the categories of defectives who may be dealt with under the Act those "in whose case such other circumstances exist as may be specified in any order made by the Secretary of State as being circumstances which make it desirable that they should be subject to be dealt with under this Act," although this appeared in the definition Clause 6 (1) *j* of the amended bill; and, further, the clause forbidding marriage with a defective no longer appears.

As regards "discharge"—a question which directly affects the liberty of the individual—the provisions are now specified in the Act, and not left to the regulations to be subsequently framed. A commissioner will have power to discharge at any time any person detained under this Act without certain exceptions.

A parent or guardian may withdraw a defective who has been placed by him in an institution or under guardianship, at any time on giving notice in writing for the purpose to the Board, unless the Board, after considering what means of care and supervision would be available if he were discharged, determine that the further detention of the defective in the institution or under guardianship is required in the interests of the defective.

It will be seen here once more that the interests of the defective are to be the determining consideration, and that the presumption is to be that he may be discharged by his friends unless it is held to be undesirable in his own interests, and not the other way.

2. *Matters nearly Affecting the Medical Profession.*

The constitution of the Board of Control is left as in the amended bill of last session. There are to be not more than fifteen commissioners, of whom not more than twelve shall be paid. Of the paid commissioners at least four shall be medical commissioners. Hitherto half of the paid commissioners have been medical practitioners; now the proportion may be as low as one-third, and there is no provision, as there well might be, that the paid woman commissioner should be a medical practitioner.

Provision is made to remedy a defect of the former bill and to secure that there must be a medical examination before an order is made under the Act.

The local authorities are not to be required to appoint a special medical officer to assist them in the performance of their powers and duties as in Clause 11 of the 1912 bill.

3. *The Idiots Act and the Institutions Registered under it.*

As promised, the Government, while repealing the Idiots Act, embodies clauses which largely re-enact the provisions of that Act under another form in such a way as to leave the procedure simple, as it was under that Act, and not cause hardship to the voluntary institutions.

This has involved a recasting of the definition clause. The definitions of the various classes of persons who are mentally defective which shall be deemed to be defective within the meaning of this Act are put into a clause by themselves. The addition of the words "who are mentally defective" makes it clear that the bill does not cover all classes of mental defect, and that the bill does not, as it were, purport to create and recognize as defective a condition which is not so recognized apart from the bill. This will deprive such criticisms as those of Sir Frederick Banbury of the slender ground and feeble humour which they may have possessed before.

Then in Clause 2 it is simply stated that a defective may be dealt with by being sent to an institution for defectives or placed under guardianship—

(a) At the instance of his parent or guardian, if he is an idiot or imbecile, or is under the age of 21; or

(b) If, in addition to being a defective he comes within certain categories which were defined in the amended bill of last year.

No order is required for the idiot or imbecile or for another type of defective when under 21 to be placed in an institution by a parent or guardian, but a single medical certificate as at present.

4. *Voluntary Boarders.*

This was a question to which we have previously called attention, for which no provision was made in the 1912 bill.

The present measure deals with it indirectly by establishing, in addition to State institutions, certified institutions, and certified houses, a new class of home termed "approved homes." These may be either charitable or semi-charitable institutions, or homes run for private profit. Apparently it will be open to such homes to receive defectives of all kinds defined by the Act without certificate, and without powers of detention, but it will not be open to them to receive or detain any person ordered to be sent to an institution by a judicial or other authority. Such persons may be sent to a certified house, and similarly, if powers of detention are required, a parent or guardian may place an idiot or imbecile, or a defective under 21, in a certified house under a medical certificate. It will be seen that this provides for a feeble-minded adult being cared for in an approved home on a voluntary boarder basis. It is doubtful how far this is applicable to idiots and imbeciles.

Under the bill it will be open to any one to undertake the care and control of one person who is defective without the consent of the Board, provided he gives notice to the local authority and the Board within forty-eight hours after the reception of such person. Presumably the Board will then require lunacy certificates in any case in which these seem to be applicable.

5. *Relation to Educational Authorities.*

The duty of ascertaining what children over the age of 5 and under the age of 16 are defective has been left to the local education authority and not to the local authority under this Act, which will have no duties as respects defective children, except as to those whose names and addresses have been notified to them by the Local Education Authority as:

1. Incapable of receiving benefit or further benefit in special schools or classes, or who cannot be instructed in a special school or class without detriment to the interests of the other children;

or

2. Who on or within three months of attaining the age of 16 are discharged from a special school or class and in whose case the Local Education Authority are of opinion that it would be to their benefit that they should be sent to an institution or placed under guardianship.

In the earlier bill power to deal with defective children under the Act was limited to those leaving special schools at 16.

Provision is made that the cases of defective children dealt with under the Act shall be specially reconsidered by the visitors on reaching the age of 21.

The general effect of this is to attempt an early and complete distinction between the cases suitable for treatment by the educational authorities from those more suitable to be dealt with under the Act. The former cases are reconsidered at 16, the latter at 21.

Conclusion.

Speaking generally, the arrangement of the Act is more logical and orderly, and there has been considerable simplification. Less has been consigned to regulations, and there is evidence throughout of the advice of persons accustomed to the working of machinery of this kind and of the many contingencies and special circumstances to be provided for. There is evidence all through of a conciliatory spirit and of an endeavour to meet the many suggestions and claims that must have come up for consideration from different persons or bodies likely to be affected. An illustration of this is the clause designed to meet the religious requirements of the defective. A general survey of the bill leads to the conclusion that the changes as have been made are calculated to meet many of the defects of the earlier bill and likely to disarm serious opposition.

LITERARY NOTES.

IN Boswell's *Life of Johnson* we find an instance of a physician who was a strong believer in the influence of the mind on the body. He relates that Johnson and he dined with Dr. Butler, then practising at Derby, with whom Johnson, who was always fond of the society of doctors, had a good deal of medical conversation. Johnson said he had somewhere or other given an account of Dr. Nichols's discourse *De anima medica*. He said:

Whatever a man's distemper was, Dr. Nichols would not attend him as a physician if his mind was not at ease, for he believed that no medicines would be of any influence. He once attended a man in trade upon whom he found none of the medicines he prescribed had any effect. He asked the man's wife privately whether his affairs were not in a bad way. She said "No." He continued his attendance for some time, still without success. At length the man's wife told him she had discovered that her husband's affairs were in a bad way.

It may be remembered that when Goldsmith was dying Dr. Turton said to him: "Your pulse is in greater disorder than it should be from the degree of fever which you have. Is your mind at ease?" Goldsmith answered, "No, it is not"—surely among the saddest of all recorded last words.

Dr. Benjamin Jowett, the late Master of Balliol, in his will expressed the desire that the proceeds from the sale of his works, the copyright in which he bequeathed to Balliol College, should be used to promote the study of Greek literature, especially by the publication of new translations and editions of Greek authors. The codicil contains the expression of his hope that the translation of Aristotle's works, begun by his own translation of the *Politics*, should be proceeded with as speedily as possible. The College resolved that the funds thus accruing to it should, in memory of his services to the College and to Greek letters, be applied to the subvention of a series of translations of the works of Aristotle. The series is published at the joint expense and risk of the College and the delegates of the University Press, under the superintendence of Mr. J. A. Smith, Fellow of Balliol College, and Mr. W. D. Ross, Fellow of Oriel College. The intention is that the translations shall aim at being such as a scholar might construct in preparation for a critical edition and commentary. The translation of *De Motu* and *De Incessu Animalium*,¹ by Mr. A. S. L. Farquharson, Fellow of University College, has recently been issued. He makes an acknowledgement to Dr. Guther, Fellow of Magdalen College, for valuable criticisms from the naturalist's point of view, adding that it was difficult to resist the temptation to make the notes fuller in this connexion. He defends the genuineness of *De Motu Animalium*, and says that it certainly gives, except in one difficult passage, the exact doctrine of Aristotle, and states that his defence of the genuineness of Chapter X in particular, which deals with the formal and material cause of movement, the physiological changes necessary to it, and the physical characters of "spirit," was favourably received by the Oxford Philological Society. Mr. Farquharson's notes are numerous, but terse and to the point. A good many of them are concerned with textual criticisms, but as has been implied some of them deal with natural history, and in one of them, at least, he has a dig at the author; of the quotation from the *Hiad* in Chapter IV he says that it is "wrongly quoted *more* Aristotle in order and words."

A new edition of Messrs. Funk and Wagnall's great *Standard Encyclopaedic Dictionary* will shortly be issued. The task of revision has been carried out with such thoroughness by three hundred and sixty specialists that the dictionary is practically a new work. The British specialists include Lord Avebury (financial terms), Sir George C. M. Birdwood (Indian), Admiral Sir Cyprian Bridge (naval), Colonel Sir David Bruce (tropical diseases), Sir James Crichton-Browne (medical), Sir Harry Hamilton Johnston (African), Professor J. P. Mahaffy (classical), Sir Hiram Maxim (explosives), Earl Roberts (military), Archdeacon Sinclair (ecclesiastical), Baron Rudolf Carl Slatin Pasha (Sudanese), Sir Richard Solomon (South African), and Sir William Treloar (cricket and rugs). The prospectus states that the work comprises a vocabulary of 450,000 living terms, or 50,000 more than have ever before been defined in

any one work of reference. A special feature is the number and excellence of the illustrations. All living animals are drawn to scale, and the 7,000 black and white general illustrations are supplemented by a series of colour plates. Among other useful features is the number of illustrative quotations, selected mostly from the more modern standard English and American authors, and accurately "located," the name of the author, the title of the work, the volume, chapter, page, name of publisher, and date of publication being given. It will be thus easy to trace any quotation to its source. Then there is a department of disputed pronunciation; in every such case the word has been referred to a committee of more than twenty-five leading educators and specialists, and their decision is said to form "a consensus of the best judgement of the entire English-speaking world." This department covers all general or common words regarding the pronunciation of which modern dictionaries differ. Another valuable feature is a list of synonyms in which the nicer distinctions of the meaning of words will be given; this should be useful to writers. The total expenditure on this new edition will amount, it is stated, to £300,000.

M. Lucas-Championnière recently presented to the Académie de Médecine, in the name of the authors, MM. Paul Gaffarel and de Duant, a book entitled, *La Peste de 1720 à Marseille et en France*. It is a volume of considerable size, with figures and plans giving full details of that famous epidemic. The authors are not doctors, but all available documents are reviewed and minutely studied, not so much from the medical as from the historical, administrative, and picturesque points of view. These points of view, however, are very interesting, especially as in medical works they are often omitted, and without them the history of an epidemic is imperfect. The disturbance in the life of a city and a whole country by a great epidemic and the administrative needs created by the means of protection, of prophylaxis, and reparation, deserve every attention. It is a valuable work of erudition, which is likely to be serviceable. Even at the present day, when we hope that such scourges may not occur, it is useful to know their history, in order that we may take the means of protection that may become necessary.

In the quarterly *Bulletin of the Medical Library Association* (N.S., vol. ii, No. 3, January, 1913) Mr. Charles Perry Fisher, Librarian of the College of Physicians of Philadelphia, gives an account of the changes in medical periodical literature that have taken place since January 1st, 1909. He gives a list of the periodicals relating to the science of medicine that have made their first appearance since that date, of those that have ceased to appear, and of periodicals that have changed their titles during the same period. Great pains have been taken to ensure accuracy, and the list is believed to be fairly complete. The following is a summary according to languages:—*English*—104 new periodicals, 31 that have ceased to appear, and 32 that have changed their titles. *German* 44 new, 15 defunct, and 12 appearing with a changed title. *Italian*—22 new, 3 discontinued, and 4 changed title. *Spanish*—20 new. *Russian* 5 new, and 1 changed title. *Dutch*—5 new. *Swedish*—1 new; and *Czech*—1 new. The great numerical preponderance of periodicals in the English language is accounted for by the number issued in the United States. The following figures, made up principally from the list of current medical periodicals and allied serials issued by the New York Academy of Medicine, may be taken as approximately representing the existing number of medical periodicals: United States, 630; Great Britain and Colonies, 152, making a grand total of 782 periodicals in English; German, 461; French, 268; Italian, 75; Spanish, 29; Dutch, 13; other languages, 26; total, 1,645. Mr. Fisher says justly: "This is a mighty total for one branch of science. Even if we eliminate reports, proceedings, and transactions, which certainly have their proper place under periodical publications, we have a current list of what are technically called 'journals' of about 1,200 titles."

Messrs. W. B. Saunders Company will publish shortly a thoroughly revised edition of Dr. J. W. H. Eyre's *Elements of Bacteriological Technique*. The book has been rearranged and a new chapter dealing with the study of animals experimentally infected has been added.

British Medical Journal.

SATURDAY, APRIL 5th, 1913.

TRADE UNIONISM AND MEDICINE.

In another part of this issue will be found an article dealing with the legal considerations which arise from the proposal to establish a medical union or unions with objects and regulations rendering registration under the Trade Union Acts possible. The article is a great deal longer than we could have wished, but it seemed necessary to set out the terms of the clauses in the Acts, and an attempt has been made towards its end to state impartially the conclusions which seem inevitably to flow from the premisses.

In the correspondence which has occupied so much space in the columns of the JOURNAL recently, the term "trade union" seems to have been used rather as a counter; its value has not been clearly defined. Yet, in approaching any new subject, the all-important first step is to define the terms used. For the want of this there has been, we venture to think, a disposition to attribute to trade unionism virtues and effects which are conferred upon it not by Acts of Parliament, but by the spirit and the methods which inspire it. Acts of Parliament have been passed to define the powers of trade unions. Each succeeding Act has swept away some previous limitation of common or statute law, but each has sought, perhaps with diminishing conviction, to safeguard the rights of the individual, whether a member of the union or of the general public.

It has been said, half seriously, that in the last resort the final argument of the trade unionist is brickbats. That there is a certain amount of truth in this jeer may be granted; but violence is no necessary part of trade unionism. It is, in fact, contrary to its fundamental principles, which are those of fellowship, and loyalty to each other, among men of the same calling. This may and should be recognized; but it is not a necessary conclusion that the only way for the profession of medicine to attain the same end is by way of registration under the Trade Union Acts. That may, as many now believe, be the right road, but we seem in some danger of mistaking a means for the end. The end is a united profession, strong in its unanimous determination to seek certain objects. A similar end has been the goal of trade unionism; but the successes of trade unionism have been attained through the solid union and hard-bitten determination of members of trade unions. Actuated by this solidarity and determination, they have devised means, and have induced Parliament to remove certain legal obstacles that stood in their way.

But first they have relied on their own grit and their own resources. They have put their hands in their pockets and paid heavy subscriptions and levies. Dr. Cox, in an address delivered as President of the North of England Branch in 1907, stated that inquiries he had then recently made showed that in the case of six trade unions as to which he had been able to obtain information, the amounts paid by the members for organization and protective purposes

alone, quite apart from sick and benevolent benefits, varied from one-fiftieth to one-eightieth of the workman's total income, and we understand that subsequent information showed that in one instance the proportion reached a fortieth of the workman's total income. To take an instance, which is more recent, it appears that the members of the London Society of Compositors paid last year a subscription of 1s. 6d. a week and a levy of 1s., a total of 2s. 6d., or £6 10s. a year. The weekly subscription and levy was high because the members had determined to reimburse the funds of the society for the expenses incurred during a strike in the previous year. This object has been to a considerable extent attained, and the weekly subscription is now 1s. 3d., and the levy 6d., a total of 1s. 9d. a week, or £4 11s. a year. In the return he gets for this are included provident advantages, of which the most important are a superannuation allowance and weekly payments if unemployed, which together account for about tenths of the total expenditure. The remaining expenditure is on trade union purposes of collective defence, and amounts probably to about 25s. out of the total of £4 11s. a year. This he is prepared to pay in quiet times, and willingly provides very much more—two or three times as much—in emergencies. Other workmen in employments in which wages are lower make a contribution as large in proportion to their earnings. No apologist for the profession can claim that doctors make altogether a good showing when compared with the above-mentioned and many other classes of workmen. This may seem a digression, but the point of it is that it is not the Trade Union Acts that count, but the spirit of the men who have caused them to be enacted, and who now make use of them. The question that arises for us is whether the same end may not better be attained without resorting to the same means, which are clearly in certain respects not well adapted to our purpose.

In this country it is not essential that a combination of persons to promote a common object should have legal sanction, but if it is to have any corporate existence in the eye of the law and enjoy a legal status it must obtain State recognition. In seeking this it appears to have three courses open to it—to obtain a charter from the Crown, to become registered under the Companies Acts, or to seek registration under the Trade Union Acts. The licensing corporations possess charters, some of them of respectable antiquity. The British Medical Association is registered under the provisions of the Companies Acts which permit recognition of an organization which does not trade for the profit of its individual members. It was brought into existence to supply the deficiencies of the chartered corporations, which, with real regret it must be admitted, have not risen to the height of their opportunities. Had they shown a higher sense of duty, greater wisdom, and more elasticity, the British Medical Association might never have been called into existence to take up the work they left aside. A few years ago the British Medical Association applied for a Charter from the Crown which would have greatly facilitated the work which the members of the profession, for the most part diplomates of the chartered corporations whose help had failed, had set it to do. The Association had to undergo the humiliation of the refusal of a State recognition often granted to bodies of far smaller membership and far less importance to the welfare of the State. It is useless now to seek to apportion the blame for this rebuff, but it was not all on one side.

The strength of trade unionism lies not in forms or laws, but in the union and solidarity it has bred. This solidarity it has brought about partly by encouraging the growth of a feeling of fellowship among men engaged in the same calling and partly by politically making the growth of this feeling keep pace with the material interests of the individual members.

The proposal to form a medical union or unions registrable under the Trade Union Acts is one which needs to be threshed out, and, so far as the administration of the JOURNAL is concerned, the desire is to give full scope for the beating out of the grain from the chaff. While, therefore, inviting discussion, we venture to submit that the use of counters should be given up, and that we should deal with real values, distinguishing the essential from the accidental. Some of the discussion which has already taken place seems to have failed to make this distinction.

SYPHILIS AND CANCER OF THE TONGUE.

DESPITE the great amount of work that has been done in different parts of the world during recent years in the various problems of cancer, the immediate causative factor has so far eluded even partial solution: and the search for a cause would seem hitherto to be as fruitless as the mediaeval quest of the philosopher's stone. Only in a negative sense can we be said to have approached the difficulty. Many of the opinions and speculations of former days that clustered round and obscured the problem have been got rid of, but there are only contending theories still with which we may attempt to satisfy an insistent question. There will be those who will continue to advocate a germ or parasitic theory of cancer genesis; and, indeed, of the finding of parasites there is no end, but all have come, whatever may have been their temporary vogue, sooner or later to nothing. It is but natural, too, that the mind of man in constructing hypotheses on which to base a prospective investigation should choose the most easy generalization from sets of known phenomena. It is easy, for example, to comprehend a possible parasite, not perhaps demonstrable by known means of staining, cultivation, or isolation, which, becoming incorporated with the substance of a cell, causes division and propagates with it, and any one possessed of such a belief may easily spend his life in this quest, but it is no difficult task to argue, both *a priori* and from recent observations, against such an assumption. The problems, however, of that unceasing cell division which constitutes cancer are probably only soluble as parts of a greater biological problem. A recent writer has put the case as follows: "Those properties that pass from parent to offspring, shaping the growth of constituent parts, marvellously reproducing in minute pattern the structural characteristics of the ancestors as a species, or still more marvellously repeating the little details that give an individuality to a progenitor, have always been in the domain of mysterious fact, obtrusive to our eyes, but inscrutable to our minds. All the cellular components of the living body obey laws governing the limits of their reparative or reproductive activity. Why they should cease multiplying when they have fitted into or restored a predestined scheme is quite beyond our knowledge. Cancer is anarchistic to the economy. It is a multiplication of cells derived from parent tissue normal to the body; springing from it, it grows without heed to the order

of things, lawless in its origin, lawless in its progress. Until we recognize that, ignorant of the laws that govern and limit normal growth one cannot hope by some chance observation to light upon the causes that operate at the inception of that cellular disloyalty, we cannot appreciate the profundity of the problem."¹

Whatever be the immediate cause of malignant change, there are often predisposing or mediate factors that preside at its onset, and we may suppose that, were these mediate factors obviated, the cancerous process would not ensue. By piecing together the appearances found in precancerous and early cancerous lesions we can formulate a series of pictures of the events in their sequence. But it would be wrong to generalize from such observations, for the simple reason that in the great majority of cancers no history of definite preceding, nor histological evidence of accompanying, irritation can be obtained. The factor of irritation is, however, sometimes very definite. To the old classic example of the irritating clay pipe as a predisposing cause in the production of cancer of the lip may be added other striking examples, such as the kangri pot of Kashmir in association with the occurrence of squamous carcinoma of the skin of the abdomen, betel-nut chewing with the production of epithelioma of the cheek and tongue, lupus with skin cancer, bilharziosis with cancer of the bladder, nematode with cancer in the rat (Eibiger),² and the accidental production of epithelioma of the hands amongst x-ray workers. In other cases, again, an association of different definite irritants has a conspicuous part in bringing about malignant cellular proliferation.

In the lecture published in this issue Mr. Charles Ryall traces the various factors that, operating together, bring about cancer of the tongue. These he considers to be primarily syphilis, and secondarily smoking and other milder forms of irritation on a vulnerable organ. The points he puts forward in support of his thesis are the results of clinical observations extending over many years at the Lock and at the Cancer Hospitals. By keeping under observation cases of syphilis that showed lingual lesions he has noticed the onset of cancerous ulcers in the tongue, and by a careful interrogation of patients who presented epithelioma of the tongue he has found a history of syphilis in over 80 per cent. of cases. In further support of the association may be evidenced the frequency with which cases of lingual cancer give a positive Wassermann reaction of their serum. The mild irritation of tobacco smoking under normal circumstances may not affect the tongue, but when the patient is the subject of syphilis it would seem to determine the localization of tertiary lesions in that organ. A tertiary syphilitic lesion of the tongue may be, and probably often is, a precursor of lingual cancer. The vulnerable organ now responds to irritations which otherwise would be innocuous, and chief amongst these sources of irritation is tobacco. In syphilitic glossitis there are changes in the epithelium, proliferations here and denudations there, whilst beneath the papillae there are going on cellular changes, round-cell infiltration, lymph stasis, and fibrotic contraction, resulting in the production of superficial puckering and fissures. In these fissures debris collects and small ulcers are apt to form; continually irritated, the epithelium of the edges grows into these ulcerated fissures, into an abnormal non-resistant tissue, and malignant proliferation of epithelium may result. It may be that the mild

¹ Leitch: Fourth Report of Caird Cancer Research Laboratory.

² BRITISH MEDICAL JOURNAL, 1913, vol. 1, p. 400.

irritation produces an exaggerated repair by epithelial cells, and that this reparative tissue itself, still subjected to irritation, goes on reproducing; but why, on passing beyond the confines of its focus of origin to where the irritation no longer obtains, it should not be arrested, is a crucial fact for which no one has furnished a plausible explanation.

In the later stages of such an ulcer the diagnostic points are clear, but while it is still minute and productive of but little pain only microscopic examination of a portion removed can settle its nature, as the late Sir Henry Builin so frankly and conclusively pointed out in this JOURNAL a few years ago. Mr. Ryall emphasizes the undesirability of attempting to solve the condition by the administration of anti-syphilitic remedies, or by the result of the Wassermann reaction, seeing that such a large percentage of lingual cancers supervene on, or are associated with, syphilitic tongue lesions. An early diagnosis is essential, and under these circumstances operative measures bring hope of total eradication of the disease, and much can be done at any stage to mitigate, if not to cure, a most distressing condition; but, in view of the part that syphilis plays in the production of lingual cancer, it will be agreed that here, at any rate, thorough treatment of a predisposing condition that is so clear may succeed in preventing such a grave sequela.

MILK AND DAIRIES BILL.

Once more the President of the Local Government Board has brought in a Milk Bill. Every year that he has occupied the position he now so worthily holds the President has brought in, or intended to bring in, a Milk Bill. Some years circumstances were too strong for him, and the Milk Bill was crushed out by bills which were considered more important. Other years the Milk Bill saw the light of day, but after a brief existence was cast into that limbo for bills where they never become Acts. One died a few weeks ago when the last Parliament was prorogued. The new bill, phoenix-like, arises from its ashes. In the main it is very like its predecessor, and we sincerely hope that it may meet a better fate. The main objects of the bill are to provide for: The more effective registration of dairies and dairymen; the inspection of dairies, the examination of cows, and the examination of milk; the prohibition of the supply of milk from a dairy where such a supply has caused or would be likely to cause infectious diseases, including tuberculosis, and the prevention of the sale of tuberculous milk; the regulation of the importation of milk so as to prevent danger to public health arising therefrom; the issue of regulations for securing the supply of pure and wholesome milk, and the establishment by local authorities in populous places of milk depôts for the sale of milk specially prepared for infants. The provisions as to the inspection of dairies and the prohibition of the supply of milk are based on the provisions of the Public Health (Scotland) Act, 1897, and the clause as to the prohibition of the sale of tuberculous milk is taken from the model milk clauses which have been incorporated in many local Acts, but the scope of the enactment is somewhat extended. Under the order of the Board of Agriculture, as to payment of compensation in cases of slaughter, which comes into force on May 1st the Treasury has agreed, subject to the assent of Parliament, to sanction the payment of one-half the

net amount to be paid for compensation for the next five years.

In the bill there are two entirely new clauses, No. 16, which deals with the cost of structural alterations, and No. 24, dealing with procedure on appeals to courts of summary jurisdiction. Clause 14 deals with the appointment of veterinary inspectors, and says that the council of any county or sanitary authority shall, when required by the order of the Local Government Board, appoint not only veterinary inspectors, but also a bacteriologist. This is a step in the right direction. In Clause 27, which deals with the application to London, there is a very important omission. In the former bill the London County Council occupied a position of paramount importance. The paragraph in the clause giving them that power in the last bill has been deleted and the powers under the bill are given to the sanitary authorities, and only in case of default to the County Council. If this had been proposed during the period when the Progressives were in power in London, it would have met with determined opposition from that party. But the policy of the Municipal Reformers has been in favour of delegating powers to the borough councils, who are for London the sanitary authorities, and they may accept the clause as it stands and look upon the President of the Local Government Board as a good Moderate. On the whole, we are inclined to think that if in carrying out a Milk Bill the London County Council was given the right to shape the policy the work would be done more energetically, and the effect would be more harmonious than it would be if carried out by several authorities within the area of the county. In dealing with the question of a pure supply of milk, any bill on right lines should give power to see to the health and cleanliness of the cow, its environment, and the people who care for it. The bill, we think, gives this power. Under Clause 15 the Local Government Board asks for large powers to make such general or special orders as it thinks fit for the purpose of carrying out the Act, and among these powers are the care of the cow, the cowshed, the workers, and the vessels used for or containing the milk. Though it is not so clear that the bill under 15 (1) (g) gives the Local Government Board power to deal with the transit of the milk, yet such power may be obtained under this subsection, which reads: that an order may be made as to "the manner of conveyance of milk intended for sale for human consumption, and the identification of cisterns and vessels used for such conveyance." When the milk has arrived at the milk dealer in the town, under the interpretation of the Act the expression "dairy" includes not only any farm, farmhouse, or cowshed, but any milk store, milk shop, or other place from which milk is supplied, and with these places the bill gives the sanitary authority power to deal. The distribution of the milk from the shop by the milkman on his rounds gives great opportunity for tampering with the milk and the introduction of impurities. Power to deal with these evils does not seem to be specifically given in the bill, but that is a matter in which it can and should be strengthened during its passage through the House. The bill as it stands, though far from perfect, is a distinct step in the right direction, and if the friends of public health in the House of Commons are determined that the people of this country shall have pure milk to drink, and unite in amending the bill to achieve this purpose, we are hopeful that the bill, when it becomes an Act will accomplish the end they desire.

The Milk and Dairies Bill does not apply to Scotland

or Ireland, but as far as Scotland is concerned the gap has been filled by the Milk and Dairies (Scotland) Bill introduced by the Secretary for Scotland on April 1st. We are glad to note that by this Scottish bill it is intended to ensure the purity of milk supplies and to regulate dairies in Scotland, as the purity of the supply, which is of paramount importance, is thus given due prominence. Clause 3 of this bill deals with the appointment of veterinary inspectors, but differs from the English bill in that it makes no definite reference to the appointment of a bacteriologist—a defect which should be remedied. The Scottish bill is more definite in the question of the notification of employees suffering from illness, for it declares in Clause 12 that if any person resident at or employed in connexion with any dairy, or who resides in the same house as any person so employed, shows symptoms of any infectious disease the dairyman on becoming aware thereof shall forthwith report to the Medical Officer of Health for the district the existence of such illness; it would provide also that it shall not be lawful for any such person to milk cows or handle milk vessels or in any way to take part or assist in the conduct of the trade of a dairy. The veterinary inspector would have power, with the consent in writing of the owner, to apply to any cows in any dairy within the district the tuberculin or other reasonable test for the purpose of discovering whether such cow is suffering from tuberculosis. To the local authority power is given to enforce the provisions of the bill, but it may if it think fit delegate that power to a committee or committees. These are some of the differences between the English and the Scottish bills in so far as they more precisely touch the question of public health. It would be for the benefit of the community and the improvement of both these bills if their authors, old colleagues in the London County Council, would put their heads together and arrange that the deficiencies in one bill be supplied by the good points in the other, so that both countries might ultimately have the advantage of the best possible Milk and Dairies Act.

ACTIVATORS IN FOODS.

DURING the last five or six years many references have been made to observations and researches tending to show that certain common articles of diet contain minute quantities of substances which are of so much importance in nutrition that their absence may prevent the normal growth of young animals, or lead to actual disease in them or in adults. The steps by which the subject has been opened up have been recorded from time to time in the JOURNAL, but the matter possesses so much scientific interest, and has already attained so much practical importance, and is likely to increase so greatly in both respects, that the summary of present knowledge which has been prepared for us by Mr. E. A. Cooper, Beif Memorial Fellow at the Lister Institute, will be read with profit, and will be useful for reference in the future. The facts ascertained as to the etiology of beri-beri first put physiologists on the track.¹ The epidemiological observations of Eykman and Braddon showed that beri-beri was associated with a diet of polished rice, that is to say, rice from which the outer covering was completely removed. Braddon added the significant observation that the disease did not ensue if the rice was parboiled before polishing. The characteristic lesion of beri-beri is polyneuritis, and Eykman showed that birds fed on polished

rice developed extensive polyneuritis, and further that this condition could be cured by giving the birds aqueous extract of rice-polishings. Later it was shown that exclusive diets of various pure carbohydrates induced polyneuritis in birds, and that foodstuffs other than unpolished rice could prevent it, but that their preventive properties were destroyed by heating to 120° C. An exclusive diet of polished rice causes a loss of body weight as well as polyneuritis, and it has been found that the addition to the polished rice diet of an amount of a foodstuff sufficient to prevent neuritis may fail to check the loss of weight. The general conclusion is that there is removed from rice during the process of polishing a nitrogenous substance which is essential to normal metabolism, especially of the nervous system. It is probably a pyrimidine base, but it exists in such minute quantities and is so easily destroyed during chemical manipulations that its exact nature has not yet been ascertained. The outbreaks of beri-beri which have occurred from time to time among the crews of sailing ships on long voyages have been an epidemiological puzzle. Their investigation in the light of the new knowledge as to tropical beri-beri seems to have proved that they are due to replacing rye bread and peas in the crews' dietary by white bread, and has suggested wider generalizations; *pari passu* the problem of scurvy has been attacked along the same lines. Here Mr. Cooper has to deal with very recent work, and what he has to say with regard to scurvy and infantile scurvy and their dependence on a deficiency of certain specific accessory substances in the diet will be read with particular interest in this country to-day. Of even greater immediate practical importance here and now are, perhaps, recent investigations showing that the abstraction or destruction of certain substances present in small amounts in normal or unmodified foods leads to a failure of growth. The composition of these substances has not yet been ascertained, but whatever their nature they appear to possess the power of so stimulating metabolism as to cause growth at the normal rate. It will be seen, therefore, that these observations on beri-beri, on scurvy, and on growth, have opened up a new field of inquiry in dietetics. They serve to show that some modern methods of preserving and preparing food have been running on wrong lines, that we have been disturbing the balance of nature, and that we must hark back to the original scent.

VENTRIFIXATION OF THE UTERUS.

THE recent discussion on ventrifixation in the Obstetrical and Gynaecological Section of the Royal Society of Medicine clearly shows how much diversity of opinion still exists among representative gynaecologists upon fundamental points, such as the general usefulness of the operation, and the risks, immediate and remote, which attend it. The introducers of the discussion were all convinced advocates of the operation, two of them—Professor Henry Briggs and Dr. Arthur Giles—having between them performed it in over 1,100 cases, with results which gave them unqualified satisfaction. At the other extreme of opinion was Professor Herbert Spencer, who stated that he had only done the operation 27 times in 1,000 abdominal sections, and declared his conviction that, "as ordinarily performed," the operation was unscientific and dangerous. Other critics, less strenuous in their opposition, regarded with disapproval the frequency with which the operation was performed at the present time. Underlying these striking differences of opinion there was clearly an equal divergence upon the fundamental question as to the clinical importance of the so-called malposition of the uterus which ventrifixation is designed to correct. Little divergence of opinion emerged upon the importance of correcting prolapse and procidentia, and the value of

¹ There was a short discussion on the subject in the Section of Physiology at the annual meeting of the British Medical Association at Liverpool last year, opened by a paper by Funk (BRITISH MEDICAL JOURNAL, September 28th, 1912, p. 787).

fixation of the uterus when combined with plastic repair of the pelvic floor seemed to be very generally accepted, though Dr. Archibald Donald declared that all cases of prolapse could be permanently cured by colpoperineorrhaphy alone when properly performed. With regard to backward displacements, however, great diversity of opinion clearly existed among gynaecologists of large experience, and to this difference is mainly attributable the striking want of unanimity displayed in regard to ventrifixation. By more than one speaker the introducers of the discussion were asked, "What are the symptoms of backward displacement?" Until gynaecologists have settled this fundamental question no discussion of the methods of treating this condition can reach conclusions likely to be accepted as authoritative by the profession. Two or three points of practical importance finally emerged from the discussion. When ventrifixation is properly performed—that is, in such a manner as to leave the fundus free—it may be accepted that there is practically no risk of complications should pregnancy subsequently occur. The cases of rupture of the (ventrifixed) parturient uterus which have been from time to time recorded have now been shown to be the result of faulty technique. Further, it may be accepted that in a very large proportion of cases—95 per cent. in Dr. Giles's series—the malposition can be permanently corrected by this operation. On the other hand, it must be borne in mind that the operation is not free from either operative or post-operative risks; fatalities have been recorded in the practice of gynaecologists of repute from peritonitis and from pulmonary embolism, and more remotely from intestinal obstruction due to strangulation of a coil of intestine by bands of peritonic adhesion formed between the parietes and the uterine wall, or between the shortened round ligaments and the uterus. An operation so simple and easy of performance as ventrifixation is undoubtedly attractive to operators; but it is clear that it should not be recommended or undertaken without due consideration of the question which so often taxes the surgeon's judgement—namely, Is the malady of sufficient gravity to justify the risk to life involved in the proposed operation?

THE WELFARE OF THE DEAF.

In the penultimate of the series of lectures which he has been delivering under the auspices of the National Bureau for Promoting the General Welfare of the Deaf, Dr. Kerr Love showed that a great proportion of all cases of deafness observed during the first months of life are due to congenital syphilis, and put in a strong plea for the compulsory notification and treatment of all cases of syphilis in children.¹ In his concluding lecture he dealt mainly with congenital deafness of another type, that which is both congenital and hereditary. According to his investigations this form of deafness could not be held responsible for more than 15 per cent. at the outside of all instances of deaf-mutism. Previous discussions on the point had been vitiated, he suggested, by the frequent acceptance of deafness in several children of one family, or of cases of partial deafness or hardness of hearing in an earlier generation as proofs of inheritance. Deafness was a symptom which might not only be due to a very large number of totally different causes, but was present to a greater or less extent in the vast majority of all individuals at some time or other of their existence. He agreed that members of some families showed a special tendency to develop oto-sclerosis, and that this might possibly be a form of hereditary deafness; but little was known as to its true etiology, and meantime it was safer to admit to the rank of hereditary deafness only cases in which the patient was not the subject of congenital syphilis, but was born deaf, and was a member of a family in previous generations of which like cases were known to have

occurred. Though precise Mendelian ratios could hardly be expected among the deaf, a large collection of family trees the lecturer exhibited supported the conclusion that true hereditary deafness conformed to the Mendelian theory. The condition was transmitted either wholly or not at all. Its subjects were hardly ever merely just hard of hearing, or, conversely, totally deaf, their degree of perception of sound was a fairly constant quantity. The feature was recessive, and was most commonly transmitted through hearing people. Assuming that hereditary deafness was Mendelian, Dr. Kerr Love proceeded to show that consanguinity in the parents produced the maximum chance of hereditary deafness occurring in the offspring. Taking his estimate of the total number of hereditary deaf people in Great Britain—namely, 3,600—and those of their forbears whom he assumed to be deafness-carriers, though possessed of hearing themselves, he pointed out that there must be over 10,000 people in the country whose marriage was likely to be followed by the propagation of deaf-mute but otherwise healthy children, and that repressive measures, if they were to be successful, must apply to the whole of these 10,000, and not only to those who were themselves the subject of deafness. He showed himself, however, by no means in favour of direct interference with the marriage wishes of the deaf. The right step to take was to put an end to conditions originally established by well-meaning persons in the interests of the deaf themselves, but which in the long run tended to increase the number of deaf persons. Communication between deaf persons being easy, and a bond of union between them already existing, it was natural that the deaf should tend to associate with the deaf, and hence that they should intermarry. This tendency was greatly promoted by the present custom of segregating deaf-mutes during the educational period of their life, and the remedy lay in the spread of the day-school system, so that the deaf out of school hours should not associate with one another. Furthermore, speech and lip reading should be made the ordinary means of communication between teacher and scholar and between the deaf and their hearing friends. Finally, all the deaf during the last year of their school life should be warned against the danger of intermarriage.

INTERMEDIATE HOMES FOR INCURABLES.

"The Christianity of the future," said George Tyrrell near the end of his life, as we have been reminded by the article in the Literary Supplement of the *Times* which made some stir a fortnight ago, showing once more, if there were need, that man doth not live by bread alone—"the Christianity of the future will be mysticism and charity." The saying runs counter to some current doctrines reflected in current legislation. But charity rests on an impulse of human nature which helps most to distinguish man from the brute. The feeling of pity for misfortune is deep-rooted in at least the higher races of man, and will not easily be bred out. Charity suffereth long and is kind, and nowhere is there greater scope for the exercise of this long-suffering virtue than in caring for those incapacitated from taking their due share in the work of the world by incurable disease or deformity, and of such none can make a stronger appeal than the young. Our attention has recently been called to the fact that there was a chasm in this field of charity across which certain charitable persons have built a slender bridge. The Home for Incurable Children at "Northcourt," Hampstead, is well known to many, and the larger homes for incurables, such as those at Streatham and Putney, still better, but at Northcourt girls are not kept after the age of 16, nor are women admitted into the Streatham or Putney homes until they are 30 or 35. It is, therefore, often a problem where to send them during the intervening years. They are frequently homeless, or, if their

¹ BRITISH MEDICAL JOURNAL, vol. ii, 1912, p. 1682.

parents are living, they are not able to afford to give them the care and attention necessary to maintain the benefit derived from previous treatment. In order to meet this want, the first "Intermediate Home for Girls" was opened at Upper Hale, near Farnham, about three years ago. It is known as The Mary Yolland Home, and is primarily intended for cases from Northcott, who pay 7s. a week; when there are vacancies, however, others are admitted for a small extra payment (usually 8s. a week). These payments do not cover the cost of upkeep, so that subscriptions and donations are gratefully received by the Honorary Treasurer at 14, St. Stephen's Square, London, W. Applications for admission must be made on printed forms, to be obtained from the Honorary Secretary, 5, Kensington Square, W., and must be approved by the medical officer and committee. No person who is epileptic, mentally afflicted, or phthisical is eligible for admission. There are ten beds, and there is a vacancy now, owing probably to the fact that two girls have become well enough to earn their own living, and are leaving the home. The President is the Bishop of Winchester, and there is a strong representative local committee, in addition to a committee of management in London. Dr. Coad of Farnham is the Honorary Medical Officer and Dr. Rice-Oxley the Honorary Consulting Physician. The home is excellently situated on high ground, and has a pleasant, well-stocked garden. Dr. Coad is able to report that under the matron's judicious care the inmates have been encouraged to help themselves more and more, so that they are doing things for themselves which six months ago both they and others thought it impossible for them to do. The girls are taught and encouraged to do needle-work, and won gold stars at the Home Arts Exhibition at the Albert Hall in May, 1911. They are glad of orders, and receive 15 per cent. on the price of all articles sold. Any one caring to visit the home will be welcomed by the matron.

IN MEMORIAM—EDWARD ADRIAN WILSON.

On March 27th a memorial service for Dr. Adrian Wilson was held in the chapel of Cheltenham College, the day being specially selected as the probable anniversary of the death of Wilson and his fellow explorers in the Antarctic expedition. Cheltenham College has always shown itself very jealous in caring for the memory of its old boys who have distinguished themselves, and in honouring Dr. Wilson it links up the past with the present, and so exerts a profound influence in making them feel that their future will be appraised, when the time comes, by those who, whether now their masters, schoolfellows, or mere on-lookers, will then be their critics. Ceremonies of this kind are no rare occurrences at Cheltenham College, for it has become a great training school for the army, and it is owing to this partial specialization that the very beautiful chapel contains so many mementoes of men who have died in the military service of their country. At the east end is a stone reredos of rare beauty, raised to the memory of fifty-four Old Cheltonians who were killed in the last Boer war, and scattered over the walls and placed beneath the canopies of the stalls are brass tablets to the memory of those who distinguished themselves in their various careers. Among these tablets is one to Dr. Wilson's uncle, Sir Charles W. Wilson, K.C.B., F.R.S., who surveyed Jerusalem, Palestine, and Sinai, and went up the Nile to open communication with Gordon at Khartoum. Among the statues in the reredos are three of especial note at this moment—one to Livingstone, whose centenary has just been celebrated; one to Sir John Franklin, who discovered the North-West Passage; and one to Dr. Edward Jenner, who lived in Cheltenham, and made some of his vaccine investigations there. Truly is Wilson honoured beneath the shadow of the effigies of departed heroes and benefactors. Perhaps the most striking monument in this chapel is

the memorial to the late Frederic W. H. Myers; it consists of a bronze medallion portrait and a remarkable emblematic wood carving of the Tree of Life interspersed with birds and animals, the whole leading up to a fresco by Eadie Reid portraying the commencement of the Resurrection. The legend on the tablet—"Striving to win his own soul and his comrades' homeward way"—seems especially applicable to Wilson and his companions, whose gallant attempt to win their "homeward way" failed by only eleven miles! The exact nature of the memorial to Wilson has not yet been determined. That it will be worthy of him and fitting may surely be anticipated, because the whole atmosphere of the school is one of beauty, of duty, and of reverence, and the spirit of the man who was the subject of the day's reunion in this Pantheon of distinguished Old Cheltonians will arouse corresponding high ideals in the minds of those who came under the spell of his courage and devotion and who have the responsibility of perpetuating his admirable qualities. At the service there was a crowded attendance—the 600 boys of the school; the father, mother, and other relatives of the deceased, and many respectful sympathizers and admirers. The choral service was intoned by the Rev. P. Hattersley-Smith, well known to all Old Cheltonians, and a very eloquent and human address was given by the Principal, Canon R. Waterfield. In recording the names of Wilson and his deceased comrades the whole congregation stood up, and a great impression was produced when the Principal declared that it was Dr. Wilson's intention, had he returned safely, to have taken orders. Canon Waterfield also read a letter from the late Captain Scott, in which he said that "Wilson was the finest character I ever met. Practical, loyal and unselfish, humorous and tactful—the most popular member of the party." When the memorial has been placed in the chapel, Cheltenham School, the Principal said, will have done its best for one of its most distinguished sons. It trained him for five years in his youth, and it will preserve his noble example and courage by a permanent mark which shall keep him ever present to the young minds whose best appreciation will be shown by their efforts to emulate him.

DOCTORS IN DISPRAISE OF MEDICINE.

It is remarkable that some of the bitterest things said in dispraise of medicine have come from the mouths of doctors. In 1748 François Quesnay, whose reputation as a physician is overshadowed by his fame as a pioneer in social economics, published an essay on the great quarrel between the physicians and surgeons in France. He begins by saying that the first point to be decided is whether these professions are useful or injurious to society and whether they should be abolished or allowed to continue to exist. It may be gathered that he was sceptical as to the utility of drugs, for he points out that among the poor treatment is very simple, consisting in bleeding and the administration of *tisanes*, a few purgatives, and very little else. This, he says, is "perhaps the best" that can be done. It is related that when Lieutenant, first physician to Louis XVI, was near his end in 1780, his confessor, wishing to assure himself that he was in a right frame of mind, plied him with questions as to his belief in all the mysteries of religion. At last the dying man, wearied by these interrogatories, declared that he believed in everything except medicine. James Gregory, President of the Royal College of Physicians, Professor of the Practice of Medicine in the University of Edinburgh, and First Physician to His Majesty in Scotland, in his *Memorial to the Managers of the Royal Infirmary* (second edition, 1803, p. 137), says: "Of the many bitter sarcasms which I have heard of on my own profession and professional brethren, one of the severest, I think, was that of

Dr. Garth on his deathbed; when one of his friends who thought he had repeatedly owed his life to the care and skill of the doctor came to see him, sorry to lose his friend and physician, yet anxious to ask him what physician he would advise him to send for if he should again be taken ill, 'Send for the nearest,' said Dr. Garth." These utterances need not be taken too seriously. They are indications of the state of mind expressed by Du Maurier many years ago in a drawing showing an anxious wife trying to induce her sick husband to send for one of his colleagues and being met with a refusal because "we all go in for thinking each other quacks now." Doctors as a class are perhaps, in Bowen's famous phrase, too conscious of each other's unworthiness, and are apt in their haste to extend this feeling to the art which they practise.

INDIAN REVENUE AND THE OPIUM TRADE.

The financial statement recently laid before the Viceroy's Legislative Council by Sir Guy Fleetwood Wilson shows the Indian revenue to be in a highly satisfactory position. A surplus of some seven millions has been realized on the year 1912-13, derived for the most part from railways and opium. In regard to the latter, it appears that, owing to high prices obtained from sales by the Government of certified opium in the earlier months of the financial year, the actual revenue derived from this source alone is likely to be £5,063,000, as against £3,600,000 which was budgeted for. Sir Guy Fleetwood Wilson, in his annual review of the Indian finances, dwelt upon the novel and exceptional aspect of the opium question with which the Indian Government is now confronted in respect of the trade with China as governed by the agreement of May 8th, 1911. The period of revolution, which was marked by a recrudescence of opium consumption and cultivation, has been followed by repressive action on the part of the Republican Government, which outbids the severity of the former Imperial régime. The result is that in Shanghai and Hong Kong, the great markets of the Indo-Chinese traffic, the trade is at a standstill. The Indian Government claims that its own policy has been throughout correct and simple, and dictated by a sincere desire to help China towards a great moral reform. Sales of Indian opium are suspended; the amount to be sold for non-Chinese consumption in 1913 has been reduced so as to minimize smuggling into China, and the Government has purchased from the native States an amount of Malwa opium which would otherwise have been exported by them to China during the current year. It would appear to follow almost of necessity that a reduction will soon have to be made in the poppy cultivation at present carried on as a monopoly by the Indian Government. Any attempt to enforce the sale of the drug upon China would be resisted here as well as there, and the time is surely fast approaching when the much criticized and oft condemned Indo-Chinese opium trade will be no more.

SANITARY ADMINISTRATION IN ILFORD.

The population of Ilford, Essex, in 1891 was about 10,000, and in 1911 it was 78,000. This large increase has of necessity involved additional responsibilities in connexion with the sanitary administration of the district, and the urban district council was well advised in 1909 to appoint Dr. C. F. Stovin as a whole-time medical officer of health, he having been a part-time officer during the previous eleven years. Dr. Stovin prefaces his annual report for 1912 with an account of what he conceives should be the relation of a medical officer of health to the district council and to the other officers of the council. The views he expresses would be readily endorsed by other medical officers of health, and are quite in accordance with the recognized policy of the Local Government Board, which is that the medical officer of health must be the head of the Public Health Department. In the course

of inspections of houses made by members of his staff, Dr. Stovin appears to have been startled at the large number of drains to comparatively new houses which were found to be defective. Dr. Stovin states in his report that among 277 houses inspected in three years because a drainage nuisance was believed to exist there was not one where the drains were not defective. This serious condition is said to be due to the fact that the by-law of the district council requiring concrete to be laid under every drain laid to a new house has not been sufficiently enforced. It might be supposed with these facts before them that the members of the urban district council would give all the support possible to the medical officer of health in his endeavours to improve the sanitary condition of the town. Instead of this, however, they are alleged to have placed obstacles in his way and hampered him in carrying out his duties. Dr. Stovin suggests that the only way out of the deadlock which has arisen is to ask for an inquiry into the circumstances from some expert authority; the Public Health Committee of the British Medical Association has expressed the opinion that the proper body to make such an inquiry would be the Local Government Board. What objection there can be to carrying out this suggestion it is difficult to understand, and in the interests of good government the district council will do wisely to give effect to it promptly and wholeheartedly.

SECRET REMEDIES AT THE ANTIPODES.

We referred recently to the fact that the Government of the Commonwealth of Australia had obtained the permission of the British Medical Association to reprint as a parliamentary paper the two volumes, *Secret Remedies*¹ and *More Secret Remedies*,² issued by it in 1909 and 1912 respectively. The two volumes are printed together, and form a folio document of 245 pages. The single index given with the second volume, *More Secret Remedies*, is reproduced, and serves as an index to the whole. So far as we have observed the two volumes are reprinted in the Commonwealth Blue Book without alteration or curtailment. No introductory letter or report appears in the print, and apparently the Commonwealth Government is of opinion that the matter speaks for itself, and requires no introduction or recommendation to ensure adequate attention from the public and from the members of the Commonwealth Parliament. It will be seen from a report published at page 724 that the Select Committee on Patent and Proprietary Medicines has resumed its sittings in London, and that further evidence is being tendered on behalf of the proprietors of proprietary preparations. The two volumes, *Secret Remedies* and *More Secret Remedies*, are on sale in this country as published by the British Medical Association, and can be obtained through any bookseller. There can be no doubt that their effect has been to educate public opinion and incidentally to call the attention of proprietors of newspapers to the use which is made of their advertisement columns to commend to the public preparations often sold at most extravagant prices, and for which extravagant claims are almost invariably made.

THE APPOINTMENT OF TUBERCULOSIS OFFICERS.

We are afraid from information we have received that some of the county councils have not gone about the appointment of tuberculosis officers in a manner most calculated to make this service the most efficient available. It is, of course, quite right and proper for county councils to have the benefit of the advice of the medical officer of the county as a professional man in sorting out and settling points of distinction between various candidates in respect of their special suitability for such a post.

¹ *Secret Remedies: What They Cost and What They Contain.* London: British Medical Association. 1909. (Price 1s., post free 1s. 3d.)
² *More Secret Remedies: What They Cost and What They Contain.* London: British Medical Association. 1912. (Price 1s., post free 1s. 3d.)

but it cannot be necessary that candidates for these appointments should, in addition to their special knowledge of tuberculosis, have had special training in public health, a qualification which we believe has been made a requirement for several of these appointments. A competent knowledge of bacteriology is all that ought to be expected in addition to the candidate's special qualifications for the work. There seems to be a disposition in some quarters to make the tuberculosis officer a member of the staff of the Public Health Service, in subordinate charge of a subdepartment. There must be co-operation, but subordination is unnecessary and undesirable. In matters of administration, in the wider meaning of the term, the medical officer should be in command, but in his clinical work the tuberculosis officer should be unhampered. The importance of the clinical work makes it always desirable that he should have some knowledge of general practice, and this experience is far more valuable than the possession of the D.P.H. Medical officers of health would be well advised to give attention to this aspect of the subject, and to take care that they are not biassed in favour of candidates who may have shown a disposition to specialize in public health administration.

AMENDMENT OF THE INSURANCE ACT AND REGULATIONS.

THE State Sickness Insurance Committee at its meeting on Thursday, March 27th, spent the greater part of its session in considering a report on the amendments desired in the Insurance Act and the Regulations made under it. The result of its deliberations will be found in the report published in the SUPPLEMENT, page 304. The attention of readers is particularly directed to these important recommendations, which will be reported to the Council at its meeting on April 23rd, and we would venture to suggest that any observations upon them which members may feel disposed to make should be addressed to the Medical Secretary for the consideration of the Committee, which will meet again on Thursday April 10th.

MR. C. J. BOND, F.R.C.S., senior surgeon to the Leicester Royal Infirmary, has resigned that position. The board has accepted his resignation with regret, and will propose to the governors to elect him honorary consulting surgeon and vice-president. Mr. Bond has been elected deputy chairman of the board in succession to Sir Arthur G. Hazleigg; in this way he will retain an active interest in the work of a hospital to which, as the board stated in a special minute, he has by his ability and high character rendered great services.

Medical Notes in Parliament.

Mental Deficiency Bill.

THE print of Mr. McKenna's revised Mental Deficiency Bill was issued on Tuesday last. It embodies most of the points agreed upon as a result of the discussions in Committee on the bill of last year, and accordingly differs in some important respects from the original form of that proposal.

The power and manner of dealing with defectives becomes Part I of the present bill instead of Part II in the former one. Part II relates to the central and local authorities for dealing with the mentally defective; Part III is concerned with the certification and provision of institutions, and Part IV with general matters, such as offences, penalties, legal proceedings, etc.

PART I.

Clause 1 is devoted to the definitions of mental defect within the meaning of the Act, which are as follows:

- (a) *Idiots*; that is to say, persons so deeply defective in mind from birth or from an early age as to be unable to guard themselves against common physical dangers.

- (b) *Imbeciles*; that is to say, persons in whose case there exists from birth or from an early age mental defectiveness not amounting to idiocy, yet so pronounced that they are incapable of managing themselves or their affairs, or, in the case of children, of being taught to do so.
- (c) *Feeble-minded persons*; that is to say, persons in whose case there exists from birth or from an early age mental defectiveness not amounting to imbecility, yet so pronounced that they require care, supervision, and control for their own protection or for the protection of others, or, in the case of children, are incapable of receiving proper benefit from the instruction in ordinary schools.
- (d) *Moral imbeciles*; that is to say, persons who from an early age display some permanent mental defect coupled with strong vicious or criminal propensities on which punishment has little or no deterrent effect.

The definition of imbeciles has been altered from the form proposed in the first bill in which they were described as those who are capable of guarding themselves against any physical dangers but who are incapable of earning their own living by reason of mental defect existing from birth or from an early age. The definition of the feeble-minded differs materially from that which was proposed in the first bill and which gave rise to considerable criticism. It defined them as those who, whilst capable of earning their own living under favourable circumstances, were incapable through mental defect existing from birth or from an early age either of (1) competing on equal terms with their normal fellows, or (2) of managing themselves and their affairs with ordinary prudence. It will be seen that the new proposed definition as applied to children refers to those who are incapable of receiving proper benefit from the instruction in ordinary schools. It is not difficult to prophesy that controversy may arise over the word "ordinary." The definition of mentally infirm persons as proposed in the original bill is omitted. It will be remembered that it related to those who through mental infirmity arising from age or the decay of their faculties are incapable of managing themselves or their affairs.

The Second Clause of the present bill sets out the circumstances under which defectives may be dealt with. On comparing it with the corresponding portion, Clause 17 (1), of the former bill, it will be noticed that defectives "may" be dealt with by being sent to or placed in an institution or placed under guardianship. In the former bill it was provided that the classes specified "and no other shall" be subject to be dealt with under this Act. The new clause provides that a defective may be dealt with under the Act at the instance of his parent or guardian if he is an idiot or imbecile or under the age of 21, or if "in addition to" being a defective person he is either found neglected, abandoned, or cruelly treated, found guilty of an offence or ordered, or liable, to be sent to a certified industrial school, or is undergoing imprisonment or penal servitude, except when in prison under civil process, or who is an habitual drunkard within the meaning of the Intoxicating Liquors Act, or who is one whose case has been brought forward by the local education authority, or who is in receipt of Poor Law relief at the time of giving birth to an illegitimate child, or when pregnant of such a child. These provisions differ in some important respects from those in the former bill, the most notable alterations being the omission of those "in whose case it is desirable in the interest of the community that they should be deprived of the opportunity of procreating children," and in such other cases "as may be specified under regulations made by the Secretary of State." The provisions also are modified to accord with the new arrangements proposed for the local education authorities under the Elementary Education (Defective and Epileptic Children) Bill which is summarized elsewhere.

Clause 3 relates to the power to deal with defectives at the instance of a parent or guardian, and Clause 4 sets out the authorities at whose instance a defective may otherwise be dealt with. They are either (1) by the judicial authority as defined in the bill, (2) by an order of the court in the case of defectives found guilty of certain offences, or (3) by an order of the Secretary of State in the case of prisoners or defectives in lunatic asylums, reformatories, and industrial schools. The judicial authorities are defined in Clause 17 as being county court judges, police or stipendiary magistrates, or specially appointed justices, or judicial authorities for the purpose of the Lunacy Acts. Clause 5

relates to the presentation of the petitions which may be lodged by a relative or friend of the alleged defective, or by an officer of a local authority, but the petition must be accompanied by two medical certificates, or by a certificate that medical examination was impracticable. The petition must set out various circumstances as detailed in the clauses, and if it is not presented by a relative or by an officer of the local authority, it should contain a statement of the reasons as to why it is not. Clause 6 deals with the hearing of petitions, which may, if desired by the person to whom the petition relates, be conducted before the judicial authority in private, in which case no one shall be present except the petitioner, the person to whom the petition relates, any two other persons appointed for the purpose by the person to whom the petition relates, and those signing the medical certificates and the statutory declaration, except with the leave of the judicial authority. In the cases where the petition is accompanied by a statement that a medical examination was impracticable, the judicial authority, unless the petition is dismissed, shall order a medical examination. Clause 7 relates to variations of the order, and Clause 8 provides that where a person is convicted of an offence, but where the court is satisfied on medical evidence that he is a defective, they may postpone the passing of sentence with a view to procedure under the Act. Clauses 10, 11, and 12 relate to the effects of orders which, except as specified, expire at the end of one year. On renewal orders may be extended by the Board of Control to five years, provided that in the case of a defective under the age of 21, his case shall be reconsidered within three months of his attaining that age. Clauses 13 to 18 contain various provisions supplemental to the foregoing.

PART II.

The Board of Control for the purposes of the Act is dealt with in Clauses 19 to 24. It is to consist of fifteen commissioners, of whom not more than twelve shall be paid. One of the paid and one of the unpaid commissioners shall be a woman, four of the paid commissioners shall be legal commissioners, and four medical commissioners. Those who hold office at the commencement of the Act, as commissioners in lunacy become as from the commencement of the Act paid commissioners of the Board of Control. The legal commissioners are to be appointed on the recommendation of the Lord Chancellor after consultation with the Secretary of State, and the other commissioners by the Secretary of State after consultation with the Lord Chancellor. The Secretary of State, also after consultation with the Lord Chancellor, shall appoint one of the commissioners to be chairman, and the Secretary of State may direct the board, subject to his regulation, to appoint an administrative committee. No commissioner other than the chairman shall receive a salary exceeding £1,500 a year. The chairman and the paid commissioners shall hold office during His Majesty's pleasure, and the unpaid commissioners for such a term as the Secretary of State may determine. The various disqualifications for the office of commissioner are contained in Clause 22, and their general duties in Clause 23. They may be said to embrace the supervision and control of the defectives, the co-ordination and supervision of the administration of the Act by the local authorities, and the inspection and certification of places for the reception of defectives. The board is to provide and maintain institutions for defectives with criminal or dangerous propensities, and is to administer the money grants made by Parliament for the purposes of the Act. Clauses 25 to 32, being the remainder of Part II, relate to the local authorities charged with duties in respect of defectives.

Except in the case of the local education authority, the local authority for the purposes of the Act is the council of a county or county borough. The authority is required to constitute a committee for the care of the mentally defective, which may contain persons other than members of the council, and all matters relating to the exercise of authority under the Act stand related to this committee, except the power of raising a rate or borrowing money. It is to be the duty of the local authority, subject to provisions of the Act and the regulations of the Secretary of State, to ascertain what persons in their area are defective, and to make provision for them, provided that they

are not required to do so where the contribution out of the money provided by Parliament towards the maintenance of the defective is less than one-half of the cost to the authorities of his maintenance. Exception is made also of those who are under the charge of Poor Law authorities, and nothing under the Act is to affect the powers or authority of the Lunacy commissioners or of the local education authority. The duty of ascertaining the defectives amongst the children is cast upon the local education authority, as well as the ascertainment of which of them are incapable by reason of their mental defect of receiving benefit from instruction in special schools or classes. Notice is to be given to the local authority of the names and addresses of defective children by the education authorities.

Parts III and IV of the bill, except as they are modified to suit the other alterations, do not materially differ from the arrangements proposed in the bill of last year.

Defective and Epileptic Children.—A short bill has been introduced by Mr. Pease, entitled the Elementary Education (Defective and Epileptic Children) Bill. It is introduced as carrying out part of the arrangement come to last year in Committee on the Feeble-minded Bill. To meet the general criticism that, in view of the fact that it is found that many children classed as backward, or as more or less defective, prove, as the result of training in special schools, to be educable and capable of being made self-supporting, it was agreed that a bill should be introduced this session to make the Defective and Epileptic Children Act, 1899, compulsory and avoid an unnecessary enlargement of the class of feeble-minded which, under the Home Secretary's bill, may become a charge on the community. The first and operative clause of this small bill introduces words into Subsection 1 of Section 2 of the Act of 1899 which alters its permissive character and makes it obligatory as respects children whose age exceeds 7 years. If amended as proposed by the italicized words, the subsection will read thus:

When a school authority have ascertained that there are in their district defective children they may, and in the case of *mentally defective children whose age exceeds seven years shall*, make provision for the education of such children by all or any of the following means.

The various means referred to in the principal Act are the establishment of special classes in public elementary schools, the boarding-out of such children for instruction or the establishment of special schools for defective children. The local education authority also may establish special schools for epileptic children, or alone or in conjunction with another authority contribute to the support of existing approved schools or jointly assist in the provision and maintenance of new ones. In the bill now introduced it is provided that the Board of Education, without prejudice to other proceedings, may make a deduction from the grant otherwise due to any local authority who neglects to make the provision required for defective children in its district. It is also provided that a local education authority may obtain an order from a court of summary jurisdiction requiring the parent of a mentally defective child to send it to a suitable certified school failing other suitable provision for the child.

Food Adulteration.—In reply to Sir John Lonsdale and Mr. Peto, Mr. Burns announced that he had in preparation a bill dealing with the question of the purity of food and hoped to introduce it shortly.

London Water Supply.—In reply to Sir John Lonsdale, who inquired as to the reported contamination of part of the London water supply, Mr. Burns stated that the Metropolitan Water Board had found that the very unpleasant taste in the water was due to the decay of algae, and stated that it was not injurious to health. The source of the trouble having been discovered, steps, he said, had been taken to remove the ground of complaint.

School Clinics.—Mr. Pease has informed Mr. King that attendance at clinics for special examination are

allowed by the Board to be registered and counted for grant, provided that satisfactory arrangements are made for the registration.

Epizootic Abortion.—In reply to Mr. C. Bathurst, Mr. Runciman stated that the results of the experiments of the inoculation of cows and heifers as a preventive of contagious abortion had so far been encouraging; but that only the county of Devon up to the present had adopted an Order on the lines recommended by the Departmental Committee.

LONDON.

A DISPENSARY AND SCHOOL CLINIC.

THE third annual report of the St. George's Dispensary and School Clinic, Surrey Row, Blackfriars Road, S.E., contains an analysis of cases which affords evidence of the extensive work carried on. Especially satisfactory are the figures from the dental clinic, which show that parents are gradually being trained to acquiesce in the treatment of the dental defects found in their children. A large part of the report is occupied by an article by Mr. A. G. Wells upon the work of the nose, throat, and ear clinic. Mr. Wells claims to have been singularly successful in the selection of cases of adenoid hypertrophy upon which to operate, so that although the operation was performed for a great variety of symptoms it was a successful measure in all but a trifling minority of the cases. He also makes some remarks on the connexion between adenoid overgrowth and the symptoms of what has been described as Mucous Disease by Dr. Enstace Smith. Mr. Wells attributes the great success achieved to attention to the following three points: great pains were taken to avoid frightening the children; the anaesthetic was always given by the same anaesthetist; and the children attended regularly after the operation to practise breathing exercises.

MEDICAL INSPECTION OF CHILDREN UNDER SCHOOL AGE.

In our summary of the latest report of the medical officer to the Board of Education¹ it was noted that certain passages therein seemed to foreshadow an attempt to secure that children shall be subjected to medical inspection not only during school life, but from birth onwards. The possible advantages of such a measure were described in an annual report of the City of Westminster Health Society some two years ago, and in the latest report of that body is given an account of an actual attempt to secure them. It began in January last year, when this society, which has the advantage of the co-operation of Dr. F. J. Allan, M.O.H., opened in Soho a medical centre; this has carried on throughout the year the work commonly done in well-organized school areas, including the equivalent of entrant, intermediate, and "leaver" examinations, an inspection clinic, the process known as "following up," and the securing of treatment. Knowledge of the children was in the first instance obtained through the operation of the Notification of Births Act, the mothers being afterwards persuaded to bring the children at the desired intervals to the inspection centre, where the work was done under the supervision of Dr. David Forsyth. Altogether some 374 children were examined (including re-examinations). The more important defects stated to have been observed are set forth in the following table:

| Age Period: | 0-1 Year. | 1 Year. | 2 Years. | 3 Years. | 4 Years. |
|-------------------|-----------|-----------|-----------|-----------|-----------|
| | per cent. |
| Teeth ... | — | 2.6 | 18.1 | 34.0 | 65.6 |
| Tonsils ... | — | 7.8 | 16.9 | 24.0 | 26.9 |
| Adenoids ... | 1.5 | 10.4 | 22.9 | 38.0 | 53.3 |
| Rickets ... | 13.0 | 25.9 | 9.6 | 8.0 | 3.0 |
| Diet modified ... | 49.6 | 22.8 | 6.0 | — | — |

¹BRITISH MEDICAL JOURNAL, January 11th, 1913, p. 79.

The numbers on which this table is based are small, but inasmuch as they represent, we believe, the first published statistics in regard to the physical deficiencies of the child population in each of the first five years of life, they possess a certain interest. The outstanding feature of the table is the rapid rise year by year in the proportion of disease, this being specially notable and continuous in the case of dental caries, a defect which is possibly responsible for more ill health among children than any other single cause. It is pointed out in the report that a large majority of the children at the age period 0 to 1 were found to be healthy, but that only a small minority reached the fifth year without developing at least one physical defect of some kind. It is added that the later the age the more extensive usually was the disease, except, of course, in regard to rickets. The inferences drawn are that large numbers of children healthy in every respect at birth at present become within five years the physically defective entrants whom the educational authorities are required to restore as far as possible to their original state of health. Since most of these defects are preventable, and can be remedied more speedily and more cheaply during infancy than school age, it is suggested that in large degree the problem of the defective child resolves itself into the problem of the under-school-age child. Finally, it should be noted that the children to whom the report relates came mainly from homes not of the poorest class, the fathers being chiefly tailors, cooks, waiters, policemen, and firemen. Hitherto the work has been confined to the more northerly half of the city of Westminster, but the society hopes to extend it. It regards it as of great educative value.

BIRMINGHAM.

HOSPITAL SATURDAY FUND.

THE Hospital Saturday Fund for last year, which was the fortieth annual collection, amounted to £22,842 3s. 4d., and is the largest amount ever collected in one year. At a meeting of the board of delegates £10,000 was voted for distribution among the medical institutions of the city. The total number of patients admitted into the convalescent homes supported by the Hospital Saturday Fund was 3,429, distributed as follows: At Tyn-y-Coed, Llanrhos, 1,245 men; at Marle Hall, Llanrhos, 1,446 women; at the Red House, Great Barr, 632 children and 105 women. Since the fund's first convalescent home was established twenty-one years ago, 44,770 patients have been received—19,304 men, 19,241 women, and 6,225 children. The home for consumptives—the Sir William Cook Memorial—on Romsley Hill, will be opened during the summer, and part of the building will be used before then for the treatment of male patients. The Insurance Act was a disturbing factor in the collections at certain works, but happily the great majority of contributing firms continued their subscriptions, and in nearly all cases in which they were suspended the collections have been commenced again. There is no valid reason why the contributions under the Act should interfere with the Hospital Saturday collections, as the benefits offered by the fund are distinct from those accruing under the Act. The hospitals of the city are still required for the wives and families of insured persons, and even for insured persons themselves for consultations and for special and institutional treatment, while the Hospital Saturday convalescent homes are needed just as before.

BIRMINGHAM MEDICAL INSTITUTE.

In the annual report for 1912 the financial position of the institute is shown to have been considerably improved. The special fund for the improvement, which was started last year, has reached over £500, and there has been an increase of £25 in subscriptions. The library now contains 15,026 volumes; during the year 173 volumes were added; 67 periodicals—39 foreign and 28 British—were supplied to the reading room. The following officers have been elected for the ensuing year: *President*, Mr. Christopher Martin; *Vice-Presidents*, Dr. Douglas Stanley and Dr. Henton White; *Honorary Secretaries*, Dr. W. Glogg and Dr. Beckwith Whitehouse; *Honorary Librarians*, Dr. Branson and Dr. Sawyer; *Honorary Treasurer*, Mr. Frank Barnes.

Scotland.

[FROM OUR SPECIAL CORRESPONDENTS.]

DR. LIVINGSTONE IN 1857.

At the March meeting of the Directors of the Edinburgh Medical Missionary Society, Professor Crum Brown, President, in the chair, Dr. Sargood Fry read the minute of a breakfast meeting of the society which had been held on September 23rd, 1857, when Dr. Livingstone had been present as a guest. Professor J. Y. Simpson and Professor James Miller had commended the medical and missionary work of the great explorer; and Dr. Livingstone had given some notes of his surgical, medical, and obstetrical practice in Central Africa. The minute continues:

Dr. Livingstone mentioned that his operations had consisted almost entirely in the removal of tumours, which were invariably of a benign character, the only exception being one resembling melanosis; that he had never met with cancer or scrofula, calculous disorders, or consumption. He observed that the natives make capital patients, never calling out under the knife as used to be the case in other countries before the days of chloroform. Their treatment of fractures is on the whole very successful. They use the bark of a tree for splints, and, as union is generally rapid, few subsequent deformities are met with. More than once Dr. Livingstone had noticed cases of dislocation which had escaped being reduced. He had not found occasion to perform any of the so-called capital operations of surgery, but among other minor operations he had cured one native lady of squint. Dr. Livingstone alluded with quiet humour to his behaviour towards other practitioners, never condemning their practice before the patient, but taking them aside, when he generally found them very ready to acquiesce in his views of treatment. He also spoke of his fame as an obstetrician, in which branch he had no competitors, being decidedly at the top of the tree. He alluded to one case in which having cured a native lady of some complaint, he or his medicine got all the credit of a child which she bore fifteen months afterwards, so that the celebrity thus acquired was the source of no little inconvenience, as he was supposed to possess a specific.

Dr. Livingstone thinks that although the native prescriptions are often sufficiently absurd, there is reason to believe in the efficacy of some from their being widely known among various tribes, and over vast territories. He has no doubt that many medicines exist in these countries which may yet prove valuable additions to our *materia medica*. But in the management of febrile diseases the native doctors possess nothing equal to quinine. Dr. Livingstone was in the habit of combining it with an aperient in the form of a pill, which agreed so well with his patients, and became so famous, that had it been in this country it would have eclipsed even Morrison's pill.

This minute, which was doubtless from the pen of Mr. Benjamin Bell, F.R.C.S.E. (father of the late Dr. Joseph Bell), ends with a reflection (a somewhat uncommon thing in minutes) in the following words:

Although the meeting of which we have endeavoured to give a very meagre sketch was not a regular meeting of the Medical Missionary Society, demanding a formal minute, it was certainly a notable occasion in our history, bringing before us a *real* medical missionary, a *true man* raised up by Providence for a great purpose; one of those persons in regard to whom panegyric seems out of place, and who go straight forward to the accomplishment of their work quite independently of either praise or censure. May his short visit be instrumental in awakening all of us to greater earnestness in our several spheres, and to a more thorough sympathy for those families of our race who are still sitting in darkness, without God, and without hope!

DR. LIVINGSTONE'S GRANDSON AND GRANDDAUGHTER.

In connexion with the centenary of the birth of David Livingstone, it is interesting to note that on March 18th, the Livingstonia Committee of the United Free Church of Scotland appointed Dr. Hubert Francis Wilson and Miss Mary Ruth Wilson, grandson and granddaughter of the explorer, the one as a medical missionary and the other as a missionary to Livingstonia, to the station of Chitambo, the place where, it will be remembered, Dr. Livingstone died and where his heart is buried. Dr. Wilson received

his medical education at Cambridge and Glasgow, and holds the degrees of B.C. and B.A.Camb.

ROYAL EDINBURGH HOSPITAL FOR SICK CHILDREN.

At the annual meeting of the above institution, the Chairman, Mr. James Clark, K.C., C.B., referred to the improved accommodation which had been secured for the nursing staff during the year, and to the opening of a special ward for the treatment of ear and throat patients. The annual subscriptions, however, still showed a tendency to fall off, there having been a drop of £200 in 1912; fortunately there had been enough coming in as legacies to meet the increased expenditure; but he thought it was a pity that they were not in a position to pay their way with their annual subscriptions. The Lord Provost referred to the fact that for fifty-four years the hospital had done splendid service in the city, and commended its claims to the liberality of not only the Edinburgh but the Scottish public. Dr. Graham Brown, the President of the Royal College of Physicians, said that it was no light thing that in 1912 over 9,000 children had for the most part benefited, and quite in an extraordinary way, from their treatment at the hospital. They were drawn to the hospital not only from Edinburgh itself but from all over Scotland by the magnetic force of the trained experts on the medical and surgical staff. Further, the hospital served also as a school for the training of medical men in the expert management and treatment of the diseases of childhood.

EDINBURGH ROYAL INFIRMARY.

At their meeting on March 31st, the managers of the Edinburgh Royal Infirmary appointed John Dixon Comrie, M.A., B.Sc., M.D., F.R.C.P.E., an assistant physician to the institution for a period of five years. Dr. Comrie is Lecturer on the History of Medicine in the University of Edinburgh and honorary secretary to the Post-Graduate Courses in Medicine of the university and the Royal Colleges. There were four other candidates. At the same meeting the termination of Dr. George Mackay's term of service as one of the ophthalmic surgeons of the institution was intimated. The managers minuted their high appreciation of the value of Dr. Mackay's twenty-four years of work in the infirmary, and appointed him one of the consulting ophthalmic surgeons thereto.

Ireland.

[FROM OUR SPECIAL CORRESPONDENTS.]

TUBERCULOSIS SCHEME FOR COUNTY FERMANAGH.

THE Fermanagh County Council has decided to appoint a whole-time tuberculosis officer, who will be debarred from other medical practice, and whose duties will be largely administrative. It has been suggested that a central tuberculosis dispensary should be established with four observation beds and four branch or district dispensaries. With regard to a sanatorium, the ideal scheme would be for the council to join with several other councils in erecting and administering one such institution; but the Women's National Health Association has bought Rossclare, is turning it into a sanatorium, and has suggested that it should be taken over by the county council. Rossclare stands on high ground on the shore of Lough Erne with no shelter of any kind; so exposed is it that the growth of the few trees around is clipped by the prevailing winds, and some sleeping boxes erected in the sheltered parts of the grounds in the lee of the main buildings were blown down. The soil is stated to be so heavy and impervious that it is impossible during six months of the year to walk about with comfort. There are no facilities for farm work or kitchen gardens. Some fourteen years ago this place was used as a sanatorium, but Dr. Kidd of Fermanagh and three other doctors formerly connected with the sanatorium have expressed the opinion that the site is unsuitable. It appears that there is at present a recommendation that the council should engage 20 beds from the Women's National Health Association at 25s., but it is being urged that it would do more wisely to build a joint sanatorium with some neighbouring county councils.

New South Wales.

(FROM OUR SPECIAL CORRESPONDENT.)

PUBLIC HEALTH ADMINISTRATION.

THE retirement of Dr. Ashburton Thompson from the position of Principal Government Medical Officer and President of the Board of Health after a long and successful official career is announced to take effect in March. Upon his retirement the Department of Health is to be considerably enlarged by the addition of other departments which should have been attached to it long ago. Dr. R. Paton, who at present occupies the position of Inspector of Hospitals and Charities, will be appointed as Dr. Thompson's successor, and this department will in future be attached to the Health Department. By these means the way will be opened up for some important developments. Dr. Paton is the President of the Tuberculosis Advisory Board, and he will thus have a large share in shaping the policy of the Government in regard to tuberculosis dispensaries, and possibly also public dispensaries for persons ineligible for membership of the friendly societies.

THE GOVERNMENT AND PUBLIC HEALTH QUESTIONS.

According to an announcement by the State Premier (Mr. McGowan) public health questions will take a prominent position in the policy of the Government to be enunciated in view of the general elections to be held towards the end of this year. It is announced that provision for maternity cases will be an outstanding feature. Maternity hospitals are to be established in the crowded centres of population, and maternity annexes are to be provided at country hospitals. Where the patient cannot get or be brought to the hospital she is to be visited by a doctor and a nurse wherever practicable. A maternity allowance is also to be provided, but this is not to be a cash payment. The State will simply guarantee the doctor and the nurse certain payment. In every centre doctors and nurses will be available by arrangement with the Government at rates to be fixed. A patient may call in any doctor she pleases. His bill will be guaranteed up to the rate fixed by the department. If the medical man selected happens to be a specialist and demands a special fee the patient will have to pay the difference. The intention is that every case shall receive proper attention either in a well-conducted hospital or at home, and in either case at the expense of the State.

The antituberculosis dispensaries which it is proposed to establish are to be called "Hospitals for the Diseases of the Throat and Chest." The Waterfall Hospital for Consumptives is in future to be called the "Waterfall Sanatorium." Further matters to be taken up are the medical inspection of oversea consumptives, hygiene in schools and Government departments, milk supplies, and accommodation houses for patients who do not care to live in boarding houses. District nursing is also to receive attention. The idea is to use the existing machinery of the hospitals. The various hospital committees have been advised that hospital funds may be legally used in payment of services for nursing patients in their own homes. The hospitals will be paid subsidies on any money raised for the treatment of eligible cases in this way.

This policy has been approved by the Political Labour League which recently held its meetings in Sydney, but it is very doubtful whether the Government will be able to finance this extensive scheme. It shows, however, the general trend of opinion on medical matters, and it is generally believed that before long the profession will have to face the introduction of a national insurance scheme.

TUBERCULOSIS DISPENSARIES.

The tuberculosis dispensary established by the New South Wales Branch of the National Association for the Prevention and Cure of Tuberculosis has been actively at work for the last three months. An important part of the work of the dispensary is the examination of contacts; it is stated that 50 per cent. of those in contact with the patients were found to be infected.

At the Royal Prince Alfred Hospital the question of dealing more adequately with the treatment of tuber-

culosis has engaged the attention of the medical staff and the board of directors. As a result of a series of conferences between the honorary medical staff and the medical members of the board of directors, it has now been decided to form a special tuberculosis dispensary in connexion with the out-patient department of the hospital. The following is a report of the conference:

The treatment of tuberculosis is no new departure at this hospital, but in the past the cases have been distributed over the various departments. This conference now recommends that a special antituberculosis dispensary be established without delay to deal with tuberculosis as efficiently as possible, on the lines of such dispensaries as the Victoria Dispensary in Edinburgh and the Paddington Dispensary in London. The conference would point out that the hospital has already organization in existence which only needs to be expanded to meet the new conditions of the new department. It also desires to point out that it would be in the best interests of the patients, the public, and the hospital as a teaching institution that such work should be carried out in connexion with a large general hospital. The conference makes the following recommendations:

1. That the aforementioned antituberculosis dispensary should be a part of the outdoor department of the hospital.
2. That if possible separate waiting and examination rooms should be provided.
3. That the department be open for the treatment of patients on two evenings and two afternoons a week, and that the evenings should be reserved exclusively for those who are unable to attend during the daytime, and that definite reasons be given for night attendance.
4. That the work of the department be carried out by a staff of four physicians, selected from the existing staff, assisted by an additional special resident medical officer, who should, if possible, be a senior officer.
5. That two nurses be attached to the department, one for males and one for females, to assist the visiting physicians, to visit the homes of patients, to advise them as to sleeping accommodation, isolation, preparation of food, disposal of sputa, care of utensils, etc., and to bring contacts to the department for examination. Nurses who have been specially trained in hygiene should be employed for this work.
6. That printed instructions be given to each patient as to the disposal of sputa, diet, value of open air and sunlight, the infectious nature of the disease from which they are suffering, etc.
7. That tuberculin and medicines be provided through the dispensary of the hospital.
8. That special observation wards be provided for diagnostic purposes and for temporarily housing patients prior to their removal to the various sanatoriums such as Waterfall, Rookwood, Wentworth Falls, and Thirlmere.

THE SANATORIUM TREATMENT OF TUBERCULOSIS IN NEW SOUTH WALES.

The annual report of the Queen Victoria Homes for Consumptives shows that 93 patients were admitted to the sanatorium for men at King's Tableland during 1912, and 94 discharged. Fifty-one patients were in residence on December 31st, 1911, and 49 on December 31st, 1912. The average number of beds occupied daily was 49. Since the opening of the sanatorium in 1903 over 1,000 patients had been under treatment; 80 per cent. of the patients came from Sydney and suburbs and the remainder from the country. The age of the patients varied from 11 years to 58 years, the average being 30 years. Tubercle bacilli were found in 69 per cent. of the cases. A family history was given in 34 cases. Haemoptysis had occurred in 40 cases before admission, and a previous history of pleurisy in 32. Haemoptysis occurred in 17 patients while in the institution. The number of patients that improved amounted to 79.8 per cent. Five deaths occurred during the year.

During the same period 94 patients were admitted to the sanatorium for women at Thirlmere, and 91 discharged; 40 patients were in residence on December 31st, 1911; 43 on December 31st, 1912. Of 94 patients, 86 came from Sydney and surrounding suburbs within a radius of sixteen miles. The remaining 8 came from various country districts. A family history of consumption was admitted in 32 cases (equal to 35 per cent.), probable in 4 others, and denied in 55. Exposure to infection by contact with tuberculous patients, whether relatives or not, was known to have occurred in 46 cases (equal to 50 per cent.), and probable in 7 others. Four patients gave a history of consumption in the family without exposure to infection as well, while 17 cases with a family history free from tuberculosis gave a definite history of exposure to infection.

Sir Philip Sydney Jones, President of the Board and also of the National Association for the Prevention of

Consumption, in supporting the motion for the adoption of this report, said it was the desire of the Queen Victoria Homes for Consumptives to establish antituberculosis dispensaries, but they were anticipated by the National Association. Referring to the establishment of a dispensary in connexion with the Royal Prince Alfred Hospital, he said that there were many advantages to be gained by the association of a tuberculosis dispensary with a general hospital. The board of the Queen Victoria Homes for Consumptives hailed the establishment of dispensaries as a move in the right direction, for the dispensary was a valuable aid to the work of the sanatorium, as it was very difficult to secure patients in the early curable stages. The labourer would not give up work very often until he had reached a stage when his chances of recovery were almost *nil*. The work of the nurses attached to the dispensaries was most valuable in discovering cases of early infection among the contacts.

Correspondence.

THE FORM AND POSITION OF THE STOMACH.

SIR,—Most teachers of anatomy have come to the conclusion that the definite information concerning the true form and position of the living stomach which is afforded by radioscopic examination can no longer be ignored, and that such knowledge should be used to supplement what the student learns from the dead and distorted stomach in the dissecting-room. In many British schools these shadow pictures of the living stomach are regarded as an indispensable part of the student's instruction in anatomy; for I know that the magnificent series of skiagrams which Dr. A. E. Barclay kindly permitted me to make use of in my department is also being employed in several other medical schools in this country as well as in America.

Under these circumstances it is somewhat disconcerting to the mere anatomist, who imagined, when he introduced the results of radioscopic examinations of the stomach into his instruction, that he was doing his best for the students committed to his care to prepare them for clinical work, to find a distinguished surgeon like Dr. Gray, in the *BRITISH MEDICAL JOURNAL* of March 29th, practically advising him to shun radioscopy and to pin his faith to the old dissecting-room methods, and the belief in a "middle sphincter" and the immobility of the pylorus.

After the Liverpool meeting of the British Medical Association there was an informal discussion of the whole subject of the form and position of the stomach at a meeting of the Anatomical Society of Great Britain and Ireland, held at St. Mary's Hospital, London, last November, and the impression left upon my mind was the remarkable unanimity of opinion on the part of those anatomists who had seriously investigated this admittedly difficult problem.

The large series of radiograms taken by Dr. Barclay, which have been critically examined in this department by Professor Wingate Todd, seems to prove quite definitely that—

(1) The form and position of the stomach vary with posture.

(2) That in the erect posture the usual form of the normal stomach, when empty of food, is a J-shape, the medial edge of the large left limb (lesser curvature) of which is vertical, and the upper part of its right side is "blown out" to form a bladder (filled with gas above the level of the oesophageal opening) occupying the left cupola of the diaphragm.

(3) That the bend of the J lies as low as the umbilicus; and

(4) That the pyloric extremity is opposite the second lumbar vertebra (or the disc between it and the third), a full vertebra's depth lower than its position when the subject is in the prone position.

I do not think that Dr. Gray's statement of his belief in the presence of a "middle sphincter" is likely to carry conviction at the present time, even though he qualifies the term as being used "for the sake of brevity," and apparently only in reference to "the earlier part of gastric digestion."

The impartial study of a large series of radiograms

showing the altered position of the stomach when the subjects are in the prone and erect attitudes respectively leaves no room for doubt that the pyloric extremity of the stomach sinks as much as the depth of a vertebra when the subject arises from the prone to the erect position; and I am told by some of my surgical colleagues that they have found this borne out in their experience of actual manipulation of the pylorus.

I have ventured to enumerate this series of widely admitted facts, because they are based upon the examination of a large number of radiograms of patients, some of whom I was privileged to see Dr. Barclay demonstrate to Dr. Gray some time ago.—I am, etc.,

G. ELLIOT SMITH,

Department of Anatomy, University of Manchester,
March 5th.

THE AFTER-EFFECTS OF GASTRO-ENTEROSTOMY.

SIR,—I am sorry that Mr. Gray fails to appreciate that "practically unanimous agreement" was accorded to my opening address on "The Anatomy of the Normal Stomach" at last year's meeting of the British Medical Association. It is true, none the less, that all the radiographers present agreed with me in every detail, and the opinion of anatomists may be judged from the fact that my drawing of the "normal stomach" is being reproduced in the new editions of two of the standard textbooks of anatomy.

Mr. Gray says that he carried out a series of observations on normal stomachs many years ago, and came to certain conclusions. That is the very reason why I recommended him to carry out another series *now*. When I first investigated the stomach with the *x* rays I was led, in common with Mr. Gray and many others, to erroneous results, owing to our methods being inaccurate. We have all changed our views since then, thanks to increased experience and better technique. Mr. Gray alone seems to be content to ignore recent advances in our knowledge.

Mr. Gray says he was unable to see Dr. A. C. Jordan's work at Guy's Hospital, as I recommended him to do. But did he not, at the suggestion of Mr. A. H. Burgess, of Manchester, recently visit Dr. A. E. Barclay, who, in the presence of Professor G. Elliot Smith, demonstrated to him the normal anatomy of the stomach with the *x* rays? Both Mr. Burgess and Dr. Barclay tell me that he expressed himself as convinced that Dr. Barclay's views on the subject, which are identical with mine, were correct. May I ask Mr. Gray what new facts have since come to light which have caused him to go back to his old theories of the anatomy and physiology of the stomach, the error of which Dr. Barclay was one of the first to point out?

It is, I fear, useless to explain again the object of my paper on some of the ill results which may follow gastro-enterostomy to one who attempts, like Mr. Gray, to criticize my paper before he has read it, as up to now only a short abstract has been published. I happened, in the course of the last three years, to be consulted by a number of patients for indigestion, which had returned at various intervals after gastro-enterostomy had been performed. I was able to separate from these a group of some 15 cases presenting very similar symptoms to each other; a posterior gastro-enterostomy had been performed upon them by various competent surgeons, in most instances, as I stated in my paper, for duodenal ulcer. As I was fortunate to find the cause of the symptoms, and consequently was able to relieve the patients more or less completely, I ventured to publish the result of my investigations. I really fail to see why this should make Mr. Gray so angry with me, even if he has not yet seen such cases in his own practice.

I also described one remarkable case in which the operation had been performed for pyloric obstruction. If Mr. Gray had waited for the appearance of my paper, he would have seen that here again it is incorrect to say that no mention was made of the condition for which the operation was done. In this case I discovered why little or no relief had followed the operation, and I was able to show how an unsuccessful case could be converted into a successful one. Surely it was worth while publishing it in order that others should be able to recognize and relieve the condition.

The fact that a very large proportion of Mr. Gray's patients are still free from symptoms after the very short interval which has elapsed since they were operated upon, is no reason for neglecting to discover why the unlucky minority are not free from symptoms and how they can be relieved.

Finally, Mr. Gray asks me whether I can offer any other explanation than his "Conclusion 3" for certain figures published in the *Archives of the Roentgen Ray*. As neither I nor any one to whom I have shown his letter have been able to understand the meaning of Conclusion 3, my answer must be in the negative.—I am, etc.,

London, W., March 31st.

ARTHUR F. HERTZ.

IMMEDIATE OPERATION IN APPENDICITIS.

SIR,—The letters on immediate operation for appendicitis come from two main branches of the profession, hospital surgeons and general practitioners. As I happen to combine these two functions I can, perhaps, see more clearly the difficulties of each.

With few exceptions all surgeons advise early operation, and any other standpoint seems to me astounding. Very many general practitioners still remain to be persuaded, some because they lack experience of the results of early operation, others, like Dr. Hunt, because, while they approve in theory they hesitate in practice, as they think the difficulties in some cases are insurmountable. I hope to show that they are not, except in the most exceptional circumstances.

May I first give my comparatively small experience as a surgeon, and then speak from the standpoint of the general practitioner?

I have operated on about 150 cases of all sorts, from the very earliest to those with large abscesses or spreading peritonitis. I have not lost one case where the disease was localized to the appendix, and all these have run a quick, uncomplicated course to recovery. Of the remainder, two cases of spreading peritonitis and one with a large abscess died. The later cases, such as those with large abscesses, have always had a longer illness, two with such serious complications as empyema.

The mortality of early cases is *nil*, that of all cases is 2 per cent. Surely these figures support the plea for immediate operation? The price paid for this policy of immediate operation is that I have "looked and seen" a normal appendix five times, but with the compensation that the correct diagnosis was made without serious injury to the patient.

Now for the difficulties of the general practitioner. In my experience, especially in the early hours of the disease, when the general practitioner alone is responsible, the diagnosis may be extremely difficult. By the time the surgeon has been called it is often much easier, although possibly still very doubtful. Dr. Hunt puts forward two other difficulties—the expense and the time lost from business. My contention is that they are not as real as Dr. Hunt thinks. Many capable surgeons can be found to operate for small fees. Then as to the time required for recovery, may I quote my last four early cases operated on in private?

1. A soldier, who returned to his regiment feeling perfectly fit within a month.

2. A gentleman farmer, who began to walk about his farm and superintend on the fourteenth day, and was hunting, without permission, on the twenty-eighth.

3. A young lady, who comfortably walked two miles on the fourteenth day.

4. A schoolboy, who went home well within a fortnight.

All four were able to leave the nursing home in ten days or less.—I am, etc.,

Guildford, March 30th.

ERIC W. SHEAF.

PHYSICAL SIGNS OF MYOCARDIAL INVOLVEMENT.

SIR,—I note with pleasure that Dr. Thomas Lewis accepts the *a-c* interval of the polygraph tracing as a satisfactory index of auriculo-ventricular conductivity. The observations to which he refers in such kindly terms have been chiefly directed to the measurement of this interval at various stages of cardiac rheumatism; whether when published they will be as convincing to others as they have been to myself remains to be seen, but the fact stands that it is only by such routine examinations that

the precise state of conductivity in cardiac rheumatism can be determined.

Dr. Alexander Morison's interesting letter scarcely concerns me except where he says I impute chronic myocardial disease to a series of bacterial insults. My view of the course of cardiac rheumatism is not quite as he reads it. As I say in the letter which appeared in your issue of March 15th, I regard the direct effect of the inflammatory spots on the myocardial functions as probably small. The course of cardiac rheumatism is one of repeated acute invasions between the ages of 6 and 20 or thereabouts; each of these invasions causes direct but temporary injury to the cardiac muscle, and direct permanent injury to the valves and pericardium. At or soon after the patient has passed the age at which he is prone to these direct insults to his myocardium—supposing, that is to say, that his heart has survived these frontal attacks—the mechanical effects of the valvular and pericardial injuries begin to tell on the cardiac muscle, which at length breaks down. I gather from Dr. Morison's letter that this is in most respects his own view of the course of the disease.—I am, etc.,

Clifton, Bristol, March 31st.

CAREY COOMES.

BOVINE AND HUMAN TUBERCULOSIS.

SIR,—In the *BRITISH MEDICAL JOURNAL* for January 11th there is a letter by Dr. T. Readman in which he states that the "poorer classes in China do not suffer from tuberculosis."

Where this idea originated I do not know, but it is not a fact.

All forms of tuberculosis exist in South China, the commonest being tuberculosis of the lung, of the glands of the neck and of the joints and spine. The only form of tuberculous disease I have not yet met with is *lupus*, which is very rare. The disease in its various forms follows the same course as in England, and the only form of the bacillus I have seen is the "human" type.—I am, etc.,

J. PRESTON MAXWELL, M.D., F.R.C.S.

Yungchun, via Amoy, China, Feb. 21st.

ALIMENTARY TOXAEMIA.

SIR,—In Professor Saundby's recent contribution¹ to the discussion on alimentary toxæmia at the Royal Society of Medicine he writes, on p. 544, that "Oxaluria or oxalaemia may be fairly reckoned to be of alimentary origin, for oxalic acid is introduced preformed in the food, or is the product of carbohydrate fermentation in the stomach which may occur when the hydrochloric acid is deficient."

This statement is not only difficult to understand, it is almost as surprising as if it had been asserted that the uric acid responsible for gout were formed in the stomach. If oxalic acid, and therefore oxalates, are produced by gastric fermentation, how is it that crystals are never found when the elements resulting from an Ewald test meal, for instance, are subjected to microscopic examination? What biological chemist, indeed, ever thinks even of looking for them?

Mr. Mackenzie Wallis's observation on indicanuria in conditions of mental depression, referred to on p. 542 by Dr. Andrewes, is interesting, but can scarcely be said to be very new. To general practitioners who, like myself, have constant recourse to the French semeiological method of urinary analysis, where the specimen examined is compared to a standard urine, this fact has been familiar for many years. I may add that exophthalmic goitre is the pathological condition where perhaps the largest quantity of indican is present in the urine.—I am, etc.,

Nice, March 20th.

A. W. GILCHRIST, M.D.

MIND CURES.

SIR,—Although your able leader under the above heading is by no means the first word spoken officially in this country in favour of rational psycho-therapy, it cannot be said that the medical profession is quick to respond to the advice of its leading organs in this particular. For some years our foremost medical journals have urged upon us the necessity of regarding seriously the phenomena that may be conveniently grouped under the heading of "mind

¹BRITISH MEDICAL JOURNAL, March 15th.

cures," and of endeavouring to formulate a scientific system of practical treatment that will enable them to make use of the principles evidently at work in such examples of mental therapeutical action. But in spite of this we are faced with the lamentable circumstance that, at the present time, there is in London no systematized instruction for would-be students of psycho-therapeutics, no official demonstrations of treatment by suggestion, hypnotism, and allied processes, and no centre of research in this branch.

On the other hand, it appears that there are still many medical practitioners who refuse to accept either the reality of "mind cures" or the necessity of including the procedures of suggestive therapeutics in our approved schedule of remedial agents. Not infrequently there is open hostility to everything connected therewith. But where treatment by suggestion and its congeners is objected to, there must be definite grounds for objection; then, Sir, let us hear from individual objectors their reasons for antagonism, that they may be answered by those who are accustomed to "mind cures" as a routine part of their practical work.—I am, etc.,

London, W., March 31st.

EDWIN L. ASH, M.D.

EARTH-EATING.

SIR,—The notes on geophagy in the *JOURNAL* of February 1st, p. 254, are very interesting. It is or has been a widespread custom. Humboldt relates that the Ottomacs have this pernicious habit. He saw at Banco, on the banks of the Magdalena, Indian women who were employed in pot-making, eating clay from time to time. Auguste de S. Hilaire observed earth-eaters in Brazil, near Fazenda de Macauba, and amongst the Machucalis; several of the latter died in consequence. In the south of the Province of Saint Catherine many men and women were victims to this habit, preferring the clay of which white ants made their dwelling. The taste for earth-eating was so strong that slaves who were muzzled rolled themselves in the dust in their endeavours to suck in particles of earth. The Prince of Wied-Neuwied observed earth-eaters on the coasts of Brazil. De Castelnau saw geophagy in Eastern Bolivia. The habit has also been noticed in the Antilles, in Jamaica, Hayti, Porto Rico, St. Thomas, St. Martin, Guadeloupe, Martinique, St. Domingo, in Guiana, Peru, Louisiana, Alabama, Georgia, Florida, and South Carolina. Hindu and Chinese women have been known to eat meerscham, and pregnant women in all countries have been known sometimes to have resort to geophagy. In some countries "rock butter" (native alum) is eaten. Hermbstaedt saw quarrymen in Thuringia spread this rock butter on their bread. In some parts of Russia they used to eat gypsum with their bread.

Closely allied to this geophagy seems to me to be the imbibition of earthy particles (involuntarily, of course) in drinking waters, which in some cases may be the cause of endemic goitre. There is no doubt that the use of muddy waters is frequently associated with this disease. Simion relates, for instance, that the waters of Rosières-aux-Salines and those of the goitrous localities of the valley of the Seille are often muddy. The same fact was noticed at Bussièrès-les-Belmont by Lacordaire, in the Jura by Ogérian, in Württemberg by Dürr. The drinking water which flows down a mountain-side must necessarily contain a large amount of suspended earthy matter, and Mead, the celebrated English physician, attributed the enormous goitrous tumours amongst the inhabitants of the Alps to mineral particles in their drinking water.

Julius Caesar Scaliger wrote:

In eâ parte agri Taurini quae Valdoeca (vallis anseris) appellatur, multis gula turgida fit, Penè omnes et amentes et inepti ad loquendum (cretinism and deaf-mutism).

Hoffmann was of the same opinion:

Struma oritur ex aquarum potu quae graves sunt et copiosam terram recondunt.

I am aware that goitre is now supposed to be due to an organism, but it is possible and probable that the nature of the waters may have something to do with the development of a specific organism.

Pearlth, Feb. 3rd.

LOUIS E. STEVENSON, F.G.S.

THE NEGLECT OF VACCINATION.

SIR,—Dr. Killick Millard's first letter, speaking of "the medical officer of health rather than the public vaccinator," "sanitary reform," "public health measures," seemed to imply methods of dealing with small-pox without recourse to vaccination. It is satisfactory to learn from his letter of March 17th that medical attendants and nurses and contacts in Leicester are vaccinated, and it is immaterial to the benefit of the community whether they are vaccinated by public vaccinators or by other practitioners. I hold to my conviction that "sanitary reform" and "public health measures" fail to diminish susceptibility to small-pox, and this is supported by the fact that Dr. Killick Millard has experienced in Leicester nineteen outbreaks of small-pox—a liberal, even generous, number for objectors to vaccination to inflict on themselves and their neighbours.

I advocate maintaining "an army of public vaccinators and vaccination officers and medical inspectors and all the expensive machinery of public vaccination," not "for the sake of vaccinating a few contacts in the rare event of an outbreak of small-pox," but in order to continue the present facilities for vaccination throughout the year, which are used by hundreds of thousands; the man in the street and his children have the same right as Dr. Killick Millard's family to vaccination, which he admits "as a scientific operation for conferring complete but temporary immunity against small-pox was never in a stronger position than it is in to-day"; if public vaccination were discontinued I fear the difficulties of controlling outbreaks of small-pox would increase until they became insuperable.

Public vaccination is not very expensive to the nation, public vaccinators and vaccination officers being usually paid by small fees for the cases with which they deal, not by salary, and medical inspection being a part of the work of the Local Government Board's medical officers and included in their salaries, the real burden and grievance is maintaining small-pox hospitals and their staffs—a natural sequel to allowing objectors to vaccination to practise free trade in small-pox.—I am, etc.,

Brent Knoll, March 22nd.

J. W. PAPILLON, M.R.C.S.

The Services.

SANITARY TRAINING OF THE TERRITORIAL FORCE.

MAJOR FREEMAN has summarized in the *Journal of the Royal Army Medical Corps* the results of sanitary training in the Territorial Force, and the lessons to be learnt so far as sanitation is concerned from five years' experience of Territorial camps throughout the country. It is satisfactory to learn that, although still far from perfect, sanitation has made great strides during these past five years, and that the general standard is high. Two factors, he considers, handicap the training: the paucity of trained regimental medical officers, and the absence of an organized sanitary squad. The superior attraction of work with a field medical unit accounts mainly for the first factor, and the remedy suggested is the training of every medical officer with a field ambulance in his first year of service. With regard to the sanitary squad, men do not readily enlist for such duties as fall to its lot, and when the work has to be done by fatigue parties and defaulters a highly trained quartermaster who can properly supervise it is absolutely essential. Major Freeman would do away with the "water duty" men as such, and in a country where a good water supply is generally available there is something to be said for this. The men would be of much more service as hospital or sanitary orderlies, and in some such capacity they are generally employed. The sanitary company as at present arranged is "merely an expensive and wasteful luxury," and the suggestion is to transfer to it the medical duties of the Royal Engineers, so that it would have a great and useful future before it. The duties which it is suggested this reorganized sanitary company should deal with are:

1. Sanitary field engineering.
2. Water supply on a large scale.
3. Preservation and storage of food.
4. Epidemics and infectious outbreaks.
5. Disinfection on a large scale.
6. Sanitary disposal of dead animals and men.

And concrete examples are given of the work which it would perform in the mobilized Territorial Force. This reorganization would involve "all N.C.O.'s having a sanitary qualification, and, if possible, be sanitary inspectors in civil life; the officers must all be medical officers of health, some must hold specialist qualifications."

In this way a very valuable unit might be formed. For Territorials Major Freeman insists that "camp sanitation" is not of much value, as in a war such as they are organized for buildings will be used where possible and tents not at all.

The weakest spot in the organization is considered to be in connexion with the clearing hospital, which will be formed by voluntary aid detachments of the Red Cross Society, for the personnel cannot get the necessary training in sanitation. The suggested remedy is the formation of a nucleus for the clearing hospital from the R.A.M.C.T., each nucleus consisting of an officer and fifteen men.

The proposals put forward are worthy of careful consideration, coming from an officer of wide experience. Certainly, as he points out, the time is now ripe for some readjustment of the work between the R.E. and the R.A.M.C.; it is impossible that the existing system could stand the test of mobilization.

Universities and Colleges.

UNIVERSITY OF ABERDEEN.

Degree.

At a meeting of the Senate on March 26th, the degree of LL.D. (*honoris causa*) was conferred on William Stephenson, M.D., F.R.C.S.Edin., Emeritus Professor of Midwifery in the University.

The following received ordinary degrees and diplomas on the same occasion:

- M.D.—*B. J. Alcock, *F. Macrae, *A. F. Wallace, W. Ainslie, J. Ritchie.
 M.B., CH.B.—†L. W. Bain, †W. P. Mulligan, G. A. E. Argo, W. Baxter, R. M. Boyd, R. W. Brown, W. M. Fowler, A. R. Grant, F. M. Griffith, J. Humphrey, J. Jaffé, J. G. Johnstone, A. C. W. Knox, W. McCombie, A. J. McCroadie, A. G. McLean, J. R. MacNeill, F. C. Merrill, L. J. Moir, J. Proctor, A. L. Robb, B. T. Saunders, J. S. Stewart, F. G. Stuart, A. A. Turner, J. T. Watt, J. L. D. Yule.
 D.P.H.—J. Chalmers, G. Leggat, P. M. Rennie, Captain, I.M.S., J. M. Taylor.

* Honours for thesis. † Second class honours.

UNIVERSITY OF DURHAM.

THE following candidates have been approved at the examinations indicated:

- FIRST M.B.—*Elementary Anatomy and Biology, Chemistry, and Physics*: H. J. Dingle, H. A. Lake, W. I. F. Powell. *Elementary Anatomy and Biology*: P. V. Anderson, E. F. H. Bell, J. S. Clark, E. C. Dunlop, A. I. Humphreys, C. G. Irwin, T. Kirsopp, H. M. Leeto, R. S. Millar. *Chemistry and Physics*: Stephanie P. L. H. Daniel, C. T. Helsham, D. Henegan, D. E. Hearn, P. Hickey, M. C. Joynt, C. D. Newman, H. Sterne-Howitt, I. Soliman. *Elementary Anatomy*: F. R. Sturridge.
 SECOND M.B.—*Anatomy and Physiology*: R. N. Craig, J. A. Charles, L. B. Freve, H. K. Graham-Hodgson, G. Irving, *A. E. Raine, A. Smithwaite, B. Sergeant, A. C. Taylor, R. Welch.
 THIRD M.B.—*(All Six Subjects)*: *C. H. Keay, P. A. Clements, A. C. Freeth, C. S. P. Hamilton, F. W. Harlow, W. Herberston, Ah Chit Jap, C. W. Morris, G. D. Newton, H. A. P. Robertson, E. K. Ryan, D. C. Scott, C. G. Strachan, A. G. Taylor, E. J. Tyrrell. *(Four Subjects)*: E. Bramley, A. G. Macfarlane, A. Patterson.

* Awarded second class honours.

QUEEN'S UNIVERSITY OF BELFAST.

THE following candidates have been approved at the examinations indicated:

- FIRST M.B.—*Physics*: J. F. Ainley, G. V. Allen, D. D. Anderson, Annie E. E. Beattie, R. R. Clarke, Janie Clarke, Jane Copes, J. Craig, Margaret Crawford, Marion Crawford, W. Cupples, J. W. Gaston, W. Gilmore, C. Graham, F. Hopkins, T. F. Ingram, D. L. Ireland, S. M'C. Kirk, J. Lascelles, S. Lees, J. C. Loughbridge, H. H. McClelland, J. M'Cormack, A. M'D. M'Mullan, P. Macarthur, J. P. O'Kane, J. E. Rea, M. H. Turnbull, H. W. Wild, C. J. A. Woodside. *Chemistry*: J. F. Ainley, D. D. Anderson, Annie E. E. Beattie, T. M. Boyd, J. C. Carson, B. R. Clarke, Janie Clarke, J. Craig, Margaret Crawford, W. Cupples, Dorothy I. Dobbin, J. Dunlop, J. W. Gaston, C. Graham, F. Hopkins, T. F. Ingram, D. L. Ireland, J. Lascelles, S. Lees, J. C. Loughbridge, Olga R. I. Love, J. M'Cormack, A. M'D. M'Mullan, P. Macarthur, T. J. Marner, R. G. Meyer, J. P. O'Kane, Annie M. Orr, W. Sanderson, M. H. Turnbull, H. W. Wild, C. J. A. Woodside. *Zoology*: J. Adams, J. Boyd, J. H. Davison, C. A. W. Ramsay. *Botany*: S. T. Alexander, C. Barton, J. Boyd, Marion Crawford, P. Ewart, J. G. M. Leyden, B. W. M'Kinney, M. O'Kane, C. A. W. Ramsay, J. Scott, T. Wallace.
 SECOND M.B.—*Anatomy and Physiology*: Eileen M. Bell, D. Corry, C. F. Davey, Mary E. Henry, J. W. McKee, J. R. M. MacKenzie, F. P. Montgomery.
 THIRD M.B.—*Pathology, Materia Medica, Medical Jurisprudence, and Hygiene*: H. T. Chatfield, T. P. McQuaid, S. A. D. Montgomery.
 FINAL.—S. Acheson, S. R. Armstrong, E. S. Dixon, L. D. J. Graham, J. R. Henry, J. V. Holmes, E. Jefferson, B. C. Lettis, H. H. C. Lynch, S. McComb, J. McFadden, E. McSorley, I. W. Magill, W. M. O'Farrell, J. Patrick, J. H. Porter, A. E. H. Reid, H. V. Walsh.
 M.A.O.—H. B. Steen.
 D.P.H.—*Both Parts*: T. Arnold.

It is stated that a Pasteur Institute is to be established in St. Louis, under the direction of Dr. R. B. H. Gradwohl. It is to be conducted on the lines of the New York Pasteur Institute.

Obituary.

ALFRED LEWIS GALABIN, M.A., M.D., F.R.C.P.,
 CONSULTING OBSTETRIC PHYSICIAN TO GUY'S HOSPITAL.

WITH the death of Dr. Galabin on March 25th there has passed away a prominent member of the medical profession whose name has been for many years intimately associated in the minds of all of us with that science and practice of midwifery which he has so ably expounded.

Alfred Lewis Galabin was born at Grove Lane, Camberwell, on January 10th, 1843, and was the last of an old Huguenot family directly descended from Jean Galabin, whose château was at Jonequières, near Orange in Provence. This Jean Galabin fled from his estates when the Edict of Nantes was revoked in 1685, and eventually settled at Greenwich under William III, whose princedom had been at Orange near Jean's birthplace. One of his descendants was bridgmaster to the City of London and had his official residence in Tooley Street near the hospital which his great-grandson was afterwards to enter. A. L. Galabin's father was a civil servant who lived at Camberwell and was married to Margaret Woods. Her father was descended from a Quaker family, and lived at Tapley, Bishopsteignton, the house to which his grandson eventually retired and in which he died, having taken the house fifty years after his grandfather left it.

After a few years spent at a private school in Camberwell, Galabin entered Marlborough in 1857, where he remained under the headmastership of Cotton, afterwards Bishop of Calcutta, and Bradley, the famous Dean of Westminster. In 1862 he went up to Trinity College, Cambridge, as a minor scholar, and had those rooms in Nevile's Court which were afterwards converted into guest chambers for Royalty and other distinguished visitors. He was one year junior at Trinity to Lord Alverstone and Lord Rayleigh. In 1864 he won a major scholarship on his College Foundation, and in 1866 achieved the great distinction of a "Double First," being placed twenty-first Wrangler in the Mathematical Tripos, and bracketed ninth in the First Class of the Classical Tripos. His college awarded him the Wrangham Medal for his first-classes in the two triposes and in every college examination. He soon started working at the elementary medical subjects, and in 1868 was elected Fellow of Trinity at the same time as Sir Frederick Pollock, the eminent jurist. He proceeded M.A. in the next year.

In 1869 he entered Guy's Hospital, a contemporary of Mr. W. H. A. Jacobson; having been at the university, he ranked as a third year's student, and so went straight into the wards, where he was under Cock and Cooper-Forster, Wilks, Pavy, and Moxon. He took the diploma of M.R.C.S. in May, 1872, and the degree of M.B.Camb. in June of the same year. In 1873 he held the appointments of house-physician and resident obstetric assistant, and took the degree of M.D. In this year he first began to write, and his mechanical bent and mathematical training showed in the subject which he chose. In the *Journal of Anatomy and Physiology* he discussed the dynamic causes of the secondary waves of the pulse, and he also published a pamphlet on the Connexion of Bright's Disease with Changes in the Vascular System. These were followed by many papers in the *Guy's Hospital Reports*, and other publications on the sphygmograph and its tracings, the value of which to the clinician he was one of the first to point out. He invented one form of the cardiograph, and demonstrated it before the Lord Mayor at a meeting at the Mansion House.

There is no doubt that at this period his intention was to practise as a physician and not as a gynaecologist, but fate ruled otherwise. He had been appointed assistant physician at Great Ormond Street, and had applied for a vacancy which had occurred among the physicians of the Middlesex Hospital, when he was, in February, 1874, offered the appointment of assistant obstetric physician at Guy's, vacant by the sudden death of Dr. J. J. Phillips, who had only been appointed assistant five years before. He accepted the post, and thus determined his career, though at that time nobody expected that the retiring and rather bookish young man would develop into the eminent surgeon and brilliant operator that he afterwards became.

He had no period of tedious waiting such as has often fallen to the lot of consultants; as soon as he had finished his resident appointments he was placed on the staff of this big London hospital, and was fully embarked on the career of a gynaecological specialist.

He was convinced that a gynaecologist should be trained as a surgeon and not as a physician, and lived to see his speciality removed from the domain of medicine into that of surgery.

In 1874 he married Harriett Mignon, daughter of the Rev. H. G. Baily, incumbent of Swindon from 1847 to 1900, who was descended from a Huguenot refugee settled at Plymouth in 1700. Thus both husband and wife were of Huguenot ancestry. They took up their residence at 14, St. Thomas's Street, which house they shared with Dr. le Gros Clark, one of the surgeons to St. Thomas's Hospital. In the same year Dr. Galabin became M.R.C.P.Lond. He continued publishing papers on his pulse tracings, but soon began to secure an extensive gynaecological practice, and his writings subsequently followed his speciality. In 1876 he published in the *Guy's Hospital Reports* his first report of the Guy's Hospital Lying-in Charity, in which he analysed with consummate skill a series of 23,591 consecutive cases of labour, a series which he so often quoted to such good purpose in his *Manual of Midwifery* written ten years later.

He was now placed on the Council of the Obstetrical Society, and in 1878 was elected Fellow of the Royal College of Physicians, as soon as he was eligible for election.

He resigned his assistant physicianship at Great Ormond Street, and in 1882 was appointed full obstetric physician at Guy's on the retirement of Braxton Hicks. In 1884, when practice was increasing, he moved to 49, Wimpole Street, where he lived for twenty-five busy years until his retirement from practice. He held all the offices in the Obstetrical Society—librarian, secretary, treasurer—and was president for 1889-90, a year for which he also held office as president of the Hunterian Society. He now had a very large practice, and became one of the leading English obstetricians. He was examiner in obstetrical medicine at Oxford, in midwifery at London, and in midwifery and diseases of women at Cambridge. He once examined at all three universities in the same year; he also examined at the Conjoint Board and for the University of New Zealand. He edited the *Obstetrical Journal* for some years.

In 1903 he retired from the staff of Guy's under the age limit, and was appointed consulting obstetric physician. He continued to practise until, in 1909, he finally left London and went to live at Tapley, Bishopsteignton, a house with a beautiful garden in South Devon, which he had leased as a week-end residence since 1898. Even here he occasionally saw patients, and was willing to assist in difficult cases at the local hospital.

He was a member of the British Medical Association, and was Vice-President of the Section of Obstetric Medicine of the annual meeting in 1887, when it met in Dublin, and President of the Section in 1892 at Nottingham.

As a consultant Dr. Galabin was very successful; he was most careful and thorough in his examinations, and soon won the confidence of all his patients. He was methodical and kept elaborate case-books. As an operator he was brilliant, and always kept abreast of the times in his technique. When he first began operating antiseptics has just been introduced, and he lived to see it superseded to a great extent by aseptic methods, which he adopted.

But it is by his books that he is known, and it is by his books that his name will be remembered. Galabin's *Midwifery* has been read by a multitude of medical students in England for the last twenty years—the combination of gynaecologist and mathematician enabled him to reduce midwifery almost to the domain of an exact science. His easy style and command of English enabled him to write a very readable book, in which the descriptions of all the various fetal movements during labour are mechanically sound. The book, which he modestly called a *Manual of Midwifery*, was first published in 1836; the seventh edition, in which he was assisted by Dr. George Blacker, was considerably enlarged, and was published under the title of

The Practice of Midwifery in 1910. This work was widely read abroad, was translated into Italian and Greek (1895), and is still regarded as the standard textbook on the subject. His other most important book was *Diseases of Women*, first published in 1879, of which a sixth edition was issued in 1903. The late Matthews Duncan once said, "Everything Galabin says is worth listening to, everything Galabin writes is worth reading twice."

In manner he was very quiet and reserved, and, though he had read and thought deeply on most subjects, it was difficult to get him to talk thereon or to utter the opinions he had formed. He would often listen to a voluble talker for some time, and then utter a quiet remark—prefaced by a modest "I suppose"—which completely summed up the matter, and often put it in quite a new light. He was a staunch moderate Churchman; in politics he was originally an old-fashioned Liberal, but became a Unionist when that party split up. He never espoused Tariff Reform, and called himself latterly a keen Unionist Free Trader. He was very fond of music but no musician.

His health was never robust even in childhood, and his aunt's diaries still extant contain many entries of the poulticings and nursings of "little Lewis." In 1886 he had his first attack of tachycardia, and was then found to have valvular disease; the attacks were frequently repeated, but he was able to go through two necessary but severe operations, and for the last two years of his life his heart gave him hardly any trouble.

He was a very good chessplayer, and was a member of the Four-handed Chess Club from its foundation in 1885. He was very fond of travel, and went abroad nearly every year, at first with college friends, and later with wife and daughter. He was a devotee of the mountains, but had not the physical strength necessary for mountaineering. He was a good walker, and had walked over all the great Alpine road passes. He was a member of the Hellenic Travellers' Club. A camera and a botanist's vasculum were always carried on his walks, and, in fact, botany was his great hobby. He always loved a garden but never had any opportunity of enjoying one until he went to Tapley in 1893, and then his happiest days were spent in his garden planning new beds and restocking old ones. Fresh supplies were always brought back from his Continental tours, so that he had in profusion cyclamens from Monte Generoso, shrubs from the Dauphinée, and ranunculi from Cannes. As a neighbour (an old Guy's man) said: "If I show Galabin anything new in my garden, he scribbles it on his shirt cuff and the plant is soon flowering in his garden." He loved flowers, and this month, when he heard in Sicily that the flowers in England were much earlier than usual, he turned homewards sooner than he had intended, and hurried across Europe to see his daffodils at Tapley before they were over. He only went once round his garden; pneumonia set in, and he died after five days' illness, under the shadow of a spreading cedar that his grandfather had planted. He was buried at Bishopsteignton on March 29th in a grave lined with his own daffodils, and the service was read in the church in which his mother and father had been married. He was a man of noble simplicity and most straightforward character, but one of those quiet thinking men whose powers are perhaps never fully revealed to their associates, and of whom, therefore, no adequate appreciation can ever be recorded; but in this instance the power of the man can perhaps hardly be more forcibly shown than by saying that, while his bent seemed to be all in the direction of original physiological investigation of the diseases of the circulation, finding his way in medicine barred for the time, he accepted the opportunity offered to him of an obstetric appointment, and thenceforth devoted himself entirely to the special and very alien branch of work.

Few could have been bold enough at his outset to suppose that under his somewhat slender and delicate-looking frame there existed the nerve and determination sufficient for a successful surgical career. Yet it was so; and Galabin had the reputation of being a bold, a careful, and a very successful operator in all the major operations of obstetric surgery, while his kindly and gentle manner inspired confidence in his patients, and was greatly appreciated in a sick room.

Of his home life one need only say he was fond of

home, fond of seeing his friends, who soon found out that, although at first he might seem somewhat impenetrable, he was generally ready to say something worth listening to on most subjects that came up for discussion by the way. And by those who knew him well he will be remembered and regretted.

He leaves a widow and one daughter, who is married to Mr. Harold Michelmore, the well-known West Country tennis player.

ROBERT HUNT, M.R.C.S., L.R.C.P.,

CONSULTING SURGEON, BLACKBURN AND EAST LANCASHIRE INFIRMARY.

DR. ROBERT HUNT, one of the best known and most highly esteemed practitioners in Lancashire, died at his residence at Blackburn on Wednesday, March 19th. He had been in perfect health and was playing golf on the previous Saturday; next day pneumonia commenced and threatened from the very beginning to prove fatal. This fact was only known by those in immediate touch with him, so that his death was a shock as well as a cause of the deepest regret to the community.

Robert Hunt, a member of a well-known Lancashire family, was born at Preston in 1856, and after completing his general education at the Grammar School in the same town became a student at Owens College, Manchester. Subsequently he spent a year or two in London, and became M.R.C.S. in 1877, and L.R.C.P. in 1882. He held various resident appointments at the Manchester Royal Infirmary and the Monsall Fever Hospital, and finally settled down to practice in Blackburn. He was appointed to the honorary staff of the Blackburn and East Lancashire Infirmary, and remained an active worker on the surgical side until some three years ago, when he was appointed honorary consulting surgeon. He was also medical referee to the county court, a certifying surgeon under the Factories Act, and a public vaccinator. A man of exceptionally fine physique, Dr. Hunt was an all-round sportsman in the very best sense of the term. As a young man he was a renowned exponent of Rugby football. For several years in succession he was an International player; indeed, he and two of his brothers created a record in this connexion, for they were all three International players in the same year, Dr. Hunt being English three-quarters back and his brothers playing in the same team as forwards. In his later years he was an active member, and for a long time captain, of the Pleasington Golf Club, and up to a comparatively recent period had been a good shot. His other characteristics are well described in the following note from one of his colleagues:

"Bob," as he was affectionately spoken of by his friends, had one outstanding characteristic. This was a diffidence about his achievements as an athlete or as a surgeon. No one ever heard him speak of his days as a Rugby International, or of his prowess on the golf links and with the gun. As a surgeon he possessed in a marked degree good judgement, and his manipulative dexterity was the envy of his colleagues. He was specially good at plastic work, and took great pleasure in operating for harelip and ruptured perineum. As a golfer he was the most difficult man in the club to beat, as he never gave in while the faintest possibility of winning remained.

In ambulance work Dr. Hunt also took much interest; indeed, the local branch of the St. John Ambulance Association practically owed its origin many years ago to his energies. The parent body, the Order of St. John of Jerusalem, made acknowledgement of this by appointing him an honorary associate, and the post of examiner was one of those that he held at the time of his death. He was also a member of the Preston and Blackburn Division of the British Medical Association. His death leaves a blank both in the professional and social life of Blackburn which will prove difficult to fill. He was married, and is survived by his wife and by two sons.

We have to record the death, on March 30th, at the age of 58, of MR. ALFRED CHUNE FLETCHER, of the Charterhouse, where he was resident medical officer to Sutton's Hospital. He was the son of a journalist in Hereford, and received his early education at the Grammar School in that city. He became a student at St. Bartholomew's Hospital in 1877, obtained the diploma of M.R.C.S. Eng. in 1881, and was house-surgeon to the hospital. In addition to the appointment by which he was best known he was medical officer of the Merchant Taylors' School,

and had earned the confidence and esteem of many patients and friends in all parts of the country. We have received from a lay correspondent a tribute to his memory, in which, after deprecating any desire to estimate his attainments as a medical practitioner, he writes: "Perhaps you will allow me to refer to what in my opinion constituted a greater merit than any professional skill, and that is the great hold which as a man and as a superior he had, by his gentleness, consideration, and scrupulous regard for the self-respect of others, managed to acquire upon the affections and regard of those subjected to his authority while resident medical officer at the Charterhouse. Remarkably kind as he was to the fairly considerable staff of attendants and nurses that worked under him, helping them with many a kind action, his merit showed forth most conspicuously in his conduct towards the pensioners, not a few of whom had previously lived in good positions. Not every one in authority would have been equally careful to avoid wounding their self-respect by harsh or haughty conduct. Dr. Fletcher never did so, and the result is, I find, a genuine, grateful regard retained for his memory, such as would have gratified him could he be made aware of it, and such as shows that kindness and consideration under circumstances such as his are not thrown away." A member of the profession who signs himself "A. E. P." adds that he had known Mr. Chune Fletcher for over twenty years, and could truthfully say, "We shall not see his like again."

WE regret to announce the death of DR. MICHAEL AHERN, of Brosna, co Kerry, after an illness of some weeks. He had been in charge of the Brosna and Knocknagashel Dispensary Districts for more than a quarter of a century, and was one of the most popular medical men in Kerry.

SURGEON-GENERAL T. J. MURPHY, late A.M.D., who died on March 10th, aged 82, obtained the diploma of L.R.C.S.I. in 1852, entered the service in April, 1854, was promoted Surgeon in 1865, Surgeon-Major in March, 1873, Brigade Surgeon in November, 1879, and Deputy Surgeon-General in May, 1882. He retired with the honorary rank of Surgeon-General in September, 1884.

DEPUTY INSPECTOR-GENERAL G. SAUNDERS, C.B., died on March 6th at Tunbridge Wells, aged 89. He took the diploma of M.R.C.S. Eng. in 1845 and became M.D. Aberd. and M.R.C.P. Edin. in 1872. He joined the service in December, 1845, becoming Surgeon in 1854, Surgeon-Major in 1865, and retired in February, 1871, with the honorary rank of Deputy Inspector-General. He served in the Crimea, was present at the battles of Alma and Inkerman, the capture of Balaclava, and the siege of Sebastopol. He was mentioned in dispatches and was awarded the medal with three clasps and the Turkish medal. He was senior medical officer at Hong Kong during the fever epidemic in 1865 and was mentioned in dispatches and awarded the C.B.

Public Health.

POOR LAW MEDICAL RELIEF AT BURNLEY.

THE Burnley *Express* has published a report of a recent meeting of the Burnley guardians, when letters were read from the Burnley Division of the British Medical Association and the Poor Law Medical Officers' Association of England and Wales protesting to the Local Government Board against the proposed scheme for furnishing medical relief in the area of the union. The Local Government Board asked for the comments of the guardians. The letter from the Burnley Division was as follows:

I am instructed by the Committee of the Burnley Division of the British Medical Association to request the consideration of your honourable Board to the dispute of the district medical officers of the Burnley Union—a matter which was brought to your notice by a letter from me dated December 9th, 1912.

It will be within your knowledge that the whole of the nine district medical officers of the union resigned their positions, having failed to obtain what was considered by them and by the medical men in the district adequate remuneration, or remuneration which was equal to that paid in similar surrounding unions. An increase of stipend was offered to some of the district medical officers in June last, but even with this increase the amount was still inadequate. As a counter move the guardians have decided

to divide the union into fifteen medical areas instead of nine as heretofore, and have dismissed all the public vaccinators with the object of utilizing the fees for vaccination towards making out the small salaries to be paid to the district medical officers. My Committee desires to inform you that in December last the Mayor of Burnley met the district medical officers and officers of the Burnley Division, and kindly offered, if agreeable to them, to approach the guardians with a view to a settlement of the dispute. This was gladly agreed to by the medical men but refused by the guardians.

Various points were then put forward, namely, that the present board of guardians would shortly vacate office; that no good reasons had been given for the proposed divisions and the dismissal of the public vaccinators; that even with the increase of payment proposed, the remuneration in the Burnley area would fall far short of that paid in adjoining unions; that the salaries proposed in the various new districts did not correspond with the work likely to be required; and that the making of the district medical officer a public vaccinator in his own district greatly conduces to underpaid Poor Law work.

The letter of the Poor Law Medical Officers' Association pointed out that the comments by the Burnley Guardians on its last letter had in no wise answered the points raised by it against the proposed arrangements, and submitted further criticism, similar to that of the local profession. Special stress was laid on the undesirability of allotting the public vaccination of every Poor Law medical district to the district medical officer. In some cases it might be convenient and unobjectionable; but to divide a union like Burnley into fifteen distinct vaccination districts was a proceeding so unusual as to demand explanation. This, it was stated, had not been forthcoming.

The guardians resolved unanimously to make no comments on the above letters. This, no doubt, was the easiest course, but whether it will commend itself to the Local Government Board remains to be seen. That body by sending down the letters evidently considered that the former comments of the guardians on the previous letters were insufficient. In all the circumstances we cannot but agree with the Council of the Poor Law Medical Officers' Association, "that the *impasse* that has arisen imperatively calls for investigation of the conditions under which medical relief is being administered in the Burnley Union."

Medical News.

A MOVEMENT has been started to commemorate the visit of His Majesty King George to Aden by the erection of a female hospital, the want of which has long been felt.

DR. JAMES DEVON, Medical Officer to H.M. Prison, Glasgow, has been appointed a Prison Commissioner for Scotland, in the place of the late Mr. Thomas Robertson.

THE International Association of Medical Psychology and Psychotherapy will hold its annual meeting at Vienna on September 18th and 19th, immediately before the opening of the Congress of German doctors and scientists.

THE King has granted permission for Captain Robert G. Archibald, M.B., R.A.M.C., to accept the Imperial Ottoman Order of the Medjidieh of the Fourth Class conferred upon him by the Sultan of Turkey in recognition of valuable services rendered.

THE Lord Chancellor has added the names of fifty-seven gentlemen to the Commission of the Peace for the County of London. Among the names are those of the following members of the medical profession: Sir Thomas Boor Crosby, Dr. W. J. Frankish, Dr. Wheeler-O'Brien, and Dr. T. Rushbrooke.

THE third tour organized by the Voyage d'Études Médicales will start on August 25th, and will include visits to watering places and climatic stations in the south-west of France, beginning with Arcachon, Dax, and Biarritz, and concluding with Bagnères-de-Luchon on September 6th. Further particulars can be obtained from Dr. Carron de la Carrière, 2, rue Lincoln, Paris.

ON the strength of a recent epidemic of ophthalmia at the Park School, Hanwell, the State Children's Aid Association has addressed to each member of the various boards of guardians concerned a letter urging that this "unnatural gathering" should be broken up. Had these children, it is suggested, been cared for in small groups on the family plan, the primary case or cases would have been more readily detected and much unnecessary suffering avoided.

THE competition in mothercraft, which we announced as in prospect some months ago, is to take place on the afternoon of Saturday, April 12th, at the Infant school in Charing Cross Road. This is the last day of the "health week" which has been organized by the National League for Physical Education and Improvement; the competition has been arranged through the affiliated Associa-

tion of Infant Consultations and Schools for Mothers. The names of a hundred competitors have been entered from sixteen different centres, and the contest between them promises to be keen. Apart from individual prizes to competitors, a challenge shield will be awarded to the centre securing the highest aggregate number of marks. Admission to view the competition will be by ticket, price 1s. Early application should be made to the Secretary of the Association, at 4, Tavistock Square, since only a limited number are available.

A PLAN for the establishment of a sanatorium for tuberculosis in the province of Shantung, one of the most thickly populated parts of Central China, has been approved by the English and American missions which have united for purposes of medical education, and by the council of the Shantung Christian University. As far as is known, there is at present no public institution in China intended solely for the treatment of tuberculosis. The need for such a sanatorium is shown by the fact that 50 per cent. of the patients in some of the mission hospitals suffer from tuberculosis.

AN illustrated pamphlet descriptive of the tours to Norway and the northern capitals arranged for the coming summer by the Royal Mail Steam Packet Company can be obtained on application to the company's offices in Moorgate Street. The vessel set apart is the *Arcadium*, one of nearly 9,000 registered tonnage, equipped as a yacht, and supplied with various modern conveniences, such as bedsteads instead of berths, and a swimming bath and gymnasium. The cruises will vary in length from thirteen to twenty days, the rates ranging from £1 a day upwards.

A DEPUTATION from the Eugenic Education Conference recently held in London had an interview with Mr. Trevelyan, Parliamentary Secretary to the Board of Education, on April 2nd, asking that an inquiry should be held as to the advisability of encouraging the presentation of the idea of racial responsibility to students in training and children at school. The deputation, which was headed by Major L. Darwin, President of the Eugenics Education Society, and including the Head Master of Eton, Mr. Nicholls (ex-President of the National Union of Teachers), the Dean of St. Paul's, and Miss Tuke (Principal of Bedford College), stated that it was not desired that eugenics should be an extra subject in the curriculum, or that it should be required to be taught by unwilling teachers, but it urged that the training college curriculum should be adapted to include the biological and physiological knowledge on which an eugenic ideal could be based, and that the subject should be approached from the evolutionary standpoint. Mr. Trevelyan said that the board, while unable to make sex hygiene or eugenics a compulsory subject of instruction in elementary schools or training colleges, recognized the importance of the matter, and had no wish to discourage experiments in teaching on those lines.

LORD LONSDALE, in an appeal on behalf of Charing Cross Hospital, makes reference to the strenuous efforts of the managing body during the last eight years to place the institution on a sound financial basis. It is greatly to their credit that within that short space of time they have reduced the debt by £35,000; but—unhappily there is always a big But in such appeals—there remains a balance of £62,000 still to be paid. In addition to that sum money is required for further improvements, amongst which are the opening of a free children's ward, and the reopening of five closed wards as pay wards. At present young children have for lack of room to be placed in the adult wards, much to the discomfort of the other inmates, and also of the sufferers themselves. The pay wards are intended for persons who are unwilling to accept charity and yet unable to afford surgeons' fees and the expense of a nursing home. The charge is to be two guineas a week, payment which will cover whatever operative measures may be necessary. The privilege of admission to these wards will, it is stated, be strictly limited to persons of moderate incomes. To pay off the outstanding balance and to defray the cost of these contemplated improvements a total sum of £70,000 is required. Lord Lonsdale's appeal is addressed particularly to the theatrical and sporting community. Owing to its situation the hospital receives a large number of patients connected with theatres, and all patrons of the drama may therefore be expected to take a keen interest in the institution. The Charing Cross Hospital has behind it a fine record of excellent work for the benefit of the sick poor and for the advancement of medical science, and it is to be hoped in the interest of suffering humanity that the development of its field of usefulness will not be hampered by lack of means.

Letters, Notes, and Answers.

Authors desiring reprints of their articles published in the *BRITISH MEDICAL JOURNAL* are requested to communicate with the Office, 429, Strand, W.C.2, on receipt of proof.

Queries, answers, and communications relating to subjects to which special departments of the *BRITISH MEDICAL JOURNAL* are devoted will be found under their respective headings.

QUERIES.

INTERMITTENT GLYCOSURIA.

DR. J. L. THOMAS (Brynnaur) writes: Mrs. X., aged 47, a multipara, and still regular in menstruation, complained much pruritus pudendi, and the usual symptoms of glycosuria in women of that age. There was a history of extreme and habitual constipation, but of good health, and no sample symptoms began. As she was menstruating, and no sample of urine was then procurable, she was provisionally put on laudanum, alkalis, and full doses of nuxvomica. The usual instructions with regard to diet were given. The first sample of urine—morning, fasting—had specific gravity 1030 and no sugar. It was pale and cloudy, and contained bacilli of the *coli* group. A sample for the afternoon of the next day was of specific gravity 1050, and contained much sugar. She has in three weeks much improved with treatment, but urine after fasting and after meals showed the same results, although the amount of sugar is much reduced. Is the glycosuria of chemical or bacterial origin?

INCOME TAX.

M.B. joined a partnership a year ago without buying any book debts. The income tax assessment for the year is £471, but the actual profits of the firm £290 only. He has borne his share (four ninths) of the tax on £471, and asks what his remedy is.

If our correspondent's income from all sources does not exceed £400 he can in any case claim repayment of tax on £100 upon application to the local surveyor of taxes. With regard to the amount of the assessment on the firm's profits, this is not excessive if the profits, including the year's outstanding book debts, amount to this sum. M.B.'s profits for the year cannot be calculated only by reference to the cash receipts in the first year, since he has become entitled also to his share of the book debts arising in the year. No adjustment of the gross assessment can be obtained unless the profits of the practice as a whole have been less than the assessment, owing to the change of partnership or some other specific cause; if they have been less than the assessment application should be made to the surveyor of taxes for adjustment on this ground.

PATHOGNOMIC.

We regret that by an oversight we have left the following letter from Dr. E. A. Constable (West Green, N.) unnoticed. Under date January 8th he wrote: May I ask which *English* dictionary is responsible for "pathognomic"? (*BRITISH MEDICAL JOURNAL*, January 4th, Epitome of Current Medical Literature, para. 6, "Lignens Phlegmon"; It., *patognomico*; Sp., *patognomico*; Fr., *pathognomonique* (Worcester's Dictionary).

The form "Pathognomic" is given in the *New English Dictionary on Historical Principles* (Oxford, Clarendon Press). It is stated to be from the "false form" *παθρηνωμικος*, which is described as equivalent to "pathognomic." The following examples of the use of "pathognomic" are given in that Dictionary: *Boul's Mere Cognit.*, VI, 185: "The Pathognomic Symptom of this Disease, and that which first invaded the Patient" (1755). Charles Parvyn's *Emotions*, VIII, p. 205 (1872): "Constant tremulous agitation . . . pathognomic of the earlier stages of general paralysis." *Pathognomic* is used in the same sense by T. Goodwin in *Trial of the Christian's Growth* (1643): "such symptoms are Pathognomicall and peculiar to them." In the *Edinburgh Review*, July, 1874, p. 183, occurs the phrase: "With the advance of power of pathognomic expression coincides a certain loss of pathognomy." *Pathognomy* occurs in Good's *Study of Mania*, fourth edition, I, p. 585 (1822-23). The form may be defended on the ground of convenience of pronunciation, and it has an analogue in "physiognomic," from the Greek *φυσιογνωμικος*. There are other instances in medical terminology of shortening up words. We need only refer to formic acid, which on strict etymological principle should be "formic" acid (*formica*),

ANSWERS.

THALATTA.—Oleate of mercury was, we believe, introduced as a cleanly and efficient substitute for mercury ointment to produce mercurialization byunction. The mercury oleate ointment, *B.P.* (1898), consists of mercury oleate 1 part, benzoated lard 3 parts. The *Extra Pharmacopoeia*, fifteenth edition, p. 558, contains formulas for oleatum hydrargyri 10 per cent., oleatum hydrargyri liquidum, cum morphina (1 in 60) and oleatum hydrargyri liquidum. The first two contain 10 per cent. of yellow mercuric oxide, the last mentioned 5 per cent. The rubbings are usually weighed up in grease-proof paper of weight 10 to 30 grains, or the equivalent of the liquid preparation may be employed.

UNDERFEEDING.

DR. BINNIE DUNLOP (London, S.W.) writes: The report on the diet of the labouring classes which has just been issued by the Physiological Department of Glasgow University reveals, as you say, that "there must be a large percentage of the people in Glasgow to-day who cannot obtain the bare minimum in the way of food." Is this to be wondered at in view of the prevailing ignorance of parental prudence among the poor, and of Mr. Seebohm Rowntree's authoritative estimate that, if expended with the utmost scientific care, a weekly wage of 25s. 8d. would only provide the bare necessities of life for a family of three children? It is surely time that, on humanitarian, economic, and political grounds, we recognized the fact that few urban wage earners can do justice to more than two children. Vital statistics show that falling birth-rates are accompanied by falling death-rates, and that they will continue to be so until the latter have reached the normal—about 10 per 1,000 per annum, as in New Zealand. At present, therefore, the principal aim of medical officers of health should be the abolition of underfeeding. So I beg to submit my opinion that there are only two genuine propositions, and but one practicable one, for the abolition of underfeeding—either (1) that every adult wage-earner should receive from the State an additional so many shillings a week for each child he may have; or (2) that the poor should be encouraged to beget no more children than they can themselves afford to maintain properly.

LETTERS, NOTES, ETC.

BRADZINSKI'S SIGN.

In the review of the fourth edition of Dr. Louis Fischer's *Diseases of Infancy and Childhood*, published in the *BRITISH MEDICAL JOURNAL* of March 22nd, p. 617, it was said that Bradzinski's sign in meningitis was there first mentioned in a textbook written in English. The fact that the sign was described in Dr. Cantley's *Diseases of Infants and Children*, published in 1910, was overlooked.

SUNSHINE IN 1912.

DR. H. DRAPER BISTON, STATES M.O.H. (Guernsey), writes: The past year (1912) seems to have been in the British Isles very gloomy, with but little sunshine. As has often happened before, Guernsey holds the record for 1912 with 1,701 hours of sunshine. The year was, however, the least sunny on record here, the average of past years having been 1,925 hours.

A LARGE DOSE OF VERONAL.

DR. A. GOLDNEY CHERRY (Highgate, N.) writes: On March 8th I was called to a man, aged about 60, who, presumably about 6.30 the previous evening, had swallowed 125 grains of veronal. It was not discovered till 10 a.m. the following morning, when his bedroom door was forced open. I saw him about 10.45, and I was told that he had not had some opium as well. I washed it out with potassium permanganate in addition, finishing with the administration of hot coffee and a couple of beaten up eggs through the stomach tube. With six hourly injections of strychnine $\frac{1}{10}$ grain, the constant inhalation of oxygen, and rectal feeding, I had the satisfaction of bringing him round, but he remained quite unconscious till the morning of March 11th. Now that the authorities have put veronal on the scheduled list of poisons, it seems a great pity they did not at the same time make it obligatory for no chemist to supply it without the prescription of a medical man.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

| | £ | s. | d. |
|-----------------------|-----|-----|-----|
| Eight lines and under | ... | ... | ... |
| Each additional line | ... | ... | ... |
| A whole column | ... | ... | ... |
| A page | ... | ... | ... |

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Wednesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive unregistered letters addressed either in initials or numbers.

An Address

ON

RHEUMATOID ARTHRITIS.

DELIVERED AT A MEETING OF THE SUNDERLAND DIVISION
OF THE BRITISH MEDICAL ASSOCIATION,

BY

SIR JAMES BARR, M.D., LL.D., F.R.S.E.,

PRESIDENT, BRITISH MEDICAL ASSOCIATION.

MR. CHAIRMAN AND GENTLEMEN.—When, at the request of my friend Dr. Todd, I consented to give an address to your Division on rheumatoid arthritis, I was told that this complaint is fairly common in this district, and he was specially solicitous that I should give you a few infallible tips on treatment; but I am too old to deal in infallibilities—it is only the young men in all ages who propound infallible cures, which as a rule are short-lived, and the patients become sadder, and the doctors perhaps wiser, men. If it had not been for these cocksure gentlemen, I feel confident that we would have known more about this disease than we do at present; there is a statement made by Karl Pearson in reference to another subject, which is very applicable to this one:

It is a very uphill battle to contest one after another the various dogmatic statements made by a small section of the younger medical men on the basis of statistics which are hopelessly inadequate, if they are not misread or perverted.

There are few diseases in which greater confusion exists as to their nature and causation than those of the joints, and yet every writer seems to think that he, at least, knows all about the subject. I believe it was Robert Lowy who said that "it does not matter what you say so long as I understand what you mean," but herein lies our difficulty. If you read any textbook dealing with arthritis, you will be a clever man if you know what the author means; and, on the other hand, you may probably consider that the writer does not himself know. You will find a whole series of diseases inextricably mixed up under the same name, or different names applied to the same disease. You find such names as rheumatoid arthritis, infective arthritis, toxic arthritis, arthritis deformans, osteo-arthritis, chronic rheumatism, rheumatic gout, indiscriminately applied to a variety of affections of the joints and to different stages of the same affection.

Arthritis deformans is a common name for the disease with which we are dealing, but if you wait for deformity before correctly diagnosing the disease you may have to wait for years until the patient is becoming a hopeless cripple. Again, some call this affection an infective arthritis, and others call it a toxic arthritis without offering any proof in support of their contentions. As a rule, the less these gentlemen know about infections or toxins the more dogmatic their statements. Good bacteriologists do not talk in this manner, because they have been taught by Koch:

1. The organism in question must be present in the tissues, fluids, or organs of the animal affected with, or dead from, the disease.

2. The organism must be isolated and cultivated outside the body on suitable media for successive generations.

3. The isolated and cultivated organism on inoculation into a suitable animal should reproduce the disease.

4. In the inoculated animal the same organism must be found.

What author who boldly asserts that rheumatoid arthritis is an infective disease has conformed to those postulates, or what is the toxin that lights up this affection? This toxin is as vague and indeterminate as the imaginary "stimulus" which is supposed to initiate and maintain cardiac contraction.

Because certain cases of arthritis have been associated with pyorrhoea alveolaris or an ulcer in the rectum, and have been cured by a vaccine, it has been promptly assumed that all cases of rheumatoid arthritis are due to some germ or other, or to its toxin. But such evidence as this is no proof whatever that these easily remediable cases are similar or in any way allied to the chronic poly-articular inflammations of the synovial membranes and periarticular structures of the joints which we designate

rheumatoid arthritis. No doubt many organisms, such as the tubercle bacillus, the gonococcus, the *Diplococcus intracellularis* of Weichselbaum, the pneumococcus, the influenza bacillus, the streptococcus and staphylococcus, not unfrequently set up a monarticular or a polyarticular arthritis, but such cases should be easily differentiated from rheumatoid arthritis. It is often marvellous how a case of gonorrhoeal rheumatism, especially if monarticular, can be rapidly cured by a few injections of a gonococcus vaccine. The worst case of suppuration of many joints which I have ever seen was due to the *Diplococcus intracellularis*.

Perhaps the most popular view of this affection in the present day is to look upon it as a toxic arthritis, due to one or more toxins produced by the intestinal flora, but no attempt has been made to show the nature of the toxin or its special affinity for the joints, or what the liver has been doing to allow it to pass its portals. The urine shows no evidence of intestinal putrefaction, and this vague hypothesis rests on no firmer foundation than the imagination of some writers. Such evidence is of no more value than that of the Irishman who, not wishing to reveal his ignorance, when hard-pressed on cross examination acknowledged that he was perhaps putting a hypothetical case before his lordship and the jury, but when asked what is an hypothesis he replied that in faith he did not know, but he thought it was some part of a pig; so those gentlemen do not know what is the toxin, but they think it is some part of rheumatoid arthritis.

Osteo-arthritis is frequently used as a synonym for rheumatoid arthritis, but really the two conditions are diametrically opposed. The former usually occurs at a later age; the disease runs a very chronic course without any exacerbations. There is thickening of the synovial membranes, erosion of the cartilages, eburnation of the ends of the long bones and the formation of osteophytes. It usually affects many joints, but one hip-joint may be the only one involved. In this category must be included Heberden's nodes, and spondylitis deformans. It is true that the deposition of lime salts may take place in the final stages of rheumatoid arthritis, but this only occurs after the disease is over and the deformity left. It is Nature's clumsy method of effecting a cure.

RHEUMATOID ARTHRITIS.

By a process of elimination I am now in a position to define what I mean by rheumatoid arthritis. It is a low, chronic, polyarticular inflammation with frequent acuto exacerbations. There is thickening of the synovial membranes and the periarticular fibrous tissue, with slight serous effusion into the joints. The muscles generally are wasted, irritable, and contracted; the deep reflexes are increased, and there is frequently neuritis, especially of the nerves supplying the joint structures. The joints are at first stiff, grating and painful on movement. In my experience the large joints, especially the knees, shoulders, and ankles, are first involved, and one joint only may be at first affected, especially if it had been previously injured. In this stage of the disease, if recognized and energetically treated, it rapidly disappears; but unfortunately the disease is not then usually diagnosed, but is called chronic or subacute rheumatism and treated accordingly; or if it be recognized, the patient is told that it will eventually cripple her, and nothing can be done except to try and delay its progress. If the disease be allowed to progress, as it practically always is, then you get the smaller joints affected, such as the wrist joints, carpus, metacarpo-phalangeal and first phalangeal joints, and the joints of the toes. You then get the characteristic fusiform swelling of the joints, and of course diagnosis can no longer be delayed. The further swelling of the joints is accompanied by increased effusion, erosion of the cartilages and rarefaction of the articular ends of the bones from absorption of the lime salts. From the disorganization of the joints and muscular contraction you get well-marked arthritis deformans. It is still possible to cure the disease, but not the deformity. If, however, you keep hunting after the germ and its toxin, the patient as well as her joints will become a hopeless wreck.

Etiology.

In dealing with the nomenclature I have to some extent referred to the etiology. As I believe with Newton that

we should admit no more causes of natural phenomena than such as are both true and sufficient to explain their appearance, I shall at once pass over the score of causes which have been set down in textbooks, and now state my own view as to the immediate cause of the disease, and afterwards lay bare the foundations of my belief. The proximate cause, in my opinion, is a mild chronic acidosis, which extracts the lime salts from the fibrous tissue, muscles, nerves, cartilages, and bones. I thus look upon this affection as a general disease, and the apparent localization in the joints is due to their structure and liability to injury. The extraction of the lime salts from the fibrous tissue causes it to swell and its vascularity increases; with the loss of the lime salts the muscles get into a condition of irritable weakness—they waste, readily contract, cramp frequently occurs, all the deep reflexes are exaggerated, and even a state of rhythmic tremor may be set up. There is not much lime in the nervous tissue, but its abstraction leads to a marked result; neuralgic pains readily occur, and even neuritis is easily established. The patients frequently complain that the pains are worse at night, and this is almost universally ascribed to the heat of the bedclothes, a regular *post hoc, propter hoc* argument, but when the patient is in bed in the daytime the pains subside, though "the heat of the bedclothes" remains the same. The condition really is that the blood is less alkaline at night; it is consequently capable of holding more lime, which is taken up from the tissues. The night pains can usually be obviated by a drachm of sodium bicarbonate and 15 grains of lime carbonate in a glass of milk at bedtime.

As more and more lime gets absorbed, you get swelling of the periarticular tissues and effusion into the joint; this serous effusion is often bloodstained, and inflammation in the joints soon attacks the cartilages, from which absorption of the lime salts takes place, followed by their erosion and thinning. The ends of the bones in the afflicted joints are attacked last, and absorption of the lime salts with rarefaction takes place; these parts of the bones are selected as they are easily damaged from use and become more vascular. The deposition of lime salts readily takes place in parts which are not functioning, and if you wish to cause absorption you must see that the function of the part is restored—for example, if you wish to decalcify rigid costal cartilages, you must not merely use decalcifying remedies, but you must also make the patient take respiratory exercises.

I frequently use decalcifying agents, but I am always quite alive to the danger of producing rheumatoid arthritis, and so such an untoward event has never occurred in my hands. Perhaps some of my followers will accomplish this, but it will not be without warning. If people were more careful in their diet they would not require so much physio.

Sex.

Women are much more liable to this disease than men. There is nothing in the constitution of a woman which should make her specially susceptible to this disease, but the very same conditions which make her less liable to arterio-sclerosis render her more prone than men to rheumatoid arthritis. In the poorer classes, where this disease abounds, she is badly nourished, lives on tea, bread-and-butter, and various carbohydrates, which readily undergo acid fermentation in the stomach; there is a poor supply of milk and other proteins. She gets very little lime and other alkalis, while she is liable to exhausting discharges, such as menorrhagia, leucorrhoea, excessive lactation, and mucous colitis, which rob the system of its lime. The leucorrhoea is usually due to the *Bacillus coli* or other organisms, but so far as the rheumatoid arthritis is concerned it is not the organisms, which are practically outside the body, but the loss of lime, which works the mischief. It most frequently occurs in women between the ages of 15 and 35, during their most active menstrual period. It does not usually start after the menopause, but if then already present other causes may maintain it in an active condition. The thyroid gland is more active in women than in men, and this leads to active calcium metabolism. It is essentially a disease of debility, and nutrition is readily affected by worry, anxiety, overwork, frequent childbearing, loss of blood, etc.

Among the associated conditions which to some extent

stand in a causal relation must be specially mentioned an almost invariably dilated stomach with deficient motor action and obstinate constipation with occasional diarrhoea. For the maintenance of the motor function of the stomach and bowels a certain amount of calcium and potassium salts are necessary, while in these cases the supply of both is deficient. This leads to stagnation with acid fermentation, and the production especially of lactic and butyric acids; this tends to increase the excretion of lime rather than its absorption. The late Dr. O. T. Williams showed how the insoluble lime soaps damage the mucous membrane, setting up mucous colitis; but in this case they have the further deleterious effect of robbing the system of lime.

The amount of lime taken up from the intestinal tract when administered in the form of food or medicine is very variable. In many cases only a small fraction of that administered reaches the blood, while many individuals absorb it freely and excrete it as rapidly. Apart from individual peculiarities, this to a large extent depends on the form in which it is presented for absorption; the tribasic phosphate is a very fixed salt and almost entirely insoluble, yet I have heard a professor of therapeutics assert that this salt cures the toothache of pregnancy. Such child-like simplicity and therapeutic faith deserve a place in the Kingdom of Heaven if there be no retribution for culpable ignorance. The sulphate is rather insoluble but it is readily decomposed in the intestinal tract, and so presented to the mucous membrane in more assimilable forms; the same can be said for the carbonate. The chloride, the lactate, the glycerophosphate, and the iodide of calcium are all easily assimilable forms; the iodide is an especially active salt, but from its stimulating effect on the thyroid gland it is not always advisable in this disease. The oxalate of lime is very insoluble, though it may be decomposed in small amount by the hydrochloric acid of the stomach; the citrate of lime is fairly soluble, but the citric acid hastens elimination. Where sodium citrate is added to cow's milk it splits off the fixed lime from the casein, and thus lessens the density of the curd. When the stearin and palmitin of beef and mutton fats are decomposed by the lipase in the intestines, their saturated fatty acids readily form insoluble lime soaps; but, on the other hand, the oleate of calcium is easily assimilated.

Lime exists in two states in the blood—first, as a fixed albuminate of calcium, and, second, as free ionizable calcium; the amount in both states varies considerably, but especially in the latter. When the blood is very alkaline the fixed lime is fairly constant, but as the alkalinity increases the blood holds less free lime and part of the free ionizable calcium is thrown out into the tissues, or excreted by the bowels and kidneys.

The fixed lime in the form of large molecules of calcium albuminate increases the viscosity of the blood, lessens the capillary velocity, and diminishes transudation of albuminous fluids, hence where the blood is well charged with fixed lime you do not get any albuminuria; on the other hand, with diminished alkalinity and the presence of acid salts with an alkaline reaction the blood holds a considerable amount of lime, which is readily excreted by the bowels and kidneys, and leaves the blood ready to take up more lime from the tissues or alimentary tract. So long as the blood is more or less saturated with lime the fixed calcium remains constant, but where the acidosis is not completely saturated with lime or alkalis the fixed calcium may be split off from the albumen, and then you readily get transudation. Hence, in the early stages of rheumatoid arthritis the urine is usually free from albumen, but in the later stages or during acute exacerbations when the fixed lime is lessened you get albuminuria, and also effusion into the joints and tissues. Dr. Sydney Ringer made experiments on the swelling of laminaria when immersed in water, and he found that sodium and potassium chlorides retarded, but did not lessen, the amount of fluid taken up; on the other hand, even minute traces of the chloride or other soluble salt of calcium greatly and persistently restricted the swelling of laminaria. Among the causes of dropsy the presence of sodium chloride in excessive amount must be recognized; and in the treatment of this affection Widal and many others have recommended a salt-free diet; but I have shown that in many cases this is not enough; you

must to some extent replace the sodium salts in the tissues with calcium salts. In rheumatoid arthritis there is usually a deficient supply and excessive excretion, though, of course, the activity of the process is an ever-varying quantity.

Symptoms.

We have already referred to the dilatation of the stomach, deficient motor function, acid fermentation and intestinal stasis; when the latter is very marked and persistent you get pigmentation of the skin with dark lines round the eyes. The function of the liver and pancreas are impaired, and the patient is usually troubled with flatulence. There is anorexia, but very rarely vomiting. As was originally pointed out by Kent Spender, there is a moderate tachycardia, and this is associated with excessive function of the thyroid, which leads to excessive calcium metabolism, fibrillar tremor, myotatic irritability, and rather free action of the skin. There is general muscular wasting, muscular irritability and contraction, frequently spasm and cramp, and at later stages neuritis with atrophy of the interossei and muscles of the thumb with deformity of the hands. The neuritis and symmetry of this disease have led many to imagine that it is of nervous origin, but as Sir James Paget pointed out, the decay of a leaf is symmetrical without any nerves. The quadriceps extensor femoris and deltoid are frequently much wasted. The muscular wasting leads to weakness, fatigue, and weariness, but although there is usually general emaciation and malnutrition, the existence of the disease is quite consistent with the presence of a considerable amount of adipose tissue. There is a slight effusion into the joints, swelling of the periarticular tissue, and the joints become fusiform in shape, stiff, and tender. The skin over the joints becomes attenuated and glossy. All the deep reflexes are exaggerated except where the action is limited by the stiffness of the joints. There is often much general pain and tenderness from effusion into the sheaths of the muscles, and the presence of sarcolactic acid; these pains, as well as those of the joints, are worst at night. There are frequently acute exacerbations with intermittent pyrexia. At such times the affected parts feel hot, and there is rather profuse perspiration, increased muscular weakness, and general lassitude. At other times the extremities may be cold and somewhat livid, or the fingers may feel "dead and numb."

At a later stage a radiogram shows wasting of the cartilages and rarefaction of the articular ends of the bones; this leads to more or less irreparable deformity. The lungs are not affected; the muscle of the heart may be weak and irritable, and the blood pressure is low, but any valvular lesion which may be present is due to other causes, or may be induced in Nature's methods of cure. The brain is not involved, except so far as the irritability of the patient's temper may be considered evidence of such involvement. At any rate, the patient is never stupid nor mentally lethargic, though migraine is not uncommon; there is often slight anaemia. The urine is usually clear, amber, acid (except from the effects of treatment), deposits urates during febrile attacks, contains an excessive amount of lime and phosphates, occasionally a trace of indican, and a little albumen in the later stages.

Treatment.

The earlier the recognition of the disease the more successful the treatment. Our attention should be first directed to the *prima via*, the teeth should receive scrupulous attention and all sepsis should be eradicated; the acid fermentation in the stomach should be eliminated, and this is most readily accomplished by cutting off all saccharine and farinaceous articles of diet, and placing the patient for a few days on an abundance of red meat with plenty of hot water. Red meat produces ammonia, which neutralizes the sarcolactic acid in the muscles; thea milk to which some sodium bicarbonate and chalk or lime water have been added, junket and cream. The sour milk craze in this disease has fizzled out. Afterwards green vegetables and farinaceous food, except oatmeal; a fair amount of fat should be given, especially olive oil or cod-liver oil; at least an ounce of one of these oils should be given every night at bedtime. Baroa gravy, fat bacon, cream, butter or margarine are valuable adjuncts, but beef and mutton fats had better be eschewed. The patient should take a liberal allowance of table salt

with meals. All acids and acid fruits, rhubarb, tomatoes and asparagus should be avoided. When saccharoses are considered permissible, glucose and honey are better than cane sugar or jams, but perhaps a little marmalade may be occasionally allowed. When the patient is improving, grapes, bananas, nuts, stewed prunes and figs may be allowed; saccharine is better than sugar, more especially if the urine has become alkaline under treatment, and tends to deposit phosphates. Regarding drink, there is nothing better than pure water, especially when hot, weak tea, milk and soda water (containing about 30 grains of sodium bicarbonate to the pint), plain barley water, and raisin tea. Avoid all sweet and acid drinks, wine and malt liquors. Regarding alcohol, I think the patient is better without any, but if for any particular reason a little is ordered it should be in the form of whisky, gin, brandy, sloe gin, or liqueur cognac.

To correct the acid fermentation and improve the motor function of the stomach a good combination consists of 30 grains of sodium bicarbonate, 10 grains of potassium bicarbonate, and 15 or 30 grains of aromatic chalk in a glass of milk about half an hour before meals, and a double dose at bedtime; often smaller doses suffice. An excellent stomachic of calcium chloride, hydrochloric acid, and minute doses of the perchloride of iron is very useful after meals; a small chologogue pill should be regularly administered to keep the bowels open; for this purpose an excellent mixture can be made with the sulphate, bicarbonate, and salicylate of sodium and liquorice. The pancreas is also usually at fault, and to improve its action I often prescribe a capsule of holadin and bile salts about two hours after meals. In these cases the thyroid gland is usually too active, and so all preparations of iodine and thyroid should be avoided. Possibly suprarenal gland and pituitary extract might do good, as Dr. Blair Bell has shown that these secretions tend to retain the lime in the system, whereas the thyroid increases its elimination, but personally I do not care to prescribe such powerful drugs when milder remedies may suffice. It is imperative to get lime into the tissues and to lessen its elimination, but herein lies our difficulty, as no matter how much is administered by the mouth it may be as rapidly excreted as it is absorbed, and so none may reach the tissues; but on the other hand the acidosis in the blood may be taking lime from the tissues as well as from the intestinal tract. In order to get the lime into the tissues there must be a liberal oral supply, and the blood must be kept very alkaline. For this I prescribe freely chloride of sodium and potassium, sodium bicarbonate, chalk, lactate of lime, and calcium glycerophosphate. If it be desired to get calcium rapidly into the tissues it may be given in a very dilute form subcutaneously, say a pint of sterile normal saline solution with 0.05 per cent. of calcium chloride, and 3 per cent. of syrup of glucose. If the calcium chloride be administered hypodermically in a concentrated form, it may readily produce gangrene of the skin and adjacent tissues. Iron is best administered in the form of underdone red meat, and yolk of eggs; arsenic, potassium iodide, guaiacol, and a host of remedies commonly prescribed are worse than useless.

Leucorrhoea should be treated with injections, and any infection of the urinary tract should receive attention. Here vaccines will often prove useful, and the same may be said for pyorrhoea alveolaris.

General massage and the Aix douche improve nutrition, and are highly beneficial; the hot air and electric light baths applied to affected joints often give much relief, but can scarcely be looked upon as curative agents. When you have cured your patient you can send her or him to Egypt, Timbuctoo, or any health resort. Encourage the patient to take a fair amount of exercise short of fatigue when the disease has subsided, and to live a godly, righteous, and sober life in this present world.

THE late Dr. William Carter, formerly Professor of Materia Medica and Therapeutics at Liverpool University, left estate valued at £35,591.

A BILL has been introduced into the North Carolina State Legislature making it unlawful for any medical practitioner or other person to prescribe or recommend any drug or preparation without knowing its true nature and composition. The bill would also require the prescriber to make known the nature of the composition to the patient if requested.

The Harveian Lecture

ON

THE VARIOUS FORMS OF FIBROSITIS AND THEIR TREATMENT.

DELIVERED BEFORE THE HARVEIAN SOCIETY OF LONDON ON
APRIL 10TH, 1913,

By ARTHUR P. LUFF, M.D., B.Sc.LOND.,
F.R.C.P.LOND.,

PHYSICIAN TO ST. MARY'S HOSPITAL.

ALLOW me to express my gratitude to the President and Council of this society for the honour conferred in asking me to deliver this lecture. I feel that some excuse is perhaps necessary in selecting for my subject one of the minor maladies, but it is one that has a very appreciable influence on the comfort and enjoyment of life, is very prevalent, especially in this country, and, in my opinion, is well worthy of more attention than it has hitherto received at the hands of the medical profession.

It happens to be a disease in the treatment of which I have had considerable experience for many years, and I therefore thought that the present would be a fitting occasion to lay before you the results of that experience in the treatment of this common and painful malady.

The affections that I am dealing with in this lecture are the more or less chronic affections which are generally labelled "rheumatic," but which undoubtedly are not the sequelae of acute rheumatism, and which are in no sense connected with that disease. Whereas acute rheumatism is more common in the first half of life, the various forms of chronic rheumatism are much more common in the second.

PATHOLOGY.

In the great majority of the cases of so-called chronic rheumatism, the pathological change is in the white fibrous tissue in various parts of the body, and to this condition the term "fibrositis" has been very aptly applied.

The essential pathological change in fibrositis is an inflammatory hyperplasia of the white fibrous tissue in various parts of the body, associated with exudation and proliferation of the connective tissue elements leading to swelling and thickening of the affected fibrous tissues. This condition may undergo absorption and so completely disappear, or, if not suitably treated, it may pass on to organization with the formation of nodules and patches of thickening.

The articular structures proper—synovial membrane, cartilage, and bone—are not primarily affected, but the parts implicated are the fibrous tissues of the joints, muscles, and bones, especially the aponeuroses and insertions of the muscles, the muscle sheaths in which the muscle spindles lie, the bursae, fasciae, the fibrous ligaments and capsules of the joints, and the periosteum. Such affections cause pain and stiffness in these structures, are especially apt to recur, and are commonly referred to as rheumatic or even gouty in their origin. This inflammatory hyperplasia of the fibrous tissues occurs in patches, and is started by exposure to wet or cold, by injury, or by some irritant, microbe or toxic, conveyed in the blood. The inflamed and swollen fibrous tissue is tender, painful on pressure or on movement, and can frequently be felt on palpation, or is evident by the consequent elevation of the skin. Sudden movement of the affected muscles generally causes excruciating pain, while the local pain on pressure is one of the most diagnostic features of these cases.

The indurations may be widespread, but generally are well defined, and vary in size from an eighth of an inch to one inch in diameter. They may be situated in the subcutaneous tissue, the muscles, tendons, aponeuroses, the capsules and ligaments of the joints, the bursae, the sheaths of the nerves, and periosteum. The pain is especially aggravated by any sudden movement of the muscles which compresses or stretches the affected fibrous tissues and the sensory nerve filaments.

The microbic causation of fibrositis is probably a rare

occurrence, but Ware¹ has been able to demonstrate the presence of gonococci in the inflamed muscles of the posterior axillary fold secondary to a gonococcal arthritis of the shoulder-joint. In the great majority of cases the inflammatory hyperplasia is due to a toxæmia, exposure to cold, strains, etc.

A. Schmidt² has endeavoured to explain the pathology of muscular rheumatism by the assumption of a neuralgia of the sensitive muscle nerves due to a lesion of the posterior spinal roots, but he admits that in the only case in which he had the opportunity of examining the spinal cord the minutest microscopical examination failed to reveal any anatomical changes in the roots. Moreover, it is obvious from his paper that he confuses cases of acute or subacute rheumatism with fibrositis.

ETIOLOGY.

Local fibrositis may result from several causes, of which the following are the commonest:

1. *Cold, Damp, and Wet.*—In a very large number of cases the only assignable cause of the fibrositis is a history of exposure to cold and wet. Sometimes the attack comes on acutely a few hours after the exposure, as in many cases of lumbago, stiff neck, intercostal "rheumatism," and other forms of so-called muscular "rheumatism." At other times stiffness gradually develops after the exposure, and passes on to the condition of chronic fibrositis. The exposure may be due to draughts, remaining in wet clothes, lying or sitting on damp ground or some cold substance, or the simple advent of damp or cold weather. Sleeping in basement rooms to which ground air gains access is a common cause, and is entirely obviated by the building of houses on beds of concrete. A very common cause of lumbago from exposure to a local draught is sitting on a draughty privy or water-closet; this, no doubt, accounts for the prevalence of that affection in rural districts, combined with the constant strain of the lumbar muscles amongst so many agricultural labourers. Many persons are readily affected by the approach of rain and by a lowering of the barometric pressure. Longstreth states that the painful symptoms do not correspond to rain but to the fall of barometric pressure, and Stockman suggests that possibly the atmospheric changes may increase or lessen the lymph pressure in the body, and so increase or lessen the tension in the affected fibrous tissues.

2. *Extremes of Heat and Cold.*—Sudden and considerable variations in temperature constitute by no means an uncommon cause of a generalized fibrositis, which takes the form of so-called "muscular rheumatism," following on the resulting chill.

3. *Local Injuries.*—These are responsible for a large number of cases of local fibrositis. Traumatic fibrositis is a definite form, and is induced by sudden and severe strain on tendinous and ligamentous structures. Such a form may persist for a lengthened period, for whereas the slighter forms of muscular fibrositis, such as "stiff-neck" and mild forms of lumbago, are usually of brief duration, that which affects the tendinous and ligamentous structures may persist for weeks and even months. Golf produces a number of such injuries, the fibrous tissues of the muscles and their attachments to the arms and back being specially affected in this game. "Tennis elbow" is another instance of traumatic fibrositis.

4. *Absorption of Irritating Toxins from the Alimentary Tract.*—It has long been recognized that disorders of the alimentary tract may give rise to "rheumatic" pains. Oral sepsis is undoubtedly responsible for the development of some forms of chronic rheumatism, as likewise are flatulent dyspepsia, chronic constipation, colitis, etc. The aching in the joints and the lumbar region that occasionally occurs the day after a lengthy dinner, especially if several wines have been indulged in, is due to irritation of the fibrous tissues by the toxins absorbed from the intestinal tract, and which have been produced there by abnormal fermentation. This pain, whether in the joints or the lumbar region, which follows excessive indulgence at the table, is generally attributed to gout, and, as a rule, the champagne, claret, or port is blamed for it. I am convinced, however, that this articular or muscular pain has, in the great majority of cases, no relation whatever to gout, and that it is due to a

self-generated systemic poison owing to the inability of the gastro-intestinal tract to deal properly with the various articles introduced into it.

5. *Tonsillitis and Pharyngitis*.—The aching pains that occur in various parts of the body in connexion with these affections are well known, and are doubtless due to toxic absorption and consequent irritation of the fibrous tissues.

6. *Influenza*.—Many individuals are personally acquainted with the aches and even severe pains in the muscles, joints, and bones which accompany this disease. These are in all probability due to the fibrositis set up by the specific microbe or its toxin. It is not uncommon to find fibrous nodules and thickenings left as sequelae of this disease.

7. *Febricula*.—A "feverish cold" is generally accompanied by aching pains in the muscles, joints, and bones. The attack, which is sometimes described as a "rheumatic cold" or an "influenzal cold," is microbial in its origin, and the pains are no doubt due to irritation of the fibrous tissues by the microbe or its toxin.

VARIOUS FORMS OF FIBROSITIS.

The white fibrous tissues in practically any part of the body may be affected, but the liability is greater in certain situations, which will now be dealt with.

Muscular Rheumatism.

This affection is always a fibrositis. Any of the muscles may be affected. Affection of the muscles of the lumbar region constitutes one of the forms of lumbago; affection of the muscles of the neck constitutes stiff-neck; affection of the deltoid muscle constitutes "deltoid rheumatism"; affection of the intercostal muscles constitutes "intercostal rheumatism." The abdominal muscles may be affected, and such nodular fibrositis in these muscles may cause either continuous pain, or severe paroxysmal pain. Undoubtedly such cases have been mistaken for appendicitis, renal or biliary colic, abdominal adhesions, gastric ulcer, etc., and this I believe is the explanation of many laparotomies that have been performed with a negative result. The so-called "growing pains" of children are, in my opinion, due to fibrositis, since the healthy growth of a child should not be painful.

Muscular fibrositis of the shoulder and upper arm muscles is at times a very distressing malady, and so severe is the pain in the affected muscles that any attempt at passive movement causes an involuntary contraction in them, which contraction in its turn considerably augments the pain. The result is that under such conditions the shoulder-joint appears to be fixed, and gives the impression of the presence of firm adhesions within the joint. In some of these cases of brachial fibrositis the interference with sleep on account of a difficulty of securing an easy posture in bed, as well as the pain produced by each movement of the arm, are extremely trying to the patient.

In severe cases of brachial fibrositis the inflammatory condition may spread to the adjacent nerve sheaths, and so cause a secondary brachial neuritis. It is not uncommon for the tendinous attachments of the muscles to be especially affected, and I have seen several cases in which the fibrositis has been limited to the insertion of the deltoid, so that the pain has been entirely confined to that locality.

Fibrositis of the occipital and perierianial aponeuroses is a common form of headache, and one which is frequently overlooked. The indurations are most apt to occur in the retrocervical muscles, especially the trapezius, and in the temporal and other cranial aponeuroses. The attacks of headache are always associated with painful stiffness in the affected muscles. This form of fibrositis is especially due to the exposure to draughts through lack of covering to which this part of the body is necessarily subjected. I am frequently meeting with such cases of headache and fibrositis among those motorists who persist in riding in an open car with the front wind screen up, so that the neck and back of the head get the powerful back draught. I always advise such that it is far preferable in an open car to have the upper part of the wind screen raised or open, so as to face the wind and avoid the exposure of so vulnerable a part as the back of the neck and head to draught.

Lumbago.

This is a very typical form of fibrositis. It may be an affection of the fibrous elements of the lumbar muscles, but more commonly it starts as a localized affection of the insertions of the muscles in the vicinity of one or both of the sacro-iliac joints, since the fibrous attachments of the muscles to the back of the sacrum are especially liable to overstrain. It spreads by continuity of the fibrous tissue, as is manifested by its affecting the tendinous attachments of the neighbouring muscles, by its affecting the sacro-iliac joint itself, and by its often spreading through the joint and reaching the sheath of the sciatic nerve. This explains the very frequent association of some degree of sciatica with an attack of lumbago. In many cases of lumbago the extension of the inflammation to the sacro-iliac joint causes that synchondrosis to become loose, and so to be acutely painful on movement. The production of the pain of lumbago is usually sudden, the patient frequently ascribing it to a sudden strain or wrick, especially on rising in the morning; but although the production of the pain is generally sudden, yet the condition on which it depends has been gradually developed. A violent strain on the spinal ligaments following railway accidents and other injuries may set up a fibrositis with long-continued susceptibility to pain on any tension, a condition which I think is not infrequently ascribed to malingering.

Dupuytren's Contraction.

This is a localized fibrositis caused by habitual postural use of the hand. It is frequently ascribed to gout, but, according to my experience, the condition has no connexion with that disease. Certainly, I have never seen any gouty deposits in the thickened tissues, nor is the affection commoner amongst gouty subjects.

Fibrositis of the Plantar Fascia.

A fairly common form of localized fibrositis is that which affects the plantar fascia. This causes pain in the sole of the foot when the weight of the body is on it, and if not arrested is liable to lead to the development of flat-foot. The fibrositis is sometimes localized to the attachment of the fascia to the inner tubercle of the os calcis, and then constitutes one of the commonest forms of painful heel. If the inflammation persists at this point it is liable to cause a local periostitis and osteitis, resulting in the formation of a bony spur, which, if not removed, constitutes a permanently painful heel.

Fibrositis of Bursae.

A chronic fibrositis of bursae is fairly common, and especially occurs in connexion with the subacromial bursa. This condition, which explains the frequency of stiff and painful shoulders, is very apt to be mistaken for arthritis or fibrous ankylosis of the shoulder-joint, or for brachial neuritis. Severe pain as regards abduction and rotation are the chief symptoms, and the pain may be so severe as to prevent restful sleep. The pain is often felt at the insertion of the deltoid, and I believe that many cases of so-called dislodgement of the biceps tendon from its groove are cases of subacromial bursitis. Küster³ in 1902 gave the first clear explanation of the mechanical importance of this bursa, which is the same as the so-called subdeltoid bursa. The other bursae which exist about the shoulder-joint are relatively unimportant, as inflammation in them is of but little mechanical importance.

Fibrositis of Joints.

Chronic fibrositis of the joints is most frequently met with in the knuckle-joints and finger-joints of those engaged in hard manual labour, especially when associated with damp surroundings. Pads upon the finger-joints constitute a chronic form of localized fibrositis, and have been thoroughly described by A. E. Garrod. They form excrescences which are almost confined to the dorsal aspects of the interphalangeal joints of the proximal row, and are only very rarely seen upon the terminal joints of the fingers. They are usually present upon the fingers of both hands, and vary in size from that of a split pea to that of the half of a hazel nut. Sometimes they are quite painless, but more often pain of various degrees of severity is complained of, especially when the fingers are flexed or if the lumps are knocked.

Patients suffering from these pads generally seek medical advice under the apprehension that they are the precursors or accompaniments of rheumatoid arthritis, or that they are due to chronic gout. There does not, however, appear to be any connexion between these pads and either rheumatoid arthritis or gout. There is, however, an intimate connexion between these pads and Dupuytren's contraction of the palmar fascia, and it is fairly common to see the two conditions together.

Fibrositis of the Subcutaneous Tissue.

A form of fibrositis to which Ralph Stockman⁴ has recently drawn attention is a chronic subcutaneous fibrosis, which when it occurs in people with a large amount of subcutaneous fat is identical with the disease known as "adiposis dolorosa" (Dercum's disease). It consists in an irregularly spread, patchy, chronic inflammation of the subcutaneous connective tissue which involves the small peripheral nerves, so that the affected parts are painful on pressure, and are also subject to aching or pain from exercise, weather changes, indigestion, etc. These pains are usually designated as "rheumatic," and the condition is, in fact, one of so-called "chronic rheumatism." In the subjects of subcutaneous fibrosis the fat tends to form in more or less lumpy masses round the hypertrophied fibrous tissue. It is an exaggeration of this condition which constitutes the disease known as "adiposis dolorosa." The abdomen, flanks, hips, thighs, shoulders, and upper arms are in general the parts most affected.

Chronic Villous Synovitis.

Although, according to the strict interpretation of the term, this is not a form of fibrositis, yet it may be conveniently referred to here, as its correct treatment is similar to that of other chronic rheumatic conditions. It is a purely local condition and not a manifestation of a general disease, and is frequently described as "arthritis sicca." It usually occurs in the knee and is characterized by crepitus or creaking on movement and by pain and tenderness on use. The crepitus during movement of the joint is frequently unpleasantly audible to the patient, and is especially caused by going up or down stairs. The capsule and the ligaments of the joint are more or less relaxed and the synovial membrane is passively congested and loose. The crepitation on movement is due to the folds of the flabby congested membrane rubbing together; in other words, it is a true creaking and not a bony grating. If further relaxation of the synovial membrane results, hernial-like projections of the synovial fringe may be produced which are apt to cause a catching or locking of the joint when it is moved. In this class of cases the fluid in the joint is generally quite normal, although, if there be great irritation, some excess of it may form. The condition is very frequently mistaken for rheumatoid arthritis, but there is no erosion of cartilage and no eburnation of the ends of the bones, consequently bony grating can never be produced in such joints.

A valuable aid to the recognition of this condition, and to its differentiation from rheumatoid arthritis, is the careful auscultation of the joint, to which A. E. Garrod⁵ has drawn useful attention. I have for many years practised this method of auscultation, and am thoroughly convinced of its great utility as an aid to diagnosis. The knee-joint should be slowly flexed and extended during the examination, and in this way the peculiar crackle or crepitus that is produced by the thickened and flabby synovial membrane is easily distinguished from the crunch or grating sound that occurs in cases of rheumatoid arthritis, and which is due to abrasion or erosion of the cartilages.

GENERAL TREATMENT.

A saline aperient should always be given at the onset of an attack of acute fibrositis, and repeated as necessary. If the attack is a severe one, confinement to bed may be necessary, and it is important to recognize the beneficial influence of rest in such cases. For severe attacks of lumbago and intercostal rheumatism firm strapping with the brown-holland strapping plaster secures the necessary local rest of the affected muscles. In all cases of brachial fibrositis the arm should be carried in a sling and should be moved as little as possible during dressing and undressing.

Drugs.

In the treatment of the different forms of fibrositis salicylates are of little curative value, as they do not exercise the same specific action as in acute rheumatism. Aspirin is of decided use for the relief of pain in severe cases, but it should only be given with that object. It acts better than sodium salicylate, owing to the fact that the introduction of the acetyl radicle increases the analgesic action of the salicylic acid. It probably also exercises a beneficial effect in cases of abnormal intestinal fermentation. Perhaps the best method of administering this drug for the relief of pain consists in giving 10 grains of aspirin with 6 grains of pyramidon in a cachet every four hours. Potassium iodide is, in my experience, the most valuable drug in the treatment of fibrositis. It seems to exercise a direct effect in removing the hyperplasia and serous exudation in the fibrous tissues. It should always, if possible, be given in full doses of 10 or 12 grains, and should be combined with tonics, such as nuxvomica or the compound glycerophosphate syrup. If the iodide produces severe symptoms of iodism, one of the organic iodine compounds may be tried. Of these I have found iodipin, in the form of tablets, extremely useful.

Fibrolysin.

This is a chemical combination of thiosinamin and sodium salicylate, for which the claim has been put forward that it has a softening effect upon all forms of pathological fibrous tissue. In a former paper⁶ I reported on the use of it in a somewhat limited number of cases of fibrositis, and I then gave a somewhat guarded favourable opinion as to its being of use in properly selected cases. I now propose to lay before you the results of an extended experience of the use of this drug, an experience which, I may at once state, does not support the somewhat favourable opinion that I formerly expressed. I have obtained the results of its use in 83 cases of various forms of fibrositis, some of which I treated throughout, but in the majority of which I am indebted to careful reports furnished me by the various medical men who, on my advice, carried out the treatment. They were all carefully selected as cases likely to be favourably influenced by the use of fibrolysin. In 18 out of the 83 cases the use of the drug had to be discontinued, owing to the injections causing rise of temperature, malaise, nausea, headache, and, in some cases, palpitation, vertigo, tendency to syncope, severe general pains, and a purpuric rash. This leaves 65 cases in which a full course of forty injections of fibrolysin, together with massage of the affected parts, was employed. No good whatever resulted in 46 of the cases; in 11 of the cases there was some improvement, which was permanent in 10 of the cases and transient in 1; in 8 of the cases there was permanent cure. So that the numbers converted into percentages are:

| | | | | | |
|------------------|-----|-----|-----|-----|--------------|
| No benefit | ... | ... | ... | ... | 71 per cent. |
| Some improvement | ... | ... | ... | ... | 17 " |
| Cured | ... | ... | ... | ... | 12 " |

In every one of the cases of rheumatoid arthritis and other forms of infective arthritis in which, after complete arrest of the arthritis, a full course of fibrolysin was used in the endeavour to reduce or remove the fibrous thickenings around the joints no improvement whatever resulted. Similarly in all the cases of Dupuytren's contraction of the palmar fascia that were treated no benefit resulted. The 8 cases that were cured comprised 4 of diffused or localized fibrositis with nodules, 3 of fibrous thickenings and adhesions around a single shoulder-joint, and 1 of severe thrombosis of both femoral and external iliac veins with thickening of the walls of the veins. In this last case complete absorption of the thrombi and of the thickenings of the venous walls resulted, but massage was not resorted to until after complete disappearance of the thrombi.

From these results it appears to me that fibrolysin has a very limited use, and I cannot avoid the inference that the claims that have been put forward for this preparation must be considered extravagant.

LOCAL TREATMENT.

For the complete dispersal of the indurations in most cases of fibrositis, and certainly in the severer cases, local treatment must be adopted. This may best be considered

under the following headings: External Applications, Heat and Electrical Treatment, Massage and Exercises, Surgical Treatment.

External Applications.

In the early stages of an acute fibrositis hot fomentations are useful. Afterwards one of the best external applications in my experience is a mixture of equal parts of chloral hydrate, camphor, and menthol. These three substances form a liquid when well rubbed together. This liquid should be painted over the painful area, and then be gently rubbed in with the fingers. Some patients find the cold sensation produced by the menthol objectionable; in such cases the menthol may be omitted and equal parts of chloral hydrate and camphor employed, which also form a liquid when rubbed together. Another useful external application is to paint the painful area with tincture of iodine, and then to apply a hot linseed poultice or a very hot fomentation. The heat converts the iodine into vapour, which exercises an anodyne effect, and, probably by absorption, directly acts on the affected fibrous tissues. In the later stages the aconite, belladonna, and chloroform liniment applied on lint is frequently most beneficial. In cases of a very localized fibrositis counter-irritation is sometimes of great use, especially in the form of the thermo-cautery.

Heat and Electrical Treatment.

In localized forms of fibrositis, and especially where fibrous deposits occur—such as in lumbago, thickening of the ligamentous and fibrous structures surrounding or entering into the composition of joints, deposits in muscles, tendons, and tendon sheaths, and in chronic villous synovitis of the knees—the most effective form of local treatment that I am acquainted with is the employment of heat followed by ionization of the affected part. This treatment has a very remarkable effect in causing the absorption of thickened fibrous tissues. Heat increases the supply of arterial blood, and so causes a state of active congestion, stimulates leucocytosis and metabolism, lowers blood pressure, causes diaphoresis, relieves pain, and enhances the effect of the ionization that is to follow. If heat is to be applied to the entire body, the electric light cabinet bath is the most convenient form, but in the treatment of localized forms of fibrositis it is preferable to concentrate the heat on the affected part only, and I am confident that far better results are obtained from the employment of dry radiant heat than from the employment of heat alone. C. F. Bailey⁷ considers that the ideal type of radiant heat should be as nearly as possible like sunlight, and should give a spectrum ranging from the ultra-red to the ultra-violet. This type of spectrum can apparently only be obtained from lamps of a very high candle power, such as the so-called leucodescent radiant heat apparatus, which consists of a single 500-candle power lamp in a funnel-shaped projector lined with a reflecting surface. The method of applying the heat is to sway the lamp slowly backwards and forwards over the affected part for about twenty minutes. It must be applied directly to the skin, and anything like a severe burning sensation should be obviated either by the temporary removal of the lamp or by brushing with the hand that part of the surface which is being treated. When the lamp is switched off, the part feels burning hot to the touch and the surface is red and mottled from vascular dilatation. If such radiant heat alone is used, it very definitely relieves pain, softens fibrous indurations, and causes improvement in joints and their surroundings as regards improved flexibility and reduction in size. These results are, however, considerably enhanced by subsequent ionization.

The exposure to heat should be immediately followed by ionization with iodine ions, which, in my experience, are more effective than other ions on account of their solvent action on fibrous thickenings and deposits. The iodine is introduced into the affected tissues from a 2 per cent. solution of lithium iodide to which sufficient liniment of iodine has been added to give the fluid a sherry colour and so ensure the presence of an excess of iodine. Pads of lint six-fold thick are soaked in the hot solution and applied to the part to be treated. A copper chain-

mail electrode is then spread over the pad and bandaged on, leaving the connexion exposed, which is then attached to the negative pole. The positive pole is similarly connected to another pad soaked in a weak solution of common salt or of lithium carbonate. Another method, though not so efficacious, in my opinion, as the employment of lithium iodide, is to paint the skin of the affected part with iodine liniment and apply a pad soaked in a weak solution of lithium carbonate with the electrode connected with the negative pole, the positive being applied as before. The strength of the current that should be employed varies with individual patients, but should range from 15 to 40 milliampères. The ionization lasts for twenty minutes, and should be repeated daily if the skin will stand the treatment, otherwise it should be used on alternate days. Many cases improve very rapidly from the first, but in severe cases a course of daily applications for four weeks is required. While this ionization treatment is being carried out it is very important that the administration of potassium iodide by the mouth should be continued. As C. F. Bailey has pointed out, any iodine compounds lying in or circulating through the affected tissues are broken up by the current and locked up in the tissues temporarily, instead of being carried through the blood vessels and excreted. In addition nascent iodine ions are much more energetic than when they combine into soluble non-ionized salts; also the general migration of all kinds of ions, which takes place along the course of the current, may produce an effect of commotion in and stimulation of the tissues which is beneficial.

In cases of acute fibrositis, especially in acute lumbago and painful affections of the knees, shoulders, and elbows, it is advisable at the first two or three sittings to employ a 2 per cent. solution of sodium salicylate in place of the lithium iodide, in order to produce immediate relief of the severe pain. The salicyl ion is introduced into the painful region, and it is remarkable how rapidly it will relieve the pain, just as salicyl ionization rapidly relieves the pain of severe neuralgia and some forms of neuritis.

In cases of chronic villous synovitis of the knees this combined heat and ionization treatment is most effective, and in all cases gives the most satisfactory results.

Doubt has sometimes been expressed as to whether actual penetration of ions into the affected tissues occurs during ionization, but the experiments of N. S. Finzi⁸ conclusively prove that certain ions penetrate into the tissues of joints and the subcutaneous tissues. In addition it has been shown that strychnine applied at the positive pole, or potassium cyanide at the negative, rapidly kill an animal under experiment with all the characteristic symptoms of the respective toxic substances. Moreover, it is quite easy to demonstrate the presence of iodine or lithium in the urine after respective ionization with those substances.

Some observers have stated that the chlorine ion is quite as efficacious as the iodine ion, and is less caustic, but my experience is that the iodine ion is more effective, and I have never met with any bad effects from its causticity.

It is a matter of common experience that the improvement started by a short course of heat and ionization treatment will continue to progress for some days after the treatment is left off. This is probably explained by the ions forming with the colloids of the animal tissues a sort of condenser, which is discharged by degrees. The ions therefore remain for a certain length of time at the place of their introduction, so that this region remains for several days as a kind of local medicated bath the therapeutic power of which is considerable. It may therefore be claimed that ionic medication is founded on a truly scientific basis, in that the ions exert a direct therapeutic effect, that they are for a time localized in the affected tissues, and that they are afterwards slowly and gradually liberated.

In cases of lumbago the static wave current may be substituted for ionization. F. H. Humphris⁹ records excellent results with this form of treatment. It produces a local vibratory effect, and muscular contraction takes place, so that the wave current tends to remove the infiltration by squeezing out the serous exudation from the affected tissues, and thereby relieving the pain. From my experience of a number of cases that I have had successfully treated, I can thoroughly recommend the

employment of local heat followed by the use of the static wave current.

Massage and Exercises.

Massage is very useful in the later stages, but it should only be employed when it causes no pain. The manipulations should be very gentle at first, so as to promote removal of exudation and to relieve the tension. Afterwards more vigorous massage is most efficacious in dispersing the indurations and fibrous thickenings, and in removing the stiffness of the affected parts. General massage should not be employed, but the tender and affected areas should be carefully marked out for treatment. Massage should not be used to affected joints, but only around them, so as to improve the circulation in their neighbourhood. I have frequently seen the most disastrous results to joints from their over-zealous manipulation by masseurs and masseuses, as such treatment only increases the inflammation and bruises the synovial fringes. The same remarks apply with equal force to acute affections of the bursae and tendon sheaths, and to fibrositis of nerve sheaths until the acute affection has entirely subsided.

During the very painful stage of muscular rheumatism as complete rest as possible of the affected muscles must be enforced, but later on exercises of the muscles are of great benefit. Either light dumb-bells or Indian clubs, of from 1 lb. to 2 lb. in weight, should be employed, and such movements are to be performed as will bring the affected muscles into action. The exercises should be performed on rising in the morning, and should not occupy more than from ten to fifteen minutes. After the exercises a cold or tepid bath should be taken, and the skin be briskly rubbed with a rough towel.

In cases of chronic subcutaneous fibrosis in very fat people (*adipositas dolorosa*) massage is quite ineffective, and often unbearably painful. In such cases it is essential, first of all, to get rid of the superabundant fat by means of a strict diet, and by the administration of thyroid gland.

Surgical Treatment.

In a few cases, generally of long standing, where the fibrous nodules do not yield to the measures above mentioned, and where by implication of, or pressure upon, nerves they cause persistent pain, excision may be necessary.

Adhesions in the subacromial bursa have sometimes been treated by breaking them down under an anaesthetic, but the procedure is a dangerous one, as the normal joint structures are more easily torn than the dense adhesions in the bursa, and the brachial plexus and axillary vein are liable to be damaged. Another objection is that when the adhesions alone are ruptured there is a tendency for them to re-form.

Spa Treatment.

This is most useful in protracted cases of fibrositis, especially when the waters are strongly radio-active. Undoubtedly the radio-active emanations of such waters are powerful adjuncts in the dispersion of the thickenings and deposits.

Diet.

Unlike gout, no special dieting is required in these affections. Moderation should be the keynote of all prone to the various forms of fibrositis, and especially should they avoid foods which their experience has taught them to be apt to produce gastro-intestinal fermentation. It has become of late years a fashionable craze to attribute many of these forms of "chronic rheumatism" to uric acid, but I am firmly convinced that that harmless by-product of the human economy plays no part whatever in the development of the various forms of chronic rheumatism or fibrositis.

Underclothing.

With regard to the underclothing that should be worn by rheumatic individuals, I must confess that I am a convert to the view that porous linen underwear is the most suitable. It allows of the free evaporation of perspiration, and so prevents a more or less sodden garment from remaining in contact with the skin, which so frequently happens with those who wear woollen underclothing. I am convinced that in the latter case such sodden garments are a frequent cause of many of the

forms of fibrositis. Some individuals find that in winter linen underwear is too cold, and in such cases a thin silk vest may be worn over the linen. This will be found to constitute a thoroughly warm, comfortable, and safe form of underwear.

Residence.

The most suitable soil is gravel, sandstone, or rock, at a fair elevation, and with good subsoil drainage. Houses should be built on a bed of concrete, so as to prevent entirely the entrance of ground air. Residence on a clay soil should be avoided if possible, but in my experience the worst soil of all is a shallow gravel soil in a cup or depression of clay, which allows the subsoil water to accumulate and frequently to reach close to the surface. Many of the gravel sites lauded by house agents are veritable traps for the development of fibrositis.

A STUDY OF THE TYPES OF ORGANISM IN A SERIES OF BONE AND JOINT TUBERCULOSIS OF CHILDREN.

By JOHN FRASER, M.D., Ch.M., F.R.C.S.E.,

ASSISTANT SURGEON, SICK CHILDREN'S HOSPITAL, EDINBURGH.

(From the Royal College of Physicians' Laboratory, Edinburgh.)

THE British Royal Commission justified its existence when it showed, beyond all manner of doubt, that human tuberculosis was in a certain proportion of cases due to infection with the bovine bacillus. It has remained for individual observers to investigate local groups of tuberculosis, and to expose the relative types of bacilli present.

I wish to record some investigations of a study of 70 cases of bone and joint tubercle.

Technique.

The preliminary necessity was to obtain in pure culture the actual organism which produced the lesion of an individual case; as it is exceedingly difficult, and in the majority of cases impossible, to cultivate the tubercle bacillus directly from an active lesion, guinea-pigs were used as intermediaries. The diseased tissue, obtained in each case by operation, was inoculated into the animal subcutaneously or in bulk. For a period of six weeks the animal was permitted to live; at the end of that time the disease was extensive in the glands and the internal organs, and from them the organism was easily cultivated.

There are various suitable media, and of such Dorset's³ egg medium is undoubtedly the best; it is a preparation of egg-yolk and water, sloped, and inspissated in tubes. Upon the surface of the medium portions of the diseased organs are rubbed, and it is of advantage sometimes to actually wound the surface of the medium. The inoculated tubes, sealed with paraffin to prevent evaporation and infection, are incubated. In fourteen days a growth is apparent.

With the growth of the organism the first step is completed. The second stage consists in identifying the organism, and this identification is at once proceeded with. There can be no doubt that it is possible to distinguish absolutely between the human and bovine types of the bacilli. Cultural and morphological tests are uncertain in their interpretation.

A bacillus which grows rapidly and profusely upon egg medium is in all probability human, yet there exists a margin of doubt, which deprives the test of any absolute value, and the same applies to morphological distinctions. A short, squat bacillus staining uniformly suggests a bovine origin, but occasionally human bacilli possess identical characters.

1. There are three tests which give trustworthy evidence of the type of bacilli. In 1905 Theobald Smith⁹ formulated a test, which depended upon the changes produced in glycerine bouillon by the growth of the tubercle bacillus. The glycerine bouillon is rendered faintly acid, and the

acidity is carefully estimated by titration; 0.05 per cent. is a suitable degree. The tubercle grows as a pellicle upon the surface of the medium, and at intervals of ten days small quantities of the fluid are removed and the acidity estimated. In the case of the human bacillus the degree of acidity progressively increases; in the instance of the bovine bacillus the acidity diminishes and the medium may even become alkaline. The test is reliable, but it is difficult to perform, and mixed infection of the medium is very hard to prevent; should such occur the experiment is useless.

2. The second reliable test is based upon the fact that glycerine exerts a stimulating effect upon the growth of the human bacillus, while it has a distinctly retardative influence on the bovine bacillus (Cobbet).² The glycerine is incorporated with Dorset's egg medium (4 per cent.), and upon this medium the organism under investigation is grown. Control inoculations are made with fully identified human and bovine bacilli. By the rate and degree of growth of the bacillus its identity is established. The bovine organism grows scantily, if at all; the human bacillus spreads rapidly and profusely.

3. The simplest and yet the most reliable test is that usually termed the animal test. It is based upon the fact that the bovine bacillus is especially virulent for certain animals, more especially the calf and the rabbit. If a rabbit of an average weight of 2,000 grams is inoculated intravenously with a small amount (0.01 mg.) of the suspected organism, one of two results will follow. If the bacillus is human the animal will show little change, its weight will remain constant or increase, and if at the end of six months it is killed and examined the tuberculous disease will be found to be limited to a few chronic lesions in the internal organs. The result of inoculation of a bovine bacillus is very different. After inoculation the animal rapidly emaciates and loses weight; in six weeks it is usually dead, and a *post-mortem* examination shows an acute miliary tuberculosis. The test is absolutely reliable, and the smaller the quantity of bacilli introduced the greater the difference (Oehlecker).³

Investigation of Cases.

In each individual case a systematic plan was followed.* The diseased tissue was inoculated into a guinea-pig, and from the infected animal the organism was grown in the manner I have described. The identity of the organism was established by submitting it to a series of five tests, and observations were made upon (1) the cultural characters, (2) the morphological appearances, (3) the distinctive growth upon glycerine egg medium, (4) the reaction upon glycerine bouillon, (5) the result of rabbit inoculation. From the result of these tests a definite result was come to as regards the identity of the bacillus. Tests 1, 2, 3 and 5 were carried out in every case; Test 4 was performed only in eleven instances.

Results.

On every occasion the diseased material was obtained by operation. The proportion of bone and joint cases in the series was practically equal—39 were instances of joint disease, 31 of bone disease. The age incidence was absolutely limited to 12 years and under. The cases were patients of the Edinburgh Sick Children's Hospital, and therefore may be said to have been drawn from a comparatively localized area. For two reasons the series may be considered unique—the age limit and the localized sources from which the material was obtained.

Small groups of bone and joint tubercle have been investigated by different observers.

The British Royal Commission⁴ examined 14 cases, with one exception adults; 13 of the series were due to the human bacillus; 1 case was found to contain both human and the bovine bacilli. Park and Krumweide⁵ investigated a series of 17 cases; 6 of these were children under 5 years of age, 10 were children from 5 to 16 years old, and there was a single adult case. In every instance a human bacillus was the causative factor.

Kossel, Weber, and Heuss⁶ published the results of an examination of 36 cases; 12 were obtained from adults, and each contained the human bacillus; 24 were cases of

children, ages ranging from 1 to 16 years, and one of these contained the bovine bacillus. Henschen, Jundell and Svensson⁴ investigated a small series of 3 cases; they were adults, and all owed their origin to the human bacillus. Burekhardt¹ has recently investigated a series of cases of surgical tuberculosis; the group included 29 cases of bone and joint tubercle. He found that 3 cases of joint tuberculosis contained the bovine bacillus. The respective ages were 11, 19, and 14 years.

I have to announce results which are very different from any of the above. Out of a total of 70 investigations, in 41 instances the bovine bacillus was present, in 25 cases the human bacillus occurred, and from the remaining 3 cases both human and bovine types were isolated.

These results are so striking that one naturally seeks for factors which may help to explain their uniqueness, and the factors which have most bearing are those of age, family history, and milk supply.

Age.

The age incidence has been absolutely limited to 12 years and under. This limitation is all-important, for in such an age group there are certain special distinctions.

1. The feeding is of a special type—milk, human or cow's, is the staple article of diet.

2. The lymphatic and absorptive arrangements of the abdomen are peculiar—a fact which is evidence of the high percentage of occurrences of abdominal tuberculosis (4 per cent., Thomson¹⁰).

Bearing these facts in mind, there is much to be learnt from a study of the age tables of the series. The facts are best illustrated by dividing the age period into groups: Group 1, to 3 years; Group 2, from 3 to 6 years; Group 3, from 6 to 12 years.

In the first group the questions of milk feeding and unusual lymphatic arrangements have their strongest bearings. Twenty-eight cases were included in the first series; twenty-three of them were bovine and five were human. In the second and third series the proportions were more equal. In group No. 2 ten were due to the human bacillus, nine to the bovine bacillus. In group No. 3 eleven were human, while nine were bovine.

TABLE I.—Type of Bacillus in 67 Children in Relation to Age.

| Age Period. | Human Organism. | Bovine Organism. |
|------------------------|-----------------|------------------|
| To 3 years | 5 | 23 |
| From 3 to 6 years ... | 10 | 9 |
| From 6 to 12 years ... | 11 | 9 |

Family History.

As a matter of routine, the family history was noted in each case investigated. In 21 instances there was a definite history of pulmonary tuberculosis having occurred in some member of the family in which the child lived, and in 50 per cent. of these cases the child was actually living in contact with a consumptive.

The practical bearing is more evident when it is stated that out of the 21 above mentioned cases 15, or 71 per cent., were due to the bacillus of human tuberculosis.

In 52 cases there was definitely stated to be no family history of tubercle; 43 of these were bovine in origin, while only 9, or 17 per cent., were human. The difference is very striking, and the figures of the first group are explained by direct infection of the child from the consumptive patient with whom it stayed.

TABLE II.—Types of Bacillus in Relation to Family History.

| | Human Bacillus. | Bovine Bacillus. | Percentage of Human. |
|---|-----------------|------------------|----------------------|
| History of pulmonary tubercle in family | 15 | 6 | 71 |
| No history of tubercle in family | 9 | 43 | 17 |

Milk Supply.

Practically speaking, the bovine bacillus is introduced into the body by a single route—that of infection from the

* For full details of experiments see the *Journal of Experimental Medicine*, vol. xvi, No. 4, 1912, p. 432.

alimentary tract, and the medium by which it is introduced is infected milk. As far as possible observations were noted of the source of milk supply in each of the above cases: 25 cases were nourished in infancy upon human milk, 41 were entirely fed upon cow's milk; in 3 instances the source of origin was doubtful.

Of the 25 cases brought up on human milk, in only 6 cases was the bovine bacillus found. The remaining 19 were infected with the human type. In the second group, those nourished upon cow's milk, out of a total of 41, no less than 37 were due to infection with the bovine bacillus. The remaining 4 were human. In the complete series there were 4 children less than 1 year old. All these children were nourished upon cow's milk, and in every case the bovine bacillus was the organism present.

TABLE III.—Types of Organism in Relation to Milk.

| Source of Milk. | Human Bacillus. | Bovine Bacillus. |
|-------------------|-----------------|------------------|
| Human milk | 19 | 6 |
| Cow's milk... .. | 4 | 37 |

It is interesting to note that in no instance was any attempt made to sterilize or pasteurize the milk.

CONCLUSIONS.

1. It is possible by certain tests to distinguish between human and bovine types of tubercle bacilli.

2. A considerable proportion of bone and joint tubercle of children in Edinburgh is due to infection by the bovine bacillus.

3. The bovine bacillus is introduced into the body by the drinking of infected milk.

4. A considerable proportion of the cases of tubercle due to the human bacillus are the result of the direct infection of the child by a consumptive co-resident.

My thanks are due to Mr. Stiles and Dr. James Ritchie for materials and help. The McCunn and the Carnegie Trustees have provided financial assistance, and I wish to acknowledge my indebtedness to them.

THE International Congress on the prevention of the deterioration and the adulteration of foodstuffs will be held at Ghent on August 1st, 2nd, and 3rd. M. Henry Carton de Wiart, Minister of Justice, is an honorary president, and the presidents are the Burgomasters of Brussels, Ghent, Antwerp, and Liège. The work of the congress will be divided into four sections: Chemistry; hygiene; consumption, education and popularization; legislation. Among the subjects on the programme of discussions are the following: Protection of food substances against dirt; Regulation of the production and of the trade in table waters (mineral, aerated, etc.), as well as of ice and water sold to consumers; Is it necessary to institute official methods for the analysis of foods? Regulation of the production and trade of milk and its by-products destined for human food; To what degree can the incorporation of antiseptics be tolerated in foodstuffs? The basis of organization of a service of inspection in the trade and in the manufacture of foodstuffs; The conditions of places of production (factories) of foodstuffs and retail shops. Rules for the washing of glasses in public-houses. Reports to be presented should be in the hands of the secretary before May 1st, 1913. In connexion with the congress there will be an exposition of foodstuffs and the methods by which they are prepared for consumption, and by which they are adulterated. The milk supply will occupy a prominent place in the exhibition, well-kept and badly-kept farms, and the right and wrong method of transport, and so forth, being shown. Communications should be addressed to M. Antony Neuckens, Secretary of the Congress and the Exhibition, Hôtel de Ville, Brussels.

CLINICAL DEMONSTRATION OF AN OPERATION FOR PROLAPSUS UTERI COM- PLICATED BY HYPERTROPHY OF THE CERVIX.*

By W. E. FOTHERGILL, M.A., B.Sc., M.D.,

SURGEON TO THE ST. MARY'S HOSPITALS, AND ASSISTANT GYNAECOLOGICAL SURGEON TO THE MANCHESTER ROYAL INFIRMARY.

When prolapse is complicated by hypertrophy of the cervix, it is usual to begin the operation for its relief by amputating a suitable portion of the cervix, and suturing the resulting wound in the customary way. Then an anterior colporrhaphy is performed, a fresh incision being made separate from that required for the amputation of the cervix. If the anterior vaginal wall is removed at all freely the two incisions approach one another very closely, a poor and narrow bridge of sound tissue being left between them. Further, the amputation of the cervix tends to shorten the anterior vaginal wall; and thus, when the colporrhaphy has been completed, the cervix still points downwards and forwards, and the uterus is left in a

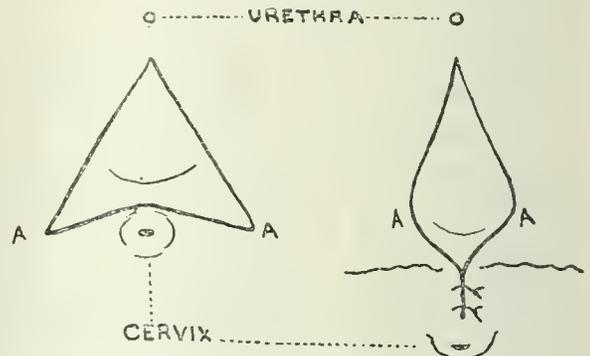

Fig. 1.—Colporrhaphy incision for prolapse.

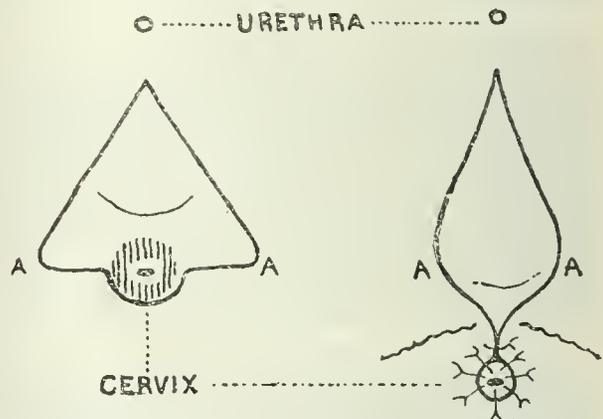

Fig. 2.—Incision for amputation of cervix with colporrhaphy in prolapse complicated by hypertrophy of cervix.

position of retroversion which is very favourable to the recurrence of prolapse.

For some time I have been using a single incision for both the amputation of the cervix and the anterior colporrhaphy, and have found the results more satisfactory than those obtained by doing the operations separately one after the other.

In order to make clear this little modification in technique it is necessary to explain once more how I treat ordinary cases of prolapse in which the cervix is not hypertrophied. The anterior colporrhaphy is done so that the wound is broad above and narrows to a point near the urethral orifice. The piece of vaginal wall removed is, roughly, an equilateral triangle with its base touching the cervix and its apex near the opening of the urethra. The easiest way of making the incision is to pull down the cervix with a vulsellum and then to pick up with forceps two points about 3 in. apart, one directly to the right, the other directly to the left of the

* Given in the Post-Graduate Course at the Manchester Royal Infirmary, March, 1913.

os uteri. The vaginal wall is put on the stretch and is cut through between the tips of the instruments. It is then easily separated from the bladder and parametria, and a triangular portion is cut away. This extension of the wound into the lateral vaginal fornices exposes the connective tissue on either side of the cervix—the right and left parametria. When the wound is closed from side to side, the tissues which previously lay at the sides of the cervix are united in the middle line in front of the cervix, which is thus pushed back towards the hollow of the sacrum. This manoeuvre tilts the fundus forward, so that the uterus becomes anteverted. The suturing begins at the cervical end of the wound, for, as the stitches are tied one after another, this end of the incision, with the cervix behind it, disappears from sight; and, if the incision has been broad enough, cannot be seen again. The closing of the lower part of the wound corrects the cystocele, and thus anterior colporrhaphy, done as above described, remedies both the retroversion and the cystocele, whose combination is the characteristic feature of classical prolapse. Interrupted sutures are used, for if a continuous suture, or even a series of mattress sutures, be employed, the incision is shortened, and thus the cervix is pulled downwards and forwards. This spoils the operation, whose special aim is to push the cervix upwards and backwards. To complete the treatment the vaginal outlet is restored to its normal size by repairing the perineum, the upper part of the posterior vaginal wall being left alone.

The modification of this operation which I have been using in cases of prolapse complicated by considerable hypertrophy of the cervix is as follows: The cervical canal is dilated, and a circular incision is made round the cervix with a knife. The vaginal wall (also the bladder, if necessary) is then snipped free with scissors and is pushed back from the cervix, which is next deeply split into anterior and posterior lips. These lips are then amputated so as to leave the uterus about 3 in. long, and a few sutures are inserted in the stump of the cervix to control bleeding.

The vaginal wall is next incised for an inch or so on either side of the circular wound already made, the new cuts extending directly to the right and to the left. The anterior vaginal wall is now separated from the parametric tissues and from the bladder, and a triangular portion, with its apex near the urethral orifice, is cut away.

In closing the wound thus made the stump of the cervix is stitched into the posterior part of the incision. The first suture brings together the central point of the posterior margin of the vaginal incision and the mucosa lining the posterior wall of the cervical canal. The second and third sutures unite vaginal wall and vaginal mucosa right and left of the first; and so on, until the sides of the vaginal incision come together in front of the stump of the cervix. By this time the newly constructed os is beginning to disappear upwards and backwards. The lateral edges of the vaginal wound, with the subjacent connective tissue, are brought together in the middle line from behind forwards, and the line of suture disappears from view as the later sutures are tied and the urethral end of the incision is reached. Finally, the perineum is repaired as before.

This method of operating has been found convenient both when the elongation of the cervix is mainly supra-vaginal and also when the vaginal portion is chiefly involved. It is not necessary to discuss the various causes of hypertrophy of the cervix; but, before leaving this subject, I should like to express complete scepticism as to the existence of the so-called tensile elongation which was supposed to be produced by the dragging upon the cervix of prolapsed vaginal walls. Such a change might possibly occur after the uterus has been fixed to the abdominal wall by a ventrifixation. But if the uterus is not fixed above, how can it be lengthened by pulling on it below? The theory of tensile elongation seems to be a relic of the times when the uterus was thought to be held up by the broad and round ligaments. Now that the cervix is well known to be the most firmly attached portion of the organ, the theory of tensile elongation may surely be allowed to drop gently into oblivion. All the forms of cervical hypertrophy and elongation can easily be explained without its assistance.

A "SUPPURATING" BRANCHIAL CYST.

BY

C. A. ROBINSON, B.A., M.B., B.C.,

AND

GORDON W. THOMAS, M.B., B.S., F.R.C.S.,

LEOMINSTER.

The following case is, perhaps, sufficiently rare to be worth recording:

Mrs. B., a young married woman, was seen by my partner, Dr. C. A. Robinson, towards the end of 1911, when about five months advanced in her first pregnancy. She then had a small swelling on the left side of the neck, beneath the sterno-mastoid muscle, which was of recent appearance. Deciding that the swelling was neither malignant nor tuberculous, Dr. Robinson advised that it should be left alone for the time. It did not fluctuate, and was thought to be a small fibrous or fatty tumour. As pregnancy advanced it gradually increased in size.

The patient was confined early in April, 1912. Later in the month we saw her together. The swelling was then large, occupying the upper half of the neck, and extending well forwards into the anterior triangle and also backwards into the posterior triangle beneath the sterno-mastoid muscle. It fluctuated very distinctly and was not tender. The patient gave no history of enlarged glands or carious teeth, but there was a history of tuberculous disease in her family. With an exploring syringe thin turbid fluid was found. An attempt to drain the cavity at its lower end, by an incision under local anaesthesia at the posterior border of the sterno-mastoid, proved unsatisfactory.

On May 5th, 1912, under an anaesthetic, the former incision was enlarged, after another incision had been made along the posterior border of the sterno-mastoid, near its upper end; a large amount of thin turbid fluid was evacuated, and a good sized drainage tube passed through from one opening to the other. As the amount of discharge diminished the tube was gradually shortened, being left in at the lower end, as the upper incision soon healed. When, however, the tube was removed it was found that a reaccumulation of fluid occurred, and it was clear that the cavity had not been closing up inside to the extent supposed.

On June 2nd the patient was again anaesthetized; the old incisions were reopened and the intervening tissues slit up on a director along the posterior edge of the sterno-mastoid, thus laying the cavity completely open. On digital exploration the cavity was found to extend far forwards into the anterior triangle of the neck and upwards nearly to the mastoid process. Its lining wall was perfectly smooth, with no suggestion of granulation tissue. There was no sign of a connexion with the cervical spine (caries) nor any trace of broken-down gland tissue. The cavity was swabbed clean and packed with iodoform gauze. It was at this stage that we suspected the condition might be a suppurating cyst (possibly branchial), as the diagnosis of retro-pharyngeal abscess or abscess due to a breaking-down tuberculous gland found no support at this operation, and the smoothness of the wall of the cyst was suggestive. The wound was dressed daily for some time, but granulation tissue was not readily formed. With a view to destroying the lining membrane, iodized phenol was applied. This was successful as far as the anterior (and larger) portion of the cyst was concerned, as it gradually filled up completely.

The upper part of the cyst did not heal in like manner, in spite of careful packing with gauze, and thus a sinus was left, 3 in. long, passing upwards along the posterior border of the sterno-mastoid. This sinus was drained by a small tube and was repeatedly treated with iodized phenol, but did not heal; removal of the tube at once resulted in accumulation of thin purulent fluid.

The patient was loth to undergo another operation and went on in this state for several months. Finally she consented, and the third operation was done on February 4th, 1913. She was then about five months pregnant (a second time). A solution of methylene blue in hydrogen peroxide was first injected into the sinus, so as to stain the whole cavity and any side tracks which might otherwise have been overlooked. On slitting up the sinus it was found to lead into a small cavity, the wall of which consisted of dense fibrous tissue; the lining membrane was greyish and irregular with a granular surface. The wall of the cavity and sinus, with a good deal of surrounding scar tissue, was dissected out almost completely. Part of the fibrous wall, which was closely adherent to the internal jugular vein was left. The cavity was packed with iodoform gauze, and the latter, soaked in iodoform and glycerine emulsion, was used for the subsequent dressings. The patient stood the operation well. The cavity filled up remarkably quickly. Two or three small portions of lining membrane which had been left behind had to be touched with iodized phenol, which destroyed them successfully.

Healing was complete one month after operation. A piece of the tissue removed was sent for microscopical examination to the Clinical Research Association, and the following is the report:

We agree that this specimen is a suppurating branchial cyst or dermoid. It is lined by epidermis, and shows much leucocytic infiltration beneath the lining membrane, and in the

surrounding tissues. There are the usual masses of lymphoid tissue associated with it. There is no evidence of tubercle or new growth.

Even if, at the second operation, we had definitely known the nature of the case, it would have been practically impossible to dissect out the wall of the cyst, owing to the size of the latter, and the fact that it extended forwards deeply into the anterior triangle, so as to be almost in contact with the pharynx. Therefore the treatment adopted was probably the best in the circumstances, even although a further operation was necessary to complete the cure.

There was no obvious cause why the cyst should suddenly enlarge and "suppurate" (the fluid was not true pus), unless the fact of pregnancy occurring had any bearing on the matter.

The report of the Clinical Research Association, together with our knowledge of the anatomical relations and the nature of its contents, confirm us in the view that this was a branchial and not a dermoid cyst.

TWO CASES OF PENETRATING WOUND OF THE HEART TREATED BY OPERATION.

BY

ERIC DE VERTEUIL, M.B., B.S.LOND.,

ASSISTANT RESIDENT SURGEON, COLONIAL HOSPITAL, PORT OF SPAIN.

It has been my lot to have the opportunity of operating on a penetrating wound of the heart on two separate occasions within such a short space of time as three months; I am therefore happy to be able to place before my colleagues the details of such an uncommon experience in the hope that they may prove useful to some and interesting at any rate to others.

CASE I.—*Penetrating Wound of the Left Ventricle: Operation Two and a Half Hours after Injury: Complete Recovery.*

Whilst acting as Resident Surgeon at San Fernando Hospital, Trinidad, B.W.I., on October 19th, 1912, I was hurriedly summoned, about 3.15 p.m. to see a case just brought in and reported to be dying. I found the patient to be a well-nourished coloured boy, aged 14, suffering from severe shock and hæmorrhage apparently caused by a small stab on the left side of the chest.

History.

The following history of the wound was obtained: About 1.30 p.m. on that day he was in the street just near his house playing at "rounders" with his friends, when, on stooping hurriedly to pick up the ball, the handle of an ice-picker (an instrument similar to the large blade of an ordinary penknife fitted on to a wooden handle about 4 or 5 in. long) which he had in his left coat pocket, pressed hard against the front of his left thigh, thus driving the blade into his chest. On rising he felt some sort of pain in his chest, and to his surprise saw the ice-picker securely stuck in his side. This he forcibly withdrew, and for a few minutes felt none the worse, but, as he was bleeding from the wound, he hurried to his house to remove his blood-stained clothing. The pain over his heart now became very severe, and he could breathe only with difficulty, and, as his condition seemed to be rapidly getting worse, he was put into a cab and quickly brought to the hospital, where he arrived as before mentioned in a moribund condition about one and three-quarter hours after the accident.

State on Examination.

He was cold and collapsed, with large beads of perspiration on his forehead, and the pulse could hardly be felt at the wrist. There was acute dyspnoea, and he was extremely restless, and insisted on lying on his left side, as he felt he would die if made to lie on his back. The stab was a small vertical penetrating wound about one-third of an inch long, situated between the fifth and sixth ribs on the left side of the chest, about one inch within the nipple line, and extended in an upward and backward direction, but with a probe no opening into the chest wall could be discovered. The area of cardiac dullness was definitely increased, but the heart sounds could be heard fairly distinctly. There was no hæmorrhage from the wound.

Diagnosis.

The position and direction of the wound, the severe shock and signs of internal hæmorrhage, the increased area of cardiac dullness, the intense dyspnoea, and the absence of hæmoptysis and cough, all pointed to an injury of the heart. Hot water bottles were quickly procured, and a warm saline enema with 15 drops of adrenalin given, while strychnine gr. $\frac{1}{15}$ and adrenalin $\text{m} \times \text{j}$ were injected hypodermically, and the

patient was put to lie on his left side, with his head low. I also gave instructions to get the operation theatre and all necessaries ready as quickly as possible in case there should be no improvement in his condition.

Operation.

About 3.50 p.m., as the patient showed no signs of improvement and was, in fact, fast sinking, I decided on operating at once. An intravenous infusion of normal saline with 10 drops of adrenalin was given, but the fluid flowed extremely slowly and only about \bar{z} ij could be infused altogether, this, no doubt, being due to the failing circulation. The area around the stab was infiltrated with about \bar{z} ij of a solution of cocaine and adrenalin in normal saline (cocaine gr. \bar{z} , adrenalin $\text{m} \times$, normal saline \bar{z} iv) and the wound prolonged upwards and downwards. The opening into the thorax between the fourth and fifth ribs now became clearly evident, and a probe which was inserted was seen to move with the heart-beats, thus confirming the diagnosis. As the patient was now having great pain and seemed very distressed, Dr. Greaves, assistant surgeon to the hospital, administered some chloroform, but after a few minutes respiration ceased and the pulse could no longer be felt. Artificial respiration was immediately resorted to, a capsule of amyl nitrite given as an inhalation, and an injection of strychnine and digitalis given hypodermically. The case now seemed quite hopeless, but after about three minutes voluntary respiratory movements could again be detected. I therefore hurriedly continued the operation, and exposed the fourth and fifth ribs, and with a pair of rib scissors cut away their costal cartilages. At this stage the patient became very restless, and seemed to be in great pain, necessitating the administration of a little ether by the open method. The pleural cavity was rapidly exposed, and a quantity of clots of bright red blood escaped with every movement of respiration, and for a time neither the pericardium nor the lung could be seen. I quickly removed the clots and swabbed out the cavity as far as possible. The pale, collapsed left lung now came into view in the upper part of the wound, and was hurriedly examined, but no injury was found. I then pulled up the pericardium with a pair of Spencer Wells forceps, and at once saw a small hole, through which bright arterial blood was slowly pumping.

This opening was immediately enlarged sufficiently to allow of a thorough examination of the heart, large clots were removed from the pericardial cavity and the apex of the heart was seized with a pair of Spencer Wells forceps and pulled half out of the thorax, when a vertical penetrating wound of the left ventricle about $\frac{1}{2}$ in. long was seen near the interventricular septum about half-way between the apex and the aorta—pumping bright arterial blood with every contraction of the left ventricle.

I hurriedly stitched this with some very fine silk by pulling the heart well out of the thorax with the forceps, thus steadying it sufficiently to allow the stitching, but on relaxing the heart once more the pumping was noticed to be still going on. The stitches had been too tightly inserted, and had cut through the muscle of the left ventricle, making the opening larger than before. I therefore removed these stitches and used rather thicker silk, pulling less tightly and taking great pains that the stitches should not enter the ventricular cavity for fear of thrombus formation. It was necessary to insert five interrupted sutures before the hæmorrhage could be checked. During this procedure, which lasted quite twenty-five minutes, the anaesthetist noticed that the patient's pulse was very much stronger and he was taking the ether well. The removal of the blood from the pericardial cavity, and the stimulation of the heart by the forceps and stitching had evidently markedly improved the heart beats.

It is interesting to note here that whilst the heart was being pulled on to enable the stitches to be inserted, the beats gradually diminished and weakened, but immediately returned to the normal on being relaxed into the thorax.

As soon as I had satisfied myself that the wound was securely sutured and there was no more danger of hæmorrhage, the pericardial cavity was thoroughly irrigated with normal saline and all clots removed, and the opening into the pericardium was stitched with catgut. The pleural cavity was then also thoroughly irrigated and all clots removed, and the pleura and pectoral muscles

stitched with silk across the gap formed by the removal of the fourth and fifth costal cartilages. The skin incision was then brought together with silkworm gut sutures (no drainage tube or gauze being left in), the dressing applied, and the patient hastily returned to his bed and laid flat on his back.

Progress.

The patient's condition had definitely improved after the operation, but the dyspnoea was still urgent and he was experiencing great pain over the heart, which had to be relieved by hypodermics of morphine at intervals. Saline 5x and adrenalin m v were also given per rectum hourly for four hours and then two-hourly throughout the night, and he was able to take small quantities of warm milk and brady at short intervals. The following are notes of the further progress of the case:

October 20th (the day following the operation). He was positively better; respirations 36, pulse 148 and regular. The dyspnoea was much lessened by propping with a head-rest, and the pain relieved with hypodermics of morphine and an icebag, which latter was kept over the heart continuously for the next five or six days.

October 22nd. There was distinct pericarditis of the dry type, which gradually spread over the whole cardiac area, the heart sounds being at no time muffled. The pneumothorax on the left side caused by the collapse of that lung at the time of operation persisted until about October 27th, after which there was some dullness behind, probably due to a small pleural effusion. Slight pleural friction could be heard for a few days after the operation.

October 26th. The skin stitches were removed and the wound had almost healed.

October 30th. The patient seemed altogether out of danger, and he was allowed to take a good meal. Temperature 98.4°, pulse 96, respirations 24. The heart sounds were perfectly clear and the pericarditis had quite disappeared. About 5 p.m. on this day he was suddenly seized with acute abdominal pain over the right side of the abdomen, nausea, vomiting, and collapse, and there was no pulse at the right wrist, the right hand feeling quite numb. An icebag was kept over the abdomen and heart, and morphine, strychnine, and digitalis given hypodermically. About 9 p.m. the pulse was appreciable at the elbow and he was resting quietly.

October 31st. On this morning the pulse at the right wrist could not only be felt but was definitely stronger than that at the left wrist, and his condition was still serious. The nausea and vomiting continued throughout the day, and the pain seemed to become localized over the right kidney, and on November 1st the urine was found markedly albuminous, but no red blood corpuscles were found on microscopical examination.

November 3rd. On this day the pulses were about equal and the patient seemed comparatively well, but the albuminuria was still marked and continued for some weeks. Embolism of the right radial and renal arteries seems to be the only satisfactory explanation of the above symptoms, caused no doubt by the dislodging of emboli from a clot over the wound in the left ventricle probably brought about by a full stomach after the first heavy meal.

November 7th. His condition gradually improved, but by this date the temperature had become definitely septic, and the left base was explored; no fluid was found, but the pleura felt very much thickened.

November 10th. The patient complained for the first time of a swelling over the site of an intramuscular injection of quinine given on October 22nd, and on incision a fairly large abscess, deep down in the muscles of the thigh, was opened and drained.

Result.

By November 18th the abscess wound had healed and the patient was rapidly gaining strength, and on December 7th he was discharged from hospital as cured. I am much indebted to Dr. Turpin, resident surgeon of the hospital, who kindly supplied me with his notes of the case from November 12th (when I was transferred to Port of Spain Hospital) to the time of the patient's discharge from hospital.

I had an opportunity of seeing the patient on December 17th, and found his condition as follows: He was well nourished and showed no symptoms of cardiac trouble;

there was no palpitation, pain, or dyspnoea, and he was able to walk about without any discomfort. (I had advised him not to attempt any running or violent exercise for a few months.) The scar had been replaced by a keloid; the apex beat was over the sixth rib in the nipple line and the space between the excised costal cartilages was not visible on inspection, the distance between the cut ends being only about $\frac{1}{2}$ in. The mitral, aortic, and pulmonary sounds were quite clear and no murmur could be heard. On percussion the area of cardiac dullness was very little, if at all, increased. The lungs seemed normal, except for a slight impairment at the left base behind, probably due to some thickened pleura.

On March 3rd, 1913, the patient again came under my observation, and I am happy to be now able to report his "complete recovery." He looks well, and has obviously put on a considerable amount of weight since last I saw him. The apex beat is in the fifth interspace, well within the nipple line. The area of cardiac dullness seems quite normal, and the aortic, pulmonary, and mitral sounds are perfectly clear and distinct. The pulse is 92, regular, and of good tension. The urine still contains a trace of albumen.

He has been attending school since January, and assures me that he is now able to run at top speed, and walk up and down hill with very little discomfort, though he thinks he is not yet able to do quite as much as he could before the accident.

CASE II.—Penetrating Wound of Right Ventricle: Operation Five Days after Injury: Death.

A. M., a well-developed coloured boy, aged 15, was admitted at 4.35 p.m. on January 1st, 1913, into the Colonial Hospital, Port of Spain, Trinidad, B.W.I., by Dr. Proctor, Assistant Surgeon to the Hospital. The history obtained was that he had stabbed himself with a knife during an altercation with his father about half an hour previously, since when he had been bleeding profusely from the wound. The patient remained during the next five days under the care of Dr. Proctor, who has been kind enough to supply me with the following notes.

State on Admission.

The patient was cold and collapsed, and sweating profusely, there being no pulse at the wrist. There was a small bleeding punctured wound over the third left costal cartilage near the sternum extending backwards and downwards and slightly inwards for about an inch. This was carefully probed, but no opening into the chest wall could be made out. The heart sounds were feeble, but there were no murmurs, and the area of cardiac dullness was not increased. The lungs were normal.

A mixture of ether, strychnine, and ammonia was administered at short intervals, and about 2 pints of normal saline with 10 minims of adrenalin given two hourly per rectum, and about 1 pint of normal saline infused under the breasts. The wound was dressed and firm pressure applied, but as the haemorrhage continued, the area around was infiltrated with a solution of cocaine and adrenalin, and the stab wound enlarged, but no bleeding point could be found; however, after tightly packing the cavity with gauze the haemorrhage was checked.

By 9 p.m. the patient's condition had slightly improved, and the pulse was now perceptible at the wrist. On the next day (January 2nd) he seemed much better, and had a fairly good pulse—there had been no further haemorrhage.

Progress.

On January 3rd and 4th the improvement continued and the patient seemed quite comfortable. The temperature had remained normal since after admission, but on the evening of the 4th it registered 100° F.

On January 5th there were a few crepitations at the left base and some indefinite signs over the left lung in front: the heart seemed normal. The patient now felt comparatively well and was found out of bed on several occasions, though persistently warned that he must on no account leave his bed.

On the morning of January 6th some secondary haemorrhage occurred from the wound, which had to be repacked with gauze wrung out of adrenalin, and for the first time since admission the area of cardiac dullness was noticed to be definitely increased. There was also acute pain over the pericardium, and the pulse had become weak and rapid. Normal saline and adrenalin were given per rectum two-hourly, and strychnine and digitalis injected hypodermically.

This day, about 1.30 p.m., he was reported as having got suddenly worse, and I was called to see him. I found him restless, cold, collapsed, and sweating, with a running pulse at the wrist, and suffering from acute dyspnoea of a panting nature. The area of cardiac dullness extended from the third to the eighth rib, and there was definite pleuro-pericardial friction near the wound on the left side. There were crepitations at both bases, but no signs of fluid. There was no external haemorrhage going on.

Diagnosis.

From the direction of the wound, the sudden increase of the area of cardiac dullness, and the restless collapsed condition of the patient, I concluded that there must have been a penetrating wound of the heart of a valvular nature which had closed down shortly after the injury owing to the feeble contractions of the heart brought about by the extreme loss of blood, most of which had drained out of the pericardial sac and through the external wound. As the patient recovered, however, and the cardiac contractions became more forcible, some secondary haemorrhage occurred from the stab wound in the heart (probably brought about by the patient's exertion in getting in and out of bed), but as the external wound was now closed, all the blood remained in the pericardial cavity, thus causing the symptoms which were now present. In the circumstances, and as the patient was rapidly growing worse, I decided on operating at once, with a view of stitching the wound in the heart and arresting the haemorrhage, this seeming to give the only possible chance of recovery.

Operation.

About 3 p.m. the patient was brought to the operating theatre in a wheel chair and placed on the table in a semi-recumbent position. The whole area around the wound had been thoroughly infiltrated with a solution of cocaine and adrenalin ($\frac{1}{2}$ per cent. of each) in normal saline solution, about twenty-five minutes previously.

An incision about $4\frac{1}{2}$ in. long was now made, starting from the second left costal cartilage going through the stab wound in an outward and downward direction and ending about the sixth rib within the nipple line, thus exposing the third, fourth, and fifth costal cartilages and the intercostal muscles in connexion with them. A careful examination now revealed a punctured horizontal wound, about $\frac{3}{4}$ in. in breadth, between the fourth and fifth left costal cartilages near the sternum, which, on probing, was found to pass in a backward, downward, and slightly inward direction for a distance of about $1\frac{1}{2}$ in. to 2 in., the probe moving up and down with the heart beats, which could be distinctly felt. On removal of the probe, a great quantity of dark venous blood immediately welled up from below. The diagnosis of a punctured wound of the heart having been now definitely confirmed, the operation was continued.

The fourth and fifth left costal cartilages were completely exposed, the intercostal muscles attached to them above and below separated, the pleura freed from their under surfaces, and with a pair of rib shears the cartilages were cut away sufficiently to allow of a complete examination of the pericardium and heart. At this stage the patient became very anxious and restless, and insisted on having an anaesthetic. Ether (by the open method) was therefore administered, and after about four minutes the operation was proceeded with and the pleura incised. There was an immediate rush of air into the pleural cavity as the left lung collapsed into the upper part of the thorax, exposing an extremely distended pericardial sac occupying the greater part of the left side of the chest. The pericardium was found extremely thickened and inflamed, and was incised for about $3\frac{1}{2}$ in., allowing a quantity of dark blood to escape from the pericardial cavity, which was quickly swabbed out, when some fairly rapid venous oozing was noticed to be going on. There was well-marked pericarditis over the visceral pericardium, and the heart muscle was felt to be much softer than normal, probably due to myocarditis.

The left ventricle was now thoroughly examined, but no wound could be discovered, and as the direction of the stab and the venous condition of the blood pointed to a wound of either the right ventricle or right auricle, it became necessary to make as complete an examination of these compartments as possible. The apex of the heart was, therefore, carefully seized with a pair of Spencer Wells forceps and an attempt made to pull the heart out sufficiently to allow of this examination, but this proved impossible, as the tissue was very soft and yielded to the slightest pressure or pull. A silk suture was then passed through the apex of the heart and a further attempt made to pull it out by this means, but this also proved unsuccessful, as the silk cut through the muscle very easily, setting up a fairly smart haemorrhage, which, however, was quickly controlled by means of three interrupted sutures. As the haemorrhage, however, still continued from the stab wound, some very hot saline was poured over the heart, but this too failed to have any effect. By this time the patient's condition was very grave, and all attempts at getting at the source of the haemorrhage had perforce to be abandoned. An intravenous saline infusion was at once started and the heart beats seemed

to improve for a while, the pericardium and pleura being meanwhile stitched with catgut and the pectoral and skin incision brought together with interrupted silkworm-gut sutures. Before the stitching had been completed, however, the patient expired.

Post-mortem Examination.

On the next day a post-mortem examination was held, and, as anticipated, a punctured horizontal valvular wound, about $\frac{3}{4}$ in. long, of the right ventricle about half-way between the apex and base of the heart was found penetrating into the ventricular cavity. The stab had gone through the chest wall directly into the pericardial sac without penetrating the pleura, and there was a fair amount of extravasated blood beneath the sternum along its whole length. The lungs showed some congestion of the bases and there were some old pleuritic adhesions on both sides. The other organs seemed normal.

Conclusions.

In the light of the experience gained from these two cases, I venture to put forward the following conclusions and suggestions:

1. A great many cases of penetrating wounds of the heart might easily escape recognition if too much reliance be placed on the failure of the probe to enter the thoracic cavity; but when it is borne in mind that a stab wound (made often with the *thin* blade of a knife) in that position usually has to traverse several layers of muscles, the fibres of which run in various directions, it can easily be conceived how difficult it would be to detect the opening into the chest by means of a probe. I think that all such wounds in the vicinity of the heart which give rise to symptoms of shock and collapse (even in the absence of other signs, such as an increase of the area of cardiac dullness, etc.) should be immediately enlarged and the thoracic walls sufficiently exposed for a thorough examination for a possible wound of entry, which, if found, would necessitate an immediate operation.

2. It is not usually known that the proportion of recoveries amongst the 124 cases recorded of operations of suture of the heart after injury is as high as 40 per cent. (vide Thomson and Miles, *Manual of Surgery*, 1909); there seems little doubt, therefore, that the proper treatment for all such cases rests with the surgeon and not with the physician, who up to now holds such strict monopoly of the chest and its contents.

3. The choice of suture—that is, catgut or silk—for the heart wound seems to me of paramount importance, and it is strange that such little attention is paid to it in the various textbooks. My former esteemed professor, Mr. Waring of St. Bartholomew's Hospital, for instance, recommends in his *Manual of Operative Surgery* interrupted sutures of catgut, whilst in the *Manual of Surgery*, by Thomson and Miles, 1909, "interrupted sutures of fine silk or catgut" are recommended. As to the use of ordinary catgut, I feel quite certain that it is unsafe, as it is too elastic and does not hold sufficiently long to ensure firm union between the edges of a muscle which is continually contracting and retracting. Iodized or chronic catgut, however, which lasts a great deal longer, may, I think, be used with safety, but I very much prefer, and can see no reasonable objection to, the use of thin silk applied not too tightly. Excellent results are obtained by the use of such silk in abdominal operations in which sepsis can certainly not be excluded, and I feel sure that the great power of absorption of septic matter possessed by the peritoneum is also possessed to the same degree by the pericardium. Should the wound be an obviously septic one, I would, of course, prefer chronicized or iodized catgut.

4. The selection of the ribs to be removed seems to me also an important consideration. Complete exposure of the pericardium and heart can easily be obtained by removing the fourth and fifth costal cartilages—instead of the fifth and sixth, or fourth, fifth, and sixth as recommended by some—thus leaving the sixth rib in position as a support to the heart when the patient is in the erect position.

5. I note that most writers lay much stress on the necessity of trying to avoid opening the pleural cavity—no doubt for fear of causing a pneumothorax. In both my cases the pleural cavity was opened and a pneumothorax caused, and I must confess that, in spite of their very grave condition at the time of operation, their symptoms were not aggravated by this procedure. My first case shows how quickly and completely such

a pneumothorax can be recovered from. On the other hand, there are two distinct advantages in opening the pleural cavity. In the first place, owing to the collapse of the lung in the upper part of the thorax, the pericardium and heart are more completely exposed, and the operation thereby much facilitated; and, secondly, it permits of a thorough examination and cleansing of the pleural cavity from all blood clots, which one can never exclude with certainty, the pleura being in most cases wounded at the same time as the pericardium.

6. As regards the after-treatment, in addition to the usual treatment for haemorrhage an icebag kept over the heart continuously and hypodermics of morphine are extremely useful adjuncts for allaying the distress and pain. Complete rest in bed for at least three weeks after the injury must be thoroughly enforced for fear of embolism.

7. With regard to the "incision," I note that the trap-door method first used and described by Parozzani in Italy is recommended by some. This consists in making a horizontal incision along the fourth interspace dividing the superficial structures and the pleura, and a second incision vertical to this, dividing also the fifth, sixth, seventh, eighth, and ninth ribs, thus forming a trap door the hinges of which are the rib cartilages. I can see no necessity for such a radical procedure. The ordinary straightforward incision gives ample room, which could be further increased if necessary by making transverse incisions at right angles to it as suggested by Waring.

In conclusion, I have to thank the Surgeon-General (Dr. H. L. Clare) for his kind permission for the publication of this report.

THE NASCENT IODINE TREATMENT OF LUPUS NASI.

By P. W. BEDFORD, M.B., Ch.B.,

FORMERLY HOUSE-PHYSICIAN TO THE SALOP INFIRMARY.

An article appeared in the BRITISH MEDICAL JOURNAL of March 23rd, 1912, describing Dr. Pfannenstill's method of treating lupus and laryngeal tuberculosis by means of nascent iodine. As the results obtained in those instances were so satisfactory as compared with other methods of treatment, it was thought that it might with advantage be employed in a case that had hitherto resisted treatment. The patient selected was a definitely tuberculous girl 12 years of age, who in addition to lupus nasi had tuberculous kyphosis and scoliosis of nine years' duration, and had also at one time suffered from a tuberculous ulcer on the wrist which had healed rapidly under tuberculin treatment. Further, she had reacted strongly to the von Pirquet and the subcutaneous tuberculin tests.

These details are recorded because when Dr. Pfannenstill's report was first published the point was raised whether the cases cured by him were actually tuberculous and not syphilitic.

In this case, then, there was no doubt as to the diagnosis, for though Wassermann's test was not applied, there was no evidence obtainable that the lesion was syphilitic.

When the nascent iodine treatment was first instituted, she had been under the influence of that form of tuberculin known as B.E. for a period of six months, having begun with a dose of $\frac{1}{100000}$ mg. hypodermically, and had attained to so large a dose as $\frac{1}{4}$ mg. without, however, its having exerted any appreciable effect upon the course of the disease. The technique employed in this instance was slightly modified, chiefly in the direction of simplification, as follows:

1. Instead of two solutions, only one was used; it consisted of 1 pint of a 3 per cent. solution of 10 volume hydrogen peroxide, to which had been added 1 oz. of acetic acid (B.P.).

2. The solution was applied hourly instead of every few minutes.

3. A spray was employed to make certain of attacking that portion of the disease that lay within the nasal cavity.

4. A "nosebag" of lint was extemporized to keep the gauze and gauze plugs in position.

5. Poultices were applied to remove the crusts before beginning the treatment, and were also resorted to at intervals during the course.

After treatment for a fortnight the patient was obviously much improved both in her local condition and in her general health. Up to this point the tuberculin injections were still being employed; these were now discontinued, and it was noted that during a period of one week the disease remained stationary. The injections were accordingly resumed, and benefit again began to accrue.

From this time onward the patient made steady progress until, eight weeks from the commencement of the treatment, the diseased surface had completely healed over with soft, smooth scar tissue, and the cure was complete.

It was thought advisable, however, to continue the administration of the sodium iodide and the tuberculin for a few days longer; but instead of the peroxide solution an application consisting of linimentum eaphorae ammoniatum, with the addition of some tinctura capsici, was used locally as a counter-irritant. The peroxide was discontinued because it was considered probable that the patch having healed, the solution was not being brought into actual contact with the disease should it be lying deeper. The sodium iodide, which was given in doses of $7\frac{1}{2}$ grains by the mouth every four hours, did not produce any symptoms of iodism, nor was the latent phthisis aggravated by the treatment.

The patient, on being discharged, was instructed to report herself at once should the disease show any signs of fresh activity, but up to the present time—that is, two months later—this has not occurred.

The question that naturally suggests itself in this case is: Was the cure due to the nascent iodine treatment alone or to its use in conjunction with tuberculin?

On the one hand is the fact that six months' treatment by means of tuberculin alone had no effect upon the disease, which, on the contrary, continued to spread. And, on the other hand, when the tuberculin was discontinued, the disease remained stationary.

A reasonable explanation would be that the hydrogen peroxide merely acted as a counter-irritant, causing a local increase in amount of the antibodies produced by the tuberculin, whilst the iodide helped by exerting its usual beneficent influence on a strumous condition. In support of this contention may be cited the manner in which tuberculous glands often melt away under tuberculin injections combined with the local application of suction cups.

Whatever the explanation may be, the result was so eminently successful, both as regards cure and cosmetic effect, that the nascent iodine treatment of lupus calls for a wider publicity and a greater usage than it appears to have gained in this country.

I am indebted to Dr. H. Willoughby Gardner, Senior Physician of the Salop Infirmary, for his kind permission to publish the notes of this case.

THE Berliner Ankufts- und Fürsorgestellen (Organization for Inquiry and Care), under the direction of Geheimrat Püttler, of the Charité Hospital, is one of the most beneficent institutions for the poor sick inhabitants of Berlin. Aid is given to people suffering from lung diseases, cancer, and to inebriates. It is particularly difficult to assist the latter and their families, as the authorities have very little power in such cases. Legally a drunkard can only be taken to the workhouse if he is so much addicted to drink and loafing that he is neither able to support himself nor those dependent on him and if public charity has to be called upon. As long as a drunkard is doing some work, be he treating his family ever so ill, no legal proceedings can be taken against him, and even the police are powerless unless some actual mischief has occurred. In cases like this the organization exerts its influence. Only a small percentage are cured of their drinking habits and brought back to regular work, but in about 50 per cent. of all cases the efforts to improve the impoverished circumstances of the families have been successful. Of the 1,277 cases of drunkenness which in 1912 became known to the organization, 60 were under the age of 30, 497 between 30 and 50, and 275 over 50 years old. The age of 445 could not be ascertained. Only 3 out of 1,277 were women.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

A CASE OF PAROXYSMAL HAEMOGLOBINURIA.

A boy aged 13 complained of feeling cold and shivering for several hours. On the next day there was headache and discoloration of the urine. On the third day he came under observation. He was well nourished, of high colour, and complained of slight headache. The pulse (90) was of normal volume and tension; the temperature was normal. The right kidney seemed slightly tender but not enlarged, the left could not be felt. He was passing a normal quantity of deep red-brown urine. He had had two previous attacks of a similar kind two years and three months earlier respectively. The urine on standing deposited much mucus, and became almost clear above and of a dull claret colour. The specific gravity was 1022; it was strongly acid and exhibited on boiling one-sixth albumen. The deposit on microscopical examination showed abundant uric acid crystals, but no red corpuscles or renal casts. Seven days after the onset the urine became normal in colour and entirely free from albumen.

ANTISTREPTOCOCCAL SERUM IN APPENDICITIS.

The patient in the following case, a man aged 35, had complained for eighteen months of pain in the abdomen. It was aggravated by food, and pointed towards gastric or duodenal ulcer, for which the case had been treated by three previous medical attendants.

On January 5th, 1913, he was seized at 4.30 a.m. with violent pain in the abdomen and sickness. The abdomen was rigid, the liver dullness absent, and the patient's forehead covered with perspiration. There were also symptoms of collapse. In view of the previous history perforation of a gastric or duodenal ulcer suggested itself.

A surgeon was called in by me, and he thought it possible the mischief was above the umbilicus, and accordingly made his incision above the umbilicus. No trouble being found there, he extended his incision. The mischief was found in the appendix, which had perforated, and had quite a pint of pus lying in its neighbourhood.

The appendix was removed, the pus swabbed out, and drains put in the right flank and end of the incision. The temperature remained high, and reached 101.6° on January 19th. On January 27th fluid was noted in the right pleura. Thinking the fluid would probably become purulent, I arranged with the surgeon to come down and resect a rib. However, by February 1st the fluid had disappeared, but the temperature still remained up, being 101.2° on the evening of that day, and running up to 102.8° at 4 p.m. on February 2nd.

On February 4th his condition was very serious, and the surgeon was of opinion the man would die. On February 5th I gave 10 c.cm. of antistreptococcus serum, and repeated the injection next day. The effect was remarkable, the temperature falling to 97.2° and remaining below normal for fifteen days.

On February 20th the temperature again rose to 99.4°, running up, the next day, to 100.2°, and the chest was filling up with fluid. The serum was immediately used again, with the same favourable result—a gradual drop of the temperature. The patient has since made a complete recovery and has gone away for a change.

WOLVERHAMPTON GENERAL HOSPITAL.

HYPERTROPHIED SIGMOID IN A BOY TREATED BY EXCISION.
(By W. F. CHOLEMELEY, F.R.C.S.Eng., Honorary Surgeon
to the Institution.)

THE following case is of interest, on account of the enormous size of the sigmoid, the age of the patient, and the probable cause of the condition.

The patient, a boy aged 6 years, was admitted on November 13th, 1911, under the care of Dr. Codd, when the following notes were taken: A history to the effect that he had had an imperforate anus at birth, which was successfully operated on; ever since he had been very constipated, the bowels occasionally not being open for three weeks.

State on Admission.

The boy was very pasty in appearance. His abdomen moved well, but showed much distension and visible peristalsis. On pressure the abdomen pitted, and did not regain its normal shape for some time. The rectum was much distended, and full of soft faeces of a doughy consistence.

The boy was ordered a course of enemata, for the most part twice a day, and at the end of twelve days, the abdomen having become much smaller, he was transferred for surgical treatment.

Operation.

The case was looked upon as one of a large dilated colon, and on November 22nd I operated with a view to doing an ileocolostomy.

The abdomen was opened in the left iliac region, and what appeared to be a thin-walled translucent cyst presented in the

wound as soon as the peritoneum was opened. This proved to be thinned and distended bladder, and was emptied by means of a catheter. The caecum and appendix next appeared in the wound, and had to be pushed on one side before the contents of the abdomen could be examined.

Before I could examine the abdomen at all thoroughly the patient became so collapsed that it was evidently too risky to do any more. The abdomen seemed to be almost entirely occupied by an enormously distended and hypertrophied sigmoid, which was full of soft faeces. The wound was rapidly closed and the boy taken back to bed. I decided, before making another attempt, to try to get the bowel more empty and the boy in better condition.

With these objects in view he had daily a simple enema, as well as a dose of castor oil and a mixture containing mag. sulph. It required all this to bring about a good daily action. Urine was passed only once a day. Under this treatment the child improved in health, the abdomen became softer and smaller, and no longer pitted on pressure.

Second Operation.

On January 10th, 1912, the abdomen was again opened, but this time in the middle line below the umbilicus.

The distended bladder again presented in the wound and was found to reach up to the spleen. A catheter was passed, and, after the bladder was empty, a careful examination of the abdominal contents was made and the following found: The sigmoid had pushed the intestines to the left side, including the

caecum and ascending colon, and occupied the whole of the right side. The sigmoid and rectum were very large, the walls hypertrophied, and were half filled with soft faeces. The pelvis was entirely occupied by the distended rectum; in fact, it was lined with it, the bladder being pushed up and the peritoneum ending at the brim of the pelvis.

The wound was enlarged to reach from the umbilicus to the pubes, and the dilated gut, which reached up to the liver, easily delivered from the abdomen.

No difficulty was experienced in separating the gut from the descending colon or from its mesentery. Only one vessel, the sigmoid, at its origin from the inferior mesenteric, required ligation.

The difficulty began at the lower end of the sigmoid, as here the gut was very large, the walls much thickened, and fixed all round to the pelvis. A curved clamp was applied as low down as possible, and the sigmoid removed. It was found possible to bring the divided end of the descending colon and to suture it to the divided end of gut in the pelvis, the method being the same as that used by Billroth when suturing the duodenum to the stomach after pylorotomy, except that the sutures were continuous. I used three layers of sutures, but not being confident that the bowel would heal well, as its vitality did not seem strong, I drained the abdomen by means of a small tube passed down to the line of sutures.

The rectum was found to be as much distended as the sigmoid, or as much as the size of the pelvis would allow, but was not excised, as I considered that it would be too severe an operation.

After-Progress.

The child stood this operation very well, and was very little collapsed. A catheter had to be passed for the first two days, and on the third day, as no urine was passed, and the bladder became very distended, a catheter was tied in, and kept there for a week.

Two days after the operation the drainage tube was removed, rather earlier than I had intended. The lower end had a rather suspicious smell, but I did not think it wise to try to replace it. On January 12th, while under an anaesthetic, to have a catheter passed, the anus was dilated and the rectum examined. This was found to be full of hard scybala.

Enemata of olive oil were given to soften the scybala, but without much result, so a few days later, as the lower abdomen was becoming distended, I cleared out the rectum under ether. A very large mass was got rid of, and the anus again dilated. The distension of the abdomen disappeared. The line of suture from the inside felt quite firm, but must have been strained, as on the 18th, while the daily enema was being given, a good deal of it came through the sinus left by the drainage tube. The rectum was washed out daily, the amount coming through the sinus getting less and less, until February 5th, when it ceased.

After February 7th no more enemata were given, the bowels opening naturally. Occasionally a little syrup of figs was given.

Result.

The boy improved rapidly, and on February 19th he went to a convalescent home. The bowels were acting every day without any purge or enema, and the abdominal wound was quite healed, with the exception of the sinus left by the drainage tube. When last seen the wound in the abdomen had healed after the intestinal sutures had come away, and there still was no difficulty with the bowels.

REMARKS.

The removed portion of bowel, which was about a third full of soft faeces, weighed 2 lb., and when emptied of its contents held 3½ pints of water.

The cause of the dilatation and hypertrophy of the bowel was, I have no doubt, the condition of the anus, and the neglect on the part of the child's parents in not seeing that the bowels acted daily. The operation for imperforate anus had been successful up to a certain extent, but left a tight stricture of the anus.

The dilatation of the sigmoid had gone on to such an extent that there seemed to be no power left in the muscular coat. This was shown by the amount of purgatives necessary to get a daily action of the bowels before the sigmoid was removed. After its removal no purge of any kind was needed.

THE late Dr. Richard Allanson Gaskell, J.P., V.D., of Glendavon, Huyton, Liverpool, left estate valued at £107,825 gross, with net personalty £81,309.

The nineteenth International Congress of Hydrology, Climatology, and Geology will be held at Madrid this year in October (15th to 22nd). It will devote itself specially to the study of the hydrology and climatology of Spain, with the special object of making known the wealth of that country in watering places and climatic health stations. In connexion with the congress there will be an exposition of plans, specimens, etc., relative to the subject with which the congress proposes to deal. All correspondence should be addressed to the General Secretary, Dr. Rosendo Castells, 10, Encarnacion, Madrid.

Reports of Societies.

ROYAL SOCIETY OF MEDICINE.

SECTION OF DISEASES OF CHILDHOOD.

At a meeting on March 28th, Dr. J. WALTER CARR, Vice-President, in the chair, the following were among the exhibits:—Dr. FREDERICK LANGMEAD: (1) *Tremor* in a girl aged 10. It was unassociated with any sign of organic disease, and was probably congenital. (2) "*Nervous cretinism*." The case was so called after the description given by Major McCarrison, I.M.S., and was one of cretinism complicated by cerebral diplegia. It was shown to raise the question as to the relationship between cerebral diplegia and deficiency of the thyroid gland. McCarrison had found that about a third of the cases of cretinism endemic in some valleys in India is associated with cerebral diplegia. (3) A case of *Imperfect ossification* of the cranial vault in a boy aged 4. A small hole persisted at the posterior end of the sagittal suture, where cerebral pulsation could be seen and felt. Dr. F. G. CROOKSHANK and Mr. SIDNEY A. BOYD: *Congenital deformity* of the thorax in a boy aged 6½ years. A gap was present in the bony thorax on the right side, and through it bulged a considerable hernia of the lung. The upper arm fitted closely into the gap if apposed. Mr. A. S. BLUNDELL BANKART: *Achondroplasia* in a girl aged 7 years. Great enlargement of the epiphyses existed, and shrinking of the diaphyses. The condition simulated rickets, but the head was neither rachitic nor achondroplastic. The joints were very lax, the wrists permitting movement through an angle of 180 degrees. Opinions were expressed in favour of rickets as the correct diagnosis. Mr. LIONEL E. NORBURY: *Circumscribed serous meningitis* in a boy aged 13 months. There had been convulsions followed by right facial paralysis and tremor of the right hand and arm, right leg, right side of mouth, and also of the tongue and lower jaw. The left parietal bone had been trephined over the Rolandic area, and the pia arachnoid found swollen and oedematous. The tremor gradually disappeared; only slight facial paresis remained. Dr. REGINALD MILLER and Dr. LEONARD PARSONS expressed the opinion that the condition was one of polio-encephalitis. Dr. R. C. JEWESBURY: *Acute poliomyelitis* which affected the muscles of both hands. Dr. F. PARKES WEBER: *Congenital eversion of the great toes* and other abnormalities in an infant 7½ months old. Dr. LEONARD PARSONS: (1) Sections from a case of *Progressive muscular atrophy* (Werdnig-Hoffmann type). The affected muscles showed fibrosis; some fibres were larger than normal, but the majority were smaller and contained an enormous number of nuclei. Many showed fatty degeneration. Only about a third of the usual number of cells were seen in the anterior corn of the cord. (2) *Diffuse sarcomatosis* of the brain and spinal cord. The primary growth was in the cerebellum, and was a mix-celled sarcoma. Its method of spread was due to "infection" of the cerebro-spinal fluid. Mr. SEYMOUR G. BARLING: *Hair-ball* removed from the stomach of a girl aged 7. It presented an exact cast of the stomach, and consisted of a felted mass of hair and string. Dr. J. T. LEON: A lung showing *Acute tuberculosis* which had spread from its root. No generalized tuberculosis had occurred.

MANCHESTER MEDICAL SOCIETY.

The presidential address, delivered by Dr. J. J. Cox on March 5th, dealt with *Multiple infective arthritis*, a subject which the speaker discussed in all its aspects, though paying special attention to the arthritis deformans type. The latter was most probably due to some as yet undiscovered organism or organisms most easily affecting individuals at certain stages of development and in certain conditions of health. The toxins produced might act in various directions: (1) By elimination through the joints, causing the articular and periarticular characteristic deformities and loss of proper function, especially seen in hands and fingers; (2) upon the nervous system, as shown by rapid pulse, sweating, loss of cutaneous sensibility, atrophy of muscle, at times preceding the joint changes, and a Babinski reflex fairly often met with; (3) upon

the blood-making functions, as shown by profound anaemia; (4) upon the lymphatic glands and spleen (Dr. Still's disease). The theory of the neural origin of arthritis deformans should probably be given up altogether. The theory of Poncet and Leriche, that many cases of infective arthritis were due to the effects of an attenuated virus of tubercle, meant that the joint changes in question stood towards tubercle as did the parasyphilides to infection with the *Spirochaeta pallida*. There was urgent need for thorough research on arthritis deformans, especially in regard to the bacteriology of the urine. In treatment few drugs were of much avail except guaiacol, arsenic, and potassium iodide, aided by iron and cod-liver oil. The patient's strength must be kept up well by proper and generous diet. Chronic intestinal stasis must be thoroughly dealt with by aperients, Plombières douches, and skilled massage. Every patient with chronic constipation was perilously near the risk of developing arthritis deformans, for a recent investigation at the Devonshire Hospital, Buxton, showed that 78 per cent. of the arthritis deformans patients had a history of chronic constipation. It would be well also to try the effect of giving in the early stages hydrochloric acid and glyceropepsine, on the lines which Drs. Woodwark and Wallis, following up the work of Dr. Helen Baldwin in 1904, had recently advocated.

LIVERPOOL MEDICAL INSTITUTION.

At a meeting on March 27th, Mr. ROBERT JONES, President, in the chair, Mr. COLIN CAMPBELL, in a note on four cases of *Graves's disease* treated by fresh thyroidectomized goat's milk, supplied reasons for holding that the prevalence of the disease was increasing and that cases did not "tend to get well." Non-recovery was the rule, whilst deaths were more frequent than cures. His experience of the various serums had been unfortunate. The cases treated with fresh milk had improved comparatively quickly; one, he might say, was cured. Possibly much of the benefit derived from the use of goat's milk was due to its nutritive qualities rather than to its antithyroid action. Mr. THURSTAN HOLLAND said he had treated 50 cases of *Graves's disease* by x rays with satisfactory results, and thought that method much more reliable than any other. Dr. WARRINGTON thought that Dr. Holland had made out a case for x -ray treatment, but said that all remedies that had been tried and vaunted were ultimately found unsatisfactory. Mr. KEITH MONSARRAT said he had seen surgical treatment very successful in properly selected cases. Dr. G. C. E. SIMPSON, in a paper on *Appendicitis in children*, said that in the records of the Liverpool Infirmary for Children no case of appendicitis, perityphlitis, or pericolicitis appeared from 1876 to 1891, and from 1884 to 1891 only 2 cases of abdominal abscess led to a fatal result among an annual average of 15,000 patients. In 1892 a case of iliac abscess was recorded, and from that time there had been a steady increase in the frequency of these cases; in the last five years there had been an average of 24 cases per annum, the figure rising to 34 in 1910-11. The average death-rate was high, being 23 in 160 cases, or nearly 15 per cent. The speaker had himself treated 34 cases, and urged that the disease was increasing in frequency and in severity, so that no opportunity should be lost of impressing on the public the importance of abdominal pain in a child. Dr. A. SROOKS said that while he had been Resident at the Infirmary for Children in 1884 a case of abscess of the brain and liver had been recorded which was secondary to a pin in the vermiform appendix. He was much struck by the frequency of the disease now as compared with its great rarity thirty years ago. He did not think these cases were missed by the practitioner of those days. In Dr. West's book on *Diseases of Children*, published in 1859, were recorded 4 cases, and the description of the disease showed that the author recognized its existence and its rarity. Mr. R. W. MURRAY said that in a paper fifteen years ago he had advocated treating these cases by hot fomentations and temporizing measures until the abscess pointed, and then opening and draining. He could not now repeat such a recommendation, for the poison had increased in virulence, possibly owing to food adulteration. Mr. F. T. PAUL said that in his early days he remembered

only three cases of appendix disease in five years, during which every fatal case at the Liverpool Royal Infirmary was examined after death. He believed that there was always a foreign body in the appendix at the first attack. When the case was not seen at the very onset it was necessary to use judgement as to operation. In some cases he thought it wise to wait for an interval operation; no hard and fast rule could be laid down. Dr. MACALISTER thought investigation was needed as to the cause of intestinal diseases, and especially in regard to food habits. Appendicitis was closely related to the other intestinal disorders, such as colitis, and he thought the condition of the teeth had much influence in these diseases. Mr. ARTHUR EVANS drew attention to the fact that a right-sided basal pneumonia might be mistaken for appendicitis. Dr. W. B. WARRINGTON read a paper on *Meningitis serosa*, which he said was chiefly associated with otitis, but was also associated with other infective diseases, as tuberculosis. The term implied a condition in which there was a pathological collection of clear sterile fluid in the intracranial cavity. In the diagnosis from abscess of the brain the chief guiding marks appeared to be: (1) The sudden and acute onset of symptoms with an otitis; (2) the fluctuating course of the symptoms; (3) the absence of constitutional signs often associated with brain abscess; (4) a study of the localizing signs, which differ from those sometimes met with in abscess. Serous exudates into the intracranial cavity might occur in association with distant sites of suppuration—for example, after appendicitis and puerperal infection. He had also seen it follow a blow on the head and a mental shock. In one case serous apoplexy occurred in a young man, the result of starvation and exhaustion, and terminated in complete recovery.

GLASGOW SOUTHERN MEDICAL SOCIETY.

At a meeting in the Faculty Hall on March 20th, Dr. J. A. AITKEN, President, in the chair, an address entitled *The passing of tuberculosis* was delivered by Sir R. W. PHILIP, the honorary President. Sir Robert said the optimism reflected in this term was justified by tangible evidence; a hopeful factor was that the medical profession and the public were now together handling the question of tuberculosis as one of the live problems of the hour. In dealing with the sites of invasion by the bacillus, he laid particular stress on the posterior nares, faucial and tonsillar regions, as being specially vulnerable. A fact of significance was that successful inoculation might be accompanied by little, if any, local change, especially in childhood, when the mucous surfaces were more absorbent and succulent. This explained the great frequency of infection with limited evidence of surface lesion. After infection the further course consisted for the most part in a gradual spread by way of the lymphatic system. First, one or two glands in the neighbourhood of the point of inoculation became enlarged, and then progressively others at a greater distance, the extent depending on the degree of resistance which the patient offered. There was evidence suggesting that the glands exerted a definite antagonist influence. In this respect he referred not to gross deformity of glands, but rather to progressive infiltration of chain after chain of glands so slight in degree that they were mostly overlooked. The determination of tuberculosis at the lymphatic stage would be a common event if such lymphatic tracts were scrupulously supervised in childhood and adolescence. It was at the lymphatic glands that tuberculosis ought to be opposed, and when thus opposed its further spread within the system was readily prevented. The tuberculous toxins seemed to act especially on neuromuscular structures with progressive loss of sarcous substance and associated enfeeblement and irritability of muscle, and to this might be referred the early signs of motor weakness both of limbs and viscera, the feeling of tiredness, the disinclination for effort, the softening pulse, and the gastro-intestinal sluggishness. These were generally in evidence long before cough or expectoration, or other indication of local lesion. To wait for the appearance of tubercle bacilli in the discharges was to wait much too long. Many years ago he instituted at the tuberculosis dispensary a "march-past" of the infected households. This systematic examination led him to the conclusion that tuberculosis among children was far commoner than

had been supposed, indeed that at least 30 per cent. of children were affected. This had been entirely confirmed by bacteriological and pathological observations in different countries. If the principle of the "march-past" were universally carried out, not merely at the tuberculosis dispensaries, but in general practice, tuberculosis in its grosser forms would disappear.

GLASGOW OBSTETRICAL AND GYNAECOLOGICAL SOCIETY.

At a meeting on March 26th, Dr. LINDSAY, President, in the chair, Professor TEACHER gave a demonstration of gynaecological specimens illustrating various conditions, the most noteworthy being sections of the genital gland of a case of hermaphroditism showing both ovarian and testicular tissue elements, specimens of ovarian pregnancy, and a specimen of a uterus showing ectopic pregnancy in a rudimentary Fallopian tube. A lantern demonstration was also given on the embedding and development of the early human ovum. During its course Professor Teacher reviewed existing knowledge of the subject, more particularly in relation to the work of Professor Bryce and himself. He stated that the *Teacher-Bryce ovum* preparation still represented the earliest known stages of the human ovum, the only more recent specimen at all comparable in age being that of Young of Edinburgh. This was apparently intermediate in development between it and the ovum of Peters, but was probably abnormal. Several very valuable ova of about the age of Peters's had been found within the last five years, and the examination of these had confirmed and extended the discoveries due to that famous preparation.

HUNTERIAN SOCIETY.

At a meeting on March 26th Dr. ARTHUR LATHAM, in opening a discussion on the *Uses of tuberculin*, said the intensity of the von Pirquet reaction was of service in estimating the dosage and spacing of doses in a course of tuberculin. By the use of tuberculin at the King Edward VII Sanatorium the number of patients who lost their tubercle bacilli had been increased by 17 per cent. over what was obtained merely by sanatorium treatment. If the real nature of pleurisy in early adolescence were recognized and the case properly treated by sanatorium methods and tuberculin therapy, probably a considerable number of cases of pulmonary tuberculosis could be avoided. As to the particular form of tuberculin to be selected for use, results showed that this was of no great importance; the chief thing was for the observer to know the value and the limitations of the particular brands he used. In many chronic cases S.B.E. was preferable to the ordinary bacillary emulsion. He had never been convinced of the truth of the statement that bovine preparations should be used in lung infection and human in examples of "surgical" tuberculosis. A large proportion of surgical tuberculosis was due to infection from human sources, yet the upholders of cross-vaccination treated all cases of this form of the disease with human preparations. The fact that great improvement followed in many of these cases showed that cross-vaccination was not essential. Dr. CRACE-CALVERT agreed that pleurisy should never be neglected, as very often it was the precursor of definite lung disease. Sanatorium and tuberculin treatment were complementary, as one provided the stimulus to the production of antibodies, and the other the powers of response. Most patients were suitable for the use of tuberculin if they were carefully watched first, and if very small doses were used at the start. He used bacillary emulsion, as it resembled an ordinary vaccine, and was slowly absorbed, and therefore caused a more lasting production of antibodies. The intensive system of dosage increased the tolerance and decreased the sensitiveness. If the same site were always used for the injections it was sometimes difficult to inject, apparently owing to the inflammatory condition, and if so a general reaction was very likely to occur. Even if tuberculin aided in the production of cavities, it was often a good thing, as it was preferable to have simply a ring of scar tissue round an

empty cavity rather than a mass of dead tissue containing bacilli, and this cavity formation did not make more liability to haemorrhage, as the focal reaction tended rather to the obliteration of vessels. Patients treated with tuberculin certainly lost the bacilli from their sputum more readily than those not treated, and so the tendency to relapse was greatly reduced.

LONDON DERMATOLOGICAL SOCIETY.

At a meeting on March 18th, Dr. MORGAN DOCKRELL in the chair, Mr. E. H. ROSS described certain *Intracellular protozoal parasites found in guinea-pigs*. They exhibited asexual, sexual, and conjugate stages, while the male elements developed into microgametes indistinguishable from spirochaetes. They led to much cell destruction and produced anaemia and lesions comparable to those of human syphilis. There was reason to believe that they were conveyed from animal to animal during coitus, and they could be found in the blood of the young of infected mothers. Similar intracellular parasites had been found in every case of untreated syphilis so far examined, and some had been seen to develop into spirochaetes. Rabbits and hares likewise suffered from a condition indistinguishable from syphilis, and in the lesions corresponding organisms could be found. Dr. Castellani, the speaker, and his brother, Dr. H. C. ROSS, had found similar parasites in a fatal case, which was apparently one of anaemia, but might be one of sprue. The PRESIDENT spoke of the results of his observations on patients after giving salvarsan—namely, that they obtained a complete freedom from the parasites for a time, but that they returned before long, and that it was necessary to continue with mercury. Dr. W. GRIFFITH considered that from a practical point of treatment it might be well to examine the blood of patients for these amoeboid bodies, and only give salvarsan when they and the spirochaetes were found free in the blood. Dr. KNOWSLEY SIBLEY said the paper confirmed the views he had always maintained—namely, that the *Spirochaeta pallida* was not the essential virus of syphilis, and now they were told it was a spermatozoon. The fact that the same organism was found in earth-worms suggested to his mind that the origin of the syphilitic virus was Mother Earth. Moreover, the fact that the male organ in some of the African tribes was much longer and more pendulous than in Europeans, and that these tribes spent much of their time squatting on the earth, might explain the contamination of the mucous membrane from the soil. The following were among the exhibits at the meeting:—The PRESIDENT: A woman, aged 35, who had had a peculiar lesion on the bridge of her nose for some two years, which he was inclined to consider was a *Rhinoscleroma*. Dr. SIBLEY: A case of *Lupus* in the inner canthus of the right eye in a man, aged 28, who had had it for four years; he had treated it with one application of carbon dioxide snow for two minutes, and had obtained a very good result. Dr. J. L. BUNCH: A girl, 17 years of age, with an obvious *Dermatitis artefacta* lesion on the leg. Dr. GRIFFITH: A case of *Mycosis fungoides* in an old man.

THE estate of the late Dr. Campbell Boyd, recently president of the Chelsea Clinical Society and honorary secretary of the Irish Medical Schools' and Graduates' Association, has been sworn at the gross value of £14,637, the net personalty being £12,867.

At a meeting of the British Oto-Laryngological Society held at the rooms of the Medical Society of London on April 3rd, it was decided that the society should have no president, but that a chairman should be elected at each meeting. The following gentlemen were appointed members of council:—Metropolitan: Dr. Fred. Spicer, Mr. Chas. Heath, Dr. Coubro Potter, Dr. L. Hemington Pegler. Provincial: Mr. Geo. Jackson (Plymouth), Dr. Barclay Baron (Bristol), Dr. Livingstone (Newcastle), Dr. Gogarty (Dublin), Dr. Walton Browne (Belfast), Dr. James Harper (Glasgow), Dr. Potts (Maidstone), Mr. Adair Dightou (Liverpool), Dr. Haring (Manchester), Dr. Little (Bristol), Dr. Percy Jakius was elected honorary treasurer, and Dr. Walker Wood, 30, Canfield Gardens, N.W., honorary secretary.

Reviews.

DUBLIN REMINISCENCES.

SIR CHARLES CAMERON, C.B., in his recently published *Reminiscences*,¹ has given his readers a number of incidents in the history of Dublin during the last sixty years, interesting both from a medical and social point of view. At the age of 14 the author appears to have been threatened with consumption, as he had a prolonged cold with a severe cough and occasional hæmoptysis; he was therefore sent to Guernsey, where he spent nearly two years, and completely recovered his health and strength. From an early age he took a great interest in chemistry, and in 1852, when the Dublin Chemical Society was established, he was unanimously elected its Professor of Chemistry; he was then 22 years old and a medical student. He gives an amusing account of his first lecture; he began at 8 p.m. to an audience of about 70; he used no notes, but continued talking and making experiments till a card was quietly passed up with the words written on it, "Do you know it is past 10 o'clock?" In 1856 he became professor of chemistry and natural philosophy in the Dublin School of Medicine, and two years later chemical lecturer in the original School of Medicine, subsequently renamed the Ledwich School of Medicine. In 1862 he was appointed public analyst; he was the third person appointed to such an office, and is now the senior holder of it in the United Kingdom. In 1868 he became professor of chemistry and hygiene at the Royal College of Surgeons, and has been medical officer of health for Dublin for thirty-two years.

In some recollections of meetings with various famous actors and actresses, he describes how he was invited by Miss Olga Nethersole to a supper at the Shelbourne Hotel, and when asked by her if there was any dish he would particularly like, he said that if he was at home he would have a bowl of bread and milk. Miss Nethersole said that was exactly the kind of supper she usually had; so they each had their bowl of bread and milk, while the rest of the party had an elaborate champagne supper. An amusing story is told of Dr. Evory Kennedy, at one time Master of the Rotunda Hospital. In his early days a gentleman called to engage Kennedy's services for his wife, and inquired the fee. Dr. Kennedy said "ten guineas"; the gentleman observed, "I suppose that is ten pounds?" but the doctor repeated, "ten guineas." In due time the doctor was sent for, performed the required services, and, being winter, took up a position in front of the fire. The gentleman appeared and said, "Your fee is ten pounds, doctor?" "Oh, no; ten guineas, as I have already told you." The gentleman left the room, and on returning paid the doctor his fee. Dr. Kennedy took it, and putting his hands behind his back felt only ten coins wrapped in paper; he slipped the coins in his pocket and threw the paper in the fire. What was his disgust when he got home to find that the coins were shillings, and that they had been wrapped up in a £10 banknote which he had burnt.

For eleven years Sir Charles acted as expert for the Government in cases in which bloodstains had to be examined and human viscera analysed for the detection of crime. He tells some stories of cases of unusual interest, and describes how in one case he had to attend the court in the country every day for months and calculates that during the trial of this one case he travelled altogether 6,144 miles by train.

To Sir Charles Cameron is largely due the foundation in 1897 and subsequent success of the Corinthian Club in Dublin, which resembles the Savage Club in London. There are few men probably who have had a larger experience of public dinners and greater practice in speaking at them, and he tells us that sixty years' experience of dinner parties enables him to state that cases of inebriety at them are becoming rarer and rarer. The book ends with an account of how the Dublin poor live; of this he shows an intimate knowledge, gained during the thirty-two years that he has been chief health officer of Dublin. According to the census of 1911, 33.9 per cent.

of the total families live in a single room. He gives instances of family incomes of 10s. a week and even less. He says a man's desire for matrimony appears to be inversely proportionate to his means for maintaining a family, and quotes a humorist who said that half the population of Dublin are clothed in the cast-off clothes of the other half.

The book is interesting, but it might have been easier to read had it been written in a more consecutive style.

DIABETES.

It is the claim of the general editors of the series of International Medical Monographs that the books which appear under their auspices are not merely compilations but real contributions to medical science written by first hand authorities engaged in extending the confines of our knowledge. In the volume, *Diabetes, its Pathological Physiology*,² by Professor J. J. R. MACLEOD, this claim is amply justified, for the value of his original work is well known. It contains the subject matter of eight lectures delivered during the summer of 1912 in the Physiological Laboratory of the University of London, and the researches of the author and his collaborators form its basis. Often, indeed, such investigations cannot be directly applicable to the work of the practitioner, but they are the foundation of his progress, and although in the pathological physiology of diabetes the amount of research has been enormously disproportionate to the results which have accrued either to our knowledge of the disease or our means of treating it, yet there can be no doubt that in both these respects our grasp of the subject is deeper and wider in consequence of the work of the last thirty years. The special difficulty of the subject is well illustrated by the career of the late Dr. Pavy, who devoted himself with extraordinary persistency and great ability for fifty years to the elucidation of these questions, and yet could not claim to have arrived at more than provisional answers to any of them. The work of the laboratory, however illuminating, must, as Professor Macleod says, be supplemented by observations at the bedside; therefore it is most desirable that those who are interested in diabetes should make themselves acquainted with the work done by such physiologists as Professor Macleod and his co-workers. The recognition of minute traces of sugar in the urine is complicated by the presence of other reducing substances, such as creatinin and uric acid. Benedict's modification of the cupric-sulphate test and Hammersten's modification of Nylander's bismuth test are most serviceable; these two tests should be used in doubtful cases, and the urine fermented with yeast and the test repeated. If the detection of traces of sugar in the urine is difficult, its estimation in the blood presents obstacles even greater, because it is necessary first to remove the proteins, and in doing this much of the sugar goes too. However, these technical difficulties are now overcome by the method of precipitating with dialyzed iron (Rona and Michaelis) and extracting the precipitate with water. It is now believed that the effect of Claude Bernard's puncture is not directly on the liver, for it may be prevented by poisoning the sympathetic ganglia with nicotine or by removal of the adrenal glands; the conclusion is that glycogenesis is stimulated by excess of adrenalin and also by direct nervous impulses. That the pancreas forms a hormone which acts upon the liver is probable but not finally settled, nor is it known definitely what relation the islands of Langerhans bear to this secretion, although it seems clear that it is not solely derived from these structures. Removal of the pancreas affects the glycogenic power of the liver by first upsetting its glycolytic function, and this effect is not solely due to the unrestrained action of the adrenals. Professor Macleod believes that *post-mortem* glycogenesis is identical with that which occurs during life and that the increase is not due to an increase of ferment, but to changes in the environment in which the ferment acts. He discusses at some length the effects of different conditions such as the action of acids and alkalis, asphyxia, hæmorrhage and

¹ *Reminiscences of Sir Charles Cameron, C.B.* Illustrated. Dublin: Hodges, Figgis and Co., Ltd.; London: Simpkin, Marshall and Co. 1913. (Demy 8vo, pp. 181. 5s. 6d. net.)

² *Diabetes, its Pathological Physiology.* By John J. R. Macleod, M.B., Ch.B., D.P.H. International Medical Monographs. London: Edward Arnold; New York: Longmans, Green and Co. 1913. (Demy 8vo, pp. 234, figs. 5. 10s. 6d. net.)

muscular exercise. On page 198 he blames the practice of insurance companies of refusing all applicants whose urine reduces Fehling's solution, yet on page 3 he appears to admit that such a person may be "a latent case of diabetes." We cannot speak for all insurance companies, but so far as we know if the urine reduces Fehling's solution, but there are no indications of diabetes, the case is reserved for further examination, and not rejected forthwith. We have only touched on a few of the points of interest, but hope that we have said enough to stimulate readers to go to the book itself.

Professor VON NOORDEN's lectures on *New Aspects of Diabetes*³ were delivered in the New York Post-graduate Medical School last October. The first three were devoted to a restatement of the pathogenesis of diabetes in the light of recent researches. The fourth is devoted to treatment, and contains little that Professor von Noorden has not told us before; but those who are not acquainted with his methods will find in it a detailed description. In addition to the four lectures there is a supplementary chapter on acetonuria, especially in its relation to the dietetic treatment of diabetes. He regards as the most important disturbance of metabolism in diabetes the inability of the hepatic cell to fix carbohydrates; this inability varies in different persons, and is often in the same case not constantly maintained at the same level. The inability is probably due not to a want of power to form glycogen, but to a tendency to decompose the just formed glycogen too rapidly. The sugar derived from albumen is formed, he thinks, during gastric digestion, but is absorbed and carried to the liver, where it acts like any other carbohydrate; he explains the comparative harmlessness of protein diet in diabetes by the time required for the digestion of the albumen, so that it reaches the liver gradually, but he sees reason to believe that there is a difference hitherto unexplained in the action of various proteins, that derived from muscle having a much greater exciting action on the liver than that derived from eggs or vegetables. For this reason he finds the commercial product "Glidine" of use in treatment of diabetes. Further, the flesh of fish, especially of large fish, induces a smaller output of sugar than the flesh of other animals. He believes the liver possesses the power of forming sugar from fat, and that not only the fat of the food but the deposits of fat in the tissues are drawn to the liver for this purpose. He does not believe that the formation of sugar from fat involves a stage of glycogen formation, for in animals fed upon fat no glycogen is found in the liver. He thinks that muscle has not the power of utilizing fat, but that fat must be first converted into sugar; he admits, however, that this doctrine is not yet established. He holds that the thyroid gland is the great promoter of oxidation in the body, but that under normal circumstances the pancreas exercises a restraining effect upon it; when, as in pancreatic diabetes, the function of the pancreas is diminished or destroyed the thyroid action is unrestrained. The liver is the seat of sugar formation, and is what he calls the "sugar factory," but it is only in severe and extensive disease of the liver substance that the formation of sugar is seriously disturbed. On the other hand, the sugar-forming function of the liver is easily stimulated. He holds that the pancreas in health exercises an inhibitory action upon the liver and favours the storage of glycogen; in pancreatic disease carbohydrate storage diminishes or ceases; the suprarenal bodies and the chromaffin system generally stimulate the production of sugar. A large dose of adrenalin causes the rapid disappearance of glycogen from the liver and produces glycosuria which may last for some hours, acting, in fact, precisely in the same way as Claude Bernard's diabetic puncture, for it is by its stimulating effect upon the adrenals that this experiment produces its well-known effect. Von Noorden does not consider that there is such a thing as a true non-genous diabetes, the influence of the nervous system being confined to causing temporary glycosuria or aggravating an existing diabetes. Acetonuria, he thinks, is

normally prevented by the special carbohydrate metabolism in the liver, and that in the absence of glycogen in the liver cells the formation of acetone bodies is favoured. As those kinds of diet which at first lead to acetonuria after a time cease to do so, and it is known that many animals, even man under certain conditions, live perfectly well on a diet of protein and fat without acetonuria resulting, he suggests that a state of tolerance may be created so that when the conditions have lasted for some time less acetone is formed. He uses this as an argument in favour of persevering with a strict diet in suitable cases of diabetes, in spite of moderate acetonuria at first. If we may summarize von Noorden's principles of treatment, they are the individualizing of the case, the recognition that excess of protein may do almost as much harm as excess of carbohydrate, and the desirability of interposing days of fasting or of a diet of vegetables and eggs in the treatment of all cases. He aims at the complete removal of sugar from the urine, and claims that this is not so difficult as is sometimes supposed. It is a pity that these lectures have not been more carefully edited, so as to remove awkward and obscure expressions which are perhaps due to the shorthand reporter, perhaps to the lecturer endeavouring to express himself in a foreign language. We find, on p. 40, "hyperplasia" for "hypoplasia"; pp. 71-2, "assured" should be "assumed"; on p. 73 we are told that the lectures have been published "shortly," meaning "recently," and "editor" is used where the English word is "publisher." We commend these lectures to our readers, and congratulate the New York Post-graduate Medical School on having arranged so interesting a course for its members.

HAEMATOLOGY.

DR. ARTHUR PAPPENHEIM has at last given to the profession a condensation of the bulky contributions which he has made to the subject of haematology.⁴ Those of us who have followed much of what he has written have had to qualify appreciation with a very real desire that he would for once omit from his publications those frequent "asides" which render his writings severe mental gymnastics. It is always difficult to ascertain wherein he differs from other teachers. The perusal of the fifty odd pages of the book he has addressed to students and practitioners gives just that clarification which is needed.

The reader need fear no wide excursions into the domains of the physics and chemistry of the blood, but will find a clear account of those most cardinal examinations of the blood which have a real application at the bedside—the staining of blood films, the counting of the red and white corpuscles, and the estimation of the amount of haemoglobin. Side by side with the descriptions of what Dr. Pappenheim considers the one and only perfect method, the methods are given by which the blood changes met with in various clinical states may be correctly read. Generally we do not find much variation in his "constants" from those of other writers, and the object of the reviewer should be to point out wherein lies the special claim for the appreciation of this particular presentation of the subject. It will be found in the accounts given of the normal and pathological morphology of the leucocytes. In health the mononuclear lymphoid agranulocytes are composed of small lymphocytes and large monocytes; the polymorphonuclear true granular leucocytes include neutrophile leucocytes, eosinophile leucocytes and mast cells. In disease "young" forms and "degenerated" forms of leucocytes occur, the former yielding subgroups according as they conform to agranulocytes or granulocytes, the latter the so-called "stimulation," or plasma cells. The reader will find the distinctions between all these types well set out in the letterpress, and should he desire some pictorial presentation of their distinctions we would recommend as almost necessary an appeal to the excellent atlas (BRITISH MEDICAL JOURNAL, October 13th, 1906, p. 955; *ibid.*, August 13th, 1910, p. 378) by the same author, reference to which has already been made in reviews in this JOURNAL.

³ *New Aspects of Diabetes: Pathology and Treatment*. By Professor Dr. Carl von Noorden. Lectures delivered at the New York Post-graduate Medical School, Bristol; John Wright and Sons, Ltd.: London; Simpkin, Marshall, Hamilton, Kent and Co., Ltd. 1912. (Demy 8vo, pp. 160. 6s. net.)

⁴ *Technik der klinischen Blutuntersuchung für Studierende und Aerzte*. By A. Pappenheim. Berlin: Julius Springer, 1911. (Demy 8vo, pp. 55. Mk. 2.)

Two quotations from the introduction of Dr. SCHILLING-TERGAU'S book⁵ will give the reader an idea of what is to follow: "Apart from etiological factors (as malaria and other parasites) or a small number of exceptional diseases (leukaemia), an absolute determination of various diseases by means of the blood picture is impossible"; such a sentence shows breadth of view. "It should be the rule in every case of internal disorder to examine at least one blood preparation; by not carrying out a permanent blood control in suitable and doubtful cases we commit a scientific mistake." This speaks for thorough-going routine work which will not leave to chance the detection of the true state of affairs. The first part of the book, comprising twenty-two pages, is devoted to a very condensed account of the technique of blood examination, and closes with a model chart which will facilitate blood counts, and with a scheme of relationship between blood formation and blood pictures. In the fifty odd pages of the second part will be found a very concise account of the morphology of red and white corpuscles, of "stimulation" forms, and of "degeneration" forms of each variety of blood cell. Then follows, with a certain feeling of relief to the clinician, the third section, giving an interpretation of various blood pictures. The volume closes with short notes on the protozoa of the blood and a scheme for the full examination of the blood. The plates are excellent, and the second, especially, is useful because of its schematic representation of cells as they appear in the blood-forming organs, and as they appear in the blood.

FETAL MALFORMATIONS.

MALFORMATIONS of the fetus are of interest to a greater or less extent to most medical men, and we can thoroughly recommend to those who have not had an opportunity of reading it in the original, the English translation of Professor BIRNBAUM'S *Clinical Manual of the Malformations and Congenital Diseases of the Fetus*,⁶ which has been recently completed by Dr. G. Blacker.

The practical interest of many malformations is primarily obstetrical, and the subject is dealt with mainly from an obstetric point of view; at the same time there is a great deal of information that must be of value to those who are engaged in other branches of surgery. There is nothing strikingly original about the work, but the author claims for it, and the claim is, we think, quite justified, that it is a genuine attempt to present within a reasonable scope the main facts gathered and condensed from the general literature of this subject. The result is a volume that has, as far as we are aware, no rival in the English language. The value of the work, especially from a student's point of view, has been enhanced by some careful explanatory notes added by the translator, and although these have considerably increased the size of the work their merit quite justifies their inclusion.

After briefly dealing with the theories as to the causation of malformations from a general point of view, the author proceeds on an anatomical basis to describe in sequence the deformities associated with the various regions of the body, and in each chapter the clinical aspect receives an appropriate consideration, and an outline of a suitable obstetric treatment is given. The discussion of each subject is concluded by a record of its literature and every opinion is duly recorded. Obstetrical injuries to the skull, besides forming a favourite topic for an inquisitive examiner, have a definite practical importance, and the chapter devoted to their consideration is full of valuable material.

Double monsters are, of course, clinical rarities, but they possess a very definite interest for the obstetrician, and the failure to diagnose the condition may be attended with the most serious results to the mother. The section assigned to their consideration is of a high order of merit, and the difficulties to be contended with in the

diagnosis and treatment are carefully and lucidly dealt with. A classification that will satisfy all demands is not easy, and several are submitted for consideration. This chapter should certainly be read carefully by all students of gynaecology.

The book is completed by an all too brief dissertation on the legal rights of monsters. In future editions of the work we should very much like to see this particular subject dealt with at greater length.

The illustrations are excellent and are mainly from the Göttingen Clinic, which would seem to be particularly well equipped with this type of specimen. The translation of this laborious work has been in excellent hands, and English obstetricians should be greatly indebted to Dr. Blacker for a very valuable addition to their literature.

NEUROLOGY.

THE handbook by BRUNS, CRAMER, and ZIEHLEN on diseases of the nervous system in infancy⁷ (not including psychoses) will be fully appreciated by neurologists and be welcomed by paediatrists. The authors have so arranged it that Cramer treats of the functional derangements, such as nervousness, hysteria, epilepsy, etc.; Bruns of the affections of the spinal cord and the peripheral nerves, including polymyositis, myositis ossificans multiplex progressiva, etc.; and Ziehlen of those of the brain and the meninges. Practically the book is a series of monographs. Each of the contributors has acquitted himself of his task in a manner worthy of his established reputation. It is no disparagement to the book to say that it contains nothing original, nothing that calls for special discussion, nothing that rouses controversy. What, however, may truly be added is that it gives an excellent account of facts and theories that ought to be known to those for whom it is more immediately intended, and that it is written with consummate skill partly from a rich personal experience, partly from an intimate acquaintance with the literature. The subject is introduced by a reminder of the differences in the anatomy and physiology of the young and growing and the fully developed organisms, in order to explain the differences in the clinical manifestations of disease at an early and a later period of life. The authors confirm the fact that most nervous affections of infancy are entirely or mainly of endogenous origin; and Cramer rightly insists on the great responsibility which parents and teachers incur by misguided dealings with children of neuropathic disposition. An otherwise arid description of the symptoms is relieved by illustrative cases as well as by photographs of the characteristic features which the various forms of the disease impress upon the patients. There are also illustrations of the macroscopic and microscopic appearances of the lesions, where such exist, of the parts chiefly affected. Diagnosis is fully discussed, and the various methods of examination which help to right conclusions are explicitly stated. The treatment which each author recommends is eminently practical and based partly upon his own experience, partly upon the critical examination of the writings of other trustworthy observers. Cramer reports cases of functional derangements which show what an accomplished physician can effect by judicious management, provided he meets with the willing co-operation of the parents. Bruns and Ziehlen, who deal with organic diseases, set out without prejudice the indications and contraindications for operative interference. Each chapter is also furnished with an exhaustive list of the literature, which will be very useful to future inquirers. The book deserves, and will, we hope, obtain, a wide circulation, not merely amongst specialists but also amongst general practitioners, under whose notice the nervous affections of children always come in the first instance. If our earnest hope in that respect should not be fulfilled, it will probably be because its bulk will prove somewhat deterrent to the busy physician. We cannot refrain, however, from stating that there is a redundancy of newly coined technical terms such as tachyochæmorrhysis, bradyochæmorrhysis, pleonaemia, pleocythaemia, etc., which seem to possess no advantage over others equally expressive and more generally familiar.

⁷ *Handbuch der Nervenkrankheiten im Kindesalter*. Von Professor E. Bruns, Professor A. Cramer, and Professor Th. Ziehlen. Berlin: S. Karger. 1912. (Sup. roy. 8vo, pp. 992, Abbn. 189, Tfd. 3. Mk. 30.)

⁵ *Das Blutbild und seine klinische Verwertung*, etc. (The Blood Picture and its Clinical Significance Including References to Tropical Diseases). Concise, technical, theoretical, and practical instruction in microscopic blood examination. Von Dr. V. Schilling-Tergau, Oberarzt, Kommandiert am Institut für Schiffs- und Tropenkrankheiten in Hamburg. Jena: Gustav Fischer. 1912. (Med. 8vo, pp. 100; 3 lithographic plates and 11 illustrations. Mk. 4.50.)

⁶ *A Clinical Manual of the Malformations and Congenital Diseases of the Fetus*. By Professor Dr. R. Birnbaum. Translated and annotated by G. Blacker, M.D., B.S., F.R.C.P., F.R.C.S. London: J. and A. Churchill. 1912. (Roy. 8vo, pp. 394; figs. 58; plates 8. 15s net.)

The monograph on the functions of the cerebellum written by Dr. ANDRÉ-THOMAS of Paris a few years ago has been translated by Dr. W. C. HERRING of New York, and the work has been well done. Since 1895 André-Thomas has published a long series of clinical and experimental works upon the functions of the cerebellum, and the lucidity and thoroughness with which he discusses this very complex problem leave nothing to be desired. In the translation, which has the title *Cerebellar Functions*,⁸ the first 53 pages are given to the anatomy and histology of the cerebellum; then follow 47 pages on the results of experimental lesions of its structure, and 30 pages on the symptomatology of its various morbid affections. Then follow 75 pages dealing with the interpretation of the facts given in the preceding part of the book, and discussing the connexions between the cerebellum and the organic functions, sensibility, intelligence, and motility. The whole subject is notoriously complicated. Perusal of this volume leaves the impression that the results of destruction of the cerebellum are fairly well understood; disturbances of motility follow, particularly disturbances in the association of movements—the movements become ill-measured, discontinuous, and the tonic maintenance of equilibrium is lost. The cerebellar hemispheres act mainly each on its own side of the body; when one of them is destroyed its functions are in part taken on by the cerebral hemisphere and labyrinth of the opposite side, but with the characters of regularity, precision, tonicity, and ready equilibration replaced by irregularity, clonicity, and instability, as a result of the substitution of cerebral for cerebellar regulation of the movements. The book gives a clear and sound account of present knowledge of the subject.

NOTES ON BOOKS.

THE edition of *The Medical Annual*⁹ for 1913, both in its arrangement of matter and in its style, conforms very faithfully to the model of its thirty predecessors, and its anonymous editor has once more managed to provide himself with a good staff of writers. For the most part these all bear names familiar to the medical public in connexion with one or other departments of medicine or surgery, and many of them are old contributors to this particular publication. The result is a volume which, written succinctly throughout, supplies an excellent summary of the progress of medical science during the previous year, together with a vast amount of information on most subjects connected with the practice of medicine. A perusal of one or two sections suggests that to a person with special knowledge of the subjects concerned it may sometimes seem that points have been overlooked, but there is no doubt that taken as a whole this book will fulfil the needs of general practitioners as amply as its predecessors. This year is supplied a short glossary of new terms which it is intended to extend year by year. Most of those in the present list relate to bacteriology, and are self-explanatory to persons conversant with this science; to others they must convey comparatively little information, even when their meaning is explained in dictionary form.

The latest issue of the *Transactions of the American Laryngological Association*¹⁰ relates to the proceedings of that body at its thirty-fourth annual meeting, and contains some twenty-six papers, which, for the most part, cover fairly well trodden ground. The chief exception perhaps is one in which Dr. Clarence C. Rice asks, "When should singers having vocal disability be allowed to resume work?" The obvious answer would appear to be, "When the vocal disability has disappeared, or in other words, when they can sing. This, too, would seem to be commonly the right answer, since the facts recorded in the paper or mentioned by subsequent speakers indicate that it is often exceedingly difficult to determine by an examination of the throat, even when supplemented by a voice trial, whether a given singer will get through an evening's work successfully and without subsequent harm. Some vocalists can sing to the perfect satisfaction of an

audience and harmlessly to themselves when their throats are inflamed, and in no case, it is suggested, can a sound opinion be given except by a laryngologist who takes into consideration the personality of the singer as well as the state of his throat.

The favourable opinion which we formed of the *Handbook of Practical Hygiene*¹¹ when it was issued in 1909 has not been lessened by a perusal of the second edition. Lieutenant-Colonel BEVERIDGE and Major WASHILL have revised the volume in many particulars, have introduced descriptions of improved methods of analysis, and have added to the chapters on sewage and the analysis of foods much new matter, so that the student and public health officers may be certain of finding the most recent views upon these subjects. In the chapter on foods there is an account of the methods to be adopted in the examination of preserves and of ice cream, and the methods of examining other articles has been elaborated. An entirely new chapter on chemical disinfectants adds much to the value of the volume, for it includes several pages devoted to a description of the most recent processes adopted in the standardization of disinfectants. Apart from the question of standardization, the authors consider that a disinfectant should be non-poisonous when diluted to its working strength, and should, if for general use, not resemble any potable liquid in appearance or smell, that it should not attack metal or glass, and should not destroy or stain linen, etc. If intended to be used for the disinfection of the skin, it should not be irritating, and should not be absorbed to any appreciable extent from abrasions or wounds. If emulsified in working dilutions, it should not separate out to any appreciable extent in twenty-four hours in a long cylinder such as a mixing jar.

Any one interested in the fascinating group of plant organisms—the liverworts—will welcome Sir EDWARD FRY'S little book, or "small essay," as the author would doubtless call it, on *The Liverworts, British and Foreign*.¹² It is a companion volume to that on British mosses by the same author, a second edition of which appeared in 1908. The liverworts are of more than ordinary interest from an evolutionary point of view, since they appear to be transitional forms between the algae and the true mosses. Moreover their great heterogeneity is in itself attractive, for, as the author says, they "present to one's mind the idea of a crowd of organisms which have not made up their minds in which line they shall go, and which are trying experiments in all directions to see which is best for them to take." Well written and easily understandable, it is not a mere popular account of the group but a serious contribution. To any one in search of a hobby we can thoroughly recommend the liverworts, and we can recommend this book to commence with, a very elementary previous knowledge of botany being required. The production of a book of this character and of its forerunner by one who has led such an active and busy life is in itself a fact of which the author may be proud; it is evidently a hobby which has become a "labour of love." A word of congratulation is also due to his daughter, Miss Agnes Fry, for the illustrations, and to her active co-operation the author bears testimony.

Among the papers contained in the latest issue of the *Transactions of the American Climatological Association*¹³ tuberculosis bulks less largely than on some previous occasions. Several papers deal with pure climatological questions, notable among them being the address of the president, Dr. A. D. Blackader, on the advantages of residence in a cold, dry climate in the treatment of some forms of disease. Dr. J. M. Anders puts in a plea for inclusion of the subject of climatology in the curriculum of medical students in America, and Dr. H. L. Barnes deals with the occurrence of pneumonia in open-air sanatoriums. In a paper on tuberculosis dispensaries Dr. Cleave Floyd concludes that their work cannot be measured in terms of "cases cured," their usefulness being almost entirely along the lines of diagnosis, isolation, and prevention.

⁸ *Cerebellar Functions*. By Dr. André-Thomas. Translated by W. Conyers Herring, M.D., N.Y. Nervous and Mental Disease Monograph Series, No. 12. New York: The Journal of Nervous and Mental Disease Publishing Company, 1912. (Roy. 8vo, pp. 225. Price \$3 00.)

⁹ *The Medical Annual*. Thirty-first Year, 1913. Bristol: John Wright and Sons, Limited, (Demy 8vo, pp. 702. Price 8s. 6d. net.)

¹⁰ *The Transactions of the American Laryngological Association*. New York: Published by the Association, 1912. (Med. 8vo, pp. 358.)

¹¹ *The Sanitary Officer's Handbook of Practical Hygiene*. By W. W. O. Beveridge, D.S.O., Lieutenant-Colonel R.A.M.C., and C. F. Washill, Major R.A.M.C. Second edition. London: Edward Arnold, 1912. (Cr. 8vo, pp. 244, interleaved with blank pages for notes, 6s. net.)

¹² *The Liverworts, British and Foreign*. By the Right Hon. Sir Edward Fry, G.C.B., and Agnes Fry. London: Witherby and Co. 1911. (Cr. 8vo, pp. 82. 2s. 6d.)

¹³ *Transactions of the American Climatological Association*. For the year 1912. Vol. xxviii. Philadelphia: Printed for the Association, 1912. (Med. 8vo, pp. 380.)

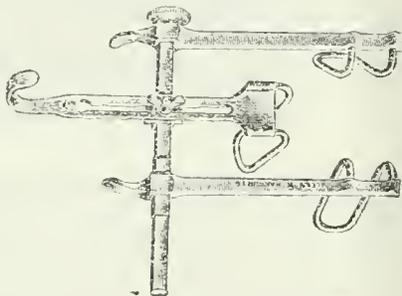

The somewhat belated issue of the *Proceedings of the Canal Zone Medical Association*¹⁴ for the half-year ending September, 1911, contains some twenty-two papers. About ten belong to the field of tropical medicine, while the rest are of a miscellaneous order. Among the former is an excellent summary of existing knowledge on the subject of oriental sore by Dr. S. T. Darling. It would appear that only four cases in which diagnosis has been confirmed by microscopic examination have so far been recorded in the new world. A case was reported in Brazil, however, as early as 1895, and there is ground for believing that in the tropical regions of America it is a commoner condition than has hitherto been recognized.

¹⁴ *Proceedings of the Canal Zone Medical Association*. For the half-year April to September, 1911. Vol. iv part 1. L.C.C. Press: Quartermaster's Department, Mount Hope, Canal Zone. (Med. 8vo, pp. 258.)

MEDICAL AND SURGICAL APPLIANCES.

An Abdominal Retractor.

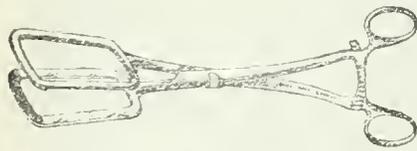

DR. LAURENCE C. PANTING, of Truro, has designed a retractor consisting of the well-known Gossett Retractor with the addition of a third blade, which, while securing retraction of the lower part of the wound when pulled upon by a piece of stout silk or rubber tubing, has the additional advantage of fixing the instrument firmly. This third blade can by slightly relaxing the screw shown in the illustration be moved backwards or forwards, or completely removed, while by tightening the screw it is firmly fixed in any desired position by bringing into apposition two corrugated surfaces. Lateral movement

is not restrained, but the blade naturally tends to assume a position midway between the other two blades. Dr. Panting, who has had the instrument in frequent use for the last eighteen months, finds that it has entirely fulfilled his expectations. It has been made by Messrs. Allen and Hanburys.

A Vaginal Clamp for Wertheim's Hysterectomy.

Mr. J. BASIL HALL, F.R.C.S. (Bradford), writes: The accompanying illustration shows a clamp for the vagina in cases of Wertheim's hysterectomy which Messrs. Down Bros. have made for me. If any excuse is necessary for the introduction of such an instrument, it may be found in the fact that on a recent visit to London Mr. Down showed me some half-dozen experimental designs of instruments intended for that purpose. Moreover, every operator whom I have consulted has confessed that he has found much difficulty in the universal application of any of the clamps at present in use. My own personal experience of these instruments has been most unsatisfactory. The application of the clamp I have designed is very simple. When the uterus is isolated from all its attachments and the vagina is freely exposed, the jaws of the clamp are opened and passed over the fundus uteri. The uterus is

then slipped through the fenestration of one of the jaws (preferably the anterior) and the clamp is pushed down until the transverse limbs of the jaws lie across the upper end of the vagina, when the clamp is closed. All septic discharge is thereby shut off from the operation field, and at the same time the instrument can be used as an efficient tractor, and slipping is impossible. The width of the jaws at the widest point is 3 in., which allows plenty of room for any manipulations in the pelvis. The instrument can be used for any case except one in which a large fibroid coexists with malignant disease, when the fibroid must first be enucleated. I have only used this instrument twice, but it acted admirably on both occasions. Dr. Oldfield of Leeds has also used it twice, and speaks most favourably of it. I am confident that it will prove of great value in the successful accomplishment of the operation for which it was designed.

THE LISTER MEMORIAL FUND.

In addition to the committees which have been formed by the Universities of Oxford, Cambridge, and Durham in support of the Lister Memorial Fund, other universities are taking steps to promote the success of the memorial, and arrangements have been made for the formation of committees in the British Dominions beyond the seas and in foreign countries.

The proposal is that the memorial shall be of a three-fold character, and consist of (1) a simple marble medallion bearing a sculptured portrait of Lord Lister to be placed in Westminster Abbey among the monuments of the nation's illustrious dead; (2) a larger and more conspicuous monument to be erected in some public place in London; and (3) the founding of an International Memorial Fund, from which either grants in aid of researches bearing on surgery or rewards in recognition of important contributions to surgical science will be made, irrespective of nationality. A considerable sum of money is required to carry out these proposals. Donations should be sent to the Treasurers of the Lister Memorial Fund at the Royal Society, Burlington House, London, W.

Among the subscriptions recently received are the following: Clothworkers' Company £100, Grocers' Company £52 10s., Ironmongers' Company £25, Mercers' Company £105, Merchant Tailors' Company £262 10s., Skippers' Company £105, Society of Apothecaries £52 10s., Corporation of the City of Glasgow £52 10s., Royal College of Physicians £21, Royal College of Surgeons £52 10s., Royal Dublin Society £50, Royal Horticultural Society £52 10s., the Royal Society £50, Pharmaceutical Society £10 10s., Physiological Society £10 10s., Royal Microscopical Society £5 5s., Royal Sanitary Institute £5 5s., the Manchester Co-operative Wholesale Society £21.

The following medical societies have subscribed the amounts stated:

Lord Strathcona has sent a donation of £100, and Professor Ehrlich, of Frankfort, a donation of 500 marks.

MEDICAL SICKNESS, ANNUITY, AND LIFE ASSURANCE SOCIETY.

THE thirtieth annual meeting of this society was held at the rooms of the Medical Society of London on April 3rd, under the presidency of Dr. F. J. ALLAN, Chairman of the Executive Committee.

CHAIRMAN'S ADDRESS.

THE CHAIRMAN congratulated the members on another year of successful work. During the year the society had received 179 new proposals, 81 proposals for additional sickness benefit, and now numbered 3,112 members, a net increase of 74. In 1912 the society had paid away in sickness and accident benefit £17,339; the margin between that sum and the amount received for premiums was comparatively small. In the earlier days of the society, when most of the members were under 30 years of age, the amount of sickness experienced was naturally not so great as must be experienced when the members reached a more advanced age. From statistics prepared by Mr. Addiscott showing the amount of sickness experienced in

periods of five years it was seen that during the past five years the amount had very nearly reached the expected amount of sickness allowed for in the tables. He thought the society was nearing a time when the sickness expenditure might be fairly regular, but he considered it probable that it would be somewhat higher than it was at the present time in proportion to the premiums. In one of the last five years the sickness experienced had exceeded the expectations by 6 per cent. The society gave members greater value for their money than any other company could offer them. On looking through the prospectuses of a number of companies doing similar work he found that the sickness benefit ceased at 60 years of age instead of 65, and that the sick pay was for twenty-six weeks, instead of during the full period of incapacity, as provided by the society, and further that the contracts of the companies were terminable at the end of any year if the company desired it, whereas the contracts with the society could not be annulled so long as the member complied with the rules. Another point was that the premiums were not so moderate as those of the society. The society did not discard a man who became permanently ill, as was shown by the fact that there were at present not less than 49 chronic cases receiving very nearly £4,000 a year; 6 had been drawing sick pay for twelve years. In some instances the sick pay received by members was the sole source of income. Owing to the depreciation in stocks, the committee had thought it advisable to write down the securities by £6,830, thus bringing them to the market price at the close of the year; it was hoped, however, that the low price of stocks would not always continue. One of the reasons why the society could afford to offer the advantages it did at such low rates was that there were no shareholders for whom a profit had to be earned; another reason was that the management expenses were extremely low, as the committee, the treasurers, and trustees gave their services without remuneration. He regretted to inform the members that they were about to lose Dr. G. E. Herman and Dr. F. S. Palmer, who had acted as treasurers of the society for a considerable time; they had both been very zealous in carrying out their duties and in many other ways had been of very great assistance to the society. Certain changes in the staff had taken place during the past year. Mr. Addiscott had retired from the position of secretary, and had been succeeded by Mr. Sutton; the committee, however, had been able to retain Mr. Addiscott's services as actuary. It appeared that some members were under the impression that a bonus was paid every five years, but he desired to state clearly that no such promise was ever made by the society. On some occasions bonuses had been paid; at the present time members reaching the age of 65 were granted bonuses, and in the case of members dying before the age limit the bonus was paid to the relative, but the society gave no guarantee that this state of affairs would continue. He hoped the members would bring the advantages offered by the society to the notice of their friends.

Dr. VINRACE said he had hoped that by some arrangement the society would have been able to continue to pay benefits to members as long as they lived, and not leave off at 65 as at present.

After answering certain other questions in connexion with the report the CHAIRMAN moved:

That the report of the Committee and the audited accounts for the twelve months ending December 31st, 1912, be received.

The motion having been seconded by Dr. PICKETT was carried.

Election of Officers.

The list of officers for the ensuing year submitted to the meeting by the Committee was approved.

Votes of Thanks.

On the motion of Dr. BRINDLEY JAMES, seconded by Dr. DE HAVILLAND HALL, a vote of thanks was accorded to Dr. Herman and Dr. Palmer for the services they had rendered to the society.

The CHAIRMAN proposed a vote of thanks to the BRITISH MEDICAL JOURNAL, the *Lancet* and the *Medical Press* and

Circular, for publishing reports of the proceedings of the society, which was carried.

Dr. VINRACE proposed, and Dr. BRINDLEY JAMES seconded, a vote of thanks to the Chairman for the very able manner in which he had conducted the business of the society; this was carried, and the Chairman's response closed the proceedings.

THE PARLIAMENTARY COMMITTEE ON PROPRIETARY MEDICINES.

STEEDMAN'S SOOTHING POWDERS.

On April 3rd further evidence was given with regard to a booklet entitled, "Hints to Mothers, by M.D. of London," issued by the proprietors of Steedman's Soothing Powders. Earlier evidence with regard to this matter was reported in the BRITISH MEDICAL JOURNAL of February 15th, 1913, p. 349.

Mr. Uredenburg, the literary representative of Messrs. Raphael Tuck and Co., gave evidence that he wrote the health hints contained in the book, obtaining his information from various encyclopaedias and popular medical works. He then submitted the matter to his own medical attendant, who, in returning the manuscript, wrote: "I have to congratulate you upon having written a very up-to-date little book. I really find nothing to object to in it from beginning to end, and indeed nothing of importance to add to it. . . . I presume it is not necessary for my name to be put on the book, as some of my professional brethren would object to that, and call it a form of advertisement. I, however, thoroughly approve of the book." The witness said he explained to the doctor that the book was written on behalf of an advertising firm. The matter was next sent to Messrs. Steedman, and the references to the soothing powders were inserted according to their instructions. The manuscript, as amended, was not, however, resubmitted to the doctor.

The Chairman intimated that having received the doctor's name from Messrs. Steedman, a communication had been sent and a letter had been received from him bearing out the evidence just given, and strongly protesting against his name being introduced in connexion with the booklet.

In reply to Mr. Glyn-Jones, the witness said that he did not tell his medical man precisely to what use the matter submitted to him was to be put, as he himself did not know at that time. He was certain the doctor did not see the matter after the references to Steedman's powders had been inserted, although Messrs. Steedman might have been under the impression that he did.

Mr. J. A. South, manager of Messrs. Steedman, Limited, was then recalled, and reminded by the Chairman of his previous statements with regard to the book purporting to be written by an M.D. of London, and that if the doctor did not write the whole of it, it was certainly submitted to him. The witness said he had since sent a letter to the Committee correcting that statement. He read correspondence from Messrs. Tuck to the effect that they had been successful in getting an M.D. to approve of the following words appearing on the title page of the book: "Compiled from the works of the highest medical authorities and revised by an M.D." The letters made it clear that the name of the medical man must not appear in the transaction. The witness added that when his firm asked for a proof that the doctor knew that their advertisements would appear in the book amongst the matter for which he made himself responsible, the letter read by the last witness was shown to them. He regarded the use of the word "advertisement" in that letter as implying that the doctor fully understood that the booklet was an advertising one, and as the date was subsequent to the insertion of references to the soothing powders he took it for granted that the manuscript had been resubmitted to the doctor.

Dr. Chapple remarked that the doctor's use of the word "advertisement" referred to the advertisement of his own name, and not to the advertising use of the booklet.

The Chairman: You know generally what are the relations of the medical profession and medicines of this kind. Is it possible that a medical man of good standing would lend his support to a book that was from beginning to end an advertisement of a proprietary medicine?

The Witness: You think medical etiquette would not allow him to do it?

The Chairman: Of course I do.

The Witness: I think there are higher motives. The doctor might think it would be for the benefit of humanity, having regard to the value of Steedman's powders.

The Chairman: Have you met any doctor who would do that for a proprietary medicine?—I do not know that I have.

In reply to a further question, the witness agreed that his only ground for believing that the doctor had seen the booklet in its complete form was the inference he drew from the last sentence of the letter. Directly Messrs. Steedman learnt that they were incorrect in the supposition that a medical man vouched for the complete work they withdrew the booklet from circulation; those in stock were being destroyed.

Dealing with the evidence given on the previous occasion as to the composition of Steedman's powders, the Chairman reminded the witness that Mr. Hake, on behalf of the company, stated that the analysis of the powders given in *Secret Remedies* was incorrect. Packets of the preparation had been submitted to the Government analyst, and the Chairman asked the witness whether he had any objection to the report being read.

Mr. South: I should certainly object to your reading it, and I should object to saying if it is right or not.

The Chairman: I will not read it at the moment, and the Committee will reserve its decision on the matter.

HEADACHE POWDERS.

Mr. John Lawson, manager of Daisy, Limited, Leeds, proprietors of the Daisy cure for headaches, gave evidence as to the use of acetanilide and phenacetin in headache and neuralgia powders. He said that nine headache and neuralgia powders were reported on in *Secret Remedies*, and of these six had little sale. Following the more stringent administration of the medicine stamp duty, his firm prepared, in addition to the headache cure, a head powder which could be sold by unlicensed shopkeepers. They had been reluctant to introduce this, and had suggested to the Board of Inland Revenue that the sale of head powders should be prohibited except by licensed vendors; competition, however, had compelled them to put the powder on the market. The Inland Revenue authorities stipulated that the ingredients of the head powder should be essentially different from those of the Daisy cure, and therefore phenacetin, instead of acetanilide, was used. The witness quoted a number of medical opinions in favour of the use of acetanilide and phenacetin for headache and neuralgia, in opposition to the evidence given by Professor Dixon that acetanilide ought never to be used under any circumstances and that no medical man would now prescribe it. He submitted that the Registrar-General's return for the last ten years did not support Professor Dixon's statement that many deaths had been due to the taking of this drug. The dose of acetanilide in each Daisy powder was 5 grains; this was the quantity their experience showed to be necessary to cure the pain in an adult. The *British Pharmacopoeia* dose was 3 grains, but in the previous edition it had been 10 grains. He did not think it would be in the public interest, when this drug and similar ones were present in a proprietary medicine, that the fact should be stated on the label. The public would learn that acetanilide was the usual remedy for headache and neuralgia, and persons of a saving disposition might buy it in large quantities and do their own dispensing, with the result that variable doses would be taken.

The Chairman: Your argument suggests that any drug recommended in a medical textbook as suitable to be prescribed by a doctor after diagnosis may properly be sold broadcast to the public under a fancy name for purposes of self-medication?

The Witness: I see no objection.

Mr. Harry Lawson asked if the witness had heard of any protests from the medical profession against the use of the headache powders. He replied that there had been general criticisms, and endorsed a remark by Mr. Lawson that the medical press advertised a similar preparation to the Daisy powder under another name. He added that under the Insurance Act doctors were prescribing phenacetin very widely, and to a less extent acetanilide.

A CASE OF MIRBANE POISONING.

DR. GRAHAM GRANT sends us the following note on a case of poisoning by mirbane or nitro-benzene which recently came under his observation:

Nitro-benzene, or mirbane, possesses a strong and pleasant odour of bitter almonds; its taste is not at all unpleasant; it is yellowish-brown in colour, and a statement that the liquid might be diluted and consumed as a beverage might not appear improbable to ignorant persons. It is being sold in the commercial world by the gallon and without restriction.

A. B. collects waste paper in city offices. He found while doing so four small bottles, which he carried into the street and showed to an inquisitive passer-by, who offered the opinion that the stuff was a good spirit for cleaning clothes. This view was accepted by several persons, and a boy obtained one of the bottles, which he gave to C. D., telling him it was "a good spirit," but, according to C. D., he did not add "for cleaning clothes." The latter took it home and placed it on the chest of drawers. Two days later he suggested to his wife, who had been ill for some time, that a little of the contents might do her good. He gave her some and took some himself; how much can only be surmised from the fact that it was a 2-oz. bottle; if it was full at the time, they must have drunk about $\frac{1}{2}$ oz. between them, as there was $1\frac{1}{2}$ oz. left. This took place at about 10.30 p.m., and I was called at 11.15 by the landlord. On my arrival I found the man of an ashy pale colour and much distressed; the pulse was weak, the pupils were somewhat dilated and equal; in mind he was rational. I instructed a constable to give him an emetic of salt and water while I turned my attention to the woman. She was comatose, deeply cyanosed, the pulse was almost imperceptible, and the breathing stertorous. The breath of both smelt strongly of bitter almonds. I washed out the woman's stomach with salt and water and injected strychnine subcutaneously, but she was clearly past aid and died at 11.45. The man had copious emesis and the vomit had the characteristic smell. I decided to send him to the infirmary on an ambulance, but as soon as we attempted to move him he collapsed and had to be carried downstairs.

By the coroner's order I made a *post-mortem* examination and found evidence of alcoholism, some atheroma of the aorta, chronic bronchitis, and nephritis, but these conditions were not sufficiently advanced to have had a material influence in bringing about the death. There were numerous points of congestion in the brain and an excess of fluid in the ventricles. The blood was of a magenta colour and coagulation absent; it seemed also to be greasy. The examination showed nothing more of interest.

At the inquest the man C. D. gave evidence, generally to the effect I have indicated, till he was asked "Was the taste unpleasant?" To this he was unable to give a definite answer, and to settle the point I tasted it myself. I did so by inverting the bottle on my finger tip, which took up probably about two drops (I am open to correction as to the amount). At first I was only able to say "It was a sweet burning taste, and not repellent." The coroner suggested that perhaps I had not taken enough; but I subsequently found he was wrong in that respect. In a few minutes I felt a numbness of the tongue—somewhat like that produced by cocaine; this was followed by salivation. I experienced slight swimming in the head—I thought for the moment the court was too warm—but this passed away while I was giving evidence, and may, perhaps, have been due to the smell rather than the taste. I tasted the mirbane at 11 a.m., the vertigo was transient; the salivation lasted about an hour, and the numbness of the tongue about three hours.

As the coroner remarked, "This is a case of great public importance, and the sooner mirbane is placed on the poisons list the better," with which opinion I think all will agree.

According to Thorpe's *Dictionary of Applied Chemistry*, 1912, mirbane, or *essence de myrbane*, was first manufactured in France by Collas. It was used to scent soap and as a bitter almond flavouring. It is chemically nitro-benzene, more commonly spoken of as nitro-benzol. Dr. J. C. Cain, the author of the article in Thorpe's *Dictionary*,

states as follows: "When the nitro-benzol is to be sold as 'myrbane' it is distilled under diminished pressure in order to obtain a perfectly clear and transparent liquid such as the users of myrbane demand. It is customary to use toluene imperfectly freed from benzene for this purpose, that article being cheaper and yielding a somewhat more fragrant myrbane than benzene alone." In *Poisons: their Effects and Detection*, by A. and M. Wynter Blyth, it is stated that 1 gram (15.4 grains) would probably be sufficient to kill an adult, and that spirituous liquids especially hasten and intensify the action of nitro-benzene, so that a drunken person, *ceteris paribus*, taking the poison with spirits would be more affected than taking it under other conditions. In one case which occurred in Vienna a woman who took about three and a half ounces, and was admitted into hospital in a highly cyanotic condition with small pulse and superficial respiration, eventually recovered. It is stated that the more characteristic pathological appearances seem to be dark brown or even black colour of the blood, which coagulates with difficulty, venous hyperaemia of the brain and its membranes, and general venous engorgement. The blood gives the spectrum of acid haematin; its power of carrying and imparting oxygen to the tissues is diminished, and its content of carbon dioxide increased. It is further stated that on drinking the poison there is a burning taste in the mouth shortly followed by very striking blue or purple appearance of the lips, tongue, skin, nails, and even the conjunctivae. Discoloration may precede vomiting by as long as an hour; the skin becomes cold, there is great depression, the pulse is small and weak, and the breathing slow and irregular; this is followed by the sudden development of unconsciousness, and the whole condition may closely resemble apopleptic coma. The shortest period mentioned in which nitro-benzene has caused death is four or five hours. Inhalation of the vapour of nitro-benzene produces symptoms similar to those of alcoholic intoxication deepening into a coma. "Benzene Collas" used to be, and perhaps still is, a very popular domestic application for taking grease spots out of cloth.

MOTOR CARS FOR MEDICAL MEN.

A FEW SIMPLE AND USEFUL CALCULATIONS FOR MOTORISTS.

By R. BRUCE FERGUSON, M.A., M.D.Cantab., D.P.H.

In these days when so many motorists are their own chauffeurs, and even mechanics, it is always interesting and often useful to compare notes with one's friends regarding the expenses, actual performances, or potential possibilities of one's car. To enable one to do so satisfactorily figures are essential, and for this purpose a few simple examples are given below, in the hope they may prove of some slight assistance.

Horse Power and Insurance Premiums.

A few years ago a friend purchased a small car. The makers' rating was 8-h.p., and at this figure he insured it. He afterwards discovered that he might have exercised the option of selecting either the makers' rating or the R.A.C. (Treasury) rating, which is calculated according to the following formula:

$$H.P. = \frac{d^2 \times n}{2.5}$$

where *d* = diameter of cylinder in inches, and *n* = number of cylinders.

In his case the number of cylinders was 2, and their diameter 75 mm., and taking the usually-adopted computation of 25 mm. to the inch, he estimated the horse-power as $\frac{(3)^2 \times 2}{2.5} = 7.2$, and insured his car the next year as a 7-h.p., thus saving 8s. Before his next premium was due I pointed out to him that his inaccurate assumption of 25 mm. making an inch was costing him annually more than the price of his driver's licence, and that the correct figure was 1 mm. = 0.03937 inch. The formula thus becomes:

$$\frac{(0.03937 \times d)^2 \times n}{2.5} \text{ where } d = \text{diameter in millimetres.}$$

When simplified this will read: $\frac{d^2 \times n}{1613}$

The horse-power of his car is therefore $\frac{(75)^2 \times 2}{1613} = 6.93$.

Since the insurance company neglects fractions of a horse-

power, he now insures it as a 6-h.p. car, and saves a further sum of 6s. every year.

Ton-miles per Gallon.

The comparison of the merits of two cars by the number of miles they will run on a gallon of petrol is not an entirely satisfactory method, since it fails to take into account the weight of the car, accessories, and passengers. It is better to estimate the number of ton-miles per gallon.

If *P* = weight in pounds of car, accessories, and passengers, *M* = the number of miles run, and *G* = the number of gallons of petrol used, then *P* × *M* = the number of pound-miles, and $\frac{P \times M}{2240}$ = the number of ton-miles obtained from *G* gallons, and $\frac{P \times M}{2240 \times G}$ = the number of ton-miles per gallon.

Volume Swept Out by the Pistons at Each Revolution.

This is simply the estimation of the cubic contents of that portion of the cylinder in which the piston moves.

If *d* = diameter of cylinder in millimetres, and *s* = length of piston-stroke in millimetres, then the sectional area of the cylinder will be $d^2 \times 0.7854$ square mm., and the cubic contents will be $d^2 \times 0.7854 \times s$ cubic mm., or

$$\frac{d^2 \times 0.7854 \times s}{1000} \text{ cubic centimetres, or}$$

$$\frac{d^2 \times 0.7854 \times s \times 0.061}{1000} \text{ cubic inches.}$$

The latter may also be expressed as $d^2 \times s \times 0.000048$ cubic inches.

To obtain the total volume, multiply finally by the number of cylinders.

A Problem in Tyre Sizes.

As the matter of tyre sizes is one which, to my knowledge, puzzles many a motorist, an example on the subject may not be deemed out of place.

One very hot summer's day I found a friend making heroic but ineffectual attempts to place upon a front wheel a tyre which he had just removed from a back one. It was then discovered that the tyre previously on the front was a 30 × 3 in., whilst the back tyre, which it was now wished to place on the front, was a 30 × 3½ in. It was argued that the latter should go on the front wheel easily, since it was the larger tyre; but therein lies the fallacy, for it is only larger in the sense that it will hold more air, the sectional areas of the two tyres varying as the squares of their diameters, namely;

$$\text{As } (3)^2 = (3\frac{1}{2})^2; \text{ or as } 36 : 49.$$

The larger tyre thus holds 36 per cent. more air than the smaller. In other respects, however, the 3½ in. tyre is smaller than the 3 in., as can be easily demonstrated. A "30 inch tyre" means that when the tyre is on the wheel and fully inflated, a vertical line dropped from the highest point of the tyre to the ground measures 30 in. If the depth of the tyre be 3 in. at the top and 3 in. at the bottom, the diameter of the wheel itself (without the tyre) measured from rim to rim will be 30 - (2 × 3) = 24 in. If, however, the depth of the tyre be 3½ in., the wheel itself can only have a diameter of 30 - (2 × 3½) = 23 in., and on actual measurement this was shown to be the case, the back wheel being the smaller of the two. The failure of the effort was thus due to the attempt to place upon a 24-in. wheel a tyre which was made for a 23-in. wheel.

It will be readily seen that a 710 × 90 mm. tyre can replace a 700 × 85 mm., since in each case the rim-to-rim diameter will be 530 mm.

For example, 710 - (90 × 2) = 530 in the former, and 700 - (85 × 2) = 530 in the latter.

Similarly, 760 × 90 is interchangeable with 750 × 85, and also 810 × 90 with 800 × 85.

The fact that it is occasionally possible to stretch a tyre on to a wheel slightly too large for it does not in any way affect the accuracy of the explanation given above.

THE National Health Society, 53, Berners Street, has recently issued a kind of poster, price 1d., containing a series of hints in regard to keeping houses and their inhabitants healthy. Recollection of them is facilitated by their being given in rhymed verse, and with one single exception the statements made all seem undeniably sound; while, in respect both of rhythm and rhyme, the author, "F. L." is fully entitled to hold up his head in the company of the minor poets of the age.

LITERARY NOTES.

PROFESSOR SAUNDBY of Birmingham has in the press a new work on *Old Age: Its Care and Treatment in Health and Disease*. It will be published shortly by Mr. Edward Arnold.

Messrs. William Hodge and Company, Edinburgh and London, announce for early publication a new volume in their series of Notable English Trials. It is entitled *The Trial of Dr. Lamson*, and is edited by Hamilton Adam, who is the author of several well known works on criminology. Dr. Lamson was tried in the year 1832 for the murder of his nephew, Percy Malcolm John. This is one of the few cases recorded in which the poison used was aconitine. The trial took place before the late Mr. Justice Hawkins, and resulted in the condemnation of the prisoner. The volume will be illustrated with portraits of the prisoner and counsel engaged in the trial.

Mr. Alban Doran has contributed to the *Journal of Obstetrics*, under the title "Burton (Dr. Slop), his Forceps and his Foes," a very interesting account of the life and fortunes of Dr. John Burton of York, who was born in 1710 and died in 1771. Mr. Doran summarizes Burton's work, and gives many quotations from his *Essay on Midwifery*, his letter to Dr. Smellie, his *Treatise on the Non Naturals*, and his *British Liberty Endangered*, with the account of his persecution by the Whigs, Dr. Jacques Sterne and Laurence Sterne. The article contains also a full and interesting analysis of the passages on Dr. Slop in *Tristram Shandy*, and it is shown that the curse of Ernulphus was probably a parody on the letter to Smellie—both being curses all through. The so-called Burton's forceps figured in his *Essay on Midwifery*, and the forceps used by Burton himself are illustrated, and it is seen that they are not the same instrument—the latter is preserved in the library of the York Medical Society. We understand that Dr. Auden first recognized the fact that Burton apparently did not use the forceps which he invented.

In the article on the origin of the name Livingstone published on March 29th, p. 676, there is a misprint, *sén* should be *féin*. The correspondent who called attention to this misprint also expresses the opinion that the correct translation of *Muc an leigh* given by Dr. Maclean as "Son of the physician" should be "The son of the leech," or physician, or, as one might say, Leechson.

Shakespeare's *Holofernes* would have found his intellectual nose sorely offended at the present day, when the smell of false Latin rises thick from popular books and periodicals. Medicine is supposed to be a "learned" profession, but alas! our literature is full of awful examples of what it would be an insult to a noble animal to call dog Latin. The most recent we have come across occurs in the *St. Bartholomew's Hospital Journal* for January, where there is an allusion to the "hausti" of that venerable institution with which so many scholarly men have been associated. How much scratching of Priscian's head has the Latin fourth declension caused! It is only fair to say that there has of late years been considerable improvement in regard to this particular barbarism. *Meati*, which at one time used to be common, has almost ceased to vex those who have retained some faint recollection of the Latin grammar. The same may be said even more emphatically of *apparati*. We are not of those who insist on pedantic adherence to the classical plural in words such as "sanatorium" and "serum," which have acquired the freedom of the city in our English speech. But such monstrosities as "hausti" create new words which are neither Latin nor English, and are merely illiterate. These errors, unfortunately, do not stand alone. To quote only a few recently met with in medical journals: we not long ago found mention of a condition called *diverticula spuria intestinalis*; an Indian journal referred to an *apologium*; a French one described a book as written *in usum medicis*; while an English contemporary produced the following remarkable variant of a common phrase, "*Concilium vult decepi, and decepi it will be!*" From a casual inspection of American periodicals, we call the following flowers of classical speech: *corpus cavernosus* and *angina pectorides*; while a leading journal

of surgery contained a paper with the remarkable title, "A Resumé of the Treatment of *Infertilis Masculinus*!"! And medical journals are not the only or the worst offenders. One of our great Radical dailies quite lately spoke of an *annus mirabile*, while, as if to balance the distribution of ignorance, a Conservative paper told us, after an unsuccessful election, that the voters of its own political complexion *militaverunt non sine gloria*. Such a heading as *De res medici*, which appeared recently in the most important Liberal paper of Spain, may be dismissed with a shrug of the shoulders, but we confess we were shocked to come across such a phrase as *vulgum pecus* in that very superior paper *Le Temps*. This solecism, however, seems less surprising when we recall that it was in *Le Temps* that the amazing injunction *Reddite Caesaro quod est Caesari* appeared some years ago. A French writer has put into the mouth of Abelard the un-Horatian proplecy, *Non omnis moribus*; another, with a vague recollection of the Vulgate, declares that there is *nil novo sub soli*, while a third shows his knowledge of the same version of the Scripture by quoting a familiar text in the novel form, *regnum meum non est ex hoc saeculi*. A paraphrase of Wellington's advice to speakers, "Say what you have to say; don't quote Latin; and sit down," would be a useful guide to writers.

The depopulation of France, caused by the steady decline in the birth-rate of that country, has given rise to much anxiety amongst the thinking portion of the French nation. Numerous remedies have been proposed to check the growth of this grave social evil, but as yet none have produced any marked effect; and French politicians at the present moment are face to face with a danger they are apparently powerless to combat. M. Henri Meurisse, who has contributed an interesting article on the subject to the March number of *L'Hygiène*, quotes several of the foremost medical men in France, who are nearly all agreed that the decay of religion and the increased luxury and cost of living lie at the root of the trouble that is slowly draining France of her life-blood. In the country districts, where the peasants still cling to their ancient faith, large families are even yet the rule rather than the exception, but elsewhere they are almost unknown, thanks to the spirit of an age that places creature comforts before the joys of family life. Amongst the French working classes compulsory education, combined with military service, have also done much to lower the birth-rate, since both prevent the child supporting himself, and cause him to be a burden on his parents long past the age when an earlier generation was earning its own living in the workshop or the field. It is difficult to see how to grapple with a problem that is the inevitable result of a high degree of civilization, and which, it is hardly necessary to add, affects us almost as closely as our neighbours across the Channel. Legislation is powerless to cope with a situation brought about by the improvement of the individual at the expense of the race; and it needs something more than the endowment of parenthood to overcome the reluctance of the modern woman to face the risks of maternity and induce her husband to burden himself with the full responsibilities of married life. The same number of *L'Hygiène* also contains a charming description by M. André Maurel of the principal galleries and monuments of Florence, and a short article by M. Fabre-Domergue on the bedding of oysters.

The April number of *Bedrock*, among other articles, contains the following: Modern materialism, by W. McDougall, M.B.; mimicry, mutation, and Mendelism, by Professor E. B. Poulton; immunity and natural selection, by Dr. Archdall Reid; the suppression of venereal diseases, by Dr. James W. Barrett, who gives an interesting account of the measures taken to that end in Melbourne; and the milk problem, with special reference to supply, by Dr. Eric Pritchard. There is also a very pretty quarrel on telepathy as a fact of experience between Sir Oliver Lodge and Sir E. Ray Lankester, in which these doughty champions exchange many shrewd thrusts. While acknowledging the logical subtlety of Sir Oliver Lodge, our sympathies are with Sir E. Ray Lankester, who takes up the position that the existence of telepathy has still to be proved scientifically. Till the fact is established it seems futile to discuss its *a priori* possibility.

British Medical Journal.

SATURDAY, APRIL 12TH, 1913.

MEDICAL CERTIFICATES UNDER THE INSURANCE ACT.

IN the JOURNAL of March 22nd a note was given (p. 640) of a case heard in the King's Bench Division on March 8th, before Mr. Justice Bailhache, in which an insured person sued for a declaration that a resolution passed by his approved society preventing the society from accepting, as evidence of the incapacity of its members within the meaning of the National Insurance Act, 1911, certificates of medical practitioners not on the panel was illegal, *ultra vires*, and unenforceable. The action was dismissed with costs, the judge stating that the case was one which ought to be decided under Section 67 of the National Insurance Act by arbitration. The credit for bringing this important case before the courts is due to the London Committee, and we understand that it has entered an appeal.

This is a matter which deeply concerns not only the members of approved societies but the general public and the whole medical profession, and is a subject which ought immediately to have the serious attention of the medical corporations and the General Medical Council.

There is nothing in the National Insurance Act to support the contention that the medical certificates enabling insured persons to claim sickness and disablement benefit must necessarily be signed by a doctor who is on the panel, and it has been officially stated that the responsibility of deciding what kind of evidence approved societies will require before they pay sickness or disablement benefit to an insured person is a matter for the determination of the approved society alone. It is difficult to see on what grounds an approved society can hold that it is necessary that such certificates as it requires should be signed by a doctor on the panel. On a rough estimate the doctors on the panel comprise barely one half of the total profession in this country, and we have not heard it contended by the most ardent supporter of the Insurance Act that the doctors who are not serving under it are any less competent or any less likely to give a trustworthy certificate than those on the panel. The profession as a whole, quite irrespective of its views on the Insurance Act, will object strongly to a form of discrimination which by implication casts a reflection upon one section of the profession as compared with another. An approved society which is not satisfied with a certificate, whether given by a panel doctor or a doctor outside the panel, has its proper remedy. It can always claim to have the patient examined by a doctor of its own choice.

It is true that before the Act came into operation there were some clubs and friendly societies which insisted upon medical certificates coming from the doctor elected by the club. The situation is not now at all parallel. A doctor attending the insured person is not now employed by the club, and in some areas where a large majority of the doctors

are on the panel it would seem that the approved societies will in fact be bound to accept the certificate of practically any medical practitioner. It seems clear that the fact that a medical practitioner is upon the *Medical Register*, and thus has the imprimatur of the State, should be a sufficient guarantee. If in the instance of any individual registered practitioner his actions prove that he cannot be trusted, there is a remedy which it is quite certain the General Medical Council will not be slow to enforce. If he comes under the censure of that body, he will either mend his ways or will cease to be competent to give a legal certificate. The discipline of the medical profession administered by the General Medical Council under the powers conferred upon it by Parliament is strict and strong enough to make it abundantly certain that the certificate of any registered practitioner may be taken for all the purposes of the National Insurance Act just as it is for the not less serious purposes of a court of law.

It may be anticipated that the licensing bodies will give early attention to this matter, which very nearly concerns the interests of a large number of their graduates, members, and licentiates, who will undoubtedly look to them to vindicate their rights. The claim now made by and on behalf of the approved societies seems to infringe the rights granted to these bodies by statute or charter. Time was when the chartered corporations were always ready to defend their privileges. For a generation they have been slow to move, owing probably to the defect in their constitution through which their numerous members and licentiates do not form part of the body corporate. Even the greatest sticklers for formality, however, admit that each college owes a duty to those admitted to the *Medical Register* on the evidence of its diploma, but they boggle at the next step, which is to take action with the other colleges when rights common to all diplomates are involved. We are quite prepared to be told that this is not a matter which can properly be raised through the press. So be it. But then let the diplomates of each corporation make representations each to his own college. That would be an entirely regular course, and such representations would not, we are certain, be ignored. If each college considered the matter and recorded its opinion, the General Medical Council will afford a common meeting place where combined action may be concerted.

The matter is one with which the General Medical Council cannot in any event fail to occupy itself, and we have no doubt that attention will be directed to it during the coming session. The Council has statutory powers, and has the duty of protecting the profession generally in the enjoyment of the rights and privileges, few as they are, conferred upon it by the Medical Acts. It would be very well if the representatives not only of the colleges, but of the universities also, came up to the May meeting in possession of the considered opinions of the bodies they severally represent.

THE INFECTIVE NATURE OF INFANTILE PARALYSIS.

PHYSICIANS who have studied the diseases of children have long assumed that infantile paralysis—or acute poliomyelitis, as it is better called—is an infectious disease. Until recently the grounds for this belief were the local and epidemic distribution of the cases, the frequency with which outbreaks occur at certain seasons especially the early autumn—the

acute course of the febrile stage, and the inflammatory nature of the lesions revealed in the spinal cord by the microscope. In addition, the careful collection of the statistics of the epidemics and the study of the geographical distribution of the cases has helped to strengthen the evidence here. Dr. F. E. Batten has done much to bring home such knowledge to the members of the profession in this country. Yet, although various microbes had been associated with the disease by different observers, there was no unanimity of opinion as to the exact nature of the organism causing infantile paralysis until quite recently; and even now we are still in the dark as to many points connected with the life-history of the ultra-microscopic virus that is universally believed to be the infecting agent.

All the more recent work of the many bacteriologists on the Continent, in the United States, and in England who are engaged in this study may be said to be based on the researches of Landsteiner and Popper. In November, 1908, these authors produced in monkeys (a hamadryad and a macaque) a disease indistinguishable from infantile paralysis as we see it in children. The infecting agent they used was emulsion of the spinal cord taken from a boy of 9, who had succumbed in four days to an attack of acute anterior poliomyelitis, and infection was produced by injection of the emulsion into the peritoneal cavity of the monkeys. One of the animals fell ill on the sixth and died on the eighth day; paralysis of the legs was observed in the other on the seventeenth day, and it was killed two days later. In both the pia mater was found to be infiltrated *post mortem*, the grey matter of the cord was soft, circumvascular and diffuse infiltrations were marked, and the ganglion cells were badly damaged, particularly in the anterior horns. Analogous changes were also found in the cortex of the brain. Attempts to infect three other monkeys with this material proved abortive, but since that date it has been abundantly proved that the disease can be transmitted from one monkey to another. Studies of the virus have demonstrated further that it can pass through a porcelain filter and can be preserved for many months in glycerine. It is easily destroyed by many germicides, of which hydrogen peroxide is one, but is resistant to the vapour of formaldehyde and to carbolic acid in strengths below 0.5 per cent.

Armed with this knowledge, Kling, of Stockholm, assisted by Wernstedt and Pettersson, took advantage of the occurrence of a number of cases in that city in 1911 and 1912 to prosecute a research into the distribution of the infective material, using as a test the production of the disease in monkeys confirmed by an examination of their spinal cords. He found that washings from the mouth and intestines of a number of children acutely ill with poliomyelitis or killed by the disease, produced the disease in apes, as did similar washings obtained *post mortem* from the mouth, nose, trachea, and small intestine. By the same method the virus was shown to be present also in the mucous secretions of a number of persons in close relationship with the sick, and even in those of some whose relationship was less obvious. Not all of these suffered from symptoms, but some of them did, although their illness, not being followed by paralysis, would not in other circumstances have been ascribed to the same infection; these Kling identifies with the "abortive" cases which have been so often described in epidemics of poliomyelitis (by Wiekman and others). He found the virus, for example, in members of four different families, some of whom had suffered from headaches, malaise, and other symptoms, and some

had not, whilst in one member of each family paralysis had supervened. It appeared, therefore, that the adults were affected by the disease, though it did not chance to have produced in them the paralysis which so often follows in children. We do not know whether apparently healthy people whose secretions contain the infection are carriers of the germs—that is, are the infectors—or whether they are infected from the sick but are able to resist the virus, presumably by means of antibodies in the blood, and to prevent it from harming their own nervous systems. So far as investigation has gone it appears that carriers are more numerous than sick children in the proportion of at least four or five to one. The virus is resistant to digestion, since it passes through the stomach of a monkey without being destroyed, and may be readily recovered from the faeces of human patients or carriers of the disease. It is most virulent in the first fortnight of the illness; in animals inoculated with material obtained at a later stage both the symptoms induced and the microscopic changes in their spinal cords are less marked, but virulence is regained by the passage, since a second animal is severely affected. There is no evidence at present as to whether infection is conveyed directly, or indirectly as by parasites, but an attempt to recognize the virus in flies from an infected house was unsuccessful, and so were experiments made upon fleas. But the question cannot yet be regarded as settled; the recent epidemics in Sweden (there were 3,840 cases in 1911) showed a tendency to the production of many instances of infantile paralysis in large and densely inhabited dwelling places, and this may be dependent on some form of parasitic transmission.

For how long should the patients be quarantined as infectious to others? Kling examined washings from the mouth and the intestine repeatedly at various intervals of weeks and months in nine typical acute cases, and found that the virus was still present in both the washings six months after the attack in one patient. Four months after the attack it was present in the mouth-washings of two or three of the patients, and in the intestinal washings of two or three others. Hence he concludes that any theoretically adequate quarantine is a practical impossibility, but notes the fortunate fact that the virus thus carried lessens in virulence as time passes. The quarantine should be for at least a fortnight. Kling holds that the great majority of adults and many children may be infected with the virus without being a penny the worse for it; whether because the virus is weak or because the resistance of such individuals is high, he is uncertain, but he inclines to the latter view. Every acute case he believes to be surrounded by a number of abortive cases of infantile paralysis, and by a still larger number of perfectly healthy people, who are all carriers of the infection, and therefore potential sources of infection to others. All these persons appear to develop a relatively high degree of immunity to subsequent infections with the virus, a fact which may explain the comparative immunity of towns or villages visited by epidemics of infantile paralysis to further epidemics occurring during, at any rate, the next few years. The same phenomenon is met with, according to Kling, in successive epidemics of cholera and of typhus fever.

Quite recently Flexner and Noguchi have succeeded where many others have failed, and have grown the virus of acute poliomyelitis outside the animal body, and demonstrated its presence in the media employed. The growths were made anaerobically under a layer

of paraffin, in a solid agar medium containing sterile unfiltered ascitic fluid, or brain extract and sterile rabbit kidney. Minute colonies were obtained, composed of globular or globoid bodies averaging in young cultures 0.15 to 0.3 μ in size, arranged singly or in short chains or in masses. Cultures from human tissues in the third, and from monkey tissues in the fifth generation have caused typical experimental poliomyelitis in the monkey.

THE APPENDIX IN SURGERY AND GYNAECOLOGY.

THE appendix vermiformis hangs, so to speak, on the border line between abdominal surgery and gynaecology. Every one recognizes that the general surgeon must be prepared to deal with it in his sphere of work; but it is perhaps hardly so clearly recognized that the gynaecologist likewise must be ready to treat appendicular affections when he meets them, and he may meet them any time. The surgeon commonly handles the appendix, but the gynaecologist occasionally has to touch it. There is also another aspect of the subject: the business of the gynaecologist is to search out and put right (operatively or non-operatively as occasion demands) morbid states of the uterus and its adnexa (tubes and ovaries), and his mind and methods are directed thereto; but the surgeon has these structures less prominently in view, and yet they may at any time obtrude themselves upon him and call for his skill. The gynaecologist commonly handles the uterine adnexa, but the general surgeon now and again is forced to touch them.

There can be no doubt that it is so. The medical literature of the day has abundant evidence to prove it. Take the case of which Dr. Colin Faulkrod was speaking to the Obstetrical Society of Philadelphia the other month.¹ The abdomen was opened on the diagnosis of right-sided extrauterine pregnancy; a diseased appendix and a dermoid cyst of the right ovary were found. Or take Dr. F. C. Hammond's experience told to the same society.² He was asked to operate for suspected appendicitis, and there were all the symptoms of it; but he made the routine bimanual examination and found a round fluctuating mass on the right side of the pelvis: so he opened the abdomen, found and removed an ovarian tumour which had twisted its pedicle four and a half times, and, discovering that the appendix was healthy, left it alone. Again, cases are known, but not always reported, in which the surgeon opens the abdomen, removes an innocent appendix, and then passing his hand down into the pouch of Douglas, pulls into sight a pus-tube which bursts in his fingers.

Further, appendicitis and a pus-tube may coexist. Dr. George M. Boyd³ made a vaginal examination before operating on a case which had been diagnosed as appendicitis, and found a swelling behind and to the left of the uterus: he opened the abdomen in the middle line and not by a lateral incision (as he had thought of doing), and removed both a pus-tube and an inflamed appendix vermiformis; had he not made the vaginal examination, he might have made his incision on the right side, have removed the diseased appendix, and never have discovered the pyosalpinx.

If, however, the surgeon or the gynaecologist have any lingering doubts about the way in which their two spheres overlap in the right lower quadrant of

the abdomen, let them peruse Dr. Basso's monograph⁴ of a hundred pages on the vermiform appendix in physiological and pathological states of the female generative organs. Traversing all the field of medical literature for his information and using the material of Professor Resinelli's clinic in Florence for his facts, Dr. Basso has discovered many things which it is well worth the while of both the surgeon and the gynaecologist to know and to consider. There is, for instance, the pelvic position of the appendix in from 13 to 40 per cent. of women; the fact that in recent statistics appendicitis appears to be almost as frequent in women as in men; the demonstration of the causal connexion between appendicitis and inflammation of the ovary, tube, and parts about these structures, and conversely between the inflammation of the uterine adnexa—adnexitis and periadnexitis—and appendicitis and periappendicitis; the coexistence of appendicitis and adnexitis of independent origin; and the occasional occurrence of appendicitis as a sequel to operations on the pelvic organs. Dr. Basso rightly insists upon the difficulty of distinguishing between gynaecological complaints and those due to appendicitis by means of symptomatology; for instance, some forms of dysmenorrhœa can hardly be separated from cases of pain due to chronic appendicitis. Even careful abdominal, vaginal, and rectal examination will not always serve to diagnose between surgical and gynaecological states. There is much else in Dr. Basso's article that is of importance; in that part of it, for instance, which shows the intimate relation which may exist between appendicitis and pregnancy, labour, and the puerperium; but enough has been quoted to establish his principal contention.

His principal contention is that the gynaecologist must have so exact a knowledge of the diagnosis and operative treatment of the abdominal organs as to be able to intervene in purely gynaecological cases with safety and security, and also to deal with the organs outside the genital sphere in cases of erroneous diagnosis, and when these organs have been accidentally injured by the separation of adhesions, etc. We must agree with him in this, for the pelvic cavity is not shut off as is the cranial; indeed, it is not even separated from the abdomen, as the thorax is, by a diaphragm, and on the imaginary boundary lies the appendix vermiformis. The gynaecologist, therefore, must know at the least enough abdominal surgery to be able to deal with intestinal, and especially with appendicular, conditions.

The surgeon also has his lesson to learn. He must not only think of the appendix when he has to do with trouble in the lower quadrant of the abdomen on the right side; he must also let the presence of the uterine adnexa in the near vicinity have its place in his mind. He must therefore be prepared to practise the diagnostic methods of the gynaecologist, and must not neglect the vaginal and the bimanual examinations; and lastly, he must have a sufficient knowledge of the technique of gynaecological surgery to enable him to cope with pyosalpinx, ectopic gestation, multiple adhesions of the ovaries, and ovarian cysts.

There are several unsolved problems connected with the appendix; there is, for example, the question of the performance of prophylactic appendicectomy on all the occasions on which the gynaecologist opens the abdomen, and this in its turn cannot be settled until we know whether the appendix has glands in it secreting a useful fluid, and acts as a protection against bacteria, or is a functionless rudimentary part which the human subject is best

without; there are several such problems, and Mr. Corner's article in the *JOURNAL* of February 15th (p. 325) throws some light on this one: but it is certain that the gynaecologist as well as the surgeon must know what to do with the appendix when he finds it diseased, and the surgeon as well as the gynaecologist must be prepared to treat any of the morbid states of the genital organs which may be confused with or coexist with appendicitis.

HOLIDAY MAKERS AND CONVALESCENTS.

A kind of interim pronouncement in regard to the vexed question of attendance on insured persons resident for the time being elsewhere than in the areas to which they habitually live has been made by the Insurance Commissioners to the Bournemouth Insurance Committee, and is reproduced in the *SUPPLEMENT* (page 318). It purports to be an explanatory letter, and, apart from the interest of its topic, possesses, as an exercise in style, a certain curious quality of its own. Not unto every man is it given to write sentences each containing an average of eighty words with no particular stops; few people, too, would have conceived the jest of explaining away a supposed misapprehension by a statement to which each and every reader is likely to attribute a different meaning—if he does not give up in despair the attempt to find any meaning at all; and certainly no writer could have avoided with a greater air of ingenuousness all attempt to tackle the real questions at issue. We will assume that the word "adequate" in the second paragraph should read "inadequate"; but even then considerable difficulty remains in putting any logical construction on the three paragraphs as a whole. The Commissioners indicate a belief that they will be able to overcome the administrative difficulties that have already arisen between various Local Insurance Committees in the matter of adjustment of their accounts, and the fair payment of the medical men employed by them. This belief may be justified if the term "removal" is limited to its ordinary significance. Should it, however, be meant, as would appear to be intended in the first paragraph by the use of the words "removing at very frequent intervals," to cover changes of residence for however short a time and however often repeated, it seems safe to prophesy failure for the Commissioners' plan, whatever it may be. No system primarily devised to meet the case of insured persons who definitely change their domicile could in practice be applied with equal success to the case of insured persons who are merely visitors to an area for a few days. Every year during week ends and for longer periods hundreds of thousands of members of the insured classes pay visits to pleasure and health resorts. So long as capitation payment for medical attendance is in vogue, it must pass the wit of man to devise a method which would apply equally well to the case of true removals and of such individuals. The whole contention in this paragraph of the letter rests on the assumption that an insured person in good health going for a holiday will have the foresight to notify the Insurance Committee of the area in which he is a permanent resident, and also, it would seem, the Insurance Committee of the area in which he proposes to spend a few days or weeks. The Insurance Commissioners were very clearly warned that this assumption was not sound at the conference which took place on March 5th. The insured persons who are leaving home because they are ill or convalescent will without doubt take this trouble—as will possibly also the careful mother of a young family—but common experience of healthy human nature is sufficient to convince any one that most other holiday makers will not. The misapprehension, then, does not seem to be on the side of the doctors. Probably, however, it may be deduced from the third and concluding paragraph of the letter that the Commissioners do not deceive themselves on

this point, and already realize that only two alternatives are open. One is boldly to declare that they do not expect Local Insurance Committees to recognize, for the purposes of medical attendance, the casual presence within their area of an insured person, and intend to limit the right to such attendance to persons permanently resident within any given insurance area. This would seem to be rejected in the third paragraph of the letter. The other alternative is to put at the disposition of Local Insurance Committees, and out of some source other than those at present known to be available, a sufficient sum of money to pay an agreed visiting fee for any medical attendance which may be required by an insured person temporarily within the area of a committee. There is one point in this pronouncement, however, on which the Commissioners are apparently deceiving themselves. Whatever else is obscure therein, it is clear that the Commissioners are disposed to hold that a panel medical officer will have no cause for complaint if he receives payment for attendance on "a removal" at the same rate as that paid for persons permanently resident in the area. Possibly this is true if the meaning of the term "removal" is strictly limited, as indicated above, to mean permanent change of residence; but if it is made to cover the presence in a town or village of an insured person for only a week or a month, or any like period, very just cause for discontent will arise. In such cases the insured is only likely to be assigned to a medical man because he happens to be ill, and it is almost needless to point out that there is a very great difference between accepting, say, 6s. 6d. or 7s. a year for a person who may possibly not require any medical attendance at all throughout its duration, and receiving, say, one fifty-second part of 6s. 6d. a year, or 1½d., for a week's attendance on a person who is actually ill when placed on the practitioner's list. Nor is this the only rock in the path of the Commissioners. At present the majority of panel medical officers believe that for every person on their list they will receive a sum of not less than 6s. 6d.; indeed, they have received assurances to this effect on numerous occasions from Mr. Lloyd George and others. What will they say if they are invited to agree to a deduction from this sum being made whenever it is brought to the notice of their local Insurance Committee by the Insurance Committee of some other area that such person has chosen to absent himself for a longer or shorter period from the area in which he habitually resides and earns his living?

THE NATIONAL INSURANCE ACT IN BEING.

THE notes in this week's *SUPPLEMENT* on the proceedings of various Local Insurance and Medical Committees are well worthy not only of perusal but of careful study. Culled from many different parts of the country, they put before us in a living way things as they really are, not as they ought to be or may in future be according to the after-dinner optimism of Mr. Masterman. Insurance Committees, Local Medical Committees, and individuals all emphatically declare that things are in many respects far from right. The London Insurance Committee wants to know if the present system cannot be improved, and has instructed its Medical Benefit Subcommittee to consider and report on the subject. Last Tuesday a meeting of panel doctors was held in London. It was a regular field day; Dr. Richmond, one of the Honorary Secretaries, had to admit that the acting Local Medical Committee was not of a representative character, and a motion thanking the Committee for its services, and requesting it to continue them was defeated. Out of the 5,800 doctors in London 1,282 were on the panel on the day of the meeting, and 1,074 of these had signed renewal agreements. The Lindsey (Lines) Insurance Committee has decided to import a whole-time medical man because no doctor has accepted service on the panel

in three of the districts. At Sheffield the Committee "does not at present contemplate any limit being placed on the number of persons accepted by practitioners"; at Middlesbrough a maximum of 1,750 patients to any individual doctor is fixed, and Newcastle thinks 1,500 is enough for a doctor to manage. In Bucks the Insurance Committee has no funds to pay for a consulting medical referee. The doctors in Bournemouth, in common with all medical men at seaside and other holiday resorts, are in trouble about the payment for visitors. In Berkshire also, as in many other rural counties in England and Wales, the same difficulty is acutely felt. The Medical Committee sent a report to the Bournemouth Insurance Committee on this matter, and it in turn appealed to the Commissioners for advice and help. The Commissioners' letter in reply is a tangle which we have tried to unravel above. Bournemouth, in common with other insurance areas, has difficulty also about an income limit. One of the medical representatives on the Insurance Committee proposed an income limit, but it was rejected by 18 votes to 5. In East Sussex only four members on the Insurance Committee voted for an income limit. At Newcastle-on-Tyne an effort to reopen this question with the Insurance Committee was without avail. In Blackpool the discussion was deferred for further consideration, but the fate of other similar applications in other parts of the country is not encouraging. In this matter the expected is being realized, and the local fight is becoming a defeat of the profession in detail. The knotty question of mileage is still unsolved. Of the Treasury grants, amounting to £60,000, Scotland gets £10,000 for the Highlands and Islands and £16,000 for the Lowlands, leaving £34,000 for England and Wales. Whether the sum allowed will be enough to recoup the expenditure involved remains to be seen; this much, however, should not be forgotten by those who participate in the grant—that they would never have lingered a penny of this £60,000 but for the determined fight made on their behalf by the British Medical Association. Places wide apart as Newcastle and the Isle of Wight enter protests against the notion that this is a smooth-working Act. Medical practitioners in the former signed the renewal agreements under protest, and it is expected that some will retire from the panel. They also seriously considered the necessity of raising a war fund, and ultimately decided to refer this very important matter to the Council of the British Medical Association. At a meeting at Ryde, the Isle of Wight Local Medical Committee joined in the general chorus of dissatisfaction and criticism. Compared to the fighting doctors the chemists have been amenable; but even they are not satisfied, if we are to judge them all by their Scottish brethren, who passed a resolution unanimously affirming that the existing drug tariff is not sufficiently remunerative to secure an efficient pharmacy service, and a second resolution, also adopted unanimously, protesting that the alteration of Regulation 30 (I) in favour of the doctors was inconsistent with the promises of the Chancellor of the Exchequer. The working of the Act, indeed, seems to satisfy no one but the Financial Secretary to the Treasury. When every allowance is made for the difficulty of getting so huge a piece of machinery to work, and admitting to the full its many imperfections, some of which the Government will seek to remedy by the promised amending Act, there remains the conviction, to which we have already given expression, that the Insurance Commissioners are failing to exercise the central co-ordinating influence the country expects them to exert. It will now have to discount the optimistic, we had almost written boastful, utterances of the Chairman of the Joint Committee, who appears to be wholly unaware of the width and depth of the dissatisfaction and the half-amused contempt with which such a piece of blundering obscurantism as the Bournemouth letter is read by practical men in touch with the actual facts.

THE OLD LEPER HOUSE AT PRESTWICK.

EXCAVATIONS are being carried out on the site of the old leper hospital of Saint Ninian at Prestwick, the Ayrshire watering place so well known to West of Scotland golfers. A short account of the excavations has been given by Mr. Kirkwood Hewat in the *Glasgow Herald*. The hospital is mentioned by Sir James Simpson in his article on leprosy and leper hospitals in Scotland and England. He says that at Kilcais or Kingcase on a bleak muir in the parish of Prestwick, about two miles from the town of Ayr, there stood for several centuries a hospital for lepers. The general tradition of the surrounding country is to the effect that this hospital was founded by King Robert the Bruce, but Simpson thought it probable that it existed before that monarch's day. Whether he was the founder of the hospital or not, he seems to have been a very liberal benefactor; in connexion with this it may be recalled that it is generally stated by historians that Bruce himself was a leper and died of the disease. The hospital at one time possessed extensive property in the parish of Dundonald and in Kyle Stewart, but as was so often the case the gifts of charity were gradually diverted to private uses. No records remain from which the original extent of the Kingcase Hospital can be estimated. The only remnants of the buildings left when Simpson wrote (1841) consisted of the massive side wall of a building 36 feet long and 17 wide, believed to be the ruins of the chapel of the hospital. From this it may be judged that before it was despoiled of its revenues and land the grounds were of considerable extent. During the later years of the institution the number of lepers maintained in the Kingcase Hospital was limited to eight, but in its more prosperous day the number was probably larger. The lepers lived in huts in the vicinity of the chapel. The hospital was under the direction of an official who had the title of prior. There are frequent references to it in the borough records, which go back to 1470. These records show that the regulations were very strict against lepers going into the town or having dealings with its inhabitants. For instance, under date November 13, 1481, we read: "Andro Sauer is fund in daili reperand to Kingcase . . . and is abill till infect the hale toune, and weris the seik folkis clathis and bonnettis." Fourteen years later we read: "The quhilk dai Mariam Miller, Elane Broune, and Ane Duncane ar ilk ane severale in amerciaments for the selling of ale and intrometin of the folkis of Kingcase agane the stautis of the toune." And much later, in 1693, a very heavy penalty is imposed upon the "Lipper Folke" if they intrude "upon the priviledges only proper to the burges and fremen." Robert Gordon, in his description of Kyle in the time of Charles I, mentions the chapel of Kingcase Hospital, and states that the persons who shared in the charity were lodged in huts or cottages near it; and in the records of the Presbytery of Ayr a commission was intimated from the Lord Chancellor to "visit the Hospitals of Kingesse, Air, and Maybole—all having interest in the hospitals to compeir." Already the remains of no fewer than twenty-four "Lipper Folke" have been exhumed, and traces or impressions made by many coffins have been seen. Nearly all the bodies lay at the eastern end of the church, more than half the length of which has been disinterred. The walls are from three to four feet thick. The chapel had coloured window lights, as is indicated by a fragment of a window that has been found. The window was of mica, not glass. The town council of Prestwick some time ago acquired the ground surrounding the well associated with the memory of Robert the Bruce. It has restored the well, and has placed in the new wall surrounding it a bronze tablet with a suitable inscription. The excavations, which have been in progress for some weeks, are still proceeding.

THE DEVELOPMENT OF THE FUNCTION OF VISION.

DR. MOREAU, of St. Etienne, has recently had the opportunity of studying the sense of vision in a person born blind in whom the obstruction to light falling on the retina was removed.¹ The subject was a boy, aged 8 years, who had suffered from complete congenital bilateral cataract accompanied by constant nystagmus; he had lived with his father, a poor peasant, and had received absolutely no education. The left eye was operated on first and a dense cataract removed; a bandage covering both eyes was applied and the patient left at rest in bed for a week. When the dressing was removed at 10 o'clock one morning the boy was seated on his bed in the ward exposed to the daylight; the cornea was found to have healed perfectly. When after a few minutes the hand was held about 12 in. from the boy's eye and he was asked what he saw, he seemed bewildered and made no reply; the dressing was replaced; two days later it was removed in the dark room and the ophthalmoscopic lamp was placed behind the patient so as to illuminate the hand shown to him; asked what it was, the child leant forward, stretched his neck and rotated his head, opening his eyes very wide, but finally said, "I don't know." When he was allowed to touch it he said at once, "the hand." He did not fix the hand with his eye, but groped for it like a blind person. In subsequent trials when shown any object he at first always said, "I don't know," but after a time he substituted a new answer, and to every object shown him said, "It shines." Dr. Moreau remarks that the visual impression received was evidently not of a contour but of a luminous object. Three weeks later the other lens was removed, and when in due time the vision of that eye was tested he recognized the hand at once, but Dr. Moreau believes that this was because he had become accustomed to have the hand shown to him, so that he rather guessed than saw what it was. Bilateral vision did not really improve his answers; in each case he had to touch the object before he could recognize it. Examination of the fundi showed the absence of any lesion, and the pupils moved quite freely. He soon learnt to recognize colours, and even slight difference of tint. It is well known that contrasted colours on the same plane may in certain circumstances appear to be on different planes—for example, in a red pattern on a blue ground the red may seem in front of the blue; this illusion is particularly marked in some old stained glass. Dr. Moreau tested his patient on this point, but the results were negative, as the boy could always tell which colour was the nearer to him. His first acquirement was the recognition of the degree of illumination of objects; next he distinguished their colours, and could say whether an object was red or yellow. It was not easy for him to recognize the relative size of objects, but this, Dr. Moreau points out, is a difficulty all children have to learn by experience to overcome. He could find his way about the ward with his hands tied, but in the courtyard of the hospital he lost his way unless he was allowed to feel; this was attributed to lack of any visual memory of the landmarks. He learnt to count very quickly, but he could not make out the numbers of dominoes very well, probably because nystagmus and strabismus prevented his fixing the dots clearly. Dr. Moreau divided the two internal recti, which improved both conditions, but did not cure them completely. One night he was taken on to a verandah on the first floor opening on a garden 60 or 80 metres long. The verandah was lighted by three arc lamps with round glass shades, which were at a lower level, one on the left and two on the right; the moon, which was very clear, helped to light the verandah. When the child arrived on the verandah he believed that it was covered with snow; he stooped to pick it up and was disappointed

to find none; he took the moon for an arc lamp, and thought it was quite near to him. An attempt was made to teach him to read, and he succeeded in learning to read letters 1 cm. long, but at this stage he was taken away by his family, and his instruction ceased. Two years later Dr. Moreau went to see the boy, taking with him most of the objects which had served for education in hospital. He did not know Dr. Moreau nor could he recognize the cube which he had often seen at the hospital. He had lost the notions of square and round. He recognized the colours of playing cards but could not distinguish the suits as he had formerly been able to do. Dr. Moreau concludes that it is evidently wrong to believe that a person born blind can at once see the external world after a successful operation. Though the eyes have been rendered capable of perceiving, the utilization of this ability which constitutes the act of vision must be acquired; the operation merely prepares the way for education which is the principal factor; the occipital lobes can register and preserve visual impressions only as the result of apprenticeship and of methodical training. The education must be continued for a long time with untiring perseverance, for if it is interrupted the result is not merely to leave matters stationary but to allow those visual perceptions already acquired to be forgotten. The observations in this case are extremely interesting. They are strictly in accord with knowledge of the development of other functions. They may help to dissipate certain popular notions which have overlooked the fact that it is not solely the optical instrument but the visual centres which are essential for vision, and that for the recognition of external objects long training of these centres is necessary.

SPINAL ANALGESIA.

SPINAL analgesia is not yet so thoroughly established in favour as many of its advocates would like. As in many other novel procedures, enthusiasm in its use outran discretion, and accidents of varying severity forced many surgeons back on inhalation anaesthesia for routine work. But almost every one grants that there are many occasions when this method of abolishing pain appears to be the best, and spinal analgesia may be said to hold a definite and possibly an enduring place. The records of surgeons whose experience is extensive are therefore very valuable. Dr. William S. Bainbridge has published a brief summary of his personal experience in 1,055 cases.¹ He points out that three general classes of solutions have been evolved: (1) Those of specific weight lighter than cerebro-spinal fluid—Babcock's "diffusible" solution made with alcohol belongs to this class; (2) those of approximately equal weight—solutions in water or normal saline; (3) the "non-diffusible" solutions rendered heavier than cerebro-spinal fluid by the addition of glucose or other such substances. The solutions of the second class are those generally employed, and stovaine or tropacocaine is usually the analgesic agent. Among all these cases there were no accompanying or post-operative symptoms of permanent or serious moment save in seven cases. There were two deaths, one surmised to be due to status lymphaticus and the other not thought to be brought about by stovaine poisoning. The second death occurred unfortunately at a demonstration to the Clinical Congress of Surgeons of North America in New York in November, 1912, and apparently raised some questionings, as a coroner's inquiry followed. The jury found that the man did not die of stovaine poisoning, but that death was caused by "pathological conditions," some of which were known before operation—atheroma, chronic nephritis, hepatic enlargement, stenosis of the aortic valve, and emphysema. We have some difficulty in understanding why operation for "inguinal hernia at times irreducible causing great

¹ *La Semaine Médicale* (No. 13, 1913), from the *Loire Médicale*, January and February, 1913.

¹ *Journal of the American Medical Association*, vol. lix, p. 1855.

suffering" was thought of at all in such a bad patient, even though he was insistent. In the remaining five failures temporary partial paralysis followed by complete recovery occurred in one, no cerebro-fluid could be found in one, in two cases there was considerable respiratory depression, and there was one case of idiosyncrasy in which repeated punctures failed to produce analgesia. In Dr. Bainbridge's view the real objections to the procedure are that the operator cannot recall the dose, he is committed to it, and that in prolonged operations the analgesic effect may pass off before the surgeon's work is finished.

DR. FRIEDMANN'S TREATMENT OF TUBERCULOSIS.

THE turtle serum vaccine for tuberculosis introduced by Dr. F. F. Friedmann, and described by him in a paper published in the *Berliner klinische Wochenschrift* of November 18th, of which an account was given in the *BRITISH MEDICAL JOURNAL* of December 7th, 1912, is being investigated in the United States, where Dr. Friedmann now is. We are informed that his colleague, Dr. Piorowski is at present in London. We learn from the *New York Medical Journal* of March 29th that the following statement has been made by the United States Public Health Service regarding its investigation of the Friedmann treatment for tuberculosis. On March 8th the Secretary of the Treasury, on the recommendation of the Surgeon General, caused a board of medical officers to be detailed to make a thorough investigation of Dr. Friedmann's alleged cure for tuberculosis. These officers proceeded immediately to New York, and arranged with Dr. Friedmann for demonstrations of his remedy upon persons suffering from tuberculosis. These demonstrations are being carried on in certain New York hospitals through the courtesy of their respective authorities, and will be continued until sufficient information has been obtained for the forming of an opinion as to the merits of the treatment. Dr. Friedmann has submitted to the board a culture of the bacteria which, he states, are used in his method of treatment. In addition to the observation of persons under treatment by Dr. Friedmann, the board of officers will make experiments to ascertain whether this culture is, as Dr. Friedmann asserts, harmless to warm-blooded animals. Considerable time will necessarily be required to carry out these investigations, and in the meantime the public is advised that tuberculous patients should not travel long distances in the hope of receiving the treatment. Those to whom it is administered for demonstration purposes are selected by the hospital authorities from among their patients, the number selected constituting only a small proportion of available volunteers. Certain statements purporting to be expressions of the opinion of the board of officers of the public health service carrying on the investigations have appeared in the newspapers. These officers have expressed no opinion, and will not be in a position to do so until the work has advanced sufficiently far to warrant some conclusion in regard to Dr. Friedmann's treatment.

SOUTH AFRICAN INSTITUTE FOR MEDICAL RESEARCH.

AN Institute for Medical Research in South Africa is being established at Johannesburg on the southern portion of the ground lying to the west of the general hospital and to the south of the fort. There has hitherto been no medical research institute in South Africa. A Veterinary Institute was erected and equipped by the Government some time ago at Durborg, eight miles from Pretoria, but though the need for a medical research institute has been pressed by members of the medical profession, financial objections have prevented any forward movement. Recently, however, the Government and the leaders of the mining industry

collaborated, with the result that generosity on both sides has provided not alone for the building and equipment but also its maintenance. The new institute at Johannesburg is to serve the whole of South Africa and will be called the South African Institute for Medical Research. The industrial diseases of the Transvaal will probably first call for consideration, owing to the mortality which they have occasioned, but the work will not be limited to these diseases, and it is hoped to attract skilled workers from Europe to aid the director in his researches: it is probable that research fellowships will be available for suitably qualified medical men desirous to carry out special lines of research. The proximity of the institute to the general hospital, which is the largest in South Africa, and the fact that it will be equipped with four wards, with twenty or thirty beds for the treatment of patients, will serve to associate the institute with medical work in Johannesburg. When the institute is in full working order, it is probable that courses in bacteriology and pathology will be arranged for medical students. Two appointments have already been made to the staff. The director of the institute is Dr. Watkins-Pitchford, and the statistician, Dr. G. D. Maynard. Dr. Watkins-Pitchford was formerly House-Physician to St. Thomas's Hospital, London; he studied plague in India, enteric fever in South Africa during the war, and small-pox in London. For the last ten years he has been Government Pathologist and Analyst for Natal, and last year was transferred by the Union Government to Johannesburg. Dr. Maynard was formerly M.O.H. for the suburbs of Pretoria, and subsequently Assistant Medical Officer to the Witwatersrand Association. It is expected that the building will be completed in about a year.

THE PATHOLOGICAL MUSEUM OF THE ANNUAL MEETINGS.

THE pathological museum is always a very interesting and instructive part of the annual meetings of the British Medical Association. Such a museum is being organized in connexion with the annual meeting in Brighton next July. The committee appointed for the purpose intends to arrange the material under four heads: (1) Exhibits bearing on discussions and papers in the various Sections, and in this respect invites the co-operation of secretaries of Sections; (2) specimens and illustrations relating to any recent research work; (3) instruments relating to clinical diagnosis and pathological investigation; (4) individual specimens of special interest, or a series illustrating some special subject. It is also proposed to bring together series of exhibits relating to neurology, and to heredity and mental and physical deterioration, and a series of x-ray and other photographs. While making this general plan the Committee is none the less anxious to receive specimens falling under Class 4 above. The museum will be established in a central position in the same building as that in which the Sections will meet, and will be easy of access. The honorary secretary of the Committee is Dr. H. Miller Galt, Pathologist to the Stephen Ralli Memorial Laboratory at the Royal Sussex County Hospital, Brighton.

DR. W. W. KLEN, of Philadelphia, has interested himself in the Lister Memorial Fund, and has already received subscriptions in response to an appeal to the medical profession in America.

SIR JAMES PORTER, K.C.B., who has been Director-General of the Medical Department, R.N., since 1903, will be succeeded on May 11th by Surgeon-General Arthur William May, R.N., who was Deputy Director General from 1905 to 1909.

DR. A. J. CHALMERS, D.P.H., late of Ceylon, to whose work in connexion with the etiology of pellagra we have recently had opportunities of calling attention, has been appointed director of the Wellcome Research Laboratories at Khartoum, in succession to Dr. Andrew Balfour, who has been appointed director in chief of the Wellcome Bureau of Scientific Research, which has its head quarters in London.

Medical Notes in Parliament.

[FROM OUR LOBBY CORRESPONDENT.]

Ventilation of the House of Commons.—On the vote for the House of Parliament Buildings and the Civil Service Estimates, on Thursday, April 3rd, a discussion took place on the ventilation of the House.

Mr. Mildmay complained especially of the air in the House of Commons itself, and objected to its being pumped up through the gratings in the floor and under the seats. He stated that during the Home Rule debates in the cold weather, he had been accustomed to bring in a rug so as to block up the holes near his feet, as it made his legs and feet cold.

Sir Frederick Banbury supported Mr. Mildmay in this complaint, and said that the effect of the ventilation, so far as the seat on which he was accustomed to sit was concerned, was to make the members' feet cold and their heads hot, which, he pointed out, was precisely opposite to what was desirable in the interests of debate.

Dr. Addison complained of the depressing effect of the air in the House, and passages, and libraries, and stated that sometimes members seemed to be surrounded with a sort of warm-air blanket. By the courtesy of the Speaker and the Commissioner of Works, Dr. Leonard Hill, F.R.S., had been permitted two days before, in company with the engineer, to make some observations on different parts of the House as to the rate of cooling. He had used a metre consisting of half a litre of water at the temperature of 104° surrounded by wet stockinette, kept wet by a wick leading from a graduated tube of water. Dr. Hill stated that in an ordinary comfortable room the fall of temperature from 100° to 97° F. in such an apparatus would take from three and a half to four minutes. The readings taken in the House were as follows:

Under the Gallery:

No. 1, 4.38 minutes; No. 2, 4.28 minutes.

Under Special Gallery:

No. 1, 4.50 minutes; No. 2, 4.30 minutes.

Library (centre table—window had been open at the bottom and there was a big fire):

No. 1, 4.35 minutes; No. 2, 4.15 minutes.

In the Lobby (beside the Telegraph Office):

No. 1, 4.30 minutes; No. 2, 4.10 minutes.

Dr. Addison pointed out that these observations yielded on an average of 4 min. 32 sec., which was an increase in time of nearly 20 per cent. on the average for a comfortable room. He expressed no opinion of his own as to the significance of these results, but hoped that a committee might be appointed to inquire into the whole subject.

Sir Philip Magnus supported the complaints against the ventilation and complained of the odours introduced into the House from the inlet-shaft at the river level when barges laden with offensive matters were passing along the front.

Captain Pirie condemned the ventilation in very vigorous terms, especially with respect to the dining-rooms.

Mr. Wedgwood Benn, in reply for the First Commissioner of Works, pointed out that some of the difficulty arose owing to different members having very different impressions as to what constituted comfort. He thought, however, that the air was not too stagnant. The Chamber itself was ventilated from the floor to the ceiling and the air within it was changed every few minutes by the exhaust fans in the ceiling; and he pointed out that if members insisted on opening the upper windows they would produce an air lock in the lower part of the Chamber. He explained the general system of filtering and warming the air, and reminded the House that his department had had the most careful guidance from

Dr. Gordon in arranging these matters, and that the whole system had been improved at great expense. He stated, in conclusion, that the First Commissioner was quite willing, if members desired it, to appoint a committee to inquire into the subject.

Accommodation in Elementary Schools.—In reply to Mr. King, who stated that over 25 per cent. of the schools in the Birmingham areas were overcrowded, Mr. Pease said that the Board of Education had proposals before it involving the provision of 6,000 additional places. In reply to a further question from Mr. King, Mr. Pease stated that 5,680 additional places had been arranged for in Warrington, of which 1,260 had already been provided. He also stated that proposals were under consideration for the provision of additional places in Manchester.

Insanitary Houses.—In reply to Mr. Douglas Hall, who inquired whether legislation could not be introduced to alter the closing orders of the Housing and Town Planning Act, so that a demolition order need not compel an owner of condemned property to raze the dwelling to the ground without the option of being able to turn it into uses other than that of human habitation, Mr. Burns replied that the matter had been brought to his notice on several occasions, and that he hoped to have an opportunity of suggesting an amendment of the Act of 1909 to meet the difficulty.

Pharmacy Registrations.—In reply to Mr. Charles Bathurst, who said that the Pharmaceutical Society had not taken any steps to make by-laws under Section 4 (b) of the Poisons and Pharmacy Act, 1908, providing for the registration under the Acts of 1852 and 1868 of certified assistants to apothecaries under the Apothecaries Act of 1815, Mr. McKenna stated that the matter was receiving the attention of the Privy Council Office.

Small-Pox.

H.M.S. Conqueror.—In reply to Mr. Bentham, Dr. Macnamara stated that three men only out of a complement of over 700 had been infected with the modified form of small-pox, and he could not undertake to recommend any relaxation of the regulations with respect to the vaccination of men employed in the navy.

Small-pox Hospitals.—In reply to Mr. Wardle, Mr. McKinnon Wood stated that the Scottish Local Government Board was of opinion that the small-pox hospital at Kirkealdy might be a source of infection, and that communications were taking place with a view to other arrangements being made for the reception of small-pox patient.

Town-planning Schemes.—In reply to Mr. Rowlands, Mr. Burns named four schemes which had been approved, and gave the names of boroughs or districts for which in thirty-three cases authority had been given to prepare schemes. In addition, eleven schemes were before the Board, and he was aware of 120 other cases in which the question of schemes was under consideration.

Suffrage Prisoners: Forcible Feeding.—In reply to Mr. Keir Hardie, Mr. McKenna said that during 1912 there were 240 suffrage prisoners, 57 of whom were forcibly fed, and 23 of these were released for reasons of health. Since the beginning of 1913 there had been 70 prisoners, 10 of whom were being and had been forcibly fed, and 3 of these had been released for reasons of health.

Cost of Pensions, Insurance, and Labour Exchanges.—In reply to Mr. Leach, the Chancellor of the Exchequer said that the amount on the Votes for these services for 1913-14 was £21,239,847.

Pure Food.—In reply to Sir John Lonsdale, Mr. Burns said that he was disposed to deal with bread when the Milk Bill was well on its way.

Milk Legislation.

There are three bills before Parliament which deal with milk or milk products, and it may be convenient to give a summary of each of them.

The English and Scottish bills deal generally with the

supply, distribution, and sale of milk, whilst the Irish bill is mainly limited to milk products as used for the manufacture of butter.

MILK AND DAIRIES BILL (ENGLAND).

Clause 1 provides that no person may carry on the trade of a dairyman in any dairy, unless he and the dairy are registered.

Definitions.

The expression "dairy" is defined in Clause 26 as including any farm, farmhouse, cowshed, milk store, milk shop, or other place from which milk is supplied, or in which, for the purposes of the sale or manufacture of butter or cheese, milk is kept or used. It does not include a shop in which milk is not supplied otherwise than in the closed receptacles in which it was delivered to the shop, or any shop in which the milk is sold for consumption on the premises only. The expression "dairyman" includes any occupier of a "dairy," any cow-keeper or purveyor of milk. Where the purveyor of milk does not occupy any premises for the sale of milk, Clause 1 provides that the place where he keeps the vessels he uses shall be deemed to be the dairy. The dairy and the dairyman are to be registered with the sanitary authority and the expression "sanitary authority" in London under Clauses 26 and 27 means the sanitary authority for the purposes of the Public Health Act, 1891, and elsewhere it means the District Council or the County Borough Council.

Powers of County Council.

It will be seen, therefore, that the authorities outside county boroughs are not the councils of the counties, although many responsibilities and duties are delegated to them and their officers. Under Clause 11, for example, the council of a county may exercise the powers and duties conferred under this Act in a rural district and "with the consent of the sanitary authority" in any other district. Under Clause 20, where a complaint has been made to the council of a county, either by any four inhabitant householders in the district, or by the parish council or parish meeting of any parish within it, or by the sanitary authority of any district within which milk is supplied from any dairy in the county district, or by the medical officer for the county himself, to the effect that the council of any county district has failed to carry out its duties under this Act, the County Council may order a public local inquiry and may resolve that the powers of the council of the district shall be transferred to the County Council.

It will therefore be seen that county councils may, in case of default, supersede such existing sanitary authority, and considerable responsibility in connexion therewith is thrown on the county medical officer.

Registration.

The second part of Clause 1 sets out the grounds on which a sanitary authority may remove a dairy from the register or refuse to register one, and the right of appeal to a court of summary jurisdiction against any refusal is secured to the dairyman, and, if required by him, the sanitary authority must state the grounds of its refusal.

Inspection.

Clause 2 deals with the inspection of dairies, and Sub-section (2) gives power to an authority where the M.O.H. has reason to suspect that infectious disease is caused or likely to be caused by the consumption of milk supplied from an area which is outside his own district. In such a case notice is to be given to the medical officer of a county in the case of a rural district and in other cases to the M.O.H. of the sanitary authority, and such M.O.H. is required to inspect the dairy from which the milk is supplied and the persons employed therein; and also, if necessary, the cattle—in which case he is to be accompanied by a veterinary inspector or by some other properly qualified veterinary surgeon.

Special reference is also provided in this clause for the taking of samples of milk from suspected individual cows.

Clause 3 deals with the procedure in cases where the medical officer is of opinion that the infectious disease is caused or likely to be caused by the milk supplied from a dairy.

It will be noticed that this provision applies only to milk likely "to cause infectious disease," and the expression "infectious disease" is defined in Clause 26 as

meaning any of various specific diseases there mentioned, and any other disease prescribed by an order made by the Local Government Board.

Unclean Milk.

It is not clear whether milk that is unclean without specific infection is included; but under Clause 15 the Local Government Board is given wide powers with respect to the issuing of orders, amongst them being orders which have reference to the prevention of impurities of milk intended for human consumption and the cleanliness of vessels used for or containing such milk, and for the protection of milk against infection or contamination.

Sale of Milk.

Clause 4 details the powers of sanitary authorities to make orders prohibiting the supply of milk from any dairy or dairyman.

Clause 5 requires that reports are to be furnished to the M.O.H. who gives the notice.

Penalties.

Clauses 6 to 9 deal with penalties. Under Clause 9 a dairyman is entitled to recover compensation in the case where a prohibiting order is made without due cause—disputes as to compensation being settled as provided in the Public Health Act, 1875—but Clause 25 provides that where a dairyman is charged with an offence, he shall be entitled to lay information against any other person whom he charges as the actual offender, and if he shows that he has exercised due diligence and that such person has committed the offence without his knowledge or connivance, proceedings may be taken and a conviction obtained against such other person.

In this connexion Clause 17 provides that a warranty or invoice supplied to a dairyman under the Sale of Food and Drugs Act shall not be a defence to any proceedings in respect of milk.

Tuberculous Milk.

Clause 12 relates to the sale of tuberculous milk and the imposition of penalties.

Taking of Samples.

Under Clause 13 an inspector of the Local Government Board or the M.O.H. of a county or sanitary district may take samples of milk for examination at any time before it is delivered to the consumer, provided that the powers of the medical officer of health or a person authorized by him shall be exercised only within the county or district for which he acts, except as otherwise may be directed by the Local Government Board.

Bacteriologist and Veterinary Inspector.

Clause 14 provides that the council or any county or sanitary authority or a combination of such authorities may and, when required by the Local Government Board, shall, appoint veterinary inspectors and employ a bacteriologist.

Powers of Local Government Board.

Clause 15 details the very wide and important powers which may be exercised by the Local Government Board in respect of the Act.

Where alterations or improvements are ordered to be undertaken in any premises, Clause 16 provides for the expenses incurred and the apportionment of them between the landlord and tenant under various conditions, the determination of disputes being settled by an arbitrator or by a court of summary jurisdiction.

Under Clause 18 the Local Government Board may make regulations with respect to imported milk intended for human consumption.

Milk for Infants.

Under Clause 19 the authority of any district, other than a rural district, with a population of 50,000 or upwards, is given power to maintain dépôts for the sale of milk specially prepared for consumption by infants under 2 years of age, the Local Government Board being empowered to make regulations for carrying the section into effect.

Other clauses deal with the holding of local inquiries, the serving of notices, the defrayment of expenses, and similar matters.

MILK AND DAIRIES (SCOTLAND) BILL.

This bill approaches the question in some respects from a point of view different from that of the English bill.

The definitions are approximately the same, and are contained in Clause 2.

Inspection.

Under Clause 3 every local authority may and, when required by the Local Government Board shall, appoint a member of the Royal College of Veterinary Surgeons to act as inspector under the Act, and he shall not engage in private practice in any district in which he holds office, save with the consent of the Board. Two or more authorities may combine in appointing such an inspector, and he shall not be removable from office except by and with the consent of the Board.

Clause 3 provides that it shall be the duty of the veterinary inspector at least once in every year to inspect the cattle in every dairy in the district and to report the result of such inspection, and, under Clause 19, he is at liberty to apply to any cow the tuberculin or any other reasonable test for the purpose of discovering if the cow is suffering from tuberculosis, but the test shall not be applied except with the previous consent in writing of the owner of the cow.

Under Clause 4 it is provided that it shall be the duty of the M.O.H., or the sanitary inspector, or any other duly authorized officer from time to time, and at least once a year, to inspect every dairy in the district and to report the result of the inspection. Subsection (3) of this clause also provides that the M.O.H., sanitary inspector, or veterinary inspector may inspect any dairy in any district from which milk is consigned to the district of the local authority.

Registration.

Clause 5 provides that no person shall carry on the trade of a dairyman unless the dairy is duly registered, and Subsection (6) of this clause gives the local authority power to refuse to grant a certificate of registration or to revoke such a certificate if not only the premises but "the person is or becomes unsuitable to carry on the trade of a dairyman."

In this connexion also Clauses 12, 13, 14, and 15 give very important powers to the medical officers of health and to other authorities in connexion with the supervision of persons employed in or about dairies.

Infectious Disease in Dairymen.

By Clause 12 a dairyman is required to acquaint the medical officer of health with the fact that any person either residing on the dairy or employed in connexion with it is suspected as suffering from any infectious disease, and, if such cases are discovered, the medical officer of health is required to inform the medical officer of health of the district to which the milk is consigned if it is outside his own area.

Clause 14 declares it unlawful for any person suffering from or showing symptoms of infectious disease, or suffering from any suppurating sore, or sore throat, or diarrhoea, to milk cows or to handle milk vessels, or to take any part in the conduct of the dairy, and it shall not be lawful for a dairyman to allow any such person to do so.

Clause 15 also empowers medical officers of health to examine the persons employed in or about dairies, where cases of infectious disease or any illness attributable to milk have been discovered; and Subsection (2) enables inquiries to be undertaken on the notice given by any medical officer of health to the medical officer of a district outside his own, from which suspected milk is supplied.

Provisions also are inserted for the decision of cases where a grievance is alleged on appeal in a summary manner to a sheriff having jurisdiction in the district and for providing compensation to dairymen where the claim is established.

By-laws.

Under Clause 6 it is the duty of the local authority to make by-laws for their district providing for the inspection of cattle in dairies, the structure, lighting, cleaning, etc., of dairies and their appliances, for the prevention of impurities in milk, and for securing the cleanliness and health of cows and the cleanliness of the persons attending to them, and for prescribing precautions to be taken by the dairy against the infection or contamination of milk. It will be noticed that here it is the local authority that makes the by-laws, and not the Local Government Board, as in England. Such by-laws, however, in respect of the

structure, lighting, and other provisions of the dairy are not applicable to dairies where the dairyman only sells the milk in small quantities or for their own consumption or to persons in his employment or to neighbours.

By-laws of the local authorities must be confirmed by the Local Government Board after consultation with the Board of Agriculture.

In connexion, further, with the spread of infectious diseases, the dairyman may be required to furnish to the authority a complete list of the names and addresses of his customers.

Clause 17 gives the officers of the different authorities power to obtain samples of material for the purposes of bacteriological examination. As in the English bill, a local authority may appoint a committee to exercise its powers under the Act.

Powers of Local Government Board.

Under Clause 7 it is the duty of the local authority to carry out the provisions of the Act, and under Clause 8, in the case of a local authority failing to perform the duties imposed upon them, power is given to the Local Government Board by summary petition to obtain direction "to do therein and to dispose of the expenses of the proceedings as to the said division or Lord Ordinary shall appear to be just."

Similar action may be taken by the Board in Clause 9 on the request of a local authority which is receiving milk from the area of an authority stated to be neglecting its duty.

Clause 10 sets out the subjects upon which the Board itself will make regulations. They are mainly concerned with the cooling of milk, with the measures directed to protect it against infection, contamination, and adulteration, and the manner of its conveyance and identification.

Milk for Infants.

Similarly, as in the English bill, a local authority, without in this case any distinction of the population in its area, may establish and maintain dépôts for the supply of infants' milk.

The remainder of the clauses of the bill deal mainly with matters of machinery.

IRISH CREAMERIES AND DAIRY PRODUCE BILL.

The purpose of this bill is to secure the registration of creameries and of cream-separating stations, and to secure better supervision of the manufacture and sale of Irish dairy produce.

Registration.

Premises are not required to be registered as creameries unless in the ordinary course of business the amount of butter manufactured in them on an average day exceeds 55 lb., nor is a cream-separating station required to be registered unless the quantity of cream separated on an average day is sufficient for the manufacture of at least 28 lb. of butter.

Clause 4 sets out the conditions with respect to cleanliness and freedom from contamination of materials and apparatus in registered creameries.

Clause 5 details the conditions under which the manufacture is to be carried on. The cream used in any station must either be separated on the premises by means of centrifugal force mechanically applied or have been supplied from some other registered creamery or separating station.

Clause 8 sets out the conditions under which premises may be removed from the register, and Clause 9 details the proceedings which may be taken on refusal of registration or on the removal of a creamery from the list.

Clean Milk.

Clause 12 contains important provisions directed to secure that the milk supplied shall be clean and in clean vessels, and Clause 18 relates to butter that is unclean.

Inspection: Penalties.

Clauses 14 to 17 relate to details of inspection, registration, and offences, and Clause 17 sets out the conditions under which a person carrying on business and charged with an offence becomes exempt from penalty if he shows that some other person is responsible for the fault without his knowledge or consent, and that he himself has exercised due diligence to secure the carrying out of the provisions of the Act.

Scotland.

(FROM OUR SPECIAL CORRESPONDENTS.)

TUBERCULOSIS ADMINISTRATION IN EDINBURGH.

SIR THOMAS HUNTER, the town clerk of Edinburgh, has made an inquiry into the arrangements necessary to be made for the treatment of tuberculosis under the Insurance Act, and has drawn up a report which was considered at a meeting of the Public Health Committee of the Town Council on April 4th. The Committee agreed generally to the report. The new arrangements and appointments considered necessary are as follows. Since the Corporation has agreed to receive insured persons sent by the Insurance Committee for sanatorium treatment into Colinton Hospital, it will be requisite to make arrangements for their treatment there; it is recommended, therefore, that in addition to the permanent staff of nurses and others, the Corporation should continue the present arrangement under which Dr. Alexander James undertakes the medical treatment of the tuberculosis patients upon remuneration at the rate of £300 per annum, which would be in addition to any payment made to him for duties performed by him in connexion with the other work of the hospital. It is further recommended that the Corporation should appoint a thoroughly qualified assistant medical officer of health, to give his whole time to the duties of the office, that he should have special qualifications for dealing with tuberculosis, and that he should be remunerated by a salary of not less than £500 per annum. His services should be placed at the command of the Local Insurance Committee for the purposes connected with sanatorium or other treatment of tuberculosis. It would also be necessary to appoint an inquiry officer to the Public Health Department, at a salary commencing at £150, whose time would be mainly devoted to the work of the Insurance Committee and the applications to them for sanatorium benefit to insured persons. Then it was recommended that the arrangement at present subsisting between the Corporation and the Royal Victoria Dispensary, under which the Corporation contributes £450 per annum in respect of certain benefits received in connexion with the dispensary, should be amended to the effect that the dispensary authorities should undertake to give dispensary treatment to all persons, whether insured or uninsured, sent to the institution by the medical officer of health or the assistant medical officer of health, and that in respect of this the Corporation should pay to the dispensary authorities a sum of, say, £600 per annum, or such other sum as might be arranged. It was recommended, in the next place, that the Corporation should secure the services of a thoroughly qualified consultant—for example, Sir Robert William Philip, M.D.—and arrange with him to act as consulting officer to the Corporation and the Health Insurance Committee in connexion with the prevention or treatment of tuberculosis in all its forms, whether in the case of insured or uninsured persons. The remuneration of such consultant would depend upon the agreement with him; it would probably be not less than £500 per annum. Finally, it was proposed that the Insurance Committee should be asked to contribute to the new expenditure involved, and it was suggested that it should pay one half of the salary of the assistant medical officer of health, a proportion of the £600 payable to the dispensary, a portion of the salary of the inquiry officer, and half of the sum to be paid to the consultant. If these new arrangements were carried through, it would probably be no longer necessary for the Corporation to retain its call on ten beds in the Royal Victoria Hospital, for which it at present pays £500 per annum to the hospital. Obviously these are radical and far-reaching changes, involving considerable additional expense. The recommendations of the Public Health Committee were considered at the meeting of the town council on April 9th, and after discussion were recommended to the Public Health Committee and Treasurers Committee.

In addition to the new salaries and honorariums (amounting to about £1,900) proposed in the town clerk's report to the town council of Edinburgh, it is pointed out by the Chairman of the Edinburgh Insurance

Committee in a memorandum just issued that a large sum of money will be required. The cost of treatment in sanatoriums of, say, 200 patients (insured persons and their dependants) at 25s. a week will be £13,000 a year, the cost of dispensary treatment will be £200, and the cost of additional expenditure applicable to domiciliary treatment will be £800, making £14,000 in all. The sum of money at the disposal of the Insurance Committee for sanatorium and dispensary treatment may be put at £4,000, leaving a sum of estimated surplus expenditure over income of £10,000, whereof one half would have to be guaranteed by the Corporation of Edinburgh and the other half by the Treasury.

HOUSING AND TOWN PLANNING.

A memorandum has been issued by the Local Government Board for Scotland relative to the operation of the Housing, Town Planning, etc., Act, 1909. It states that the Board has during the past three years had every reason to be satisfied with the wide interest shown by local bodies and the public generally in connexion with the administration and execution of the Act.

The records of the work done by local authorities under Part I, dealing with the housing of the working classes, afford ample testimony that greater and better directed efforts are being made for the improvement of housing conditions in Scotland. The first step was to designate officers to perform the duties imposed by the regulations, and practically every local authority in Scotland had now designated an officer or officers. During the past year the annual reports of these officers on the work done during 1911 made it evident that at the date of compilation many local authorities were still engaged making their arrangements, and, wherever it was deemed advisable, the Board communicated with the local authorities and the officers, explaining what was required of them.

Town Planning.

Upon this question the memorandum states as follows:

While the Act has only been in force for three years, the Board has had ample opportunity of noting the deep and widespread interest that is being taken in the subject. Before the passing of the Act the interests of local authorities and landowners in this matter were frequently at variance, to the detriment of the public interest. The Act of 1909, however, endeavours to establish a new relationship between these parties. It contemplates and provides for co-operation between them for their mutual advantage. In fact, it may be said that no town-planning scheme can be entirely successful where it fails to fuse the interests of the local authorities and landowners. It is, indeed, the gratifying experience of the Board that in properly devised schemes landowners are found ready to co-operate. Even indirectly the Act has been instrumental in encouraging landlords to proceed on town-planning lines by adopting better methods of developing their estates without the formalities of town-planning schemes. In further evidence of the widespread interest that is being taken in this movement it is only necessary to refer to the public conferences that are being held at different centres from time to time. These conferences are largely attended by representatives of local authorities and landowners, and by engineers, architects, and surveyors from all parts of the country, and afford an excellent medium for the exposition of the provisions of the Act, and for the discussion of its problems. So far the Board has reason to be gratified at the action taken, and being taken, by local authorities. The progress made is the more remarkable when due allowance is made for the novel character of the Act and the natural reluctance of local authorities to enter upon schemes costing time and money for benefits that may not accrue for some considerable time. Further, the Board feels confident that when the advantages of the Act have been practically demonstrated by the pioneering local authorities others will be encouraged to avail themselves of its provisions.

Provisions for Compensation.

Section 53 provides for compensation being paid to persons whose property is injuriously affected by a scheme, provided that a claim is made within a prescribed time after notice of the approval of the scheme has been published. But a person is not entitled to compensation on account of any building erected on, or contract made, or other thing done with respect to land included in the scheme (1) after the time at which the application for authority to prepare the scheme was made, or (2) after such other time as the Local Government Board may fix for the purpose. It will be seen that under (2) the Board has power to fix an earlier date than that of application,

and in several instances it has done so at the request of the local authorities. The object and effect of the above limitations in the matter of compensation are to prevent undesirable development during the preparation of a scheme. But at the same time the Board recognizes that, until the provisions of any scheme are known, legitimate development is also arrested, and it is its endeavour to minimize that as far as possible. Accordingly, in fixing a date, it is careful to require the authority to make application within a prescribed period. Further, it does all in its power to facilitate and expedite the preparation and completion of schemes, so that as little hardship as possible may be imposed on private enterprise.

Proposals for Schemes.

Under Section 54 of the Act, the Board (1) may authorize a local authority to prepare a town-planning scheme with reference to any land within or in the neighbourhood of the area, if the authority satisfy the Board that there is a *prima facie* case for making such a scheme, or (2) may authorize a local authority to adopt, with or without any modifications, any such scheme proposed by all or any of the owners of any land with respect to which the local authority might itself have been authorized to prepare a scheme. The section also provides that a town-planning scheme prepared or adopted by a local authority shall not have effect unless it is approved by order of the Board. There are thus two distinct stages in connexion with a scheme: (1) Authority to prepare, and (2) approval after preparation. Town-planning schemes submitted (but not yet authorized) from burghal and landward local authorities at Dunfermline, Inverkeithing, Dundee, and Edinburgh comprise a total area of 6,420 acres.

MILK AND DAIRIES BILL FOR SCOTLAND.

A good many medical men in Edinburgh are scanning with interest the various clauses of the Milk and Dairies Bill (Scotland) which has just been introduced into the House of Commons. It is more than twenty years ago that Dr. Sims Woodhead gave his lecture in Edinburgh on what he had seen in Denmark of the inspection of dairies and the hygiene of cows; and it is felt to be no great credit to Scotland that it is only now approaching the standard which then existed in Copenhagen. Many children who are tuberculous to-day would in all probability be healthy had some such measure as that now proposed been passed years ago. It is to be hoped that before long we shall have something like the *goutte de lait* system of France for the safeguarding of the milk supply of young children and infants. A few *dépôts* for the supply of milk especially prepared for infants exist in Edinburgh and Leith, but their number is held to be insufficient. The bill will facilitate their institution.

THE VICTORIA INFIRMARY, GLASGOW.

The managers of the Victoria Infirmary have appointed Dr. Ivy Mackenzie to the medical wards left vacant by the retirement of Dr. Love. It is in many ways an interesting appointment. Dr. Mackenzie has in a short time made so great a reputation as a scientific investigator of disease that great things are hoped from his use of the clinical opportunities afforded him at such an early stage in his career.

EDINBURGH HOSPITAL FOR WOMEN AND CHILDREN.

At a recent meeting of the executive committee of the hospital the appointment of Dr. Janet Mowat as dispensary medical officer, in place of Mrs. Barnettson, M.B., Ch.B., resigned, was confirmed.

Ireland.

[FROM OUR SPECIAL CORRESPONDENTS.]

IRISH EMIGRATION FOR THE LAST SIXTY YEARS.

The collection of emigration returns for Ireland began on May 1st, 1851. The total number of emigrants—natives of Ireland—who left Irish ports from that date to the end of December, 1912, amounted in the aggregate to 4,247,360—a figure which is within about 150,000 of the present

population of Ireland. During 1912, 29,344 natives of Ireland left the country; this is equivalent to a rate of 6.7 per 1,000 of the population, and shows a decrease of 1,229 as compared with the year 1911. The largest number of emigrants for any year of the period 1852 to 1912 was 190,322 in the year 1852, representing a rate of 30.0 per 1,000 of the population; and the lowest number was 23,295 (or 5.3 per 1,000) in the year 1908. The importance of this emigration in draining the country of those in the prime of life is shown by the fact that 85.9 per cent. of the persons who left Ireland last year were between the ages of 15 to 35, and as far back as the records go the percentage of emigrants between these ages has always been over 80, and has been as high as 86.9. Of the 14,569 males aged 15 years and upwards 63.9 per cent. were returned as "labourers," and of the 12,946 females of 15 years and upwards 71.5 per cent. were returned as "servants." During the last few years there has been a slight reduction in the numbers going to America, and an increase in the numbers going to the Colonies.

ROYAL VICTORIA HOSPITAL, BELFAST.

At the one hundred and twentieth meeting of this institution, held on March 26th, the Marquis of Londonderry, K.G., President of the Hospital, occupied the chair, and there was a large attendance. Dr. McKisack (for Dr. R. J. Johnstone, Honorary Secretary) moved the adoption of the report of the medical and surgical staff, which stated that there had been a total of 3,547 intern patients; the medical patients had slightly decreased, the surgical had increased; the work had been done at full pressure, and on many occasions the number of beds was insufficient. The hope was expressed that the erection of the new "King Edward VII Memorial Block" would soon be proceeded with; the total amount of subscriptions to the building fund promised was now £17,599, and of this about £16,000 had been collected. The financial statement for the year showed an excess of expenditure over receipts of £22, a very small sum in an annual expenditure of over £16,000; subscriptions had fallen off both from the general subscribers and from employees, and the hospital was faced with the statement that subscriptions in future from both these sources would be reduced or withdrawn altogether.

HEALTH OF BELFAST.

At the monthly meeting of the City Council on April 1st the Medical Officer of Health (Dr. Bailie) returned the death-rate as 23.9, which is higher than that of the preceding four weeks, and than that of the corresponding period of last year. Pulmonary complaints had been very prevalent. The chairman of the Public Health Committee (Dr. Thomson) said that a scheme for the treatment of tuberculosis applicable to the whole community had been prepared; the only thing that remained to be done in connexion with the scheme was to interview the Poor Law guardians as to taking over the Abbey Sanatorium, and to call a special meeting of the whole council to consider the proposals.

OUTBREAK OF DIPHTHERIA AT BOOTERSTOWN.

A serious outbreak of diphtheria has occurred at Booterstown, a few miles from Dublin. Some 15 or 16 cases have been notified, most of them in the Blackrock area, but some cases have also been reported from Stillorgan. At the last meeting of the Blackrock Urban Council the Town Clerk said that the outbreak was caused by the consumption of contaminated milk. The cases were entirely confined to those who consumed the milk and as soon as that became known the sale or consumption of the milk had been stopped. The cause of the contamination had not been discovered, but the matter was being investigated by Dr. Browne, Medical Inspector of the Local Government Board, and Dr. J. W. Boyce, Medical Officer of Health for the district. Four deaths, certified as diphtheria, have occurred in the district up to the present time. Dr. Boyce stated that there had not been a fresh case for some days, the last case being one of contact, not a primary one. The diphtheria mortality-rate in Ireland is habitually highest in the March quarter. For the December quarter, 1912, the total deaths from diphtheria were considerably below the average.

England and Wales.

BIRMINGHAM.

PRESENTATION TO DR. LLOYD-OWEN.

At a meeting of the board of management of the General Hospital on April 4th an illuminated address was presented to Dr. Lloyd-Owen on his retirement from the post of honorary ophthalmic surgeon. The address, which was inscribed on specially prepared vellum in Florentine style of ornamentation, was as follows:

To David Charles Lloyd-Owen, M.D., F.R.C.S.I.,
Honorary Consulting Ophthalmic Surgeon to the
General Hospital, Birmingham, 1913.

At a meeting of the board of management of the General Hospital, Birmingham, held on Friday, January 3rd, 1913, Mr. J. B. Clarke in the chair, it was resolved unanimously:

That this board has received with much regret the resignation of Dr. David Charles Lloyd-Owen, and desires to record its high appreciation of the very able and courteous manner in which he has performed the duties of honorary ophthalmic surgeon since his election to that office on September 30th, 1898. That the resignation of Dr. D. C. Lloyd-Owen be accepted with regret, and that in consideration of the eminent services of Dr. D. C. Lloyd-Owen it be recommended to the next annual meeting of the governors that he be appointed honorary consulting ophthalmic surgeon to the hospital.

At the annual meeting of governors Dr. Lloyd-Owen was unanimously elected honorary consulting ophthalmic surgeon.

ST. JOHN AMBULANCE ASSOCIATION.

The St. John Ambulance Association is doing most excellent work in Birmingham, as is shown by the fact that there are between 11,000 and 12,000 certificate holders in the city. A difficulty in giving instruction has, it is reported, arisen owing to the increased amount of work which has fallen upon the doctors as the result of the Insurance Act.

India.

[FROM OUR SPECIAL CORRESPONDENT.]

LUCKNOW MEDICAL COLLEGE.

The professorial appointments on the staff of King George's Medical College at Lucknow have been arranged so far as concerns present requirements. The staff of the college when it opens work in the autumn will be as follows: Principal and Professor of Surgery, Major Selby, F.R.C.S.; Professor of Medicine, Major Sprawson, M.D., M.R.C.P.; Professor of Obstetrics, Lieutenant-Colonel G. T. Birdwood, M.D.; Professor of Pathology, Major H. J. Walton, M.D., F.R.C.S.; Professor of Anatomy, Sahibzada Suiduzzaffer Khan, M.B., D.T.M.; Professor of Physiology, Captain A. E. J. Lister, M.D., F.R.C.S. Of these Major Selby and Major Sprawson have been already attached to the college for some time; the others will join in October.

STRETCHER DRILL AT AGRA MEDICAL SCHOOL.

On the occasion of the annual distribution of prizes at the Agra Medical School, Surgeon-General Sir C. Pardey Lukis, the Director-General of the Indian Medical Service, did not confine his address to the complimentary platitudes which are customary at ceremonies of this kind. It appears that students have been protesting anonymously against various details of college discipline. Even the military students have been infected by the spirit of insubordination, and have objected to stretcher drill as "coolies' work." Sir Pardey Lukis felt called upon publicly to reprove these errors. He pointed out that "the object of stretcher drill is to fit you for the training of stretcher bearers, which will be one of your most important duties when you join your regiments. Every officer of the Royal Army Medical Corps and Indian Medical Service undergoes similar training. Why should you object?" He reminded the grumblers, moreover, that "nothing which conduces to the well-being of his patient is degrading to the medical man." He might have given the axiom an even wider application; for surely

nothing which conduces to the well-being of others is degrading to anybody, whatever his calling may be.

THE WHITE PHOSPHORUS BILL.

The Select Committee of the White Phosphorus Bill, in its report, made only one amendment of any importance. The powers given under Section 6 of forfeiting matches are to be exercised by Presidency magistrates, sub-divisional magistrates, or magistrates of the first class. The Committee was opposed to postponing the date on which the bill should come into operation.

PLAGUE AT JHELUM.

The Deputy Commissioner and the Civil Surgeon have visited the deserted bazaars of the city of Jhelum, impressing on the people the benefits of disinfection and inoculation, but the exodus continues, and it has been suggested that a segregation camp outside the town would prove beneficial. A cordon of military guards is posted on the roads to prevent sepoys from visiting the city, which is being evacuated rapidly.

OPIMUM AND DRUG LICENCES.

The Chief Commissioner of Delhi has issued notifications similar to those of the Punjab Government prohibiting the holders of licences for the vending of opium and hemp drugs from holding directly or indirectly any opium, drug, or spirit licences in a native State.

THE HEALTH OFFICER OF CALCUTTA.

Dr. Pearce, the health officer of the Corporation, has accepted the proposals of the Corporation rendered necessary on account of his ill health, and has resigned his position as from February 17th.

Correspondence.

THE LIMIT OF GROWTH.

SIR,—In your leader on cancer¹ you quote from Dr. Leitch, "All the cellular components of the living body obey laws governing the limits of their reparative or reproductive activity. Why they should cease multiplying when they have fitted into or restored a predestined scheme is quite beyond our knowledge."

This, of course, is true; but may I point out that it is not quite the whole truth? It may be supplemented by the further statement, that the laws which govern at any rate the reparative activities of cells are not quite uniform in different persons. Take the familiar case of the hair. The law which governs the reproduction of this tissue is in all the same to this extent—that there is a certain length, varying with the part of the body and the time of life, to which the hair will grow, and beyond which it cannot be made to grow. However much or little may be cut off any individual hair, that hair will grow to a certain length and no longer; and, however often the operation may be repeated, the result will be the same if time is allowed. It seems as if the root or follicle of the hair knows that the shaft of that hair has been shortened, and starts to make good the lost part of the length; and it seems, moreover, as if the root knows when the deficiency has been made good, and when to cease its reparative activity. How does it know? That it is not by the weight of the hair and its pull on the follicle is evident from the fact that the cut hair of women, which is supported, grows, in the same way as that of men, to a certain fixed limit. The fact I wish to emphasize is that this limit is not the same in men and in women, nor is it the same in all men nor in all women. The fact that the hair of some men grows longer than that of others, and of some women longer than that of others, shows that the "law of reparation or reproduction" is not the same in all. Some time ago a horse was exhibited whose mane was six feet and its tail, I think, eight feet long. Was not this a kind of cancer, or, rather, a link between normal growth and cancer? The hair follicles, it seems, were either ignorant that the hair had attained its normal length, or they forgot to stop, or refused to stop, when they received the signal. The same thing sometimes happens in scars.

¹ BRITISH MEDICAL JOURNAL, APRIL 5th, 1913.

The reparative process goes too far and results in keloid, another half-way house to cancer. The main fact in cancer is that the cells do not cease to divide and proliferate when the normal limit is reached, and their activity should for the time come to an end. We see in the case of the hair and the keloid that what I may term the cessation point varies in different persons. Are not the cancerous those in whom the cessation point is naturally high, and is, perhaps in consequence, exceeded easily, and on small provocation? I may meet the objection that the cancerous are not necessarily long haired or subject to keloid by the fact, which is patent enough, that a high cessation point in one tissue does not necessarily mean a high cessation point in all. Long-haired people are not necessarily tall.—I am, etc.,

Parkstone, April 5th.

CHARLES MERCIER.

DISTILLED WATER VERSUS SALVARSAN IN THE TREATMENT OF SYPHILIS.

SIR.—Dr. Arbour Stephens's article on the above subject in your last issue is of much interest. It occurred to me some time ago that the beneficial effect of salvarsan injections might be due in part, at any rate, to the quantity of water injected. The effect of water on intractable cases of syphilis was pointed out by Mr. A. H. Ward in 1904 in a small book he wrote on syphilis. He mentions the case of a woman with chronic syphilitic ulceration which recurred continually in spite of all kinds of treatment with mercury and iodides, but rapidly healed when three pints of hot water containing only 5 grains of iodide of the pint were given daily. Dr. Stephens recommends 6 to 10 c.c.m. of distilled water given hypodermically. This is not far removed from the amount given in intramuscular injections of salvarsan, but is much less than that given for intravenous injections (about 200 c.c.m.). Whether the hypodermic or intravenous injection of water is better than administration by the mouth is open to question, but taking all the evidence into consideration it would appear that large quantities of water are beneficial in chronic cases of syphilis. This probably has much to do with the effect of the old Litmann's decoction.—I am, etc.,

London, W., April 7th.

C. F. MARSHALL.

SYPHILIS AND CANCER OF THE TONGUE.

SIR.—In your issue of April 5th, Mr. Ryall of the London Cancer Hospital states that cancer of the tongue is preceded by syphilis as an active agent in 80 per cent. of his cases. This statement is confirmed in your leader, in which you say that a positive Wassermann reaction is present in a large proportion of the cases.

For some time past I have had the opportunity of comparing the Wassermann reaction on cancer patients with all stages of syphilitics, and the conclusions I arrived at, stated recently before the Manchester Medical Society, are as follows:

Stomatitis cases of syphilitic origin give a strongly positive Wassermann reaction. In transition cases, with a mouth lesion of any magnitude, a slightly positive Wassermann reaction should be read in the light that either some other disease, such as tuberculosis, has been superadded, or that the disease has progressed to carcinoma.

I may say that very few mouth cases of a cancerous nature passing through the Christie Hospital have given a strongly positive Wassermann reaction. In cases of cancer of the tongue, although I am unable as yet to state absolute percentages, it has been the exception rather than the rule for a positive Wassermann reaction to be obtained. May I ask Mr. Ryall on how many cases the Wassermann reaction was performed, and what was the method employed? My method is one which was kindly shown to me by Mr. J. E. R. McDonagh; and in the malignant cases which have subsequently died, the Wassermann result has agreed with the *post-mortem* findings as carried out by the pathologist, Dr. C. Powell White.—I am, etc.,

ARNOLD RENSHAW,

Honorary Pathologist, Ancoats Hospital;
Pathologist, Manchester and Salford
Skin Hospital; Clinical Pathologist,
Christie Hospital, Manchester.

Manchester, April 7th.

THE NEGLECT OF VACCINATION.

SIR.—Allow me in a short space to reply to Dr. J. W. Papillon's last letter. I have certainly no wish to deprive any one of the right of free vaccination, and when the Vaccination Acts are repealed and the machinery of public vaccination abolished, or at least very much modified, I would suggest that it should be open to any one desiring it to be vaccinated (or revaccinated) by his own medical attendant, who would be entitled to a fee (from the Government or local authority) for each certificate of successful vaccination sent in. Once it is recognized that infantile vaccination, no matter how efficiently it be carried out, cannot be relied upon to protect a community from small-pox, and that the chief value of vaccination is as an emergency operation supplementing other measures, the mere question of the *quality* of the vaccination becomes of so little importance that the medical inspection of vaccination could well be dispensed with. For emergency purposes one or two small marks are probably as good as four large marks, and would meet with less opposition.

This suggestion that the office of public vaccinator should be abolished, and that every medical practitioner should be paid by the State for vaccinating his own patients, was made by Dr. George Rice, I believe, many years ago, but received little attention. It is possible that in the near future it may have to be taken more seriously. Undoubtedly there is much to be said in its favour.

One other point. The 19 outbreaks of small-pox referred to in my last letter represent so many different importations occurring during a period of several years. Many of these outbreaks were confined to the first few cases. It is futile to suggest that the "objectors to vaccination inflicted these outbreaks upon themselves," or that the necessity for small-pox hospitals is the "natural sequel to allowing the objectors to vaccination to practise free trade in small-pox." Surely Dr. Papillon does not think that any large town, no matter how efficiently infantile vaccination be carried out, could safely dispense with its small-pox hospital, or that small-pox hospitals are only required for unvaccinated patients? Even in "unvaccinated" Leicester nearly half the small-pox cases which occur (45 per cent.) are in vaccinated subjects.

Lastly, the talk about the "burden and grievance of maintaining small-pox hospitals and their staffs" is a little overdone. The cost of maintaining empty small-pox hospitals is not a serious matter compared with the cost of universal vaccination. At Leicester the small-pox hospital costs little beyond a coat of paint every few years, and the occasional services of a charwoman.

In conclusion, let me say that if the antivaccinists were to cease from their impossible task of proving that vaccination is a myth and—abandoning a position which, scientifically, is untenable—were to concentrate on the demand for the repeal of the Vaccination Acts on the ground that they are obsolete, irritating and no longer necessary, they would undoubtedly be able to establish such a strong case that it is probable that victory would soon be theirs.

Personally, I should like to see the medical profession anticipating this move of the antivaccinists by itself occupying the ground indicated whilst it can still do so with dignity.—I am, etc.,

Leicester, April 7th.

C. KILICK MILLARD.

ALIMENTARY TOXAEMIA.

SIR.—In reply to Dr. A. W. Gilchrist in the *JOURNAL* of April 5th, who expresses surprise at my statement that oxalic acid may be produced by carbohydrate fermentation in the stomach, I must disclaim any pretension to being a biological chemist, but would refer him to the paper by Miss Helen Baldwin on Oxaluria, in the *Journal of Experimental Medicine*, 1905, and, further, to the discussion in Walker Hall's translation of von Noorden's *Metabolism*, vol. i, p. 149, and vol. iii, p. 1051. I agree that the question is not settled, but I would ask, What is not a matter of controversy in biological chemistry? May I suggest that the reason crystals of oxalate of lime are not found in the microscopical examination of Ewald test breakfasts in cases of achylia is that the contents

are removed at the end of one hour—an interval too short for the results of fermentation to be manifested?—I am, etc.,

Birmingham, April 7th.

ROBERT SAUNDY.

VENTRIFIXATION.

SIR,—In your annotation for the week on this subject in your issue of April 5th (p. 736) you refer to the diversity of opinion which exists among representative gynaecologists upon fundamental points. You then state that Professor Briggs and Dr. Arthur Giles have performed the operation in 1,100 cases "with results that gave them unqualified satisfaction," while Professor Herbert Spencer had only done the operation 27 times in 1,000 abdominal sections. From the statistical point of view you would have emphasized your point much more strongly if you had stated that Dr. Arthur Giles had performed this operation 309 times in 1,000 abdominal sections.¹

With regard to your statement ament "unqualified satisfaction," is not the important point the unqualified satisfaction of the patient rather than of the operator, and can this be said to exist when 5 of Dr. Giles's 309 cases terminated fatally, and 42.2 per cent. of them had pain after the operation, even although 32.5 per cent. were stated to have less pain than before?—I am, etc.,

London, W., April 5th.

HERBERT R. SPENCER.

IMMEDIATE OPERATION IN APPENDICITIS.

SIR,—The opinions of surgeons on this subject have without doubt interested the profession generally, and have caused a large number to think over past cases which might have been saved if an early operation had been undertaken.

I have not yet seen any distinction made between cases of slight and transient attacks of appendicular colic and definite inflammatory attacks of appendicitis, and I do not think it is prudent to group these two conditions together. I admit that it is difficult and often impossible to diagnose simple appendicular colic from a true appendicitis which may be of a fulminating nature requiring operative interference without the slightest delay.

But there are cases seen in private and admitted into our hospitals of slight pain in the right iliac fossa, with few constitutional symptoms and a history of many similar attacks. These are the cases which clear up and can be safely operated on at the so-called interval stage. At the time of operation they present an appendix lying free, with a distorted meso-appendix, a bulbous tip, a thickened, velvety lining of mucous membrane, and often one or more stercoliths. The mortality in this operation is practically nil.

Great assistance in the diagnosis between these simple cases of appendicular colic and true appendicitis may be obtained by a leucocyte count, which can be made within an hour, during which time certain arrangements and preliminaries may be got through. If the leucocytosis is over 10,000 delay is, in my opinion, unjustifiable—pus is there. In some cases—but not in all, and we cannot tell which—general peritonitis will be the condition to cope with if the case is left till the next day, and the patient's chance of recovery is lessened with every hour of delay.

If there is any doubt as regards the diagnosis between simple colic and a true appendicitis there is no risk in an exploratory operation, but there may be grave danger in delay. The profession owes a debt of gratitude to Mr. Edmund Owen and to those surgeons who have upheld his opinions, and I strongly believe that the discussion on Mr. Owen's paper will enable us to get in touch with this common and (from delay) often fatal disease at an earlier stage.—I am, etc.,

Plymouth, April 5th.

GEORGE F. ALDOUS.

RECENT ADVANCES IN THE DIAGNOSIS, PROGNOSIS AND TREATMENT OF HEART DISEASE.

SIR,—The difficulty of explaining the remarkable resemblances between the parallel paragraphs which I cited from my books and Dr. Price's Toronto address, he meets

by the statement that "The whole of the passages quoted by Dr. Lewis, which he insinuates were copied bodily by me from his book, appeared verbatim and in the same order in an address which I gave at the Brighton and Sussex Medico-Chirurgical Society on October 5th, 1911," that is to say some months before my second book *Clinical Disorders* was in circulation. On the other hand, Dr. Price admits that my book *Clinical Disorders* was in his hands late in the summer of 1912; the address at Toronto was delivered on October 8th, 1912 (published March 8th, 1913, in your columns).

The Brighton and Sussex address did not appear in print, and, as is not unnatural after an interval of twelve or eighteen months, none of Dr. Price's supporters, writing in your issue of March 29th, can satisfactorily confirm the identity of the printed paragraphs of the Toronto address with the oral passages of the Brighton and Sussex address. The available evidence is admittedly based upon memory of the language used at lectures delivered at least twelve months previously. Evidence as to the priority of phrases is only of value if it is based upon printed and published matter, because such printed matter is alone available to those concerned. The whole point is that separate quoted paragraphs of the Toronto address and of my writings show an unmistakable resemblance in phraseology and order. The only contemporary published evidence which considerably bears on the substance of Dr. Price's Brighton and Sussex address of October 5th, 1911, is an article of his in your columns of October 7th, 1911, which contains several sentences and paragraphs identical in language with those of the Toronto address, but no trace can be found of the passages to which I especially directed attention, and which appeared to me to have had an origin later than the Brighton and Sussex address.

Further, I would point out that four of my quoted passages were taken from *The Mechanism of the Heart Beat*, appearing, as my publishers tell me, in June, 1911, and several months before the Brighton and Sussex address was delivered. It is quite possible that the passages corresponding to these were delivered verbatim in the address, and that they were heard by Dr. Price's friends. In one of these passages I stated that premature beats may be produced by the injection of digitalis, adrenalin, aconitine, muscarine and physostigmine. These drugs appeared together and by themselves for the first time in my text so far as I can ascertain. They reappear in Dr. Price's text in a similar argument, and again by themselves, though in a slightly different order. I spelt physostigmine incorrectly, so does Dr. Price. My statement only referred to experimental observations on animals. Dr. Price extends it, surely by an oversight, to their administration to patients. These cardiac effects of administering physostigmine and muscarine to the human subject have never been recorded, and, on account of the extremely dangerous properties of the poisons, are unlikely to be recorded.

Any suggestion that the resemblance between Dr. Price's phrases and my own is due to our both having reproduced portions of Dr. Mackenzie's works does not hold good. As a writer on these subjects, I am deeply indebted to Dr. Mackenzie's work and inspiration, but much, however, of the substance of my quoted paragraphs is not to be found in Dr. Mackenzie's books,¹ and although we have both published a thousand pages of printed matter upon cardiac-vascular questions, such resemblances in diction as I have pointed out between Dr. Price's writings and my own (and these all occur in a few pages) are nowhere to be found.—I am, etc.,

London, W., March 29th.

THOMAS LEWIS.

THE PARISH DOCTOR AND HIS OPPORTUNITY.

SIR,—The time seems ripe and opportune for the long-suffering individual known as the parish doctor to assert himself and to improve his position.

¹ More than one of your correspondents has fallen into the curious error of imagining that I claim the whole of the facts in my quoted paragraphs as original discoveries. I make no such claim; certain of the statements of fact are original, but I chose those paragraphs especially which show to Dr. Price's "the closest resemblance in point of diction." There are over 400 named references in my first book, and in the preface of the second book I clearly state my obligations to other writers.

District medical officers are appointed in many districts in London at salaries of £85 a year—that is, little over 5s. a day for an hour's attendance at the dispensary with sundry visits thrown in. No allowance is made for a holiday or payment of locum tenent. The panel doctor receives this sum for 250 insured patients.

Only last month the St. Pancras Board of Guardians advertised for a district medical officer at the princely salary of £50 a year; needless to say there was no applicant.

The scarcity of medical men affords a good opportunity of forcing the hands of the guardians and compelling a decent salary. Why not take occasion by the forelock? A request supported by a bold alternative from the district medical officers of each union to their respective boards of guardians would be certain in the present interesting situation of eliciting a favourable response.—I am, etc.,

London, N., April 7th.

J. MORLEY LYNCH.

MEDICAL OFFICERS OF HEALTH (SUPER-ANNUATION) BILL.

An Appeal to School Medical Inspectors and Tuberculosis Officers.

SIR,—In the House of Commons on April 18th there is set down for second reading the Medical Officers of Health (Superannuation) Bill. Medical officers of health, whether whole or part time, are included in the provisions of the bill, which is on a contributory basis. A memorandum on the bill is contained in the April number of *Public Health*, which sets out the strong claims for the superannuation of public health officers.

Medical officers of health are now generally recruited from the ranks of the junior branches of this service—namely, school medical inspectors and tuberculosis officers, of whom there are at least three times as many as of medical officers of health. This means that there will always be the larger proportion of officers remaining in these junior branches or the service, which are paid at a salary ranging from a half to a third of that paid to whole-time medical officers of health.

Since the Insurance Act came to the assistance of general practitioners school medical inspectors are the lowest paid members of the profession. All the arguments in the bill can be urged in the case of school medical inspectors and tuberculosis officers, and the argument contained in the following extract from the memorandum on the bill can be much more powerfully urged in their favour: "Moreover they (medical officers of health) can hardly be classed among highly-paid officials, and have thus little opportunity for saving sufficient from their incomes to enable them to retire when it might be distinctly in the public interest to do so."

My object in writing is to point out that the bill does not include school medical inspectors or tuberculosis officers, and, if possible, to have an amendment incorporated in the bill during the Committee stage to make the words "medical officers of health" include school medical inspectors and tuberculosis officers.

To this end may I ask all who are interested in this matter to write to me without delay saying whether they are in favour of such a course; and to write or interview their member of Parliament urging him to assist the passage of the bill through Parliament?—I am, etc.,

ALEXANDER GRAHAM,

London, E., April 9th.

School Medical Inspector, West Ham.

* * * The objects of the bill were stated and some of the arguments in favour of its principle were set out in an article published in the *BRITISH MEDICAL JOURNAL* on March 29th, p. 677, where the large part the British Medical Association has taken in promoting this legislation was indicated.

AN addition to its series of health cartoons has recently been made by our contemporary, the *Medical Officer*, which has now published a cartoon setting forth in graphic form the various stages of a fly's development, and the fashion in which it conveys filth to food, and thus discriminates disease. It is an authorized reproduction of one originally issued by the Department of Public Health for Queensland.

Universities and Colleges.

UNIVERSITY OF LONDON.

MEETING OF THE SENATE.

A MEETING of the Senate was held on March 19th, Dr. Herringham, the Vice-Chancellor, in the chair.

Recognition of Teachers.

The following have been recognized as teachers of the university in the subjects and at the schools indicated:

Guy's Hospital Medical School.—Dr. Thomas M. Lowry (chemistry).

Westminster Hospital Medical School.—Dr. Oliver K. Williamson (clinical medicine).

Study in Other Universities.

It was resolved to adopt a new regulation, to be numbered 7A, permitting a student, subject to certain conditions, to take subsequently to the passing of the Intermediate Examination, a course of study extending over not more than one year in another university approved for the purpose in lieu of an approved course of study taken in this university. The University of Paris was approved in connexion with the new section.

Bequest to University College.

The University College Committee reported that a legacy of £3,000 had been left to the college by the late Mrs. F. Magrath for the award of an annual scholarship, to be called the Magrath Clinical Scholarship for proficiency in reports of cases at the bedside, to be open to medical students of the college in their fourth year. A resolution was adopted approving the payment of the legacy to University College Hospital.

Professor Arthur Robinson.

Dr. Arthur Robinson, Professor of Anatomy in the University of Edinburgh, and formerly Professor of Anatomy at King's College, has been appointed a Fellow of King's College.

Appointment of Representatives.

Sir William Collins, M.D., M.S., F.R.C.S., has been appointed a governor of Christ's Hospital, Horsham; Mr. E. L. Gowland, M.B., a governor of the Wright and Gibbs School, Faversham; and Mr. H. B. Wilmot, M.R.C.S., L.R.C.P., has been nominated for reappointment as governor of the Latymer Foundation, Edmonton.

Lectures in Advanced Medical Subjects.

The following lectures will be delivered at the time and place indicated:

St. Bartholomew's Hospital Medical School.—May 1st, 5 p.m., Dr. M. H. Gordon: Sensitized Vaccines. May 8th, 5 p.m., Dr. H. Williamson: Some Factors of Importance in Determining the Significance of Albuminuria in Pregnancy.

University College Hospital Medical School.—May 5th, 5 p.m., Dr. T. R. Elliott: Disease and the Suprarenal Glands.

London Hospital Medical College.—May 19th, 21st, 23rd, 4.30 p.m., Dr. H. M. Turnbull: Physiological and Pathological Changes in the Structure of Arteries and Arterio-sclerosis.

Brompton Hospital for Consumption and Diseases of the Chest.—May 28th, 4.30 p.m.: The Site of Tuberculous Lesions at Different Ages.

The lectures are free, and are addressed to advanced students of the university and others interested in the subjects dealt with.

Advanced Lectures in Physiology.

The following advanced lectures in physiology are to be given during the third term:

Professor A. B. Macallum, F.R.S., eight lectures on surface tension and physiological processes, at the university on Tuesdays at 5 p.m., beginning May 13th.

Dr. S. A. Kinnier Wilson, three lectures on the anatomy, physiology, and pathology of the corpus striatum, at the university.

Mr. F. F. Blackman, eight lectures on the physiology of photosynthesis and respiration in plants, at University College on Wednesdays at 5 p.m., beginning April 23rd.

Professor T. G. Brodie, F.R.S., four lectures on the physiology of absorption, at King's College on Wednesdays at 4.30 p.m., beginning May 21st.

Dr. J. S. Hellane, F.R.S., four lectures on the supposed physical basis of life and mind, at Guy's Hospital on Thursdays at 4 p.m., beginning May 8th.

Dr. H. E. Roaf, eight lectures on the factors concerned in the volume and form changes of cells (growth and movement), at St. Mary's Hospital Medical School on Mondays at 4 p.m., beginning May 5th.

Further information regarding the lectures can be obtained on application to the heads of the laboratories at which they will be delivered.

Gilchrist Studentship.

Miss Maud F. Forrester-Brown, M.B., B.S., of the London School of Medicine for Women, has been appointed to the Gilchrist studentship for women.

University Studentship in Physiology.

A university studentship of £50 for one year in physiology will be awarded to a student qualified to undertake research in physiology, and will be tenable in a physiological laboratory of the university or a school of the university.

Rogers Prize.

The subject of the essay for the Rogers prize for 1914 will be the nature of pyrexia and its relation to micro-organisms. Copies of the regulations can be obtained from the Academic Registrar, and competing essays must be received by April 30th, 1914.

Presentation Day.

The presentation of graduates will take place at the University at 3 p.m. on Wednesday, May 7th. The annual university service will be held in Westminster Abbey on the same day at 6 p.m. when the sermon will be preached by the Right Rev. Bishop Boyd Carpenter. The service is open to all members of the university, who can obtain tickets from Mr. J. Dudley Whyte, 88, Gower Street, W.C., on or before May 1st.

*Pass List.**

The following candidates have been approved at the examinations indicated:

SECOND M.B. (Part I).—J. A. M. Alcock, G. E. Archer, K. E. Attenborough, O. D. Banca, E. V. Beaumont, H. J. Bansted, J. A. Birrell, M. N. Bostock, *W. W. K. Brown, L. J. F. Bull, A. W. B. Carless, L. A. Celestin, C. C. Chesterman, *A. H. Clarke, Doris M. Collins, J. D. Constantin, M. C. Cooper, J. M. Courtney, R. Coyte, T. M. Cunningham, D. D. R. Dale, R. G. Dani, T. M. Davies, M. A. B. Demerdash, Hilda M. Denton, E. de Robillard, K. Dykes, T. G. Dykes, Florence M. Edwards, T. S. Evans, G. Fehrsen, E. F. Fernando, W. Fletcher-Barrett, J. L. R. Fortier, A. R. Fuller, W. B. Gabriel, A. Girgia, E. N. Glover, H. M. Gray, R. B. Hawes, N. N. Haysom, T. L. Heath, W. E. Heywood-Waddington, E. B. Hicks, F. G. E. Hill, Mary E. A. Holiday, P. Hughes, J. B. Hume, J. W. Hyatt, T. John-Thomas, V. J. E. Lacy, E. H. Lake, H. W. Lewla, N. M. Lewis, R. T. Lewis, A. Lyell-Taylor, F. C. Mason, Cecily M. E. Maude, R. G. Mayer, Gladys M. Miall-Smith, M. W. H. Miles, G. G. Milne, L. C. Moore, G. Moulton, D. C. Norria, R. V. Norton, J. H. Onvala, Margaret S. Palmer, J. W. G. Phillips, C. V. Pink, H. T. Frys-Jones, W. M. A. Rahman, Mariamne O. Ramsay, S. D. Rhind, H. N. D. Richards, J. A. W. Robinson, K. M. Rosa, W. R. Rowlands, M. Schwartz, S. N. Scott, A. Selby-Green, A. Shafeek, C. E. A. Shepherd, R. G. Simpson, G. H. Sims, Lily D. Taylor, F. A. Unwin, R. N. Vakil, L. P. Waghorn, Lotty Weibermann, J. P. Williams, O. Williams, T. P. Williams, A. Williams-Walker, K. M. C. Woodruff, W. Yeoman.
* Awarded a mark of distinction.

SECOND M.B. (Part II).—A. W. Adama, Hannah K. Alton, *D. W. J. Andrews, E. B. Barnes, D. A. Blount, C. M. Brophy, F. W. Chamberlain, J. E. Clark, Mabel C. Clark, R. M. Dannatt, E. I. Davies, Ll. ap I. Davies, T. A. Davies, T. R. Davies, H. A. De Morgan, C. I. de Silva, J. R. Dingley, C. W. Elliaon, †H. H. L. Ellison, I. Feldman, Susan A. Finch, Charlotte I. Fox, O. Gleeson, E. D. Granger, S. A. Hall, F. J. Hallinan, J. W. Heekes, Mary I. Hounafeld, P. Hudson, S. C. W. Iredale, S. W. Isaacs, *H. C. Jennings, R. B. John, C. O. H. Jones, J. G. Jones, R. O. H. Jones, S. B. King, F. A. Knott, L. G. Le Blanc, I. H. Lloyd-Williams, E. R. Lovell, H. M. C. Macaulay, O. S. Martin, Adeline M. Matland, R. G. Michelmore, S. Miller, *H. W. L. Molesworth, R. G. Morgan, A. H. Morley, Violet Newmarch, D. O. Ogilvie, B. C. W. Pasco, L. D. Phillips, Mary O. Poonen, C. L. G. Powell, A. E. Richmond, Eveleen B. G. Rivington, T. W. Robbins, G. W. R. Rudkin, J. E. Rusby, E. A. Scott, M. C. Stark, R. G. Sterling, D. O. Thomas, W. L. Thomas, H. Q. F. Thompson, J. E. A. Underwood, G. M. Vevers, H. J. Wallace, P. H. Wells, G. R. C. Wilson, W. C. S. Wood.
* Distinguished in Anatomy. † Distinguished in Physiology.
‡ Distinguished in Pharmacology.

VICTORIA UNIVERSITY OF MANCHESTER.

MR. J. S. B. STOPFORD, M.B., Ch.B. Manchester, Junior Demonstrator in Anatomy in the University, has been appointed Senior Demonstrator. Mr. Stopford graduated with honours in 1911, and was Dumville Surgical Prizeman for the same year.

UNIVERSITY OF DURHAM.

THE following degrees and diplomas were conferred at a meeting of Convocation on March 29th:

M.D.—L. F. Browne, J. G. Campbell, W. H. Edgar, I. Hodgkinson, J. C. Hoyle, H. G. G. Mackenzie, F. W. Melvin, W. R. E. Unthank.

M.D. (for Practitioners of Fifteen Years' Standing).—D. D. Brown, J. G. B. Coleman, W. L. T. Goodridge, A. Johnson, J. S. Robertson, W. B. Stanford, E. R. Thomas, W. S. Willmore.

M.S.—B. C. Fraithwaite.

M.F., B.S.—J. S. Arkle, Theonie R. Burrell, W. L. Clements, H. G. Dodd, F. J. H. T. Frere, *C. J. Henderson, W. J. Hickey, C. H. Robson, S. Scott, R. V. Steele.
* M.B. only.

B.Hy.—P. A. Galpin, W. Hudson.

D.P.H.—P. A. Galpin, W. Hudson.

UNIVERSITY OF EDINBURGH.

Honorary Degrees.

AMONGST those to whom the Senatus Academicus of Edinburgh University has resolved to offer the honorary degree of LL.D. are Emeritus Professor W. S. Greenfield and Dr. W. Allan Jamieson, both of Edinburgh; Dr. John Stewart, of Nova Scotia; Professor J. Arthur Thomson, of Aberdeen; and Professor F. Strassmann, Director of the State Medicine Institute in the University of Berlin.

UNIVERSITY OF GLASGOW.

The Pollock Bequest.

By the death of the last surviving life-renter the bequest of £10,000 left to the university by the late Dr. Robert Pollock has

fallen due. By the terms of the bequest the income of this sum is to be allotted to the Materia Medica Department to found a lectureship.

Pass List.

The following candidates have been approved at the examinations indicated:

FINAL M.B., Ch.B.—Cocilla S. T. Anderson, Janet R. Anderson, W. L. Anderson, *H. S. Banks, *R. A. Barlow, *J. S. K. Boyd, J. L. Brownlie, A. G. Buchanan, W. L. Cassella, J. Connell, R. Craig, *W. C. Davidson, W. E. Elliot, J. Frazer, W. Fraser, *W. Forsyth, A. Glen, J. L. Gregory, J. M'F. Grier, W. M. Howells, D. M. Hunter, Jane K. M'E. Hunter, J. F. Hutton, T. P. Inglis, C. J. Kirk, Mary A. Kirk, P. A. M'Callum, J. M'Ghie, Margaret H. M'Killop, M. H. MacLeod, J. H. Magoveny, W. E. Maitland, W. Montgomery, J. L. R. Philip, Sarah A. J. Rankine, F. M. Robertson, A. W. Russell, J. J. Sinclair, N. I. Sinclair, J. A. Smith, F. A. Steven, G. Taylor, E. G. Y. Thom, A. Walker, J. C. Watt, J. Whiteside, A. M. Young.

FINAL M.B., C.M.—A. P. Aitken.
* Passed with distinction in one or more subjects of the examination.

LONDON SCHOOL OF TROPICAL MEDICINE.

THE following candidates were approved at the examination held at the end of the recently concluded forty-first session:

*† Captain C. A. Gill, *† Captain F. P. Connor, Miss C. L. Houlton, M. C. F. Easmon, J. R. Boyd, †Miss E. M. Layman, F. W. O'Connor, Miss F. M. Harper, †F. C. Doble, Miss J. McDonald, †D. Birt, †W. T. P. Meado-King, J. A. Hamilton, Miss S. O'Flynn, †G. P. G. Beckett, †Miss L. S. McLean, A. P. Watkins, J. F. H. Morgan, †W. E. Lewis.

* Passed with distinction.
† Indian Medical Service.
‡ Colonial Medical Service.

Medico-Legal.

ACTIONS FOR SLANDER.

WE learn from the *Liverpool Daily Post* of April 5th that three actions for slander brought by Dr. Agnew of Blundellsands arising out of certain injurious statements affecting him professionally which had been circulated in the locality were settled at the Liverpool Assizes on April 4th, the defendants making a full retraction and apology in open court and agreeing to pay between them damages to the amount of £1,250 and indemnity costs in the form of an order for costs to be taxed as between solicitor and client. Judgement was entered in accordance with these agreed terms. In each action the plaintiff's case was conducted by Messrs. Hempson, acting for the Medical Defence Union.

ERROR IN DISPENSING.

IN a case heard at the Fenton police-court on April 2nd, before the Petteries stipendiary magistrate, in which the prosecutors were the Insurance Committee, the allegation was that pills supplied to an insured person were not in accordance with the prescription of the medical man. The prescription was for pil. ferri gr. 3, manganese peroxide gr. 1, arsenious acid gr. 5. It was admitted on behalf of the defendants that a mistake had been made, but it was stated that this was due to an oversight. The magistrate imposed a fine of £3 and costs. The proceedings were taken under the Sale of Food and Drugs Act.

Public Health

AND

POOR LAW MEDICAL SERVICES.

POOR LAW MEDICAL RELIEF AT BURNLEY.

THE Local Government Board has addressed a letter to the Burnley Guardians stating that in view of the representations made to it the Board thinks it desirable that the question at issue with regard to the appointment of district medical officers should be deferred for consideration by the new board of guardians, and that in the meantime the temporary arrangements should be continued. The guardians decided to act in accordance with this intimation.

DR. W. B. ORME has been seconded from the Federated Malay States Service to act as Principal Medical Officer at British North Borneo for a period of three years.

To give Germans living abroad every facility to fulfil their military duty at home, German medical men have been appointed to examine young men in the United States, Canada, Norway, Spain, Italy, and Russia, and others have recently been added in Sumatra and Manila.

THE firm of Meister, Lucius, and Brünning completed last January the fiftieth year of its existence, and in commemoration of that fact has published a handsome volume giving some account of its labours in the field of synthetical and other pharmacy during this long period. The great development undergone by the firm is demonstrated by ground plans and other illustrations of its factories at Hoechst-on-Main at early and recent dates.

Obituary.

JORDAN LLOYD, M.Sc., M.D., Ch.B.BIRM., M.B.,
M.S.DURH., F.R.C.S.ENG.,

SENIOR SURGEON TO THE QUEEN'S HOSPITAL AND PROFESSOR OF
SURGERY IN THE UNIVERSITY OF BIRMINGHAM.

By the death of Mr. Jordan Lloyd Birmingham loses one of its most eminent citizens and the Queen's Hospital and the University a most brilliant surgical teacher. Indeed, it is no exaggeration to say that the surgical world is poorer by his removal, and the gap he has left only time can fill. Although the unsatisfactory state of his health was known to himself and to his intimate friends, his death came with shocking suddenness, for with characteristic pluck and cheerfulness he continued to perform all his duties with unabated enthusiasm, and had sought in no degree to lighten the onerous burden of philanthropic duty which he had borne for so many years. On Friday, April 4th, he had done a hard morning's operating at the Queen's Hospital, and perhaps few outside the medical profession realize the physical strain that that implies. He complained of being tired and drove to his house in Edgbaston, but was then seized with a heart attack, which proved fatal before any medical assistance could be obtained.

Jordan Lloyd was the second son of the late Dr. John Lloyd of Small Heath, Birmingham, and was born in 1854. His father was a remarkable man who studied medicine late in life, and took the M.B.Lond. when this distinction was rare in Birmingham. He taught anatomy for many years in Queen's College; he was an amateur musician and artist, amiable but eccentric in many ways, and although much appreciated by numbers of poor people among whom he worked, he did not attain and was perhaps careless of worldly success. He was not anxious that his clever son should follow in his footsteps, so that the boy, after receiving a fair education at King Edward's School, entered the office of the *Birmingham Daily Post* as a proof reader. At the same time he lived with his father, assisting him in his practice, and ultimately gave up journalism for medicine. He began his medical studies at the age of 21. His college course was extraordinarily brilliant; he swept off every prize and exhibition it was possible for him to gain until his contemporaries ceased to compete with him. As soon as he was qualified he was appointed house-surgeon to the Queen's Hospital, and afterwards continued his studies in London and Newcastle-on-Tyne where he graduated M.B. and M.S. Durham, taking the first place in both examinations. Soon after returning to Birmingham he became a Fellow of the Royal College of Surgeons.

In 1881 he was elected casualty surgeon to the Queen's Hospital, and two years later honorary surgeon, a post he held up to his death. For many years he lectured on operative surgery in the Medical School, but in 1910, on the retirement of Mr. Bennett May, he was appointed to the joint Chair of Surgery with Mr. Gilbert Barling, and undertook the greater share of the work; he was an examiner in surgery to the University of Durham. His duties as surgeon to the Queen's Hospital were insufficient to satisfy his craving for work, so that he sought and obtained the post of visiting surgeon to the Poor Law Infirmary, which involved no inconsiderable number of operations. In 1889 he was acting surgeon to the 1st Warwickshire Volunteers, and on the formation of the Territorial Army he received a commission as Lieutenant-Colonel R.A.M.C.T., and was appointed officer commanding 1st South General Hospital South Midland Division. At one time he lectured on physiology at the Midland Institute; he was a St. John Ambulance lecturer and lecturer to the Birmingham Athletic Institute.

He held most of the offices in the Birmingham Branch of the British Medical Association, presiding over it in 1903-4, and was for a few years on the Central Council. All who were present at the Birmingham Meeting in 1911 will remember his brilliant Address in Surgery. He was an ex-President of the Midland Medical Society, and of Queen's College Medical Society. He gave the Ingleby Lectures in 1891. He was consulting surgeon to the Children's Hospital, the Dental Hospital, and the West Bromwich Hospital, and a Justice of Peace for the city.

It is to be regretted that he never found time to

incorporate the fruits of his great experience in a book, but he postponed it to the time when he should have less to do—a time that never came. He would have retired from the Queen's Hospital next year under the age limit. His comparatively few contributions to surgical periodical literature were invariably striking and original. For two years (1886-88) he edited the *Birmingham Medical Review*, in conjunction with the late Dr. Foxwell.

This catalogue of his many activities may be incomplete, but shows how fully occupied was the life he led.

In 1887 he married the eldest daughter of the late Mr. Mercer H. Simpson, the proprietor of the Theatre Royal, and leaves a family of three daughters and a son.

Mr. GILBERT BARLING, Vice-Chancellor of the University of Birmingham, writes: Mr. Jordan Lloyd was a very brilliant surgeon, especially as a manipulator—bold, quick, and very ready in any difficulties. He had, above all things, a most keen and vivid interest in his work. It was not merely a matter of earning an income or holding an office. The study of disease in itself and the opportunity to relieve it was to him a real gratification and an ever-present interest. He was a very fine teacher and lecturer, and the Address in Surgery which he gave at the Meeting of the British Medical Association in Birmingham in 1911 was a brilliant performance—quite a *tour de force*. In his earlier days, when of course he had more leisure, he made a number of interesting inquiries and researches into various forms of surgical disease, and the papers he wrote at that time are still quoted as authoritative on the conditions of which they treated. It had been a matter of great regret to his friends and colleagues during the last few years that his health had seemed to be rather strained, and that he was not always able to do himself full justice. He will be long and affectionately remembered as a brilliant son of the Birmingham School of Medicine.

Professor SAUNDBY writes:

I have known Mr. Jordan Lloyd since he came to the General Hospital as resident surgical assistant in 1876. I was much impressed by the ability he displayed, and I had some conversation with him about his education, urging him to try for higher qualifications, as he had not entered for the first fellowship or the London M.B. He told me his father thought it was unnecessary, and as it was his intention to join his father's practice he should only try for the ordinary diplomas. However, his own, and probably his father's, views became modified by his wonderful success as a student, and he was undoubtedly encouraged greatly by his teachers, the late Mr. Sampson Gamgee, Mr. Furneaux Jordan (to both of whom he always expressed himself as owing much), and by Mr. Lawson Tait, who early appreciated his surgical talent. I watched his progress with sympathy, and, although others better qualified can express what was thought of his originality and skill as a surgeon, I saw enough to show me that he stood in the front rank as an operator—bold in resource, and marvellously capable of carrying out his carefully devised plans. His almost boyish enthusiasm for his work lasted throughout, and enabled him to overcome the disadvantages of a frame never robust, and of the ill health that weighed him down during recent years.

He was a charming speaker, with something to say that was always fresh, and no man enjoyed greater popularity as a teacher and consultant; in both these capacities he will be greatly missed. He was of a singularly affectionate disposition, and possessed a winning manner which gained him many friends and softened his relations with those who at times differed from him in policy. His domestic life was especially happy. His last words were highly characteristic of the man: "What shall I do? I shall have to give up my work!" He lived for his work; he could not take holidays; when he went away he fidgeted all the time, and wished himself back at work. He did not employ a secretary but wrote all his own correspondence, and would not accept assistance from his wife or daughters. Although he had been warned of the dangerous nature of his recent attacks he would not reduce his work. He did four or five operations on the Friday morning, and, unfortunately, one of the patients, a child, stopped breathing; he performed artificial respiration

himself, and had the satisfaction of seeing it recover, but it is only too probable that he gave his own life in exchange. He drove home in a cab, but on arrival collapsed and felt sick; he lay down on the hearthrug in front of the dining-room fire and had a terrible anginal attack, which was relieved by amyl nitrite; he described it as worse than anything he had gone through before. He sat on the sofa, but after a short interval began to retch again, complained of a return of the pain, drew two or three deep breaths, and died before any medical assistance had arrived. Two of his daughters were with him, but his wife, who had been out shopping, arrived before they had realized that he was dead.

Emeritus Professor BENNETT MAY writes:

Jordan Lloyd followed soon after me on the staff of Queen's Hospital, and at once it became apparent that we had acquired a man of the keenest powers of observation with a fresh and original mind, whose manual dexterity foretold what he soon became—an artist in his work, a master of surgical handiwork, and *facile princeps* as an expert operator. He rapidly gained the first place in the estimation of all at the hospital, and his prestige he retained until his untimely death. His professional life covered the great period of the surgical renaissance to which he has contributed in an important degree. It is perhaps difficult to single out any special subject with which to associate his name, for his range was wide and in most directions he excelled; to many he made valuable improvements and additions. Perhaps his work in kidney and gall-stone surgery may be especially mentioned, as these subjects then offered a fine field for his almost unrivalled powers of surgical diagnosis, which he carried into action with rare ability and success. His work in cranial surgery also was extremely good, both in diagnosis and execution. I do not think any one can have removed the Gasserian ganglion oftener or with more brilliant success; it was an operation he did in masterly style. Moreover, he possessed an instinctive and almost magical accuracy in the diagnosis of fractures. His emphatic but always genial and engaging manner gave force to his opinions, which he expressed with freedom but always naturally and unaffectedly, while his merit as an exponent of surgery is too well known to need comment. Like other wise and honest men he did not hesitate to condemn and to drop what he knew to be useless or believed to be wrong. We, his colleagues, knew that we were the better for him, and that it was good for us to know him and to work with him. Of success in practice and of wide and warm professional and public esteem he reaped ample measure, but, now that it is too late, I do wish that a man of such substantial and rare abilities, who did so much for humanity and finally died in its service, had received some form of public honour or recognition. It should have been.

Professor J. T. J. MORRISON writes:

The sudden sundering, after nearly thirty years, of a friendship ripening with time into close intimacy and affection, leaves a beclouded sense of loss which may be understood but cannot be expressed. Under this shadow to pen a fitting tribute to the memory of Jordan Lloyd within narrow limits of time and printed space is a hard task, and I can but offer a few inadequate sentences.

By the untimely passing of Jordan Lloyd a host of personal friends and the whole profession are made the poorer. At the Birmingham University and the Queen's Hospital it is no disparagement of the competent men who succeed him to say he cannot be replaced. For he was a man of genius, with the rare adjuncts of a sunny disposition and common sense. His personality was, indeed, chiefly notable inasmuch as he possessed in himself many fine qualities not often found so developed and assembled in one man.

His clear intellect gave him distinction even among first-rate men. But in addition to being thus endowed, he was a man of strict integrity, dauntless courage, intense energy, and iron will. And all these elements of character were pervaded by the warmth of a genial soul, whose unflinching current of cheerfulness, and not seldom mirth, made him the most delightful of companions. By means of his many public and private activities he was one of the best known men in his native city of Birmingham, and he was also one of the best liked. His unaffected friendliness to high and low alike, which never diminished, was one of his winning charms. He had a large measure of that essential in the equipment of a surgeon—sympathy—and his sincere kindness was instinctively felt by his patients, even the poorest. On occasion, actuated by a keen sense of justice, he could be a strenuous fighter—always by honourable methods, for, if he was a resolute antagonist, he was also one of the fairest. As a colleague he was loyal to the core.

It is not too much to say that his influence in promoting comradeship will be no less missed than the stimulus of his surgical zeal.

He was a devoted husband and father, brimful of happiness in the home circle, which he entered from the "crowded city's jar" to find solace in the love of an affectionate family. On the deepest subject of all I know, from privileged converse, that his attitude was thoughtful and reverential.

In contemporary surgery Jordan Lloyd was one of the recognized masters. The range of his surgical knowledge was very extensive, and I have never met his superior as a diagnostician, nor his peer as a brilliant operator. Working as he did for years in three public institutions and with a large private practice, it may be doubted if any surgeon in this country has performed more major operations. The scene of many triumphs was the Queen's Hospital theatre, where his astonishing manual dexterity (aptly termed by a colleague "three-handedness") won the admiring envy of beholders. But there were other traits

Photograph by]

JORDAN LLOYD.

[Lafayette, Manchester.

—coolness, rapidity, boldness within safe bounds, precision, and ingenuity were all conspicuous, and the results were an unsurpassed success. Until recent years Jordan Lloyd was unfamiliar with other clinics. Trained in Birmingham on old-fashioned lines, his originality forsook outworn grooves, raising him at once to the front rank, and marking his work from first to last with an intensely individual stamp. He looked askance at what he deemed superfluous apparatus, holding that a surgeon must rely on his cultivated faculties to the utmost, and in keeping with this view the contents of his instrument bag were of unique simplicity. As a chief, he was unsparing of himself, and he obtained the unstinted service of his house-surgeons, whom he inspired with his own enthusiasm, many of them being now distinguished hospital surgeons. His rapid success in practice was a loss to surgical literature, for it left him little connected

As a teacher Jordan Lloyd's power of lucid exposition was remarkable, and he could draw from rich stores of knowledge garnered in the main from first-hand experience. Lectures were enlivened by vivid word pictures and the play of humorous fancy in a way that impressed his teaching indelibly. That he was the most popular teacher in the school was shown by the throng of successive generations of students crowding to his weekly out-patient clinic.

His force and skill were unabated to the end. A fortnight ago I heard him deliver an excellent speech from a public platform; and on the last morning he performed with masterly technique the day's quota

of six operations while death was clutching at his heart. The promised holiday was too distant, and Jordan Lloyd, tireless worker and lovable man, is gone, prematurely, because his spirit was too ardent for a fragile frame.

... Quantum instar in ipso est!
Sed nox atra caput tristi circumvolat umbra.

Mr. C. LEEDHAM-GREEN (Surgeon to the Queen's Hospital, Birmingham) writes:

By the sudden death of our colleague, Jordan Lloyd, English surgery has been deprived of one of its most gifted exponents. Endowed with quite exceptional ability, and unfavoured by any adventitious circumstances, through sheer talent he rapidly rose to a leading position in his profession. As an operator he had few equals, for, possessed of wonderful manipulative dexterity and fertility of resource, he was an expert craftsman in every sense of the word. The rapidity and precision with which he would carry out the most difficult of operations with the minimum of assistance at times almost bordered on

the marvellous. Owing to this rapidity of execution and to the infliction of the least possible damage to the tissues, he dispensed, and successfully dispensed, with much of the elaborate detail of aseptic technique on which less gifted men have to rely. His popularity with the students was unbounded, for, in a genial and easy manner he would portray at the bedside the salient features of a case with an incomparable vividness and lucidity. All Jordan Lloyd wrote, all he said, and all he did, was stamped with an originality and illumined by a flash of genius, which raised it far above the commonplace. For his colleagues his death can never efface the inspiration of his life and work.

SAMSON GEMMELL, M.A., F.F.P.S. GLASG.,

REGIUS PROFESSOR OF MEDICINE, GLASGOW UNIVERSITY; SENIOR PHYSICIAN TO THE WESTERN INFIRMARY, GLASGOW.

By the death of Dr. Samson Gemmell, Glasgow has lost one of her most distinguished medical men. Professor Gemmell seems to have been in his usual vigorous health, and, except for a trifling shortness of breath, had no indication that there was anything wrong. In the beginning of the week he had completed the final examination for the medical degrees by presiding at the meeting of examiners to determine the pass list. On April 1st he had paid his usual morning visit to the Western Infirmary, and thereafter, as was his custom, had walked over the hill up to the college, and so home to his house. During part of this, his last, walk he was accompanied by one of his university colleagues, with whom he had discoursed vigorously on university and political topics. Soon after reaching his house he was seized with illness, and before assistance could be obtained had almost breathed his last. It is believed that he succumbed to heart failure.

At the time of his death he was in his 66th year. He was born in the little Ayrshire village of Cairnie, and received his early training there before proceeding to the University of Glasgow

for his education. One of a large family, Gemmell was brought up in a strict fashion by his father, who was a rigid disciplinarian. At first destined for a Civil Service career, Gemmell spent the first three years of his college life in the arts side, but when it was found that, owing to a physical defect, he was debarred from entering the Civil Service, he commenced the study of medicine. His great industry and mental ability soon gained for him an honoured place among his contemporary students, and he crowned a distinguished undergraduate career by obtaining, in 1872, the medical degree with honours. Thereafter for some time he acted as houseman in the Royal Infirmary in the medical wards under the late Sir William Gairdner, and afterwards for a short time acted as a demonstrator of anatomy under Professor Allan Thomson. But his interests really lay in the clinical aspects of medicine, and he proceeded to develop his clinical knowledge by the study of fevers. Accordingly, for the next three years, from 1873 to 1876, he acted as resident physician at the City of Glasgow Fever Hospital, and came under

SAMSON GEMMELL.

[T. and R. Annan, Glasgow.

the influence of the late Dr. J. B. Russell. On giving up that appointment he commenced private practice, and was fortunate in being taken on by the late Sir William Gairdner as his university assistant. This post he held for eight years, and during the last four of them he also acted as clinical assistant to Sir William Gairdner.

The next important step in his career took place in 1880, when Gemmell was made Professor of Medicine in Anderson's Medical College, succeeding the late Matthew Charteris, who had been called to fill the chair of materia medica in the university. In the same year he joined the Faculty of Physicians and Surgeons. From the very beginning of his Andersonian career Gemmell proved a success. His class soon outnumbered the corresponding university class. His command of English and his power of expressing himself in flowing phrase impressed his hearers and stamped him an interesting and successful lecturer. Meantime he was increasing his clinical experience. In 1881, after the usual service as extra-dispensary physician, he became full physician to the Dispensary of the Western Infirmary. In 1886 he was appointed physician to the Hospital for Sick Children, and in 1887 he obtained wards in the Royal Infirmary. His success as a clinical teacher was almost as great as his success as a lecturer on medicine, and after five years' work in the Royal Infirmary he was transferred to the Western Infirmary to fill the vacancy caused by the retirement of Dr. Tennent in 1893. He retained his connexion with the Western till the last, and at the time of his death had been for several years senior physician.

After lecturing with great success in Anderson's College for ten years a vacancy in the Chair of Clinical Medicine was caused by the promotion of Professor McCall Anderson to the Regius Chair of Medicine. To the vacant Clinical Chair Dr. Gemmell was appointed, and thereafter for eight years filled it with distinction. On McCall Anderson's death, in 1908, Professor Gemmell was pressed by his colleagues to become Regius Professor of Medicine, but he had no personal desire or ambition to resume the arduous task of theoretical lecturing. Eventually, under severe pressure, and only on the plea that it was his duty to his Alma Mater, he unwillingly consented to the desire of his colleagues, and duly became Regius Professor of Medicine. His consent once given, he threw himself whole-heartedly into the work, and again his unrivalled powers of exposition repeated the old story of his Andersonian success. Though a busy consultant, whose services were in constant demand by the professional brethren, he allowed nothing to interfere with his university work, and ungrudgingly devoted his forenoons to his professorial duties. He had his reward in the loving esteem and respect in which he was held by his students.

Indeed, it is entirely as a teacher that Professor Gemmell will live. Trained under the late Sir William Gairdner, he was the chief exponent of Gairdnerian methods in the Western Infirmary. His continual insistence on the necessity of a sound knowledge of physical signs has had a beneficial effect on many generations of students. Few students who have ever passed through his wards are ever likely to forget how to write a good clinical report: not only must the facts be accurately observed, but the phraseology in which the report was made had to be in good, crisp, vigorous form. Dr. Gemmell was by no means antagonistic to the modern advances in the methods of diagnosing disease, but he was by nature of a sceptical disposition, and a long experience had taught him the lesson that "all that is new is not true, and all that is true is not new." His attitude to the newer development of medicine is perhaps more truly indicated by the fact that his clinical assistants were men actively engaged in developing these very new methods. As a clinical teacher Dr. Gemmell had a great power of eliminating the unessentials, and getting down to the essential features almost immediately. As a professor he struck the average student as being rather inaccessible, but those in trouble knew how kind he could be. He did not mix much with other men, and infinitely preferred the quiet of his study and the companionship of his beloved books to any social function.

It is a great pity that a man of Dr. Gemmell's powers of observation and description had not more frequently contributed to medical literature, but as a matter of fact his writings are singularly few. By far the best known are

his articles in Finlayson's *Clinical Manual*, which makes it all the more to be deplored that his matured judgements have not received permanent record.

M.B. GLASG. writes:

We have lost Samson Gemmell. The inward meaning these words convey can only be conceived by graduates of my Alma Mater and by those whose proud privilege it was to reckon him as their friend.

It is only three short weeks ago that the writer walked through Kelvingrove Park with him, when Professor Gemmell discussed the life of a great man who had passed away, and finished his remarks by saying: ". . . and so you see, even though he had attained to a ripe age, his physical and mental faculties were as active and acute as they were twenty or thirty years ago, and there he was nipped off, in the midst of all his great powers of doing good, not only to his own nation, but to the whole world. It seems strange how these colossal minds with their wealth of intellectual lore are gathered in, and so many of the riff-raff that could well be spared— from our point of view—are left." How well his remarks on that occasion now apply to himself those who knew him will appreciate. No man was ever more fitted for his position in this life than Samson Gemmell, and that he was justly proud of it was shown when he wrote: "Fortune has favoured me by my appointment to the chair held by Cullen, Black, and Gairdner. . . ."

To his students Gemmell was a continual inspiration. In his wards every case was gone into with the thoroughness of the born clinician, and woe betide the man who showed evidence of slovenliness in his clerking! At these times he would assume a satirical manner, pointing out the errors in composition or physical examination in such a fashion as was engraven in the memory of the greatest sluggard for life. Afterwards, when walking home, he would place his arm affectionately round one's shoulder and say: "Oh, if you boys only knew how jealous I am of your futures, and that you may all do well, you would then know that it hurts me more to speak like that than it does you who are spoken to."

Men who were made of the proper stuff felt instinctively when in contact with Gemmell his absolute genuineness and thoroughness, and so he was affectionately known to them as "Sammy" Gemmell. Not only was he the true friend of his students, but in one or two minutes he had endeared himself to his patients in the wards. I used to marvel—when a student—at his seeming omniscience, for often when he sat down at a bedside he would inquire of the patient where he resided, and no matter what out-of-the-way hamlet he came from, Gemmell could almost always remind him of some landmark, or quote some passage on a stone in the local kirkyard, or know some local worthy which made the man first wonder, then become his ardent worshipper during the remainder of his residence in hospital. But as with slovenly students, so with the malingering or carping patient, there was no bond of sympathy there, all sign of friendship was non-existent, and though his remarks were few they were barbed.

Professor Gemmell felt his responsibilities keenly, and the time he devoted in his wards was given in the most unaguanimous fashion for so busy a man, though I suppose he felt he was only carrying out his duty. He loved his wards, and writes: ". . . I yet hope to see you here, if it were for nothing but to show you my splendid wards in the 'Western'"; and there he was always to be found every morning at nine o'clock going his round, which was performed in no perfunctory fashion, but with the most assiduous attention to the last detail, a habit so essential to his nature.

His classes, clinical and systematic, were always the most sought after, and his systematic lectures were delivered with such an abundance of clinical detail that one saw clearly in his mind's eye the patient suffering from the disease he was for the time describing. In the wards of the Sick Children's Hospital, Gemmell's handling of a child was an object lesson for every man, for he loved children. I remember him telling me with great glee how he had shocked an old lady who was unaware that he was unmarried, and who had asked him how many children he had. He had replied that at the present moment he had some twenty-eight! He then nodded his head in the

direction of the Sick Children's Hospital, and with a smile said to me, "They're all up there, and I love every one of them."

It has always been a matter of keen regret to me that so great and grand a man in the profession was not more widely known. There are pigmies in intellect compared to him whose names are known throughout the length and breadth of the land by reason of their writings, but Sainson Gemmell seemed to have an aversion to public writing. I remember telling him that I thought of publishing a case we had been discussing, and he remarked: "Be careful what you put in print for in a few years you may have reason to regret it." I offer this as a possible reason why there is left on record so meagre an account of the magnitude of his life's work, though I do not wish to convey the impression that he was afraid of his convictions—far from that—for Gemmell was essentially a strong man. Nevertheless, it is a thousand pities, and the world is left so much the poorer.

THE LATE DR. CHUNE FLETCHER.

DR. BERNARD MYERS writes: The news of the untimely death of Dr. Chune Fletcher has come as a great shock to his large circle of friends, both lay and professional. It is indeed hard to realize that one so robust looking as was Dr. Fletcher has parted from us and joined the great majority. How deeply he will be regretted is comprehended when we reflect on the sterling manly qualities of one who was not only greatly gifted by Nature physically but who also embodied within himself a remarkable personality, being possessed of a fine intellect, a truly kind heart, and the very essence of courtesy and tact. His knowledge of medicine was thorough, whilst his untiring attention to his patients won for him their heartfelt gratitude and lasting affection. Those of his professional brethren who had the pleasure of his intimate acquaintance will bear me out when I state that Chune Fletcher was the ideal medical man. Dr. Chune Fletcher had done a good deal of most interesting work in medicine, but being of a retiring nature he preferred to use his knowledge quietly in the interest of his patients and for the benefit of his professional brethren. Indeed, I believe that nothing gave him greater pleasure than to lend a helping hand to another medico. Among other subjects that he worked at were the medical treatment of adiposity and also paralysis agitans. He certainly achieved some almost remarkable successes in these complaints. Dr. Fletcher was a born post-prandial speaker. Probably his faculty for saying the right thing at the right time, together with his other qualities, would have ensured him brilliant success at the bar. An old Bart.'s man, he retained his intense interest for his old hospital to the last. To go over Bart.'s with him was almost equivalent to being instructed by one of his delightful dissertations upon the whole history of Bart.'s, Smithfield, and the ancient tournaments.

DR. HENRY WATERS died at his residence, Stanley Road, Bootle, Liverpool, at the early age of 39, on March 29th. He received his medical education at the University of Edinburgh and graduated M.B., C.M. in 1899, and before settling in Bootle had been honorary physician and surgeon to the Berwick-on-Tweed Infirmary. For seven years Dr. Waters had been an active working member of the British Medical Association, and devoted much time and energy to the furtherance of its interests. He had filled the offices of chairman and secretary of the late Bootle Division, and from 1908 to 1911 was the Representative of the Division at Representative Meetings. He was also a member of the late Provisional Medical Committee of the Liverpool Division. It had been painfully evident to many of his colleagues that for some time his health was in an unsatisfactory state, but he persisted in keeping at work until compelled at length to yield late in December last; since then he had been confined to bed. The interment took place on Monday, March 31st, at Longmoor Lane Cemetery, and was attended by a number of the local members of the profession, by whom the late Dr. Waters was held in the highest esteem. He leaves a widow and two children to mourn the loss of husband and father.

DR. HENRY PRESCOTT ROBERTS, late of Ealing, died in a nursing home at Ladbroke Grove, London, on March 16th, aged 65. He was educated at Edinburgh, where he took the M.B. and the L.R.C.S. in 1868 and the M.D. in 1877 and entered the Bombay Medical Service as Assistant Surgeon on April 1st, 1869, becoming Surgeon on July 1st, 1873. His whole service in India was spent in military employment, chiefly in the 9th Bombay Infantry, and during it he served with the Malta-Cyprus contingent in 1878, and in the Afghan war. On December 11th, 1880, he resigned his commission and returned home, and soon after settled in practice in Ealing, where he remained about thirty years. He retired from practice and settled in Hythe about two years ago.

DEPUTY SURGEON GENERAL JOHN MILLS, Bombay Medical Service, retired, died at Yateley, Hants, on April 1st. He was born in 1831, and got his first commission as assistant surgeon on April 3rd, 1848, becoming surgeon on June 15th, 1864, and surgeon-major on April 3rd, 1868; he retired with a step of honorary rank on January 1st, 1876. In the days when he went to India almost every young medical officer of the Bombay Service had to begin with a tour of duty in the Indian Navy, and he spent his first few years of service afloat. In 1853-55 he was on furlough, and on his return served in the Persian war, being present at the battle of Khushab, and receiving the medal and clasp. After the war he was posted as Superintendent of Vaccination, Southern Division, became civil surgeon of Dharwar in 1861, and in 1862 of Kolhapur, a post which he held for five years, going on leave again in 1867. On his return to India he was appointed medical officer of the 21st Bombay Infantry, then the Marine Battalion, now the 121st Pioneers, and spent the rest of his service in that regiment.

BRIGADE SURGEON CHARLES FREDERICK OLDHAM, Bengal Medical Service, retired, died at Great Bealings, Suffolk, on March 25th, 1913. He was born on January 2nd, 1832, educated at St. George's Hospital, took the M.R.C.S. in 1858 and the L.R.C.P. Edin. in 1859, and entered the Indian Medical Service as Assistant Surgeon on July 27th, 1859. He became Surgeon on July 27th, 1871, Surgeon-Major on July 1st, 1873, Brigade Surgeon on October 24th, 1887, and retired on February 28th, 1890. After joining the service he served for some time in the Aligarh Levy, afterwards the 39th Bengal Native Infantry. In the Sixties he was for some years a civil surgeon in the Punjab, at Gurdaspur and Dalhousie, and afterwards medical officer of Bahawalpur State. In 1875 he was posted to the 1st Gurkhas, at Dhamsala, and spent the rest of his Indian service in that regiment. He took part in the Perak Expedition of 1875-76, gaining the medal and clasp, and in the Afghan war in 1878-79, with the 21st Colonial Field Force, when he received another medal. In 1871 he published a work entitled, *What is Malaria, and why is it most Intense in Hot Climates?*

DEATHS IN THE PROFESSION ABROAD.—Among the members of the medical profession in foreign countries who have recently died are Dr. Ascherson, the famous botanist of Berlin; Dr. Algernon T. Bristow of Brooklyn, professor and visiting surgeon at the Long Island College Hospital, and editor of the *New York State Journal of Medicine*, aged 61; Dr. Luiz da Cunha Feijo, professor of obstetrics and gynaecology in the faculty of medicine, Rio de Janeiro; Dr. Howitz, sometime professor of gynaecology in the University of Copenhagen, aged 84; Dr. Huber of Memmingen, an authority on the history of medicine and author of numerous contributions to the literature of that subject, and also to that of helminthology in which he was a specialist; Dr. T. E. Moret, extraordinary professor of ophthalmology at Buenos Aires; Dr. Prince A. Morrow, a leading dermatologist of New York, aged 66; Dr. O. Pertik, professor of pathological anatomy at Peste; Dr. Max Reiner, lecturer on surgery in the University of Vienna, aged 46; Professor Seeman, director of the Physiologico-Chemical Institute of the Academy of Practical Medicine, Cologne; Dr. Hugh A. Stewart, professor of pathology at Columbia University; and Dr. N. P. Tischutkin, lecturer on histology in the Military Medical Academy, St. Petersburg, aged 45.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

PRIZE DISTRIBUTION AT HASLAR.

THE course for Acting Surgeons, Royal Navy, was brought to a close on March 28th at Haslar, when the prizes were delivered by Surgeon-General Howard Todd, C.B., K.H.S.

The Instructing Medical Officers reported that the young medical officers had been diligent, had shown interest in their work, and had taken advantage of the opportunities afforded them of acquiring the special knowledge necessary. Special commendation was given to Acting Surgeons Malone, Whelan, and Cory for the zeal and ability they had generally displayed.

The Gold Medal was gained by Acting Surgeon A. E. Malone, of Dublin University, who obtained the highest aggregate marks in the London, Greenwich, and Haslar examinations. The Silver Medal was gained by Acting Surgeon H. M. Whelan, of University College, Cardiff, and the London Hospital, who took second place. The group prize for the subjects in which instruction is given at Greenwich was awarded to Acting Surgeon A. E. Malone. The group prizes of the instruction given at Haslar were awarded as follows: Group I: Acting Surgeon H. M. Whelan. Group II: Acting Surgeon R. F. P. Cory (St. Thomas's Hospital).

The order of seniority as determined by the results of the examinations held at London, Greenwich, and Haslar is as follows:

| | Marks. | | Marks. |
|-------------------------|-----------|---------------------------|-----------|
| 1. A. E. Malone, M.B. | ... 3,664 | 6. J. T. D. Higgins, M.B. | ... 2,872 |
| 2. H. M. Whelan ... | ... 3,502 | 7. J. G. Boal, M.B. | ... 2,860 |
| 3. R. F. P. Cory ... | ... 3,467 | 8. F. S. B. Wickham ... | ... 2,845 |
| 4. H. St. C. Colson ... | ... 3,371 | 9. S. Punch ... | ... 2,833 |
| 5. G. A. Finegan ... | ... 3,669 | | |

SANITARY TRAINING OF THE TERRITORIAL FORCE.

MAJOR E. C. FREEMAN, M.D., writes: I am very grateful for a kind and sympathetic review, in the *JOURNAL* of April 5th last, of an article of mine which has appeared recently in the *R.A.M.C. Journal* on sanitary training of the Territorial Force. Your reviewer has, however, misread my views on one important point, and I would ask your permission to make the necessary correction, as the matter is a vital one. Nothing was further from my mind than to suggest that "camp sanitation" was not of much value to Territorials. In war, although Territorials will have no tents, they will very frequently have to bivouac in the open; in the early stages of mobilization they will probably be under canvas, and every year during training they are in camp for a fortnight. Disease germs do not distinguish between peace and war or between camps and bivouacs. What I wished to convey was that the sanitary companies of the Territorial Force should not, as at present, confine their training to camp sanitation, but should go on and learn the working of town water supplies, sewage systems, and so forth, because in war the Territorial troops will be frequently quartered in towns, and arrangements will therefore have to be made for a great and sudden influx of population into these places—often after the municipal services have been broken down or seriously injured, and much more than a knowledge of camp sanitation will then be required to cope with these conditions and prevent epidemics. But the sanitary companies should be specialists, and it was about them I wrote. For the rank and file of the Territorial Force, or of any other troops, I would insist on the immense importance of a knowledge of camp sanitation, and for that we have worked in the East Anglian Division for the last five years.

THE total number of students in the universities of Austria in the winter session 1912-13 was 30,591. Of these 6,439 belonged to the faculties of medicine, of whom 420 were women. The total number of medical students matriculated in the medical faculty of Vienna during the past winter was 2,505, of whom 152 were women. In the University of Graz there were 572 students, including 12 women. At Innsbruck the number of medical students was 350, 3 of whom were women. In the German University of Prague there were 572 in the medical faculty, of whom 21 were women. At the Czech University of Prague there were 932 medical students, of whom 51 were women. In the University of Lemberg 629 belonged to the medical faculty, 106 of these being women. At the University of Cracow there were 600 students of medicine, of whom 62 were women. The number of medical students still shows an increase, this tendency being specially notable in the case of women.

Medical News.

THE State Sickness Insurance Committee, at its meeting on April 10th, referred to the Amendments Subcommittee a motion by Dr. Beaton to the effect that any Insurance Act Amendment Act should provide for (1) free choice of doctor whether on or off the panel, (2) a satisfactory income limit for all insured persons, (3) such increase in the number of doctors and representatives of employers on the Insurance Committees as shall prevent the insured persons having a permanent majority on these committees.

MR. JOHN JONES, of Wrexham, has left £50,000 to the Wrexham Infirmary, of which he was vice-president, and has also given for the use of the infirmary Roseneath House and grounds, Wrexham, and the Claremont Hydro-pathic at Rhyl.

WE are asked to state that the offices of the National Medical Guild, to which reference was made last week (p. 729), are at 34, Villiers Street, Strand, London, W.C. The rules of the Guild will be supplied on application to the general secretary.

MESSRS. LEITZ, of Wetzlar and London, have recently celebrated a kind of jubilee by presenting to Professor Ehrlich the 150,000th compound microscope made by them. On an earlier like occasion, the completion of the 100,000th Leitz microscope, they presented the instrument to the late Professor Robert Koch.

AS announced in our advertisement columns, an examination for commissions in the Royal Army Medical Corps will be held on July 23rd next. Applications to compete should be sent in to the Secretary, War Office, by July 14th. Owing to the reduction of the garrison in South Africa it is improbable that more than five commissions will be available.

A CONFERENCE on the feeding of elementary school children, and of those in various philanthropic and other institutions maintained for children of like class, is to be held at the Guildhall on June 30th and July 1st this year. It has been organized by the National Food Reform Association on the same lines as those of the conference on diet and hygiene in public secondary and private schools in May, 1912.

THE spring course of museum demonstrations at the Royal College of Surgeons of England will begin on Monday next at 5 p.m., when Mr. Shattock will demonstrate specimens illustrating hypertrophy. On the two following Mondays he will show specimens illustrating atrophy and lipouata respectively. Professor Keith will give demonstrations on April 18th, 25th, and May 2nd, on acquired deformities of the foot and spine, and on the formation of peritoneal adhesions and bands before and after birth. The demonstrations will be given at 5 p.m. on each day.

THE annual meeting of the Ophthalmological Society of the United Kingdom will be held on April 24th and 25th at the house of the Royal Society of Medicine, 1, Wimpole Street, W. There will be a morning and afternoon session on each day. The morning session on Friday, April 25th, will be given up to a discussion on vascular and other retinal changes in association with general disease, and the afternoon to a demonstration of cases at Moorfields. An exhibition of ophthalmic instruments, etc., will be held during the two days at the house of the Medical Society of London.

THE second list of stewards of the dinner of the Royal Medical Benevolent Fund and Guild, to be held on April 30th, under the chairmanship of H.R.H. Prince Arthur of Connaught, to celebrate the title "Royal" conferred by the King last year, has been issued. It includes the names of Dr. T. Dyke Acland, Professor D. W. Finlay, Lady Godlee, Director-General Sir William Gubbins, K.C.B., Sir Frederic and Lady Hewitt, the Hon. Mrs. Mark Ilovell, Dr. H. Maenaughton-Jones, Director-General Sir James Porter, R.N., Dr. S. J. Sharkey, Sir Frederick Treves, Professor Sims Woodhead, and Mr. G. A. Wright.

THE Finsbury Medical Guild celebrated its inauguration at a supper which was held on April 3rd, at the Holborn Restaurant. Fifty members and medical friends were present, and Dr. F. J. Smith was the guest of the evening. Amongst those present as guests were Drs. E. B. Turner, Buttar, Gordon Ward, Gordon Lane, and Whitelaw. The President, Dr. Eber Chambers, was in the chair, and a presentation was made to Dr. W. F. Roe, which took the form of a substantial cheque, in recognition of his services

as honorary secretary to the City Division Provisional Medical Committee. The testimonial was subscribed to by the members of the profession in the City Division, many of whom were present. During the evening songs were contributed by several of the members.

At a special meeting of the Board of Governors of the Leicester Royal Infirmary last week, Mr. C. J. Bond, whose resignation of the office of senior honorary surgeon had been received with much regret, was unanimously elected vice-chairman of the board. In acknowledging the appointment, Mr. Bond said that looking back to 1875, when he became acquainted with the infirmary as a pupil, the points that chiefly struck him were the great growth in the size and work of the institution, and the enormous development of surgical and medical science. He looked forward with hope, although in the immediate future there might be stormy times. The country could not do without hospitals, and it was, therefore, essential that they should be thoroughly efficient and up to date.

WE are requested to state that at a meeting of members of medical unions and other bodies in East and North-East London and the County of Essex held in the City on April 2nd, to "consider the best means of co-ordinating the work and policy of the said unions," a resolution to the following effect was carried with only one dissident: "That in view of the coming representative meeting at Brighton, the British Medical Association be requested to summon a meeting of the chairmen and secretaries of all statutory and provisional Local Medical Committees and all other bodies interested in medical organization, as soon as possible, for the purpose of considering the national organization and consolidation of the entire medical profession."

THE *Journal of the American Medical Association* has collected a number of facts as to deaths in the medical profession of the United States and Canada, and the results are published in the issue of January 4th. During 1912 the deaths of 2,120 American and Canadian doctors were noted in the journal. Estimating the number of doctors in the two countries at 150,000, this figure is equal to an annual death-rate of 14.13 per 1,000. For the ten previous years the death-rates were as follows: 1911, 15.32; 1910, 16.96; 1909, 12.26; 1908, 17.39; 1907, 16.01; 1906, 17.2; 1905, 16.36; 1904, 17.14; 1903, 13.73; 1902, 14.74. The average annual mortality for the period from 1902 to 1912 inclusive was, therefore, 15.93 per 1,000. The age at death varied from 22 to 99, with an average of 60 years and 23 days. The general average of death since 1904 is 59 years, 9 months, and 28 days. The number of years of practice varied from 1 to 76, the average being 33 years 2 months 14 days. The average for the past nine years is 32 years 4 months and 8 days. The following figures show the causes of death: 187 deaths were attributed to general diseases, 264 to diseases of the nervous system, 278 to diseases of the circulatory system, 176 to diseases of the respiratory system, 95 to diseases of the digestive system, 147 to diseases of the genito-urinary system, 334 to senility, 4 to diseases of bones, 36 to suicide, 90 to accident, 12 to homicide, and 4 to other causes. Among the principal assigned causes of death are senility, 334; cerebral haemorrhage, 219; "heart disease," 200; pneumonia, 153; external causes, 138; nephritis, 127; accident, 90; after-operations, 86; tuberculosis, 55; cancer, 38; suicide, 36; appendicitis, 29; angina pectoris, 25; typhoid and arterio-sclerosis, each 24; diabetes, 18; septicaemia, 17; gastritis, 12; anaemia and meningitis, each 11; myocarditis, 10; paresis, mental alienation, embolism, cholelithiasis, and cirrhosis of the liver, each 9; influenza and bronchitis, each 7; intestinal obstruction and peritonitis, each 5; hernia, 4; erysipelas, rheumatism, endocarditis, gastric ulcer, prostatitis, and turneriosis, each 3; malaria, dysentery, alcoholism, pleurisy, anaesthesia, and enteritis, each 2; and pellagra, uncinuriasis, drug addiction, locomotor ataxia, mastoiditis, pulmonary oedema, and placenta praevia, each 1. The causes assigned for the 90 deaths from accident were poison, 16; falls, railways, automobiles and animals, each 10; drowning, 9 (4 doctors went down on the *Titanic*); asphyxia and firearms, each 5; burns and street cars, each 4; strangulation, crushing, and freezing, each 2; and sunstroke, 1. The 36 doctors who ended their lives by suicide selected the following methods: Poison and firearms, each 15; asphyxia, 4; strangulation and cutting instruments, each 1. Of the 12 homicides, 11 were due to firearms, and 1 to a crushing injury from a blunt instrument. Of these 5 occurred in feuds or affrays.

Letters, Notes, and Answers.

Queries, answers, and communications relating to subjects to which special departments of the BRITISH MEDICAL JOURNAL are devoted will be found under their respective headings.

QUERIES.

HYPERTROPHIED PROSTATE.

X. X. asks for suggestions for the treatment, short of enucleation, for enlarged prostate of only few months' duration. The patient is 59, strong, and of steady habits. He has had two very acute attacks presenting the usual symptoms. He is possibly gouty.

ANSWERS.

L.R.C.P. LOND. is referred to the announcement in the BRITISH MEDICAL JOURNAL of December 21st, 1912, p. 1734.

LETTERS, NOTES, ETC.

TOTAL ABSTINENCE—FROM WATER.

DR. JOHN HADDON (Denholm, Hawick, Scotland) writes: I had not studied the physiological action of foods upon me long before I saw that I must also study the effect of drink as well, and I came to the conclusion that a man living rightly as to food should never drink any fluid. It is one thing to be convinced and quite another to act upon one's conviction, but a health conscience is being evolved, and when conscience is at work it sometimes gains the mastery. My efforts to follow the dictates of this new conscience have been sadly interfered with by my medical faith. In 1911 I determined to live as I think I should before going to the annual meeting of the British Medical Association, that I might show myself, living upon no more protein than fruits contain, but my weight was coming down so fast that my faith failed me and I did not succeed in carrying out my intention. Last year, however, I determined to try again, going from home before the date of the annual meeting of that Association, so that I might be away from my scales and pay no attention to my weight, but I could not help seeing the change in my features, which astonished me. The cheek bones became prominent and the skin seemed to have got thinner, but, skeleton-like as I looked, I felt even more fit than I had done at times when I looked stouter, and I persevered, and was able to show myself living on fruit alone. When I got home and found my weight had come down to little over 7 st., I began to relax the stringency of my diet, my medical faith suggesting that that was not heavy enough for a man who once weighed 11 st. 9 lb. Since then, however, I have continued my observations and experiments, and by watching a dog deprived of all food, with water beside it, I am confirmed in my conviction—that we can do without any drink, even when fasting. The subject of this experiment is a deerhound bitch, which had just finished sucking a pup. She gets very fat when suckling, and she had a sort of mange and was scratching herself and making her skin bleed. I had bathed her and failed to cure the irritation by local applications, when I determined to try what effect a fast would have. I tied her up where she could get no food and left a dish of water beside her. She drank water for two or three days, and then she stopped taking any. The skin rapidly improved, she ceased to scratch, and I kept her fasting until she was free from all superfluous fat, but she never touched the water again. The lower animals are guided by instinct, and I knew they fasted from food when ill, but I did not know that they would abstain from water when fasting, and that seems to me a most pregnant fact, which even our physiologists may not know, and which some of them will, I have no doubt, appreciate. I had come to the conclusion, through my observations on the physiological action of foods, that we were, as it were, being drowned through deficient elimination, and I was gratified to hear in the Physiological Section at the last meeting of the British Medical Association that it had been proved by microscopic examination of the brain that the nerve cells were being drowned. They were shown on slides through the lantern, burst, like a ripe gooseberry after a heavy rain, with the nucleus escaping from the cell. Thus, physiologists have confirmed me in my conviction that feeding as he ought a man should never drink, even water.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 425, Strand, London, not later than the first post on Wednesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *postes restant* letters addressed either in initials or numbers.

An Address

ON

MALINGERING, VALETUDINARIANISM,
AND THEIR PREVENTION.DELIVERED BEFORE THE PATHOLOGICAL SOCIETY
OF MANCHESTER.

BY

BYRON BRAMWELL, M.D., F.R.C.P.E., LL.D.,

PHYSICIAN TO CHALMERS HOSPITAL, EDINBURGH; CONSULTING
PHYSICIAN TO THE EDINBURGH ROYAL INFIRMARY.

The subject of malingering and valetudinarianism and their prevention is of very great practical importance at the present time: it is a large subject of great complexity, in which I have always been much interested. During my first year of practice I was engaged in a big "railway case"; since then I have had a large experience in that kind of practice; as medical officer to a large insurance company which deals with claims under the Workmen's Compensation Act, in the capacity of Medical Referee for Scotland, and as a hospital physician and private practitioner, I have seen many cases in which the question of malingering has presented itself.

DEFINITION.

I would define a malingerer as one who feigns sickness or who deliberately (knowingly and wilfully) induces or protracts an illness, with the object of avoiding duty, claiming money compensation, exciting sympathy, or for any other reason.

You observe that I use the words "knowingly and wilfully." The term "unconscious malingering" is sometimes used; but it is an absolutely erroneous term; the term "unconscious malingering" is a contradiction in terms; the very essence of malingering is wilful and deliberate (conscious) deceit. It is essential to draw a distinction between *malingering*, conscious and deliberate simulation of disease or exaggeration of symptoms, and *valetudinarianism*, unconscious or subconscious simulation of disease or exaggeration of symptoms.

Until recently, malingering was chiefly found amongst: Soldiers; prisoners; schoolboys; conscripts (in those countries where there is universal military service—the reverse condition being not infrequently met with in this country amongst young fellows who have passed the Army examinations, but who have been rejected on their "medical"); hospital patients—"hospital birds" as they are termed; hysterical young women; club patients; persons injured or supposed to be injured in railway accidents; and persons who have been accused of some crime, such conditions as epilepsy or insanity being set up as a defence.

All of us who are engaged in hospital practice will, I am sure, allow that since the Workmen's Compensation Act was introduced cases of malingering and valetudinarianism have become very much more common. In the last edition of my book on the *Diseases of the Spinal Cord*, published in the year 1895, I discussed in detail concussion of the spinal cord, and referred to the injuries which are so common in pitmen, as the result of falls of stone and coal on the back. I came to certain conclusions as to the nervous symptoms which these patients manifest. I need not read the whole, but my third and fourth conclusions were as follows:

3. That colliers who have suffered from concussion of the spinal cord (I mean, of course, concussion pure and simple) very rarely subsequently suffer from organic disease of the spinal cord or its membranes.

4. That they very rarely indeed manifest the train of nervous symptoms which so frequently occur after railway accidents and injuries.

The Employers' Liability Act came into force on January 1st, 1881, under it a claim was only sustainable in the event of there being a defect in the condition of the works, or of there being negligence on the part of the employer or those in his service.

The first Workmen's Compensation Act came into operation on July 1st, 1898, and was limited to certain classes of employees. An amending Act came into operation on July 1st, 1901, extending the earlier Act to employees engaged in agriculture.

The present Workmen's Compensation Act came into operation on July 1st, 1907, and practically all classes of employees came within its scope.

I then went on to say:

The two last conclusions may in the future be of no small importance, quite irrespective of the subject of railway accidents and injuries with which we are at present immediately concerned. The tendency of modern legislation is to compensate employees who have been injured, provided that the accident is not the result of their own carelessness or error. Now I venture to predict that if the Legislature should enact that colliers are entitled to compensation for the injuries so received, nervous symptoms will in the future be found to result much more frequently from falls of coal and stone on the back than is at present the case.

This prediction has been abundantly verified: my experience during the last five years in the wards of the Edinburgh Royal Infirmary shows that colliers who have been injured in this way very frequently manifest the nervous symptoms characteristic of traumatic neurasthenia or traumatic hysteria. In colliers these nervous symptoms are very much more common than they were five years ago.

Dr. Dickson of Lochgelly, who has for twenty years had a large colliery practice in the county of Fife, stated at a recent meeting of the Edinburgh Medico-Chirurgical Society that traumatic neurasthenia is now a common topic of conversation in the villages of Fife, that the *morale* of the Fife miner, which before the passing of the Workmen's Compensation Act was high, has become much deteriorated, and that the duration of illness after accidents has become much prolonged; he stated that the average time for recovery from a fracture below the knee, which before the introduction of the Workmen's Compensation Act was three months, is now over six months.

It cannot be doubted that the Workmen's Compensation Act has tended to the production of malingering and valetudinarianism. It must, however, be remembered, as a set-off against this, that modern methods of clinical investigation and examination have made it easier than it used to be to detect fraud.

Now I venture to predict that, when the National Insurance Act comes into full operation, malingering and valetudinarianism will become very much more common in cases of ordinary sickness and illness (irrespective of accidents and injuries) than in the past, and the duration of ordinary (non-accidental) illness will be greatly increased, and consequently that there will be a great increase in the medical attendance required, and in the expenditure required for sick pay and allowances during ordinary illness.

*Varieties and Degrees of Malingering and
Valetudinarianism.*

Various varieties or degrees of malingering may be described.

I.

There are cases in which perfectly healthy persons feign disease, induce disease, or claim that they have received an injury and profess to be suffering from symptoms due to that injury.

These cases, in which absolutely healthy persons claim to be suffering from the effects of injury or disease—pure malingering—are, in my experience, extremely rare. They are occasionally met with in club patients, in schoolboys, in hospital patients ("hospital birds"), in accused persons, and in persons who have been in a railway collision or other accident, but who have not been really injured; indeed, cases have occurred in which people who have not been in an accident at all have feigned symptoms, taken to bed, and claimed large damages from a railway company on account of an alleged injury. No case of that sort has come under my own notice, but I have seen several cases in which there has been gross exaggeration or malingering pure and simple.

CASE I.

I remember one case in which a train ran into the buffers at a station; a gentleman who was seated facing the engine was thrown forwards into the arms of a buxom lady who was sitting opposite him; his hat was knocked off and was indented—it was a new silk hat—that was the only damage which he seemed to have sustained. A few days after the accident he began to suffer from the ordinary symptoms of "railway spine"; these symptoms gradually got worse; he brought a claim against the railway company, which was eventually settled out of court for £100.

The following are brief details of three cases of pure malingering:

CASE II.

In the *Times* (June 22nd and 29th, 1899) a case is reported in which a man claimed £500 damages and £33 18s. expenses from the London and North Western Railway Company for injuries received by falling into a hole, which it was alleged was improperly protected, on the platform at the Kensal Rise Station. The company proved that the man was an impostor of the worst possible class, and that no such accident as he alleged had occurred. The man was eventually tried at the Central Criminal Court for trying to obtain money by false pretences, and sentenced to six months' imprisonment.

CASE III.

In the *Railway News* (October 29th, 1904) a case is reported in which a man sued the London and North Western Railway Company for £5,000 damages for injuries sustained during the shunting of a train. Out of 500 persons in the train—it was a Saturday afternoon and a very crowded train—the pursuer, who was bumped during the shunting, was the only person who complained of injury or made a claim against the company. From the moment the carriage in which this man was seated was bumped, he set himself to work up a false claim. He pretended to be stunned by the shock, but was sufficiently wide-awake to obtain the names and addresses of two of his fellow passengers, whom he produced as witnesses. After the alleged accident he went into a nursing home and became a cripple, deaf, half-blind, and unable to walk except with a stick, at such times as he thought exhibitions of suffering would help his case against the company.

The company found on inquiry that his record was a very bad one—"his whole business seems to have consisted in obtaining goods on credit under various aliases, selling them and pocketing the proceeds"—and had him watched by detectives. When he thought himself secure from observation, "he was a strong, active man, jumping on and off omnibuses and trains in motion, carrying his own portmanteau and rugs, making trips to Richmond and other places, playing with a football with his children in a park at Brighton, and otherwise making the best of a blighted existence."

After his cross-examination at the trial his counsel closed the case, and the jury found a verdict for the company without calling a single one of their witnesses.

The man was subsequently arrested, tried for perjury at the Central Criminal Court, convicted—the jury not finding it necessary to leave the box—and sentenced to nine months' imprisonment with hard labour.

CASE IV.

At a recent meeting of the Medico-Chirurgical Society of Edinburgh Sir Thomas Clouston mentioned the following case: A clergyman got into some sexual difficulty. The charge, if proved, would have involved the loss of his livelihood. He pleaded insanity, was certified by two medical men, one of them of very high standing in the university, and sent to an asylum. Sir Thomas Clouston was sent for to see the patient; the asylum attendant informed him that the man spent much time in attentively reading a green-bound book. This book was Sir Thomas Clouston's clinical lectures. In the chapter on delusional melancholia every one of the symptoms which this man manifested was underlined. It is hardly necessary to say that the plea of insanity was not sustained.

II.

There are cases in which, after an accident or injury, the results or remains of previous disease are said to be due to the injury.

These cases are more common than cases of pure malingering in persons who were previously perfectly healthy; fortunately they are not very common, for in some instances they are extremely difficult and perplexing. We all know how frequently functional symptoms are combined with organic disease, and how easy it is to mistake the results of old organic disease for those of recent disease, more particularly in cases in which one is unacquainted with the patient and the previous history, and especially in cases in which erroneous, misleading or false statements are made regarding the previous history and previous condition of the patient. I have met with cases in which a congenital club-foot, a very old-standing facial paralysis, an ear discharge recurring for many years, an old scar on the cornea, epilepsy, tabes and spastic paraplegia were said to be due to recent accidents.

CASE V.

We had a case not very long ago in my insurance office in which a severe conjunctivitis was said to be due to dust getting into the eye during the patient's work, but in which it was proved that the patient was suffering from gonorrhoeal conjunctivitis. I do not say that this patient was malingering. I mention the case as an illustration of the difficulty there frequently is in excluding previous disease, and in proving that symptoms, which are said to be due to a recent accident or injury, are in reality the result of previous disease.

There is, of course, a strong tendency in the human mind to try and find a cause for any and every illness, and if a person has received an injury, even some time before the development of an illness, he not unnaturally perhaps attributes the illness to that injury. Poliomyelitis anterior acuta is a striking illustration in point. It is now known to be an infective condition, due to a germ poison; formerly it was often thought to be due to exposure to cold, a chill, or an injury; and in cases of poliomyelitis anterior acuta, occurring as these cases often do in robust, healthy children, nurses were often blamed for supposed injuries to the children in whom the disease developed.

In some cases included under this head the patient knows that the condition which he attributes to the accident was previously present—he is deliberately lying; but in others—as, for example, in cases of early tabes, of which I have seen more than one case—he may not know this; he is not deliberately and wilfully trying to deceive.

In cases of this kind a minute and careful inquiry into the previous history as to the exact nature of the accident—whether the degree and kind of injury was sufficient to account for the symptoms and conditions which are present—will in many cases enable one to arrive at a correct conclusion; but there is often great scope for differences of opinion. In some cases of this kind the difficult question arises as to the relationship of trauma to the causation of the particular diseased condition which is present, such as spinal lesions, cerebral tumour, aneurysm, cancer, and innumerable other conditions which are not infrequently said to be due to an accident.

Then, further, in some cases the question occurs—supposing the man is a diseased man when he gets the accident, is he entitled to receive compensation for the damage he has sustained? In my opinion, one is no more justified in injuring a diseased man than a sound man; but, of course, the amount of compensation which a diseased man should receive is, in many cases, very different from the amount of compensation which a sound man should receive. In cases of this kind the whole circumstances of the case have to be carefully considered and taken into account.

CASE VI.

During the first year that I was in practice I met with an interesting case of this kind. A girl, who was carrying a young child subject to epileptic fits in her arms, was larking with a young man; in attempting to strike her, it was said in play, he hit the child; the child immediately had a fit and died in the fit. The young man was committed by the magistrate for manslaughter, and tried at the Newcastle Assizes. I was a witness in the case; I had made a *post-mortem* examination. Mr. Justice Brett, in summing up, laid it down that if the jury were satisfied that the child died from the fit, and that the fit was induced by the blow, they should bring in a verdict of manslaughter; but, he said, the degree of manslaughter was for him to judge, and not for the jury. The jury returned a verdict of manslaughter; the judge discharged the prisoner; he thought that as he had already been some time in prison while waiting for the trial, he had had sufficient punishment.

Cases every now and again occur in which persons who have been apparently perfectly healthy up to the time of an accident die apparently as the result of the accident, and in which it is found after death that they are and have for many years been the subject of grave organic disease. In India many cases have been recorded in which a slight blow has ruptured an enlarged spleen and caused death. The following are cases in point:

CASE VII.

A stationmaster received a slight head injury; immediately after the accident he became ill and died a few weeks later, apparently as the result of the injury. Up to the time of the injury this man had never complained of illness; he had for many years performed his arduous duties without ever being off work; he was, however, the subject of advanced cirrhosis of the kidney and marked arterio-sclerosis.

CASE VIII.

A labourer, aged 53, employed at the Peterhead harbour works, received an accident—injury to the back, left side, and left leg—by being struck by a skip of stones on August 13th, 1909. He resumed light duty on September 24th, 1909, and some time afterwards returned to full work. In June, 1910, he sustained another slight accident, a blow on the left side; he was off work for a week, and during that time complained of shortness of breath. He subsequently had to leave off work altogether, because of shortness of breath on the slightest exertion.

I examined him on behalf of the Government on August 16th, 1912. He then stated very definitely and positively that up to the time of the first accident he had been perfectly well, and that for the previous ten years he had been employed as a labourer in the Peterhead harbour works and had not been off work through illness for a single day. I found the heart decidedly enlarged and its action irregular, the blood-pressure markedly above the normal (180 mm. of mercury), and a small quantity of albumen in the urine; the pulse was 120. The man complained of pain in the left side and of shortness of breath on the slightest exertion. He seemed to be a straightforward, truthful man.

I gave it as my opinion that his physical condition unfitted him for the work of a labourer. I stated that it was impossible to say definitely whether the disease—the cirrhotic condition of the kidney, which seemed to be the fundamental lesion—was in existence or not prior to the receipt of the first accident; but, whether this was so or not, it seemed obvious that his illness had either been produced or seriously aggravated by the injuries which he had sustained. Consequently, I thought, from a purely medical point of view, that the man was reasonably entitled to adequate compensation.

I have seen many cases of this kind; in some of them it was difficult to determine how far the accident was responsible for the result.

III.

Cases in which patients who are suffering from the effects of an accident or injury or from ordinary illness not due to accident or injury, exaggerate their symptoms, or do not get well as they should be expected to do, but continue to suffer and go on claiming compensation.

These cases are very common—in fact, of every-day occurrence. They are the cases which will give rise to so much difficulty under the National Insurance Act.

In ordinary practice the aim of the patient—at all events, of the great majority of patients—is to get well as soon as possible, and he makes every effort to aid the doctor in getting him well. But if it pays a patient better to be ill than to be well, or if a patient is lazily inclined and is content to take a holiday on sick pay—it may be half-wages—there is no inducement to get well; in fact, there may be an inducement to remain ill—to prolong the illness indefinitely.

In some of the cases included under this head the patient deliberately exaggerates or wilfully prolongs the illness; that, of course, is malingering—partial malingering, I call it. But in many cases the patient simply does not get well and does not return to work, because he has no powerful inducement to get well and to return to work; he goes on complaining for weeks, or it may be months, from symptoms. In many of these cases there is no deliberate intention on the patient's part to deceive; he is not malingering; he is a valetudinarian, not a malingerer.

We all know how very important the influence of hope is in enabling our patients to get well, and how a clever doctor who expresses a confident opinion that his patients will get well, and who inspires them with hope, does get them well much quicker than another man who takes a gloomy view of things, who shakes his head, and who does not inspire them with hope and confidence.

Any mental anxiety, such as impending litigation, the prospects of the ordeal of a trial, of being examined and cross-examined in the witness-box, retards the patient's recovery. Every one who has had much experience in railway cases knows that these patients never get well, or very rarely indeed get well, until the case is settled, until the litigation is ended; and that they then often get well with remarkable rapidity.

Now, I do not for a moment suggest that all of these patients are wilfully exaggerating or malingering, many of them are perfectly genuine sufferers; they are merely bad cases of valetudinarianism.

CASE IX.

One of the most striking cases of this sort which has come under my notice was that of a man, aged 53, whom I examined on behalf of a railway company, some two years after an accident, in which he had been slightly injured. He was suffering from the most marked symptoms of traumatic neurasthenia that I have ever seen; in addition, there were some symptoms, which time does not permit me to describe in detail, suggestive of organic disease. I pointed out in my report that it was a case in which the patient would probably get heavy damages. He claimed £7,000; he got £3,500. I am informed that this man returned to work a few weeks after the settlement, and that he has apparently been perfectly well and doing his work regularly ever since. Now I saw no reason to doubt that he was an

honest man; I did not think he was malingering; I thought, and I still think, notwithstanding the result, that it was a bad case of valetudinarianism and not a case of malingering. At all events, the case shows the important influence which settling the claim, especially if there is a very considerable amount in the way of damages, has in getting the patient well.

I have seen many cases of the same kind in which the symptoms were the result of ordinary accidents and injuries—miners and others who have been injured, and who do not get well until the claim is settled; after which they usually, in my experience, rapidly get well.

Most of us who have had much experience in railway and other compensation cases will, I think, agree that in some cases the lawyers have a good deal to do in fostering these claims and in preventing a settlement. The following anecdote expresses this. There was a bad railway smash in which a few persons were killed, several injured, and many apparently totally unhurt. One of the passengers who was unhurt, while walking down to his office a few days afterwards, was met by a friend, who said, "I was sorry to see you were in that terrible accident; I hope you were not hurt?" The man shook his head, and said, "I don't know, I have not yet seen my lawyer." But the lawyers are not only to blame. I have heard of a medical man who made it his business to hunt up persons who had been in a railway accident, and to coach them up in manufacturing false or exaggerated claims.

The subject of valetudinarianism is one of very great difficulty and of very great importance. In many cases it is quite impossible to differentiate with accuracy and certainty, on purely medical grounds, partial malingering and valetudinarianism, and the other grounds on which one has to make a differential diagnosis are often insufficient to enable us to give a positive and dogmatic opinion. In many cases we suspect malingering, but it is only in rare cases that we are justified in positively stating that a patient is malingering. In many cases, too, it is difficult to say whether a patient is a valetudinarian or not.

In many cases—for example, slight and static valvular lesions of the heart, bronchitis with emphysema, pain and stiffness in the back the result of back injuries, sciatica, or neurasthenia—it is difficult or impossible to say when the patient is sufficiently well to return to work. The patient may say, "I am not sufficiently well to work; I still feel shortness of breath on exertion; I still cough and spit; I still feel my leg stiff and painful; I still feel nervous and weak."

Formerly (before the introduction of the Workmen's Compensation Act and the National Insurance Act) many of these patients, especially men with wives and families depending on them, would make an effort to return to work at the earliest possible date. Nowadays there is not the same inducement to get well and to start work, and cases drag on for weeks or months. I repeat that many of these patients are not malingerers; they are merely valetudinarians. These are the cases in which there is likely to be so much difficulty in the future.

The following case is an illustration of the way in which these cases drag on, as the result of valetudinarianism and want of effort on the part of the patients to get well and to help the doctor in getting them well:

CASE X.

A. L., aged 20, was severely burned while at work on May 22nd, 1909. I examined her on April 13th, 1910, and advised that she should go into the Edinburgh Royal Infirmary for treatment; systematic exercises, injection of fibrolysin, and passive movements were employed, and she was discharged on June 22nd, very much better. I again saw her on September 26th, 1910; extensive cicatrices the result of the burn were present on both arms; those on the right arm did not interfere with its usefulness, those on the left arm and hand made the fingers somewhat rigid. The patient at this date claimed to be totally and permanently unfit for work; I reported that she was fit for light work, and if she only made an effort to use the left hand she would in the course of time be fit to do ordinary work. The patient received compensation at the rate of 10s. a week from the date of the accident—May 22nd, 1909—till November 13th, 1910. The case was then settled, £55 being given in a lump sum in addition to 10s. a week which she had received in the way of compensation.

In connexion with this part of the subject, the question arises whether a patient who refuses an operation which has been advised for the cure of his disease is entitled to go on receiving compensation for his illness. It is a difficult question for the insurance companies, for if they

were to insist upon an operation, and if the patient should happen to die as a result of that operation, they would obviously incur a very grave additional responsibility. The following is a case in point:

CASE XI.

A quarryman, aged 30, received an injury to the right elbow (a cut), the result of a fall in the quarry, on July 9th, 1908. The ulnar nerve had evidently been divided. There was weakness and wasting in the small muscles of the right hand, and some loss of sensation in the area of distribution of the right ulnar nerve. I saw him on February 4th, 1909, and advised that he should go into hospital for observation and treatment. The question of operation—cutting down on the divided nerve and suturing the two ends—presented itself. The patient refused operation. Improvement gradually occurred under medical treatment. The claim was ultimately settled on September 24th, 1909, the man receiving £27 10s. as damages.

There are, of course, cases in which the Workmen's Compensation Act and the National Insurance Act are godsends. Over and over again I have seen patients—say, with organic heart disease—decent hard-working men with wives and families dependent on them, insist on being discharged from hospital before they were fit to return to work, with the laudable object of supporting their dependants. Those are the cases which one desires to see insured—and well insured—well compensated and well looked after, medically and otherwise. I know of no sadder case than that of a man who insists on being discharged from hospital in order to support his wife and family, when one knows that the hard laborious work and strain to which he must subject himself will, in the course of a short time, be certain to result in another breakdown. These cases will still, I fear, be too frequently most inadequately provided for.

The cases of malingering which most frequently occur in physicians' practice are nervous cases; they are by far the most common and by far the most difficult cases. Purely surgical cases are, comparatively speaking, rare; the ophthalmic surgeon sees a large number of cases; the aurist a few cases; the dermatologist some cases. I have seen several cases in which skin lesions have been deliberately produced by young women, some, but not all, of whom were hysterics.

DIAGNOSIS.

The diagnosis of malingering is often extremely difficult; it has to be based partly on medical and partly on collateral evidence.

It is, of course, a more difficult thing to recognize that an article is adulterated than to recognize the genuine article. It is unnecessary to say that the success of the malingerer depends upon the exactitude with which he is able to represent the medical picture. I could feign many diseased conditions, such as an epileptic fit, an attack of angina pectoris or insanity, so perfectly as to defy detection. Fortunately for diagnosis, malingerers are very rarely skilled and experienced in the conditions which they attempt to represent; they usually overdo their part.

It is very difficult to feign organic disease; it is the functional conditions which are easily simulated. Consequently, the first thing in making a diagnosis in a case of suspected malingering is to make a careful medical examination and to exclude organic disease.

In nervous cases the differential diagnosis of organic and functional disease, unless one is specially skilled and experienced in nervous disease, is often very difficult. One sees this in private practice in cases in which there is no question of compensation and no suspicion of malingering. One sees cases in which experienced hospital physicians and surgeons differ with regard to these cases, in which one man says that there is, and another there is not, organic disease. Many cases of this kind have come under my notice. Let me give you two striking illustrations:

CASE XII.

A female, aged 21, single, a domestic servant, was admitted to the Edinburgh Royal Infirmary on November 16th, 1911, suffering from great difficulty in walking, due to shortening and contracture of the left leg. The history was that two years previously she had fallen down a flight of stairs and received an injury to the hip and back. For some weeks after the injury she went on working, but with great difficulty. She then was admitted to a large hospital; the surgeon under whom she was admitted diagnosed the condition as organic disease of the left hip-joint; she was discharged five weeks later, a heavy boot

with a big sole and high heel being prescribed. For eighteen months she remained in the same condition, complaining of her hip and walking with great difficulty. She was then sent to see my son, Dr. Edwin Bramwell, by Dr. Garnett Wright, who with Dr. Edwin thought the condition was functional.

On examination it was found that the left leg was 3 in. shorter than the right; there was very marked twisting of the pelvis and great deformity. The condition appeared to me to be purely functional; but I thought it well to have a surgical opinion. I asked Professor Alexis Thomson to see the case; he was unable to do so until the beginning of December; until this date, therefore, nothing was done in the way of treatment. At Professor Thomson's suggestion two x-ray photographs were taken; the first seemed to show that the neck of the right femur was very decidedly shortened; this appearance, however, was fictitious, due to foreshortening in the photograph; the second photograph showed that the left hip was absolutely normal. Professor Thomson agreed that the case was purely functional, the shortening being due to a functional contracture.

On December 7th, 1911, the patient was placed under chloroform; the two legs were found to be the same length and have remained the same length ever since. The patient was told she was now perfectly well and would be able to walk in the course of a short time. A week later she was running up and down the long ward and was completely restored to health. She has remained well ever since.

CASE XIII.

A female, aged 19, single, was admitted to the Edinburgh Royal Infirmary on June 3rd, 1911, suffering from inability to open the mouth. Two and a half years previously a molar tooth on the left side was extracted under cocaine; the patient fainted when the cocaine was injected; half an hour later the jaw became rigidly closed and had so remained ever since. A month after the contracture developed a dentist opened the jaw and kept it open with a gag for a short time; a fortnight later she went into a large hospital under the care of a distinguished surgeon; the jaw was, she says, scraped and a gag was placed in her mouth to keep the jaw open; this treatment was ineffectual.

On examination, nothing abnormal except the rigid contracture of the jaw muscles, was found. The condition was diagnosed as a functional contracture. The patient was told that there was no organic disease and that we would speedily cure her. She was isolated behind screens, and was given hypodermic injections of H₂O. On June 14th she could open her mouth as wide as she had ever been able to open it. She has since remained quite well.

These are two remarkable cases. Had they come into court it cannot be doubted that both patients would have received heavy damages, and that laymen would have jeered at the difference of medical opinion. The point I wish to make is that these differences of opinion are constantly occurring in private practice, and that the differences of opinion which so frequently occur in courts of law are in many cases honest differences, and due to the difficulty in diagnosis which many of these cases present. Let me give a striking case in point—a case in which the late Sir William Banks, who all of us who knew him will agree was as honest and reliable and truthful as he was experienced, made a grave diagnostic mistake.

CASE XIV.

A man, aged 30, fell from the mast of a ship in January, 1902, and sustained a severe injury to the lower part of the back. He was awarded £1 a week as compensation. In April, 1904, my insurance company—the Scottish Union and National—applied at the Liverpool County Court for the review and diminution of this weekly payment. It was stated that unless the case were reviewed this man, aged 32, might go on drawing this compensation of £52 a year for the next forty years, and the sum of £2,000 which would thereby be involved was very substantial compensation for an accident, the compensation for which, had the man been killed outright, would have been only £300.

Professor Paul and Sir James Barr were called on behalf of the insurance company. They stated that, in their opinion, the man's bent condition and general crippled appearance were due to a mental delusion on his part, and not to any organic change.

Sir William Banks was called on behalf of the man, who appeared to be a perfect cripple, and could only walk with the assistance of crutches. Sir William Banks had no reason to think that his condition was due merely to a mental delusion on his part; he thought that he was suffering from a chronic inflammation of the bones and joints at the bottom part of the spine, and that they had become so fixed that they would not properly unbend. He was of opinion that, in all probability, the patient would never be again fit for the kind of work he had hitherto followed, but he might, in time, sufficiently recover to do some light work. He did not think the man was shamming. In July, 1910, the claim was settled for £600; £571 had been previously paid in compensation and costs.

The patient continued to go about on crutches until June 13th, 1911. He was then cured "like the shot of a gun," to use his own words, by bathing in the holy well at the shrine of

St. Winifride. For eight years he had been hobbling about on crutches; when he got out of the water he was able to walk back to the hospice, leaving his crutches in the crypt of the well.

He was seen by an inspector of the insurance company on August 12th, 1911; he then looked the picture of health, was upright, was walking at a quick pace, and was able to walk several miles a day driving sheep.

Now, if experts differ in this way, it is impossible to expect the ordinary general practitioner to come to a correct conclusion as to the nature of many of these most difficult cases.

Then there are diseased conditions, some of them very serious, which the most expert and experienced physician is unable to detect—such, for example, as small, deep-seated thoracic aneurysms (which even the x rays may not disclose), and disease of the coronary arteries, with severe angina pectoris. I have seen cases of this sort in which it was impossible to detect any definite evidence of organic disease in which the patients have died from the condition soon after my examination.

In those cases of suspected malingering in which there are symptoms or signs of organic disease—I am speaking more especially of cases said to be due to accident or injury—one has to make sure, as I have previously stated, that the organic lesion was actually due to the accident or injury, and that it was not present before the receipt of the injury. A careful inquiry into the previous history will usually enable us to determine this point. In cases of partial malingering it is often impossible to say how far the symptoms are genuine and due to the results of injury or to the organic disease which is present, and how far to malingering and wilful exaggeration on the part of the patient.

Certain things show that there is organic disease—such, for example, as localized muscular atrophy, the reaction of degeneration, paralysis of the sphincters, acute bedsores, the Babinski sign and ankle clonus (if perfectly typical and persistent, and not merely temporary and evanescent), complete loss of the knee-jerks on reinforcement, optic neuritis and optic atrophy, definite changes in the cerebro-spinal fluid, "skew-deviation" of the eyes. It must, however, be admitted that apparent exceptions to some of these statements are sometimes met with. Paralysis of the sphincters, for example, which is usually a very definite sign of organic disease, was said to have been present for six weeks in the case of the man who got £3,500 damages, to whose case I have already referred—that was one of the things in the case that we thought positively indicative of organic disease.

Let me here say a word or two with regard to the value of electrical tests in cases of paralysis. Some people seem to think that one can differentiate paralysis and malingering by means of electrical tests. That, of course, is not the case. It is hardly necessary to say that in many cases of permanent paralysis the paralysed muscles respond actively to the faradic current. At the last meeting of the British Medical Association there was a discussion on the Medical Training for the Detection of Malingering,¹ and the gentleman who introduced the discussion is reported to have said:

Other numerous examples of the many varieties of malingering could be given—for instance, cases in which joints, though freely flexible to passive are apparently rigidly fixed to voluntary movement, and cases in which muscles, though apparently paralysed, readily respond to the faradic current, are so common as not to be worthy of discussion in detail.

In other words, that statement implies that if a paralysed muscle contracts to the faradic current it is not paralysed. There must be some error in the report, for I cannot conceive that the gentleman who introduced that discussion could possibly have made such a statement. In a recently published book on malingering, equally erroneous statements as to the effect of electricity in cases of paralysis and of the value of electrical tests in the diagnosis of malingering are made.

Then, again, it is sometimes concluded because a stiff joint or a contracted limb relaxes under chloroform and the joint is normal that the case is one of malingering. I have seen many cases, and published some of them, in which rigid contractures, due to functional nervous causes, have lasted for weeks and months and years, in which the contractures have been relaxed under anaesthetics, and the condition has been rapidly and completely cured by

appropriate treatment (a confident opinion that there was no organic disease and that the patient would rapidly get well, together with isolation, the electric current, and hypodermic injections of H_2O). Cases XII and XIII are striking illustrations.

Modern methods of research, such as electricity, the x rays, the perimeter, are often, I need hardly say, of very great use in the differential diagnosis of obscure cases, in differentiating functional and organic disease, and as an aid to the detection of malingering. The following is a case in point:

CASE XV.

A girl, aged 13, complained of blindness. She appeared to be in robust health. Ophthalmoscopic examination showed that the fundus was perfectly normal; there was no headache and no vomiting; with the exception of the impairment of vision, there were no symptoms. Careful examination with the perimeter showed the presence of a central scotoma. Dr. George Mackay, who kindly examined the patient, diagnosed a retrolubar neuritis, an exceedingly rare thing in an apparently healthy young girl aged 13.

Corroborative non-medical evidence is the second class of evidence which one has to trust to. If a nervous case presents unusual symptoms which one cannot explain by a syphilitic or other apparent cause, one suspects malingering, more especially if the patient has anything to gain by deception.

In cases of this kind one has to lay traps to detect the deceit. I have the records of some railway cases in which the patients have been watched by detectives, the malingering proved, and the supposed patients convicted either of perjury or of trying to obtain money by false pretences (see Cases II and III).

One of the ordinary tests which one employs in cases of nervous disease is Romberg's test; it is not of great value, because inability to balance the body steadily in the erect position may be due to psychical causes or to weakness as well as to inco-ordination, and because it is so easily simulated. In employing Romberg's test in cases in which one has reason to suspect deceit I take care to see that the patient does not know what I am testing. I tell the patient, for example, that I am going to see whether he can hold out his hand steadily, and then, when his eyes are shut and his feet close together, bring the tip of his forefinger accurately in contact with the tip of his nose—the finger-nose test. I show him what I wish him to do. I see at once whether he has Rombergism or not. He thinks I am testing his ability to touch his nose, whereas I am testing his ability to stand steadily in the erect position with his feet close together and his eyes shut. That is an example of the sort of trap one sets; an experienced observer gets into the habit of using many dodges and traps in cases of this kind. Everything that the patient does and how he does it, both during the examination and when he does not think that he is being observed and examined, should, of course, be noted.

CASE XVI.

At the Glasgow meeting of the British Medical Association the late Professor Grainger Stewart showed a most remarkable case—an old woman who had an epileptic fit whenever she went into the dark. Professor Grainger Stewart took her to Glasgow in a first class carriage, and he told the meeting that she had a fit in each of the tunnels. The case attracted much attention. Shortly after the meeting I one day followed this patient into the surgical entrance of the hospital; she went down the stairs, immediately inside the entrance, into a very dark corner, struck a match, and lighted her pipe. She was very indignant when I asked her why she had not had a fit.

Now, from what I have said it will be apparent that there are many cases in which one suspects malingering, but there are few cases in which one can definitely certify that a patient is a malingerer. As pointed out in an article in the *Times* of November 7th, 1912, the panel doctor who certifies that a patient is malingering assumes a grave responsibility, and if he makes a mistaken diagnosis runs a great risk of a complaint being made against him, and of getting into grievous trouble and of having his name struck off the panel. In giving certificates one should be very careful in the wording of the certificates; except in very clear cases, one should avoid definitely stating that the patient is a malingerer; in doubtful cases one should say that, "So far as my examination, knowledge, and experience enable me to judge, the patient is fit to return to work," or, "So far as I am able

to detect, there is no organic disease and the patient is able to return to work." The doctor who is asked to certify whether a patient is malingering ought to be perfectly independent of the result.

Repeated examinations are often necessary in order to determine whether a patient is suffering from functional or organic disease, and whether he is malingering or not. The German plan of obliging these doubtful cases to go into hospital, in order that they may be under skilled observation and repeated examination, is a good one.

THE PREVENTION OF MALINGERING.

In order to prevent malingering under the National Insurance Act I would suggest:

1. *An exhaustive medical examination by the panel doctor.* The only sure means of detecting malingering is careful medical examination and careful medical observation by a competent doctor. In cases of prolonged sickness and in cases of repeated sickness the patient's fellow workmen no doubt often become suspicious, but the malingering may have gone on for weeks or months before that suspicion is aroused. In most cases malingering can only be detected in its earlier stages by the medical attendant.

2. *In doubtful cases consultation with a specialist.* The panel doctor must be protected, and the only way to protect him is by giving him the opportunity of calling in an expert to decide upon the nature of the case and to give a certificate. The consultant must be a specialist in the particular department of medicine or surgery which is concerned in the particular case; a physician, for example, who has no special knowledge of nervous disease cannot give a reliable opinion on a difficult nervous case; a surgeon cannot be expected to give a reliable opinion on a difficult eye case or ear case.

The expert should be perfectly independent of the result, and these experts should, of course, be properly paid.

In the *Times* (November 9th, 1912) Dr. F. C. Mears suggests that "in every case where the evidence of disability rests solely on the word of the insured person, he should be compelled by law, at the expiration of a fortnight's sick benefit, to appear before a quorum of not less than half the doctors on the panel of his district, and if the decision of this tribunal is final and without appeal, malingering will die out in a very short time." In my opinion, a quorum of half the doctors on the district panel would be very unwieldy. A committee of three would be surely sufficient. But why should all this additional gratuitous work be put upon the already underpaid panel doctors? Further, the panel doctors are not experts, and it is the opinion of experts which in difficult cases is required.

3. *Observation and repeated examination in hospital in doubtful cases.*

4. *A time limit to the purely functional cases and in cases in which there is no obvious organic disease.* In cases of neurasthenia, for example, the patient ought not to be allowed to go on drawing pay indefinitely. A certain time limit should be laid down. The patient should be told that there is no organic disease; that, medically speaking, he is quite fit to work; that unless he goes back to work on a certain day the money payment will cease. This plan would no doubt entail a real hardship in some genuine cases of functional disease, such as neurasthenia—and there are many such—but I am afraid this hardship must be faced.

It would be exceedingly difficult to lay down a time limit in cases in which there is organic disease—in a case of organic heart disease, for example, in which, as I have already pointed out, it is often exceedingly difficult to decide whether the patient is fit for work or not. But in cases in which there is no obvious organic disease I would certainly suggest that there ought to be a time limit.

In some countries the patient who claims sick benefit has to make a direct money contribution towards such sick benefit; if such direct contribution is sufficient in amount, it will, of course, stop much malingering and much valetudinarianism. Unfortunately, under the National Insurance Act no money contribution is required except the weekly payments which all insured persons have to make.

REMARKS ON MALINGERING.

BEING AN INTRODUCTION TO A DISCUSSION OF THE SUBJECT AT A MEETING OF THE LEICESTER DIVISION.

By C. J. BOND, F.R.C.S.,

CONSULTING SURGEON TO THE ROYAL INFIRMARY, LEICESTER.

INTRODUCTION.

We may regard malingering as a fraudulent attempt to obtain pecuniary benefit or exemption from work or duty on the plea of some assumed, misrepresented, or exaggerated disability, illness, or injury. There is no doubt that during the last few years malingering has increased among industrial workers. It was formerly chiefly prevalent in the army, the navy, and the pauper class. Apart from the pecuniary loss to employers of labour and to insurance societies, and the demoralizing effect of successful malingering on the person who makes the fraudulent claim, malingering injures society as a whole, because unjust claims tend to increase the amount of the premium demanded by insurance societies against the risk of accident and illness.

It is necessary to remember that a claim may be false without being fraudulent. It may be founded on a genuine although mistaken impression concerning the presence of certain symptoms and disabilities without any intention to obtain benefit by fraud. Everything depends on the motive. We must bear the motive in mind when considering the undoubted increase in the number of persons who, since the commencement of the Insurance Act, have consulted doctors on the panel for slight ailments which, under ordinary circumstances and before the commencement of the Act, would have been disregarded. That the motive underlying this increased request for medical advice is not in many cases fraudulent is shown by the fact that the majority of the patients seeking advice do not cease work or claim sickness benefit. The novelty of the situation created by the Act and the desire to ascertain whether medical benefit under the Act is bona fide has no doubt operated in some cases.

Moreover, this early seeking of medical advice has its beneficial side from the public health point of view. Experience in Leicester and other towns already shows that in some cases the detection of serious illness which would have otherwise escaped recognition has been brought about by this means.

THE PSYCHOLOGY OF THE INDIVIDUAL IN RELATION TO MALINGERING.

It is important to remember that the fraudulent misrepresentation of symptoms and disabilities which constitutes malingering shades off into a genuine but exaggerated idea of the importance of slight symptoms.

The attitude of mind which underlies malingering is not confined to the working classes.

Owing to a false notion of the status of public bodies, and to a false idea of what should be the normal relationship of the individual to the State, it has come about that individuals, in all classes of society, take up an attitude, in regard to claims against public authorities or the Government, different from that which they would think it right to adopt towards a fellow citizen. This desire to get all that can be got when entering a claim against an insurance office or a railway company is partly the result of a predatory habit of mind natural to some persons, and partly the outcome of an evolutionary struggle between individual and group interests, and partly, no doubt, to the reluctance of some companies to grant even legitimate claims except under compulsion.

Nevertheless, it is important to realize that deception in regard to the payment of income tax or the exaggeration of a claim for compensation against a public company or the Government, may be just as much a form of malingering and just as fraudulent as an attempt on the part of a workman to obtain compensation or to avoid work by the exaggeration of the symptoms of a disease, or the effects of an injury contracted during employment.

It is probable that the effect of recent legislation (for example, the Workmen's Compensation Act, 1906, and the National Insurance Act, 1911) will be to increase malingering in England as like legislation has already increased it in Germany and France. Thus Ewald¹ states that the

large number of nervous workmen in Germany in whom the thought of compensation has become a fixed idea is giving anxiety to German legislators, while M. A. Brissaud in France describes a new disease "Psychical Accident" as the result of the French accident law of 1898.

CHECKS.

In view of these facts it is very important to check this growing tendency to malingering and the exaggeration of disabilities by:

1. Making the presentment of fraudulent claims difficult and unsuccessful, and in some cases a punishable offence.
2. The formation of a more enlightened public opinion concerning the right relationship of the individual to the community, and the education of all classes of society in the duties and responsibilities of citizenship.

LEGAL INFLUENCES WHICH PROMOTE MALINGERING.

Every medical man who has had any experience of accident and disease in connexion with industrial life must have realized that what we may call the fraudulent or predatory attitude on the part of some claimants for compensation is frequently strengthened if not manufactured by interested societies and unscrupulous persons. A bona fide wish to put in a reasonable claim grows and develops under the stimulating influence of a speculative action at law into an overpowering desire to obtain a victory even at the expense of justice, and when the obtaining of a verdict means the aggrandisement of needy and unscrupulous persons the danger of injustice is very considerable.

Other factors of a medical kind also play a part. The chances of legal success in any complicated case are undoubtedly increased by the gaps which still exist in medical and surgical knowledge, and by the contrary inferences which are drawn and the different opinions which may honestly be formed by different medical men about the same medical facts, all of which differences may be magnified and distorted by opposing legal parties.

It is at any rate probable that out of the 48,565 claims for compensation in 1911 under the Workmen's Compensation Act, a larger proportion would have been settled out of court were it not for the influences of a legal kind which were brought to bear upon needy and, in some cases, not too honest claimants.

It seems probable, therefore, that there is a need for the genuine, as contrasted with the speculative, poor man's lawyer.

THE POSITION OF THE DOCTOR IN REGARD TO MALINGERING.

Apart from the guardianship of his own interests, the medical man is in a position of a public servant whose duty it is to protect society against fraud in his special field of work. In carrying out this duty the less the medical man is penalized or affected by considerations of self interest the better for the community.

Thus, in regard to this question of the detection and suppression of malingering, the doctor tends to be influenced by:

1. The risk of offending his patient and his patient's family.
2. The method by which he receives remuneration for his services—that is, whether by capitation fee or by payment for services rendered.

The first difficulty can be best overcome by the appointment of medical referees (not on the panel) under the Insurance Act, whose duty it should be to examine and report upon cases of unusually prolonged illness and doubtful claims for benefit.

It is true that the Medical Service Subcommittee, with its equal number of medical men and representatives of insured persons, and its independent chairman, affords some machinery for the hearing of complaints between doctors on the panel and insured persons; it is not probable, however, that this body will be much used, or will be of any great value in checking malingering, in which the problem is not only the detection of the confirmed malingerer, but the bringing of considerable numbers of insured persons into more reasonable mental attitudes

about symptoms to which they attach undue importance, and in regard to claims for sickness, disablement, and other benefits to which they erroneously think they are entitled.

The problem is how to bring this salutary influence to bear in an early stage, and in an authoritative way, before any definite complaint has been formulated on either side. This can be done most efficiently and with least friction by the appointment of medical referees (as suggested by Sir John Collie).² If overlapping is to be avoided and an authoritative tribunal is to be secured, these referees must be appointed either by the whole of the approved societies conjointly in any district, or by the Insurance Committees in conjunction with the societies, or by the Commissioners.

The second difficulty can be met by the adoption of the method of payment per caput, though this has other disadvantages. It certainly tends to increase the work thrown upon hospitals.

Every social, municipal, and legislative forward movement which tends to promote the preventive and public health side, as opposed to the commercial side, of medical practice reacts beneficially on the public conscience; it helps to discountenance that peculiar mental attitude which tends to magnify individual disabilities, which seeks to obtain immediate relief of symptoms by short cuts and patent medicines, and which exaggerates the importance of individual claims.

One of the strongest arguments in favour of gradually building up a unified, State-controlled public medical service is, that such a national health system would relieve those upon whom the burden of providing funds for hospital and institutional treatment now falls, of the fear of the loss of annual subscriptions. But it would do more than this—it would raise the status of the practitioner of medicine, it would make him a member of the Civil Service and place his interests and his work on a firmer basis. He would be able to give advice and treatment with the single object of promoting in his patient a physiological way of life, and he would be unhampered by any anxiety about possible resentment on the part of the patient towards himself and his advice.

ADDITIONAL SAFEGUARDS AGAINST MALINGERING.

1. The periodical oversight of insured persons in receipt of sickness and disablement benefit by visitors appointed by approved societies. (The term "visitor" may possibly include medical visitors and thus possibly provide for the appointment of medical referees.) This, although provided for in the model rules issued by the Commissioners, is permissive, and has not been adopted by all societies.

2. The issue of rules by all societies providing for the compulsory medical examination—and, if necessary, re-examination—of all cases of unusually prolonged illness and in cases in which it appears probable to the officials of the society (or to the medical men on the panel or to the Insurance Committee) that unfair claims for benefit are being made. In this way the working of the Insurance Act would be brought into harmony with the provisions of the Workmen's Compensation Act, which provides in Section 14 for the compulsory examination and re-examination of persons claiming compensation.

3. Some system of registration showing in any case the total amount of sick pay and pecuniary benefit received, and the proportion which this bears to the average wages when at work. In regard to this point, however, it is necessary to recognize the undoubted right of every workman, like every other citizen, to obtain pecuniary benefit and exemption from toil by thrift—that is, to insure up to any extent that he may think desirable so long as it is clearly understood that this extra insurance does not carry any peculiar right to sickness or disablement benefit by the misrepresentation of some disability, or to obtain idleness by the misuse of public funds.

4. Another difficulty relates to the rigidity of the rule which in many cases forbids partial employment and insists on total disablement during the receipt of benefit. Any attempt to test recovery by a return to partial work entails the loss of the right to further compensation or benefit. Benefit and compensation, in fact, do not, like illness, reach a maximum and gradually decline; they begin suddenly and end suddenly. Hence the reluctance on the part of the workman and his legal adviser, and in

some cases his medical adviser, to declare off the funds. No doubt the administrative difficulties in the way of granting partial sick benefit and allowing partial disablement under the Insurance Act are very great, but here also the appointment of medical referees with discretionary powers, subject to revision on appeal in certain cases, might possibly provide a partial solution of the difficulty.

5. Finally, much depends on the attitude of medical men themselves, and the extent to which they realize that the interests of the doctors on the panel in any area are corporate interests, and that if one practitioner is over-lenient and careless in the matter of prescribing and signing certificates, all his colleagues will be affected, not only by the extra drain on the funds available for medical benefit, but also by the false standard which is thereby set up in regard to demands by insured persons on the time and attention of other medical men.

A PLEA FOR MEDICAL REFEREES VERSUS INSPECTORS.

By SIR JOHN COLLIE, M.D.,

MEDICAL EXAMINER TO THE LONDON COUNTY COUNCIL.

THE following suggestions are based upon considerable experience of the practical working of the Workmen's Compensation Act, and are made with a view to minimizing abuse of the sickness and disablement benefit clauses of the National Health Act.

The attitude of the profession with regard to suggested "inspectors" under the Act is hostile, but judging from interviews I have had with medical friends who are working the Insurance Act I believe the profession would welcome the appointment of medical referees under the Act, whose duty it would be to assist the medical men on the panel to put down malingering, and thus to safeguard the funds available for sickness benefit.

I believe that in a short time from their appointment the assistance of such officials, whose functions I am about to suggest, would be largely in requisition in doubtful and difficult cases, provided it is made abundantly evident from the beginning that they are appointed not to report on the conduct of the medical men, but on the conduct of the assured, and that their *raison d'être* is solely to assist the medical men who are working the Act in dealing with cases of suspected malingering.

The approved societies might fairly be expected to pay towards the remuneration of these officers either an annual sum, or so much per consultation, and would find—as has already been found in Germany—the saving much greater than the cost.

The difficulty of deciding whether a patient is incapable of work is a very real one. It arises in two classes of cases:

1. Those who consider themselves incapable of work, but are in fact able to do it.
2. Those who are capable of work, know it, and yet are determined to remain on the sick list as long as they dare.

In practice it will be found that the funds of the approved societies will be depleted from both these sources, and probably to a much greater extent by the former.

The first class is the more difficult to deal with. Its size is scarcely yet appreciated by the friendly societies or by those who are responsible for the administration of the Act. It embraces many who are often erroneously called "malingerers"; it includes a large proportion of those who are known in the law courts as "traumatic neurasthenics," and not a few of those known in the out-patient departments of hospitals as suffering from "functional nerve disease." It embraces a great number of complaining people who have no special temptation to remain in idleness, and who, until the passing of the Act, were in receipt of no special sick benefits. It is certain that there will be a considerable increase of unnecessary medical attendance if these people are allowed indefinitely to take advantage of the sick benefits under the Act.

Experience of a small selected group of employees in the public service showed that strict supervision reduced the total number of those whose illnesses lasted more than twenty-eight days by 50 per cent.

In men the condition is usually associated with an obscure want of mental balance and an apparent loss of courage and feeling of manliness. I fear it will be found in even greater proportion amongst the female operatives who come under the benefits of the Act.

Generally speaking, medical practitioners treat these complaining folk sympathetically, and assume their genuineness, and, even when doubts arise, accept and treat them as cases of chronic illness. Yet the majority are curable. If they are not treated energetically at an early stage they tend to become chronic, and a proportion lapse into true malingerers. This class is peculiarly responsive to its environment and are very reflective of the mental attitude and personality of their medical attendant. I feel assured that medical referees, if appointed, would have a vast influence for good in a multitude of these cases which are bound to be exceedingly troublesome to doctors on the panel and very costly to the committees unless properly dealt with. The medical referee's influence, however, will entirely depend upon whether he works in co-operation with the doctor on the panel.

A single consultation will be found, as a rule, not sufficient. Patients of this type do not give up the fetish of ill health at the single bidding of any one. Two, three, or even more visits with the doctor in attendance may have to be made before the assured is successfully led out of his morbid mentality.

Subjective sensations in those predisposed to introspection have a peculiarly demoralizing effect on many of the working classes. Unless at an early stage in their history these unfortunate people are led out of themselves long periods of time are wasted in supposed helplessness, which, apart from the economic aspect of the loss of their labour, must have a debilitating effect upon the character not only of those concerned but of their associates.

The subjoined table is extracted from the 62 cases of functional disease which I recently sent to the Maida Vale Hospital for Nervous Diseases. All were settling down to chronic invalidism, and had they not been isolated from their sympathetic friends and environment, would have been pensioners for life. The cases represent a class which, unless it is recognized and grappled with, will entail an enormous amount of unnecessary medical attention, and will be a fruitful source of annoyance and irritation to hard-worked practitioners.

With regard to the second class—those who are capable of work, know it, and yet are determined to remain on the sick list as long as they dare: Out of 14 million insured persons, the aggregate number of malingerers is likely to be considerable.

The question is one of diagnosis. The natural antipathy that every practitioner has to accuse of fraud those who have trusted him will, at first at any rate, tend to influence the number of those who complain unnecessarily. Medical men as a rule are not on the outlook for simulation of disease. They are accustomed day by day to treat people who are genuinely ill, most of whom they have for years had good reason to trust, and often it is not until the case becomes wearisome and the fraud is irresistible that the idea of malingering is forced on the busy practitioner. When diagnosed, the question resolves itself not so much into a matter of treatment as a battle of wits. Under these circumstances most medical men will dislike the position in which they will find themselves. If, therefore, friendly societies, local committees, or the Government require this sort of work done, then special assistance should be put at the disposal of the practitioner, and medical referees, whose primary duty it is to look after the business part of the contract, should be appointed.

Experience teaches that a considerable proportion of insured persons who, after receiving compensation for accidents under the Workmen's Compensation Act, have been forced back to work either by the arbitration courts or threats of arbitration proceedings, will, after a few days' half-hearted work, again put themselves on the sick list. It is to be feared that in these cases, where

| Occupation. | Nature of Illness. | Days of Disablement prior to Entering Hospital. | Days in Hospital. | Result of Hospital Treatment. |
|----------------------------|--|---|-------------------|---|
| A. A., clerk | Neurasthenia; obsession of diabetes | 163 | 58 | Returned to work after fortnight in country. |
| A. B., seaman | Alleged injury to back | 302 | 51 | Resumed work. |
| A. C., surveyor | Neurasthenia complicated with alcohol | 56 | 26 | Returned to work. |
| A. D., carman | Typical traumatic neurasthenia; gave himself up to introspection | 434 | 45 | Resumed work. |
| A. E., stevedore | Alleged traumatic neurasthenia | 6 years & 8 months | 42 | Satisfied nothing the matter; discharged from hospital; weekly payments stopped; county court proceedings; judge and medical assessor decided fit for work. |
| A. F., seaman | Functional neurosis; back kept at almost right angle | 612 | 45 | Resumed work as a seaman. |
| A. G., tram driver | Treated for myelitis for 13 weeks, full pay most of time; ordered to hospital, where he had fits, blackening his face to give them realistic effect | 428 | 70 | Interview in hospital; plain speaking; walked to my house, distant 1 mile, the next day; resumed work within a week. |
| A. H., engine driver... .. | 7 years previously off work whole year with strained back; now having been off work 9 months with back again said to be strained, was sent to me for examination with a view to superannuation; sent to hospital for observation | 8 months | 11 | Told he would be reported as a malingerer and lose pension if he did not immediately resume work; left hospital next day, resumed light work, six weeks later resumed full work, and has been at it the last five and a half years. |

compensation has been stopped, further attempts will freely be made to claim sick benefit under the National Health Act, by the simple process of attempting to give the alleged disability a medical instead of a surgical nomenclature. For instance, a workman who has had a not very serious injury, but who has suffered from concussion at the time of the accident and has been much shaken, eventually recovers; his wounds heal, and he has all the physical appearance of health; but he is still somewhat nervous, has lost the work habit, is introspective, and refuses even to attempt work of any kind. By threats of, or it may be by actual legal process, the employer shakes off his liability, and the workman, at last aroused to his responsibilities, obtains temporary light work for a few days. This under the circumstances is naturally distasteful. He is full of complaints, but has none of the usual stigmata of disease; he insists he is weak, declares he simply cannot work; his illness is now called "neurasthenia," "general debility," or, what is much more likely, he exalts some *symptom* such as neuralgia, indigestion, etc., is successful in getting a medical certificate of unfitness, and becomes a more or less chronic patient, and wastes the time of many a hard-worked practitioner for months, it may be for years.

Those accustomed to dealing with illegitimate prolongation of disabilities following accident will appreciate how, under certain circumstances, much ingenuity is likely to be spent in trying to persuade medical men to transfer an alleged illness from the category of *accident* to *disease*, and thus become a pensioner on the National Insurance Fund.

If such a scheme as I indicate were to work successfully, the advice of such experts as I advocate will not require to be forced on, but will be actually welcomed and applied for by the doctor in attendance.

I believe the appointment of medical referees cannot be long delayed. Assuming that the notice of a suspected case reaches a medical referee not from the doctor in attendance, but from either the Insurance Commissioners, the Insurance Committee, or an approved society, his first and invariable duty would be to put himself in communication with the doctor in attendance. If this is not done antagonism would at once be aroused, and very rightly a spirit of opposition fostered which would be fatal to the success of the scheme.

One difficulty likely to arise will be where large approved societies employ their own medical referee, who sees assured persons not at their own houses, but either at the society offices or at his own consulting room, and where a considerable number of cases are daily submitted to the medical officer, under some such rule as that adopted by the London County Council and the Metropolitan Water Board, whereby every such case is certified by the chief medical officer every twenty-eighth day. Under these circumstances it would be impracticable to

ask or expect the practitioner in attendance to meet the medical referee. Yet this difficulty can be got over; the doctor in attendance in every instance would be communicated with prior to the medical referee seeing the case, and a clear statement made in writing that his patient is being interviewed solely for the purpose of the medical referee reporting progress to the Commissioners, the Insurance Committee, or the approved society, that no opinion will be expressed to the patient, and no suggestion of treatment will be made to the patient.

In the event of difficult points arising it should be the duty of the medical referee to call upon the doctor in attendance and discuss the matter.

With regard to the question of the selection of the medical referees. The personal qualities of sound judgement, absolute integrity, and fearless independence are of infinitely more value than academic distinction. Nor do I think that mature age is necessarily a qualification which should have undue influence in the selection of men to fill these posts—given the qualities above referred to, many comparatively young men are often well suited for work of this sort.

The difficulties are: That approved societies would probably be unwilling to pay sufficient remuneration to command the best men; that they might be found to be lacking in sufficient judgement to make a proper selection; and that local influences and prejudices might lead to the selection of members of the profession known to members of the elective body, but who are not the best candidates. The professional status of the medical referee is a matter of much moment, and he should, in my opinion, have the status and emoluments of a Government servant.

If it were decided to appoint whole-time officers, and these were made responsible to the Insurance Commissioners, some arrangement might be made whereby they were assigned wide areas, which would in many ways tend to maintain their independence. Small boards of referees would, with little difficulty, be constituted for difficult cases in large centres.

A difficulty which the Government is sure to have, and one with which a staff of trained medical referees could best grapple, is the question of "incapacity for work" as opposed to the suggestion—so often made—that because a man cannot work *at his work* therefore he is unfit for any work.

Further, the medical referee would be particularly useful in cases of disablement benefit. I think probably there is much reason to fear that a large number of frauds and semi-fraud will be perpetrated in this connexion. I speak from experience, for of the first 80 cases presented to me for examination when I acted as chief medical officer to a society, 40 returned to duty forthwith at my instigation, many of whom had been drawing sick pay for long periods.

Many pensioners could be saved entering upon chronic

invalidism if treated firmly at an early stage, but when weekly payments have been made for periods extending over months it will be considered an "injustice" to withdraw it: it will, therefore, be necessary at a very early stage to have these cases visited and reported upon, preferably by independent medical men. For this purpose a medical referee visiting staff would be particularly useful.

The practical experience of the working of the Asylum Officers' Superannuation Act, 1909, is of assistance in this connexion. It will be remembered that Clause 3 (subsection 1) of this Act provides for the re-examination of pensioners at intervals of a year. As medical officer appointed under the Act for the County of London, I can well appreciate the difficulty a medical man is in when asked to revise at intervals the advisability or otherwise of continuing a pension in which the pensioner considers he has a vested interest, merely because so many antecedent weekly or monthly payments have been made.

For these and other reasons which the exigencies of time and space prevent my setting out in further detail I have formed the opinion that medical referees should be appointed. Their coming is inevitable. Their advent will be welcomed. The sooner they are arranged for the better for those members of the profession who are about to wrestle with difficulties which I know well, for the special nature of my work compels me to encounter them daily.

STUDIES ON BERI-BERI.

FURTHER FACTS CONCERNING THE CHEMISTRY OF THE VITAMINE-FRACTION FROM YEAST.

By CASIMIR FUNK,

BEIT MEMORIAL RESEARCH FELLOW.

From the Biochemical Department, Lister Institute.)

[WITH SPECIAL PLATE.]

At the end of 1911¹ I described a method for the isolation of the vitamine-fraction from rice polishings. At this time only a single substance was detected, which was studied to some extent in its chemical properties and curative power. Early in 1912² I was able to show that the same method might be successfully used for the isolation of the vitamine-fraction from other foodstuffs, namely, milk, yeast, brain, and lime juice. Even at this time it was noticed that the isolated pure substance of the melting point 233° had a slightly diminished curative power as compared with the crude product. As a second substance at that time could not be isolated, there was no explanation of this fact available. Since then I have been able to show³ that a number of purin and pyrimidin derivatives possess a slight curative effect—a very interesting fact, which, however, did not simplify the problem.

It was therefore conceivable that besides the substance of the melting point 233°, small quantities of other substances might be present in this fraction, the physiological effect of which therefore would be the resultant of the individual actions of these constituents.

A fractionation of the yeast extract was therefore carried out on a large scale and the results of this are shortly summarized in this preliminary communication.

The alcoholic extract of 100 kg. dried yeast was prepared, following the method already described in my earlier papers. The fractionation itself was carried out without any change of methods and only the silver and baryta fraction which represents the vitamine-fraction was carefully investigated. The total amount of substances obtained in this fraction from 100 kg. of dried yeast was 2.5 grams. This initial product was crystalline and melted at 210° (uncorrected).

A number of pigeons were treated with this product. Polyneuritis was induced in them by artificial feeding with an exclusive diet of polished rice. After a time, varying from ten to twenty-one days, they developed the characteristic symptoms of avian polyneuritis, as they are represented in the figures 1, 3, and 5. By a series of controls it was found⁴ that the animals in this condition

live rarely longer than six to twelve hours, twenty-four hours being perhaps the utmost limit. The product mentioned above was injected into the pectoral muscle in quantities varying from 4 to 8 mg. and in each case a complete recovery was obtained (Figs. 2, 4, 6). Before and after treatment the animals were kept on an unchanged diet of polished rice. In spite of that they lived after the recovery for four to six days without any symptoms of neuritis. As the food did not secure a new supply of vitamine, the birds developed neuritis again after the injected substance was apparently used up for metabolic processes. In one of these cases after a new supply of substance a second cure was effected.

CASE I.—Severe symptoms of polyneuritis; 4 mg. of the above-mentioned product were injected into the pectoral muscle. Three hours later a great improvement; next day a complete recovery; four days later shows again symptoms, and dies.

CASE II.—Severe symptoms (Fig. 1); 8 mg. injected. Two hours later a complete recovery (Fig. 2); was able to fly away, and had to be photographed, therefore, in a cage; relapsed after six days, and was again cured by a new injection of the product.

CASE III.—Severe symptoms (Fig. 3); injected 4 mg. Recovery after three hours (Fig. 4); lived for four days.

CASE IV.—Polyneuritis (Fig. 5); injected 8 mg. After three hours a complete recovery (Fig. 6), which lasted for four days.

We see from these experiments that the initial vitamine-fraction possesses the undiminished curative power of the original yeast extract. As in some cases the change of diet alone (an addition of maize, for instance) is capable of improving very markedly the condition of the sick birds, the fact that an unchanged diet of polished rice was kept throughout the experiment cannot be too much emphasized.

By a further fractionation I was able to separate the crude fraction into at least three substances, each of which has been carefully purified (recrystallization till constant melting point) and analysed. The original product (2.5 grams) yielded the following substances:

Substance I.—1.6 grams, melting at 229° (corrected); needles and prisms nearly insoluble in cold water. When mixed with the substance previously obtained from yeast² it does not show any depression of melting point; the substances might therefore be regarded as identical.

Substance II.—0.4 gram, very soluble in cold water, and gives a difficultly soluble picrate. The substance melts at 235° (uncorrected).

Substance III.—0.3 gram, more soluble in water than the first substance; melts at 222° (uncorrected).

These observations have an interesting parallel with the case of pituitary extract, as recently recorded by Fühner,⁵ where also in the first instance a crystalline fraction was isolated, which showed the whole physiological action of the gland, but on further fractionation was found to consist of not less than four different substances. Each of these had a specific action, but the effect of the original product could only be obtained by the collective action of all the four substances. It will be interesting to see whether the same is the case with the vitamine-fraction, or whether a single substance plays a preponderating part in the process of cure.

For therapeutic purposes, therefore, the best results may at present be expected by a paracenteral administration of the whole vitamine-fraction, especially in acute cases which have proceeded too far to be influenced by a change of diet—in such cases, for example, as have been described by Strong and Crowell⁶ and Schüffner.⁶ This fraction which is suggested to be employed contains the active constituents unimpaired of the original starting material, and is free from any harmful substances.

ALIMENTARY TOXAEMIA.

PAPERS READ AT THE ADJOURNED DISCUSSION AT
THE ROYAL SOCIETY OF MEDICINE.

CUTANEOUS INDICATIONS OF ALIMENTARY TOXAEMIA.

By JAMES GALLOWAY, M.D., F.R.C.P.,
PHYSICIAN TO CHARING CROSS HOSPITAL.

FROM the days when we were house-physicians, the occurrence of alimentary toxæmia, as the term is understood in this discussion, must have been familiar. Many of us may recollect the occasion when we were called to the casualty department late on a Saturday evening and found awaiting our services a vigorous looking young man, whose features were scarcely recognizable on account of an outburst of severe urticaria. We found on inquiry that his week-end dissipations had been stimulated by a diet of stout and winkles, and our judgement as to the cause of the urticaria was supported when we found that the best treatment in such cases was the administration of an emetic, followed by a copious black draught. No doubt remained in our minds that the urticaria was due to alimentary toxæmia, caused by poisons absorbed from his alimentary tract.

In such a case as this the relation in time between the disturbance of the alimentary tract and the visible indication of disease is so close that their causal relationship is admitted by all. But in the case of most other indications of intestinal and visceral disturbance the relationship between the probable cause and its manifestation cannot be so easily traced. Even with the knowledge now at our disposal as to the nature of the poisons derived from various fermentative processes, the chain between cause and effect cannot be distinctly demonstrated; mathematical methods of proof are not applicable, so that all we have to offer in support of our beliefs are the conclusions drawn from individual or collective clinical experience. Nevertheless, little doubt is left in the mind of the clinician that causal relationships do exist, and it may be well to point out at this time some of the more obvious external signs of disease of the alimentary tract.

The poisons capable of producing toxæmia resulting in these manifestations of disease seem to come from two sources: first, those contained in the food itself or arising from the food by the action of ferments in the alimentary tract—these ferments may be those normally produced by the various accessory glands or may have some abnormal origin owing to disease or other causes; secondly, those resulting from fermentative or putrefactive processes due to the action of organisms which may be normal denizens of the alimentary tract or interlopers. Most of the external manifestations seem to be more easily traceable to the first group of poisons rather than to the second, though this may very possibly be due to the fact that the noxious consequences of the action of many of these organisms, such as bacteria, are more difficult to appreciate and to trace to their original source.

The outward manifestations group themselves easily in four main categories:

1. Those resulting from disturbances of the blood vessels which disappear leaving no permanent trace. In this category may be grouped the varieties of urticaria, evanescent or of long duration, the types of erythema, including exudative and vesicating forms.
2. Morbid conditions in which an inflammatory lesion progresses to actual infiltration of the integuments with cellular elements and terminating in persisting deformity such as dilatation of blood vessels, atrophy, persistent dermatitis, ulceration, and scarring.
3. Purpura in its different forms—punctate, diffuse, and often associated with other hæmorrhagic manifestations.
4. Pigmentation due to increase or abnormal distribution of pigments closely related to those of the normal type, such as melanin, or in other cases to pigments more recently derived from hæmoglobin and due to hæmolysis resulting from the circulating intestinal toxins.

GROUP I.

Of the first group, the various forms of simple or acute urticaria are by far the most common. The relationship between the ingestion of an unusual article of food such as shellfish or certain fruits, with the consequent outburst of urticaria, is so close as to leave no reasonable doubt that the poisonous material is contained in the ingested substance, or is very easily elaborated from it by the digestive ferments. A little more difficulty is felt when dealing with other varieties of the disease, such as the recurring type of urticaria, in which the lesions are usually not so severe or extensive as in the acute single attack, or the chronic variety, in which the lesions are usually diffusely scattered, though not large individually and leave indurated lesions, giving rise to the term "papular urticaria." These papules not infrequently develop long-standing pigmentation, and may even resemble the rare condition known as "urticaria pigmentosa," of which the exact morbid relationships are still unknown.

In reference to the causation of these less common types of urticaria, the connexion between ingested poisons and the production of the lesion is not so easily traceable, but information gathered from clinical investigation strongly indicates the existence of the connecting chain. For instance, in one case it may be discovered that some individual article of food little suspected to be the cause has by a process of elimination been at length excluded from the dietary. As soon as the sufferer denies himself this treasured delicacy, the troublesome and long-standing urticaria disappears. Also, although the treatment of the chronic and papular varieties of the disease is by no means satisfactory, and often very disappointing in its results, the largest amount of success follows treatment by careful selection of the diet—sometimes by restriction of proteins, at other time by refraining from carbohydrates, accompanied by treatment adapted to keep the alimentary canal in a healthy state.

The relation between the various forms of erythema and alimentary toxæmia is more obscure. That such a relation does exist is borne out by the clinical experience of the causation of some of the simpler forms of erythematous eruption.

Take, for example, the simpler types of non-exudative erythema. It is well known that such outbreaks are apt to occur after the disturbance of the lower bowel and its contents by the administration of injections, or as a consequence of lavage of the rectum and colon. The cause in this case is not likely to be due to absorption of the fluid used for purposes of washing out the bowel, but to substances pre-existing in the alimentary tract, or rapidly formed in consequence of the interference with its contents. The material absorbed into the body producing attacks of erythema in cases such as these may, with some degree of likelihood, be ascribed to the effects of bacterial decomposition. No doubt, at any rate, exists in our minds as to the causal relationship of the erythema and the administration of the injection. It is reasonable, therefore, to suspect that other conditions of the large intestine, such as those produced by disease of the mucous membrane, may manifest themselves by erythematous eruptions on the surface, and as a matter of observation simple erythematous eruptions are by no means infrequent in the course of the various forms of inflammation of the bowel. These outbreaks are very apt to be purpuric.

The types of erythema exudativum in which, in addition to dilatation of the capillaries, escape of the contents of the vessels occurs into the tissues—either the blood serum or the blood cells—are by far less common than the simple erythemas. We are less likely, therefore, to observe the association between eruptions of erythema exudativum and affections of the alimentary tract, but that the relationship does exist in many cases is more than probable. The close connexion between outbreaks of exudative erythema and diseases of internal organs has frequently been noted and emphasized by various writers, and the toxæmia producing these attacks may arise with greater probability from the alimentary canal than from other viscera. Instructive examples are quoted by Osler and other observers.

The general impression given by clinical observation of this group of external manifestations is that the urticarial type is more frequently produced by the direct absorption of noxious ingesta or as a consequence of the more simple

chemical changes in foods occurring in the upper portion of the alimentary tract from the action of the natural alimentary ferments; while eruptions of erythematous nature more frequently arise from affections of the intestines, especially the large intestine, in which the terminal processes of digestion take place, the poisonous materials involved being of a more subtle character, or perhaps due to the results of fermentations produced by bacteria or other organisms. The purpuric types of erythema seem especially to indicate that the changes occur in the colon or large intestine.

GROUP II.

The external lesions which we have been considering are those due to vascular phenomena, which leave no permanent trace behind. Closely allied to these lesions are certain others in which, in addition to the erythematous condition, tissue changes occur. Of these the criterion is the appearance of new cellular elements—neither red blood cells nor white blood cells, but newly formed cells, characteristic of various types of inflammatory infiltration. When these new cells are observed destructive tissue changes must occur in some degree, though it may be very slight, and as a result we may observe erythematous lesions with the same symmetrical disposition as some of the others we have discussed, but which do not vanish, leaving as their result atrophic, or even ulcerating, destruction of the surface. The type of this morbid state is the disease usually known as lupus erythematosus—a condition closely resembling in its distribution erythema multiforme, but terminating in some degree of destruction or atrophy. The etiology of this mysterious affection is by no means well understood, but its connexions with visceral disturbances should never be overlooked. A good deal of attention has been drawn to its peculiar relationship with certain forms of disease of the kidney. In other cases a poison arising from the alimentary tract may be suspected of being the cause. A characteristic example is as follows:

A woman of about 35 years of age came under observation with an acute outburst of lupus erythematosus affecting symmetrically not only the face but also the extremities and the trunk, accompanied by fever and much constitutional disturbance, resembling, therefore, the well-known type of the disease sometimes called "exanthematic lupus erythematosus." The duration of this case was about three years. The investigation into the possible causes of the disease were at first unfruitful, but soon it was noted that the patient was gradually developing the signs and symptoms of cirrhosis of the liver. It was not, however, till well on in the course of her malady that it became known that the patient, who in all other respects was exemplary in her social behaviour, secretly indulged in alcohol to an excessive degree.

Such cases occurring in the course of medical experience naturally give rise to the belief, and indicate with a good deal of certainty, that certain forms of alimentary toxæmia may result not only in such conditions as hepatic cirrhosis or fibrosis of the kidneys, but also in the outward and visible sign of a chronic inflammatory erythema, ending in induration or atrophy of the skin. In this relationship notice should be taken of numerous cases in which permanent dilatation of blood vessels results in the production of the different clinical types of telangiectases or even of angiomas. A good deal of attention has recently been given to the different forms of these permanent vascular lesions. Some of them seem to occur almost certainly as the result of circulating poisons affecting the blood vessels mainly. They are frequently seen in cases in which cirrhosis of the liver and kidneys have followed toxæmia arising in the first instance from the alimentary canal.

GROUP III.

The probability of alimentary toxæmia being the cause of certain cases of purpura has long been recognized clinically, for the connexion between the outburst of purpura and the disturbance of the alimentary canal is sometimes so close that it gives as clear evidence of their relationship as the outburst of urticaria following the eating of some unusual article of food. This relationship is well seen in some of the cases producing the type of the disease known as Henoch's purpura. Many purpuric

lesions arise no doubt by a peculiar development or simply by intensification of the conditions already noted producing erythema. They form, however, on account of their aspect so characteristic a group that they claim special attention.

One of the most remarkable conditions in which the connexion between poisoning from the alimentary tract and the outburst of purpura is shown is in certain stages of hepatic cirrhosis. In these cases of cirrhosis, sometimes at an early period of the disease, a patient is attacked by a violent outbreak of purpura, the lesions occurring throughout the body affecting large areas and showing profuse extravasation of blood. These outbreaks are often associated with internal hæmorrhages most commonly from the lower part of the bowel. Such attacks of purpura seem to occur in the early stages of obstruction to the portal circulation caused by the contracting of the newly formed connective tissue in the liver. As a result the portal blood containing the crude materials absorbed in the alimentary canal is forced to seek collateral channels to regain the general systemic circulation. Much of it returns directly by means of the vena cava, thus closely reproducing the conditions established by the well-known porta-caval fistula of Eck. The blood returning by these newly formed channels of circulation carries with it the products of intestinal digestion, or possibly abnormal noxious substances due to the impaired action of the alimentary canal. Under normal conditions the liver is the organ in which these materials are further elaborated, thereby being rendered innocuous, or are destroyed, but in the unusual conditions produced by portal obstruction the tissues, the blood vessels, and the blood itself are poisoned for the time being. It is under these circumstances that certain exceedingly violent attacks of purpura arise, and they strongly suggest the causation indicated. It is not surprising to find that hæmorrhages from the bowel are associated with these purpuric outbreaks. New channels are being discovered by the returning blood, such as those uniting the superior and inferior hæmorrhoidal vessels and the radicles of the internal iliac vein; extravasation is likely to occur under these circumstances from the dilated blood vessels quite apart from the noxious effects produced on the tissues by the abnormal constituents of the blood. In such a case the attack of purpura may be the first indication drawing attention to the visceral and intestinal disease. Complete recovery of the hæmorrhagic symptoms may occur, the patient being even able to resume his usual work in life. The cirrhosis of the liver, of course, remains, or gradually progresses, but the gland apparently resumes its functions as the purifying organ of the portal blood to a sufficient extent to protect the body, or the tissues of the body succeed in protecting themselves in some other way against the action of the poisoned blood. It is likely that the poisonous materials producing these changes in the tissues and in the blood are the results of the ordinary digestive processes or the simpler forms of chemical decomposition rather than of bacterial fermentations.

Another variety of purpura presents small hæmorrhagic areas of petechial or punctiform lesions. The relationship between this condition and alimentary toxæmia is very distinctly shown in the variety of disease to which the name of "Henoch's purpura" has been given. An instructive example occurred in the case of a young girl, who presented herself for treatment two or three years in succession with attacks of intestinal pain, melaena, hæmaturia, and numerous purpuric lesions. On every occasion the attack followed an autumn visit to the country, and the eating of unusual foods, such as berries and nuts.

The same type of purpura is very familiar in association with chronic inflammatory conditions of the colon, such as the varieties of colitis and dysentery. The attacks are especially prone to appear when other evidences of toxæmia or septicaemia become prominent.

There are grounds for associating the type of purpura characterized by large areas of cutaneous hæmorrhage with absorption of poisons from the upper part of the alimentary tract. These poisons may arise from infected food materials or may be produced by the normal, or only slightly abnormal, processes of intestinal digestion. The petechial and punctiform types of purpura, on the other hand, appear to occur as the result of the terminal

digestive changes or abnormal fermentative processes occurring in the lower reaches of the bowel, possibly influenced by the micro-organisms present in the alimentary tract. This is the type of purpura most often seen in cases of severe septicaemia which seem to be traceable to the pyogenic inflammations of the mouth, gums, or naso-pharynx.

GROUP IV.

A fourth group of the visible manifestations of alimentary toxæmia includes the abnormalities of pigmentation. The unhealthy, dusky discoloration of the skin occurring in various forms of indigestion is a matter of ordinary observation. Much attention has been drawn in the course of this discussion to the discoloration occurring in the cases of disease to which the name of "intestinal stasis" has been applied. It is difficult to be quite sure of the exact nature of this pigmentation. It is partly due, no doubt, to disturbances of the circulation, producing unusual conditions of opacity or translucency of the skin, but in other cases, no doubt, it is due to a definite increase in the amount of the pigments, identical with, or nearly related to, the normal skin pigment. The cases, however, which are most striking are those in which the pigmentation is due to unusual or abnormal pigments.

The first to which reference should be made is the peculiar yellow tint, probably resulting from severe hæmolytic, followed by liberation of hæmoglobin in the blood serum, and the formation of pigments, of which urobilin is one. This hæmolytic, or "urobilin jaundice," as it is sometimes called, is well seen in the severer forms of anaemia, many of which are associated with septic disorders of the alimentary tract: the poisoning in these cases, giving rise, as one of its consequences, to abnormal hæmolytic, is probably of bacterial origin. It is very usual to find these hæmolytic changes associated with obvious purpuric lesions.

The most striking of all the varieties of abnormal pigmentation is seen in the cases to which the name of "haemochromatosis" is given. The pigment in this condition is not so close a blood derivative as is urobilin, and probably more than one variety of pigment may be present. Of these a pigment still containing iron has been identified with some certainty, to which the name of "haemosiderin" has been given, while another pigment free of iron is known as "haemofuscin." The staining and discoloration of the tissues resulting from the formation and disposition of such pigments is often of a most remarkable character. In some cases it is of a pronounced slate-black colour, while in others the tint is a full mahogany brown. There can be no doubt also that the depth of the pigmentation may vary from time to time in the same case. The relationship between some of these cases of haemochromatosis with poisoning arising from the alimentary tract is very close. Cases are on record in which inflammatory conditions involving the abdomen and interfering with the action of the intestine have coincided with the development of the slate-black pigmentation already mentioned. The discoloration may show itself on the surface of the body in a degree which can scarcely be imagined unless the opportunity has arisen of seeing such a case. In one such case recovery from disease affecting the intestine following operation was accompanied by the gradual disappearance of discoloration of the most intense character. This patient was well, in vigorous occupation and health, several years after treatment.

On the other hand, the type of disease associated with enlargement of the spleen, progressive loss of health, with severe anaemia and frequently with repeated discharges of blood from the bowel, and in which cirrhosis of the liver occurs as a terminal feature, shows pigmentation of the red-brown tint. In a case presenting these features the pigmentation of the surface was of a pronounced mahogany-red colour.

In this category may also be included the cases of discoloration due to alterations in the hæmoglobin to which the names of "methaemoglobinaemia" and "sulphaemoglobinaemia" have been applied.

In many of these abnormal pigmentations the relationship to alimentary toxæmia is a close one—probably that of cause and effect.

CHRONIC INTESTINAL STASIS.

BY

ARTHUR F. HERTZ, M.A., M.D. OXON., F.R.C.P.,
ASSISTANT PHYSICIAN TO GUY'S HOSPITAL.

As my contribution to this discussion I propose to examine the evidence on which a diagnosis of toxæmia due to chronic intestinal stasis can be made. It might be gathered from what some clinicians have said that it is possible to make a diagnosis from the symptoms alone. If, for example, we could accept the statement that chronic intestinal stasis is "a necessary antecedent factor" in the development of all forms of tuberculous disease, the discovery of tubercle bacilli in the sputum would logically lead to a diagnosis of chronic intestinal stasis. Few, however, will agree with a statement for which so little evidence has been brought forward. Even the symptoms, which are by common consent regarded as characteristic of chronic intestinal stasis, are by no means pathognomonic. The worst case I have ever seen of intestinal toxæmia, in which the classical symptoms of extreme emaciation, extensive pigmentation, evil-smelling sweat, and cold extremities were present, was due not to chronic intestinal stasis but to chronic diarrhoea, the result of some intestinal infection, contracted by a lady whilst big game hunting in West Africa.

It is not at all uncommon to be told by a patient, who is in the habit of taking large quantities of aperients for constipation, that the lassitude, headache, and abdominal discomfort from which he suffers are better if he forgets to take his aperient and his bowels are not opened. His symptoms appear to be due to the absorption of poisons from the abnormally fluid faeces in his colon, and are therefore a result of the diarrhoea produced by his aperient, and not a result of his constipation. It is important before examining such cases with the *x* rays that the patient should not take any aperient for some days. When this has been done, I have often been able to demonstrate the complete absence of intestinal stasis, although many of the patients were contemplating some operation for relief of their supposed constipation. The bismuth reached the rectum in the normal time, but the patients had become so convinced that their bowels would not act without help that they made no attempt to open them, as they did not feel the violent desire which resulted from the use of their aperients. When it was explained to them what the *x* rays had shown, and also that a finger inserted into the rectum proved that it was full of faeces only waiting to be expelled, they were persuaded to try to open their bowels, and succeeded in doing so. A gentleman, 38 years old, whom I saw in April, 1910, was convinced in this way, and he has had his bowels opened regularly ever since without treatment of any sort, although up to that time he was taking an enormous quantity of aperients, and was sent to see me for an opinion as to whether the colectomy which had been advised ought to be performed.

It is well known that the frequency of the stools gives no certain evidence as to the existence of intestinal stasis. Thus a condition analogous to retention of urine with overflow may occur in the bowel, the patient being exceedingly constipated, but passing numerous small stools every day. On the other hand, in the condition aptly described as "greedy colon" by Sir James Goodhart, the patient may only open his bowels once every three or four days, and yet be perfectly healthy; in such cases I have found with the *x* rays that the passage through the bowels is generally normal in rate, but the quantity of faeces formed is so small that several days may be required for sufficient to collect in the pelvic colon to give rise on entering the rectum to the call to defaecation.

By giving some charcoal with breakfast one morning, and watching for its appearance in the stools, the total time taken in its passage through the alimentary canal can be ascertained; but this method gives no indication as to the part of the bowel in which stasis occurs.

We are therefore driven to the conclusion that the only reliable means of determining whether a patient is suffering from chronic intestinal stasis and of ascertaining

exactly what parts of the alimentary canal are at fault is a series of examinations with the *x* rays. It is, however, first necessary to determine whether large doses of bismuth salts interfere with the normal activity of the bowel, for it has rightly been pointed out that they are among the best drugs for combating certain forms of diarrhoea. In order to test this point Mr. F. Cook and Mr. E. G. Schlesinger at my suggestion took charcoal on a number of occasions at different hours in the day, their bowels being regularly opened in the morning at about 9 a.m. By this means they found the shortest time required for the charcoal to appear in their faeces. On repeating their investigations with 2 oz. of bismuth oxychloride added to the charcoal they found that the time was unaltered. I have since been able to confirm these experiments in a number of constipated individuals. I believe that bismuth salts only influence those cases of diarrhoea in which excess of sulphuretted hydrogen has developed as a result of abnormal putrefaction; this gas is a powerful stimulant to the intestinal movements, but is rendered inert by combining with bismuth. In common with many others, I now use barium sulphate instead of bismuth oxychloride, as it does not combine with sulphuretted hydrogen, and under no conditions affects the motility of the stomach or intestines; it is equally non-poisonous, the shadow it throws is as dense as that of bismuth salts, and its cost is only one-twentieth.

In some unpublished investigations Dr. Rippmann and I found that the weight of the bismuth or barium mixed with the food produces a very slight degree of distortion of the stomach, which is greatly increased in cases of atonic dilatation; it also tends to drag the caecum and the end of the ileum downwards. It is therefore clear that the smaller the dose used the more accurate will be the results obtained by means of the *x* rays. Except in very fat individuals, 2 oz. of bismuth oxychloride or barium sulphate are ample for all practical purposes; the use of 6 oz. trebles the error.

Valuable as the *x* rays are in the investigation of the motor functions of the alimentary canal, they have led to many erroneous diagnoses, owing to a want of appreciation as to what constitutes the normal. In a recent discussion at another society cases were related by various speakers in which a diagnosis of intestinal stasis was made, although the details given of the time at which different parts of the bowel were reached fell well within the normal limits. Thus one speaker concluded that the presence of bismuth between the hepatic flexure and the iliac colon thirteen hours after the meal in one of his cases suggested some mechanical difficulty in the left iliac fossa. It would be rare to find less evidence of "stasis" in a normal individual.

The first examination of a case of intestinal stasis by means of the *x* rays was made by me in 1907 after my fellow-workers and I had examined a considerable number of normal individuals. The figures which we published of the average time taken for bismuth to reach different parts of the bowel in normal individuals have since been regarded as the standard, and any case in which delay, when compared with this standard, has been observed, has too often been diagnosed as an example of intestinal stasis. The error of this is obvious when it is remembered that our figures represented the average of considerably divergent times, and more extended experience has convinced me that the normal limits are even wider than we originally supposed. Thus in fifty-eight normal individuals examined by Alan Newton seven hours after a bismuth meal, the furthest point reached by the bismuth was the caecum in four, the ascending colon or hepatic flexure in twelve, the transverse colon or splenic flexure in thirty-one, the descending or pelvic colon in eleven. Though the average furthest point is in the transverse colon, corresponding to what we described in 1907, it would clearly be incorrect to say that stasis was present in an individual in whom the bismuth had not reached beyond the hepatic flexure after seven hours.

GASTRIC STASIS.

A meal consisting of half a pint of porridge or bread and milk mixed with two ounces of bismuth oxychloride or barium sulphate is completely evacuated by the stomach in about four hours. If, therefore, any bismuth is still

seen in the stomach six hours later, gastric stasis is certainly present. It is obvious that this rule only holds good if nothing is eaten or drunk between the bismuth meal and the last examination. Supposing, for example, the bismuth meal is eaten at 10 a.m. and lunch is taken at 1 p.m., the latter becomes thoroughly mixed with the small quantity of bismuth and food which is normally still present in the stomach. Instead of all the bismuth being evacuated by 2 p.m., some will still be present two or three hours later, when it will again be mixed with the food if tea is now taken. At 6 p.m., therefore, eight hours after the bismuth meal, a small shadow may still be seen, as I have found by actual experience in normal individuals, and if dinner is taken between 7 p.m. and 8 p.m. the last trace of bismuth will not be evacuated until midnight or later. I have repeatedly seen a diagnosis of gastric stasis made because a shadow was still present in the stomach six or more hours after a bismuth meal, although this was perfectly normal, as more food had been given in the interval, and a subsequent examination, in which this source of error was avoided, showed that the stomach emptied itself in the normal time.

The nearer a bismuth meal approaches a normal meal in taste and consistence, the more reliable will be the results obtained. For this reason the bismuth or barium salt should be mixed with bread and milk or well-made sweetened porridge, instead of with water and lactose, as the latter makes a most unpleasant mess, the nastiness of which inhibits the normal gastric movements and secretion. An example of this has been recorded by Dr. Ironside Bruce. More recently I found some bismuth still present in the stomach twelve hours after a lady had taken a mixture of this sort, which had made her feel extremely nauseated. The next day she took an equal quantity of the same salt of bismuth in porridge, which she liked, and every trace of it disappeared from the stomach within six hours.

When the precautions described are taken, it is found that no connexion of any sort exists between gastric and intestinal stasis. In organic pyloric stenosis, which always gives rise to gastric stasis, the chyme, which passes through the pylorus abnormally slowly, often traverses the intestines at the normal rate. The constipation, which is almost invariably present, is due solely to the small quantity of faeces formed owing to the deficiency of chyme reaching the intestine; too little faeces therefore reach the pelvic colon to give rise on entering the rectum to a daily call to defaecation. This view is confirmed by the fact that gastro-enterostomy at once relieves the constipation by allowing an adequate quantity of faeces to form.

Conclusion.—When precautions are taken to prevent errors in diagnosis, it is found that intestinal stasis never leads to gastric stasis.

THE DUODENUM IN INTESTINAL STASIS.

Under normal conditions the bulbus duodeni or proximal portion of the first part of the duodenum is more or less constantly visible during gastric digestion. Peristalsis only occurs in it to a very limited extent, the chyme which has come to it from the stomach remaining in it sufficiently long for neutralization to occur by its admixture with the alkaline duodenal secretion, pancreatic juice, and bile. The pyloric sphincter then relaxes again, and the entry of a further quantity of chyme causes that already present to overflow into the distal portion of the first part of the duodenum, from which it is immediately conveyed by a rapid peristaltic wave. As the bismuth-containing chyme is greatly diluted in the bulbus duodeni by the digestive secretions, its shadow is less dense and defined as it passes through the rest of the duodenum, and its bulk is never sufficient to unfold and fill completely any part of it after the bulbus duodeni has been left. It generally stops for a short time somewhere in the distal part of the duodenum before being conveyed with equal rapidity into the jejunum. As it passes along the small intestine by frequent very rapid peristaltic waves, which carry it a few inches at a time, it becomes more and more difficult to recognize with the *x* rays, owing to the subdivision it undergoes at each stopping place as a result of segmentation, and to its admixture with further quantities of intestinal juice; finally it is completely lost to sight

until the chyme begins to collect in the last few inches of the ileum.

When the stomach empties itself with unusual rapidity, as it does in cases of duodenal ulcer and less frequently in certain other conditions, the duodenum at any given moment contains more chyme and bismuth than under normal circumstances; consequently, the whole duodenum, which in healthy individuals is never more than half full, even when the stomach is emptying itself most rapidly, becomes filled by the bismuth-containing chyme in its passage to the jejunum. Careful observation shows that there is no stasis; the bismuth passes rapidly into the jejunum, being replaced in the duodenum by a further quantity from the stomach. Owing to an error in the interpretation of the *x*-ray appearance, it has been thought that the duodenum was dilated in such cases, whereas it really is of normal size, but contains more chyme than usual, and therefore gives a denser and wider shadow. The so-called writhing of the duodenum, which has been described as occurring in cases of supposed intestinal stasis as a result of a duodenal kink, is nothing else than the normal peristalsis and segmentation rendered more clearly visible than usual by the great quantity of bismuth-containing chyme present. This "writhing" of the duodenum was recently demonstrated to me in the case of a woman suffering from gastric symptoms; a few days later Mr. Steward operated and found an organic hour-glass constriction of the stomach, but the duodenum was completely free from obstruction and dilatation. As the evacuation of the stomach is always accelerated by lying down on the right side, the duodenum is filled more rapidly, and may therefore be seen more readily, if the patient assumes this position before turning on his back for the examination. The skiagrams which have been published as examples of the dilated duodenum, which is stated to give rise to duodenal ulcer and to be due to obstruction by a duodenal kink, represent, I believe, a duodenum of normal size, which is exceptionally full as a result of posture, as we are told that before the skiagram is taken "it is necessary for the patient to lie on his right side for two or three minutes," whilst in cases of duodenal ulcer the rapid evacuation of the stomach is an additional factor. Moreover, the skiagram is taken in the horizontal position, although those who believe in the frequent occurrence of duodenal kinks state that they are only produced in the erect position and disappear on lying down. In over fifty cases of uncomplicated duodenal ulcer I have never yet seen a dilated duodenum or a duodenal kink, and it is a characteristic feature of the condition that the stomach is hypertonic and empties itself with unusual rapidity, the bismuth passing through the small intestine and reaching the colon with remarkable speed. These observations are in complete agreement with those of Dr. Barclay of Manchester, Mr. Rowden, who has investigated all of Sir Berkeley Moynihan's more recent cases at Leeds, Dr. Kreuzfuchs of Vienna, and many others, none of whom have ever seen the kink or dilatation, the radiographic evidence for which depends upon the unconfirmed investigations of a single observer.

The constipation, which is generally present in cases of duodenal ulcer, is not the cause of the ulceration, as in many cases it only develops after the symptoms of ulcer have appeared, and it almost invariably disappears as soon as the ulcer heals, whether as a result of medical treatment or of the performance of a gastro-enterostomy.

Conclusion.—Intestinal stasis does not lead to duodenal linking, dilatation, or ulceration, and duodenal ulcers are associated with an unusually rapid passage of chyme out of the stomach and through the whole of the small intestine.

ILIAC KINKS, ILIAC STASIS, AND THE ILEO-CAECAI SPHINCTER.

In 1903 Keith demonstrated the existence of a strong ileo-caecal sphincter in man. It was thought by many that its function was to prevent the regurgitation of faeces from the caecum into the ileum when anti-peristaltic waves passed down the ascending colon. *X*-ray investigations here, however, shown that anti-peristalsis does not occur in man under normal conditions; moreover, the ileo-caecal sphincter does not

prevent regurgitation into the ileum, as, in common with other observers, I have seen a bismuth suspension pass into the ileum when run into the colon through the rectum at as low a pressure as one foot of water. There can be no doubt that the function of the sphincter is, as Keith originally suggested, to prevent the contents of the ileum passing too rapidly into the caecum. Some recent observations made with Mr. Alan Newton of Melbourne have confirmed and amplified my earlier investigations on this subject. We have found that the bismuth-containing chyme reaches the end of the ileum an hour, or even longer, before any appreciable quantity passes into the caecum, and that the ileum is often still full four, five, or even more hours after the last traces of bismuth have left the stomach. Consequently an accumulation of chyme occurs in the last few inches of the ileum, where it remains and undergoes digestion actually for a longer period than in the stomach. During the whole of this period active segmentation, but very little peristalsis, can be seen. It is clear, therefore, that the function of the ileo-caecal sphincter is to prevent the passage of the contents of the ileum into the caecum until sufficient time has elapsed for digestion and absorption of foodstuffs to be complete, as the chyme which reaches the caecum contains only traces of nutrient material in solution. Iliac stasis is thus a normal physiological condition of the utmost importance for adequate digestion.

The ileo-caecal sphincter begins to relax at infrequent intervals some time after the arrival of chyme in the end of the ileum, but only when another meal is taken does peristalsis occur at all actively in the extreme end of the ileum in addition to segmentation; the sphincter apparently relaxes as each peristaltic wave reaches it, a great part of the contents of the end of the ileum being rapidly squirted into the caecum. In spite of this, if ordinary meals are taken after a bismuth meal, so that some bismuth remains in the stomach (in the manner already described) until the evening, the shadow at the end of the ileum may be visible in normal individuals until late at night.

The normal iliac stasis is increased in all conditions leading to spasm or to the inhibition of the normal relaxation of the ileo-caecal sphincter. In acute appendicitis, for example, the sounds which normally indicate the squirting of the contents of the ileum into the gas-containing caecum cease completely, owing probably to spasm of the sphincter, which Elliott has shown occurs in animals when the splanchnic nerve is stimulated or the neighbouring peritoneum is irritated. In chronic appendicitis similar but less marked delay often occurs. One of the most marked cases of iliac stasis I have ever seen was in such a case. Six hours after the bismuth meal the stomach was empty, but no bismuth was present in the caecum, all of it having collected in the end of the ileum, though in the average normal individual the shadow by this time would have reached the hepatic flexure. The last few inches of the ileum could be clearly defined, as they were distended with chyme. Palpation under the screen showed that there were no adhesions, the whole of the ileum being freely movable. Twenty-four hours later some bismuth was still present in the last inch and a half of the ileum and a little in the caecum and ascending colon, all the rest having passed to the rectum, from which some bismuth-containing faeces had just been evacuated. It was clear, therefore, that the only stasis in this patient's alimentary canal was in the end of the ileum. Mr. Rowlands operated and removed a diseased appendix, but found that the ileum was perfectly normal and was free from adhesions. The ileo-caecal junction was not abnormally narrow, so that it was clear that the stasis could have been due to nothing else than inhibition of relaxation or spasm of the ileo-caecal sphincter.

The end of the ileum, as it rises from the pelvis to join the caecum, bends in various directions; as the shadow on the screen is in one plane only, it is natural that it often appears as if it formed one or more acute angles or kinks; it is obvious, therefore, that no conclusion of any sort can be made from skiagrams alone as to the presence or absence of kinks. By palpating the abdomen during the examination it is easy to demonstrate that most of these "kinks" are only apparent. Sometimes the ileum appears

to be fixed where it crosses the pelvic brim, but by manipulation the whole loop can be raised out of the pelvis, and the apparent adhesions and kink disappear. Recently I saw what appeared to be a typical iliac kink, the ileum being fixed where it passed over the brim of the pelvis; no amount of manipulation had any effect upon it, but on inflating the bowel in carrying out Bastedo's test for appendicitis the distended pelvic colon lifted the last part of the ileum completely out of the pelvis, and palpation now showed that there were no adhesions and no kinks. I suggest, therefore, that before a diagnosis of an iliac kink be made with the *x* rays the colon should be inflated, if palpation has failed to separate the apparent adhesion.

Although there can, of course, be no doubt that abnormal bands may occur in connexion with the terminal portion of the ileum, even though their existence cannot be demonstrated with the *x* rays, I do not feel at all convinced that they are of any importance, except in quite exceptional cases, in which clear evidence of antecedent attacks of appendicitis can almost invariably be obtained. The obstruction offered by a genuine iliac kink is hardly ever as great as that normally offered by the ileo-caecal sphincter three inches farther on. Thus in the skiagrams published to illustrate the iliac kink the lumen is not even almost narrowed. When it is narrowed, there is nothing to show that the narrowing does not represent a division produced by the segmentation, which normally occurs with great activity in the end of the ileum. Nothing short of almost complete stenosis could lead to stasis of any importance, as the contents of the ileum are always so fluid that they can pass through a very narrow passage without difficulty. A true iliac kink, if it ever really leads to iliac stasis, probably does not do so directly, but indirectly by inhibiting the relaxation of the ileo-caecal sphincter, just as gastric adhesions may upset the pyloric mechanism.

It has been suggested that iliac adhesions ought to be surgically treated at the same time as an operation is performed for a duodenal ulcer, for gall stones, and for appendicitis. But in my experience the removal of the gall stones and drainage of the gall bladder almost invariably leads to such complete and permanent relief of symptoms that any further operation done at the same time could not improve the results. In the same way gastro-enterostomy completely cures a duodenal ulcer in a considerable proportion of cases, and if the appendix is at the same time removed the chances of recurrence are exceedingly small. I can hardly imagine that the results would be any better if iliac kinks were also dealt with, and there can be no doubt that the division of bands and membranes in such cases may lead to peritonitis, as Mr. Lane pointed out in his opening address, for I have myself performed the *post-mortem* examination on a patient with duodenal ulcer, in whom death had resulted from post-operative infection in the right iliac fossa, when adhesions in this neighbourhood had been divided in addition to performing gastro-enterostomy. Again, the removal of the appendix in acute appendicitis, if it is done sufficiently early, is rarely followed by any symptoms which could be ascribed to iliac kinks. It is true that the removal of the appendix in the later stages of acute appendicitis and in chronic appendicitis is not infrequently followed by pain in the right iliac fossa and sometimes by other abdominal symptoms; but I have also seen this occur when an iliac kink had been simultaneously dealt with.

Conclusion.—Iliac stasis is a normal phenomenon and results from the action of the ileo-caecal sphincter. Iliac kinks are comparatively rare, and do not directly increase the normal iliac stasis. The normal iliac stasis may be increased by spasm or absence of relaxation of the ileo-caecal sphincter, as a result of disease in the neighbourhood of the caecum, including perhaps iliac kinks.

KINKS AT THE HEPATIC AND SPLENIC FLEXURES, PTOSIS OF THE COLON, AND COLONIC STASIS.

In normal individuals examined with the *x* rays the hepatic and splenic flexures almost invariably appear to be acutely kinked. This, again, is the result of the shadow being cast in a single plane, as the limbs of the flexures belonging to the transverse colon are in front of those of the ascending and descending colon respectively,

and therefore the flexures appear to be acute, although they form a wide angle when looked at from the side. It is almost always possible to determine when adhesions are present between the limbs of the hepatic and splenic flexures by seeing whether they can be separated by palpation during the *x*-ray examination. In my experience it is very uncommon to find that they cannot be separated sufficiently to make it obvious that no great mechanical hindrance to the passage of the faeces can be present.

A pelvic caecum and a dropped transverse colon are often referred to as if they were invariably associated with constipation. I believe, however, that in a large majority of cases they are quite independent conditions. I have certainly seen a pelvic caecum just as frequently in strong healthy individuals with perfect digestion and no constipation as in constipated patients. Moreover, I have never been able to convince myself, when a pelvic caecum was associated with constipation, that there was any causal relationship between the two conditions, as in the majority of cases dyschezia without delay in the caecum or in any other part of the colon was present. Ptosis of the transverse colon never leads to kinking at the hepatic flexure, which invariably drops with it, but a very movable right kidney may produce obstruction in such cases. A definite sharp kink is occasionally produced at the splenic flexure, as the phreno-colic ligament is stronger than any other of the intestinal attachments. In one case, to which I shall again refer, the kink was so marked that a short-circuiting operation was required, and the transverse colon, which was situated low down in the true pelvis, was anastomosed with the pelvic colon, with which it was already in contact. When constipation is associated with visceroptosis, the former is generally due to dyschezia, which results from inefficient defaecation owing to weakness of the abdominal and pelvic muscles, this weakness being also the cause of the visceroptosis.

Most cases of constipation are more or less cumulative, the bowels never being completely evacuated, so that more and more faeces are retained. In dyschezia, for example, the rectum is never emptied, and an accumulation of hard faeces forms successively in the pelvic colon, descending colon, and even the transverse colon. If, therefore, a bismuth meal is taken without first thoroughly evacuating the bowels, the bismuth travels with more or less ease as far as the beginning of the faecal accumulation, beyond which it passes with extreme slowness, corresponding with the rate of excretion of the most distal part. If, however, the colon is first thoroughly evacuated by means of enemata, it is found in such cases that the bismuth often reaches the rectum in the normal time but owing to difficulty in defaecation it is retained there. It is only possible to distinguish such cases of dyschezia from true colonic constipation, in which delay occurs in the colon itself, by emptying the bowels completely by enemata before the examination begins. Numerous mistakes in diagnosis have resulted from neglect of this precaution.

My investigations, both with the *x* rays and by other means, have led me to realize that in a large majority of instances only part of the colon is affected in constipation. Thus, in nearly half of the severe cases I have seen in consultation the rectum, or less commonly the pelvic colon, was affected alone, the condition which I have called dyschezia being present; this can generally be treated with success by re-educating the patient to defaecate by regular habits, exercises for the abdominal and pelvic muscles, and graduated enemata. In other cases the caecum and ascending colon are alone affected; as soon as the bismuth gets into the transverse colon its passage to the rectum is normal in rate. Such cases can generally be relieved by diet and drugs, with the aid of massage applied regularly for a prolonged period to the affected part. I have not myself seen a case in which I thought an operation was indicated, but if all medical treatment failed, it seems to me that an anastomosis between the ileum and the transverse colon, with or without the removal of the caecum and ascending colon, as successfully performed by Wilms and de Quervain, would be more rational and less dangerous treatment than ileo-sigmoidostomy combined with complete colectomy. In another group of cases the passage as far as the splenic flexure is normal in rate, but considerable difficulty is experienced in getting beyond this point. This is sometimes due, as I have already

pointed out, to severe ptosis of the transverse colon, the splenic flexure remaining fixed, and sometimes to unexplained muscular weakness of the distal part of the transverse colon. If such cases are examined by means of a barium enema it is generally found that the fluid run in from the rectum passes without difficulty into the transverse colon; moderately large enemata without the aid of drugs or other treatment, with the exception of an abdominal support if ptosis is present, are then often successful. In two of my cases, however, all medical treatment failed to give relief, and Mr. F. J. Steward effected an anastomosis between the lowest part of the transverse colon and the pelvic colon in one instance, and between the two limbs of the splenic flexure in the other, with satisfactory results.

The comparatively rare cases in which the whole of the bowel is involved are generally amenable to treatment by diet, massage, and drugs. I have up to now only seen a single case, out of the very large number I have examined with the *x* rays, in which the whole of the colon was involved and in which, in spite of every form of medical treatment I could devise, the patient became steadily more and more poisoned and suffered from more and more pain. Mr. Arbutnot Lane was good enough to operate on this case for me in December, 1911, and the relief, which was almost instantaneous, has proved permanent and complete. I am therefore convinced that when the whole of the colon is involved, and when thorough and prolonged medical treatment has proved completely ineffective, the operation of ileo-sigmoidostomy is the only rational treatment.

Conclusion.—Ptosis of the intestines does not lead to stasis, except in rare instances at the splenic flexure, a pelvic caecum and a pelvic transverse colon being compatible with perfect health and normal intestinal action. In most cases of constipation a single part of the bowel, such as the rectum, pelvic colon, ascending colon, or splenic flexure, is alone involved, and treatment should therefore be directed to the affected part only. In those cases in which the whole of the colon is involved medical treatment almost invariably succeeds, but when it does not, ileo-sigmoidostomy, with or without colectomy, is indicated.

THE BACTERIOLOGICAL EVIDENCE OF INTESTINAL INTOXICATION.

BY

J. C. G. LEDINGHAM, D.Sc., M.B.,
CHIEF BACTERIOLOGIST, LISIÈRE INSTITUTE.

My interest in the question of alimentary toxæmia is naturally confined to the bacteriological and biochemical evidence which has been advanced by the school of Metchnikoff in support of their master's thesis. That thesis, as has frequently been explained in previous contributions to this discussion, asserts that the poisons elaborated by the micro-organisms of the intestinal tract, and particularly those harboured by the large intestine, are the most potent factors in the production of a long array of symptom-complexes loosely grouped under the term "auto-intoxication," and further, that these same poisons are the essential causes of the sclerotic changes in the organs which accompany old age. The thesis, as you can understand, is, therefore, a perfectly straightforward one, and one which ought to admit of both observational and experimental bacteriological proof. In the absence of proof capable of satisfying the bacteriological critic the thesis must remain little more than a fascinating hypothesis. It will be my purpose, therefore, to discuss as briefly and succinctly as the time at my disposal permits the main bacteriological evidence which Metchnikoff and his pupils have brought forward during the past four years in support of the theory of intestinal intoxication. This evidence has been sought for in the following types of research:

I. An investigation of the flora of the large intestine or of the faeces, with a view to the classification and identification of the various bacterial groups and their biochemical properties.

2. Experiments on the toxic action of filtrates of special groups of these micro-organisms in animals.

3. Analogous experiments with substances of definite chemical composition, especially indol.

4. Alteration in the intestinal flora as the result of food changes, constipation, and operations undertaken for the removal of the large intestine.

In connexion with the first of these lines of research the main work has been done by Metchnikoff himself and his pupils, especially Distaso, who have built on the earlier work of Tissier, and I would here point out that French authors are too prone to the assertion that our knowledge of the intestinal flora has been in the main the outcome of French work. Such, of course, is by no means the case. In fact, the chief contributions to our knowledge of the coliform group have come from workers in this country and in America. It is, however, to the anaërobic flora particularly that Metchnikoff and his pupils have directed their attention, as it is these proteolytic anaërobics which they specially incriminate as playing the chief rôle in what they call "intestinal putrefaction." It would be out of place to enter into a description of these various anaërobics, as I am convinced that the question of the classification and identification of these groups is far from settled, and there are probably far more names than bacteria to correspond.

It is doubtful if much that is new on this subject has emerged from recent French work. The chief putrefactive organisms whose cultural and biochemical properties have been studied in connexion with intestinal putrefaction have been *B. perfringens*, *B. sporogenes*, and *B. putrificus*, but it cannot be said that we have yet accurate methods of differentiating anaërobics. One must also mention the acidophile or acetogenic organisms which by the French observers are regarded as highly beneficent organisms by virtue of the inhibitory effect exercised by their acid products on the growth and activity of the putrefactive types.

Of these acetogenic organisms which have the property of producing acid from lactose and of being able to grow in acid media the most important perhaps is the *B. bifidus* of Tissier. This author found that this organism is the chief representative of the flora of the breast-fed child, a statement which more recent work has confirmed. It may be noted that *B. bifidus* is a strict anaërobie, and is Gram-positive.

A very similar organism to which attention has been paid is the *B. acidophilus* of Moro. As the child passes on to more varied food there is a gradual change in the flora from the purely fermentative type represented by the acid formers above mentioned to a combined flora of the fermentative and putrefactive type, using the term "putrefactive" in the sense of ability to break down nitrogenous constituents to the stage of peptones and proteoses and mono and diamino acids. Further katabolism of these cleavage products is effected mainly by the representatives of the *coli* group, many of which have the power of producing indol from tryptophane, and some of producing phenol from tyrosin.

Now it is seen that in the adult normal human flora the Gram-positive acetogenic organisms, represented by *B. bifidus*, are rare, and never predominate as in the young child. The predominant group is that of the *B. coli*, and in addition there are the representatives of the putrefactive anaërobic group (*B. putrificus*, *B. perfringens*, *B. sporogenes*, etc.).

Indol is formed chiefly by coliforms, and only to a small extent by these putrefactive anaërobics. It is, therefore, all the more surprising that Metchnikoff and his school should have drawn so much attention to the anaërobics as the chief factors in intestinal putrefaction, while at the same time their energies should have been devoted to the investigation of the toxic action of indol, a product chiefly of coliform activity. How far the indican in the urine is an evidence or a measure of intestinal putrefaction by micro-organisms is not yet completely settled, but admitting for the sake of argument that it does come from the action of micro-organisms in the intestine, it is not at all clear why it should be regarded by Metchnikoff and his school as the chief toxic agent produced by their action. Indol, of course is a substance of definite chemical composition, while the known bacterial toxins are of unknown chemical composition. How far,

then, the Metchnikoff school is justified in taking a simple substance like indol as the toxic product *par excellence* of the action of putrefactive intestinal microbes is extremely doubtful. Recently the opinion has been revived by Emmerich that in cholera the symptoms of intoxication are not due to specific vibrio toxins but simply to the nitrites, which, as you know, the *V. cholerae* is capable of forming in the test tube.

Little support has been given to this view in the case of cholera, and it would therefore seem all the more gratuitously to regard indol as the main toxic product of putrefactive organisms the pathogenic action of which has been only very insufficiently studied.

Let us see, therefore, what has been the main result of the experimental work performed with these putrefactive anaerobes and with their presumed chief toxic product indol. In one of his earliest papers Metchnikoff tested the toxic action of filtrates of some of these anaerobes. Filtrates were tested intravenously on rabbits in doses of 7 to 8 c.c.m. per kilo of body weight. These are very large doses. For an ordinary full-grown rabbit this would mean at least 20 to 25 c.c.m., and it is not surprising that in some cases a fatal result ensued. Great variation, however, was apparent in the toxic power of these filtrates (*B. perfringens*). Nevertheless the result of these experiments led Metchnikoff to state that in the putrefactive organisms of the digestive tube we have a source of auto-intoxication. Further experiments on this line were performed by his pupil Kerontschewsky, who tested filtrates of anaerobic organisms isolated from rabbits' faeces. Occasionally quite potent filtrates killing in 1.3 c.c.m. per kilo were obtained, but in other cases doses of 20 c.c.m. per kilo did no harm. The strongest filtrate was prepared from *B. perfringens*.

Experiments were also performed on rabbits by intracerebral injection of filtrates, and there was some very slight evidence that antibodies to these organisms appeared in the blood serum.

In the case of dogs fed daily with broth cultures of *B. perfringens* (in very large doses, 200 to 500 c.c.m.), progressive loss of weight occurred with slight anaemia, and when the animals were killed some evidence of sclerotic changes in the kidneys were found. It is surprising that nothing worse happened after such heroic dosing!

It must not be supposed, however, that the putrefactive organisms are the only defaulters. The flora of the large intestine is, according to Metchnikoff, wholly bad, and therefore we have other series of experiments with preparations of staphylococci, *B. coli*, etc.

According to Manonélian, atheromatous plaques appeared in the aorta of a large proportion of rabbits inoculated repeatedly with staphylococci (in 73 out of 86), and also in monkeys. These plaques occurred at the level of the arch of the aorta. It must be noted, however, that Weinberg found spontaneous atheroma in 4 to 19 per cent. of rabbits. More recently Bertrand and Berthelot have isolated from the faeces of patients suffering from chronic auto-intoxication an organism which, when grown on a special medium containing histidine, yields a highly toxic product apparently identical with β -imid-azoethylamine, a base previously obtained by Ackermann in the putrefaction of histidine, and also by Barger and Dale in ergot. The organism which yielded this toxic product belonged to the coliform group, and, according to the authors, was closely related biochemically to the *B. lactis aerogenes*. The authors make the statement that this particular organism was never found in the faeces of normal healthy people. This is a very important statement, and confirmation must be awaited before it can be accepted.

I turn now to the animal experiments performed with definite chemical substances which are understood to arise from the action of micro-organisms in the intestinal tract. In these experiments by Metchnikoff, Dratschinski, and others, potassium phenylsulphate and indol have been the chief substances whose toxic action on animals has been investigated.

With potassium phenylsulphate atheromatous changes in the aorta of rabbits, guinea-pigs, and monkeys were produced, and small cell infiltrates in the liver and kidney. Rabbits received by the mouth 0.04 gram of paracresol during a period of one to four months, and 61 per cent. of the rabbits showed atheromatous

plaques. Dratschinski gave similar doses of indol daily to guinea-pigs by the mouth, and obtained evidence of atheromatous degeneration of the wall of the aorta with chronic interstitial processes in the organs, such as the liver, kidney, and suprarenal capsules. These foci in the wall of the aorta invariably contained calcareous deposits, and the question to be decided was whether these foci met with in the animals intoxicated with indol were merely further stages in the development of the cartilaginous foci met with in similar situations in normal guinea-pigs, especially those of advanced age. Such foci were met with in 67.5 per cent. of normal guinea-pigs weighing 250 grams and over. The author was of opinion that hyaline and calcareous foci encountered in the intoxicated animals were distinct from the cartilaginous foci found in normal animals, and concluded that intoxication with indol was the exciting cause. It does not appear to me, however, at all proven that the indol, if it affected anything at all, did any more than hasten the calcareous transformation of these normal cartilaginous foci, and the question of the influence of indol in this connexion must still be considered as undecided.

I now come finally to discuss the changes which have been stated to occur in the composition of the intestinal flora in cases of intestinal stasis and in cases which have suffered resection of the large intestine. This question has recently been attacked by Distaso who had the advantage of obtaining material from Mr. Lane's cases.

Distaso roughly classifies the organisms of the intestinal tract according as they do or do not produce indol. In the normal adult man the faeces, as is well known, show a preponderance of indologenic organisms of the coliform group. In constipation, according to Distaso, there are practically no Gram-negative organisms, but there is a great abundance of spores, the indol-formers being now of the sporulating type. There is also an absolute diminution in the quantity of bacilli present. The conclusion drawn by Distaso that the flora of constipation is an index of intoxication is entirely unsupported by the evidence he adduces. In cases operated upon for removal of the large intestine it was observed that the flora showed not so much a qualitative change as a quantitative change with a consequent alteration in the functional activity of the organisms concerned. Before operation the flora was one typical of constipation, while after operation the indologenic organisms had largely given place to the acetogenic (that is, *B. bifidus* and *B. acetogenes*) which are regarded as highly beneficial. The effect of this change, according to the author, is that the acid produced by the latter organisms inhibits the activity of, or actually destroys, any putrefactive organisms present. The evidence on which this statement is based was the fact that, when the faeces were inoculated on a potato medium, marked acid formation took place, while growth on broth containing boiled white of egg only rarely was followed by proteolysis indicating an action on the part of the putrefactive organisms. It is very questionable how far it is legitimate to assume that the function of a flora in the body can be determined by an *in vitro* experiment of this rough order. To prove a change in flora of this character would require far more extensive bacteriological and biochemical research than has so far been devoted to the subject, and it is indeed remarkable that the author should make the astounding statement "that after this study the theory of chronic intoxication by the work of intestinal organisms cannot any longer be in doubt." As a matter of fact, it is not clear from the paper how often the faeces were examined in these cases, and whether samples were taken at operation from the bowel above the resection.

If, as stated, only two examinations of the faeces at a year's interval were made, the data so obtained would be of little value. Such cases would require to be examined repeatedly before and after operation, and under all conditions of diet.

Distaso further asserts that the intestinal flora of the normal adult is noxious, and yet he asks the reader to rejoice with him over the microscopical appearance of the faecal flora of one of these operated cases. This flora, of which a drawing is appended, is characterized as "*une des plus belles*," but certainly the flora of the constipated person—a drawing of which is placed alongside—seems far

the more attractive. With regard to the work done by the Metelnikoff school on the influence of food on the composition of the faecal flora, I would merely refer to certain experiments of Bertrand, who found that rabbits fed on potatoes always gave a marked indican reaction in the urine, while those fed on carrots gave no such reaction. When a carrot-fed rabbit was placed on potato diet indican appeared. The intestinal flora of the two groups did not differ qualitatively, but the potato-fed rabbits had more *B. coli* in the faeces. No quantitative data on this point are supplied. Bertrand's view was that in the potato-fed rabbit there was much less acid production from the fermentation of sugar than in the carrot-fed rabbit, and consequently there was nothing to inhibit the formation of indol by the coliforms present. Also it is stated that the flora of the potato-fed rabbit was very poor in amylolytic species, but data on this point are wanting. It cannot be said that work of this kind advances the subject far. One is tempted to ask why chemical examinations of the intestinal contents were not made at various levels, and accurate records kept of the organisms met with at these levels. In all the recent work on auto-intoxication and on sour milk therapy, it has to be remembered that the inhibition of intestinal putrefaction by milk and milk constituents, especially milk sugar, was known years before Metelnikoff popularized the administration of milk soured by lactic acid bacilli (see an excellent survey of this subject by Kendall, 1912, *Journal of Medical Research*, vol. xxv, p. 117), and, as pointed out by this author, the effect of such treatment may be due, not to acid produced by the bacilli supplied, but to that produced by *B. coli* acting on the sugar, which is generally increased in the diet. Protein is thus spared, and consequently protein decomposition products do not appear. A bacteriological basis for the view that the activity of lactic acid bacilli inhibits that of the putrefactive organisms in the intestine is still lacking.

In conclusion, I am of opinion that the investigation of the biochemical action of intestinal organisms yields a very large and promising field for future research, and may throw a flood of light on this question of auto-intoxication, but it does not seem to me that the results achieved in the types of researches so far published by the Metelnikoff school lend any very marked support to the thesis.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

LONG SURVIVAL AFTER REMOVAL OF MAMMARY CARCINOMA.

This record may be of interest. A lady had a scirrhus of the breast removed in 1898. A recurrence was more widely removed in December, 1899. She lived to November, 1910, when she died of extension to the lungs, aged 68.

During the greater part of the interval she enjoyed very fair health, was able to travel abroad, to see her daughter married, and grandchildren growing up.

Putney, S.W.

JOHN GAY.

AFTER-HISTORY OF A CASE OF MYELOID SARCOMA OF THE FEMUR TREATED BY SCRAPING.

In the *JOURNAL* of February 26th, 1898, I reported the case of myeloid sarcoma of the femur operated upon in 1895. Since then the patient has remained in perfect health, and recently writes, "My health is very good; my knee is sometimes painful, but is fairly strong; I cannot bend it. I am able to attend to my work (a wheelwright's), and have walked ten to twelve miles in a day. There is still a slight discharge from the wound, which I dress about once a week." Obviously this is a better result than that obtained by amputation.

Professor Bloodgood of Baltimore, in a paper published in the *Transactions* of the American Surgical Association, 1910, had collected two cases besides this one, which had been similarly treated, and had both done well.

From the discussion at the Surgical Section of the Royal Society of Medicine in November last, at which no example of treating myeloma of the femur by scraping was mentioned, it must be inferred that the method is not practised at the London hospitals. In the hope that surgeons will give it a trial I venture to again draw attention to the case which has been under observation for eighteen years.

FRANK HINDS, M.D.,
Honorary Surgeon, Worthing Hospital.

LARGE FIBROMYOMA OF THE URINARY BLADDER.

The following case is interesting from the fact that fibromyoma is exceptionally rarely found in the bladder.

Mrs. H., aged 44, was admitted to the Walsall Hospital on February 2nd, complaining of retention of urine, pain over the region of the bladder—both of three months' duration—and of haematuria of one week's duration. The usual points of differential diagnosis were considered, and in order to facilitate the examination she was anaesthetized. On vaginal examination, a large, hard tumour was felt over the anterior vaginal wall. The uterus was freely movable and normal in size. It was decided to explore the bladder, and for this purpose the urethra was dilated until it admitted the forefinger. By this means it was ascertained that the tumour was occupying practically the whole of the bladder and was firmly fixed in the region of the trigone. Subsequently the bladder was opened suprapubically and the growth, which was the size of a closed fist, removed after ligating the pedicle. She made an uninterrupted recovery.

Microscopically the tumour was composed of interlacing bundles of smooth muscle tissue, with a small amount of stroma and well formed blood vessels. There was no evidence of malignancy.

I am indebted to Mr. Caddick for permission to publish this very interesting and extremely rare case.

Walsall.

CLINICAL AND SCIENTIFIC PROCEEDINGS.

OXFORD AND READING BRANCH: MAIDENHEAD DIVISION.

CLINICAL MEETING.

At a well-attended meeting of the Maidenhead Division of the Association held at the Guildhall, Maidenhead, on March 27th, after Dr. G. E. MOORE, who was in the chair, had entertained those present to tea, Mr. ANGUS MACNAB, F.R.C.S., read a paper on *Recent operative procedure in glaucoma*. The inefficiency of iridectomy in the treatment of chronic glaucoma and the study of the pathological material available had combined to lead to the view that the criterion of success in the surgical treatment of this disease must be the establishment of a fistulous track between the anterior chamber and the sub-conjunctival lymph space. He described briefly and lucidly the methods of Professor Lagrange, Lieutenant-Colonel Herbert and Elliot, I.M.S., and paid a tribute to the skill of these surgeons. The detailed technique of Herbert and Elliot's operations was described, the speaker's preference being for Elliot's method by means of a special trephine. The important point in both these operations was that the aperture should be close up to the corneal margin. Mr. MacNab was heartily thanked for his interesting paper. Dr. J. J. PATERSON, D.P.H., followed with an amusing paper on *Quacks and their methods*. He had a regular Odyssey of adventure to relate in his personal experiences with some well-known quacks; and although some of the narratives might not perhaps be quite appropriate for a lady's boudoir, the success of his crusade in exposing some of these gentry was heartily appreciated. The meeting then adjourned.

Reports of Societies.

ROYAL SOCIETY OF MEDICINE.

Monday, April 14th, 1913.

Sir FRANCIS CHAMPNEYS, President, in the Chair.

Resumed Debate on Alimentary Toxaemia.

MR. J. B. LAW FORD, in reopening this discussion, said the relation of disorders of the alimentary tract to eye diseases was still largely a matter of hypothesis. In recent textbooks on ophthalmology there was an absence of dogmatism on the subject, or no reference at all to it. In Germany and America many papers on this branch of the subject had appeared during the last few years, revealing great difference of opinion. Five years ago de Schweinitz said there was no ocular disease known to be due to intestinal autointoxication. Recently, however, a number of observations had made it probable that alimentary toxaemia was a contributory factor. In any case, it was a good working hypothesis, which would help to explain the clinical manifestations better than any other. That toxaemia resulted from mouth sepsis, especially gingivitis and pyorrhoea alveolaris, could no longer be doubted. The association of the latter condition with chronic irido-cyclitis was well known to all ophthalmic surgeons, and one of the first to recognize this was Mr. William Lang. Yet most of the subjects of pyorrhoea did not have irido-cyclitis, and some patients with irido-cyclitis had sound and clean mouths. Recurrent and relapsing forms of scleritis, episcleritis, and sclero-keratitis, were met with in subjects of pyorrhoea, yet careful treatment of the mouth had often failed to benefit these ocular conditions, and vaccine treatment in most instances had been disappointing. Tonsillar disease had frequently been thought to cause ocular inflammation, and it was permissible to assume that the tonsils might generate a toxin capable of inducing ocular lesions. The same might be said of choroiditis; and the occurrence of infection of the choroid in puerperal septicaemia was well known. The choroidal inflammation which he considered to be freely associated with pyorrhoea was localized exudative choroiditis, though this certainly owned other causes as well. Asthenopia, of varying type, unrelieved by the correction of refractive errors, had been recorded in patients the subject of pyorrhoea, and had been said to disappear on the treatment of the oral disease, but he had not met with such a case. The relationship of ocular lesions to enterogenous toxaemia was a more difficult problem. The diseased conditions of the intestines were invisible and the tests for pathological processes were not yet absolutely reliable; consequently diagnosis had to be largely a matter of exclusion. Until recent years syphilis, rheumatism, gout, and gonococcal infection were the accredited causal agents of many of the inflammatory affections of the eye, but in a good proportion of cases of keratitis, episcleritis, sclero-keratitis, irido-cyclitis, and choroiditis all these causes could be excluded. Here intestinal toxaemia could reasonably be invoked. Maladies accompanied by an abundance of intestinal toxins, such as dysentery, were accompanied by ocular lesions, such as retinal haemorrhages, retinal phlebitis and choroiditis. Inflammatory lesions affecting the uveal tract occupied a foremost place in the category of ocular diseases ascribed to enterogenous toxaemia. In a case reported by Bacquis of relapsing choroiditis associated with stenosis of the intestine, the relapses coincided with the recurrent blockages of the gut. Elschnig considered that in all cases of iritis in which syphilis could be excluded as a cause examination of the intestinal condition should be made. The type of ocular disease was similar to that following oral sepsis. Choroiditis of varying type was met with in patients with marked indicanuria and other intestinal derangements, and in whom other likely causes of choroidal inflammation could be excluded. More than one writer had attributed cataract to intestinal toxaemia; cataract was a frequent sequel of any form of chronic uveitis. In episcleritis and sclero-keratitis, when tubercle as a cause could be excluded, their possible dependence upon toxaemia should be considered. He had seen

relapsing sclero-keratitis in patients whose urine contained abundance of *Bacillus coli communis* and in whom there were other signs of toxæmia. The association of recurrent attacks of phlyctenular keratitis with gastro-intestinal disturbance in children was well known. Certainly treatment of the intestinal condition benefited the ocular. Some authorities, such as Ulthoff, doubted a causal connexion between gastro-intestinal auto-intoxication and lesions of optic nerve and retina; but there were cases calculated to modify that doubt. Many years ago Herner considered that the gastric derangement induced by tobacco and alcohol was partly responsible for the optic nerve lesions found in cases of poison by those drugs. Acute retro-ocular optic neuritis might be a result of auto-intoxication, and support was afforded by some recorded cases; also to the idea that the optic neuritis associated with chlorosis was due to intestinal toxaemia. He had not found records of cases of oculo-motor paralysis in which auto-intoxication was a probable cause. Recurrent haemorrhages of the retina and vitreous in young men, described by Eales, had been attributed to oral or intestinal sepsis, and obstinate constipation was nearly always present in these cases. The causal relation of toxaemia to infective processes in eyes on which operations had been performed was a matter of great importance. Ophthalmic surgeons were familiar with unexpected iritis and irido-cyclitis arising several days after an uncomplicated operation, such as for cataract, and it was conceivable that these were examples of toxaemic troubles, and that the altered conditions of life and the diminished tissue change inseparable from operations and confinement to bed might favour the development of toxins, and that they might become active in the part of the uveal tract which had been operated upon. There was much evidence in support of the contention that ocular and toxaemic conditions were often related, and there was encouragement to pursue investigations with the object of removing the present doubt on the subject.

Professor Dixon, F.R.S., said he regarded a toxin as a substance which, when injected into an animal, produced an antibody. Toxins administered by the mouth to healthy men and other animals were not absorbed. When digestion occurred under normal sterile conditions the products of such digestion were non-poisonous, but the case was different under the influence of certain putrefactive processes. Sulphuretted hydrogen might then be produced, which had been said to cause chlorosis. If the amount of ammonia in the portal vein was increased, definite pathological conditions of the liver might be produced, and the continuance of the procedure led to a type of hepatic cirrhosis. The important toxins produced in the alimentary canal of which anything was known were those produced from amino acids, which themselves were non-poisonous, but if acted on by certain micro-organisms occurring in the alimentary canal, they became poisonous by parting with one molecule of carbon dioxide. Tyrosin was non-poisonous, and if taken in even large quantities by the mouth would not only cause no harm, but would act as a food substance. But if tyrosin were grown in broth and inoculated into an animal with human faeces, it lost its molecule of CO₂ and became poisonous. Putrefaction in the alimentary canal was a normal process, and small quantities of these poisonous amines were being continually produced, and the micro-organisms in the intestinal tract probably exerted a beneficent influence; the body depended on these extraneous organisms for the effectiveness of digestion. The speaker then described and illustrated by the epidiascope some of the pressor substances which acted definitely on plain muscle. The chronic effects of toxic substances in the alimentary tract were felt on the kidneys and the arterioles. The kidneys were enlarged and the glomeruli and tubules greatly dilated, the former containing granular debris. The arterioles became degenerated.

Dr. LEDINGHAM then dealt with the bacteriological aspect of the question, in a paper which is published at p. 821. He was followed by Dr. GALLOWAY, whose paper will be found at p. 815.

Dr. MANTLE (Harrogate) said that large numbers of cases of functional disorders of the alimentary canal found their way to Harrogate, and in many of them apparently trivial lesions in the mucous membrane of the

nose and tonsils were the cause of lesions in joints. Too much stress could not be laid on pyorrhoea alveolaris and dental caries as a cause of early alimentary disturbances. There were thousands of constipated persons who had no bad symptoms, probably due to the cells of the mucosa forming such a strong barrier of defence, combined with the antitoxic function of the liver. Sometimes the toxin affected the respiratory mucous membrane, causing attacks of asthma; and it was well known that certain articles of food caused rashes to appear on the body. The alimentary toxins showed a special affinity for nerve centres; the lethargy associated with intestinal stasis was within the knowledge of all. Sir Lauder Brunton had stated that the *Bacillus coli* seemed to have a special power of producing fatigue toxins. In five cases, all females, the speaker had seen purpura associated with intestinal toxæmia, and in nearly all there was mucous colitis and pyorrhoea.

Mr. J. G. TURNER was sure there was justification for the assertion that there was a toxæmia due to dental sepsis, the symptoms being due partly to local sepsis produced in the mouth, and partly to that manufactured in the alimentary tract lower down. Dental sepsis was due to four factors: dental caries, pyorrhoea, tartar, artefact conditions leading to sepsis; and they were all governed by the one root factor, stagnation—the stagnation of germs and of soft, sticky, starchy, sugary food; it might be termed germ carbohydrate stagnation. The mouths of fishes and of wild animals were free from dental sepsis. But when animals naturally wild were kept in captivity for exhibition and they were fed on bread and soft, pappy foods, their mouths became septic with pyorrhoea, tartar, and dental caries. Domestic dogs and cats afforded everyday examples of this. A considerable number of the monkeys at the London Zoological Gardens died from acute enteritis; long before this occurred putrescent material could be squeezed from the gums. Marginal gingivitis was found in children of all ages, and it gradually merged into true pyorrhoea. He strongly advocated a return to whole-meal bread and the removal of all offending teeth. Man could live at all ages quite well without teeth. Everything in the mouth must have a smooth surface, and there should be no cavities or pockets for the accumulation of debris. Vaccines were likely to be unsatisfactory, as their effect was naturally evanescent.

Dr. A. F. HERTZ then read the paper published at page 817.

Mr. FRANK COLEMAN said toxæmia might be caused by the mouth in three ways: (1) Lesions of the buccal cavity, namely, of teeth and gums; (2) imperfect mastication, due to inefficient teeth or want of teeth; (3) mouth breathing. Lesions of the buccal cavity might allow of direct bacterial invasion of the blood, but some of the bacteria were also shed into the mouth and swallowed. The pulp of a tooth, so long as it was alive, could exert a defensive action against the invasion of micro-organisms; but when the pulp was involved by caries conservative dentistry was at best only a compromise. A pulpless tooth acted as an irritant, and the mucous membrane around such a tooth was rarely healthy. Carious cavities in teeth in which the pulp was not involved were a potential source of alimentary toxæmia. Caries being a gradual process, the patient was able to develop antibodies, which in some way neutralized the toxins absorbed from the teeth and gums. One might take the infective area as a square inch per affected tooth socket, hence the mouth might contain a very generous incubating chamber for harmful organisms. Gingivitis sometimes affected the mucous glands of the cheek, stippling it with greyish-white opaque nodules, which were firm and shotty to the touch. These glands had been found by Goadby to contain *Staphylococcus viscosus*. The scouring action of the tongue and lips was much diminished in defective mastication, and the deficient blood supply to teeth and gums during this defect also made the tissues less resistant. The only reliable treatment of sockets affected with pyorrhoea alveolaris was, he agreed with Mr. Colyer, the removal of their contained teeth.

Dr. GUSTAVE MONOD (Vichy) drew attention to the soil in the particular person as a special factor determining the manifestation of his disease. By hepatism, meaning inadequacy of the liver cells, a vicious circle was estab-

lished, the toxins set free reacting in turn on the cells of the liver. The bowel then suffered a diminution of its tonicity, and there was a lowering of intraperitoneal pressure. Ptosis might then result, showing itself first on the hepatic flexure of the colon, then on the right kidney, and later on the stomach, left kidney, liver, and spleen. Glenard held that in most cases movable kidney was a sequel to toxæmia. One means of breaking the vicious circle was, he agreed with Dr. Mantle, by means of spa treatment.

The debate will be resumed on Monday, April 21st.

CLINICAL SECTION.

At a meeting on April 11th, Sir W. WATSON CHEYNE, Vice-President, in the chair, the following were among the exhibits:—Mr. E. M. CORNER and Mr. P. H. MITCHENER: *Chronic bone disease*. At first the condition was thought to be syphilitic, and later on to be enchondromata. Finally the disease was regarded as due to developmental error, possibly connected with a nervous lesion. Mr. CORNER: *Ossification of the brachialis anticus* of a young man, presumably due to a partial rupture of the muscle. Mr. CORNER and Mr. C. V. ANDERSON: *Recovery after severe electric burns*. During convalescence signs of paralysis of the left median nerve developed, but no burn or scar accounted for it. The case ultimately recovered. It was suggested that it might be due to the passage of an electric current from below upwards in the nerve or to some electrolytic change. Mr. C. H. FAGGE: (1) *Myeloma* of the head of the tibia seven years after enucleation. (2) *Re-formation of the fibula after complete removal of the diaphysis* for acute infective periostitis. The patient was a boy, aged 11, and the infection was produced by the *Staphylococcus aureus*. The fibula had become almost completely osseous. Mr. LIONEL E. C. NORBURY: *Re-formation of the tibia after resection of the diaphysis* for chronic osteo-myelitis (?) syphilitic, in a boy aged 10. Dr. F. PARKES WEBER: Two cases of *Ateleiosis*; one of a man, aged 45, the other of a woman, aged 20, in whom was also a slight congenital malformation of the hands and feet. Both were imperfectly developed sexually, but mentally alert. Mr. P. MAYNARD HEATH: (1) *Pseudo-hypertrophy of the breast* in a girl, aged 16. There was no tumour in the enlarged breast, but it was lumpy and appeared to be divided into more or less separate lobules. (2) *Congenital cyst in the parotid region* in a girl aged 16. The swelling could be made to disappear on pressure. Mr. LAWRIE MCGAVIN: (1) A man, aged 32, who had sustained a simple fracture of both bones of the right leg. The fibula had been plated. Considerable swelling persisted in the right knee. (2) A man, aged 38, in whom Bassini's operation for double hernia had been followed by thrombosis of the left internal saphenous vein. (3) A man, aged 63, with (?) a mixed tumour of the left sub-maxillary salivary gland. (4) A boy, aged 16, who had had a psoas abscess which was possibly not tuberculosis. Mr. LOCKHART MUMMERY read a short paper on a case of *Ulcerative colitis* in a man aged 49, which terminated fatally. It was of interest for two reasons: First, because recovery failed to occur after appendicostomy; secondly, because the appearances produced in the colon closely imitated those of multiple polypi.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.

At a meeting held on April 3rd, Dr. STANLEY RISELEY (President) in the chair, Dr. A. G. YATES, in a paper, *Some recent conceptions of hysteria*, discussed, first, the etiology of functional nervous disorders. This was obscure because as yet no pathological changes had been found to account for them. This failure had in recent years led to an elaborate attempt to define the neuroses and explain their causes in terms of psychology. Symptoms were thus explained, not on the basis of physical changes in the tissues, but on that of abnormal mental functions. Both Janet and Freud assumed the existence of subconscious mental processes, the former arguing that in the hysterical mind the portion concerned with conscious mental activity was quantitatively diminished, and unable to contain at one and the same time as many thoughts, feelings, or emotions as the normal mind. The expression "field of consciousness" was a convenient one, to include the whole

mass of ideas, sense impressions, etc., of which a person was at any one moment conscious. It might be represented diagrammatically by two circles, one within the other. The inner circle would represent the particular idea, object, or feeling towards which the mind was at that moment directing its attention. In the outer circle might be placed all the other mental processes of which the mind was at the same moment conscious, but less distinctly. This was the peripheral portion of the field. The diagram might be still further extended by adding a third circle outside, to represent the subconscious portion of the mind. By such diagrams the normal could be compared with the hysterical mind, simply by making the circles representing the conscious field larger in the former than in the latter. In other words, a number of mental processes which in the normal mind were retained within the conscious portion were, in the hysterical individual, transferred to the subconscious area. Present sense impressions were often unable to gain admission into the diminished conscious area, with the result that anaesthesia was produced. In the hysterical fit, the area of personal consciousness was not merely diminished, but, for the time being, obliterated, and the mind dominated by some idea, impression, or event of the past. This mechanism was sometimes quite apparent, but not always. It seemed probable, nevertheless, that this apparently meaningless paroxysm was the result of some idea or memory of the past, fixed within the subconscious sphere in a mind in which that sphere was abnormally active and large, but possessed of a diminished facility or outlet into the neighbouring sphere of consciousness. Such a fixed idea from time to time burst its barriers, flowing out with irresistible force and flooding the already diminished field of consciousness; it thus took complete command of the individual and spent itself in a display of long-pent-up emotion. All the other phenomena of hysteria, such as occur during the interparoxysmal period, were likewise explained on the assumption of some fixed subconscious idea finding an outlet by these varied manifestations. Freud looked upon the condition as the result of some mental shock. The corresponding painful emotions, instead of gaining a suitable outlet, were repressed or driven down into the subconscious area of the mind, so that they were no longer felt. They were still active, however, and some outlet must be provided. This was effected by the conversion of these submerged emotions into the physical and mental phenomena known as the symptoms of the disease. By a method of treatment known as "psycho-analysis," Freud had been able to trace the connexion between some original painful emotion and such hysterical phenomena. It was a long and tedious process, but Freud believed that by analysing the enormous mass of ideas and chains of thought which he obtained, he could discover the hidden cause of the symptoms, and claimed that its revelation to the patient would effect a cure. These two theories resembled one another in assuming that the causative factor was some mental impression buried in the subconscious mind. Two cases were shown illustrating the rhythmical tremor of hysteria. In one case the left forearm had been partially paralysed from birth. It had, however, given no trouble until six months ago, when it became painful. Subsequently the tremor developed in it, and within the last few days it had also affected the other arm. Mr. W. W. KING, in a paper on the *Toxaemias of pregnancy*, said that these toxaemias often manifested themselves as disturbances of metabolism, which could be recognized by urinary examination. The nature of the toxin was unknown, but it was probably composed of a number of different elements, as suggested by Leith Murray. Recent work also indicated that the internal secretions from the ductless glands were important factors in toxæmic pregnancy. The early vomiting of pregnancy was not "physiological," and any but the mildest cases required treatment. The symptoms of pro-eclamptic toxæmia should be explained to all primiparae. Glucose in the urine in pregnancy might be due (1) to diabetes; (2) to hypersecretion from the pituitary gland; (3) to inability of the liver to store up glycogen. The last type was of toxic origin, and often associated with headache, neuritis, or muscular twitchings. The glucose disappeared when the patient was placed upon a meat-free diet.

BRADFORD MEDICO-CHIRURGICAL SOCIETY.

At the March meeting, Dr. EURICH in the chair, Dr. OLIVER, in a paper on *Loss of sight from loss of blood*, said that in 106 cases of which he had discovered records most of the patients were over 40. In 25 per cent. of the cases the disturbance of vision occurred either during or immediately after the haemorrhage, in 20 per cent. within the first twelve hours, and later than this in more than half the cases. There was no constant relation between the amount of blood lost and the severity of the eye affection. In half the cases there was no improvement of vision. In complete blindness the pupils were dilated and showed no light reaction. Treatment appeared to be of little use. In introducing a discussion on the heart from the physiological standpoint, Dr. CLOW remarked that in any irregularity of the heart three things had to be considered: (1) The inception of the stimulus for contraction; (2) the power of conduction of the auriculo-ventricular bundle; (3) the capacity of the heart-muscle to respond to the stimulus. In any given case of heart mischief it should be determined which of the following conditions was present: Was the nervous mechanism at fault? Did the fault lay in the condition of the heart muscle? If the muscle were good, was the load too heavy? In the first group—that is, the functional—there fell sinus irregularity, occurring chiefly in the young, and extra-systoles, occurring chiefly in elderly people. It was only since the introduction of the polygraph that these conditions had been understood. Drugs for the heart were unnecessary, but the exciting cause should be treated.

NOTTINGHAM MEDICO-CHIRURGICAL
SOCIETY.

At a meeting on March 19th, Mr. W. G. LAWS, President, in the chair, Mr. H. HERBERT, speaking of *Headache*, said that when headache was due to ocular causes it generally occurred fairly regularly after much use of the eyes; such headaches were not always cured by a visit to an oculist, because the patients sometimes omitted to wear glasses. In other cases, where manifest defects had been corrected, other defects became manifest later, and again, when patients were neurasthenic, they got into the habit of having headaches; sometimes the oculist was not allowed sufficient time to complete his examination of the eyes. Mr. H. B. TAWSE, discussing headache from a nasal point of view, said that it varied in intensity and character according to the locality of the condition originating it. In children adenoids frequently caused headache owing to the deficient oxygenation of the blood. Nasal polypi caused headache, but this was not constant. Other causes were the pressure of pus and hypertrophied tissue. The nose should be thoroughly examined in all cases of persistent headache.

At the meeting on April 2nd, Mr. R. G. HOGARTH, speaking of the production of *Local and spinal anaesthesia*, said that in using novocain it was not necessary to inject the solution into a nerve but only into the surrounding perineural tissue. When operating on small areas, it was sufficient to infiltrate the tissue for about two inches round the intended incision, with a 1 per cent. solution of novocain. In operating on such areas as the scalp or fingers it was sufficient to infiltrate at right angles to the sensory nerves supplying this area. For instance, the hand could be anaesthetized by infiltrating the median, ulna, and radial nerves. Brachial plexus anaesthesia could be produced by injecting 60 c.cm. of a 2 per cent. solution of novocain into the brachial plexus as it passed over the first rib. The three divisions of the fifth nerve could be anaesthetized as they passed out of the base of the brain. For gaiter operations it was necessary to infiltrate underneath as well as all round the tumour. Empyemata could readily be opened by blocking the three intercostal nerves concerned. Mr. C. H. ALLEN, speaking of spinal anaesthesia, said that no very serious sequelae after its use had been recorded in this country. Headache and pyrexia very often followed, but the headache was generally relieved by phenacetin. The chief advantages of the method were absence of post-operative shock, complete muscular relaxation, no venous engorgements or respiratory movements, no starvation, and no post-operative sickness. As a disadvantage was

urged the uncertainty of the anaesthesia. The method was contraindicated in cases of advanced sepsis. It had been employed over 200 times at the Nottingham General Hospital without any fatality, and in very few cases was the anaesthesia imperfect.

LIVERPOOL MEDICAL INSTITUTION.

At a meeting on April 3rd, Mr. R. W. MURRAY in the chair, Mr. ARTHUR EVANS described three cases of *Acute pancreatitis* on which he had operated during the past eighteen months. The disease was commonly difficult to recognize and was often missed even in the *post-mortem* room. His first case was a dock labourer, aged 35, who had been drinking heavily for ten days and vomiting incessantly for sixteen hours. He had intense paroxysmal epigastric pain, the abdomen was retracted and fixed, especially in the upper part; he was delirious, with a rapid thready pulse and subnormal temperature. On opening the abdomen the under surface of the omentum was sludded with white areas; the pancreas was a large mass of necrotic tissue. The patient died in six hours. *Post mortem* no calculi were found. The second patient, a woman aged 51, was fat and of alcoholic habits, and had a history of bilious attacks. She had been vomiting for several days and had pain in the upper part of the abdomen. There was no jaundice, no abdominal distension, but fixation of the upper part of the recti. On opening the abdomen there were white glistening plaques of fat necrosis on the omentum. The gall bladder contained thick viscid bile and small calculi. This patient recovered. The third patient, a healthy man aged 52, with no biliary history, was suddenly seized with severe epigastric pain and frequent vomiting. He had obstinate constipation followed by diarrhoea with green offensive stools; there was sugar in his urine. A month after this attack he was again seized with a similar attack. When the abdomen was opened there were extensive adhesions and the peritoneum was red, but no fat necrosis was seen. An irregular mass was found behind the stomach. This was drained. The gall bladder and duodenum were apparently normal. There was marked improvement after the operation, the sugar disappeared from the urine, and on the seventh day after the operation he became delirious, and died three days later. No autopsy could be held. After describing these cases, the speaker pointed out the common association of pancreatitis with gall stones; in making a diagnosis he thought the agonizing pain in the epigastrium with vomiting and collapse, tenderness and fixation in the upper part of the abdomen were the important signs. Cases were often mistaken for intestinal obstruction. Drainage of the abdominal cavity and, if necessary, of the gall bladder seemed the only treatment available. Mr. F. T. PAUL thought the intense pain in these cases was typical peritoneal pain and not due to the gland. Pancreatic cysts varied much in their results, some being easy to deal with, others discharging a secretion which was very injurious to the tissues. He had seen many obstructed bile ducts that did not cause acute pancreatitis; the causation of the latter condition was not clear. Mr. R. W. MURRAY thought the acute pain was due to the irritation of the parietal peritoneum. It was not clear how the pancreas became poisoned, and the mere blocking of the duct by gall stones might be doubted as the cause. He had seen a case in which these symptoms had come on suddenly after an operation on the knee-joint, and the patient died. Dr. STROOKES had seen a case in a woman sent into the Maternity Hospital for intestinal obstruction at full time; in that case Caesarean section was done. The child was dead; the whole of the small intestine from the jejunum to within three inches of the ileo-caecal valve was empty and collapsed. The peritoneal surface was everywhere red, the colour of tinned salmon, and studded with fine yellow spots; the large intestine contained gas, but was not over-distended; the small intestine, four inches from the caput coli, formed a loop with which the caput coli and the vermiform appendix hung down into the pelvis behind the uterus, the mesocolon being there about 6 in. long. No mass was noticed in the upper part of the abdomen. Was it possible that obstruction due to the long mesocolon had caused pancreatic trouble with the fat necrosis of the peritoneum? There had been vomiting and probably reversed peristalsis for several days. In

replying, Mr. EVANS said that he thought that the acute pain and the extreme constipation might be due to the effect of the pancreatitis on the solar plexus.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF SURGERY.

At a meeting on March 23rd, Mr. R. D. PUREFOY, President, in the chair, Mr. H. DE L. CRAWFORD read a paper on the *Intratracheal insufflation of ether*, and demonstrated the apparatus used by him. It consisted essentially in forcing etherized, warmed, and filtered air into the trachea at a point one inch above the bifurcation through a catheter which was passed through the larynx from the mouth. The air then returned between the catheter and laryngeal wall. The chief advantages were that it permitted full oxygenation of the blood even if both pleurae were opened, that no blood, vomit, or mucus could get down through the glottis, and that the anaesthetist was quite out of the surgeon's way in operations on the heart and neck. It was therefore indicated in operations on the thorax, head, mouth, and neck. He had found the method quite free from danger and very satisfactory, but emphasized the necessity for using an automatic safety valve of mercury. Mr. R. H. WOODS agreed with Mr. CRAWFORD that this method of administering ether would probably be largely used in future in certain cases. The difficulty of bleeding about the throat during operations in the nose, mouth, and pharynx was a very real one, and up to the present the way in which it had to be got over was by performing a preliminary laryngotomy and administering the chloroform through a tube. This method answered very well, but it involved an extra operation—a disadvantage which the method thus described got over entirely. Sir JOHN LENTAGNE said that he had often felt the need for some means of producing positive pressure to do away with collapse of the lungs in operations on the chest wall, and the instrument shown would appear to do this. Dr. KIRKPATRICK said the method described seemed to be one which would overcome some of the most serious difficulties which anaesthetists had to deal with. He did not know that the method spoken of by Mr. Woods was as safe as he had stated it to be, as the introduction of direct vapour by means of a tube without being heated previously was attended by a certain amount of risk, and he therefore considered that Dr. CRAWFORD'S method, since it got over this, was an improvement. The apparatus would be chiefly used for operations of the thorax, but he thought there was a considerable field of usefulness for it in upper air passage cases. He did not quite understand why it should have been specially useful for operations in the Trendelenburg position. As a sequence of the administration of an anaesthetic in this way was there any interference with the respiration? It was to be expected that after pressure had been kept up for some time there might be difficulty in re-establishing the respiration. Mr. A. A. McCONNELL said that he had seen the instrument at work, and considered it as good as any he had seen. The expense of negative pressure cabinets had up to the present almost prohibited their use. Frazer of Philadelphia used the instrument in all his head cases. He also used it in the cerebellar cases, because in the majority of these cases there appeared to be some respiratory difficulty, and the instrument acted as the most efficient artificial respirator which could be obtained. Dr. NESBITT said that from the point of view of the physician he considered the apparatus a step in the right direction. He suggested that it was perhaps a trifle cumbersome, but had no doubt that this would be overcome. Mr. H. DE L. CRAWFORD, in replying, said that he did not think that the catheter offered any impediment in tongue cases. With regard to the use of the apparatus in the Trendelenburg position, what he should have said was that Frazer used the apparatus for operations in this position as the breathing appeared to be somewhat hampered, but it was not considered that any very great advantages attached to its use in that particular situation. Referring to Dr. Kirkpatrick's question as to the recovery of patients, he pointed out that the anaesthetic was not stopped until the pressure was beginning to be compensated. He considered that the instrument would be found much more portable than those previously in use.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

At a meeting on April 4th. Dr. G. P. SHUTER, President, in the chair, the following were among the exhibits:—
 Dr. N. T. WHITEHEAD (for Dr. ARTHUR SAUNDERS): *Osteoarthritis in a girl of 11 years.* A slight injury to the left hip occurred last October. Limitation of movement gradually set in, and recent investigation with x rays revealed lipping of the cartilage and the presence of osteophytes. No possible source of infection was found beyond the presence of two carious teeth. Dr. N. T. WHITEHEAD (for Dr. J. M. BERNSTEIN): *Stenosis of pulmonary artery.* The patient complained of great shortness of breath associated with pain over the cardiac area; the latter was only a recent symptom. There was some degree of cyanosis but no polycythaemia; the heart was dilated, especially to the right of the sternum. There were no dilated veins in the neck, and the liver did not pulsate. A systolic thrill could be felt over the pulmonary valve; a systolic murmur was audible over the whole of the cardiac area, but more especially over the pulmonary valve. Dr. SEYMOUR TAYLOR said he would have expected in this case to have found evidence of the relief of the tension in the right ventricle along the line of least resistance—namely, through the tricuspid orifice—but he did not find any signs of this. He thought it possible the patient had aortic obstruction. Mr. DONALD ARMOUR: A boy who had received an *Injury to the ulnar nerve* by driving a splinter of glass into the palm of his hand. From the muscular wasting and paralysis it was clear that the deep branch of the ulnar nerve had been cut across just where it passed through the muscles of the hypothenar eminence in company with the deep branch of the ulnar artery. The superficial branch of the ulnar nerve had escaped, as shown by the fact that the inner side of the little and the adjacent side of the little and ring fingers were normal as regarded sensation. The muscles supplied by the deep branch of the ulnar—namely, the small muscles of the little finger, the inner two lumbricals, the interossei, and the two adductors of the thumb—were completely wasted. As suture was out of the question, Mr. ARMOUR suggested excising the scar, in which no doubt the proximal end of the nerve was embedded, in order to give the nerve a better chance of regenerating. Mr. TYRRELL GRAY mentioned a method, adopted in America, of scoring with a small tenotome the scar tissue in lines parallel with the nerve fibres with the object of opening up fresh paths for the regeneration of the divided fibres, but Mr. ARMOUR did not think it applicable to this case. Mr. SYDNEY G. MACDONALD: *Perineal testicle* in a man aged 28. The testicle was small and the scrotum on the same side imperfectly developed. The patient himself was well developed, cycled constantly, and suffered none of the usual inconveniences. Dr. T. C. STOREY (for Dr. H. J. DAVIS): *Epithelioma of auricle* in a man aged 72. The growth commenced as a small lump on the outer border of the pinna, and finally broke and formed an ulcer. The auricle was removed and the considerable raw area resulting skinned over with remarkable rapidity. Mr. OSWALD L. ADDISON: (1) *Genu valgum and dislocation of patella* in a stout middle-aged woman under treatment for osteoarthritis, both legs being affected. The left patella lay on the front of the external condyle of the femur, the normal patellar surface of the femur being uncovered; on the right side the displacement was less extreme. The patient was unaware of the deformity, which had given rise to no trouble until the last few months, when she began to have severe pain in the left knee. (2) *Sporotrichosis* in the leg and thigh of a boy, aged 11 years. The condition did not come under observation until it had lasted a year, and was at first regarded as tuberculosis. Mr. N. BISHOP HARMAN: (1) *Exenteration of the orbit and partial excision of maxilla and ethmoid for rodent ulcer.* The patient, a woman of 54, first noticed a small pimple on the right cheek just under the eyelid seventeen years ago. It scabbed, and she treated it herself with various caustics whenever the lump reappeared. From 1905, x ray, zinc ions, and radium, each appeared to benefit her for a time. When seen by the exhibitor in 1911 with a view to operation she had lost the whole of the lower lid, and a rodent ulcer as big as a penny was fixed to the maxilla. An operation for removal

of the growth was performed, and all seemed well until September, 1912, when there was recurrence in the orbit. A second extensive operation had then to be undertaken, with the result that the orbit, nose, and antrum, were opened into one. The great cavity left gradually sank in a remarkable way, leaving the passage of the nose exposed to view in a striking manner. There had been no lack of treatment, but an earlier appeal to surgery would have left the patient with a sound face and two good eyes. (2) *Two cases of excision of the lacrimal sac* in young women. The results in both cases were excellent.

UNITED SERVICES MEDICAL SOCIETY.

At a meeting on April 9th, Fleet Surgeon BASSETT-SMITH, R.N., President, in the chair, Major HOWARD ENSOR, D.S.O., in a paper on the *Duties of an Officer of the R.A.M.C.* attached to an infantry battalion on active service against a civilised enemy, held that a camp should be regarded as "standing" when the troops had been in occupation of it for twenty-four hours and no orders had been issued for them to move. After the expiration of this time, in the absence of orders for the battalion to move on, the site of the camp should be regarded as an area likely to be occupied by the unit for some considerable time, and the necessarily primitive system of sanitation prevailing when a battalion is bivouacking for the night only should be changed for the more elaborate one suitable for a standing camp. This would prevent the serious error of postponing the institution of sound sanitary measures in expectation of orders arriving for the troops to move almost immediately; such a mistake frequently led to the men remaining under undesirable conditions for several days. The sanitary condition of a camp was, perhaps, the best criterion of the state of discipline of the troops occupying it. A matter of great importance was the cleansing of bivouac areas before starting on the march next day, as the same area was likely to be occupied by other troops at an early date. While advocating the early transfer of febrile cases to the field ambulance when troops were on the march, the speaker favoured retaining men suffering from a moderate degree of fever with their unit, when in standing camp, for forty-eight hours, isolating them, as far as possible, in tents or shelters until it was clear that they were not likely to prove able to continue at work. Cases sent to the ambulance tended to be evacuated to the lines of communication and were lost to their battalion. In regard to duties during action, he recommended a very thorough training of the regimental bearers in the application of the first field dressing, and that they should be employed for this purpose and the protection of casualties by the erection of temporary cover, rather than for the carrying of wounded to the aid-posts, during action. Battalion stretchers, instead of being carried behind the companies by the bearers at the beginning of an action, should be carried on a cart, under the care of one of the R.A.M.C. detachments, and only brought into use when darkness or a lull in the fighting permitted the safe clearing of the wounded from the area of operations.

ASSOCIATION OF REGISTERED MEDICAL WOMEN.

At a meeting on April 1st, Dr. MARY MURDOCH (Provincial Vice-President) in the chair, Dr. HELEN BOYLE read a paper on *Early nervous and borderland cases*, including under this title cases in which nervous and mental symptoms predominated, but which were uncerifiable and had no outstanding organic disease. There was a class of emotional, highly-strung, nervous individuals very little likely to become insane, the expression of their emotions acting as a safety valve. It was often the emotionless being—who did not show distress, who was endowed with hyperstability, and was considered the prop of the household—who was liable to break down after the need for bearing up had passed, sometimes even after some months. Fat neurotic subjects were more difficult to treat than thin ones. There should be wards in general hospitals for the treatment of borderland cases. The patients would thus be freed from the stigma attending sojourn in a hospital or home for mental cases, while at

the same time the student would have the opportunity of studying this important branch of medicine. With regard to sedative drugs she advocated the use of paraldehyde, especially for senile cases, of bromides combined with arsenic, and of trinitrin in small doses; the latter by acting as a vaso-dilator often removed the necessity for a true sedative. She objected to the administration of sulphonal, recommended care with hyoscine, and said that nuxvomica often excited nervous patients, and in some was inimical to sleep. Dr. Dobson considered that dyspepsia and dilated stomach, so often found in melancholics, was frequently due to forcible feeding. Dr. CONSTANCE LONG pointed out that however much one might disagree with the universal application of Freud's views, he had unmasked the etiology of certain obscure cases of hysteria with absolute precision, and had indicated a line of treatment of inestimable value if skillfully applied. She agreed as to the value of wards for borderland cases in general hospitals. Such cases were to be found in numbers among the patients of the average general practitioner, who was launched into practice with little or no knowledge of morbid psychology. Other members having spoken, Dr. BOYLE, in reply, stated that in her experience operations for haemorrhoids had been more frequently followed by insanity than had any other operation.

Rebicus.

MALINGERING.

A Greek I fear,
Though presents in his hand he bear.

THESE words came into our mind as we read the Dedication of Sir JOHN COLLIE's book on *Malingering and Feigned Sickness*¹ "To my friend the British Workman, to whom I owe much." And we wondered in what spirit the British workman would regard it, and how he would receive the teaching of the book if he ever looked inside it. Certainly Sir John Collie is well qualified to speak with authority on malingering, as for many years he has been closely associated with insurance work, and with the consideration of questions of compensation for personal injuries received during employment. Indeed he has almost established himself as a specialist in the subject, and he suggests on the first page of the preface the point of view which he is inclined to occupy concerning it—"The cost of insuring against accidents to industrial workers is now far in excess of the actuarial estimates upon which the Compensation Acts were based; and a study of the statistics in relation to non-fatal accidents shows an increase in the number of those accidents since the advent of this legislation which cannot be accounted for even by the speeding up of machinery and the conditions of modern labour. Malingering and dishonesty must have had an influence in raising the figures to their present abnormal height." And in the opening of his book he again insists that the many provisions made by the Legislature in recent years for securing benefits to injured workpeople have undoubtedly given rise to a large number of cases of malingering. He says that the methods of the conscious deceiver are so ingenious, and the mental outlook of the unconscious exaggerator is so difficult to deal with, that the time has fully come for all medical men to look for the possibility of deceit or exaggeration in all persons claiming compensation for injuries.

We are not prepared to quarrel with this piece of advice. Every medical man should know not only something, but a good deal, upon this increasingly important subject, should be prepared at any time to make a thorough examination of such an applicant and to be ready to give in a Court of Law the reasons for his conclusions; and this he should be able to do in the simplest possible language and with the studious avoidance of needless technical expressions. We must confess to having heard members of our profession in the witness-box make use of words and language which can have had but the effect

of puzzling the lawyers, bewildering the jury and increasing the obscurity of the problem before them. We claim that all medical men should be fully acquainted with the ways leading up to the court and with the correct manner of procedure when in it. And we should greatly regret to see these important questions of real or fictitious injury left in the hands of only a few, some of whom might be looked upon as professionally and habitually inclined to take the workman's view and others that of the employer. Such a state of things could not fail to place our profession in an unfavourable position before the public. We do not wish to labour this point, and will content ourselves with the expression of the opinion that cases of this sort ought in all cases to be settled by a Judge in conference with a permanent Board of Medical Referees. We think that if the Lord Chancellor, the Home Secretary, the Chancellor of the Exchequer and the President of the Local Government Board would consider the question and agree upon the appointment of such a Court, its early establishment would prove extremely acceptable to the public and agreeable to the medical profession. Indeed, common sense appears to demand it.

The short accounts which Sir John gives of the ways of malingerers are graphic and interesting. A first-class humbug was before the Judge complaining, amongst other things, of loss of sensation in the fingers of the left hand. He was told to close his eyes and hold up both hands and to say "Yes" or "No" when either of them was gently pricked by a pin. Unfortunately for the man he called out "No" each time the pin touched the hand in which he said there was no feeling! This report brings to mind a somewhat similar case in which the malingerer hopelessly "gave himself away" (to use a common expression): A soldier in a British regiment in India was, for reasons of his own, shamming deafness—absolute and complete. No one could do anything with him or make anything of him. At last he came up before the Principal Medical Officer, who, receiving no answers to his questions, turned to his brother officers and said in the man's hearing, "Yes, a sad case of incurable deafness." He then made signs to the man to pick up his clothes and leave the room. But just as he was opening the door the doctor tossed a coin on to the floor near him, and the man, hearing the jingle, instinctively turned to see if he had dropped anything! Confinement to barracks and extra work ensued.

The chapter on the psychology of the fraudulent mind is excellent, and refers to the remarkable difference between the pain which a man has when he strains his back in his own garden or in the carriage of a rich railway company; and the problem arises as to whether, in the latter case, he is a wilful malingerer or the victim of psychological conditions consequent on the accident. But the author rightly reminds us that all malingering is not the outcome of deliberate wickedness, and that great allowance must be made for the personal equation. Certainly the uneducated workman who has met with an accident is, as a rule, unable to take a detached view of himself, or to make a stand against undesirable introspection. Pity is freely offered—and rightly so—to those medical men who have to look to club practice as the chief source of income, who have to seek for popularity from the members, and who, in consequence, are easily induced to write certificates for sick benefits. Such "kindness" is mistaken and harmful. It is surely the duty of every medical man to help the State to count amongst her citizens the maximum number of units capable of working. Professionally, it is, of course, very discreditably.

The medical examination of a patient who says that he has been injured at his work presents a problem not always easy to solve. In the ordinary way of practice an honest patient coming to his medical man is anxious to get well, and is helpful in the way in which he answers questions. But the other man is apt to keep things back, and to do his utmost to mislead. Probably every medical man is not aware of the fact that by the terms of the Workmen's Compensation Act a servant who is making a claim for personal injury is bound to submit himself to medical examination, and that if he obstructs the examination he will cease in accordance with the provisions of the Act (p. 34). It is within the knowledge of most of us that claimants are apt to make themselves extremely disagreeable, and

¹ *Malingering and Feigned Sickness*. By Sir John Collie, M.D., J.P., assisted by Arthur H. Spicer, M.B., B.S. Lond., D.P.H. London: Edward Arnold. 1913. (Med. 8vo, pp. 352; figs. 44. 10s. 6d. net.)

sometimes even obstructive, at an examination, and it is well that the Act has thus provided the medical man with some friendly assistance.

The keynote of the book is on page 35, where it is said that the examiner should be absolutely unbiassed and judicial in his attitude towards the case, and, whilst alive to the possibility of malingering, should equally be on the look-out for every indication of organic disease. That he should not be biassed in favour of the insurance company, nor should he minimize disabilities which do exist. It is indeed a counsel of perfection, but nothing less would be acceptable to the straightforward practitioner. During the medical examination it must be insisted that no third person should be in the room, as "allegations of unfair treatment and harshness are not unlikely to be made"; and even though they were groundless, if they were supported, they might lead to inconvenience. This is an important matter, and many a medical man may have been in doubt as to how he should answer the demand of a solicitor or some other third person who is not a medical man that he shall be present when the examination is made. The answer ought to be a polite "No," though, of course, the presence of the workman's own medical man is not only permissible but, as a rule, desirable. It is clearly pointed out that the medical man should keep far away from the legal aspect of the case; the question of liability is as nothing to him—he must mind his own business. And still more is it advisable that he should have nothing to do with the discussion of pecuniary compensation, though it is often advisable that he should have been informed as to the claim which a man is making so that he may understand in some measure the position which the man is occupying.

The two pages treating of *Neurasthenia* are perhaps inadequate. The term is an extremely popular one and a great favourite in a court of law, especially when it is qualified by the word *traumatic*. Voltaire regarded adjectives as mortal enemies of substantives, but he would have found it difficult to shut out this adjective from qualifying the shapeless word "neurasthenia" as used in the law courts. The two words are almost inseparable in the presentation of the case of the injured workman—especially in the absence of objective signs. It is not improbable that Sir John Collie's scant treatment of this part of the subject is due to an absence of sympathetic interest in it. Possibly even he has heard so much of it, and seen so little of it, that his belief in it is but half-hearted—or worse.

In the face of the encouragement which recent legislation has given to dishonest men to exaggerate or fraudulently to misrepresent the amount of damage which they may have met with in the course of their work, the thought naturally occurs as to what effect the Insurance Act will be likely to have in that direction. Sir John Collie speaks with authority on the subject, and says that (p. 61) for some years the accident laws have revealed to the unscrupulous the infinite possibilities of fraud, and he feels confident that, unless this fact is recognized by those who will have the responsibility of working the Insurance Act, "the moral currency" of the working classes will be much debased. Once more we turn to the beginning of this complete and valuable book on Malingering and, smilingly, try to catch the true inwardness of that Dedication.

Again (p. 100), in discussing the dishonest fostering of morbid sensations after an injury, he says that physically these men are perfectly able to work, provided they have sufficient stimulus, but that "the Workmen's Compensation Act deprives them of this stimulus." He has already (p. 9) told us of a man who was in receipt of 15s. a week (half wages) and at the same time was drawing 18s. a week from the Hearts of Oak, 10s. from a yard club and 10s. from a slate club, making in all £2 13s. whilst he was disabled, his wages being £1 10s. when he was hard at work. It was, indeed, a temptation to which many a workman might be inclined to yield! Consciously or unconsciously the injured man cannot exercise his will-power; the whole burden of his complaint lies in what he *feels*, and he becomes so "demoralized by idleness that he is determined he shall not work." It is a humbling kind of picture to paint of the British working man, and we feel sure that such a one would have no right to claim any share in that noble Dedication.

As under the National Insurance Act some twelve millions of workpeople have just been compulsorily insured, "malingering must necessarily become more frequent." In Germany since the passing of their Insurance Act the amount of malingering has gone up by leaps and bounds. The prospect is not pleasant, and as sickness benefit is only payable from the fourth day of the illness there may be a strong temptation to prolong slight ailments. It seems that when the French Republic took over the railways a remarkable demonstration of the servants' "right to illness" was manifested, 54 per cent. of them becoming "ill" at one time or another in the year. "To men between 60 and 70 years of age there will be a strong temptation to defer the return to work. There is the danger, too, of attempts being made to tide over periods of unemployment by going on the sick list," and Sir John appears firmly to hold the opinion that his "friend the British workman" will fail to stand upright in the midst of the manifold and great temptations which henceforth surround him.

The question of returning to work after an accident is sometimes made more difficult by undesirable influences privately brought to bear on the man. In one case of a typical neurasthenic the County Court Judge hinted that it should be decided before the Court of Appeal whether an employer must continue to pay weekly wages to a man who only *thinks* himself unfit for work. The County Court Judge thought that the man had been only playing at work, and he was of opinion that if he had been rich and desired to get back to hunt or shoot he would have done it. The Master of the Rolls, before whom the case came in due course, said that he did not wish to use the word "malingering," but he could find no other word to express what was in his mind. He thought the County Court Judge meant that the workman had left his work under circumstances which threw suspicion on his conduct, and that it was impossible, upon their findings, to interfere with his decision; that there was no doubt that the result of payment of compensation took away all stimulus for work (p. 269). To men like this it is not a matter of shame, but one of delight, to eat the bread of idleness. As to how long a workman who has been undoubtedly injured may postpone his return to work after he has recovered from his original injury is an interesting question. Muscles accustomed to regular and steady exercise soon get out of condition, and this loss of condition frequently conduces to a postponement of the return to work. "A workman can, according to the Act, be compensated for what he is unable to earn, but cannot be compensated for what he declines to earn."

One of the commonest complaints in connexion with injury is pain in the back, which is sometimes, no doubt, the result of a rupture of muscular or ligamentous fibres, but which "in the days of Erichsen used to be called 'railway spine.'" "Concussion of the spine" (*spinal cord* was meant) is quite unlikely to happen, and organic nerve-changes, apart from an old syphilitic infection, need scarcely be discussed. But the dull pains of old rheumatoid disease of the spine are likely to attract much personal attention after an injury, and, "remembering the Workmen's Compensation Act, the workman puts himself on the sick list, keeps his back stiff, becomes introspective and then draws from clubs and insurance companies sick pay which might (as already shown) amount to more than the man's ordinary wages" (p. 135). This may read as a hard-hearted quotation, but there are many practitioners who could speak to its truth. The tender care which has lately been lavished on the British workman has submitted him to the risk of excessive "softness" and vulnerability, but we hope that when he finds that an important work on shunning and "skrimshanking" has been dedicated to him he will harden his heart and stiffen his back in the right way. Not only are workmen shown by our author to be sometimes deficient in honesty, but medical men are occasionally found not entirely free from blame in that they are ready to give certificates of "inability to work" without even making an examination of the patient, and to fall in with the request of the patient lest he should be regarded as wanting in sympathy, and so render himself unpopular with the other members of the benefit club. One malingerer said that he could get as many certificates as he wanted "in exchange for sixpences" (p. 16). For our own part, we will say that no medical man should give

a certificate without assuring himself on each occasion of the absolute correctness of the man's statements. Friendly but firm encouragement to return to work is in every way kinder to the man than a careless help towards his becoming a shirker—and this sound teaching runs like a golden thread all through Sir John Collie's writing.

The association of hernia and malingering is especially close, because it is open to any workman who has a hernia to make capital out of it, and there may be little to depend on but the man's statement. "Of the cases that claim compensation for damages for hernia as being caused by a sudden strain, probably not one in ten is genuine" (p. 189). And the question arises whether it would not be wise for all employers of labour to require a medical examination as regards the presence of rupture in all applicants for work. The Report of the Departmental Committee on Compensation for Industrial Diseases advised to the effect that hernia may, though very rarely, be due to a sudden strain, but that what usually happens is that some cough or particular strain brings down a little further a slowly developing hernia and so causes it to attract attention. This is probably the almost universal state of affairs; the funicular process of peritonæum, never having been obliterated, had been all along prepared for the reception of the piece of omentum or bowel. It is within our knowledge that a man who declared that he had never previously been ruptured claimed damages for the recent occurrence of a hernia in his work when careful examination showed the scar of an operation which had been done in his boyhood for the so-called "radical cure." The author rightly says that the question of how far a rupture can be called "accidental" is a thorny one. "We should hear much less of hernia in the law courts if working men who have been operated on would, six weeks from the operation, consult the surgeons who operated as to their fitness or otherwise for work, instead of going to lawyers and to the 'expert witnesses' who are associated with some of those gentlemen" (p. 199).

The position of the medical man with regard to his patient, and the advice which he should give to him, and the evidence which he must be prepared to supply in Court should, of course, be entirely clear of personal influence. Friendship with the patient ought in no way to be allowed to warp the judgement of the medical man, nor should the wish to see the claimant succeed in his suit deflect his statements a hair's-breadth from the line of truth. The medical practitioner must realize the fact that what he says should by no means be directed to secure a verdict but to help the Court in arriving at a just one. And as regard the so-called "medical expert," he should give his evidence as if it were being listened to by the Council of his College or the medical members of the Senate of his University. Certainly the giving of his testimony should be independent of what may prove to be the verdict of the Court. Yet "a medical expert told me that the usual terms upon which he and several of his friends contracted with running-down solicitors were: 'No damages, no fee; but the lost fee to be tacked on to the next case'" (p. 239). A line of conduct less worthy of a member of either the profession of Law or of Medicine can scarcely be imagined! Thus, "all chance of future employment by his patron, the solicitor (and even his fee), depend upon his grossly exaggerating when giving evidence on oath."

If this book (which we have read with great satisfaction and profit) says hard things of the British workman and of certain members of the medical profession, it does not let the lawyers off free, though the author speaks with due respect of the Judges, all of whom, by the by, appear to have regarded the claimants' attitude from the same point of view as did the author. Of the solicitors' touts who hang about the doors of the hospitals in the hope of finding work by stirring up litigation, nothing can be said bad enough. In a recent accident which occurred in London, on the following morning most of those who had been hurt had as many as four letters from different legal aid societies offering to take up their cases free of charge and recommending them to have nothing to do with persons responsible for the accident! It would be difficult to imagine members of the medical profession falling so low as this, and should a line of conduct of a similar degrading nature be adopted by any of them, we might depend upon

the General Medical Council, if the facts were laid before it, taking immediate steps to vindicate professional honour. "The methods of some of these legal aid societies have at various times been commented upon from the Bench, but as yet nothing has been done" (p. 291). The movements of our sister profession are proverbially slow.

Sir John Collie's book is written in pleasant style, and though he is often dealing with abstruse questions he is never dull. There is often a suggestion of Sherlock Holmes in the way in which he has dealt with, sniffed out, and exposed deliberate instances of fraud, but although the author invariably comes out triumphant, the cases are not set out boastfully and they form excellent reading.

SMALL-POX AND VACCINATION.

THE volume, *Studies in Small-pox and Vaccination*,² by Dr. WILLIAM HANNA, is not a textbook on vaccination. It deals mainly with methods of measuring the efficiency of the vaccination in the case of the vaccinated and with the power of vaccine lymph to abort the variolous poison. It has long been recognized that the effect of vaccination varies considerably even when the operation has been perfectly done and fresh lymph only used. The protection it gives is not always uniform in what may be called "its length of life"—that is, the durability of the protection obtained. The recent epidemic in Liverpool bears the usual weighty evidence in support of the influence of vaccination. The mortality among 943 cases of vaccinated children was 2.9 per cent., while among the 220 unvaccinated children it was 27.2 per cent.; the ratio of deaths to attacks was thus nearly ten times as many in the unvaccinated as it was in the vaccinated. Dr. Hanna gives notes of many severe cases among the unprotected, where vaccination carried out promptly resulted in rapid pustulation and drying up of the rash. He suggests that probably the protection to adults by revaccination lasts much longer than the same operation in children. In discussing the interaction of concurrent variola and vaccinia, Dr. Hanna expresses the opinion that cow-pox or vaccinia may be accepted as an attenuated descendant of small-pox, and that it would be desirable to vaccinate every one threatened with variola as early as possible in the illness. Dr. Hanna has done well to encourage the practice of using vaccination as a remedial measure at the earliest possible moment when variola is suspected as present.

FOOD AND DIETS.

In the review of Dr. J. CRAIK TAYLOR'S *Diet Charts for the Use of Physicians*, Part II, published in the *JOURNAL* of April 5th, p. 718, certain errors were made which we desire to correct. The statement that ordinary bread was omitted is incorrect, and was due to an oversight, for which we express our great regret; ordinary—that is to say, non-proprietary—bread is mentioned in all the charts. The review stated that the diet charts were open to the criticism that they contained "excessive recommendation of proprietary articles"; Dr. Taylor calls attention to the following paragraph in the preface to the first edition of the *Diet Charts*, Part I:

Many proprietary foods are included in these charts as the compiler and leading physicians to whom he has gone for advice on this point are of the opinion that no difference exists between the recommendation of such foods by practitioners many times each day, and presenting similar advice upon a printed slip to patients. Further, there is no bias in favour of any particular food, as many are included and none is given a more favourable position than another.

The criticism was directed not to the mention of proprietary articles but to their frequent mention, as is shown, we think, by the use of the word "excessive." There was no intention to impute unethical conduct to Dr. Craik Taylor, and we do not feel that the words used in the review, taken in their ordinary sense and in the context, bear such an interpretation, but we emphatically state that they were not in any remotest sense intended to bear this interpretation, and that we entirely exonerate the author from having in any way

² *Studies in Small-pox and Vaccination*. By William Hanna, M.A., M.D., D.P.H. Bristol: John Wright and Son, Ltd.; London: Simpkin, Marshall, 1913. (Cr. 4to, pp. 53; plates 25; 7s. 6d. net.)

violated an ethical rule of the profession in this respect. In the review objection was taken to the mention of sherry in the chart for diabetes on the ground that it contains a good deal of sugar. The author points out that only dry sherry is mentioned, and that three analyses quoted by Hutchison give 0.215, 1.03, and 0.65 as the percentages of sugar present in three classes of sherry. Taking the first figure (for Amortillado) as typical for dry sherry, the amount is very small, and the criticism in the review was therefore mistaken and is withdrawn. The reference to the "classical formula" for imperial drink was based on recollection, but reference to standard works shows that the ordinary formula in use is as stated in the charts—namely, one drachm or less to a pint of water. With regard to the observation in the review that the medical attendant is advised in subacute and chronic nephritis to regulate the amount of meat "by the output of albumen," Dr. Taylor calls attention to the words of the paragraph in the preface to the chart to which this has reference; they are: "In the chronic type the absolute deprivation of proteid is not now practised, but the quantity of proteid allowed should be small and carefully regulated according to the output of albumen." We regret that the word "meat" should have been used in the review instead of "proteid." Dr. Taylor considers that the amount of urea is not, so far as we at present can be certain, of so much importance as the output of albumen. This is, of course, a matter of opinion, and there are, no doubt, many authorities who will agree with him. The review asked why "sweet potatoes, which are not often seen in this country," are recommended in the chart for the feeding of school children. To this Dr. Craik Taylor replies, first, that when he was a lad in Ayrshire sweet potatoes were a regular dish for some weeks in every year—a dietetic custom of which we had not previously heard; and, secondly, that the charts are not meant for circulation in Great Britain alone, and that orders received by his publishers show that the charts will be used in the colonies. This we recognize as a sufficient answer to the question.

NOTES ON BOOKS.

A PAMPHLET, entitled *Bex-les-Bains*,¹ contains a description by Dr. E. DE LA HARPE of the small Swiss health resort, better known, perhaps, as Bex-Salines. It lies just inside the opening of the Rhone Valley, about twelve miles from the end of Lake Leman, and at an elevation of some 1,400 ft. Its summer climate is sedative, and it possesses a mineral water spring conspicuous for a high proportion of chlorides, chiefly sodium, together with traces of bromide and iodide of magnesium. Its bath establishment was brought up to date last year, and the claims of the place to consideration lose nothing through being described by a medical man who is a recognized lecturer of the University of Lausanne on the subject of balneology and possessed of long experience of practice during the season at the place in question.

India possesses a perennial charm for the great majority of English men and women, many of whom are bound to it by the ties of old association, and consequently there is always a large demand for books that treat of this particular portion of "the gorgeous East." But whilst the literary market is usually overstocked with novels dealing with the Anglo-Indian adult, few writers of fiction, with the exception of Kipling, have attempted to portray the life of that interesting product of imperialism, the Anglo-Indian child. Mrs. HOBART-HAMPDEN, therefore, has almost broken new ground in her pretty story, *Tota*,² in which she relates the adventures that befell the little daughter of an English official in an out-of-the-way corner of India when kidnapped by the servants of a neighbouring rajah to be the bride of his only son. The story of the child's rescue from the rajah's palace by her elder sister and her father's faithful bearer is exciting enough to satisfy the most exacting of its childish readers. Mrs. Hobart-Hampden has evidently an intimate knowledge of native life and customs. She has drawn a most lifelike picture of the squalid splendour of the Deoban court, and the character of Tota, the pampered little

prince whose love for his English playmate inspires him with the longing to prove himself a man, is developed with real insight and sympathy. *Tota* should find a large circle of friends amongst the English children whom he admired so heartily, and who will doubtless hail with pleasure this new departure in nursery fiction. Their enjoyment of an excellent story will be much increased by the pleasing illustrations contributed by Miss Alice B. Woodward.

The sixth volume of *The Prescriber*³ is a collection of the issues of the monthly publication of that name. In this Mr. THOMAS STEPHENSON supplies his readers with short editorial notes on current questions connected with therapeutics and treatment, together with one or two short original articles on the same subject, one or two prescriptions derived from various sources, a few reviews, and abstracts of papers of direct therapeutic interest which have recently appeared in British and foreign journals. The editorial comments are notably free from bias, and, as we indicated last year, the complete volume forms a useful kind of reference book to the progress of therapeutics and pharmacy during the year to which it relates.

The fifth edition of *A Manual of Personal Hygiene*⁴ has, like the earlier issues, been edited by Dr. W. L. PYLE of Philadelphia, while the various articles are the work of ten American writers. The idea of the work would appear to be to supply information on any point connected with the care of the body and the maintenance of health, in which members of the general public, either through their own experience or statements made in newspapers or suggestions made to them, commonly take an interest. The opinion of the various authors as to these matters is set forth in plain terms, and the physiological and anatomical data on which the views are based are described in language free, so far as may be, from technical words. As a further help to the reader a glossary of such technical words as are used is supplied at the end of the volume. In most of the chapters the teaching is well expressed and seems sound, but there is a most unhappy falling off in the appendix, in which directions for the treatment of the apparently drowned are given.

The second edition of *Dental Anaesthetics*⁵ constitutes, like its predecessor, a summary of the lectures which its author, Dr. W. E. ALDERSON, delivers at the School of Dentistry at Newcastle-on-Tyne. The statements made are usually succinct and clear, and the present edition contains new matter dealing with the prolonged administration of nitrous oxide and the simultaneous use of nitrous oxide and oxygen. An important contribution to the volume is supplied by Mr. John Bolam, who deals fully with local anaesthetics under the heading of analgesia, and shows clearly that none of them should be used without full recognition of the fact that in some degree both immediate and subsequent risks are involved.

The twenty-second series of *International Clinics*⁶ consists, like its predecessors, of four volumes, issued nominally at three-monthly intervals. Also, like its predecessors, it has as editor Dr. H. W. CATTELL, of Philadelphia, who works in collaboration with some ten or twelve authorities resident in America, Great Britain, and on the Continent. The contributors are drawn from all parts of the world, and in this particular issue include a somewhat larger proportion than usual of other than American authors. All the four volumes are illustrated, and each contains two dozen or more papers written specially for this publication. Between them they represent practically all branches of medicine and surgery. Even the National Insurance Act is not overlooked, for a paper on this subject, by Dr. J. W. Ballantyne of Edinburgh, forms part of the second volume; wherein, too, the science and practice of eugenics, or race culture, are dealt with by Dr. Meyer Solomons of Washington. The same volume, among a number of articles on anaesthesia,

¹ *The Prescriber*. Edited by Thomas Stephenson, Ph.C., F.R.S.E., F.C.S. Vol. vi. Jan. to Dec., 1912. Edinburgh: *The Prescriber* Offices, 1913. (Demy 8vo, pp. 334.)

² *A Manual of Personal Hygiene*. By Walter L. Pyle, A.M., M.D. Fifth edition, revised and enlarged. Philadelphia and London: W. B. Saunders and Co. 1912. (Post 8vo, pp. 530; figs. 131. Price 6s. 6d. net.)

³ *Dental Anaesthetics*. By W. E. Alderson, M.D. Durh., M.S., B.Hy., D.P.H. With a contribution on Analgesia by John Bolam, L.D.S. Edin. Second edition. Bristol: John Wright and Sons, Ltd. 1912. (Post 8vo, pp. 115. Price 3s. net.)

⁴ *International Clinics*. In four vols. Twenty-second series. 1912. Edited by Henry W. Cattell, A.M., M.D. Philadelphia and London: J. B. Lippincott Company 1912. (Medium 8vo, pp. 314, 324, 316, 308. Price, four vols., 35s. net.)

¹ *Bex-les-Bains*. Notice Medicale par le Dr. Eugène de la Harpe. Bex-les-Bains: Imprimerie E. Opplinger. 1913. (Demy 8vo, pp. 63.)

² *Tota*. By Mrs. Hobart-Hampden. Illustrated by Alice B. Woodward. Published by Macmillan and Co., Limited. 1912. (Pp. 259. Price 3s. 6d.)

includes an outspoken protest by Mr. Lawrence Irwell in regard to the practice in America of employing nurses as anaesthetists. The third volume is made notable through a rendering by Dr. S. W. Carruthers, of Norwood, of the Latin pamphlet in which Professor Theophilus Ciesielski has set forth his experiments and views on the question of how it happens that the offspring of plants, animals, and man may sometimes be male, sometimes female. Also recorded in the same volume by Professor J. B. Roberts, of Philadelphia, are two cases in which the operative fixation of a fracture of the shaft of the femur was followed by death.

Dickens is generally believed to have drawn the noble character of Riah in *Our Mutual Friend* as a set-off to the loathsome figure of Fagin in *Oliver Twist*, which had justly offended the Jews. In the same way Mr. GEORGE TRELAWNEY would seem to have written his recent novel, *The Story of Harvey Sinclair* as an atonement for his book *In a Cottage Hospital*, to the misleading and offensive character of which we felt compelled to call attention in the JOURNAL (March 23rd, 1912, p. 691, "The Man with the Muck-rake"). It is satisfactory to find that Mr. Trelawney's opinion of hospitals has apparently undergone a considerable change. His new book contains a glowing account of the care and consideration lavished by the whole personnel of a hospital upon the inmates of its wards, and even the much-maligned medical student comes in for his share of praise. This complete *volte-face* is the most interesting feature of the book. Harvey Sinclair's adventures in search of a woman willing to become the wife of a dying man do not make agreeable reading. It requires the genius of a Maupassant to paint man in all his coarseness and brutality without losing the dignity and restraint of the true artist; and Mr. Trelawney would do well to study the methods of the great masters of literature before venturing once more amongst the pitfalls that beset the path of a writer of realistic fiction.

⁷ *The Story of Harvey Sinclair*. By George Trelawney, author of *In a Cottage Hospital*. London: T. Werner Laurie, Ltd. 1912. (Cr. 8vo, pp 224. 2s. net.)

MEDICAL AND SURGICAL APPLIANCES.

Medicated Oxygen Bottle.

SIR LAUDER BRUNTON (London) writes: It is not infrequently desirable to administer any nitrite or ethyl iodide along with oxygen to patients suffering from anginal attacks or spasmodic asthma. This is usually done by putting the medicament upon a piece of blotting paper or cotton wool in the funnel or inhaler close to the patient's face. The inconvenience of this is that it is apt to move from its position, and there is no means of regulating the strength of the inhalation. To obviate these inconveniences a bottle has been made for me by Messrs. Allen and Hanburys with two metal tubes arranged similarly to an ordinary Wolfe's bottle. One of these, however,

can be moved up and down and fastened by means of a screw, as shown in the drawing. The cotton wool or blotting paper, moistened with nitrite or iodide, is placed in the bottle. At first the movable tube is drawn well up, so that as the oxygen passes through it over the wool the vapour is dilute. As the nitrite evaporates the tube is pushed further down so as to go closer to the paper or wool, and thus a stronger vapour is obtained. When it is desired to give a diffusible stimulant ether may be employed

in a similar way, or a quantity of rectified spirit, brandy, or whiskey may be poured into the lower part of the flask and oxygen allowed to bubble through it. The bottle may also be used simply to render the oxygen warm and moist. In this case the bottle is half filled with hot water and placed in a small basin of hot water or surrounded by hot wet flannels. In some cases of bronchitis it may be advisable to add to the hot water friar's balsam, terebene, or other terebinthinate preparations.

BURBERRYS recently had an interesting display of the outfit they have provided for the Canadian Arctic Expedition, which, early in June, will start under the command of Mr. V. Stefansson into the hitherto unexplored regions bounded by Behring Strait and the Pole, the western border of the Arctic archipelago, and the known open sea north of Siberia. The materials were specially woven and proofed.

THE INTERNATIONAL MEDICAL CONGRESS IN LONDON.

AUGUST 6TH TO 20TH, 1913.

THE Seventeenth International Congress of Medicine, which will be held in London next August under the patronage of H.M. the King, will be opened by H.R.H. Prince Arthur of Connaught as the representative of His Majesty at a meeting in the Albert Hall at 11 a.m. on Wednesday, August 6th.

The last meeting of the Congress in London took place in 1881, when Sir James Paget was President. This year the President is Sir Thomas Barlow, and the Treasurers are Sir Dyce Duckworth and Mr. Makins. Sir Alfred Pearce Gould is Chairman of the Executive Committee, Sir Henry Morris Chairman of the Finance Committee, and Sir Lauder Brunton Chairman of the Reception Committee. There is also a Ladies' Committee, of which Lady Duckworth is Chairman.

The Central Office of the Congress will be in the Albert Hall. The sectional meetings will be held in rooms in the University of London, the Imperial College, the Royal School of Science, the School of Art, and the Central Technical College. These bodies have generously placed their buildings, which are all close together in South Kensington, at the disposal of the Congress. The Royal College of Physicians, the Royal Society of Medicine, St. Thomas's Hospital, the Royal Army Medical College at Millbank, and the Royal Dental Hospital are also offering accommodation for sectional meetings. The Students' Union of the Imperial College will serve as the men's club, and the authorities of Alexandra House have kindly lent rooms for a ladies' club.

There are in all twenty-six Sections and Subsections. Their sessions will be held in the morning and in the afternoon. The morning sessions will be devoted to discussions on fixed subjects, which will be introduced by eminent medical men from every part of the world who have been invited for the purpose. The invitations have been very generally accepted, and there seems no doubt that the discussions will be of great interest and importance. The work which the several Sections propose to do will be noticed in future issues.

Five general addresses have been arranged. These will be delivered by Professor Chauffard (Medicine), Professor Harvey Cushing (Surgery), Professor Ehrlich (Pathology), Mr. W. Bateson (Hereditry), and the Right Hon. John Burns, M.P., President of the Local Government Board (Public Health). They will be delivered in the Albert Hall.

It is estimated that about 5,000 medical men and 2,000 ladies will attend the Congress.

The organization of the Congress has been going on for nearly three years. It will give some idea of the magnitude of the task to state that it has taken a complete year to arrange the personnel of the various committees, and another complete year to settle the programme of the discussions in the Sections. The latter was issued on September 30th last. There are several discussions for which two or more Sections are combined. At the present time the reports drawn up by those chosen to introduce the discussions are being received and set up in type. It is hoped that all these reports which will form the basis of the discussions will be printed and bound as a separate volume for each Section before the Congress opens. A second volume for each Section will be published subsequently containing the speeches delivered and the independent papers presented at the Congress itself.

A circular will be issued on April 30th giving information on travelling facilities, both to London and in London, on hotels and boarding houses, on the location of the various sections, and on other points likely to be useful to members. Early in June the final programme of the scientific business will be published, which will include the list of independent papers accepted by the Sections and the names of intending speakers.

The office of the Congress is at present at 13, Hindle Street, W., where information may be obtained by applying to the General Secretary.

Subscriptions to the General Fund of the Congress should be forwarded to the Treasurers of the Seventeenth

International Congress of Medicine at the same address. It should be borne in mind that the membership subscription of £1 only suffices to meet the expenses of producing the *Volume of Transactions* subsequently delivered to each member. The entire cost of organization and conduct of the meeting has therefore to be provided for by private subscriptions to the General Fund.

A list of the subscriptions already received will be published shortly.

THE PARLIAMENTARY COMMITTEE ON PROPRIETARY MEDICINES.

ANALYTICAL EVIDENCE ON BEHALF OF PROPRIETARY PREPARATIONS.

On April 10th evidence was given by Mr. Ernest John Parry, consulting and analytical chemist, practising in London, who had been retained for the purposes of the inquiry by the Proprietary Articles Section of the London Chamber of Commerce. In the absence of Sir Henry Norman, Mr. H. L. Lawson presided.

The British Pharmacopœia.

The witness said he proposed to deal with the scientific evidence already given, and, with great respect to the witnesses, to correct some important misstatements of fact. He would also deal specially with *Secret Remedies*, and endeavour to convince the Committee that there were such grave defects, mistakes, and inaccuracies in that work as to cause it to fall utterly short of what it claimed, namely, to disclose what such remedies contained and what they cost. The witness controverted the statement of Dr. Tirard that the *British Pharmacopœia* was authoritative in the courts of law until it was replaced by a new volume. Mr. Parry said that a divisional court had held that the *Pharmacopœia* was only a *prima facie* standard, and might be rebutted by expert evidence. The evidence of Dr. Tirard left the very definite impression that the *British Pharmacopœia* had only introduced official substitutes for proprietary medicines where they contained poisons. The witness took strong exception to this view, and gave a list of about twenty official drugs of the *British Pharmacopœia*, most of which were free from poisons, and all of which, he said, started life as proprietary and at one time secret medicines, achieved success as such, obtained recognition of their value from the medical profession, and were ultimately included in the *Pharmacopœia* in exactly the same manner that Dr. Tirard said the substitute for Dr. Collis Browne's chlorodyne had been included. The list included Murray's fluid magnesia, and the witness said this was one of the few proprietary medicines introduced by a medical man. It was run openly as a proprietary medicine by a medical man of high standing—Dr. James Murray, physician to the Lord Lieutenant of Ireland in 1859. The witness produced a newspaper dated September 15th, 1859, in which an advertisement of this remedy appeared over the signature of Dr. Murray.

The Chairman: In those days was there the same regulation with regard to acts of that kind as there is now?

The Witness: I should say not, for there are in this paper two other advertisements of their own proprietary medicines by medical men. Continuing, the witness said that in regard to remedies sold as cures for cancer, consumption, and certain other diseases, and as to remedies dealing with sexual diseases, he was in agreement with Dr. Cox, except that he considered the measures he suggested for dealing with these were not useful and should be replaced by the remedies proposed by the London Chamber of Commerce. The case of the British Medical Association seemed to be built up on the assumption that the ingredients of a large majority of proprietary medicines were relatively inactive. Apart from the cancer, consumption, etc., "cures," he declared this assumption to be erroneous and untrue. The better known proprietary medicines contained highly active useful ingredients. He knew this because, in his capacity as an expert in drugs, some of the principal manufacturers were in continual communication with him, and samples of the various drugs used by them were regularly submitted to him for

analysis, in order to know that the highest degree of purity was being obtained.

Criticisms of the Suggestions of the British Medical Association.

The witness urged that publication of the formulae of proprietary medicines would lead to the marketing of numerous imitations. He regarded Dr. Cox's evidence as to the effect upon the sale of advertised medicines of the publication of *Secret Remedies* as an endorsement of this view; the public would still get an easy means of self-medication, and it could not be useful to injure the present proprietor for the sake of the imitator. The omission from the Sale of Food and Drugs Act of the exemption in favour of proprietary remedies, as suggested by the British Medical Association, would not effect the object desired, as, even assuming the label to be a warranty (as in fact it was), and even assuming the label to contain the formula, a prosecution would not lie unless the purchaser in buying the article recited the formula. An offence would be committed, but under the Merchandise Marks Act, of which he thought Dr. Cox had not appreciated the scope.

The witness said that from his knowledge of the medical profession and the wholesale drug trade he disputed Dr. Cox's evidence as to the attitude of doctors generally towards proprietary medicines. He knew that doctors ordered largely secret remedies of which they did not know the composition. One preparation, of which an incorrect analysis was given in *Secret Remedies*, had been asked for by 3,000 medical men since January 1st, 1913, in the form of samples, and 200 doctors had expressed in writing their approval of the remedy. In support of this statement the witness handed in for the private examination of the Committee a selection from the letters referred to.

Sir Philip Magnus: Their approval of the samples would not necessarily imply that the doctors ordered the preparation for their patients.

The Witness: There are many other secret remedies, most of which are in the two volumes issued by the British Medical Association, which from my own knowledge are prescribed regularly by the medical profession. It is quite a common practice for doctors to do so.

Sir Philip Magnus: Are the ingredients unknown to medical men?

The Witness: I am certain the average medical man could not give the slightest idea of what many of them contain.

So that when they prescribe these remedies their treatment is quite empirical?—I do not say that. The doctor gets results, and, therefore, he goes on using the preparation.

The Chairman: His knowledge is practical, not scientific?—Just so.

As to the insertion of advertisements in the *BRITISH MEDICAL JOURNAL*, the witness expressed the opinion that an announcement regarding a "diabetic whisky," conveying the impression that the amount of sugar in the whisky was reduced to the very least fraction, should not have been accepted for publication, because there was no sugar in whisky, and the quantity could not therefore be reduced.

The Analyses in "Secret Remedies."

As to the evidence of Mr. E. F. Harrison, the witness said he agreed with Mr. Harrison in his general condemnation of the extreme cases of some of the preparations dealt with in *Secret Remedies*, but he did not agree with the suggestion that "any case for new legislation must rest largely upon what was done in the worst cases and what it was possible to do." To take this attitude would be a great injustice to reputable manufacturers. He did not agree with Mr. Harrison that to compel the declaration on the label of all the principal ingredients would automatically kill out flagrant swindlers. The proprietors of fraudulent remedies would have no difficulty in concocting formulae containing small quantities of substances whose names would not give any information to the purchaser, but, on the contrary, make the remedy appear to be of a highly important and complicated nature, though possibly quite valueless. Any such requirement would therefore hurt the honest useful remedies, while leaving the fraudulent ones more or less untouched.

As to the differences between Mr. Harrison's formulæ and those claimed by the manufacturers, the witness denied that it was the case, as suggested recently in the *BRITISH MEDICAL JOURNAL*, that these differences were due to recent alterations in the formulæ. Once a successful trade was established in any article, the proprietor did not alter the formula except in quite exceptional cases; it did not pay to do so. Differences were to be accounted for by the inherent difficulty of a proper analysis of the majority of proprietary preparations. An enormous number of these preparations were totally incapable of analysis at all; there was no analyst who could do it.

Mr. Glyn-Jones: Would you not rather say, "totally incapable of accurate, complete analysis?"

The Witness: A large number of mixed inorganic preparations, such as medical men's prescriptions, are totally incapable of being analysed, or any formula being arrived at by any known means at all.

The witness proceeded to criticize the books, *Secret Remedies* and *More Secret Remedies*, in detail. He said that Mr. Harrison had probably done his large amount of work with comparatively little error and in a very able way, but as large numbers of preparations could not be accurately analysed chemically it was unfair to publish specific formulæ as if they were, in fact, complete and accurate, with merely some general admission in a preface that the formula might not be altogether complete. The editors of these books expressed their knowledge of the possibility of errors, and of the real impossibility of proper analysis in many cases, in such a way that the ordinary reader would believe, and was intended to believe, that the formulæ given were correct and true ones, resulting from a chemical analysis. It was admitted that, in general, vegetable preparations could only be identified when they contained an alkaloid or a glucoside, and the statement was made that vegetable extracts containing no such principle were not identifiable, but were only used in pharmacy for their agreeable odour or bitter taste. The witness said that this statement was so hopelessly incorrect that much of the value of the analyses in the book fell to the ground with the inaccuracy of that suggestion. If the statement were true, the *British Pharmacopœia* might go on the dust-heap, and medical men would have to admit that 90 per cent. of their prescriptions contained nothing save inert substances having either an agreeable odour or a bitter taste. He said with confidence that far more than half the vegetable preparations of the *British Pharmacopœia*, when mixed, as they usually were, several at a time, in medicines or prescriptions, could not possibly be detected by any known means by any living analyst unless they were present to such a large extent as to be recognized by taste or smell. An enormous number—probably the majority—could not even be recognized by taste or smell if there were present some strongly tasting or smelling ingredient in such quantity as to mask the taste and smell of the other bodies. This applied with considerably greater force to the drugs not in the *British Pharmacopœia*, but included in the standard works of reference. The witness concluded by giving a number of examples from *Secret Remedies* in which he affirmed that from his own knowledge the analyses were substantially inaccurate and incorrect. He was prepared to supply details, not for publication, with the understanding that they might be handed to the Government analyst for verification, so far as that was possible by analysis.

The cross-examination of the witness was postponed until the next meeting of the Committee.

THE MEDICAL HERBALISTS' ASSOCIATION.

Evidence was next given by Mr. Joseph Watmore, who said he represented the National Association of Medical Herbalists. There were 1,500 medical herbalists and botanists in this country. He claimed that with few exceptions this form of occupation was carried on carefully and honestly. The association for which he appeared desired that medical herbalists should be given the same privilege as pharmacists of being relieved from the stamp duties if they published formulæ in trade journals, and did not claim the preparation to be a cure. The witness advocated the establishment of a proprietary medicines

office, which should register the formulæ of new preparations and take action if the public did not receive articles in accordance with the registered formulæ.

THE SALE OF VERONAL AND ALLIED COMPOUNDS.

WHILE the modern development of organic chemistry has furnished the physician with a considerable number of drugs of value, it has also been partly responsible for the putting before the public, without restriction, of many new drugs which experience has subsequently shown to be at least as dangerous as earlier known substances regarded by the law as poisons, and only obtainable under more or less adequate restrictions. Since the list of scheduled poisons to which such restrictions apply can be extended at any time by an Order in Council, it is possible for the law to be kept nearly abreast of knowledge of the properties of new substances; but if the machinery works with much friction, such extensions of the Schedule may be much delayed. The initiative in making additions rests with the Pharmaceutical Society; the Council of that society must pass a resolution setting forth that certain substances ought to be included in Part I or Part II of the Schedule, and when such resolution is sent to the Privy Council the latter authority issues—or does not issue, as it sees fit—the Order making such inclusion part of the law. The present restrictions on the sale of carbolic acid were advocated for years by the Council of the Pharmaceutical Society before its resolutions were acted on by the Privy Council, and resolutions in favour of the scheduling of acetanilide have not yet led to this substance being added.

The most recent Order in Council on the subject of poisons adds veronal, trional, and a number of allied compounds to the Schedule. A resolution in favour of this being done was passed by the Council of the Pharmaceutical Society in March, 1912; the terms of that resolution would have substituted for "sulphonal" in Part II of the Poisons Schedule "sulphonal and its derivatives and the poisonous derivatives of mercaptol," and would also have added, "di-ethyl barbituric acid and other derivatives of barbituric acid and all poisonous ureides and their derivatives"; but the Lords of the Council did not approve. Since then more cases of veronal poisoning have occurred, and one in particular has attracted much public attention; the importance of restricting the sale of this substance being thus again emphasized, the Council of the Pharmaceutical Society passed a new resolution in February of this year; it was of a far less inclusive character, and, in fact, limited to the one substance, di-ethyl barbituric acid, the substance sold as veronal and under other trade names. Again, however, the Lords of the Council found themselves unable to agree to what was proposed; but, as the result of a conference with the officials of the Privy Council and the chief Government chemist, a resolution was passed by the Pharmaceutical Council at its meeting in March, which has since been approved by the Lords of the Council, and on and from April 12th the substances mentioned therein are poisons in the eye of the law and must be treated as such. The resolution was as follows:

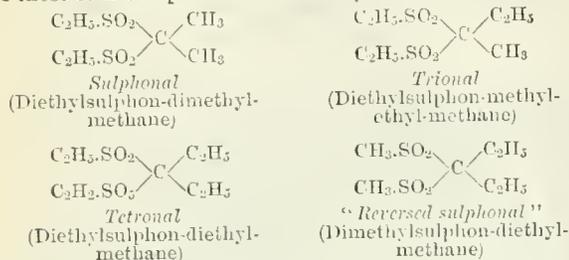

(a) That "Sulphonal" be removed from Part II of the Schedule to the Poisons and Pharmacy Act 1908, and that "Sulphonal and its homologues, whether described as trional, tetronal, or by any other trade name, mark, or designation," be substituted therefor.

(b) That Diethyl-Barbituric Acid and other alkyl, aryl, or metallic derivatives of Barbituric Acid, whether described as veronal, propional, medinal, or by any other trade name, mark, or designation; and all poisonous Urethanes and Ureides ought to be deemed poisons within the meaning of the Pharmacy Act 1858, as amended by the Poisons and Pharmacy Act 1908 and ought to be deemed Poisons in the Second Part of the "Schedule of Poisons" to that Act.

The restrictions applying to poisons in Part II of the Schedule are: (1) They can only be sold by retail or dispensed by a qualified pharmacist; and (2) when sold by retail they must be labelled with the name of the article, the word "poison," and the name and address of the seller.

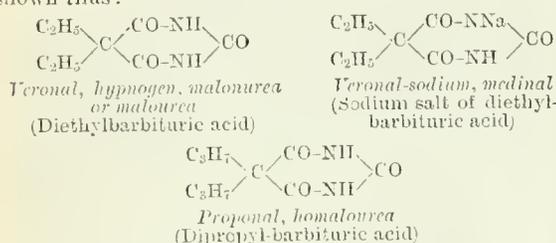

The regulations as to the keeping of poisons in special containers or away from other drugs also apply.

The number of substances thus added to the Schedule is considerable. It may prove to be the case that the first clause will be held to cover not only sulphonal, trional, and tetronal, but also "reversed sulphonal." The relationship of these four compounds is shown by their formulæ:

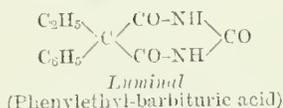

Thus the last-named is not strictly a homologue of sulphonal, but a metamereide.

The second clause includes, in the first place, the substances specified by name, diethylbarbituric acid (veronal) and propronal, with medinal (veronal-sodium) and other metallic derivatives, the mutual relationships of which are shown thus:

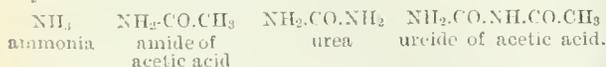

The clause also includes, in the second place, other alkyl, aryl, or metallic derivatives of barbituric acid, such as luminal and luminal-sodium.

Thirdly, all poisonous urethanes.

Fourthly, all poisonous ureides.

The vagueness apparent here is, no doubt, necessary if there is to be no risk of the amendment of the law being defeated in effect by the introduction of new and perhaps equally dangerous compounds allied to those named; but there are obvious disadvantages in the use of the adjective "poisonous," leaving it to be decided in any given case whether a compound comes under this description or not. The simplest member of the urethane group is urethane itself, which is ethyl carbamate $\text{NH}_2\cdot\text{CO}\cdot\text{OC}_2\text{H}_5$. This is described in the *British Pharmaceutical Codex* as "a safe drug, and no evil effects are to be anticipated even from 60 to 75 grs." A simple derivative of this is phenyl urethane, $\text{C}_6\text{H}_5\cdot\text{NH}\cdot\text{CO}\cdot\text{OC}_2\text{H}_5$, known as euphorine. Others used medicinally are methyl-propyl-carbinol urethane, known by the trade name hedonal, propyl-urethane, ethylidene-urethane, and chloral-urethane. It appears doubtful which of these are included, although it seems probable that the last named would be held to be included. The final group is the one which appears to leave the greatest uncertainty as to what it includes. A ureide is a compound of an acyl (or acetyl) radical with the residue of urea, just as an amide is a compound of an acyl radical with the residue of ammonia. Thus:

When the acyl radical is derived from a dibasic acid, one hydrogen atom of each NH_2 group may be replaced, as in barbituric acid:

Such compounds are usually distinguished as diureides or cyclic ureides; it has been suggested that only cyclic

ureides should be regarded as covered by the wording of the resolution, but the justification for this view is not apparent. Adalin (diethyl-bromo-acetyl urea) and brom-ural (α -brom-isovaleryl-urea) are ureides, though not cyclic, and whether they are now within the Schedule or not depends on whether they are included by the adjective "poisonous"; other familiar ureides which must be judged on the same ground are caffeine and theobromine.

It is to be noted that while it is all *poisonous* urethanes and ureides which are included, any alkyl, aryl, or metallic derivative of barbituric acid, even if proved to be non-poisonous, is covered by the wording. Some knowledge of organic chemistry will evidently now be required in deciding what are the requirements of the law in regard to artificial hypnotics, and no doubt pharmacists will show themselves fully conversant with this side of the question. In regard to whether a given substance is or is not covered by the adjective "poisonous," it will probably be thought the wiser course to take the safe line and treat any doubtful article as requiring the same restrictions as sulphonal.

UNIVERSITY OF LONDON.

FINAL REPORT OF THE ROYAL COMMISSION.

[FIRST NOTICE.]

The final report of the Royal Commission on University Education in London,* appointed in February, 1909, was issued on April 15th. It is signed by all the Commissioners, Viscount Haldane (Chairman), Viscount Milner, Sir R. Romer, Sir R. L. Morant—who, when the Commission was appointed, was Permanent Secretary to the Board of Education—Mr. Laurence Currie, M.A., banker, Sir W. S. McCormick, secretary to the Carnegie Institute for the Universities of Scotland, Mr. E. B. Sargent, M.A., to whom was entrusted the task of reorganizing the educational system of South Africa after the war, and Mrs. Creighton, widow of the late Bishop of London. It is a unanimous report, and its influence and authority will be greatly increased by this fortunate circumstance.

Prefixed to the report is an analysis which alone occupies 24 foolscap pages, and the report itself, together with an appendix containing the Commission's brief fourth report (December, 1911) recommending the early acquisition of a site in a central part of London, and an alphabetical index, fills 218 pages more.

It is thus a document formidable in bulk and in the multitude of its facts, opinions, and arguments. It has the outward form and seeming such a document commonly presents, and winds up with a long series of recommendations embodying a scheme for a new University of London to replace that which now exists, but created out of existing elements with financial and other reinforcements. On this point the Commissioners say:

115. *No compromise possible on the essential conditions of university organization.* So strongly, indeed, do we hold the view that the method of working we have described, and the conditions upon which alone such work can be done, are essential to the existence of a real University in London, and that such a University is a national and imperial as well as a merely local need, that it would be better not to interfere at all with the existing constitution than to attempt anything less fundamental. Any reconstruction worth the making must provide the University with at least a nucleus which may safely be trusted to grow and develop. The University will then avoid the gradual lowering of standards which has already brought it twice into a critical situation. We mean, of course, standards of teaching, not standards of examination.

The report, however, is a good deal more than a criticism of present arrangements and recommendations for the future. It includes a treatise on the aims of university education which will be of permanent value. In it general principles are worked out and afterwards applied to London.

The report consists of five parts, the fifth, a summary of recommendations, alone fills nineteen pages.

HISTORICAL.

Part I, which deals with the working of the present organization of the University, begins with an historical

retrospect, and then discusses the present relations of the internal and external sides of the University, and the consequences of the existing combination in the University of a large number of institutions differently related to it and of different educational standards and aims.

THE ESSENTIALS OF A UNIVERSITY.

Part II, which contains 26 pages, discusses the essentials of a university in a great centre of population. It lays down the conditions of the nature and work of such a university, and discusses the essentials of university education. It is pointed out:

First, that students should work in constant association with fellow students of their own and other faculties and in close contact with their teachers, and should pursue their work when young and able to devote their whole time to it.

Secondly, that university work should differ in its nature and aim from that of a secondary school, or a technical or purely professional school. In the secondary school definite tasks are prescribed, knowledge is acquired while the mind is specially receptive, and pupils are mentally and morally trained by the orderly exercise of all their activities; in the technical or professional school theoretical teaching is limited and directed by the application of ascertained facts to practical purposes; in the university knowledge is pursued not only for the sake of information, but always with reference to the attainment of truth.

Thirdly, that there should be close association of undergraduate and post-graduate work. Proposals which tend to their separation are injurious to both. A hard and fast line between the two is disadvantageous to the undergraduate, and diminishes the number who go on to advanced work. The most distinguished teachers must take their part in undergraduate teaching, and their spirit should dominate it all. The main advantage to the student is the personal influence of men of original mind. The main advantage to the teachers is that they select their students for advanced work from a wider range, train them in their own methods, and are stimulated by association with them. Free intercourse with advanced students is inspiring and encouraging to undergraduates.

And finally, that the influence of the university as a whole upon teachers and students, and upon all departments of work within it, is lost if the higher work is separated from the lower.

At the same time, it is considered that special research institutes should not form part of the extra organization, and the opinion is expressed that no true analogy is offered by such institutes in Berlin, Leipzig, Paris, or Brussels for the establishment of research institutes in London under university control. On the other hand, a university press under full university control is held to be an essential function of the university.

Education for evening students, though not essential to the need of a city university, ought to be undertaken by it, and the education offered to its evening students should be as good as to the day students. The cost, though greater than for day instruction, should nevertheless be undertaken.

Technological instruction, which should be included among the functions of a university, ought not to be of a narrow utilitarian kind. The university department of technology, based upon a thorough grounding of pure science, is of the highest value and importance from the practical point of view of industrial progress. It is noted also that advanced instruction of a specialized kind must be provided for occasional students already engaged in a profession or calling.

It is also recommended that the university should be enabled to establish and maintain a special centre for work in conjunction with the Workers' Educational Association; it must, however, first provide satisfactorily for its own undergraduate and graduate students, and for its professoriate.

DEGREES AND EXAMINATIONS.

It is pointed out that, though the granting of degrees is one of the chief characteristics of a university, it is not the real end of its existence. A degree should signify that the possessor has received a university education. Examinations are the main tests in English universities and

the sole test on the external side, the lapse of time between the examination being the only condition for securing the student's education. The test is thus one of knowledge only, not of education or of the quality of the work. Any examination however conducted will be injurious if based upon a syllabus too wide to be covered in the time allotted to the education of which it is intended to be a test.

GENERAL CONDITIONS REQUISITE.

The report then goes on to consider the conditions necessary for the realization of these ends. The first is said to be the provision of sound general education, the second homogeneity of university classes, the third a university quarter. By this it is meant that constituent colleges and university departments should be grouped as near together as possible; the creation of such a university quarter would lead to economy in administration, to increased co-operation between different departments of study in the interests of new lines of work, to greater intercourse between students and teachers, and probably to a better public understanding of the university and its work. The fourth condition is the establishment of university hostels and societies. The fifth is a university professoriate, that is to say, the university must provide its own teachers, appointing, paying, pensioning, and dismissing them. The sixth condition involves professorial control of teaching and examination, and the seventh financial control, by the university.

CONSTITUTION OF THE NEW UNIVERSITY.

The general outline of the constitution recommended for the University may be stated as follows:

The Court, including the Deans of Faculties and other members to the number altogether of about 200. It would be the supreme governing body and its chief function would be legislative within the provisions of the first or original statutes which would define the constitution and powers of the other governing bodies of the University. The Court would delegate powers to the Senate or to any committee of its own body. The control of the Court for the internal management of the University would be exercised entirely by means of statutes and resolutions and would take effect only by altering or setting in motion the existing machinery for the government of the University.

The Senate would consist of the Chancellor, Vice-Chancellor, Chairman of Convocation, and twelve other persons, appointed—five by the Crown, two by the Court, two by the Academic Council, two by the London County Council, one by the Corporation of the City of London. The Senate would be the executive body, having financial control and power to recommend to the Court the admission of Constituent Colleges and University Departments, the recognition of Schools of the University, and the institution of new degrees, diplomas, and certificates.

The Academic Council would consist of the Vice-Chancellor, the Deans of the Faculties, one teacher representing each group of studies for which no Faculty had been formed, and eight members of the Faculties elected by the Faculties in common session. It would advise the Senate as to the general direction of the Faculties on matters concerning research, teaching, and examination, and generally as to any action having a direct educational bearing.

The Committee for Technology would have control of the annual income of the Imperial College and of the engineering department of University College and King's College. It would report to the Senate on appointments to professorships and readerships in the Faculty, and would receive reports from the Faculty of Technology.

Other Committees of the Senate.—The other committees of the Senate recommended are: (1) a committee to supervise the curricula and examinations of students in schools of the universities and other students not in constituent colleges or university departments; (2) a committee or committees to supervise the extension of university teaching; (3) a committee to supervise school examinations.

Convocation.—The powers of Convocation are saved, but it would include all university professors and readers, and all honorary associate professors and readers, and all persons holding an honorary or *ad eundem* degree.

A *Students' Representative Council*, consisting of and elected by registered undergraduate and graduate students. It would appoint two representatives to the Court and have right of access to the University authorities by petition.

The *Faculties* would consist either wholly or in the main of University professors (including honorary and associate professors) of the subjects comprised in the Faculty, of the University readers, and of such other teachers and officers appointed by the University as the Faculty might co-opt. It would have power to determine generally the conditions for the award of degrees, diplomas, and other distinctions within the purview of the Faculty and to determine generally the course of study. It would be responsible for the conduct of examinations in constituent colleges and university departments, and would advise the Senate as to the needs of the Faculty and as to the provision and organization of the teaching within it. The Faculties recommended are arts, science, technology, economics, medicine, laws, and theology.

Professors and Readers would be teachers in constituent colleges or university departments or schools. The University would choose them for their individual excellence from the widest possible field, and would give them such remuneration, including superannuation and conditions of tenure, as would free them from the pressure of material anxiety. It is recommended that in the Faculty of Medicine the minimum salary of a professor should be £1,000, and of a university reader £300. The head of each department of a constituent college would be responsible for its control, including that of its laboratories and libraries.

Examinations.—Students in the department would be examined by the head of such department, and, under his direction, by the other teachers in the department, but at the public examination one or two assessors appointed by the Faculty would be conjoined with him. The several heads of departments and other teachers in a Faculty attached to a constituent college, together with the assessors, would form the examining board for degrees.

Colleges and Departments.—The constituent colleges would be educational institutions either established by the University or strong enough in one or more faculties to comply with the conditions for the incorporation and transfer to the University of the financial and educational control of their work. University departments would be departments dealing with a single subject of study or with a group of studies of less range than a faculty whether established by the University or placed under its financial and educational control. Schools of the University would be public educational institutions or groups of departments in larger educational institutions not under the educational or financial control of the University, but complying with the necessary conditions which include: (1) That the University shall be represented on the governing body; (2) that the principal teachers shall form a board of advice and with power to make suggestions to the governing body on academic matters. In the case of a hospital medical school it is considered that it would be sufficient for the board of teachers to report to the committee in charge of the business of the school and to be represented on that committee. (3) The University must be represented on the appointing committee in the case of teachers not directly appointed by it; in the case of a hospital medical school this provision would apply only to those teachers not on the staff of a hospital. The twelve general medical schools in London, together with the Royal Army Medical College and the London School of Tropical Medicine, should, it is recommended, be recognized as schools of the University until such time as any of them qualify for admission as constituent colleges in the Faculty of Medicine.

THE FACULTY OF MEDICINE.

In the historical retrospect at the beginning of the report it is pointed out that the movement for the reform of university education in medicine arose from the dissatisfaction felt by the medical teachers in London at the small number of university degrees obtained by their students in proportion to their total number and to the opportunities of clinical teaching. This aspect of the subject is dealt with at considerable length, and the

general trend of the conclusions reached may be gathered from the following extracts:

316. *The Grievances of the London Medical Students.* . . . We are convinced that the proper course for us to take is to consider what in this Faculty, as in others, is essential to a real university education, and to endeavour to make recommendations which will result in adequate provision being made in London for this education being open to all who are able to profit by it. The degree will follow in the ordinary course, and the grievance should naturally disappear. So far as entrance to the University is concerned, the average London student has undoubtedly been under a real disadvantage in the past, partly because the present Matriculation examination is not connected with a well-developed system of secondary education, and many of the schools from which medical students come have not prepared their pupils for that examination, while the University has in the past been loth to accept equivalent qualifications, and partly because the Conjoint Board and the General Medical Council accept lower standards of admission to the minimum medical curriculum, and the students do not realize till it is too late that they are excluded from the beginning of their course from taking a university degree. The fact is very significant in this connexion that the students of the London School of Medicine for Women, who until quite recently were not admitted to the examinations of the Conjoint Board, have not found any difficulty in taking the degree of London University, and have been able to do so on the average in a shorter time than the men.

317. *The School examination admitting to the University will ultimately remove the grievance.* It is in our opinion most regrettable that so large a proportion of the medical students in London do not graduate through its University. The whole difficulty resolves itself into one of defective education, and the true solution of it is to institute such a system of school examinations as we have recommended for entrance to the University. Every student qualified by his previous education for university studies will then be admitted as an undergraduate without any need for special preparation, or for a special acquaintance with the university regulations. When a student is once in his course will be systematic and educative. He will not be required to pass tests for which he has not had full opportunity of preparing, and he will fail only if he is unfit or has neglected the opportunities afforded him. If either of these is the case he ought not to succeed.

This chapter of the report occupies altogether forty-three pages and is followed by four more on dental education. The further consideration of the views expressed and recommendations made must be postponed. We can only now indicate that among the general conclusions to which the Commission has arrived is that university medical colleges, each with a general hospital, would be required, but the difficulties in estimating how many such hospitals would be necessary are admitted, although three seems to be contemplated. The Commissioners, however, are clear on the point that the standard of teachers in the clinical subjects of the medical curriculum in these colleges ought not to differ from that of university professors in other subjects, so that it will be necessary to appoint and pay professors of the various branches of clinical medicine and surgery to devote the greater part of their time to teaching and research. The Commission favours the adoption of the Hospital Unit, consisting of a professor with the control of wards; an out-patient department; assistants nominated by the professor with a view to complementing his own knowledge and affording him the special assistance he requires to carry on research in the direction in which he is interested; and, finally, laboratory accommodation in close proximity to the wards, not only for the service of the wards and the examinations and procedures connected with the diagnosis and treatment of the cases, but also for the purposes of research. Each university medical college would consist of three units for the three main clinical subjects—medicine, surgery, and gynaecology—with, if possible, facilities for instruction in special departments, although it is considered that in respect to some of them such instruction should eventually be provided in special clinics outside the general hospital of the medical college.

FINANCE.

The Commissioners estimate that for professorships and readerships and the maintenance of libraries and laboratories the University will require an additional income of £85,500, with a further sum of £13,500 to permit the reduction they recommend in the fees university students would be required to pay to £15 a year for arts, £20 a year

for science, and £30 a year for technology, making a total additional income of £99,000. The annual income required by a medical college in order to provide for the cost of the three clinical units recommended would be £12,000.

LITERARY NOTES.

In a thesis for the doctor's degree recently presented to the University of Paris, Dr. Paul R. Mersey discussed the heredity of mental disorders so marked in the Spanish branch of the Hapsburg family. He shows that these disturbances have often taken the special form of a morbid love of death. The most marked instance is that of the mad queen, Juana la Loca, who would seem to have initiated this heredity. In 1506 her husband, Philip the Fair, fell grievously ill. She remained with him throughout his illness, and although she was well advanced in pregnancy no remonstrances availed to make her leave his bedside for a single moment. When he died she "nor wept nor uttered cry," but mute and motionless she answered nothing to those who spoke to her except by a gesture commanding silence. She had her husband's body embalmed, and after the funeral obsequies it was deposited in the church of the Carthusians of Miraflores near Burgos. Some days later she went to that sanctuary in a religious habit and began to pray. All at once she ordered the coffin to be opened and the wrappings to be removed from the body. She threw herself upon it, kissing the hands and the feet, and uttering aloud most tender expressions. The Queen periodically returned to Miraflores, and at each visit she had the temporary tomb opened. Soon she had the body taken out of the tomb and carried to her own room, where she placed it on a bed of state clad in magnificent robes. She was as jealous of her husband when dead as she had been when he was alive. She did not allow her women to go near the bed, and those not belonging to her establishment were not suffered to enter the room. She even declined the ministrations of a midwife, although one of great age had been chosen purposely, and she was delivered of a daughter without any assistance but that of her servants. At last she was persuaded that she ought to deposit her husband's body in the vaults of Granada. She insisted on taking it there herself. After verifying the contents of the coffin for fear of deception, it was placed on a funeral car drawn by four horses. The convoy started on the night of December 20th, 1506, as the Queen declined to travel by day, saying that a widow who had lost the sun of her soul should never again show herself in the light of day. Accordingly, during the whole journey they stopped before the break of day in a church or in a monastery. At each stoppage on the way she insisted on the reopening of the coffin, and the service for the dead was gone through as if Philip had just died. The following year her father, King Ferdinand, who wished her to marry again, wrote to his physician that the Queen kept the body of her husband continually beside her. It is not known exactly how long she continued to do this, but in 1509 we find her insisting that the body should be deposited in a part of the monastery of Santa Clara, where she could see it from the windows of her apartment, and in 1518, when there was a question of moving into another dwelling, the car on which the coffin was carried was repaired, so that in case of need it could be used for its transport.

In A. Abram's valuable book, *English Life and Manners in the Later Middle Ages* (George Routledge and Sons, 1913, p. 117) there is an amusing claim by a medical man for costs incurred by him in connexion with what we should now call a breach of promise case. Although there was usually a regular contract of marriage with settlements and indentures by which those concerned bound themselves by obligations to perform the covenants, the "Early Chancery Proceedings" prove that often the marriages did not take place. Still more often the dowry was not paid. One of the cases preserved amongst these documents gives an idea of the claims sometimes brought against those who broke their promises. Walter Lemster, Doctor of Physic, demanded, on behalf of his daughter-in-law, Lucy Brampton, from Richard Narborough, Doctor

of Civil Law, who had broken his promise to marry her, after an engagement of ten years:

| | |
|--|-------------|
| For "hir Arayment, gownys," etc. | ... £20 0 0 |
| For the "Arayment" of her servant | ... 6 13 4 |
| Expenses in time of sickness caused by his unkindness... | ... 13 13 4 |
| Expenses seeking him in London and other places to speak to him about the matter... | ... 27 16 0 |
| Expenses and charges in the Courts in London, tarrying in London to speak with him, at his special request | ... 48 10 0 |
| | £116 12 8 |

The claim in respect of what the late Mr. Kruger would have called "mental and moral damages" does not seem excessive considering the engagement had lasted ten years. One would like to know whether Dr. Lemster was successful in his suit.

SCIENCE NOTES.

At the sitting of the Anthropological Section of the Australasian Medical Association for the Advancement of Science in Melbourne, Mr. L. W. S. Buehner read a paper in which he set forth the results of an examination of what are practically the only remains of the Tasmanian aborigines. He said, according to a report published in the *Australasian Medical Gazette*, that there were now only three half-castes known to be alive. Of these, two were males living on Cape Barren Island, the other was a female living on Kangaroo Island. Of the families now remaining on Cape Barren Island, most were the direct descendants of the early seal fishers, military deserters, and escaped convicts, who carried off Tasmanian aboriginal women. In 1830, after the decline of the sealing trade, there were still over 30 white men and forty-one aboriginal women on the island. Nine families, comprising over 150 persons, were represented on the island. The result of the consequent close intermarrying was showing itself in the degenerate children who attended the Government school. The islanders, as a rule, were very listless and indolent and extremely improvident. Mr. Buehner said that an interesting Mendelian problem awaited investigation, especially in one family in which the Tasmanian characteristics, after skipping the second and third generation, have come out in the fourth.

Questions of priority of an observation are always thorny and seldom of engrossing interest save to the claimants. In these notes, in our issue of March 1st, we ascribed to McGowan of Edinburgh the priority of description of a *coeco-bacillus* which is probably the cause of canine distemper, and stated that Ferry, working in the laboratories of Messrs. Parke, Davis, and Co., in Detroit, independently discovered the same organism. Messrs. Parke, Davis, and Co. have courteously written to say that Ferry's first paper appeared in July, 1910, whilst McGowan's did not appear till 1911. Both statements are perfectly accurate, and the facts are, we believe, as follows: Dr. J. P. McGowan communicated the results of his work to the Pathological Society of Great Britain and Ireland at its meeting in the first week of January, 1910, and as this society includes practically all the pathologists of this country, the reading of a paper at its meetings may be held to be "publication." The first part of McGowan's complete paper did not actually appear in the pages of the *Journal of Pathology and Bacteriology* until January, 1911. The point to be noted is that the description of the organism and experiments was very complete. Dr. Ferry's first paper appearing in the *American Veterinary Review* in July, 1910, was a preliminary report, and did not therefore state any conclusive basis on which the etiological claims could be founded: in fact, we have found no mention of fever being produced on inoculation even in his later papers. There is no reasonable doubt that, in view of later investigations, Ferry first isolated the organism. Owing to its striking morphological similarity to other organisms, thought by their discoverers to be the causal agents of distemper, it is possible that the same bacillus was previously obtained in mixed culture—an explanation which probably applies to the observations of Monckton Copeman. Be that as it may, McGowan and Ferry quite independently discovered this particular organism, and in strict justice the honours should be divided.

British Medical Journal.

SATURDAY, APRIL 19TH, 1913.

MALINGERING.

TIME was, not so very long ago, when the subject of malingering possessed for civilian practitioners in this country a degree of importance small relatively to that which it had in countries where military conscription was in force. The importance of the subject had already begun to increase before the passage of the various Acts dealing with workmen's compensation. This legislation defined and extended rights already existing under the common law, and has, without doubt, greatly increased the temptation to feign or exaggerate disabilities due to injury or to certain diseases arising out of and in the course of employment. There is already evidence that the Insurance Act has still further increased the practical importance of the subject, and it cannot be doubted that that measure has multiplied enormously the opportunities for malingering, extending them to classes hitherto more or less completely immune from such temptations.

Dr. Byrom Bramwell, in the interesting and valuable address upon malingering delivered recently before the Pathological Society of Manchester, published at page 805 of this issue of the JOURNAL, gives a definition. A malingeringer, he says, is one who feigns sickness or who deliberately (knowingly and wilfully) induces or protracts an illness, with the object of avoiding duty, claiming money compensation, exciting sympathy, or for any other reason. The words "knowingly and wilfully" in this definition will be noted. The term "unconscious malingering" sometimes used is, he says, absolutely erroneous and involves a contradiction in terms, since the very essence of malingering is wilful and deliberate (conscious) deceit. Dr. Bramwell affirms that there are instances in which the patient knows that the condition which he attributes to the accident was previously present; that is to say, he is deliberately lying. But in others—as, for example, in cases of early tabes—he may not know this, and then he is not deliberately and wilfully trying to deceive. Further on, almost using Sir John Collie's words, he says that if it pays a patient better to be ill than to be well, or if a patient is lazily inclined and is content to take a holiday on sick pay—it may be half wages—there is no inducement to get well; in fact, there may be an inducement to remain ill—to prolong the illness indefinitely.

We have taken occasion also in this issue to review the recent book on the subject by Sir John Collie, who as Medical Examiner to the London County Council and in other capacities has had a very wide experience. It will be seen that there is an agreement between practitioners north and south of the Tweed as regards the bad influence which excessive legislation has had upon the manliness of the British workman. Dr. Bramwell quotes the statement made at a recent meeting of the Edinburgh Medico-Chirurgical Society by Dr. Dickson of Lochgelly, who has for twenty years had a large colliery practice in the

county of Fife, that traumatic neurasthenia is now a common topic of conversation in the villages of Fife, that the *morale* of the Fife miner, which before the passing of the Workmen's Compensation Act was high, has become much deteriorated, and that the duration of illness after accidents has become much prolonged.

The fears frequently expressed by the father of the Insurance Act that its financial stability might be endangered by malingering seem in the way of being fulfilled, at least in some areas and among certain classes of insured persons. Owing to the fact that the proportion of the total number of insured persons who have become insured through approved societies of one sort or another is far larger than was originally expected, the problem is one which concerns these societies far more than the Insurance Committees. The chief means so far taken by approved societies seems to be the requirement that the medical certificate which insured persons must produce in order to obtain sickness benefit shall specify the nature of the disease. To this it appears, from correspondence which has reached us, some members of the profession take serious exception, on the ground that the giving of such a certificate involves a violation of professional secrecy. The answer made to this is that it is the insured person who makes the application for the certificate, and that he must be assumed to be acquainted with the conditions which the society to which he belongs has laid down. This would seem to be the view taken by the State Sickness Insurance Committee, which, at its meeting on March 27th, expressed the opinion that the question is one affecting insured persons rather than the medical profession, and that it is for the insured persons to make representations to their approved societies if any change be considered necessary. At the same time, the Committee recommended that the position of the practitioner should be safeguarded by taking care that any certificate bearing the name of the disease should only be handed to the insured person concerned, or to his or her accredited representative. From information which has since reached the Committee, however, it is doubtful whether this precaution, in Scotland at any rate, would protect the practitioner in some cases against an action for libel. Correspondents have given us instances of recent cases in which the requirement bears very hardly on the insured person—cases in which a perfectly innocent person has suffered from accident or disease producing some condition which he, or more usually she, would much prefer should not be known to any other person than her medical adviser. It seems, however, that the only sound principle is that embodied in the pronouncement of the State Sickness Insurance Committee. The principle has been recognized in the past by the medical profession, which has never hesitated to give evidence in courts of law as to the physical conditions of patients if requested so to do by the patient. The profession has enough problems of its own without unduly burdening itself with difficulties which are not of its making and which, after all, are the primary concern of the insured person.

On the general question of malingering under the Insurance Act it must, we think, be recognized by medical men who have accepted service under it that they have thereby incurred a serious professional responsibility, and that it is their duty to discountenance malingering. At the same time it must be said that in the past many friendly societies, and especially perhaps the trade unions in their

administration of the sickness benefit they granted, have been exceedingly lax. It is a far simpler and easier course for the doctor to go on giving certificates too long than to run the risk of the annoyance to which he may be subjected if he declines to give them a little too soon or even exactly at the right moment. But the difficulties consequent on a strict attitude in regard to certificates under the Insurance Act are not so great as they were to a doctor holding an appointment to a club. In the latter case the withholding of a certificate to a prominent or troublesome member of the club might entail the loss of one or two hundred club members. The same action under the Act could at the worst only entail the loss at the end of the year of the particular patient and perhaps one or two of his immediate friends. The approved societies, therefore, have an obvious duty in this respect. We have already admitted that the medical profession also has a duty, but its discharge should not be rendered more difficult by giving credence to unworthy suspicions such as spring from the allegation, easily made, that the doctor wishes to escape from his liability to give medical attendance.

The suggestion that the difficulty might be met by the appointment of a consulting medical referee by each Insurance Committee appears to be finding favour. It has been commended by the State Sickness Insurance Committee (SUPPLEMENT, April 5th, p. 305), and seems to have been approved at the recent conference of representatives of approved societies in Westminster. It will be necessary to define the duties of this official very carefully; and in Bristol, where a referee has already been appointed, medical practitioners are advised to refer to him all cases in which there is any doubt as to malingering or as to whether the insured person is capable of working without detriment to his health or convalescence. The State Sickness Insurance Committee was of opinion that such referees should in general be appointed by the Commissioners and not by the Insurance Committees. Such a method of appointment was thought to be likely to ensure more security of tenure and better status for the officer, and to tend to discourage the wire-pulling and petty intriguing which are too often apt to occur with regard to local appointments and lead to selection on political, social, or practically any other grounds rather than professional suitability; and Sir John Collie, in his plea for the appointment of medical referees, published at page 812, maintains that they should have the status and emoluments of Government servants and be responsible to the Insurance Commissioners. Whatever the method of appointment, it is most important that the referee should not be engaged in panel practice and that he should possess the confidence of the local profession, not only in his professional capacity but in his tact and judgement. It would seem, therefore, that in making these appointments the Commissioners would do well to ask for nominations from the Local Medical Committees.

That very serious evils have grown up in connexion with the Workmen's Compensation Act is recognized, and nobody has spoken more strongly than Dr. Byrom Bramwell in his address; in fact, he handles the members of two learned professions with equal severity when he tells us that most of us who have had experience in compensation cases will agree that in some cases the lawyers have a good deal to do in fostering claims and preventing settlement. He mentions a bad railway smash in which a few persons were killed, several injured, and many unhurt. One of the passengers who was unhurt, while walking

down to his office, was met by a friend, who said, "I was sorry to see you were in that terrible accident; I hope you were not hurt?" The man shook his head, and said, "I don't know; I have not yet seen my lawyer." But it is not only the lawyers that are to blame. "I have known at least one case," Bramwell adds, "in which a medical man made it his business to hunt up persons who had been in a railway accident, and to coach them up in manufacturing false or exaggerated claims."

THE GRAVE VOMITING OF PREGNANCY.

It is not every case of grave vomiting of pregnancy that calls for the induction of abortion, for it is not every case that is caused by the biochemical changes which are the result of pregnancy. Even if every instance of hyperemesis gravidarum were toxic in its nature, it would not necessarily call for the termination of the pregnancy. There are other ways of dealing with this dangerous complication of gestation than by bringing the gestation to an end, a method of treatment which Fieux¹ characterizes, with reason, as "ultra radical," and speaks of, without exaggeration, as the "cruel necessity of therapeutic abortion." Fieux himself has succeeded in curing four cases of "uncontrollable vomiting" of pregnancy by means of serotherapy. In two instances he injected serum from a woman in the early months of a normal pregnancy; in another instance he used horse serum along with that from a normal pregnant patient, and in the fourth case he employed only horse serum. The explanation of the good result in three of these cases may very easily be ascribed to antibodies developed in the maternal blood serum in response to chorionic antigens; but the equal success when horse serum alone was used is puzzling. Still, the outstanding lesson to be learnt is that there is another way of treating even the toxic cases of hyperemesis; the "ultra-radical" plan of therapeutic abortion is not the only method which promises good success.

But, as has been said, all cases of incoercible vomiting in pregnancy are not toxæmic in their origin. Dr. A. Herrgott² of Nancy has recently reported a most instructive instance of the truly reflex variety of that alarming malady. The patient was a primipara who had never had a serious illness in her life, but admitted being of a very nervous temperament. Vomiting came on at the end of the second month of pregnancy, and rapidly became alarming in frequency and severity; and the woman was sent in a very low condition into the Nancy Maternity Hospital to have the induction of abortion performed. Dr. Herrgott made a vaginal examination, and discovered that the pregnant uterus was displaced backwards (retroversion); he replaced it without difficulty, and immediately there was marked improvement in the vomiting. To his disappointment, however, the amelioration of symptoms was only temporary; in fact, four days later the patient was as seriously ill as at first. Before proceeding to more severe measures he examined the patient once more, and found that the uterus was once more displaced, and that now it was retroflexed and almost incarcerated in the pelvis. By putting the woman in the genu-pectoral position he was able once more to replace the organ, but now he fixed it in its proper

¹ Fieux, G., *Ann. de gynéc. et d'obstét.*, 2 s., vol. ix, p. 719, December, 1912.

² Herrgott, A., *Ann. de gynéc. et d'obstét.*, 2 s., vol. x, pp. 65-69, February, 1913.

situation by means of a pessary. Nearly immediate improvement followed, and some three weeks later the patient was able to leave hospital quite well, her pregnancy progressing normally.

Several lessons are to be learnt from such a case as this. In the first place, in every case of vomiting in pregnancy, even if it be of the gravest type, the pelvis should be explored and the position of the uterus ascertained; if it be abnormal it should at once be corrected. In the second place, the obstetrician should satisfy himself that the replacement has been permanent, and should even fix the womb in its proper place by means of a pessary if there seem to be any risk of displacement recurring. But there is a third lesson which does not lie on the surface, and yet is of great importance. It is this. Even when there is a uterine displacement there may also be a toxic state; the retroversion or retroflexion may not be the cause—may not, at any rate, be the sole cause of the vomiting. Consequently, if the replacement of the womb be not at once followed by marked improvement, other means—for example, the induction of abortion—should be instituted, and these without delay. Time enough must be allowed if this “therapeutic of despair,” as Herrgott calls it, is to succeed. If we do not do this, he says, we run the risk of being too late.

There still remains a difficulty in some instances of distinguishing between a hyperemesis which is purely nervous and one which is toxæmic in origin. Here Professor Whitridge Williams² comes to our aid. Believing that there are three types of excessive vomiting in pregnancy, that the neurotic is the most and the reflex the least frequent type, while the toxæmic is the most serious, Dr. Williams thinks that it is very necessary to separate the neurotic from the toxæmic as soon as possible. This can to a certain extent be done by ascertaining the ammonia coefficient of the urine. “I believe,” he says, “that for clinical purposes we can consider a given case of vomiting as toxæmic in origin whenever a seriously ill patient, presenting a high ammonia coefficient (20 per cent. or more), fails to improve after a few days’ complete rest in bed, combined with suggestive treatment, energetic rectal feeding, and the administration of large quantities of salt solution per rectum and underneath the skin.” Those who have followed Professor Williams’s researches on this subject will take note that the high ammonia coefficient test is not now regarded by him as so certain a sign of the toxæmic nature of the case as he at one time thought, yet it has a high value. Still, the great lesson to be learnt regarding hyperemesis gravidarum at the present time is that whether it be reflex, neurotic, or toxæmic in nature, the induction of abortion is not the only effective treatment available.

THE ORGANIZATION OF THE PROFESSION.

WE make no excuse for returning to this perennial question, for that it is the question of all others with the profession at the present time is evidenced not only by our correspondence columns but by the recent attempts, some of which have actually materialized, to form new organizations. These attempts have all grown out of the battle in which the profession has been engaged with the Government over the National Insurance Act, combined with dissatisfaction on

various grounds with the constitution and policy of the British Medical Association. They all of them seem to be founded on an imperfect knowledge of the evolution of the Association and of the needs and traditions—prejudices, if the term be preferred—of the profession, and seem therefore to demand close and persistent examination.

In the Nineties there was a strong recrudescence of a desire for medical reform and organization, stimulated no doubt by the example and the increasing demands of organized labour. It took the form of the establishment of a number of local medico-political societies, many of which in their day and generation, and so far as their limited opportunities went, did good work. They all failed when it came to dealing with the man who came from outside, and the setting up of any national organization and co-ordinating machinery was beyond their purview. But the demand for such wider organization steadily grew, and about 1900 it came to be a question either of the setting up of a union of these local societies or of the utilization and development of the British Medical Association, and the latter was the plan adopted at the famous Manchester Conference in 1900. As a direct result of that conference the Association was reorganized; the system of Branches having proved unwieldy, partly owing to the steady growth in the membership of the Association, smaller units of area were taken, and each such area or Division was empowered to select one or more Representatives to the Representative Body, which is the supreme governing body of the Association. The first Representative Meeting was accordingly held at Swansea in 1903.

Ever since that time the constitution of the Association has been in the melting-pot, and it is still there. One change necessitated another, and one step along the path of democratic organization opened the way to still further developments, until the Association is probably in conception, and by relatively minor changes could be made in practice, the most democratic organization of its kind in the world. Indeed, the charge most frequently brought against it of late is that it is too democratic, and that what the profession needs is more central guidance and a firmer hand. This is, of course, a matter for the members of the Association, though it must be pointed out that any general desire felt for a benevolent (or otherwise) autocracy has never been ostentatiously displayed, and any exhibition of a tendency on the part of any one to resort to that form of government would, we suspect, be strongly resented even by those who now, in an academic manner, trifle with the idea. But the Association has gradually become, beyond all question, the one representative organization of the British medical profession. That is a position not easily won and certainly not to be lightly thrown away. It is no more perfect than any other human institution. It is fettered by many legal restrictions which no expenditure of money, hard work, ingenuity, or perseverance has been able to overcome. Its best laid schemes occasionally break down, just, by the way, as trade unions which deal with the same material also frequently fail, because the material with which they both work and on which they both depend is that very imperfect thing human nature. Yet what impartial observer, taking a survey of the organization and position of the profession over the past twenty years, can fail to observe an enormous improvement? A chief symptom of this is the way in which the Association has been able to attach to itself the

² Williams, J. W., *Trans. Glasgow Obstet. and Gynaec. Soc.*, ix, pp. 91-117, 1913.

services of a very large number of active and devoted honorary workers who have made the Branches and Divisions of the Association a power to be reckoned with in every part of the empire.

To every reasoned demand for an improvement in its constitution or an extension of its powers and services the Association must always lend a willing ear. But when we find men, dissatisfied, not unnaturally, with the failures of the Association, seeking to encourage the setting up of separate societies to carry out work which they believe the Association either does badly or cannot do at all, we must enter our emphatic protest, not so much on behalf of the Association, for it is quite able to take care of itself, but on behalf of the interests of the profession at large. We distrust these "short cuts." They often prove to lead nowhere. We believe that the salvation of the profession lies in one organization, which shall steadily move to the fulfilment of the ideal of including in its ranks every member of the British profession. Already the Association contains two-thirds of the profession in this country, and can count on a large number of members wherever the British flag flies. The evolution of the ideal Association may be a slow progress, its course may be interrupted by bunkers, even by landslides, but it is not to be hastened by setting up one or a number of outside societies whose avowed object it is to occupy the whole or a part of the territory the Association has marked out for its own, namely, "the promotion of the medical and allied sciences, and the maintenance of the honour and interests of the medical profession."

We are told that these organizations are not rivals of the Association but supplementary to it. We do not question the good intentions of the promoters of these schemes. Some of them have well proved their desire and ability to further the welfare of the profession. But we believe they are mistaken. Those who have had most experience of local organization know too well the difficulties of getting practitioners to join any association formed for their welfare, and these difficulties will not be lessened by the introduction of several rival organizations with the same avowed objects if with different methods. The only possible excuses for the introduction of these rival societies would be either unreasoning complacency on the part of the Association—an assumption that its organization was improvement-proof—or a confession that the resources of statesmanship were exhausted, and that the constitution of the Association could not be modified to meet the new needs and aspirations of the profession. But there is no such attitude, no such confession of powerlessness. The Council is at this time through various committees giving earnest attention to the problems of the profession, and a way will undoubtedly be found. It would ill become a scientific profession to allow a passing mood of not incompressible pessimism and irritation to be the means of rushing it into premature adoption of methods—for example, registration under the Trade Union Acts—which have never yet been fully discussed by the profession, and which are repudiated in the strongest way by a large and important section of it. The hope of the profession in the future lies in the development of one strong organization—the British Medical Association. Its methods must be effective and well thought out, and they must not be such as will alienate any considerable section of the profession, for that would defeat the main object of such an organization, which is that the Association must stand for the profession and for every member of it—

the panel doctor and the non-panel doctor, the practitioner whose income is chiefly derived from contract practice and the man whose circumstances are such that he need never touch that kind of work, the country practitioner and the city consultant. If the Association falls short of these ideals the responsibility will lie to a great extent at the doors of those earnest but misguided persons who fail to realize that "to conquer" we must not "divide"—ourselves.

EDUCATION AND MEDICAL EDUCATION.

The hints dropped a little time ago by Lord Haldane and other members of the Government indicating that it was proposed to give particular attention in the near future to the improvement of the national educational system and the removal of some of its defects have been given body and substance by some recent events. When the vote for the Board of Education came on in the House of Commons last week a very business-like discussion arose, in the course of which the President, Mr. Pease, gave an account of the principles actuating his department and a sketch of some of the reforms it is proposed immediately to introduce. The attention given by the Board to the medical inspection of children, to physical training, to open-air methods of instruction, and Mr. Pease's remarks in respect of nursery schools, would appear to indicate that further developments in these directions may be looked for in connexion with the forthcoming proposals of the Government. The first grant in aid of medical treatment was made last year and amounted to £60,000; of this, £50,374 has been spent. During the current year the amount available for grant is to be increased to £80,000, and it is understood that next year the amount is to be increased to £100,000. It may be noted also that the amount of the grant paid to the London County Council on account of the treatment of school children in London was £13,683. It is understood that the financial provision to be made to enable local educational authorities to establish and maintain schools under the Defective and Epileptic Children Act—which it is proposed to make compulsory this year—are to be in addition to the grants made for ordinary medical treatment. Another recent event at the opposite pole of the education system is the publication of the final report of the Royal Commission on University Education in London. The report was only published on Tuesday, and it is not yet possible to form an opinion on its many wide-reaching and complex proposals, but it can be seen that it is a blend of idealism and hard-headedness. There is idealism in its attempt to devise for London a university worthy of it, and hard-headedness in the careful counting of the cost, which, at a rough estimate, is put at an additional annual income of £99,000. We can see no source from which anything like this sum is likely to flow save the State, and we imagine there is no one less likely to dispute this than Lord Haldane, the Chairman of the Commission.

INSURANCE DIFFICULTIES AND THE WAY OUT.

At the risk of being accused of "damnable iteration" we would once more invite the Joint Committee of Insurance Commissioners to begin without further delay to use the powers of co-ordination with which they were endowed by the Insurance Act. The British people have an admirable faculty of governing themselves, and making good the mistakes of party politicians in the legislature. But it is the duty of a central authority, which ought to be above and outside of party, to watch very carefully over the first movements of a complicated piece of machinery, and constantly to stand by until the engine has found itself, always ready to ease her, and lubricate the unaccustomed valves and pistons and pinions. The Joint Committee and the English Commissioners may take

the lead given them by the Scottish Commissioners in the wise, straightforward, plainly-worded conciliatory memorandum recently issued to the medical profession in Scotland. It is, perhaps, not very difficult to divine whose mind guided the pen that wrote this temperate and reasoned explanation and appeal. The better position in Scotland shows what wise counsels and a sympathetic spirit may do. Such counsels and such a spirit would be very helpful at present in England. In Wales also—but of Wales we prefer not at present to write—Wales, where the engineers seem to be letting the machine run wild, in the hope that by pressing a full head of steam the engine may be made to work somehow at whatever cost to its ultimate efficiency. In Ireland the proceedings of the Insurance Commissioners have that touch of the wicked baron of comic opera which makes the politics of that enchanted island so bewilderingly entertaining to the dull Englishman. The position is stated with some fullness by our Dublin correspondent (SUPPLEMENT, p. 339). "The quarrel is a very pretty quarrel as it stands; we should only spoil it by trying to explain it." At least, that is the impression derived from a study of the efforts in this direction of the Irish Insurance Commissioners themselves. They seem, as Mrs. Malaprop would say, "as headstrong as an allegory on the banks of the Nile," and to have brought about a position as muddled as that good lady herself.

MEDICAL AID ASSOCIATIONS.

REFERENCE was made in the issue of March 29th, p. 679, to the position created at Swansea by the proposed establishment of medical aid associations in the town. As was then stated, the Division had appealed to the honorary medical staff of the Swansea Hospital, and the resolution which the staff had in consequence adopted was then fully set out. It was presented to the Board of Management in the forcible speech made by Dr. Lancaster, senior physician at the hospital, and the discussion at that meeting was brought to an end by an offer of the Mayor to convene a conference between six medical men, six trade unionists, and six representatives of friendly societies. This conference was held, but no solution of the difficulty was reached, and the conference was adjourned. Negotiations have since been broken off by mutual consent, and the adjourned meeting of the conference will not be held. We are informed that medical aid associations have been formed at Gorseinon, Neath, and Briton Ferry, and whole-time medical officers appointed. At a meeting of the honorary staff of the Swansea Hospital, held on April 14th, the course which the members should adopt to carry out the resolution declining to allow themselves to be used as a tool to crush their brethren outside was discussed. The staff of the Swansea Hospital will, we believe, have the sympathy of the staffs of all other voluntary hospitals throughout the country, who in similar circumstances would, we have no doubt, take the same course. The staff of the Swansea Hospital has resolved that in no circumstances will it meet in consultation or have any professional dealings with any medical men holding office under a society or association employing medical men under conditions not approved by the medical profession, and will decline, except in cases of gravest emergency, to treat in hospital any member of such society or association.

THE FUTURE OF THE WELSH MEDICAL SCHOOL.

ONE result of the commercial prosperity of South Wales has been an enormous increase of population and it was natural, therefore, when the aspirations of Wales for the organization of a system of university education for the principality were realized, that it should have been decided by consent that the medical school should have its

home in South Wales and should be organized as a part of the University College of South Wales and Monmouthshire. An essential part of a medical school is a large clinical hospital and that Cardiff already possessed. There is now a very great opportunity of putting the system of clinical teaching on a sound basis consonant with the requirements of modern medicine and the highest ideals of university education. The school is still young and, on the clinical side especially, undeveloped. It is important that it should be put in the way of growing into a strong well-balanced body worthy of the national aspirations of Welshmen. Very opportune, therefore, is the publication of the final report of the Royal Commission on University Education in London, which discusses the general principles on which clinical teaching and investigation in the three chief departments—medicine, surgery, and gynæcology—should be organized. The conclusions expressed have been reached by the Commissioners, themselves all educational experts, after hearing the evidence of experts acquainted with university methods, not only in England and Scotland, but in other countries of Europe and in America. The particular application of the general principles to London, where, owing to the existence of many medical schools, the conditions are peculiarly difficult, is not now in question, but we venture to commend to those on whom the great responsibility of watching over the future of the Welsh medical school is committed the perusal of those passages of the report of Lord Haldane's Commission which deal with the later stages of medical education, those in which the student is brought into actual contact with disease and with sick and injured persons. The Commissioners have no hesitation in advising that an essential part of a university is a university medical college with a large general hospital in which clinical instruction is given. They recommend the adoption of the "unit system," the minimum number of units being three—for medicine, surgery, and gynæcology respectively. Each unit would have at its head a professor with the control of wards, an out-patient department, assistants to help in the general work of the department, and laboratory accommodation in proximity to the wards, where examinations and procedures connected with the diagnosis and treatment of the cases may be carried out and researches into the unsolved problems of disease prosecuted. Whether this particular system be adopted or not at Cardiff, it is clear that the responsibility of the newly appointed Election Committee is very great, and that what is now done will have its effect for a generation on the growth and development of the Welsh Medical School and the University of Wales. Those responsible, we have reason to believe, are anxious to make the best appointments possible, and will be guided, we make no doubt, solely by consideration of the merits and capabilities of the candidates as physicians and teachers.

CASANOVA'S IMPRESSIONS OF HALLER.

CASANOVA is the least edifying of authors. Of all men who have written so-called confessions, he is probably the frankest, as he is certainly the most shameless. Whose looketh into his *Mémoires* let him bathe himself in some moral antiseptic and be unclean until the even of the seventh day. We should not think of mentioning him here but for an interesting account he gives of Albrecht von Haller, anatomist, physiologist, physician, botanist, and poet (1708-1777). Haller must have struck even the tainted mind of the Italian swindler and debauchee as hardly any one else did whom he came across in his constant wanderings from one country to another at the orders of the police. He met Haller at Lausanne, apparently in 1760, and describes him as a man gigantic in body as well as in mind. How Haller came to receive such a blackguard is not very clear,

but Casanova's impressions of him are so little like what one would expect from such a witness that it may be worth while to reproduce them. He says: "This learned man opened up to me all the treasures of his science, answering all my questions with precision and particularly with a rare modesty which seemed to me almost excessive, inasmuch as while he explained to me the most abstruse things, he did this with the air of a student seeking for instruction. On the other hand, when he put scientific questions to me, it was with such delicate art that, if I may say so, he forced me to find the exact answer." Haller, he says, called Morgagni his master, and showed Casanova a number of letters from Morgagni and Pontedera, the botanist; with regard to the latter, he complained that his letters were almost undecipherable and of very obscure Latinity. On the question of Latin as the international language of science, Haller's views are particularly interesting in these days of artificial tongues. Casanova was shown a letter from an academician of Berlin, who said that since the King of Prussia had read Haller's letter he had abandoned the idea of suppressing the Latin tongue. Haller had written to Frederick the Great that a sovereign who should succeed in the unhappy endeavour to proscribe from the republic of letters the language of Cicero and of Virgil, would raise an eternal monument to his own ignorance. If men of letters, he said, were to have a common language for exchanging their ideas, the most suitable among dead tongues was certainly Latin, as Greek and Arabic could not be adapted like it to the needs of modern peoples. Haller took an active part in politics and rendered great service to his country. It is amusing to find Casanova approving of Haller's morals; from a man who lived steeped to the lips in almost every form of sensual depravity, this testimony, had it been required, would have been valuable. Casanova quotes Haller as expressing the excellent sentiment that the only good way of giving precepts is to show them in operation by examples, and says that Haller, being a good citizen, was also an excellent father of a family, "for what surer means of proving his love for his country was there than to give it in his children capable and virtuous subjects, a thing which can only result from good education?" His wife, who was his second helpmate, was still young, and bore on her handsome face the impression of benevolence and goodness. Casanova proceeds: "He had a charming daughter of about eighteen, of modest appearance, who only opened her mouth at table to speak sometimes in a low voice to a young man who sat beside her. After dinner, finding myself alone with M. Haller, I asked him who the young man was. He said it was his daughter's tutor." To Casanova's remark that such a tutor and so pretty a pupil might easily become two lovers, Haller answered, "Please God it may be so!" Casanova says this answer made him feel how uncalled for his reflection had been. To cover his confusion—this is almost the only instance in which he acknowledges such a feeling—he took up an octavo volume of Haller's works, which was lying near. In it he found the sentence: *Utrum memoria post mortem dubito*. This moved him to say that it appeared from these words that Haller did not believe that memory is an essential part of the soul. Haller put him off with an evasive answer. Casanova asked Haller if Voltaire often went to see him. His reply was conveyed in the following apt quotation:

Vetabo qui Cæceris sacrum
Vulgarit arcanum sub iisdem
Sit trabibus.

Haller spoke much of Boerhaave, whose favourite pupil he had been; he was, he said, a born doctor, and when a boy cured himself of an obstinate ulcer, which had resisted the treatment of the best physicians, and which threatened his life. The reader may be interested to know that the

cure was wrought by frequent rubbing with salt mingled with his own urine! Casanova stayed with Haller three days and discussed with him all manner of subjects, except religion, on which he could not induce the great man to say anything. Although attempts have recently been made to establish the accuracy of Casanova's narrative, it requires no great critical acumen to recognize from his own statements that he was a most unscrupulous liar. It is curious that a man of such austere character as Haller should have received such a notorious scoundrel as a guest and spoken freely to him. But there is nothing in Casanova's account of their intercourse which justifies doubt as to this particular story. He speaks in the highest terms of Haller, and seems, indeed, to have been overawed by the simple grandeur of the man's character—one of the most remarkable testimonies of vice to virtue in human history.

BOVINE AND HUMAN TUBERCULOSIS.

At a meeting of the Berliner medizinische Gesellschaft held shortly before Easter, Professor Orth, formerly a pupil of Virchow's and now his successor, opened a discussion on the etiology of tuberculosis in man. His views, not only in virtue of his position as a pathologist, but by reason of his being chairman of the society, had been eagerly awaited, and were listened to with the greatest interest by the members present. The address was on the importance of the bacillus of bovine tubercle in the production of tuberculosis in man, and in it he strongly emphasized his conviction that, although bovine tuberculosis does not commonly infect the adult, its power to produce tuberculosis in children and infants cannot be denied, and that in consequence a campaign of extermination of the disease in cattle must be our aim in the future. He thus departed from the thesis of Koch's famous pronouncement in London (1901), and maintained that not less than 10 per cent. of all fatal cases of infantile tuberculosis originate from a bovine source, while, according to the estimates of Koller and Wassermann, fully 40 per cent. of cervical gland tubercle and 49 per cent. of intra-abdominal cases are directly due to infected milk. Bendix states that in Germany alone 2,700 bottle-fed infants perish annually from tuberculosis, so that the term "race" disease would hardly be exaggerating the present position. The question of the convertibility of the one bacillus into the other was decided, he claimed, in the positive sense by von Eber, who in 1912, at a meeting of the Royal Institute of Public Health held in Berlin, announced that he had been able by one or more passages through cattle to produce from adults (36 per cent.) and children (53 per cent.) a virulent bovine bacillus. Professor Orth reminded his hearers that in 1906 he had experimentally shown that a primary local infection with inoculated bacilli could create a heightened, latent susceptibility to future infections, and that under such circumstances pulmonary phthisis was the most usual sequel. That a bovine infection contracted in infancy might play a similar part in the development of the disease in adult man was no unreasonable speculation. Professor Orth expressed the general trend and conclusion of his address in the words, "war against the human bacilli, but war also against the bovine." His views were criticized by Weber, a member of the Imperial Health Commission, which has only recently abandoned Koch's beliefs for views more nearly akin to those of Orth. Weber stated that *post-mortem* reports and experimental investigations had shown no recognizable parallelism in the incidence of the disease in man and cattle, nor were there any marked differences in the statistics of countries in which cow's milk was not the staple diet of bottle-fed infants and children. Of considerable importance to his argument was the fact that of 280 children who had demonstrably drunk the milk of tuberculous cows, only two, and both of these cases in

which the cervical glands were involved, had developed the disease subsequently. Moreover, seven years later, during which time they had been under the direct observation of the Board of Hygiene, not one of the 280 had died of tuberculosis.

PHTHISIS IN THE QUARRIES OF DERBYSHIRE.

THE fact has long been known that certain forms of so-called miners' phthisis are more prevalent and more fatal than others. The statistics presented by Dr. Peacock in 1860 are as eloquent at the present time as they were fifty years ago, but it is well that the question should be raised again, and no more interesting or instructive account could be given than has recently been presented by its medical officer, Dr. Sidney Barwise, to the Derbyshire County Council.¹ Within that county are well-defined areas in which three different forms of quarrying are carried on, and statistics of each of these areas are available for analysis with respect to the death-rate from pulmonary consumption. There is also a considerable agricultural area for comparison. Investigation of these statistics shows at once that the death-rate varies very strikingly in some of these areas. Comparison with a geological map indicates very clearly that it is in those districts where millstone grit is quarried and worked that the highest percentage of mortality appears. This stone contains 96 per cent. of silica, and is capable of extremely fine division into dust that may hang in the air like tobacco smoke. Unlike finely divided carbonate of lime, this silica dust is not soluble, and when inhaled into the lungs can only be removed in sputum. In all probability it is only so removed to a very small extent, most of the inhaled particles becoming imbedded in the mucous membrane of the larger tubes, sooner or later causing bronchial irritation and abraded surfaces which may form points of entry for tubercle bacilli. The statistical evidence goes to prove how frequently this course of events must ensue. In one district, where men live under similar home conditions, but with different occupations, the death-rate amongst the millstone grit workers is ten times as great as that prevailing amongst workers in limestone. It is twenty times greater than in the case of the agricultural dwellers in the same area, and seventeen times greater than in the case of workers in other occupations. The condition known as "grinders' rot," prevalent amongst metal grinders in large towns, is no doubt due essentially to the particles of gritstone from the wheel rather than from the metal which is being ground upon it. Dr. Barwise's report has a further interest in respect of the association of pulmonary tuberculosis with lime working and coal mining respectively. Notwithstanding the possible solution of lime particles within the living body, the death-rate amongst lime-quarrymen is higher than amongst coalworkers, who in their turn would seem to be no more liable to tuberculous infection than are the agricultural members of the same community. The excessively high rate amongst the gritstone workers is deserving of careful consideration and many suggestions for its amelioration are made in the report, but local customs and long-established methods are hard to overcome, and only by the steady progress of education is any material change likely to be effected. It is well, however, that all who have to run the risk of inhaling the fine dust of the gritstone should know of the undeniable danger that attends it.

SPA.

SPA was one of the most famous watering places in Europe, and so great was its renown that in England the name came to be synonymous with watering place. Besides attracting visitors from every part of Europe it

did a considerable export trade; quite early in the seventeenth century from 30,000 to 40,000 bottles of the waters were sent out every year. Throughout the eighteenth century the sale was well over 100,000 bottles; in 1842 it was 150,000. This source of revenue has been allowed to decline, and only in recent years has Spa begun to regain its former prosperity as a watering place. In *Paris Médical* of April 5th Dr. R. Wybauw gives an account of Spa in old days. It was described as *Spa Vicus Amoenissimus et Saluberrimus* in an illustration of the town in Matthacus Merian's *Topographic Westphalica*, published in 1842. Till 1792 the prince-bishopric of Liège was a small independent state. The success of Spa as a watering place was probably due to the fact that, while not far from the great European ways of communication, the little town in the Ardennes combined with the advantages of its waters that of offering a haven of tranquillity and comparative safety in the middle of the wars which had so frequently raged around it in previous centuries. The reputation of Spa seems to have arisen suddenly in the fifteenth century. It is mentioned by the chroniclers when describing the laying waste of the country by the soldiers of Charles le Téméraire. Less than a hundred years later, in 1559, Lymborh, a doctor practising at Spa, published a book on it in four languages—Latin, French, Italian, and Spanish. The town became more and more fashionable, and of all the watering places of French-speaking countries none was so universally celebrated. The visit of Peter the Great in 1717 put the pinnacle on its fame. Illustrious persons pressed around the chief spring (Pouhon), among them being Duke Cosmo de' Medici III, Queen Christina of Sweden, Gustavus III of Sweden, and Joseph II, Emperor of Austria, besides innumerable notable persons from most parts of Europe. During the four months of summer Spa was truly cosmopolitan. Such importance was attached to the waters that during the wars in the Low Countries princes and generals gave special protection to Spa to save it from the excesses of the soldiery. Among them were Marlborough and King Louis XV, and the Allies in 1814. Old medical books about Spa are numerous, but the indications given by them for the use of the waters, which are cold, ferruginous and rich in carbonic acid gas, were very vague. Spa had excellent physicians, such as Lymborh in the sixteenth, de Heers in the seventeenth, de Limbourg in the eighteenth century. In those days the waters were prescribed internally only, and in a purely empirical way; patients of all kinds were treated, from those suffering from "obstructions" to those with chronic inflammatory diseases and others afflicted with ailments dependent on "the acrimony of the humours." In reading the medical observations it can be seen that the most favourable cases were such as are still treated by the internal use of the waters—anaemia, neurasthenia, and so on. Many persons were sent to Spa for gravel and urinary diseases on account of the diuretic qualities of the waters, which were then more manifest as much larger quantities were given. Patients with venereal diseases and dropsy also went to Spa. External treatment by the gas baths dates only from the fifteenth century at Spa, and it was only at the end of the nineteenth that it was applied to circulatory affections. The patients were supposed to lead the simple life. The water was drunk in the morning fasting, sometimes also in the afternoon. Each patient carried a little ivory dial with a needle, which he moved on one division after every glass he drank. In the sixteenth century much attention was paid to diet, and recent researches on the nutritive exchanges have established a regimen similar to that laid down by Bruhezen in the sixteenth century. Spa was a lively place; the fashionable people who frequented it organized ballets, festivals, serenades, and picnics. Before the establishment in 1768 of an assembly room where games of chance, especially faro and trente et un, could be played, the garden of the Capuchins was

¹ Report on the Prevalence of Phthisis among Quarry Workers and Miners. By Sidney Barwise, M.D., D.P.H., County Medical Officer, Derbyshire County Council. February, 1913.

the principal place of meeting in the afternoon. The good fathers allowed the use of it to the nobility and gentry in exchange for a small offering. It was in the eighteenth century that gaming acquired a great importance at Spa. With the object of avoiding the multiplication of low gambling places the Prince Bishop gave the monopoly of play to one company, which naturally caused a great deal of quarrelling. The glory of Spa was destroyed by the wars of the Revolution in 1789, and those of the Empire. Its vogue, however, revived under the government of the Dutch, and at a ball on July 18th, 1821, three kings and sixteen princes were present. Soon, however, gaming came more and more to the fore, while the watering-place receded into the background. The town remained fashionable till the suppression of the gaming tables in 1873. For some years Spa has again been becoming an important health resort.

MR. C. S. TOMES, F.R.S., has been reappointed by the King a member of the General Medical Council for five years from May 20th, 1913. Mr. Tomes is the senior Treasurer of the Council.

MR. CLAUD SCHUSTER, secretary and legal adviser to the National Health Insurance Commission (England), has been appointed a legal member of the Commission and of the National Insurance Joint Committee. He will be succeeded in the office of secretary to the Insurance Commission (England) by Mr. John Anderson. The appointments will take effect on May 13th.

At the parish church of St. Paul, Deptford, last Sunday, the rector, the Rev. R. P. Roseveare, unveiled a memorial to John Harrison, founder of the London Hospital. The memorial, which has been provided at the personal expense of the House Committee, is a marble tablet bearing the following inscription: "In Memory of John Harrison, Founder and First Surgeon of the London Hospital, who died in 1753 and was buried in this Churehyard. His body lies here. His work continues at the Hospital."

Medical Notes in Parliament.

[FROM OUR LOBBY CORRESPONDENT.]

The Health of Children—Medical Treatment and Inspection.

IN connexion with the vote for the Board of Education, an interesting debate occurred in the House of Commons on Thursday, April 10th.

INFANTS.

Nursery Schools.

The President of the Board of Education, after explaining the diminution of the number of the children under the age of 5 which were now in attendance in public elementary schools as compared with 1903, said: I am also satisfied, from the inquiries I have made, that experience is disclosing the fact that the education which was given in our infant departments in the past has not really been to the best interests of the small children who have attended. That is being more and more realized by the various local education authorities in the country. In 1908 one of my predecessors asked a Consultative Committee to report upon this question, and they reported that if a mother does her duty, if she takes care of her children, if she knows the best way in which to use her narrow means, if she keeps her home clean, if there is a suitable play place for the children, and if the homes are well ventilated and kept decent, there is no better place for these little dots between 3 and 5 than under their own mother's care; but that if, on the contrary, the conditions are not satisfactory at home—these children should not be sent to a school where there exists adaptation of discipline and tuition suitable to older

children, and should not be subjected to mental pressure or physical discipline—they should be sent to what they call nursery schools, places which should be kept warm, well ventilated, where there would be plenty of freedom of movement for the children, constant change in their occupations and opportunities for sleep; and that the teacher should be very carefully selected to look after these children, and, in addition to the teachers, there should also be attendant nurses.

Schools for Mothers.

I am glad to say that parents in this country are getting to understand better than they did how to look after their infant children. At the present moment we have in the country 200 schools for mothers, we have a great number of medical officers who superintend the inspection of the babies, either by weekly or fortnightly visits, and we have a large number of most excellent workers, trained health visitors, who visit the homes of the people and give advice to the mothers and see that they follow the instruction which they receive at school as to the way in which the children ought to be cared for in their homes. The point in which the medical department has taken the most interest, and which is their greatest ambition, is to prevent and remedy the physical disability which hampers a child from taking proper advantage of the education which the State gives it.

PHYSICAL EDUCATION IN ELEMENTARY SCHOOLS.

People are too apt to forget that education in connexion with younger children is primarily physical and not intellectual, and that if a child is to be developed into a really good citizen it is essential that every child should enjoy physical training and suitable exercises even during school hours. The object of the education given to the children is to enable them to be turned out from school in a sound physical condition, and to know, when he or she leaves school, how to look after his or her own health in the following years. I believe that under the system of medical inspection which now obtains in this country, and under the medical treatment which every day is being increased in volume, we are going to secure a much healthier race in the future, and that a great number of these infants who, when they reach the age of 16 will come under the insurance funds, will not make any claims upon those insurance funds, at any rate before they reach the age of 40, with very large increased benefits to the older people in consequence of the improvement in health.

PHYSICAL DEFECTS IN SCHOOL CHILDREN.

I cannot exaggerate the importance I attach to the attention which is given to the health of the children during their school life. The conditions in this country are certainly not worse than those in other countries, but still they exhibit a great deal of neglect. As a result of inspection we are able to classify our figures, and the last figures show what a serious amount of illness and trouble there is among the children of this country at the present time when they first enter the schools. Ten per cent. have their eyesight impaired in some way or other, 5 per cent. their hearing, 3 per cent. suffer from ear disease, 5 per cent. from adenoids, 50 per cent. from serious decay of their teeth—in many cases it goes up to 80 or 90 per cent. of decay, more or less in degree—tuberculosis 2 per cent., heart disease 2 per cent., and malnutrition 10 per cent. I am glad to say that the authorities who have been comparing their statistics, one year with another, have already exhibited a real improvement in the condition of the children. The medical officer at Portsmouth informs the Board that the number of those who in 1908 came to school with dirty bodies was 13.8 per cent., last year it was only 3 per cent.; those who came to school in a verminous condition in 1908 were actually 43.3 per cent., while to-day it is 13 per cent. The medical officer informs me that as a result of the clinics which have just been established in Portsmouth he believes that the difficulty will be very greatly reduced during the current year. From the statistics we have been able to collect through this inspection it is shown that 1 per cent. of the children are regarded as mentally defective, 12½ per cent. of the children are considered backward, and 3 per cent. are considered to be gifted in an abnormal degree. In our schools we are now employing 700 nurses, and there are 21,000 schools; 943 medical

officers are at work in medical service in schools; there are 31 authorities which contribute to hospitals, 56 have already established school clinics, and there is expenditure on treatment by 229 authorities out of 317. The cost in connexion with treatment averages 2d. per child throughout the whole country, and the amount given in support of medical treatment during the financial year ending March 31st last was £50,374. Perhaps I may be allowed to pay a special tribute to the way in which this work has been taken up in London. It has been, perhaps, the most difficult place in which to organize medical treatment. The removals of the population are enormous in the confines of this great city, but, in spite of that, every effort has been made to follow up the children; arrangements have been carried out at 10 hospitals and 23 medical treatment centres, and very good work is being done. I have been rather better than my word in regard to the contribution which I gave to London, and we were able to give them a grant for the last year of £13,683. In addition to that, London receives a grant of £725 in connexion with the open-air schools which have been established by the London County Council, and which are materially beneficial to a certain section of the less robust portion of the school population.

AFTER-SCHOOL OCCUPATIONS IN LONDON.

Mr. Hoare warmly supported the expenditure of money for promoting the health of the children, and said that he believed the expenditure of public money was much needed in this field. He instanced the case of consumptive children, of whom, he said, there were about 1,200 discovered annually in London schools, and he stated, on the basis of a calculation made by the medical officer of health, that in London alone no less than £1,000,000 has been spent during the last ten years on tuberculous children who had died during the years that they would have been compelled to attend school. He quoted some interesting figures of the results of an inquiry into the occupations of children after leaving school and into the districts from which they came. He said that of the 30,000 boys who leave the London schools every year only 28 per cent. find their work in the skilled trades and 67 per cent. drift into irregular employment. He calculated that each boy had cost the community £100. He also stated that in certain representative skilled trades 60 per cent. of the boys came from the country and 30 per cent. only were London boys. He said also that 70 per cent. of the casual dock labourers in London were London boys and that 90 per cent. of the inmates of our larger common lodging houses, Salvation and Church Army shelters, were London boys.

THE BURDEN ON THE RATES.

Sir Henry Hibbert, the newly-elected member for Chorley, in a maiden speech which was listened to with great interest and attention, dealt chiefly with the financial side of education. He has been Chairman of the Lancashire Education Committee since its establishment. He welcomed the expenditure upon medical treatment and inspection; but complained that the grant was for treatment only as apart from inspection, and stated that in order to get the best results a grant should be made for the two together. In this opinion he appeared to be supported by the general sense of the House on all sides. He complained that the greatly increased cost of education during recent years had fallen on the ratepayers in very undue proportion. He stated that out of a total increased expenditure of his Board on elementary education of £921,508, the Board of Education had only contributed £100,225, and that in respect of higher education the proportions were about the same. Out of an increased expenditure of £451,901 the Imperial Exchequer had only granted £50,128.

MR. BALFOUR ON THE EVILS OF THE EXAMINATION SYSTEM.

A very important contribution to the debate was made by Mr. Balfour, who heartily welcomed the increased expenditure upon medical inspection and treatment. He said: "Undoubtedly the cost of education has gone up in consequence of the action of this House, and undoubtedly the Government have by their recent legislation forced upon the local authorities increased expenditure, and I admit have forced it upon them in a very good cause. Take the case of medical inspection, which is one of the causes. My

own sympathies are entirely in favour of medical inspection. I think many of my hon. friends agree with me that that is a great reform. I do not comment upon the details, but, broadly speaking, I call that a great reform, and I think it would lead us to an amount of knowledge connected with the health of the rising generation and the way to bring up successive generations which we do not possess at this moment. Therefore, my criticism upon the increased cost of education, so far as that branch of it is concerned, is not hostile except in so far as it bears out the statement that that charge was forced upon the local authorities by the Government and by this House, which is the statement I have already made. There are really only two questions that arise upon it. The first is, Can we in any way diminish this growing expenditure? Granting that there are lines of advance which are costly and necessary, is any of the cost which the Department and the House have imposed upon the local authorities unnecessary?"

Mr. Balfour supported the contention of Sir Henry Hibbert, and, with regard to the proportion of the cost contributed by the ratepayers and the taxpayers, he raised the general question whether we were really getting full value for the money we spent on education, and suggested that we had been led into pedantic and too narrow methods by wrong ideals, as an instance of which he criticized the examination system in the following terms:

Superstitions are very apt to grow around policies which may be adopted, but I should like to hear a really good commentary on our system of competitive examination. Ask any parent, from whatever class he may be drawn, who has a son at a secondary school or a university, what he most desires, and the answer will be, "Success in the examination." And so it goes on. I do not deny that in certain respects examinations, and even competitive examinations, are an absolute necessity. But I think we have got into the habit of talking of that which is an unhappy necessity as if it were an admirable institution. Examinations are really most soul-killing institutions. I believe they put the human mind absolutely in a wrong position with regard to knowledge. They are very bad for the teachers and very bad for the taught. You bear it said, "So-and-so's is a most admirable school, and he is the best teacher ever known." The question is asked, "On what ground?" And the reply is to the effect that a certain proportion of his scholars get such and such a number of exhibitions, or whatever it may be. That, and that alone, is the test by which we measure the merits of the system, the results upon the child or young man, and the benefit to the country. I believe it to be wholly and utterly wrong from beginning to end. I am quite aware that some of the praisers of the old system say that we got better men in the public service, and here and there, in the old times, when there was not this violent competition. I know they exaggerate greatly, but do not let the Committee believe there is no truth in what they say. There is some truth in it. We do know, and if we take the trouble we shall all know more of the manner in which you sap the vitality of the young and make them so admirably adapted to successfully pass examinations that, when they have passed them, they are successfully adapted to nothing else whatever.

Sir James Yoxall, Mr. Goldstone, Sir Philip Magnus, and other speakers joined in the debate, which was adjourned.

Medical Treatment of School Children.

In reply to Mr. Alden, Mr. Pease stated that the Board of Education was giving consideration to the question of allowing time spent on medical treatment to count for grant; but he stated that, under the grants now given, more money is received on account of the treatment than is lost through absences of children from school.

Schools for Tuberculous Children.—In reply to Mr. Hoare, who inquired as to how many schools, residential and day, there are for tuberculous children, and how many of them received grants from the Board of Education or local education authorities, Mr. Pease stated that there are seven residential hospitals or sanatoriums providing accommodation for 451 children, that are certified and receive grants from the Board of Education, and that

these hospitals are almost exclusively devoted to the treatment of children suffering from surgical tuberculosis. There are nine non-residential open-air schools certified and receiving grants which make provision for 810 children, of whom the majority are tuberculous. All the open-air schools and five out of the seven hospitals or sanatoriums are provided by local education authorities.

Small-Pox.—In reply to Mr. Crooks, Mr. Herbert Lewis stated that, according to information supplied by the medical officer of health to the Port of London Sanitary Authority, the four cases of small-pox recently landed from a liner had been vaccinated in infancy and that none of them had been successfully revaccinated. They had all suffered from a modified form of small-pox.

Sheep Disease.—In reply to Mr. Charles Bathurst, who asked whether the Board of Agriculture would publish information as to the use of turpentine in the treatment of sheep afflicted with *strongylus contortus*, at present very prevalent in the south-eastern counties, Mr. Runciman replied that the veterinary advisers of the Board were of opinion that the use of turpentine in sufficient doses to be of value would be dangerous, and that the Board at present, pending the results of investigations now in progress, was unable to advise a remedy for this disease.

Employment of Children Bill.—A bill has been presented by the Home Office to limit the employment of children and young persons in connexion with street trading and other matters. The first clause extends the age from 14 to 16 in respect of the by-laws which may be made under the Employment of Children Act, 1903, for regulating the employment of children and for prohibiting the employment of children in carrying or moving heavy weights and in injurious occupations.

Most of the remainder of the bill restricts the street trading of children and young persons. Clause 2 provides that a boy under the age of 17 or a girl under the age of 18 shall not be employed in or carry on street trading, except that a boy under that age who was lawfully engaged in street trading before the passing of the Act may continue his employment if he holds a licence granted under the Act. These provisions, however, do not apply to boroughs or districts having a population of less than 10,000 persons or to rural areas; but in any of these areas, it is to be lawful for any children over the age of 11 to be employed in or carry on street trading. The local authority is empowered to grant licences for street trading and may make arrangements with any committee constituted under the Education (Choice of Employment) Act, 1910, for giving advice and assistance to juvenile applicants. No licence shall be granted, however, to a boy for whom the authority is able to secure other and more beneficial employment suitable to his capacities and within a reasonable distance of his home; but a licence shall not be refused on the ground of poverty or of the character of the applicant, and not except on special grounds stated in writing by the authority. A condition may be imposed requiring attendance at continuation classes. An exception, however, with respect to street trading is made in favour of children over the age of 14 who are bona fide employed in assisting their parent or guardian in street trading in a proper manner and where the trade constitutes the principal means of support for the family. There are various provisions as to licensing, penalties, etc., and the definition of street trading does not include the sale in a market or fair of agricultural or horticultural produce by a person in the employment of the producer or the occasional sale in streets and public places by those engaged in delivering articles of a similar class from door to door to the customers of their employer.

Animals (Anaesthetics) Bill.—A bill has been presented by Mr. Walter Guinness, supported by Dr. Addison, Sir Frederick Bawbur, Lord Henry Cavendish-Bentinck, Mr. Butcher, Mr. Courthope, Mr. Greene, Colonel Lockwood, Sir Charles Ross, and Mr. Snowden, for requiring the administration of an anaesthetic to horses and dogs in connexion with

certain operations of veterinary surgery. The operations are specified in the schedules. In the case of horses it is required that the animal should be under the influence of some general anaesthetic sufficient to prevent the animal feeling pain in operations for radical operation for quitor, line firing, operation for stripping the sole, radical operation for poll evil, and radical operation for fistulous withers and, in the case of castration, of horses of more than 2 years of age. The operations mentioned for dogs are ovariectomy and castration, and the third schedule requires the administration of a local or general anaesthetic in horses for neurectomy or unnering, enucleation of the eyeball, and trephining. A general anaesthetic is held to include, for the purposes of this Act, chloral hydrate and, in the case of a dog, morphine.

Veterinary Surgeons Act Amendment Bill.—A bill has been presented by Sir Frederick Low which provides for the registration of existing practitioners styling themselves veterinary surgeons, and enables the Royal College of Veterinary Surgeons to conduct examinations, prosecutions, and inquiries against unqualified persons, and to have jurisdiction over the *Register* of veterinary surgeons, and to secure the protection of registered veterinary surgeons from unqualified persons practising as such under the cover of registration under the Joint Stock Companies Act.

Bill to Abolish State Vaccination.—A bill has been presented by Mr. Black, supported by Sir John McCallum, Mr. James Parker, Mr. Kellaway, Mr. George Greenwood, Mr. Snowden, Mr. Chancellor, and Mr. Pointer, to repeal the Vaccination Acts. The bill would prohibit any public money being provided for the performance of vaccination, or for the supply of lymph, and it makes it unlawful to require vaccination as a condition of admission to public employment, and to make the absence of vaccination illegal as a ground for the rejection from employment in any public or parochial service, or public institution, charity, hospital, or school.

Admiralty and Board of Trade Sight Tests.—Mr. Robertson, in replying to Mr. Cathcart Wason on April 14th, said that the principal difference between the sight tests used by the Admiralty and those recommended by the Departmental Committee on Sight Tests was that, for testing colour vision, the former used the Edridge-Green lantern and a test with assorted coloured wools. The methods recommended by the Committee consisted of a lantern specially designed and constructed for them, and a somewhat different wool test, and these tests were described in the Committee's report. For testing form vision, Snellen's test types are used by both departments, but he understood that the standard of form vision required by the Admiralty was higher than that which the Board of Trade proposed to enforce on and after January 1st next. Mr. C. Wason: Is the hon. member aware that there is a very considerable amount of dissatisfaction among the mercantile officers over this question; that there has been a very serious diminution in the number of persons who have been tested recently at Liverpool, and that a very large number of candidates have been rejected? Mr. Robertson: The two lines of the questions run in opposite directions. Now the complaint is that the tests of the Board of Trade are too strict, whereas the questions previously put with regard to sight tests suggest that the tests were not strict enough. Mr. C. Wason: The mercantile marine prefer the Admiralty test to the Board of Trade test. Mr. Robertson: We have been told in the House that the Admiralty test is more strict than the Board of Trade test. Mr. Lynch: Has the hon. member considered the advisability of abolishing the wool test altogether as being unscientific? Mr. Robertson: The wool test in its revised form is not unscientific, and the Admiralty use that test.

DURING the last session of the New Zealand Parliament a bill to amend the Births and Deaths Registration Act was passed. Registration under the new Act came into force on March 1st. One of the most important of the new regulations provides for the notification and registration of stillbirths.

Scotland.

[FROM OUR SPECIAL CORRESPONDENTS.]

TUBERCULOSIS ADMINISTRATION IN EDINBURGH.

As was stated briefly in our last week's issue (p. 791) the town council of Edinburgh considered the report of its Public Health Committee on the expenses involved in the new arrangements for tuberculosis administration, and referred the matter back to the Public Health Committee and to the Treasurer's Committee. Several speakers referred to the serious responsibilities the Council was taking upon itself and to the enormous expenses it was slipping into. On the other hand it was pointed out that it was impossible to go on treating tuberculosis under the present method, and that unless the Council was prepared to let the public health administration pass out of its hands, and set up the Insurance Committee as a sort of semi-independent authority, it must provide the administrative machinery. The medical officer of health had not time to give to the examination and determination of cases. It would be dangerous to allow a separate authority to be set up in the city, and it would be almost impossible to work through two authorities; further, before it could get a share of the Treasury grant from the two millions voted for tuberculosis the Council must formulate a scheme remitting the matter to the two committees for further report. It was agreed that a report should also be asked for on the estimates submitted by the Insurance Committee.

In connexion with the proposals for the erection of extensive new buildings for the treatment of tuberculosis, the *Scotsman* for April 11th prints a letter of protest from Dr. C. B. Gunn of Peebles. Dr. Gunn thinks "palatial sanatoriums" quite unnecessary. All that is wanted for the successful treatment of consumption is open-air shelters dotted over a hillside facing the south, and surrounding a central administration block. Dr. Gunn states that shelters can be erected by any country joiner at £8 each, and furnished for £4 more. Two hundred such shelters, therefore, would cost £2,400. The administration block with water supply and drainage need not cost more than £3,000; an additional sum of £1,000 would provide for 200 patients two large common rooms for the two sexes, to be used only during the daily cleaning of the shelters and in stormy weather. A male sick-room and a female sick-room with offices could be erected for an additional £1,000. The buildings would all be of wood and galvanized iron; and the total cost for 200 patients would be £7,400. Critics are inclined to ask what will be done when a hillside facing the south cannot be obtained.

TUBERCULOSIS ARRANGEMENTS IN LEITH.

At a meeting of the Leith Burgh Insurance Committee held on April 9th, Dr. William Robertson, the medical officer of health for Leith and medical adviser to the committee, stated that the number of cases of pulmonary tuberculosis notified in Leith during 1912 was 307. At present the local authority was treating twenty insured persons in the sanatorium approved by the Local Government Board, and if the committee had only to deal with insured persons these beds would suffice, and the cost would be £1,560 a year at the present charge of 30s. a week. Should, however, sanatorium benefit be extended to the dependants of insured persons, the local authority would be called upon to erect extra accommodation, capital charges would be increased, a larger staff would be needed, and buildings to house the supplemented staff; and altogether from forty to fifty patients would have to be accommodated all the year round for a few years at least until the incidence of the disease was reduced. The cost of treating fifty patients all the year round would be approximately £4,500 including, say, £600 for capital charges; in addition, say, £650 for dispensary treatment would have to be found, a total of £5,150. The Insurance Committee agreed to remit the report to a joint meeting of the Sanatorium and Finance Committees.

MEDICAL TREATMENT AND THE EDINBURGH SCHOOL BOARD.

The Public Health Committee of the Edinburgh School Board is faced with financial difficulties regarding the continuance of medical treatment. It was stated in March that the grant of £850 allocated to the board would be totally

exhausted by the end of the month, and the Department had not yet made intimation of the sum to be assigned for the coming year. A continuance of the present scheme of treatment will involve an expenditure of £114 18s. 7d. a month, including an estimated fee to the Edinburgh Royal Infirmary for the x-ray treatment of skin diseases. Calculating the salaries of the dentists and oculists as for ten months a year, the sum will amount to about £1,238 per annum. The Scottish Education Department has since informed the Committee that for the purpose of medical treatment a sum similar to that of last year (£7,500) has been set aside in the Scottish Estimates, but that at present the Department cannot state what proportion of that sum will be allocated to the Edinburgh Board.

MEDICAL INSPECTION OF SCHOOL CHILDREN AT LEITH.

Dr. Arthur S. Walker, the medical officer to the Leith School Board, in his report on the inspection of the school children for the year ending June, 1912, states that in only ten instances did the parents object to the examination of their children taking place in school, and in three of these cases the objections were withdrawn later. There were probably at least fifty defective children who would derive benefit from a special school. The necessity for an open-air school was now greater than ever, for it was almost certain that under the Insurance Act the consumptive wards at Pilton would be filled with adult patients. The proportion of unvaccinated children was not large, but it was matter for regret that it was showing a gradual increase. In all 10,374 children were seen during the year. Nasal obstruction was detected in 395 cases, slight enlargement of the tonsils in 200, and great enlargement in 169; there were 50 children with marked deformity due to rickets. There was great need for medical inspection rooms, so that the work could be done with as little derangement as possible of the school routine. More satisfactory results could have been got in the skin cases had x-ray treatment been available. As there is no x-ray installation in Leith, Dr. Walker suggested that it might be possible for the school board to co-operate with the hospital directorate in the installation at the hospital of a suitable x-ray apparatus, utilizing for that purpose a part of any funds allocated to them by the Education Department for the medical treatment of school children.

Ireland.

[FROM OUR SPECIAL CORRESPONDENTS.]

TREATMENT OF TUBERCULOSIS.

At the last meeting of the Dublin County Council a resolution was adopted empowering the County Council Insurance Committee to make all necessary arrangements for sanatorium treatment suitable to cases of tuberculosis occurring amongst persons other than insured persons or their dependants, and to make suggestions as to the treatment of all cases dealt with under the Insurance Act.

THE DUMPING OF LUNATICS FROM AMERICA.

At a recent meeting of the Clonmel District Lunatic Asylum, the Resident Medical Superintendent, Dr. Harvey, referred again to the very serious aspect of the deportation of insane people from America. The number of persons sent back from asylums in America was large and increasing. One or two instances had occurred since the last meeting. In one the patient had been fifty years in America when he was sent home; on landing he had been put into the train in Dublin and left to find his own way. Another patient had been fourteen years in an asylum in America when sent back to Ireland. In another instance a young man was landed at Queenstown and a telegram sent to his brother in Queen's County. He was brought home and eventually taken into the asylum. The same difficulty has arisen in Cork District Asylum; patients are dumped in Queenstown and sent up to the Cork Asylum irrespective of whether they are of Cork extraction or not. Both Clonmel and Cork Asylums are already overburdened. Dr. Harvey undertook to make out a list of people deported during the last few years, and it is proposed to bring the grievance to the notice of members of Parliament.

England and Wales.

(FROM OUR SPECIAL CORRESPONDENTS.)

BIRMINGHAM.

THE INSURANCE ACT IN BIRMINGHAM.

NEARLY all the doctors in Birmingham are continuing their services under the National Insurance Act after their first three months' experience of the working of the Act. Some have a very large number of insured persons on their lists, 3,000 and even more, and they find that the percentage of these who require treatment is very much higher than they expected. Some of these people seem to delight in having a doctor of their own, and come to him for the most trivial causes and much more frequently than they need. This is shown very markedly by the way in which the state of the weather affects attendance. On a fine day a large crowd attends the surgeries, while on a wet day only a few patients make their appearance. It is found, however, that the doctor is rarely called unnecessarily to visit insured patients, and that, therefore, the home visiting is not appreciably increased. The most popular doctors are so overwhelmed with the number of patients who attend that thorough examination becomes difficult or impossible.

A few of the approved societies will not accept certificates for sick pay unless they are signed by a doctor on the panel, and this interferes with patients making their own arrangements for treatment with doctors who are not on the panel. The number of insured persons who have not put their names down to any doctor is nearly one-third of the total number. Difficulties will probably arise when these persons are allocated to the panel doctors, as those who have a large number already on their lists will refuse to accept any more.

The National Insurance Act has considerably increased the work of the doctors generally, and so interferes with other important aspects of the lives of medical men. The officers of the Royal Army Medical Corps (Territorial Force) in Birmingham find it very difficult now to attend drills and give lectures and other instructions. On Friday nights there used to be a mess dinner at the R.A.M.C.T. head quarters before the territorial work of the evening, but that has had to be abandoned. Some officers have resigned their commissions, and it seems almost impossible to get new officers. It would appear that the officers of the R.A.M.C.T. will in the future be drawn only from doctors not on the panels, from consultants and specialists, and from dentists with medical qualifications; these are not enough to supply the required number of officers. It is reported that the St. John Ambulance Association in Birmingham has encountered the same difficulty.

Insured patients are not treated in the Birmingham hospitals unless they require special hospital treatment which cannot be given by their panel doctors. The result is that the number of in-patients has remained about the same with a tendency to increase, but the number of out-patients has been diminished by nearly one-half. At the general hospitals the out-patients consist chiefly of women and children. Insured patients are frequently sent by their doctors for consultations at the hospitals, and the consultant writes his opinion to the doctors, but does not treat the patients unless the treatment cannot be carried out at home. A few patients who have entered their names on panel doctors' registers still attempt to get treatment from the hospitals rather than from those doctors. This is, however, gradually diminishing, for all the hospitals are working together in this matter, and refuse treatment to such applicants.

In Birmingham there is a Hospital Saturday Fund which has reached for many years now to over £20,000 per annum, the contributions being received from numerous firms all over the city; a tendency to a decrease in these subscriptions is now noted. As the hospitals are needed quite as much as ever for consultations, special treatment, in-patient treatment, and for dealing with accidents, the workpeople are beginning to realize that they must continue their subscriptions or the work of the hospitals must be greatly curtailed. At first it was thought that the hospitals would suffer greatly from

loss of financial support, but the outlook is now brighter for many of the subscriptions which were withdrawn have been commenced again.

The treatment of pulmonary tuberculosis is a difficulty, as the health department seems disposed to take over completely the patients suffering from this disease. This is a serious matter for the clinical teaching in the hospitals, but it is hoped that the general hospitals will be recognized as institutions where pulmonary tuberculosis may be treated, and that the hospitals will receive some grant towards the expense of looking after this large class of patients.

LIVERPOOL.

MEDICAL INSPECTION OF SCHOOL CHILDREN.

THE education authority has established a clinic for the X-ray treatment of ringworm and has appointed Dr. W. C. Oram to the charge of it. The question of establishing a dental clinic is still under consideration. A dental clinic supported by voluntary contribution has been working by way of experiment, and it is possible that within the next few months the undertaking will be taken over and become a permanent establishment financed from the rates.

TREATMENT OF TUBERCULOSIS.

The scheme for the treatment of tuberculosis is being developed. Dr. S. McLelland, Assistant Tuberculosis Officer, with charge of the central dépôt, is to have the assistance of two other tuberculosis officers, one for the north and the other for the south end of the city. Park Hill Hospital will be altogether devoted to tuberculosis, and tuberculosis wards for 250 beds will be built at Fazackerley.

LONDON.

THE AMBULANCE SERVICE IN THE METROPOLIS.

AT the meeting of the London County Council on April 15th, the General Purposes Committee reported that letters had been received from the Hammersmith borough council and the Westminster board of guardians supporting the proposal of the County Council to utilize for the purpose of an ambulance service in London the appliances and ambulances of the Metropolitan Asylums Board, the Port of London Authority, the metropolitan borough councils, and the boards of guardians (BRITISH MEDICAL JOURNAL, November 16th, 1912, p. 1419). Mr. H. L. Jephson, a former chairman of the Public Health Committee, in moving the reference back of the report suggested that information should be obtained as to attitude of the other borough councils and boards of guardians of London towards the Council's proposals. The last Council and the one before it had taken an utterly insincere view of the ambulance question, and he appealed to the members who had just been elected to approach the matter open-mindedly and without party bias. The Council, as the only body vested by Parliament with power to deal with this matter, was responsible for the deaths of large numbers of people whose lives might have been saved had an efficient ambulance service been available. Mr. F. Briant urged that the existing ambulances owned by boards of guardians and other bodies could not be made definitely available to the Council, so that the proposals of the General Purposes Committee were fallacious. In Lambeth, a borough stretching from Westminster Bridge to the Crystal Palace, there were three ambulances belonging to the board of guardians, but these were fully occupied. There was also an ambulance attached to a small-pox hospital, but this could hardly be regarded as a suitable vehicle for the conveyance of ambulance cases. The committee should bring up a definite statement of the number of ambulances actually available in each borough. Mr. H. J. Greenwood, Chairman of the General Purposes Committee, denied that there had been any desire to burke the question. The committee had taken every step it thought desirable to get information, and had come to the conclusion that, on the whole, a more efficient service would be provided by utilizing existing agencies than by putting the ratepayers to the enormous expense of establishing an entirely new organization. On a division the amendment was lost by a large majority, and the report was adopted.

WALES.

KING EDWARD VII HOSPITAL, CARDIFF.

At the last meeting of the board of management of the King Edward VII Hospital, Cardiff, the resignation of Dr. Herbert Vachell, senior physician, due to his having reached the age limit, was accepted with regret, and he was appointed consulting physician. The chairman and Colonel Bruce Vaughan both paid tributes to Dr. Vachell's long and distinguished services. His association with the hospital had, Colonel Vaughan said, practically covered a period of thirty-six years, as he had been appointed house-surgeon in 1877, when the hospital had only one resident. He had been a member of the honorary medical staff for twenty-eight years, and for two years chairman of the medical board. Great advances had been made in the hospital during Dr. Vachell's period of service, and he would take with him into his retirement the gratitude of every member of the board, of all those who had worked with him, and of thousands of patients who had to thank him for his skill and devotion during their hour of sickness and trial in the hospital. At the same meeting twelve members of the board of management were elected to serve on the newly constructed election committee; the first duty of this committee will be to fill the vacancies created by Dr. Vachell's retirement and the death of the late Dr. Arthur Taylor.

Special Correspondence.

PARIS.

Congress on Physical Education.—Inauguration of New Hôpital de la Pitié. Results of Operations on Ovaries.

THE recent Congress of Physical Education at the Faculty of Medicine in Paris under the presidency of Professor Landouzy was even more popular than usual, and received great attention both from the medical and the lay press. This was due no doubt to the present movement in France in favour of all forms of sport, physical exercise, and military training.

The new Hôpital de la Pitié was opened on March 20th by the President of the Republic. The hospital, which contains 958 beds, is constructed on modern lines. On entering the central avenue to the hospital, the administrative block is seen on the left, with out-patient dispensary and waiting rooms. The pavilions, of three stories, are disposed in the form of an H. Two blocks are assigned to the medical section, each block containing three services, one on each floor. One branch of the H is for males and one for females. A male ward contains forty beds and has three isolation rooms; a female ward thirty-two beds and eight isolation rooms. The surgical quarters are smaller. Each service is subdivided into two wards, one for clean cases and one for septic cases, and each ward has its operating theatre. The maternity section, containing eighty-five beds, is in a separate block situated far from either the medical or the surgical wards. The kitchen, laundry, disinfection, and sterilizing accommodation are well equipped.

At a recent meeting of the Academy of Medicine M. Walthier read a paper on the after-history of cases in which ovariectomy, partial or complete, had been performed. Of the 139 patients on whom he had operated between 1901 and 1912 he had been able to follow up 98. The cure was complete in 68, in 12 some tenderness still existed on deep palpation, in 6 there was still some spontaneous pain, and in 8 no improvement had resulted. Cases of partial resection of both ovaries or total resection on one side and partial resection on the other numbered 73, and of these 18, or 24 per cent., gave birth to children after the operation. In 2 cases, complete resection of one ovary and almost complete removal of the other, the women afterwards bore children.

AMONG a good many books of interest in the 129th catalogue of second-hand medical and surgical works issued by Mr. Henry Kimpton, of 263, High Holborn, we note Sir Jonathan Hutchinson's copy of the report on leprosy drawn up by the College of Physicians in 1867. It was freely annotated by him on interleaved pages, and bound up with a variety of cuttings from journals, maps, and letters bearing on the etiology of leprosy, a subject to which, as is well known, he has devoted great attention.

Correspondence.

TRADE UNIONISM AND MEDICINE.

SIR,—The future organization of the profession is a matter of the greatest importance, and you have opened your columns lately to a discussion of the trade union aspect of the question. May I make a few further remarks on this head, prefacing them with the statement that I am a member of the National Medical Guild, and therefore somewhat enthusiastic on the point? That guild was formed with the idea that there were certain powers which the profession ought to have and which it could not obtain through any existing institution.

If this is the case it ought to be made plain, for our future organization can safely avail itself of almost anything but compromise; that will be fatal.

In the future almost all the profession will be under some sort of contract—some on panels, some Poor Law, asylum, public health (including the large number of part timers), or in other ways. The principles of state health insurance are sure to be extended, and even now there are contracts which are not exactly panel but are yet contracts.

I suggest that this state of affairs will make it necessary for the profession to have a fund to organize interference with these contracts in the form of a strike. It is not enough to compensate those who have struck or who have suffered: we must be in a position to organize striking.

I further suggest that if any body, not being a registered trade union, should organize a strike, it would be liable to attachment of funds on the grounds of conspiracy. Such holding up of the whole fighting fund might be caused by the action of a single obstinate member, perhaps prompted by some enemies of the profession, and we do not lack unscrupulous enemies.

I must confess that this seems to me a very dangerous position. I should like to know, without equivocation, whether the British Medical Association can—I believe it has been discussing the point—obtain immunity for its funds without becoming a trade union, and whether it can become a trade union.

I am a member of the British Medical Association, and shall continue a member, and I feel that I am entitled to ask this question. I have carefully studied the remarks of the solicitor to the Association, and it seems to me quite clear that the answer is in the negative. The British Medical Association can have a fund, held by the Council as a separate trust, and it can do some things with that fund, but it cannot do just the things which we shall need to do. It seems to me that if we compromise we shall be beaten in the next fight—and it is high time we thought about that next fight.

I have one more question: Can the British Medical Association undertake the return to Parliament of a member of the profession with the intention that he shall watch legislation in our interests and be the official parliamentary medium for our views? It would probably be better to have two members, one on each side, in order to avoid any party taint. I wrote to the Medical Secretary some two years ago on this subject, and he informed me it was being considered. As nothing has come of it, I suppose that the consideration was abortive. Again, it appears to me that it is of the first importance that we should have a definite official representative, and that the British Medical Association cannot provide one, owing to that action being quite outside any possible constitution that it could assume. This also, as the other, is a question allowing of a Yes or No answer; we have already tried treating the matter with a compromise.

May I in conclusion state that the National Medical Guild is advised that these two powers can only be obtained by registration under the Trade Union Acts, and that this body has been formed accordingly to obtain these powers, among others, for the profession. It is in no sense antagonistic to the British Medical Association, but supplementary. I am, etc.,

London, W., April 12th.

GORDON R. WARD.

THE FORM AND POSITION OF THE STOMACH.

SIR,—I have worked for the past three months at the Roentgeninstitut of the Allgemeines Poliklinik in Vienna, and I have been struck with the difference in opinion as

to the form and position of the stomach as expressed by your correspondents, and the teaching of Dr. Siegmund Kreuzfeldt at the Poliklinik.

I would like to give a brief account of his teaching. The patients are examined in the erect posture with the screen at 9 a.m.; no food has been taken after 8 p.m. on the previous evening.

The First Examination.—This is made before any barium is given. All that can be made out is the small round light area corresponding to the air bubble at the fundus of the stomach.

The Second Examination.—This is made after the patient has taken 6 oz. of barium water, and a view of the practically empty stomach is obtained. The air bubble is now seen to have a semicircular form, the base of the semicircle corresponding to the upper level of the fluid in the stomach. The shape of the stomach is not a J, but the pylorus is the lowest point. In normal stomachs the pylorus is in the middle line, or is on the left of the middle line, and it is directed towards the right side. It corresponds in level to the second or third lumbar vertebra.

The Third Examination.—This is made after a barium meal. The condition of the stomach now is not constant, and it may assume one of two types in the same individual.

Type A.—A well-contracted appearance of the stomach, which is filled with barium throughout, may be observed, with regular peristaltic waves, which begin at the middle of the greater curvature and pass to the pylorus. The shape of the stomach is tubular and forms a J with the pyloric part ascending, and with the pylorus looking upwards and to the right. At intervals some of the barium mass is seen to pass into the duodenum. The pylorus is always on the right of the middle line, and the greater the amount of the barium meal the more does the pylorus extend to the right. The pylorus may extend so far to the right that the masses which pass into the duodenum are directed from right to left until they reach the fixed vertical second part of the duodenum. In other cases the pyloric shadow entirely covers the first part of the duodenum, so that its barium content cannot be observed at all.

Type B.—After a varying interval the stomach shadow may gradually change in shape and Type B results. Instead of the well-contracted stomach, the badly or so-called hypotonic stomach is seen. The shadow is sac-shaped and the barium mass no longer fills the stomach, but sinks down to a certain degree. The greater curvature, which in Type A was in the upper abdomen, may now be seen in the lower abdomen. The pylorus is in the same position as in Type A, or it may even extend more to the right side. The stomach is quiet, no waves are seen, and no food passes into the duodenum. In cases in which the duodenum is not covered by the pars pylorica, we can see a light area between the pylorus and the duodenum—on the one side the shadow of the pylorus, which is convex, and on the other side the beginning of the duodenum, which appears concave and is applied to the convex pylorus. After an interval the shape changes again and Type A results. These two cycles alternate, and might be described as the systolic and diastolic phases of the stomach.

The changes are explained as being due to the reaction of the food mass in the duodenum. If the reaction in the duodenum is alkaline the shape A obtains, and the stomach contents are gradually passed in until a certain degree of acidity is present. Then the pylorus is closed, and the form B results. As the secretions from the antrae of the duodenum cause alkalescence again the shape gradually changes to type A, and when this phase exists for a certain time we may get the form and position of the practically empty stomach again.

The Fourth Examination.—This is made four hours after the meal, and the practically empty stomach is again seen with the pylorus on the left of the middle line.

It is very interesting to observe that these x-ray appearances exactly correspond to the positions of the stomach found by His in the formalin hardened specimens, with the stomach filled to a greater or lesser extent with food, in fifteen persons whose death was due to violence. These he described in the *Archiv für Anatomie*, 1903.—I am, etc.,

HAROLD BLACK, M.B., D.P.H.,

Makay Wilson Travelling Medical Scholar,
Queen's University of Belfast.

Vienna, April 8th.

SIR,—To judge from Dr. Hertz's last letter, in which he quotes remarks of Mr. A. H. Burgess and Dr. A. E. Barclay, and also from Professor Elliot Smith's letter, there appears to be considerable misapprehension as to my position in the discussion on this subject.

In order to be able to restore an abnormal stomach to a condition as near the normal as possible, one must have a conception of what the normal stomach is with regard to its position, shape, and especially motor functions, hence the importance of this subject to surgeons. I published my conception of this in 1908 (epitomising it in my letter of March 29th last), and nothing that has been published since has, so far, led me to change my view. At the interview referred to by Dr. Hertz, who states that Dr. Barclay demonstrated to me "the normal anatomy of the stomach with the x-rays," Dr. Barclay, as a matter of fact, regretted that he could not show me a normal case. He showed me several cases of probable duodenal ulcer, several of probable appendicular dyspepsia, one patient had marked gastropotosis, and another had possibly a gastric cancer.

While I stated my appreciation of Dr. Barclay's enthusiasm and courtesy, and the excellence of the x-ray work, it is impossible that I could have expressed myself as in any way convinced that my views of the normal stomach were wrong. I considered that, if anything, Dr. Barclay's demonstration supported my views. Dr. Barclay's ideas as to the position of the pylorus agreed with mine, and thereby differed from those of Dr. Jordan (whose work and results have received Dr. Hertz's approval). Dr. Jordan locates the pylorus of the normal stomach, shown in the *Archives of the Röntgen Ray* of January, 1911, as being opposite and to the left of the fourth lumbar vertebra, while Dr. Barclay places it at the level and to the right of the second lumbar vertebra, both the patients being in the erect posture. I regret that I used inadvertently, in my last letter, the word "practically" instead of *comparatively* with regard to the fixity of the pylorus. I agree that it may descend from opposite the first lumbar vertebra, which is its position when the patient is supine, to opposite the second lumbar, when the patient stands, but I deny that the pylorus of the normal stomach can be even pulled down, without damage, to opposite the fourth lumbar vertebra.

We have, therefore, two distinguished skiagraphists, both of whom are evidently relied upon by Dr. Hertz, giving widely divergent views. Does Dr. Hertz think that both views are correct? Dr. Hertz states that I alone seem to be "content to ignore recent advances in our knowledge." These recent advances in our knowledge of the form and position of the living stomach, according to Professor Elliot Smith as well as Dr. Hertz, are based upon radioscopic examination. The interpretations of Drs. Barclay, Jordan, MacLaren, and Daugherty (the latter two stating that normally the pylorus is practically a pelvic organ) in varying so widely show how far from being final some of the "recent advances" are! I fail to see how any one can be dogmatic, at present, if he is guided by x-ray work alone.

I should like now to discuss at greater length the question of the "middle sphincter," as I have called it for want of a better name. No one denies the presence of a sphincter at the pylorus, yet in some cases, as was many years ago pointed out by Dr. W. J. Mayo, the only way in which the pylorus can be located, when the abdomen is opened, is by finding the vertical vein which indicates the site of this sphincter. In such cases there may be no evidence of a sphincter, either on inspection or palpation, because it is completely relaxed. Still less will one expect to find evidence of the less definite middle sphincter, which after all only marks the beginning of the muscularly active pyloric part, especially when the muscle is relaxed under the influence of a general anaesthetic. It will be admitted, however, that the better the tone the better the action of the muscle, and the more suited will be the conditions for purposes of demonstration. In certain extragastric lesions which are causes of dyspepsia, such as duodenal ulcer or some forms of appendicitis, the stomach is in a condition of hypertonus. At least Drs. Barclay and Hertz say so, and I am perfectly in accord with them because one finds this frequently at operation. This fact has been drawn attention to repeatedly by other surgeons, for example, Sir Berkeley Moynihan,

At Dr. Barclay's demonstration to me in autumn, 1911, he admitted that in some of the cases a "check" occurred during the passage of food along the stomach at the point where I located the middle sphincter, and this even when the stronger pyloric sphincter was allowing food to pass, almost without delay. Dr. Barclay, after more recent research, writes in the *Medical Chronicle* of February, 1913, pp. 262 and 263, while discussing what he calls "duodenal irritation":

The stomach is invariably J-shaped, and not a trace of atony is observed; in fact, hypertony is often so marked that it may require quite a large quantity of food to canalize the empty stomach. Such cases are at first suggestive of an hourglass contraction, and in two of them (Nos. 97 and 273) I actually suspected the presence of an organic lesion half way down the stomach, because of the way in which the contraction of the walls resisted the passage of the food.

The action of gravity is an important factor in canalizing the empty stomach, and it frequently happens that at the lowest part of the organ there is a considerable pause in the progress of the food before it enters the pars pylorica. H. M. W. Gray, of Aberdeen, interpreted this sign as an indication that there is normally a sphincter at this point, probably indicated by the incisure of His, and on this theory laid it down that the stoma of a gastro-jejunostomy should be made beyond this point.

Dr. Barclay does not admit that this considerable pause is due to the action of a sphincter. It must be due to the action of a collection of circular fibres, and it occurs at the same part of the stomach in each case, "half way down"! Why, then, do Dr. Hertz and Professor Elliot Smith, as skilled impartial judges, object so strongly to the term "middle sphincter," a term used "for the sake of brevity" and "for want of a better name"? A study of Dr. Jordan's skiagram of the normal stomach shown in the *Archives of the Röntgen Ray*, January, 1911, will support my contention, published in the *Lancet* of December 3rd, 1910, that certain radiographers and others mistake this middle sphincter for the pylorus.

On a further perusal of Dr. Barclay's recent paper it is revealed that he has seen several cases where the spasm of this middle circular band of fibres is so intense, even after gastro-enterostomy has been done, that hourglass stomach was diagnosed, yet nothing was found at a subsequent operation "to account for the hourglass." This supports my statement, made in 1908, that the middle sphincter acts as well after as before gastro-enterostomy, and that one is able to obtain food from the cardiac end of the stomach, or see it there after a bismuth meal, even as long as 3½ hours after the food has been swallowed.

So much for hypertonic cases. With regard to normal stomachs, Dr. Barclay says (p. 261):

In many apparently normal stomachs a certain degree of spasmodic contraction of the middle of the body was noted, but in most of them the application of massage to the abdomen relaxed the spasm at once, but in a small number, notably Nos. 369 and 398, the contraction was thought to be organic in origin as it could not be relaxed by massage or the administration of belladonna. In Case 398 this spasm persisted, and was so definite that at my instance the surgeon again explored, and found nothing whatever to account for it; while in Case 369 the simple manipulation of the stomach was sufficient to effect a perfect cure, and re-examination after the laparotomy showed no trace of the contraction previously noted.

In no paper which I have seen has there appeared any explanation of why food should be checked at this part with such regularity as that recorded by Dr. Barclay. If a better name can be suggested than "middle sphincter" for this collection of fibres which so readily undergees "spasmodic" contraction, I shall be very pleased.

I may say here that a study of Dr. Barclay's paper confirms my conviction that any operative procedure which involves gastro-enterostomy should include investigation and also, when necessary and feasible at the same sitting, treatment of all parts, lesions of which may act reflexly and deleteriously on the stomach.

I am sorry that Dr. Hertz and his friends cannot understand the meaning of "Conclusion 3" in my letter of March 29th, because it seems quite clear to several medical men here in the north to whom I have shown the data on which it was founded and of which Dr. Hertz is cognizant. I have every hope that Dr. Hertz will understand the meaning of, even if he does not agree with, Conclusion 3, if he refreshes his memory by referring to my paper in the *Lancet* of December 3rd, 1910, and to that of Dr. Ribas, of Barcelona, in the *Archives of the Röntgen Ray*, January, 1911.

In connexion with this discussion I should like to ask Dr. Hertz the following questions: (1) Why, in certain cases after gastro-enterostomy, does a patient vomit bile for a few days and then stop as his strength increases? (2) Why, in certain of such cases, does the patient vomit bile-stained fluid which shows no trace of milk or other fluid which has been swallowed but a few minutes previously?

I have now read the report of Dr. Hertz's paper and the discussion on it as reported in the *Proceedings* of the Royal Society of Medicine, March, 1913. I am glad to find that the reports on which I based my criticisms did not omit or distort any detail which would have caused me to modify my objections to his views. I note that objections were raised also by several of the after speakers. I point out that I waited for a week before criticising Dr. Hertz's ideas as embodied in the reports of the BRITISH MEDICAL JOURNAL and *Lancet*. I thought he would be sure to correct at once any omission or statement which laid his views open to misconstruction.

I am sorry to hear that certain anatomists have gone so far as to accept for publication in their textbooks any drawings which are based on such conflicting data as skiagraphists have, so far, submitted. These observers, as I have shown, cannot agree about such a fundamental point as the position of the pylorus. It will be observed that Dr. Hertz has not made any references to these discrepancies.

In conclusion, I should like to point out that I prefer to base my conception of the normal stomach not only on skiagraphic findings but also on the work of anatomists such as Cunningham and Birmingham, and on what can be observed clinically and during operations, especially when the latter are conducted under local anaesthesia. The histological structure and pathological tendencies of the cardiac and pyloric portions would seem, further, to indicate that these parts of the stomach are naturally differentiated while performing their functions.—I am, etc.,

Aberdeen, April 14th.

H. M. W. GRAY.

IMMEDIATE OPERATION IN APPENDICITIS.

SIR,—As so much interest has been excited by the publication of Mr. Edmund Owen's paper in the JOURNAL advocating immediate operation in acute cases of appendicitis, I think that the following results of operation for this disease at the Hull Royal Infirmary may be instructive.

Our custom is to admit these cases in the first instance under the care of the physician of the week; if he can see the case at once, he almost invariably transfers it to the surgeon for immediate operation. If the physician is not able to see the case at once the surgeon of the week is sent for. In this way every case is operated on as soon as possible after admission.

The following is a copy from the report of the results of operation on the cases admitted during the year 1912:

| Appendicitis. | Cases. | Deaths. |
|--|--------|---------|
| Acute, with appendicectomy | 56 | 0 |
| Chronic, with appendicectomy | 52 | 0 |
| Abscess, with appendicectomy | 10 | 0 |
| With general peritonitis | 4 | 0 |
| Abscess, without appendicectomy | 54 | 4 |

In this series of 176 cases the 4 deaths were those in which the appendix was not removed, all being almost moribund. Our custom is when abscess has formed to be content with the evacuation of the pus, unless the appendix can be removed without separation of adhesions, but our statistics seem to point to the removal of the *fons et origo mali* in every case. During the past week I have operated on 4 cases, 2 of which were within thirty-six hours of the onset, and yet were only just caught in time to obviate a perforation.

I have no hesitation in advocating operation at the earliest possible moment.—I am, etc.,

EDWARD HARRISON, F.R.C.S.,

April 10th.

Honorary Surgeon, Hull Royal Infirmary.

ALIMENTARY TOXAEMIA.

SIR,—I am unfortunately unable to take part in the discussion on alimentary toxæmia, but feel I would like to add a fact of much value to the many that will doubtless be brought forward.

It concerns the case of a boy whose large bowel was removed by Mr. Arbuthnot Lane in Guy's Hospital in November, 1906. At that time the boy had intractable constipation, stasis, very marked toxæmic symptoms, and deep pigmentation, which rendered it impossible for him to follow his occupation and made his life unbearable. An interval of six years and four months have now elapsed, and he is a fine specimen of manhood; he is 5 ft. 11 $\frac{3}{4}$ in. in height, his weight is 11 st. 4 lb. as compared with 7 st. at the time of the operation; all the toxic symptoms have disappeared, the evacuations are formed, and he is enabled to follow a useful occupation, being now in perfect health.

I leave the facts of this interesting case to your consideration in view of the doubt which has been expressed by Dr. Hale White and others as to the subsequent history of these cases.—I am, etc.,

Wittersham, Kent, April 10th.

C. FORTESCUE PRIDHAM.

THE ACTION OF SALICYLIC ACID AND CHEMICALLY ALLIED BODIES IN RHEUMATIC FEVER.

SIR,—I have just read, on my return from a holiday, Professor Stockman's very interesting paper in the JOURNAL of March 22nd on the above subject.

There are some statements in it which I feel should not pass unchallenged; I cannot, of course, question his statement that with the *Micrococcus rheumaticus* "I have never been able to produce in animals any of the symptoms or lesions of rheumatic fever," but, at the same time, I can only express my greatest surprise. In the absence of details of experiments it is not possible to give an opinion as to cause of the failure, but I, and several other workers, find no difficulty in producing recoverable arthritis, relapses, etc. I have now inoculated a considerable number of rabbits, and in at least 80 per cent. of the cases arthritis has been produced where the organisms from definite rheumatic cases have been employed. Relapses have occurred in a considerable number of cases and endocarditis in a few. Again, Professor Stockman says, and I presume he is speaking of the organism isolated by me: "It is an organism difficult to grow satisfactorily and easily killed." This statement is absolutely contrary to my experience, for the organism grows with the greatest ease on ordinary culture media, lives almost indefinitely (at least three years without subculture) and resists 60° C. for over an hour.

I do not object to criticism, however severe, nor to statements that the bacteriology of acute rheumatism is still an undecided question. Every one has a right to his own judgement on the facts, but I do feel it is only fair that scientific workers, especially those of the standing of my friend Professor Stockman, should fully study the literature on the subject they are criticizing, and thus avoid such errors as I have pointed out in this paper.

In regard to vaccine therapy, Professor Stockman does not tell us whether the cases he has been dealing with were acute or chronic. As the paper deals mainly with acute rheumatism, I presume they were of that type. If so, then failure to produce curative effects, or even a reaction, does not in my opinion in any way invalidate the conclusions that the streptococcus is a causal agent in acute rheumatism. Recently Dr. Yates and I have been working at vaccine therapy, and at present, though the work is still incomplete, our view is that vaccines may prove useful in preventing relapses if used during the apyrexial period of the disease, but we are not prepared to speak very definitely on this subject at present.—I am, etc.,

Liverpool, April 8th.

J. M. BEATTIE.

RHEUMATOID ARTHRITIS.

SIR,—With reference to Sir James Barr's address on rheumatoid arthritis published in your last issue, I should like to ask him on what evidence he bases his opinion that the proximate cause of this disease is "a mild chronic acidosis, which extracts the lime salts from the fibrous tissue, muscles, nerves, cartilages, and bones." He further states that the extraction of the lime salts from the fibrous

tissue causes it to swell, while the loss of the lime salts from the muscles causes them to waste—two apparently contradictory statements. Sir James Barr is very iconoclastic in his attitude towards former workers and writers on the subject, but without venturing to enter into this special domain of his, I wish to take strong exception to a portion of one statement in the concluding part of his address, namely, that "arsenic, potassium iodide, guaiacol, and a host of remedies commonly prescribed are worse than useless."

I have employed guaiacol carbonate and potassium iodide in some thousands of cases, and I am convinced that this combination is capable in the great majority of cases of arresting the disease, and so of preventing the frightful suffering connected with movements of the affected joints, a condition which is so common in cases of unrelieved rheumatoid arthritis.—I am, etc.,

London, W., April 14th.

ARTHUR P. LUTE.

RECENT ADVANCES IN THE DIAGNOSIS, PROGNOSIS, AND TREATMENT OF HEART DISEASE.

SIR,—The letter from Dr. Thomas Lewis in your last issue does not call for comment, save that I consider the only course for Dr. Lewis to take after the appearance of the letters in the JOURNAL of March 22nd and 29th was to withdraw his insinuations and apologise. I very much regret that he has not done so. For the rest, I am satisfied to abide by the opinion of your readers who have followed the correspondence.—I am, etc.,

London, W., April 15th.

FREDERICK W. PRICE.

TUBERCULOSIS OFFICERS, SCHOOL MEDICAL OFFICERS, AND THE MEDICAL OFFICERS OF HEALTH (SUPERANNUATION) BILL.

SIR,—I should like to thank Dr. Alexander Graham for his timely letter in the BRITISH MEDICAL JOURNAL of April 12th, and to support his appeal for the urgent need of an amendment to the Medical Officers of Health (Superannuation) Bill, so that under "medical officers of health" school medical officers and tuberculosis officers will be included. The ranks of the medical officers of health in the future must be recruited from school medical officers, superintendents of infectious hospitals, and tuberculosis officers, and most of these officers look forward to entering the main branch of the public health service. I wish specially to urge the inclusion of tuberculosis officers for the following reasons:

1. They are whole-time medical officers, and as such are unable to augment their income by doing other work. A part-time medical officer of health is included in the bill. He usually has a large and lucrative general practice, and is in a better financial position than the tuberculosis officer.

2. Better men will undoubtedly apply for these posts if there is an assured superannuation scheme attached to them. The advantage to the community is obvious.

3. If medical officers of health are singled out for the superannuation scheme, and tuberculosis officers excluded, the latter will feel under a grievance which cannot favourably affect the harmonious relations between them which are necessary in the public interest.

4. It should be easy and practical to include tuberculosis officers because all these appointments are quite new, and therefore payments can be made in every case from the commencement of the appointment.

I trust every tuberculosis officer will support Dr. Alexander Graham in this important matter.—I am, etc.,

G. LISSANT COX,

Tuberculosis Officer for the County Palatine of Lancaster.

Preston, April 12th.

SIR,—Dr. Alexander Graham deserves the thanks of his colleagues in the school medical service for bringing this matter forward. The need for a scheme of superannuation in the case of medical officers of health is generally admitted, but strong as their claim is, that of school medical officers appears equally, if not more, urgent. By reason probably of the fact that the school medical service was instituted at a time when the financial burdens imposed upon local authorities had reached high water mark, the salaries paid for appointments of school medical officers compares very badly with those of their

colleagues in the public health service, and I think it has never been seriously suggested that the latter are overpaid.

As your correspondent points out, precisely the same arguments in favour of the superannuation of medical officers of health apply therefore with equal or greater force to the appointments of school medical officer. It is possible that tuberculosis officers may make a similar claim, but, seeing that as a class they are relatively better paid, I do not personally think that their claim is a matter of equal urgency.

It is to be hoped that all school medical officers will follow your correspondent's suggestions and bestir themselves with the object of securing, if possible, the necessary amendment to the bill in its Committee stage.—I am, etc.,

W. SPENCER BADGER,
(Medical Officer Education).

Wolverhampton, April 14th.

PREFERENTIAL PAYMENTS IN BANKRUPTCY.

Sir,—There is at present before Standing Committee B of this House a measure, entitled "A Bill to Amend the Law with Respect to Bankruptcy and Deeds of Arrangement."

As the law now exists under the preferential payment in Bankruptcy Act of 1838, there shall be paid in priority to all other debts, certain rents, rates, salaries, or wages of clerks, servants, workmen, etc. To these classes entitled to priority I sought to add—without success—the fees due to professional nurses. I instanced cases where, after prolonged attendance on a patient, they were obliged to accept a compensation of 2s. in the pound, the same as an ordinary trade debtor. I am confident that it only requires public attention to be drawn to the gross injustice possible to a noble profession under the existing law to have it altered.

If those interested or sympathetic will only speak out between now and the report stage of the bill, I have no doubt the necessary amendment of the law would appeal to the sense of justice of all parties in the House.

In my opinion the medical profession have also a strong claim for an amendment in the existing law, under which, as it is at present, their fees only rank as ordinary creditors'. I think that for some considerable time before a receiving order is granted their fees should rank with those entitled to priority of treatment.—I am, etc.,

House of Commons, April 15th.

PATRICK WHITE.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

EXAMINATION FOR APPOINTMENTS AS ACTING SURGEONS. AT the examination for the Naval Medical Service held on April 7th, 8th, 9th, and 10th, fourteen candidates were successful, and obtained the following marks:

| Name. | Marks. | Medical Schools. |
|------------------------------|-----------|---|
| Mr. A. M. Henry ... | 1,785 ... | Guy's Hospital. |
| Mr. G. F. B. Page, M.B. ... | 1,605 ... | Edinburgh University. |
| Mr. A. J. Patterson ... | 1,563 ... | Royal College of Surgeons, Dublin. |
| Mr. D. G. Arthur ... | 1,465 ... | St. Bartholomew's Hospital. |
| Mr. B. E. P. Sayers ... | 1,457 ... | Middlesex Hospital. |
| Mr. W. A. S. Duck ... | 1,455 ... | Middlesex Hospital. |
| Mr. P. B. Wallis ... | 1,413 ... | Cambridge University and St. Bartholomew's Hospital. |
| Mr. M. Mechan ... | 1,385 ... | University College, National University, Ireland, and Royal College of Surgeons, Ireland. |
| Mr. H. E. T. White, M.B. ... | 1,373 ... | Edinburgh University. |
| Mr. A. Simpson, M.B. ... | 1,343 ... | Edinburgh University. |
| Mr. F. C. Wright ... | 1,318 ... | St. Bartholomew's Hospital. |
| Mr. I. S. Gabe ... | 1,290 ... | London Hospital. |
| Mr. A. J. Tozer ... | 1,283 ... | St. Mary's Hospital. |
| Mr. D. P. H. Pearson ... | 1,283 ... | University College, Cork. |

The maximum number of marks obtainable is 2,400.

AN institute for the investigation of radium is now in working order at Heidelberg, and will be formally opened on May 1st. The director is Professor Ph. Lenard. There is a special medical department in connexion with the cancer institute and the medical clinic.

Universities and Colleges.

UNIVERSITY OF CAMBRIDGE.

THE following candidates have been approved at the examination indicated:

D.P.H. (Both Parts).—W. W. Adamson, A. Brownlee, G. R. Bruce, C. C. Cumming (Major, R.A.M.C.), A. da Gama, H. N. Featonby, R. D. Goldie, J. R. Haldane, A. B. Hamilton, W. Johnstone, M. J. Quirke (Captain, I.M.S.), T. Ruddock-West, W. Rutherford, F. V. G. Scholes, J. D. Smith, W. Templeton, F. E. A. Webb, A. R. Wellington, L. S. Willox.

* Passed with distinction.

UNIVERSITY OF LONDON.

SCHOOL OF MEDICINE FOR WOMEN.

THE Council has appointed Mrs. Willey, M.D., M.S., as Lecturer in Midwifery to succeed Mrs. Scharlieb, M.D., M.S., resigned.

The Dr. Edith Pechey Phipson Post-Graduate Scholarship of the value of £40 for one, two, or three years, will be awarded in June. Applications should be sent by May 31st to the Secretary. Entrance scholarships of the value of £60 for three or five years, £20 for four years, and £30 will be awarded on the result of an examination to be held on July 22nd and following days. The Agnes Guthrie Bursary for Dental Students, of the value of £60, will be awarded in September. All particulars can be obtained from the Secretary, 8, Hunter Street, Brunswick Square, W.C.

UNIVERSITY OF LIVERPOOL.

THE following candidates have been approved at the examination indicated:

D.T.M.—J. G. Becker, O. Forsyth, M. C. R. Grahame, K. K. Grieve, A. R. Hargreaves, P. Hiranand, O. E. Jackson, M. Mackelvie, J. McP. MacKinnon, R. J. A. Macmillan, C. E. F. Mount-Biggs, E. Olubomi-Beckley, D. S. Putlana, J. H. Reford, F. D. Walker, U. B. Yin, W. A. Young.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

A QUARTERLY Council was held on April 10th, Sir Rickman J. Godlee, Bart., President, in the chair.

Gifts.

A vote of thanks was passed to Dr. Charles Hose for the gift of skeletons of adult orangs and other specimens to the museum.

Prizes.

The Jacksonian Prize was awarded to Mr. F. W. Goyder, F.R.C.S., of Bradford, Yorks, for his dissertation on "The Embryology and Treatment of Cleft Palate."

The Triennial Prize, together with the John Hunter medal, was awarded to Dr. W. Blair Bell, M.R.C.S., of Liverpool, for his dissertation on "The Anatomy and Physiology of the Pituitary Body."

The subject selected for the Jacksonian Essay for 1914 is "The Pathology, Diagnosis, and Treatment of Trigeminal Neuralgia."

The subject selected for the Triennial Essay for 1913-1915 is "The Human and Comparative Anatomy and Physiology of the Cerebellum."

The Sir Gilbert Blane medals were awarded to Fleet Surgeon Richard Cleveland Munday, H.M.S. *Hyacinth*, 1910, and to Fleet Surgeon Edward Sutton, H.M.S. *Highflyer*, 1911, both members of the College.

Examiner in Dental Surgery.

Mr. F. Hopson, L.D.S. Eng., Guy's Hospital, was elected on to the Board of Examiners in Dental Surgery.

Central Midwives Board.

The thanks of the Council were given to Dr. Golding-Bird for his services as the representative of the College on the Central Midwives Board.

Disciplinary Action.

A member was removed in consequence of his advertisements and objectionable pamphlets in connexion with practices carried on in Sydney, New South Wales.

International Medical Congress.

A conversazione will be given on August 7th at the College to the members of the Seventeenth International Congress of Medicine.

ROYAL COLLEGE OF PHYSICIANS OF IRELAND.

The Fellowship.

At the meeting on April 4th the following candidates were elected to the Fellowship:

A. Croly; W. P. MacArthur, Captain, R.A.M.C.; R. J. Rowlette.

ROYAL COLLEGE OF SURGEONS IN IRELAND.

Appointments.

At a meeting on April 3rd Mr. J. S. Pegam and Mr. P. D. Sullivan were respectively appointed Senior and Second Assistant to the Professor of Anatomy.

CONJOINT BOARD IN ENGLAND.

The following candidates have been approved at the examinations indicated:

FIRST COLLEGE (Part I Chemistry, and Part II Physics).—N. J. Ainsworth, R. Aspinall-Stivala, *C. Bchencourt, F. Blake, H. H. Castle, A. M. Clément, B. S. Collings, *G. W. Coombes, *Jane Crawford, †B. Crossley-Meates, *F. G. L. Dawson, S. G. Dunn, S. E. D. A. El Daab, †A. A. H. El Zeiney, J. L. Goddard, J. P. J. Hagron, *W. R. G. Hoarnden, A. G. Hewer, J. Hope, †J. R. Houghton, *Mabel M. Ingram, T. C. James, M. Kamil, *P. Lloyd-Williams, H. McLeod, H. Masters, *H. Morris-Jones, A. Peine, E. R. Peirce, W. E. Powell, *P. Randall, F. H. Stuttaford, *F. Tagger, *C. W. Tomkinson, *C. Vincent-Brown, R. A. Walker, E. M. Webster, *G. A. O. White, B. C. Woodruffe.

* Part I only. † Part II only.

FIRST COLLEGE (Part III, Elementary Biology).—R. Aspinall-Stivala, E. R. Batho, E. G. P. Bousfield, H. W. Breese, C. H. Carroll, N. Chena, B. S. Collings, A. R. Crane, F. G. L. Dawson, H. S. Drabble, K. M. K. Duff, S. G. Dunn, H. Erskine-Gray, R. B. Gibson, J. L. Goddard, E. G. Harris, T. C. Higgins, J. Hope, R. Hope, G. H. Hyman, W. A. Jackson, A. K. I. Jones, A. E. A. Khar, E. G. Lunnion, K. F. McAlpin, A. Magill, R. K. Marwood, A. M. G. Mishad, K. R. O'Brien, A. L. S. Payne, G. A. Penman, W. B. Powell, D. S. Pracy, R. B. Rampling, F. N. Reynolds, A. H. Richardson, G. Looker, S. C. Shaw, C. Shelton, G. E. L. Simons, M. O. Sniapsen, B. L. Skeggs, H. L. Slaughter, R. M. Somersel, J. N. Terry, D. R. Thomas, H. B. Tronp, D. L. Wilson, L. H. Woods.

SECOND COLLEGE (Anatomy and Physiology).—A. W. C. Bennett, H. C. H. Bull, E. J. Coombe, G. L. Cutts, A. T. Dally, W. H. Dye, J. Fox-Russell, C. Gould, F. H. S. Greenish, P. E. Higgins, H. R. W. Husbands, R. W. Hodgson-Jones, H. L. Hughes, F. B. Jago, N. S. Jatar, J. Kyle, R. D. Langdale-Kelham, C. G. Learoyd, E. A. Levisour, S. J. L. Lindeman, R. W. Little, E. M. Litchfield, G. S. B. Long, L. A. McAfee, J. E. C. Maguire, R. H. Maingot, N. S. Neirne, N. V. Navalkar, J. P. M. Payne, F. Porter-Smith, E. A. Pritchard-Evans, I. I. A. Rahmea, E. D. Richardson, G. Robinson, E. S. Rowbotham, J. C. Russell, K. Sinha, J. B. G. Skelton, D. M. Smith, A. H. Warde, C. Whitehead, A. G. Williams, W. E. Wilson.

CONJOINT BOARD IN SCOTLAND.

The following candidates have been approved at the examinations indicated:

FIRST COLLEGE.—F. J. D. Cass, F. E. Gillieron, Martha H. Honbing, E. Butler, W. A. Mein, and E. A. Hamilton
SECOND COLLEGE.—J. J. Armistead, W. G. Bowie, *F. B. Macaskie, S. W. Hoyland, and J. V. R. Rohan.
THIRD COLLEGE.—A. Craig, Q. Stewart, A. F. Readdie, M. McL. Bainbridge, and M. Seeraj.
FINAL.—S. Wright, J. G. Lessey, W. A. Reardon, B. S. Raj, Kathleen G. Wall, J. S. E. De Soysa, G. A. Hodges, A. C. Fleming, J. W. Craig, W. Brenurn, E. B. Steele, J. A. Whittle, and S. Brennan,
* Passed with distinction.

CONJOINT BOARD IN IRELAND.

The following candidates have been approved at the examination indicated:

FINAL COLLEGE.—Mary J. Abern, B. N. Blood, J. Barrett, D. W. Beamish, H. J. Burke, P. D. Daly, A. J. Faulkner, F. E. Fitzmaurice, J. J. Glynn, T. J. Kelly, A. P. Kennedy, J. Kirker, V. J. Lawless, F. J. McCarthy, T. Mulcahy, C. Petit, C. L. Sproule, T. J. Sinnott, G. Wilson, W. Waugh.

A QUARTERLY court of the directors of the Society for the Relief of Widows and Orphans of Medical Men was held on April 9th, Sir Thomas Boor Crosby, President, in the chair. Fifteen directors were present. Four gentlemen were elected members of the society. The death of one of the widows in receipt of grants, who had been on the funds since 1872 and had received from the society the sum of £2,500, was reported. Her husband had paid in subscriptions 50 guineas. The Acting Treasurer, Dr. F. de Havilland Hall, reported that the society would shortly benefit to a very large extent under the will of the late Mr. James Brickwell, who was elected a member in 1833 and died in 1893. By his will he made the society his residuary legatee, subject to his son's life interest in the money. The total amount of the legacy will probably exceed £36,000. The invested funds of the society now amount to £101,600. The annual general meeting will be held on May 6th. Membership is open to any registered medical practitioner who at the time of his election is resident within a twenty-mile radius of Charing Cross. The annual subscription is two guineas, and there are special terms for life membership, which vary with the age of the candidate. Application forms for membership and further particulars may be obtained from the Secretary at the offices of the Society, 11, Chandos Street, Cavendish Square, W.

Public Health

AND

POOR LAW MEDICAL SERVICES.

TUBERCULOSIS IN MILK.

ORDER OF THE BOARD OF AGRICULTURE.

By the new Tuberculosis Order, issued recently by the Board of Agriculture to local authorities, which comes into operation on May 1st, the Treasury will refund to local authorities half the net amount payable by way of compensation for animals slaughtered during a period of five years from the coming into operation of the Order.

In a covering letter the Secretary of the Board of Agriculture states that it must be accepted as a fact that tuberculosis is transmissible by the agency of milk used for human consumption.

Any action which results in the reduction in the number of tuberculous bovine animals in the country must reduce the risk of the spread of tuberculosis amongst the community, and if it were possible to eradicate from this country the disease in animals, a material step forward would have been taken in the campaign against the disease in man. It is abundantly clear at the same time, the Board says, that any operations aiming at the diminution or eradication of tuberculosis in animals must be commenced with caution, and carried out with due regard to the extent to which the disease is believed to exist amongst cows, and to the importance of securing the continuance of an adequate milk supply, and of avoiding any disorganization of the important industry concerned.

The Order aims at the destruction of every cow found to be suffering from tuberculosis of the udder or to be giving tuberculous milk, as well as of all bovine animals which are suffering from tuberculosis with emaciation. While confining the provisions of the present Order to those forms of tuberculosis only, the Board has not lost sight of the fact that it may be possible in the future to take further action, but believes that heroic measures taken at the present time would only defeat their own object. Every local authority is charged with the duty of investigating reports received under the Order, with the assistance of a veterinary inspector, with a view to causing the slaughter of any animal in its district shown to be suffering from one of these specified forms of tuberculosis, and the veterinary inspector may extend his examination to any bovine animal that has been associated with the suspected animal.

Under Article 5 the local authority is required to cause every animal found to be suffering from tuberculosis to be slaughtered, the animal to be valued in its condition at the time. The compensation payable by the local authority for an animal slaughtered in cases in which the *post-mortem* examination does not show tuberculosis is a sum equal to the full value of the animal, and a further sum of 20s. Where tuberculosis is found the proportion of the value of the animal payable by way of compensation to the owner is made to depend upon the extent of the disease present. If the certificate of the examination shows that the animal was suffering from tuberculosis (not being advanced tuberculosis) the compensation to be paid to the owner is a sum equal to three-fourths of the value of the animal after deducting one-half of the costs of valuation. If the certificate shows that the animal was suffering from advanced tuberculosis, the compensation will be a sum equal to one-fourth of the value of the animal, or a sum of 30s., whichever sum is greater, after deducting from such sum one-half of the costs of valuation and examination. The Order prescribes the precautions to be taken in respect of the milk of suspected animals and their detention and isolation whilst under suspicion.

The Royal Commission on Tuberculosis established that a considerable amount of the tuberculosis in children is of bovine origin. Recent investigations have shown that a very large proportion of the cases of surgical tuberculosis operated on in the Royal Edinburgh Hospital for Sick Children were of bovine origin. It was, therefore, the duty of the Government to realize their responsibilities in this matter. It has now recognized that this form of tuberculosis is preventable, and that the only way to prevent it was by a more thorough system of veterinary inspection of dairy cows, and the slaughter of all those with tuberculosis of the udder as well as those suffering from general tuberculosis. The work of the Royal Commission showed that the latter class of cows were also capable of giving tuberculous milk.

Medical News.

DR. C. W. DANIELS will give a lecture at the Royal Sanitary Institute, 90, Buckingham Palace Road, S.W., on April 23rd, on insect-carried diseases and their prevention; the chair will be taken by Sir William J. Collins at 5 p.m.

COLONEL THE RIGHT HON. J. E. B. SEELY, D.S.O., T.D., Secretary of State for War, will present the prizes at the Royal Army Medical College, Grosvenor Road, on the conclusion of the 105th session, on April 29th inst., at 4 p.m.

THE President of the Royal Institute of Public Health and Countess Beauchamp will hold a reception at the house of the institute, 37, Russell Square, W.C., on Tuesday, May 6th, from 9 to 12 p.m., when academic dress will be worn.

A COURSE of post-graduate lectures at the Queen's Hospital for Children, Haelney Road, E., began on April 3rd, and will be continued until the middle of June. Further particulars can be obtained from the Honorary Secretary of the Medical Committee at the hospital.

AN Almoner, trained by the Hospital Almoners Council, Denison House, 296, Vauxhall Bridge Road, S.W., has been appointed to the out-patient department of the new South London Hospital for Women, which was opened on April 2nd. As the number of patients attending is not likely to be very large to begin with, the Almoner will, for the present, work half-time only.

A DINNER of the Brussels Medical Graduates' Association in connexion with the forthcoming congress in Paris of the Royal Institute of Public Health will be held under the Presidency of Dr. Harold S. Singleton at the Trocadero, on April 22nd, at 7.30. All graduates of the University of Brussels are welcome, and members are invited to bring ladies. Tickets 5s. (not including wine) may be obtained from the honorary secretary, Dr. Arthur Haydon, 23, Henrietta Street, Cavendish Square, W.

MANIFOLDIA, Limited, of West Bromwich, have placed on the market fitted cabinets for the filing in proper order for convenient reference of medical register cards and daily statistics cards used by medical practitioners working under the Insurance Act. The cabinets are made in various sizes, which are illustrated in an advertisement in this issue. The advantages of the card index method of filing are well known, and these cabinets seem well designed to meet the particular purpose.

THE nursing conference which we stated to be in preparation some months ago is to commence next Tuesday and terminate on the following Friday evening, the meeting place being the Technical Institute of the London County Council in Vincent Square, Westminster. The work will be done in two sections—nursing and midwifery. The former section will hold two sessions daily, and in both sections, apart from discussions, addresses in the nature of post-graduate lectures will be delivered by medical men. One of these we note will be an epidiascopic demonstration by Mr. Bishop Harman on the subject of ophthalmia neonatorum. The majority of the sessions, however, will be in discussions on socio-political rather than technical aspects of nursing work and midwifery: for example, the effect of the Insurance Act on nursing, the training of nurses for various special purposes, and the need of State registration and the formation among them of a national association.

THE Chadwick lecturer this year is Dr. J. T. C. Nash, County M.O.H. for Norfolk, who chose as the subject of his three addresses the evolution of epidemics. The first dealt with disease in the Middle Ages, it being maintained that bubonic plague was endemic in England for over 300 years before its final extinction after the great outbreak in 1565; it was also suggested that the theory put forward in the sixteenth century to the effect that bubonic plague was caused by a cadaveric poison fitted in with both Pectenkofer's theory of the influence of ground-water fluctuation on epidemic diseases and the most recent rat-infection theories. Incidentally it was also remarked that if the history of medical science were examined two diametrically opposite tendencies would be observed; one of these was to differentiate as distinct affectional diseases which previously had been included under one common designation, and the other to determine a persistency of type running through a long series of disorders of various designations. The second lecture dealt with specificity and evolution, more especially in regard to the events of the nineteenth century; while in the concluding lecture will be considered the scientific evidence as to evolution of epidemic disease available at

the present time. This lecture will be delivered on Monday, April 21st, being given, like the others, in the rooms of the Royal Society of Medicine.

THE good work accomplished by that branch of the National League for Physical Education and Improvement known as the Association of Infant Consultations and Schools for Mothers was manifested in a striking fashion by the competition in mothercraft held at the London County Council's Infants' Schools in Charing Cross Road on April 12th. The movement, started six years ago by Dr. Eric Pritchard, has for its object the instruction of working-class mothers in all that pertains to the care of their children, and the practical lessons of trained lady helpers who have undertaken this part of the work have produced the most gratifying results. The success of this attempt to improve the physique of the rising generation was amply demonstrated by the healthy happy babies who filled the rooms. The eighty-five mothers who took part in the contest represented the winners of competitions previously held at fifteen different London centres, and their efficiency and intelligence showed that the lessons they had received had borne good fruit. Each competitor was required to prove herself capable either of properly dressing, undressing, and tending her child, cutting-out and making or washing his garments, or preparing his food, and prizes and certificates of merit were awarded to the winner of the highest number of marks in each class. The prizes were distributed by Mrs. Boyd Carpenter, and at the close of the proceedings Bishop Boyd Carpenter expressed his appreciation of the work of the association.

IT has already been stated in the JOURNAL that Mr. Henry S. Welleome has for some years been organizing a historical medical exhibition. It will be open at 54, Wigmore Street during the meeting of the International Medical Congress in London next August. Among the large variety of exhibits will be a number of personal relics of Edward Jenner, including the lancets and scarifiers he used in his first experiments on vaccination, his case books and account books, and a large collection of his autograph letters. There will also be exhibited portraits of Jenner and members of his family painted at different periods, and illuminated addresses and medals presented to him. A list of portraits and statues of Jenner, medals, diplomas, honours, addresses, and so forth presented to him, was published in the special Jenner Number of the BRITISH MEDICAL JOURNAL which appeared on May 23rd, 1896. Some interesting exhibits relate to the history of anaesthesia. Among these are relics of Sir James Simpson and some of the earliest forms of apparatus for administering chloroform and ether, and the original autograph journal and manuscripts of Mr. Henry Hill Hickman, a forgotten pioneer of anaesthesia, an account of whom was given in the JOURNAL of November 25th, 1911, p. 1434, and April 13th, 1912, p. 843. Persons possessing any objects illustrating the history of medicine and the allied sciences who may be willing to lend them for exhibition are requested to communicate with the Secretary, 54A, Wigmore Street, London, W., who will be pleased to forward a complete illustrated catalogue.

A MEETING of the Duty and Discipline Movement, whose object is to combat the ill effects of the lack of discipline in modern homes, was held at the Caxton Hall on April 11th, with Professor Robert Saundby in the chair. A discussion on "Self-development and National Health" was opened by Dr. Eric Pritchard, who said that few people seemed to realize how largely the development of a child's character depended upon the formation of good habits at a very early age. The inculcation of such habits, however, must come from without, since the child would not develop them of his own accord, and hence the importance of bringing up children in an atmosphere favourable to the growth of such qualities as truthfulness, courage, and self-control. There was a tendency amongst parents to neglect their duty in this respect, and the training of future citizens was consequently left almost entirely in the hands of school teachers. In the course of his work as school inspector he had often been struck by the want of control of parents over their own children, who, though perfectly amenable to discipline during school hours, became absolutely uncontrollable directly they crossed the threshold of their homes. Mr. Alfred Tredgold said that the Duty and Discipline Movement was intended to counteract the deplorable results of the modern craving for ease and pleasure. Everything about the present age discourages the fostering of such old-fashioned virtues as thrift and industry; and the breakdown of the Territorial scheme showed to what a pitch the love of comfort had risen amongst the youth of the country.

Obituary.

SIR HENRY R. SWANZY,

SURGEON TO THE ROYAL VICTORIA EYE AND EAR HOSPITAL, AND
OPHTHALMIC SURGEON TO THE ADELAIDE
HOSPITAL, DUBLIN.

WE regret to announce that Sir Henry R. Swanzy died, after a brief illness, at his residence, in Dublin, on the evening of April 12th.

Henry Swanzy was a son of the late John Swanzy, a Freeman of Dublin, and was born in 1844. He was educated at Trinity College, Dublin, and graduated M.B. in 1865. He obtained the L.R.C.S. in the following year. He then went abroad and spent several years in study at the Universities of Berlin and Vienna, and was assistant to the late Professor von Graefe at his private ophthalmic hospital in Berlin. He acted as surgeon in the Prussian army during the campaign of 1866. He then returned to Dublin, and practised as a specialist in ophthalmology. In 1873 he became a Fellow of the Royal College of Surgeons in Ireland, and an M.A. of Dublin University. In 1888 he delivered the Bowman Lecturer before the Ophthalmological Society of the United Kingdom, taking as his subject the value of eye symptoms in the localization of cerebral disease. From 1897 to 1899 he was President of the society. From 1906 to 1908 he was President of the Royal College of Surgeons in Ireland. In 1905 he was granted the M.D. degree (*honoris causa*) in the Dublin University. He was also an Honorary D.Sc. of the University of Sheffield. In 1911 he received the greatest honour that the ophthalmologists of the world could bestow, when he was selected for the post of President of the Ophthalmological Section of the International Congress of Medicine to be held in London next August. He was the author of a *Handbook of Diseases of the Eye*

and their Treatment, which for many years was a standard textbook, and was recently published in an enlarged form under joint authorship. He also wrote the article on "Eye Diseases and Eye Symptoms in their Relation to Organic Disease of the Brain and Spinal Cord," in the *System of Diseases of the Eye*, published in 1900, and contributed numerous important articles to the *Transactions of the Ophthalmological Society* and to the medical journals.

Sir Henry Swanzy was surgeon to the Royal Victoria Eye and Ear Hospital, and to his exertions is largely due the erection of the present hospital, though he has not lived to see the original plans of the building completed. Sir Henry Swanzy as a man was respected by all, but his real character was only known to his intimate friends; behind a veil of modesty and shyness, which was apt to give the impression of brusqueness to those who did not know him well, was a rich sense of humour, a warm heart, and a great charity, always ready in private life to find excuses for those who failed.

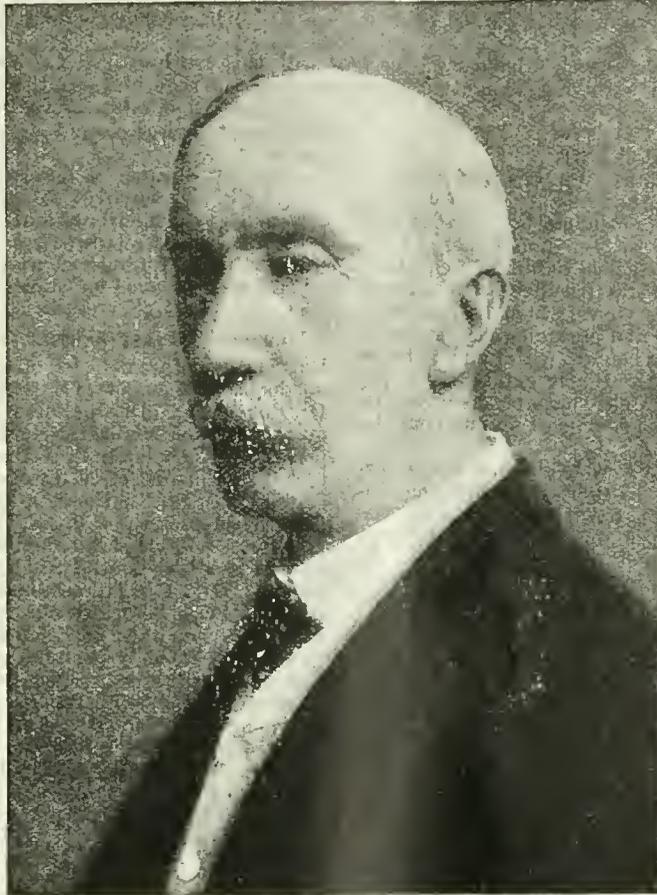

The writer of this notice can vouch for the truth of the

following story, which was typical of the man. A medical student who went to consult him about his eyes asked him his fee. Sir Henry said, "Nothing; dog don't eat dog." "Oh," said the student, "I'm not qualified yet; I am only a student." Sir Henry's reply was, "Neither does dog eat puppy." In public debate Sir Henry was unsparring and scathing to any whom he suspected of humbug and dishonesty of purpose, but with the honest striver, however inefficient, his patience was inexhaustible. His death will leave for long a blank, both in the profession and among his friends, that will be hard to fill.

Mr. PRIESTLEY SMITH, Emeritus Professor of Ophthalmology in the University of Birmingham, writes:

The news of the death of Sir Henry Swanzy, which reached me this afternoon, fills me with a sense of heavy personal loss. For very many years he has been not

only a leader among British ophthalmic surgeons, but, to those of us who knew him well, a highly valued friend. He belonged thoroughly to the present, but was a link with a distant past, for he had worked with von Graefe in Berlin. At the meeting of the British Medical Association in Cambridge in 1880, when Bowman and Donders received honorary degrees, Swanzy was there, I think, as a vice-president in our Section, already a man of grave and dignified appearance; and until quite lately he has been a frequent and active participator at meetings and congresses in this country and abroad. Time seemed to change him wonderfully little—always the same dignity with modesty, kindness, and humour. He threw himself with boundless energy into all that he undertook. No one who was present will forget his earnest, yet humorous, appeal to the members of the Ophthalmological Society when a change in its constitution was under consideration. A busy man no longer

SIR HENRY R. SWANZY.

[L. Holt and Fry, Ltd.]

young, he came from Dublin to speak and vote on a matter which was very near his heart, though of no importance to him personally, starting on his return journey a few minutes after having done so. I will not speak of his scientific eminence, of the great work which he did for his hospital, or of the high official positions which he had held and was still to hold. At this moment one thinks rather of his genial presence, of the delight of many meetings with him in the past, of his acts of friendship, and of the blank which his removal will leave among us.

Sir ANDERSON CRITCHETT, Bart. (London), writes:

A fraternal friendship had existed between Sir Henry Swanzy and myself for nearly forty years, and I cannot yet realize to the full the extent of the heavy loss which I have sustained.

"The old order changeth, yielding place to new," and his death breaks one of the few remaining links which connect us with the days of Donders, Bowman, my father, and von Graefe. He acted for some months as

assistant to the last named in Berlin, and he greatly valued his association with that remarkable genius, whose memory he held in lasting and profound veneration.

It was impossible to know Swanzy without loving him, for, with the highest qualities of intellect and of character, he combined a warmth of heart and a store of genial wit which attracted and held fast all who came within the range of his friendship.

He published one of the most excellent handbooks extant on diseases of the eye: it passed through many editions and is still in deservedly high favour; and the "Bowman lecture" which he delivered in 1888 has always taken rank as one of the best in that brilliant series, for it combined originality of thought and expression with diligent and successful research. He was ever an eloquent and a convincing speaker. Sir Henry Swanzy achieved the highest professional honours to which an ophthalmic surgeon can aspire, for he had been President of the Ophthalmological Society of the United Kingdom, and he was President-elect of the Ophthalmic Section of the International Medical Congress which is to be held in London next August.

"After life's fitful fever he sleeps well"; but our warmest sympathy will go out to the surviving daughters who mourn their irreparable loss.

Mr. J. B. LAWFORD (London) writes:

The death of Sir Henry Swanzy removes a well-known and striking personality from the ranks of our profession. One of the *doyens* of British ophthalmology Swanzy was widely known and as widely respected, and many of his colleagues and pupils were attached to him by ties which were closer than those of mere friendship. A man of decided character and strong views, which he was well able to maintain, his courtesy and charming manner were obvious to all who came into contact with him: to those who knew him intimately Sir Henry exhibited all the warmth and cordiality of his Celtic nature. As a host he was altogether delightful, and as a guest no one could be more pleasant.

No words of mine are necessary to enhance his professional reputation, earned by many years of untiring diligence. I have had many opportunities of admiring the thoroughness with which, during his later years, he kept abreast of modern developments in ophthalmology. In this he was greatly helped by his knowledge of other tongues, and especially of German, in which language he was proficient.

Rather more than two years ago Sir Henry was chosen as President of the Section of Ophthalmology of the forthcoming International Medical Congress, a selection which was a source of much satisfaction to ophthalmologists abroad, to many of whom he was personally known, and not a few of whom counted him an intimate friend. He accepted this office with considerable reluctance, and told me he was doubtful if he was physically fit for the labour it would entail. Having accepted office, he devoted much time and energy to the arrangements for the Section over which he was to preside and in which he took a keen interest. Last August he visited Heidelberg during the meeting of the Ophthalmologische Gesellschaft, and addressed the assembly, extending to the members a hearty invitation to the Congress on behalf of himself and his colleagues in this country. This year he had made all arrangements to go to Paris in May during the meeting of the Société d'Ophthalmologie Française with a view of furthering the interests of the Congress. His death, occurring so near the date of the Congress, is an irreparable loss to the Section of Ophthalmology.

TWO MEDICAL MISSIONARIES TO CHINA.

CECIL FREDERICK ROBERTSON, M.B., B.S.Lond.,
F.R.C.S.Eng.

DR. CECIL ROBERTSON, whose death from typhus fever took place at Sian Fu, Shensi, North China, on March 16th, was one of the capable young medical men who have recently joined the ranks of the Baptist Missionary Society. He was a student at Middlesex Hospital, and took the degrees of M.B., B.S.Lond., in 1907, and in 1909 he became F.R.C.S.Eng. He held the posts of house-physician and house-surgeon at the Middlesex Hospital, the latter appointment under Sir Alfred Pearce Gould. In

October, 1909, he went out to China as the colleague of Dr. Stanley Jenkins, and was stationed at Sian Fu, the capital of the province of Shensi, in North China.

When Dr. Jenkins came home on furlough in 1911 Dr. Robertson took charge of the hospital, and almost immediately after he was called to play a part in mitigating the horrors of the revolution, which in that part nearly resulted in the massacre of the missionaries, and did actually lead to terrible slaughter among the Manchus; some 15,000 were killed in Sian Fu on October 22nd and their heads were exposed on the city walls. The presence of Dr. Robertson in the city was one of the most important factors in the situation, for doctors were wanted, and Dr. Robertson was requested to go to the place where fighting was taking place and organize the ambulance department. Through scenes of the utmost horror Dr. Robertson worked with enthusiasm and skill, performing many operations when permitted to do so, though often the prejudices of the people hindered his work. After this he was called upon to operate on a brother medical missionary—Dr. Young—for appendicitis; the operation was successful.

All this work gained for him and his colleagues the gratitude of the Chinese authorities, which was shown by the presentation to him by the army of a tablet containing a laudatory address, and a red silk umbrella by the people.

A few days before his death he went a six days' ride to attend the sick child of a missionary; on his return he contracted typhus fever and died.

He was a manly Christian, and endeared himself not only to his fellow missionaries but the Chinese, and his funeral was attended by Chinese soldiers and officials.

HERBERT STANLEY JENKINS, M.D.Lond., F.R.C.S.Eng.

DR. STANLEY JENKINS died of typhus fever on April 6th, no doubt as a result of attending his junior colleague, Dr. Robertson. Dr. Jenkins was a distinguished student of the Bristol Medical School, where he won several prizes and scholarships, including a gold medal. He took the diplomas of M.R.C.S. and L.R.C.P. in 1898, the degrees of M.B., B.S.Lond. in 1901, and that of M.D.Lond. in 1903; he took the F.R.C.S.Eng. the same year.

He was not only well qualified as a medical man, but he was a leader in the Student Christian movement at Bristol; an appreciation appended from his friend, Dr. G. Basil Price, indicates the influence which he exerted. Like many another medical missionary, he exercised a great influence on boys amongst whom he worked.

For several years he held resident posts at Bristol and at St. Mark's Hospital, London. His most important work was done at the Mount Vernon Hospital, where he acted as registrar and pathologist. He wrote a report on Open-air Treatment of Consumption, published in 1901.

He went out to China under the Baptist Missionary Society in 1904 to Sian Fu in Shensi, North China. There he took charge of the medical mission work, and soon became its leader, and was greatly beloved by the Chinese.

He came home on furlough in 1911, and it was during his absence from China that the revolution occurred which has been described in the notes on Dr. Robertson's career. Whilst on furlough he did some post-graduate work in public health, but returned rather earlier than had been contemplated owing to the great strain which had come upon his colleagues. He reached China again at the end of 1912, only four months before his death.

Dr. Jenkins married the daughter of Mr. and Mrs. Thomas Loveridge of Llandaff, and his wife and children were at the coast when he was taken ill. She was able to take the two-weeks' journey to Sian Fu in time to assist in nursing him on his deathbed.

The loss of Dr. Jenkins is keenly felt not only by the Baptist Missionary Society, but by a wide circle of missionary friends. He was a thoughtful, cultured man of sterling character, unselfish to the core, and his place will be hard to fill.

DR. G. BASIL PRICE writes:

I first knew him as a school friend and afterwards at University College, Bristol, and though our friendship has only at long intervals had opportunity of being renewed, owing to his sphere of work being in China, I have never

lost the sense of personal attraction and sincere regard which he ever evoked in those who knew him.

He was to my mind an ideal medical missionary—ever imbued with the thought that his medical acumen, skill, and qualifications must be a proof, if such were needed, of his Christian spirit and work; for that reason he would not volunteer for his work abroad until he had taken the M.D.Lond. and F.R.C.S.Eng., besides holding important resident appointments.

His scientific qualifications did not spoil the missionary, but were to him weapons for that spiritual warfare in China for which he laid down his life. It will be for others to write from more intimate knowledge of his great, though all too brief, work in the land of his adoption. What will ever remain with me to his memory is the thought of his gracious, sympathetic spirit which lay behind all he did and said, and that never allowed his great personal gifts to obtrude themselves. He was in the highest sense a Christian gentleman, with enthusiastic love for his fellow-men and for his Master. A student leader in his earlier days, he became a devoted worker and leader amongst the Chinese, and had, as we hoped, a long life of untold influence before him.

Stanley Jenkins was one whose name will long remain fragrant with those who knew him, and whose influence has contributed to mould the destiny of that ancient though now young nation. His life and his death was that of the soldier who sought the battlefield and was ever ready to lay down his life, if need be, for the people he loved. Equally true might it be said of him as was said of Dr. Jackson by the Chinese Viceroy: "In life you were brave, now you are an exalted spirit. Noble spirit, who sacrificed your life for us, help us still, and look in kindness upon us all." Our keen sympathy will be freely given to his stricken wife and large family circle.

JOHN ROBERTS, M.D. EDIN., M.R.C.S. ENG.,

FORMERLY PRESIDENT OF THE NORTH WALES BRANCH OF THE
BRITISH MEDICAL ASSOCIATION.

We regret to announce the death of Dr. John Roberts, of Menai Bridge, Anglesey, on March 16th. He was born at Crug, Carnarvonshire, in 1837, and studied at the University of Edinburgh, University College, London, and later in Paris. He took the diploma of M.R.C.S.Eng. in 1859 and the degree of M.D. Edinburgh in 1861. Shortly afterwards he was appointed house-surgeon at the Royal Maternity Hospital, Edinburgh. He started practice in Manchester, and was a contemporary of Dr. Thorburn, Dr. Cullingworth, Dr. Dreschfeld, and Mr. Tom Jones. He was consulting physician to the Southern Hospital for Diseases of Women and Children, president of the Manchester Ethical Association, and honorary secretary of the Manchester and Salford Sanitary Association. He remained in Manchester for some years, where he developed a very successful practice, and was strongly advised by Sir William Roberts to remove to London. The delicate health of his wife, however, decided him to retire to Menai Bridge, Anglesey, in 1865, where he practised chiefly as a consultant.

As a man of high professional repute, and one who realized to the utmost the ideals and responsibilities of his vocation, he became widely known in North Wales. If there were any need of evidence as to the great esteem and affection—we might say veneration—in which the late Dr. John Roberts of Menai Bridge was held, it was amply shown by the large attendance at his funeral on March 19th, when, at the service at the chapel he had for so many years been a regular attendant, all the public bodies on which he had served were represented, besides many friends from a distance, and the medical men of the county. All bore witness to the loss of a common friend, of a highly gifted and eminently upright man, who had devoted a long life unceasingly, energetically, and in the best spirit to the interest of the medical profession and his adopted county. He combined in a high degree the qualities of accuracy, precision, truthfulness, and conscientiousness. He added to these qualities a kindly and friendly disposition, which grew with advancing years, and a high, dignified bearing, which never deserted him. He was recognized to be an accomplished physician: conscientiously accurate in investigation, careful in diagnosis, shrewd in estimation of character, and judicious in treatment, leaving no detail

uncared for. Decided, yet kind and considerate, he won the confidence of practitioners and patients. In general politics he was a Liberal, and during his lifetime served the county in various ways. He was one of the first aldermen elected by the County Council, was a magistrate since 1886, and a member of the Board of Guardians, the chairman of which, in proposing a vote of sympathy with the family, said that Dr. Roberts was a man of affairs, sound in judgement, kindly of heart, who was ever ready with his advice when sought.

He took great interest in the Nursing Association of the county, of which he was honorary treasurer for seventeen years.

Dr. Roberts's loss will be seriously felt throughout the county, for few men were more public-spirited and more honest and outspoken in the discharge of duty, and it may be truly said that those who knew him best loved him most.

He leaves four daughters (one of whom is a member of the medical profession) to mourn the loss of a kind and considerate father.

CECIL E. SHAW, M.A., M.D., M.Ch.,

LECTURER ON OPHTHALMOLOGY IN THE QUEEN'S UNIVERSITY,
BELFAST.

It was with deep regret that the intimation of the death of Dr. Cecil Shaw, which took place on April 10th at his residence in Belfast, was received throughout Ulster. His health had been indifferent for some years, but after a visit to Kissingen in 1910 he improved considerably, and many of his numerous friends hoped that he was permanently restored to good health, but pernicious anaemia became evident, and he was compelled to go away again in 1911 and in 1912. Despite his weakness he stuck manfully to his duties, and gave his last lecture of the winter session some nine weeks before the end.

Dr. Shaw was the youngest son of the late Rev. George Shaw, Presbyterian minister of Belfast, and was in his 50th year. He received an excellent education in the Royal Academical Institution, Belfast, and then entered the Queen's College, Belfast, where he pursued the arts course, and obtained the B.A. degree with honours in experimental science in 1883, and the M.A. in 1885. As he had already entered the medical curriculum, he was enabled to obtain the degree of M.D. in 1887. He at once began to specialize in ophthalmic, throat, and aural work, and became clinical assistant in Moorfield's Ophthalmic Hospital, and at Golden Square Throat Hospital; he also studied at Paris, Marburg, and Vienna. Settling in Belfast, he confined himself practically from the first to his specialities, in which he soon made a name, and had just reached his zenith when his tragic illness began to cross the path of success. Dr. Shaw held many appointments: he was ophthalmic surgeon, and subsequently consulting ophthalmic surgeon, to the Mater Infirmorum Hospital; assistant surgeon to the Belfast Ophthalmic Hospital, where he gave valuable aid to his senior, Dr. J. Walton Browne, in renovating the hospital and bringing it thoroughly up to date; ophthalmic surgeon, and subsequently consulting ophthalmic surgeon, to the Ulster Hospital for Children; consulting oculist to the County Antrim Infirmary and to the Ballymena Cottage Hospital; honorary laryngeal surgeon to the Forster Green Hospital for Consumption. In his earlier days he wrote a small textbook on external diseases of the eye, and from time to time made several contributions to the medical journals on his specialities; he joined in the discussions at the meetings of the British Medical Association, and at the meetings of the various special societies and congresses. He was a member of council of the Ophthalmic Society.

Dr. Shaw was a Fellow of the Ulster Medical Society, and took the greatest interest in its proceedings and in the British Medical Association; he was for many years on the Council of the former, and had held the office of vice-president. He was also one of the original trustees of the Medical Institute. But perhaps his chief interest lay in the British Medical Association. As he had numerous friends and connexions in England, he had a double pleasure in the visits to London necessitated by holding office. His untiring efforts as secretary during the visit of the Association to Belfast will long be remembered, and are still green in the grateful recollection

of his fellow members. The great amount of work he did for the British Medical Association may be gauged from the following list of the offices he held: Member of the council of the Ulster Branch 1901 to 1907; honorary secretary Ulster Branch 1905 to 1910; member of the Central Council 1904 to 1909; member of the Science Committee 1906 to 1910; vice-president of the Section of Laryngology and Otology at the annual meeting in Oxford in 1904, and of the Section of Ophthalmology at the annual meeting in London in 1910; secretary of the annual meeting of the Association at Belfast in 1909; representative of the Ulster Branch on the Irish Committee 1909 to 1911.

No notice of Dr. Shaw's life would be at all complete without mention of his numerous parerga. He was one of the best amateur photographers, and his early training in experimental science enabled him to bring to the art advanced scientific knowledge. A good camera was a constant companion on holiday, and not infrequently on professional journeys; and in the following winter a lecture, illustrated with his own slides, pleased and instructed those not so fortunate as himself in seeing the beautiful and interesting spots of the world; he also did some photomicrographic and colour photographic work. Books were an ever fresh source of pleasure, and to those whom he knew to share his tastes, his first question after the business of the interview not infrequently was, "Well, what have you been reading lately?" He read with intelligence and care, chiefly books connected with travel, but there were few subjects he could not talk on and illuminate with his knowledge; of poets he was a follower and student of Browning. He took a great interest in the Belfast Library and Society for Promoting Knowledge.

Dr. Shaw was married but had no family. The deepest sympathy is felt with his widow, who was the devoted companion in all his work and his holidays, and the untiring nurse in his long and trying illness, and also with his sisters.

GEORGE BRUCE MACDONALD, M.D., J.P.,
L.R.C.S.E.

We regret to record the death, in his 72nd year, of Dr. George Bruce MacDonald, which occurred, after a short illness, at his residence at Shepperton-on-Thames, Middlesex, on April 8th. He was descended from the old historic family of The MacDonalds of the Isles, which numbered the famous Flora MacDonald amongst its members, and was educated at Glasgow University, where, after a successful course, he graduated M.D. with honours exactly half a century ago. He took the diploma of L.R.C.S. Edin. in the same year (1863).

After some little time spent as an assistant, he "cam sooth," and settled at Southall Green, Middlesex, then a purely agricultural district, "ten miles from town," where he built up a large and widespread family practice. Here he was appointed district medical officer for Norwood parish, and in the course of time came to hold many other medical appointments, which he filled to the entire satisfaction of all concerned. Amongst them were: Divisional surgeon of Metropolitan Police, certifying factory surgeon, medical officer to the Brentford Gasworks and Great Western Railway works, and medical attendant St. Mary-lebone Schools, the Central London Schools, Southall, and St. Mary's Orphanage, North Hyde. On his well-earned retirement from active practice, some seven years ago, he was placed on the Commission of the Peace for Middlesex, and was a regular attendant on the local petty sessions bench at Brentford, as well as at Quarter Sessions, Westminster.

He went to reside at Shepperton, but his heart remained in Southall, and three years ago, such was the esteem in which he was held there, that he was unanimously requested to allow himself to be nominated for the electoral division of Southall-Norwood as its representative on the Middlesex County Council, an honour which was repeated as recently as a month ago. He was most assiduous in attending to his duties as a councillor, serving on the Public Health, Asylums, Reformatory Schools, and Education Committees. He was one of the two medical members elected to serve on the Insurance Committee, but, like his colleague, out of loyalty to his professional brethren, he declined to serve. On committees his views and opinions were always received

with the deference due to his wide knowledge and long professional experience. He attended as a member of the Visiting Committee at the Middlesex County Asylum, Wandsworth, as recently as March 29th, in excellent health and spirits; so it may be said he died in harness, for a few days later he took cold, pneumonia supervened, and he passed away regretted by all.

A thoroughly practical and busy man, Dr. MacDonald had little leisure to record his manifold experiences, nor was he much of a talker, but it was always a pleasure to listen to him, as he gave advice, derived from his stores of knowledge, often illustrated by an apt quotation or appropriate story. A kindly, big-hearted Scot, he will be greatly missed in the western parts of Middlesex by rich and poor alike, amongst whom he laboured so long and so self-sacrificingly.

GEORGE TEMPLETON, M.B., C.M., F.R.C.S.,

LONDON.

It was with feelings of consternation that the news of the disappearance of Mr. George Templeton during a skiing expedition in Norway on March 27th was received by his friends, and though for a day or two hope was entertained that his robust frame and determination of character would have enabled him to weather the storm in which he was overwhelmed, that hope was ultimately extinguished by the discovery of his body a week afterwards when the blizzard had moderated sufficiently to make systematic search possible. Mr. Templeton had been staying at Finse, between Bergen and Christiania, and had set out with five other men at about 11 a.m. to visit a hut about nine miles off, a journey which is usually accomplished in favourable circumstances on ski in about three hours. Owing, however, to the onset of a snowstorm and the severe cold, and also, no doubt, to the fact that several of the party were inexperienced in the use of ski, it was not until 4.15 that the hut was reached. At 5 p.m. the party started to return, with Mr. Templeton leading, and ordinarily two hours suffice for the journey. The others seem to have had some difficulty in keeping up the pace, but at the top of the first big hill a halt was made to allow of the arrival of the stragglers. Here Mr. Templeton and Mr. Warren moved ahead, and were never seen again, and it was not until 11 p.m. that the remaining four reached a signalman's hut five miles from Finse in a very exhausted condition. The telephone here revealed the fact that Mr. Templeton and his companion had not reached the hotel, and, though a search party was at once organized, their efforts were unavailing.

Mr. Templeton, who was born in Kilmarnock in 1869, graduated M.B., C.M. with honours at the University of Edinburgh in 1892, and took the diplomas of M.R.C.S. and L.R.C.P. in the same year. He took the diploma of F.R.C.S. Eng. in 1896. He was house-physician at the Royal Free Hospital, and subsequently became Surgical Registrar to the Hospital for Sick Children, Great Ormond Street—a post which he occupied for three years. For the next twelve years he was surgeon to the North-West London Hospital. As consulting surgeon to the Hostel of God, Clapham Common, and to Hornsey Hospital he did good work, but of late years it was chiefly in connexion with S. Barnabas's Home, Lloyd Street, that he found an outlet for his abilities.

Mr. Templeton was the embodiment of an energy which might almost be described as Titanic, and it was this which contributed to his undoing. "We did not start back until nearly 5. Dr. Templeton at once took the lead, and I kept near him to keep him in sight. I managed to keep him back a bit until about 6.30, but he got impatient at the slowness of the rest and went on, and Warren followed him. I refused to leave the others."

Such is part of the narrative of one of the survivors—Mr. Henry Green. Mr. Templeton possessed the faculty of getting at the heart of a thing rapidly and almost intuitively. In his work he was bold, original, dextrous, and successful, and his self-reliance was so great as to amount at times almost to a fault. His other interests were numerous and varied, and on all of them he brought to bear a concentration of purpose which made light of obstacles. In his private life he was courteous and kindly, and his untimely loss will long be felt by those who were privileged to be numbered among his friends.

THE LATE MR. JORDAN LLOYD.

DR. OTTO J. KAUFFMANN, Physician to the Queen's Hospital, Birmingham, who was absent from England at the time of Mr. Jordan Lloyd's death, has sent us the following personal appreciation, which will be read with interest by many of Mr. Jordan Lloyd's friends and former pupils:

I should take it as a favour to be allowed to say a few words in appreciation of Jordan Lloyd, reasons of which, the Editor is informed, have prevented my writing earlier.

For twenty years I have shared rooms with Lloyd, and we have met almost daily during that period and have exchanged opinions on matters of common interest. So one becomes well acquainted, and although in the case of most men such an intimacy would allow one to make a fair guess at their judgement on some matter of general interest, it was different with Lloyd, whose point of view of a subject was always original and uncommon, allowing him to see further than most of us can. The subject considered from his standpoint always presented a novel aspect, very usually convincing when it was made clear, and discussion with him was extraordinarily refreshing. Everything interested him, not only his professional work and speculations in pathology based on his observations, but life in whichever phase or form it came before him. Most particularly he was fascinated with the "pathology of the living," and on the phenomena which had come under his watchful attention in the operating theatre he would discourse with enthusiasm and from them would draw wonderfully correct and ingenious conclusions.

Of his great skill as an operator others have spoken. I would say a word on his judgement and reserve in holding his hand unless he was convinced that an operation would do good to the patient. For clinical judgement, especially concerning this last point, it was difficult to find his equal. Jordan Lloyd was a lovable man—strong, tender, and sympathetic, and free from all petty jealousy and envy. Scores of times we have discussed the acts of colleagues, or the attitude on some point of discussion, medical or general, of another member of the profession, and I was always impressed with the fact that he never belittled another's ability, and never questioned the fairness of his intentions; and invariably he had a good word to say for the honest effort, and an appreciation for the success, of another. A more generous-minded man it is impossible to conceive.

THE LATE DR. ROBERT FLETCHER.

We have received a reprint from the *Bristol Medical-Chirurgical Journal* of December, 1912, of an obituary notice by Sir William Osler of the late Dr. Robert Fletcher, whose name is well known in connexion with the *Index Catalogue of the Surgeon-General's Library* at Washington and the *Index Medicus*. As was stated in a brief notice of his life published last December, he was born in Bristol in 1823. He entered the medical school of that city in 1839, and passed the "College and Hall" in 1844. In 1847 he migrated to the United States and settled in Cincinnati, where he practised for some years; at the outbreak of the civil war he volunteered as a medical officer, and at the end of it was given the rank of Brevet Colonel for faithful and meritorious service. His connexion with the Surgeon-General's Library began in 1876, and ended only with his life. He was one of the principal editors of the *Index Catalogue*, and his services were handsomely acknowledged by Dr. Billings in the preface to the first volume published in 1880. Of the magnitude of that undertaking an idea may be formed from the following facts given by Sir William Osler:

In the first series of sixteen volumes, completed in 1895, there were indexed of author titles 85,663 volumes and 151,504 pamphlets, and of subject titles 168,557 books and 511,112 journal articles. Of the second series sixteen volumes have already been issued, nearly finishing the letter "S." The thirty-two volumes so far published furnish a medical reference catalogue of colossal proportions—of 286,255 book titles and 1,006,355 journal articles. Each volume contains nearly a thousand pages, closely printed, with from fifty to seventy-five separate references on each.

With the *Index Medicus* Fletcher was associated as co-editor for twenty-one years and as editor-in-chief for

nine. He also lectured for some years on medical jurisprudence at the Washington University. Afterwards he lectured on the same subject with much acceptance at the Johns Hopkins Hospital Medical School. Outside his bibliographical work he was specially interested in anthropology, and contributed largely to the two volumes of *Anthropometrical Statistics*, issued from the American War Department in 1875. He was a man of versatile mind, and his range of intellectual interests was unusually wide. Among his writings are a monograph on Prehistoric Trephining and Cranial Amulets (1882); Human Proportion in Art and Anthropometry, and Tattooing amongst Civilized Peoples (1883); Myths of the Robin Red-breast in Early English Poetry (1889); the New School of Criminal Anthropology (1891); Anatomy and Art (1895); and Scopelism (1897), the first paper on the subject in English. To the Johns Hopkins Historical Society he contributed a number of valuable papers, among them being essays on Medical Lore in the older English Dramatists and Poets (1895); the Witches' Pharmacopoeia (1896); and A Tragedy of the Great Plague at Milan in 1630 (1895). The reprint includes an interesting paper by Fletcher on some diseases bearing names of saints. It shows abundant evidence of the painstaking research characteristic of him, but is distinguished by such an error as *few sacræ* (St. Anthony's fire), which occurs about half a dozen times. He worked on in spite of illness to the end, reading proofs to within a few days of his death. He was a man of fine character, and his vast acquaintance with members of the medical profession, ranging from Astley Cooper to the leading men of the present day, made him an entertaining companion. He was very far from being the dryasdust one is apt to assume that men who spend their lives among books must be. A man of immense learning, he did not carry the dust of the library into social intercourse. Sir William Osler says:

It was a rare treat to dine quietly with him at his club in Washington. "He knew his Brillat-Savarin well, and could order a dinner that would have made the mouth of Coelius Apicius to water."

The reprint has an excellent portrait of Fletcher as a frontispiece.

DR. CHARLES TOZER SAVORY, who had reached the ripe age of 83, died on March 27th at his residence in Crouch End, where he had lived since his retirement from practice some eight years ago. The active portion of his life was spent in Stoke Newington and Canonbury, where he was in partnership with an old fellow student, the late Mr. William Pettifer. Dr. Savory, who became M.R.C.S., L.S.A. in 1862, and M.D. St. Andrews somewhat later on in the same year, was born in Monument Yard, in the City of London, in 1829, his father being William Henry Savory, a surgeon long resident in the parish of St. Mary-at-Hill. Charles Tozer Savory was thus a younger brother of the Savory who was destined to attain such fame as a surgeon, the late Sir William Scovell Savory. On completion of his general education at Rainsgate he entered on a commercial career, but at the age of 30 abandoned it in favour of medicine, and joined St. Bartholomew's Hospital as a student in 1859, the same year as that in which his brother received the honour of being appointed to succeed Sir James Paget as lecturer on general anatomy and physiology. It was a somewhat curious position, for in age the two brothers were only three years apart. Charles Tozer Savory, however, never had any cause to regret his late choice of medicine, for, though he never attained fame, he proved a successful general practitioner. In many respects he was by no means unlike his brother. He had the same handsome, dignified presence, and evidenced ability of the same order as that which gained for Sir William Savory almost as high a reputation on the platform and in the lecture-room as in the wards and operating theatre. A genial man, of wide reading and culture, Dr. Charles Tozer Savory's polished and witty conversation made him a very attractive host; in addition he was of charitable disposition, and entirely free from any tendency towards ostentation. Another marked characteristic in him was a great love of animals. Dr. Savory was twice married, and had a large family.

Letters, Notes, and Answers.

Authors desiring reprints of their articles published in the *BRITISH MEDICAL JOURNAL* are requested to communicate with the Office, 429, Strand, W.C., on receipt of proof.

Queries, answers, and communications relating to subjects to which special departments of the *BRITISH MEDICAL JOURNAL* are devoted will be found under their respective headings.

ANSWERS.

HYPERTROPHIED PROSTATE.

DR. JOSEPH S. BOLTON (Nottingham) writes: For enlarged prostate high frequency currents applied by a rectal electrode have proved useful. Dr. M. M. SHARPE (London) writes to the same effect, but adds that a special form of condenser electrode is necessary.

COUNTRY MEMBER suggests that "X. X." should feed his patient on the prostate glands of bullocks. These should be lightly cooked by steaming, and the gland substance and gravy be taken with the principal meal of the day.

SCOPOLAMINE-MORPHINE IN EXOPHTHALMIC GOITRE.

SUSSEX.—The scopolamine and morphine combination is a most excellent hypnotic in cases of exophthalmic goitre, so much so that it is frequently used as a preliminary to general anaesthesia in patients suffering from this disease. It would certainly be safer than chloroform, which undoubtedly in these circumstances is dangerous. There is no evidence that pregnancy would lessen this risk. Should the degree of narcosis obtained by an average dose—say, morphine gr. $\frac{1}{4}$ and scopolamine gr. $\frac{1}{100}$ —be insufficient, a little ether inhaled from a few thicknesses of gauze clipped into a wire frame would produce the required depth of analgesia without danger.

TREATMENT OF GOITRE BY IODINE ABSORPTION FROM THE SKIN.

DR. PETER TYTLER (Manchester) writes, with reference to the inquiry of Major Lawson in the *BRITISH MEDICAL JOURNAL* for March 29th, to state that for the last five years he has used the following method in the treatment of goitre: A piece of lint large enough to cover the growth and the skin for 3 in. or 4 in. beyond is soaked in a lotion consisting of 1 drachm of iodine tincture in 8 oz. of water and applied to the neck at bedtime and left on till morning. If a stronger solution is used it produces inflammatory reaction and prevents absorption. Dr. Tytler states that he has employed this plan in many cases but that only three have continued long enough to produce a satisfactory result. They were all young men, aged 13 years and upwards. Two were out-patients, and over two years elapsed before the swelling materially diminished. In the one private patient the swelling was reduced $\frac{2}{3}$ in. in eight months. The difficulty, he finds, is to get patients to persevere with the treatment.

INTERMITTENT GLYCOSURIA.

DR. P. J. CAMMIDGE (London) writes: If Dr. Thomas will refer to my recently-published book on *Glycosuria and Allied Conditions* he will see that the condition met with in his patient is well recognized and is not uncommon in mild cases of glycosuria. In these "the sugar excretion increases after food, usually reaching a maximum two or three hours after a meal, and diminishes during fasting, so that the urine passed in the early morning, before breakfast, may be sugar free" (p. 180). In this particular instance the infection of the bladder with coliform organisms is probably a contributory factor in producing the sugar-free condition of the urine that has collected in the bladder over-night, for in the process of their growth they decompose the sugar, giving rise to various acids and gases. The former tend to set up cystitis, while the latter give rise to the condition known as pneumaturia (p. 259). It is the acids formed in a similar way in the urine adherent to the external genitals that cause the pruritis, etc., from which many diabetics, and especially women, suffer. Sugar in the urine always denotes a disturbance in the metabolism of the body, and is not formed locally in the bladder, etc., by bacterial or other means under any circumstances.

TREATMENT OF RHEUMATOID ARTHRITIS.

DR. W. J. MIBELTON (Bournemouth) writes: Your correspondent "H. E. J." (*BRITISH MEDICAL JOURNAL*, March 29th, 1913, p. 695) does not mention which form of continuous counter irritation he would like information on. I have during the past twelve years treated many cases of arthritis deformans by such means. I have used three methods: The blister followed by savin ointment, acupuncture and irritants, and the galvanic-catheter. Either singly, any two, or all three may be employed on the same patient according to the needs of each case. I have notes of hundreds of cases treated by myself or friends, and the majority are as striking as those quoted in the *JOURNAL* of January 25th, 1913, p. 162. I have selected three at random: (1) Female, aged 46. Mother died a cripple from "rheumatism." Patient had suffered over nine years herself, gradually increasing

weakness. Knees chiefly affected, most other joints as well. In bed quite helpless when seen by me, in much pain generally. Treated vigorously by pyonex method. Within three months could walk three miles. (2) Female aged 55. All joints stiff, painful, and swollen. Travelled to Bournemouth with difficulty, accompanied by a nurse; just able to walk with crutches. Duration about five years. At the end of nine months left Bournemouth alone and walked easily without crutches. Pyonex method. (3) Female aged 55. All joints stiff, painful, and swollen. Duration over four years. Told by several doctors could be relieved only. Had become much worse as time went on in spite of much spa and other treatment. Had to be helped in and out of a bath and so on. At the end of six months could get in and out of a bath unaided and carry a baby upstairs with ease.

DR. WILLIAM ARMSTRONG (Buxton) writes, in reply to the inquiry in the *JOURNAL* of March 29th, to put forward the following points: Counter irritation by repeated blisters or electric cautery is of great value; it should be spinal in the neural form of arthritis, as well as local; in the gouty or rheumatic form, local to joints only. It cannot, of course, deal with the reflex sources of irritation, but does undoubtedly improve the nerve nutrition of the joints. Radio-active water drinking, on the other hand, considerably increases the output of the various body poisons, and therefore acts upon the source of the complaint. The dose should be strong, not less than 5,000 m.u. per litre to commence with, increased to 10,000, and later on to 20,000. The inhalation of radium emanation with oxygen is also valuable. The ideal treatment, in my experience, is a combination of the two methods. The best method of counter irritation is by means of the electric cautery, the pain of which is mitigated by a preliminary ionization with cocaine.

LETTERS, NOTES, ETC.

SCARLATIFORM RASH DUE TO VENICE TURPENTINE.

DR. CYRIL BANKS (Birkenhead) writes: I should like to corroborate Dr. William Angus's statement on the above subject by quoting a case I saw eighteen months ago whilst in temporary charge of a practice in Sheffield. A girl aged 19 had a typical finely punctate scarlet rash on the trunk and limbs. The face was flushed but free from rash. She had taken Venice turpentine—or "Veno's turpentine," as she called it—two days before to ease menstrual pain. The temperature was 99° F., as in Dr. Angus's case, but the throat was normal in appearance. There was a history of scarlet fever in infancy. I am unable to say whether desquamation subsequently occurred or not.

GENITAL FUNCTIONS OF DUCTLESS GLANDS IN FEMALES.

DR. A. COWAN GUTHRIE (Edinburgh) writes: I was much interested in the able article of Dr. W. Blair Bell on the above subject, especially where he states that "insufficiency of suprarenal secretion is the probable cause of osteo-malacia." In an undoubted case of osteo-malacia, where every other form of treatment failed to give relief, adrenalin chloride proved quite successful in bringing about a complete restoration to health. A full report of the case appeared in *The Prescriber*, November, 1909.

WASSERMANN REACTION.

THE SECRETARY OF THE WASSERMANN INSTITUTE, Sutherland House, Lloyds Avenue, London, E.C., writes: Owing to several inquiries received recently, and at the request of Geh. Med.-Rat. Professor Dr. A. von Wassermann, we beg to make the following declaration: At the inception of the Wassermann Institute, this title was chosen to express the fact that all Wassermann reactions conducted in our laboratory are made strictly in accordance with the original method and with reagents exclusively prepared under the control of Geh. Med.-Rat. Professor Dr. A. von Wassermann. The expression "under the superdirection of Geh. Med.-Rat. Professor Dr. A. von Wassermann," therefore, does not imply that Professor Dr. A. von Wassermann personally supervises the institute, but simply refers to the reagents used, as stated above. The examinations are supervised by one of the best known specialists in venereal diseases in London, and we can, therefore, guarantee that any tests submitted to us will be carried out with the greatest care and in accordance with the original technique advocated by Professor Dr. A. von Wassermann and with reagents controlled by him.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

| | £ | s. | d. |
|-----------------------|-----|-----|--------|
| Eight lines and under | ... | ... | ... |
| Each additional line | ... | ... | 0 4 0 |
| A whole column | ... | ... | 0 0 6 |
| A page | ... | ... | 2 13 4 |
| | ... | ... | 8 0 0 |

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Wednesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *postes restante* letters addressed either in initials or numbers.

A Lecture

ON

THE ETIOLOGY AND TREATMENT
OF PUERPERAL ECLAMPSIA.DELIVERED AT THE MEDICAL GRADUATES' COLLEGE
AND POLYCLINIC.

BY R. A. GIBBONS, M.D., F.R.C.S.E.,

PHYSICIAN TO THE GROSVENOR HOSPITAL FOR WOMEN, LONDON.

As the majority of those attending this College are either in private practice or intend entering upon it sooner or later, it is essential that the latest views of any subject considered, especially one of such vital interest as this to any engaged in the practice of obstetrics, should be placed before you; but, as Zweifel has termed eclampsia "the disease of theories," I shall only mention what may be regarded as the more important with reference to the etiology of this disease—so terrible in its onset and course, and so terrifying to those around. It may appear as extraordinary that such an enormous amount of writing—in 1908 alone Eardley Holland states in an admirable review that there were over 100 scientific papers on the eclampsia problem¹—has been devoted to this subject, but this is due to the fascination of the unknown. When the exact cause of a disease is demonstrable it ceases to be of such interest to the pathologist and to those who are searching for light. Until we know exactly the cause of onset of an affection it will be studied as carefully as heretofore, but with the help of modern methods of investigation the task becomes easier than formerly.

Puerperal eclampsia may be defined as a disease peculiar to the pregnant woman, and almost invariably manifesting its presence by convulsions of a tonic or clonic character, accompanied by unconsciousness and followed by coma or sleep. It may occur either during gestation, immediately before, during, or after confinement, and may be extremely slight in the manifest symptoms, or so terrible and grave as to kill immediately or within a few hours of the occurrence of the first convulsion. It is most usual to occur in the latter part of pregnancy, rarely before the fifth month, and very rarely before the fourth month; generally a short time before term, less frequently in labour, and least frequently after labour. Its frequency varies from 1 in 500 cases to 1 in 250, according to various tables. About 70 to 80 per cent. of all cases occur in primiparae. It is very difficult to estimate the incidence exactly, because most figures are taken from clinics to which patients are sent on account of the convulsions, whereas in ordinary private practice they would be treated at home. We know that 80 per cent., or between 75 and 80 per cent., according to various statistics, of those women attacked by the disease recover, and it is important to note that they recover under all kinds of treatment. Therefore there is a mortality of about 20 or 25 per cent.—a terrible mortality in any disease. I shall endeavour to see if there is any method of treatment which will diminish that mortality. In some tables the death-rate has been much higher—as much as 32 per cent. in Schroeder's clinic.

DIAGNOSIS.

There is, as a rule, no difficulty about diagnosis, but it is possible that it may be confounded with:

1. Cholaemic eclampsia, which condition seems to have been established by Braun, Frerichs, and others, and is a rare disease. There are no signs of renal mischief, such as albuminuria, oedema, etc., and symptoms point to the liver, as epigastric tenderness, vomiting, and intense headache, and pain referred to the region of the liver. A state of nervous agitation develops and convulsions follow; the patient sooner or later becomes comatose. In the severe cases jaundice always develops, and the urine may contain biliary matter or remain normal. The condition of the blood favours thrombosis; embolism and haemorrhages and petechiae, as well as purpura, are common.

2. Epileptic convulsions, which may, of course, occur at any time during pregnancy in the epileptic. There may, however, be some doubt about a case seen for the first

time in the "status epilepticus," when the patient passes from one convulsion to another, and which may terminate fatally, or when one sees the patient in the stupor or coma after an attack of epilepsy.

3. Uraemia may be the cause of some difficulty in making the diagnosis. It develops from a sudden suppression of urine, or when the kidney substance has been destroyed, and eclampsia develops in the same way when the pregnancy kidney has reached a certain stage of degeneration. But puerperal eclampsia may develop when the kidney is apparently normal, when the urine examination is consistent with health, and when there is no albumen present in the urine. Undoubtedly there are many points of resemblance between the two affections. It has been observed that the freezing-point depression (eryoscopic point) of the blood differs in the two conditions.² But, as in cholaemic convulsions, it may truly be said that only the *post-mortem* room can really decide when either occurs in the pregnant woman.

4. Coma, due to cerebral apoplexy, alcohol, or meningitis, which may come on during pregnancy, may be mentioned, as well as hysteria, acute poisoning from strychnine, phosphorus, or nitro-benzol,³ but when the whole of the antecedents of each case are considered there is not likely to be much difficulty in making a diagnosis from puerperal eclampsia.

PROGNOSIS.

This must always be serious, because the mortality of the mother is 20 to 25 per cent., and of the fetus 35 to 50 per cent. Stroganoff had a maternal mortality of 6.6 per cent. in a series of 400 cases, which is extraordinarily favourable and most unusual. But prognosis may be exceedingly difficult and uncertain, because where the convulsions may be slight and have ceased, where the secretion of urine has been re-established, and where the temperature is not high and the patient seems to be doing well, a convulsion occurs, ending in profound coma and death. Persistent high arterial tension is always unfavourable.

Speaking generally, if the temperature is not running up, the pulse is fairly good and not rapid or thready, the fits decreasing in frequency or have ceased, and the kidneys are acting well, all may go well. If convulsions commence after labour, the prognosis is, according to recent statistics, equally serious as in those cases where they commence before or during labour. According to Veit, the mortality is about 14 per cent. in primiparae and about 19 per cent. in multiparae. Olshausen considers that the mortality is about the same in both. According to Seitz, the prognosis is worse with each convulsion up to 20 or 30. The prognosis really seems to depend on the rapidity with which the attacks follow each other and the duration of the coma after the convulsion.

PATHOLOGY.

It may be briefly stated that all the organs of the body are in some manner affected, the main lesions being found in the liver, kidney, heart, and brain. In other words, it may be said that these organs are affected in puerperal eclampsia in the same manner as they are in many toxæmias. As I remarked under the head of diagnosis, the *post-mortem* room alone could decide in cases of cholaemic convulsions, with its more or less necrotic changes in the liver in its most marked degree, acute, yellow atrophy of the liver,⁴ or puerperal eclampsia, for they are really the result of profound poisoning. It was usually thought that the kidneys were the main source of trouble, considering that renal changes are constantly present in eclampsia, but in 1888 Pelletier called attention to hæmorrhagic lesions in the liver in eclampsia. Schmorl confirmed his observations and pointed out that eclampsia was distinguished by profound changes characteristic of no other disease, and that he had found in every case lesions of the liver which he considered were more characteristic than those observed in the kidneys. In 1893 he published the result of his examination of 73 fatal cases, and it may be interesting to mention more especially the changes in the kidney which took place in 99 per cent. of the cases, and which are of a degenerative nature. The macroscopic appearances are those of parenchymatous nephritis. Microscopically protoplasm of the epithelial cells of the convoluted tubes is found in various stages of degeneration, cloudy swelling, fatty degeneration,

and coagulative necrosis. Schmorl states, contrary to the opinion of Winter, that the glomeruli are not chiefly affected. In one case he found the kidneys healthy although the other organs had the usual changes. He found the liver affected in all but 27 of his cases, and says the condition consists of necrosis of cells, singly or in varying sized patches, which may be anaemic or haemorrhagic, and has met with fibrinous thrombi of the capillaries of the interlobular as well as the intralobular veins, and a fibrinous exudate between the liver cells. The macroscopical appearance of the liver shows minute haemorrhages under the capsule, as well as minute infarctions due to thrombosis of the smaller branches of the portal vein. The pathological conditions of the liver closely resemble those found in acute yellow atrophy, yellow fever, and phosphorus poisoning. There are metastatic thrombi of liver and placental cells, and fat emboli have been found in the lungs and glomeruli by Virchow and Winkel.⁵

In eclampsia there seems to be general thrombosis of capillaries. It is an affection of different organs at the same time which allows puerperal eclampsia to be diagnosed after death. It may be said of the blood that in the majority of cases the red corpuscles are greatly in excess, and that this is also true of the white corpuscles, which are much more numerous than in normal pregnancy.⁶

Dienst lays great stress on this excess of white corpuscles, as he considers that they are the origin of fibrinogen, which, according to him, is, by its increase, the actual cause of the disease, to which I shall presently refer.⁷

In the fetus minute haemorrhages have been found in the more important organs, as well as fatty degeneration or necrosis. This will show the severity of the poison, and as the changes are akin to those found in the mother, it is evident that the same kind of poison affects the circulation in both, leading to these pathological changes.

ETIOLOGY.

This part of the subject may be divided into (a) causes residing in the mother, (b) causes residing in the fetus.

Of the causes which reside in the mother, two great theories have been in vogue:

1. The pressure, or mechanical theory, due to increased intra-abdominal pressure, and the pressure of the enlarging uterus.

2. The toxæmic theory.

These, again, may be divided into predisposing and exciting causes. The predisposing causes may be said to include:

(a) Any disease of the kidney, or any condition which causes faulty elimination, because, of course, if elimination is interfered with, waste products must be retained in the circulation, and may damage the kidneys, as well as other organs.

(b) Pressure on the renal veins, or on the ureters, by an unusually large uterus, as in twin pregnancy, causing retention of urine.

(c) Abnormally large fetus or fetal head.

(d) Small pelvis.

Statistics show the occurrence of eclampsia in 11 per cent. of multiple pregnancy as compared with 1.1 per cent. of single pregnancy. Primiparae of extreme youth or extreme age are especially liable to eclampsia because of rigidity of muscles. The proportion of eclamptic primiparae to multiparae is as 3 to 1.⁸

The theory of pressure on the ureters or veins need not be discussed unless it can be shown that it in any way raises blood pressure. The secretion of urine is determined by pressure of blood in the glomeruli of the kidneys. Whatever causes contraction of the arterioles of the body generally raises pressure in the arteries, and will raise the pressure in the glomeruli also, leading to increased secretion. In certain circumstances the contraction of arterioles may be so great that the branches of the renal arteries are also constricted. Then, although the general pressure is so high, the pressure on the glomeruli falls so much that secretion of urine ceases and suppression of urine is established. This condition may explain the absence in some cases of changes in the kidney.

We know that abdominal tumours, even of enormous size, do not cause eclampsia. The exciting causes, supposing, of course, that the pathological factors are present,

may be sudden suppression of urine, partial or complete, constipation, painful contractions of the uterus, rigidity in primiparae, exhausting expulsive efforts, and emotion. After the first convulsion, the slightest shock or irritation may cause another one.

In the light of modern research it may be said that puerperal eclampsia is caused by a toxæmia—some poison circulating in the blood—and that as the poison must be derived from some changes in the body itself, it must be autogenetic, or an auto-intoxication. The whole condition is, in fact, due to defective chemistry of the body, and I may briefly lay before you the more recent views as to the causation of that toxæmia.

There can be, as far as we know at present, no "eclamptic toxin," but there must be some poison or poisons to begin the changes in the cells which lead to disorganization of the organs as a rule most affected—the liver and kidneys. Zangemeister's investigations⁹ have shown that the retention of nitrogenous substances is not to be regarded as a causal factor under any circumstances. I shall briefly relate the substance of most of the recent theories regarding the origin of the poison.

1. *The Circulation in the Mother's Blood of Fetal or Placental Elements.*

This was brought forward by Veit in 1902. It is founded on the knowledge that particles of fetal ectoderm, and even portions of chorionic villi, become separated from the placenta and gain access to the mother's blood. Veit believed that this gave rise to a poison termed syncytiotoxin, which is normally rendered harmless by an antibody syncytiolysin, which develops in the mother's serum. If the amount of poison is too great to be neutralized by the syncytiolysin, poisoning and eclampsia occur. He injected an emulsion of human placenta into the peritoneal cavity of rabbits, which led to albuminuria and sometimes death, but these results follow the injection of any animal matter. If an ovum gets into the peritoneal cavity by rupture of a tube, eclampsia does not develop. Dreyfuss says¹⁰ that there is no definite proof of the placental origin of eclampsia. Lavare has discovered a blood-coagulating ferment in the placenta, which is important when it is remembered how much thrombosis of the capillaries throughout the body takes place in eclampsia. Sievinski and others have shown that the fibrinogen content of the blood is raised in pregnancy, and is very high in eclampsia. It may be said, of course, that the cause of this disease lies in the failure of the so-called "organs of defence," including the thyroid, parathyroid, suprarenals, etc., to completely perform their functions, but we cannot speak positively concerning this point.

2. *Poisoning by Material Formed or Retained in the Placenta.*

Freund and others have attempted to prove that eclampsia is due to endotoxins contained in the chorionic villi, and particularly in the syncytium. Injections into animals of placental extracts were generally followed by death, and sometimes convulsions. The *post-mortem* examinations showed genuine thrombosis, with lesions of the liver and kidneys. Freund thought that the placenta contained poison made up of two constituents, one acting on the nervous system and the other causing thrombosis, but Lichtenstein in 1908 demonstrated that the results obtained could be produced by the injection of indifferent material.

3. *Derangement of the Metabolism of the Mother.*

With reference to this, it is important to briefly refer to the functions of the liver, and to remind you that, whilst it is the chief assimilative organ in the body, it is also the chief autitoxic and defensive organ. It must be remembered that it has to do with the disintegration of protein and the profound modification of the various products of protein metabolism (proteolytic functions). As the result of these combined processes, there occurs a remarkable degree of detoxication of the portal blood, which loses the highly toxic properties (for example, in respect of ammonia) it formerly possessed (detoxicating and defensive functions).¹¹ These processes are carried out largely by the aid of appropriate ferments (proteolytic, glycolytic) produced by the liver cells, and able to produce these effects even after death. Thus by a process of

self-digestion, or autolysis, the following products can be formed: Leucine, tyrosine, glycocholic, xanthine bases, ammonia, resembling those resulting from tryptic digestion. These ferment activities differ from those exercised by other digestive glands, inasmuch as the proteolysis and glycolysis they effect take place within the liver cell. This peculiarity exposes the liver cell in a special degree to disturbance, to the extent even, in the case of severe toxic influences, of contributing to its autolysis when it is left exposed to the action of its intracellular proteolytic enzymes, unchecked by the influences which normally control their activity. The conditions presented by the liver in acute yellow atrophy, chloroform and phosphorus poisoning, exemplify the powerful destructive actions of the proteolytic enzymes present in the liver cells. Thus the liver cell becomes exposed to the destructive action of its own proteolytic ferments. A process of self-digestion or autolysis may set in, either in the parts of the liver affected or in the whole liver, as in acute yellow atrophy, and results in the complete disintegration of the liver cell, with suppression of all its functions, not only the proteolytic and glycogenetic, but still more of its nutritive functions. The disturbances then brought about are amongst the most severe, violent, and fatal known to the body (cholaemia and hepatic toxaeemias).

The influence of the nervous system must be considered in dealing with the functions of the liver. Belief in the possible effects of mental emotion on liver metabolism, based on clinical experience, receives some support from recent pathological observations regarding the part played by autolysis or self-digestion in liver disease. If the intracellular alkalinity in the liver cell fall to a low point as the result of acidosis, of inanition, or previous liver disease, the effect of severe mental depression or emotion accompanying liver disease may well be in particular cases to depress the functional activity of the liver cell beyond the point at which it can resist its own proteolytic ferments.¹²

Herman, Masson, and others found the relative amount of urea lessened in eclampsia, and Hérouin discovered that the relation of the amount of nitrogen contained in the urea to the total nitrogen was greatly altered. The normal ratio is reduced in pre-eclamptic toxæmia and eclampsia. Study of the "nitrogenous partition" by Zweifel, Ewing, Whitridge Williams, and others,¹³ shows a marked increase in amino-acids, as well as uric acid, creatinin, and the xanthine bases. Zweifel demonstrated large quantities of sarcolactic acid in the urine, and this was also found in the cerebro-spinal fluid by Füh and Lockemann. But we have no proof, as yet, that lactic acid is the cause of eclampsia, because, as suggested by Whitridge Williams, it is probably only a result of the muscular work incident to the convulsions.

This theory of toxæmia has been much studied since Bouchard stated that our health depended on the even balance between the production and excretion of toxic substances. He considered that the urine would be a guide to the amount of toxin present. Much labour has been devoted to the analysis of the urine since then, in pregnant and non-pregnant women, with contradictory results. Tarnier and others considered the urine of the healthy pregnant woman less toxic than normal. Schumaker believed that the difference was due to the amount of concentration.¹⁴ In the urine of eclampsia, with convulsions, different observers found the urotoxic dose vary, so that the results were quite contradictory, and it was found that the more precautions were taken in collecting urine, the method of preparation, etc., the less toxic it became, and Stewart, who took care to inject only pure urine, free from bacteria, declared it was innocuous.

Owing to the influence of the thyroid gland on metabolism, Nicholson considered that eclampsia must be due to insufficiency of iodothyron, which is manufactured by the thyroid to aid the metabolism of nitrogenous substances.

Lange¹⁵ found that in 133 women during the last twelve weeks of pregnancy the thyroid gland enlarged in a little over 81.2 per cent. If iodothyron were administered, the thyroid became less in size, and enlarged when the drug was stopped. In 18.8 per cent. there was no enlargement, and of these 16 had albuminuria with casts, and 6 had eclampsia. If there is a deficient amount of iodothyron, the metabolism of nitrogenous substances

is not complete up to the stage of urea formation, and toxæmia follows. If the thyroid gland is completely removed, toxæmia may follow, causing convulsions.

Nicholson¹⁵ considers that iodothyron affects the kidneys—first, by exerting some specific action on them; secondly, if diminished, it allows the formation of toxins which damage the kidneys; thirdly, it prevents the formation of urea, and as urea is a powerful diuretic, it decreases this stimulus, for it is a marked vaso-dilator, and so maintains renal activity, since, if it is absent, it allows the secretion of the suprarenal, to which it is antagonistic, to come into action, leading to spasm of the renal arteries, which may arrest renal secretion.

The suppression of the thyroid function reduces the metabolism of cells in the same way as it does that of albumen, though the two processes do not proceed parallel with one another.¹⁷ The theory advanced by Baumann, Oswald, and others is based on the assumption that the specific activity of the colloid present in the thyroid secretion is directed to the neutralization of toxic substances, and that this neutralization takes place within the blood stream. Attempts to obtain this toxin from the blood of thyroidless animals have, however, met with no success.

4. Anaphylactic Reaction.

By anaphylaxis—a term coined by Richet in 1902—is meant the hypersensitiveness of the organism to a foreign protein. In 1908 it was suggested by Rosenau and Anderson that eclampsia might represent an anaphylactic reaction. Lockemann and others believed that the mother was sensitized during pregnancy by minute quantities of fetal protein, and would develop anaphylactic shock if any amount of fetal blood were suddenly introduced into the circulation. They identified this condition with eclampsia. Others have failed to support them. Schenk, Veit, Heynemann, and Dienst have agreed in rejecting this theory.

Budin has shown that the poison absorbed from the intestinal tract has been in close relation to the toxæmias of pregnancy. Comyns Berkeley considers that eclampsia might be primarily due to renal toxæmia, hepatic, thyroid, or intestinal toxæmia—a failure of any of these organs to perform their functions properly resulting in the accumulation of the particular waste products they customarily deal with, and consequent general poisoning of the body, so that all the organs are more or less affected, and eclampsia results. Délore and Rodet suggested the presence of bacteria in the blood, and Müller thought a bacillus of the uterus causing a general intoxication would account for eclampsia.

5. Mammary Toxæmia.

Sellheim¹⁸ advanced the theory that the poison of eclampsia was manufactured in the breast. This originated from what he had learnt of the birth palsy, and the calf disease of the cow, which in one of its developments singularly resembles eclampsia of the woman, and is considered by many veterinary surgeons to be exactly the same disease. It has been found that by the injection into guinea-pigs of small quantities of colostrum obtained from cows suffering from vitellus, the animals die with lesions of the same character as those found in eclampsia. Therefore it is suggested that eclampsia may be due to poison manufactured in the mammae.

6. The Theory of the Fetus as a Cause of Eclampsia.

Those who support this theory have in their favour the facts that eclampsia is more frequent with twins, and still more frequent with triplets; that convulsions usually cease after delivery, and have been known to cease on the death of the child *in utero*; that sometimes infants born of eclamptic mothers have convulsions after birth, and *post-mortem* evidences the same as those found in the mothers. Usually cases of eclampsia occur after the fifth month, so that waste material has had considerable time to accumulate.

Again, Dr. Drennan¹⁹ has advanced the hypothesis that the abstraction of calcium salts from the mother by the fetus is a cause of puerperal eclampsia. In that article it is stated: (1) That, although it is generally believed a certain amount of fatty infiltration of the liver cells around

the hepatic veins, the central zone of the lobule, is physiological in pregnancy and lactation, it is really pathological, and that it is due to the extraction of calcium salts from the mother's blood by the fetus, in such quantity as to deprive the mother of what should rightfully be hers, to unite with the fatty matter in her liver cells, to form lipoids—soluble fats—which would then be conveyed by her circulation, to be deposited in tissues normally the dépôts of free fat, and also as a source of fat to the fetus. (2) This fatty infiltration causes disturbed liver function, with the production of toxins from imperfect protein digestion. (3) Circulation of toxins causes fatty degeneration of liver cells, thereby increasing the liability of the liver to functionate, with resulting increased toxæmia. For those who believe in the theory of immunity, this means that the organism does not form a sufficient amount of antibodies to render harmless any excess of toxic material.

I have spent a considerable time in laying before you the more important theories of the causation of this disease because I believe that if we could ascertain the cause we should not only be able to treat the patient with more likelihood of success, but we should by prophylactic measures be made able to safeguard all pregnant women.

Sir Halliday Croom is of opinion that, as all *post-mortem* examinations show the liver and kidneys are primarily involved, an explanation may be furnished by the fact that these organs are at fault, and functionate badly. The fact that the kidneys are not perfectly sound would account for a sudden chill being the immediate cause of an attack, and a chill may be brought about in many ways, and in any weather. Nagel found, from the records of the Berlin Hospital,²⁰ that some periods of the year had practically no cases of eclampsia, and in other months they occurred in series. On referring to the Royal Meteorological Institute of Potsdam, he found that the months which were free, or almost free, from eclampsia, were those months of a high barometer and even temperature, a change bringing damp, wet, and raw weather, making existing nephritis worse, and as a consequence increasing the number of eclampsia cases. Against these views, however, it must be admitted that cases occur in which no changes in the kidney or urine are made out, although the kidneys are involved in about two-thirds of the cases of eclampsia, and albumen is found in the urine in about 84 per cent. of all cases.

TREATMENT.

It would be impossible for me here to discuss all the methods which have been advised or adopted by those who have had experience of this illness, but there are two points which ought to be borne in mind in approaching the study of treatment. First, that about 75 per cent. will recover, whatever may be done; and, secondly, the condition is so deceptive that, with reference to drugs, it is impossible to say that because a certain remedy has been successful in a few cases it will benefit all, or even the majority. Life is too short for any one man, however extensive his practice may be, to come across a sufficient number of cases in his own individual private work upon which to found rules applicable to all eclamptics. There are some practitioners who have attended many hundreds of confinements and yet have but rarely met with a case, and Croom mentions two²¹ who have had between two and three thousand cases of labour and have never had a single case of puerperal eclampsia. Therefore it is easy to conceive of a practitioner, having had a few cases treated in a certain manner, being so impressed by them, if followed by success, as to feel strongly that his treatment saved the patient. We are therefore compelled, in dealing with treatment, to draw our particulars from hospitals and large clinics where the opportunity is afforded of admitting considerable numbers. It is natural that, in dealing with an anxious case, such as one of eclampsia, the medical attendant, if within reach of any maternity or hospital, should be glad to send the patient—if suitable as a hospital patient—there, so that he may be relieved of the responsibility of her treatment, and in the full knowledge that everything possible will be done for her. Hence the facility of dealing with large numbers, and of drawing conclusions therefrom, for, as the average number of cases varies from 1 in 500 to 1 in 250, according to where the statistics are compiled, it is evident that

we must have a large number of confinements to give us data.

Prophylactic Treatment.

Although we do not know the exact cause of the disease, and therefore cannot prevent toxæmia, we do know that frequently there are signs and symptoms of pre-eclamptic toxæmia which occur, and which give us warning of the approaching storm. I shall therefore divide this subject into (a) preventive, and (b) curative treatment.

The most common signals of danger are headache, which may persist for some days without any other symptoms, or it may be accompanied or followed by nausea, epigastric pain, sickness, diarrhoea or constipation, increased arterial tension, rapid pulse, lessened excretion, dimness of vision, and disinclination to exertion, or sometimes restlessness and excitement, the urine, as a rule, containing albumen. These symptoms may or may not be accompanied by oedema of the extremities and face. In my own experience the most common symptom has been headache, which has been more or less persistent, and slight blurring of vision. Occasionally dimness of vision may come on quite suddenly, and may be marked in one or both eyes. I remember one patient at the seventh month who complained of headache in the morning, and next day had well-marked albuminuric retinitis, but no oedema of the face or extremities. In many cases, before any symptoms arise at all, if the urine should be examined, albumen may be found, and this is always a danger signal if present in any quantity. It must be said, however, that in some cases symptoms will develop and no albumen be present, and in others no symptoms appear until the first convulsion. In one case of a patient who appeared to be absolutely well about six weeks before the confinement was due, I found on examination of the urine about three-fourths of albumen. In spite of my strong opinion that premature labour should be immediately induced, six days were allowed to pass, and I was summoned to her in the country, to find her unconscious and in continued convulsions. A large amount of albumen is not, however, always followed or accompanied by eclampsia. I remember one patient whose extremities were oedematous, and whose urine was scanty and almost solid with albumen, who arrived in town, owing to unavoidable delay, only immediately before the expected date of her confinement, when she was seized with labour, through which she passed satisfactorily. Another, to whom I was summoned in the country, had a fair amount of albumen, with no pre-eclamptic symptoms, who went through labour well, and was seized with violent convulsions afterwards, from which she recovered perfectly.

When the foregoing symptoms occur, accompanied by a small amount of albumen, undoubtedly the best treatment is to put the patient to bed and feed her on milk, giving as much aperient saline medicine as may be necessary to keep up free relief. According to Nicholson, eclampsia is due to an insufficiency of iodothyryn. Milk diet does not require so much iodothyryn; but a meat diet yields too little iodothyryn, and also yields too little iodine for the manufacture of a fresh supply. Therefore the patient may get well on this simple milk diet. Should the albumen increase in amount in spite of this treatment it will generally be found that the output of urea decreases in relation to the rise of albumen. It has been pointed out by Herman that there is a great diminution in the amount of urea in puerperal eclampsia, although we know from experiments that urea is not the reason of eclampsia. If the amount of albumen is rising—a sure indication that the woman is being increasingly poisoned—we have either to allow her to take her chance of continued rest and milk causing amelioration, or induce premature labour. The latter, in my opinion, is far the better course, because, as the affection is a disease of pregnancy, when that condition is over the results of the disease will most likely pass away. As I have already pointed out under the head of etiology, painful contractions of the uterus may be sufficient to cause a convulsion. The woman is in a state of unstable equilibrium, and the least irritation may turn the balance, so that the necessary manipulation to induce labour may be the means of bringing about the one thing we wish to avoid. Yet I still say that it is more prudent to induce labour and take this risk, because if there be a risk of induction it is hardly likely that the state of

irritability will be less by the time labour spontaneously starts, even if the patient continues free from convulsions for so long.

With reference to the method of inducing labour I shall only mention that, in my opinion, the safest and simplest, provided there is no reason for hurrying, is by passing one or two sterilized bougies into the uterus with every aseptic and antiseptic precaution. I have done this on many occasions, and up to the present have not met with any difficulty or haemorrhage from the bougie passing between the uterine wall and the placenta. Even if bleeding did take place in the special case under consideration it would probably do more good than harm.

Of course, the time at which the albumen occurs or is discovered, and the amount, will influence one's opinion, for if it be before the seventh month it is natural to give the woman every chance of continuing the pregnancy sufficiently long to bring forth a living child. If, however, rest in bed, combined with a milk diet, does not seem to lessen the amount of albumen, or if other symptoms do not seem to be improving, it is far better, in the interests of the mother, not to delay terminating pregnancy, at whatever date from conception it may be.

Although the foregoing treatment is the best to prevent the actual onset of eclampsia when any symptoms or signs develop, yet we know there are cases which occur where there are no signs or symptoms whatever, and the first indication of anything being abnormal is the sudden onset of convulsions. We know also that albuminuria in large quantity may occur quite suddenly, and therefore it is important to examine the urine from time to time, although this may not always be practicable, for the patient may not be seen at all until shortly before confinement, or only when taken with symptoms of illness.

Curative Treatment.

As the etiology is still obscure, it is not possible to prescribe a causal therapeutics, but as we believe the disease to depend on some toxin, our endeavour must be to eliminate that toxin as quickly as possible, while we take care of the patient during the convulsive stage. The treatment may therefore be divided into (a) surgical, and (b) medical.

Although it will not be possible to discuss all under the first heading it will be of interest to enumerate the methods suggested.

Emptying the uterus: (a) Abdominal; (b) vaginal.
Total extirpation of the uterus.
Decapsulation of one or both kidneys.
Amputation of both mammae.
Trebining of the cranium.
Lumbar puncture.
Bleeding.
Intravenous injection of hirudin.
Injection of air into mammae.

Emptying the Uterus.

In discussing the subject of emptying the uterus, which means active interference with a patient who is in such a state that the least irritation may lead to a fresh convulsion with risk of death, it would be rather a pleasant reflection with which to console one's self that the patient would be better untouched by operative interference, because some statistics prove that emptying the uterus does not stop fits, and therefore that it does not influence the disease. But as this is a disease of pregnancy, we know that when the child is born, the woman, should she survive, is at least nearer the end of her troubles. In fact, in my opinion, puerperal eclampsia may be looked upon as a disease having a definite course to run, like typhoid fever; in this case, if the poison in the system be sufficient to kill, then the patient will not outlast the ordinary course of the disease, but if the powers of resistance, or her "defensive forces" are strong enough, she will continue to the end, and recover. Now we know that, as a rule, in eclampsia, it does not run its course until the confinement is over, and therefore it is clearly good treatment to help terminate the pregnancy, providing that can be done without adding a greater danger, either immediate or remote, to the patient, always remembering that she is in a desperate condition, because, although we know the average of recoveries, we can never tell that the next convulsion will not kill the patient in whom we are interested. Therefore it is absolutely essential that each case should be treated on its own merits.

I do not wish to burden you with statistics, but with reference to the rapid termination of pregnancy there are some I must refer to, and I would remind you that such is the interest in puerperal eclampsia that every year which passes helps us, on account of accumulating experience, to take a different view regarding figures which were collected some years ago. In an admirable paper in 1902 by Herman, who collected from the reports of different clinics 2,142 cases of puerperal eclampsia, he states that of these the fits ceased in 850 after delivery. He considers that the comparison of the cases in which the uterus was rapidly emptied with those in which it was not interfered with was to show that there was no benefit in emptying the uterus, the fits were not stopped, neither was the death-rate apparently smaller. It is only right, however, to point out, and Herman thinks the objection a fair one, that the figures showing a very high mortality among the patients delivered by operation are taken from pro-antiseptic times, and do not apply to operative delivery under conditions of the present day.

Of course, in dealing either with operative means or spontaneous delivery, the most important point for consideration is the amount of time elapsing from the moment of the first convulsion to the emptying of the uterus. There can be no doubt about the increasing mortality with the multiplicity of the fits. In 571 cases collected by Seitz from Schauta, Schlesinger, Dührssen, and others, this is clearly shown, and Reuben Peterson²² tabulated 615 cases showing the results of prompt delivery and the expectant plan of treatment of eclampsia, and the former give a mortality percentage of 15.9 as compared with 28.9, the mortality of Professor Bumm being 4.8 as compared with 31.1 by the expectant treatment. These figures are very striking as showing the advantages of prompt delivery. In this table Zweifel had a mortality of 32.6 by the expectant treatment, which fell to 15 per cent. when he changed to immediate delivery after the patients entered the clinic. This table is especially valuable, as it shows the reduction in mortality in the same clinic through a change in the methods of treatment, and I therefore hand it to you, with other tables, on a separate printed slip.

It is natural to inquire what effect prompt delivery has on the recurrence of convulsions. It was observed long ago that they were fewer in number and less severe after the birth of the child than before. It is evident that if convulsions continue after the termination of labour the patient is profoundly affected by the poison, and the danger to the kidneys, liver, etc., may be so great that the eliminative treatment is not of the least use, and the patient is fatally ill with the first convulsion.

In a table given by Peterson, modified from Seitz, out of 2,135, convulsions ceased in 52.7 per cent. after delivery, including operative and spontaneous, whereas in 453 cases of vaginal and Caesarean section the convulsions ceased in 62.6 per cent. In another table showing cases in which convulsions ceased after spontaneous delivery he gives 59.7 per cent. This is almost exactly the same percentage as that of 994 cases in which convulsions ceased after operative delivery.²³ Therefore, from the foregoing figures it may be said that convulsions cease after delivery in a little more than half of the cases, and that it seems to make but little difference as regards convulsions whether delivery be spontaneous or terminates by operation. Although convulsions cease after delivery, it is not certain that the patient will recover, for 18 per cent. die; but she will have a better chance, because where the convulsions continue after labour the mortality is 10 per cent. higher. An interesting table shows that the convulsions may be taken as an index to the extent of the poisoning of the mother, and that the fewer the number of convulsions before vaginal Caesarean section the better the percentage of safety to the mother. It varied from a mortality of 18.5 per cent. when the operation was performed after from one to five convulsions to 100 per cent. when undertaken after from sixty to sixty-four fits.

It is necessary to refer to the fetal mortality in general in eclampsia compared with that following vaginal Caesarean section. Peterson gives the fetal mortality after all kinds of treatment as 29.4 per cent., and after vaginal Caesarean section undertaken at varying periods after the first convulsion it is 21.2 per cent., which is

lower than in other series. Where only three convulsions occurred before the birth of the children by vaginal Caesarean section, the fetal mortality was only 11.8 per cent. Out of 139 cases of spontaneous delivery the mortality percentage of the fetus was 25.1. The fetal mortality is lower after spontaneous than after various operative means of delivery (25.1 and 30 per cent.), but it is not so low as after vaginal Caesarean section. The reason for this lower fetal mortality after Caesarean section is that the operation is quickly performed, and the child is subject to little traumatism, which is undoubtedly the cause of the death of many infants. In the anxiety to deliver quickly by the ordinary methods, the child is frequently apt to suffer. While eclampsia is nearly three and a half times more in primiparae than in multiparae, the mortality in the latter is higher (28.02 and 22 per cent.)

It is evident from the foregoing that prompt delivery gives the woman the best chance, and in seeing a case you will quickly have to decide upon the most expeditious manner of emptying the uterus. Much, of course, will depend upon the time when the first convulsion occurs, and whether the patient has actually begun labour. If she be a multipara, with a soft dilatable os, or a primipara where the cervix has been taken up and no difficulty offers against dilatation, then if this can be safely and fairly rapidly done, it is far better for the woman than anything else, provided there be no narrowing of the pelvis. The dilatation can be carried out with simple dilators—Bossi's dilators—or manually. On the occasions when I have used Bossi's dilators I have had no difficulty, but I am certain that it requires great care not to cause laceration of the cervix. When the cervix is fully dilated, and not before, the membranes can be ruptured, and version performed, or forceps applied. As a point of great practical importance, I am sure that thorough dilatation of the cervix is essential before version or the application of forceps if you are to feel safe in avoiding lacerations in delivering the child. Of course all this takes time, however favourable the condition of the cervix, but in spite of the comparative delay it is far more satisfactory to deliver in this manner than to perform Caesarean section. But supposing the cervix is rigid, and quite undilatable (a word which must only be used with reference to the time likely to be spent upon dilating a hard and rigid cervix), the fits are recurring, and you consider rapid delivery will give the best chance to the woman, you must decide between vaginal Caesarean section or abdominal Caesarean section, and remember that the woman will have a better chance from either operation if she has not been subjected to manipulation by other operative procedures prior to Caesarean section.

Supposing the surroundings and arrangements for the abdominal operation are satisfactory, and the patient is at term, or approaching that time, abdominal Caesarean section is easier, and provides a clear exit for the child, especially if there be the least contraction of the pelvis. In vaginal Caesarean section the difficulties which may be met with are principally connected with the injury to the bladder, the difficulty in drawing down the cervix and in suturing it, and in tearing the cervix. But out of 530 cases collected by Peterson there was no difficulty with the operation as originally recommended by Dührssen in 1896 in 214 cases, and he concludes that the anterior incision ordinarily serves all purposes, and that the additional incision in the posterior cervical lip can be dispensed with. In using both incisions the percentage of tears of the uterus and soft parts was rather higher than when only one was used.

Taking into consideration that in Dührssen's operation the parts operated on are high up, that often one must trust to touch, because everything is not in sight, that haemorrhage may also tend to obscure the field of operation, and that when finally version or forceps are used, with the knowledge that injury may be done to the bladder or uterus, I think that most will prefer the abdominal route. This is probably more true to-day than when Dührssen's operation was originally introduced, because the field of Caesarean section has become more extended. The earlier methods of operation have been improved upon. There are modifications of the uterine incision, and, of course, the most important development is the extraperitoneal Caesarean section introduced by

Frank, of Cologne, in 1907. In this operation the peritoneum can be stripped from the bladder and uterus, so that the risk of infection becomes lessened.

Freund states that the methods in use in the Charité in cases of eclampsia are early delivery in order to diminish the severity of labour, venesection, and isolation. In 551 cases which were delivered in the first hour the mortality was 0 per cent. The mortality rapidly deteriorated with the duration of the disease at time of operation.

Decapsulation of the Kidneys.

According to Kermauner,²⁴ decapsulation carried on before delivery is of no value. Unilateral decapsulation only is irrelevant, and has had to be given up. Bilateral decapsulation carried out some hours after delivery yielded, according to Balsler's collection of cases, thirty-seven deaths out of a total of ninety-one—that is, 40 per cent. As it is possible that favourable rather than unfavourable cases are published, the results must be regarded as of small value.

Total Extirpation of the Uterus.

This has been carried out on the assumption that the poison, or part of the poison, causing eclampsia was manufactured in the uterus.

Amputation of the Mammary Gland.

Sellheim²⁵ records a severe case of *post-partum* eclampsia recovering after amputation of the mammae, and Martin, who has published a case of severe eclampsia recovering after the same operation, believed that the fall of blood pressure caused by the operation had a great deal to do with its success.

Lumbar Puncture.

Bataski²⁶ published cases treated by lumbar puncture. When the arterial tension denotes a permanent state of hypertension, he considers it more rational than venesection. He withdrew 20 to 35 c.c.m. of cerebro-spinal fluid, which was followed by relief in each case.

Medical Treatment.

I may enumerate some of the many remedies suggested in this affection, and then indicate what seems to be the most satisfactory means of treatment. Anaesthetics, morphine, chloral, veratrum viride, adrenalin, thyroïdin, parathyroïdin, hirudin, nitroglycerine, to act on the peripheral system; erythrotetranitral, calcium chloride, potassium chloride, serum treatment, removal of colostrum, hot packs and hot-air bath, oxygen, the injection of air or oxygen and potassium iodide into the mammae, lumbar anaesthesia.

As the treatment should be eliminative, based on the knowledge of a toxæmia, our object is to get rid of the poison as quickly as possible, or dilute it. A good dose of magnesium sulphate or some other saline may be given at once, or some prefer croton or castor oil, so that rapid aperient action may be secured. If there are reasons against rapidly emptying the uterus, one of the best means of diminishing the poison is to bleed freely and to use saline injection, or transfusion directly into the circulation by a vein. Bleeding is one of the oldest remedies, and in former days very free bleeding was practised. Ramsbotham²⁷ used to take "from 40 to 60 oz. and even more in the course of a very few hours." Of course, each patient will not stand the same amount of loss, but about 500 c.c.m. or 600 c.c.m. may be withdrawn at first, or an amount until the pulse becomes affected or the patient turns pale. There is no better means of diluting the poison than by these two simple methods, for, if no transfusion apparatus is at hand, continuous proctoclysis can be kept up by a small catheter in the rectum with normal saline solution.

Theoretically, hot packs and hot-air baths, by drawing off perspiration and tending to increase the thickness of the blood, ought to be harmful, but practically they seem to do good in some cases. Little²⁸ has had great success with the use of hot-air baths.

Döderlein²⁹ and Leopold advised against sweating, but if the patient can drink plenty of fluid, and if the saline solution be flowing freely into the intestine, rectum, or vein, then dilution of the poison is taking place and no harm can come of it. You must, however, remember that

such treatment is of no good if the patient is already oedematous, and if the kidneys are not acting at all.

Some prefer to give at once a large dose of morphine or chloral hydrate. If the patient is very restless, I prefer chloral. Of course, if there is high blood pressure the morphine reduces it, for it is a powerful vaso-dilator, but, if possible, it is better to do without it, because it undoubtedly adds risk to the child, and it is not without danger to the mother, with kidneys insufficiently acting. If the tension is high, veratrum viride will certainly lower it, and has long enjoyed a reputation in this affection. If the uterus has been emptied, and the convulsions should continue, with high tension of the pulse, this drug is well worth trying, but it must be used with care, for it is very powerful.

The patient may be kept soothed with some anaesthetic; and although chloroform is certainly more convenient, yet, if it is to be administered for a considerable time, it must be remembered that chloroform poisoning produces changes in the liver which are practically the same as those caused by the disease. Ether may be substituted for it, for Mr. Bellamy Gardner informs me that it does not attack and disintegrate the cells of the liver as does chloroform. For the actual convulsions, the inhalation of oxygen may be used when the surface of the skin becomes dusky.

According to Zweifel,⁸⁰ between 1887 and 1892, when chloroform and sweating but no venesection were employed, the mortality amounted to 32 per cent. In the years 1892 to 1895, when operation was done without chloroform and morphine and without sweating, the mortality sank to 15 per cent. He advised against sweating, because it thickens the blood, and is in favour of artificial dilution of the blood, and the excess of acid in the blood to be combated by the administration of vegetable acids.

Lichtenstein⁸¹ recommends venesection, usually withdrawing 500 c.cm. of blood, and states that his recoveries amounted to about 24½ per cent.

There are two methods of treatment which deserve to be mentioned, because in the hands of some they seem to have been efficacious. One is the therapeutic employment of normal serum from pregnant women, as carried out by Mayer (Tübingen) and the other is the use of large doses of thyroid gland. I have already said that I have no intention of mentioning nearly all the many remedies which have been suggested, but anything which is likely to act as a direct antidote to the poison is worthy of consideration, and thus may act in this manner. Nicholson⁸² considers that thyroid extract is the ideal vaso-dilator in cases of eclampsia, but that it is necessary to use large doses; 30 or 40 grains are given at first, and a second dose of 20 or 30 grains in six or eight hours if there should be no improvement. He considers that the noteworthy points in relation to this treatment are the unusually early re-establishment of the renal functions and the rapid and complete disappearance of symptoms. He believes that normally thyroid secretion is the opposing influence which safeguards renal circulation from a dangerous over-action of the internal secretion of the suprarenals, which acts as a constrictor of the arteries and capillaries. Englemann has injected hirudin (leech extract) intravenously with the object of inhibiting the coagulation of the blood and preventing thrombosis, and recently Licht⁸³ has published cases of intramammary injections of air.

I need not weary you by detailing other remedies, but I feel sure that the best results will come to those who regard this, in the light of our present knowledge, as a poison in the blood acting on the nerve centres; and as our treatment of all poisons is by an antidote when the poison is known, and by elimination, and, failing this, dilution when the poison is unknown, so the simplest way of regarding a patient suffering from puerperal eclampsia is as one suddenly poisoned, and treat her accordingly. Therefore anything which will, in any degree whatever, strengthen the defensive forces of the body, will do good. My belief is that venesection, combined with the endeavour to eliminate the poison, and dilution with saline transfusion will be of most service.

There are many cases in which no treatment is of any avail, and which are mortally ill from the moment of the first convulsion. There are others, again, which are not so seriously affected, although this can never be known

at first, and therefore they are the ones which may recover under any treatment whatever, and are the cases where one is apt to have an exaggerated idea of the importance of any special line of treatment if it happens to be successful.

If the temperature be steadily rising, the patient comatose, with a rapid pulse, tending to be more frequent and thready, a tepid bath may be given if this be possible. The patient may be put into a warm bath, which is gradually cooled down to 80° F. or lower, and allowed to remain in for twenty minutes. This doubtless acts in the same way as it does in serious cases of typhoid fever or acute rheumatism.

Conclusions.

From the foregoing it may be concluded:

First, that in spite of all the labour which has been spent upon investigation, we know of nothing which we can definitely state gives rise to the disease, although everything seems to point to poison circulating in the blood as being the cause.

Secondly, that without any doubt recent statistics show that the best treatment is that of rapidly emptying the uterus—by whatever means this may be most safely accomplished—after the first few convulsions; that is to say, without indefinite delay. The woman and the child are thereby given the best chance of life, and, as already stated, the maternal mortality has been lowered in the hands of some to under 5 per cent.

Thirdly, that the greater the delay in carrying out this treatment after the onset of the first convulsion, the greater will be the danger.

We must hope that the time is not far distant when, by continued research, the knowledge of the actual cause will provide us with a weapon to surely prevent the onset of this disease, and relieve the accoucheur of the future of one of the most terrible complications of the lying-in room.

FROM statistics of the number of women pursuing higher studies in Prussia which have recently been published it appears that in the last winter session the total number was 2,980, as against 2,892 in the previous year. Of these, 361 were students of medicine, as against 329 in the corresponding session of 1911-12.

A MEETING of the committee of the German Society for the Repression of Quackery was held at Dresden on March 9th, when the following officers were chosen for the ensuing year: President, Professor Beythien; Vice-President, Professor Schmorl; Secretary, Dr. Neustatter; Assistant Secretaries, Drs. Decker and H. Weber; Treasurer, Dr. Eger.

THE USES AND ABUSES OF PROPRIETARY FOODS IN INFANT FEEDING.*

BY

HECTOR CHARLES CAMERON, M.D., M.R.C.P.,

ASSISTANT PHYSICIAN AND PHYSICIAN IN CHARGE OF THE CHILDREN'S DEPARTMENT, GUY'S HOSPITAL.

For the past year or more one subject has been interesting us particularly in the children's department at Guy's Hospital, where we come in contact with a very large number of infants suffering from all the disorders which are the common result of artificial feeding. We have examined all cases of infantile dyspepsia, among the artificially fed with the object of estimating the part played in the production of the disturbance by the proportion of sugar in the diet, and we have come to the conclusion that excess of sugar is by far the most common cause of dyspepsia, at any rate among the children from such a poor neighbourhood as Bermondsey and the river side. I believe that in the past far too little attention has been paid to this particular aspect of infant dietetics. Sugar, which is commonly added with so free a hand by the mothers, is looked upon by them merely as a flavouring agent, and not as the constituent of the food most vital for the growth of the child and for the development of animal heat. It is quite common to find that a heaped teaspoonful of cane sugar is added to each of ten feeds for an infant whose weight totals but 8 or 10 lb. This amount is equivalent, weight for weight, to the consumption by an adult weighing 10 st. of about 2 lb. of pure cane sugar in the course of the day. That all infants on receipt of such an amount do not immediately respond by developing diarrhoea is evidence of the enormous tolerance for sugar and the great demand for sugar which the growing child shows.

In contrast with this apparent neglect of the importance of carbohydrate excess as a factor in the production of dyspepsia, there is no doubt that in the past the difficulties of protein digestion have been much exaggerated. Cow's milk, as every one knows, contains a very high percentage of casein, and it is to this single peculiarity that in the history of infant feeding a vast deal of attention has been directed. A difficulty in digesting the casein of cow's milk has been regarded as the crux of the whole matter. When an infant fed on cow's milk is sick the vomit is apt to consist of a dense curd of casein, and it seemed natural to attribute this to a special difficulty in the digestion of a substance which is present in amounts so strikingly in excess of the proportions found in human milk. In order to prevent the formation of this clot a whole series of devices has been recommended from time to time—for example, the use of barley water, of lime water, of sodium bicarbonate, and more recently, of sodium citrate.

At one time confirmation of the belief in the indigestibility of casein was found in the appearance in the stools of milk-fed infants of certain white curd-like masses which were presumed to be formed of undigested casein. Such stools, indeed, are commonly described by nurses and mothers as "undigested." It is long since these white curds have been proved to consist not of casein at all but of soaps. I believe, too, that the vomiting of casein curds is not to be looked upon as implying an inherent difficulty in the digestion of casein, but is an accident due to the nature of the food. If an infant fed upon cow's milk happens to develop dyspepsia it has no option but to vomit a dense curd, because such curds are formed normally in the process of digestion. Any good which results from the use of lime water, sodium bicarbonate, or sodium citrate, is, I think, due not to the prevention of the clotting process, but to the effect upon the acid fermentative dyspepsia which is the actual cause and occasion of the vomiting.

Dyspepsia in infancy is nearly always of a nature to be benefited by the addition of alkalis. The fats, and especially the sugars, tend to undergo fermentative changes, with the result that a great excess of volatile fatty acids is formed. As a result the contents of the stomach become intensely acid, and even the breath may have a sour, rancid odour. When these acid gastric con-

tents reach the intestine, they act as a powerful stimulus to peristalsis. In spite of the free flow of alkaline succus entericus which their presence provokes the reaction of the intestine is always acid. The stools are green, watery, and so sour that the anus and any part of the skin which comes in contact with them is apt to be irritated and excoriated. The stimulus to peristalsis may be so great that the tense coils of intestine may be visible through the abdominal wall, while the pain is such that the whole body of the child is thrown into restless movement.

On the other hand, an infant fed upon a diet so poor in sugar as unaltered cow's milk is not likely to suffer from these symptoms of diarrhoea and vomiting. Upon a pure milk diet the stools are formed, clay-coloured and alkaline, because the volatile fatty acids, as a result of the low content of sugar in the food, are all held bound as soaps by the alkaline salts of the succus entericus. A diet of whole cow's milk, therefore, often results in constipation because the natural stimulus to peristalsis is absent. The very great success which whole-milk feeding has achieved proves, I think, two things. It shows that infants are able to digest the large amounts of casein without disturbance, and that the great majority of infants, among the sugar-fed children of the poor at any rate, are for a time likely to benefit by a change to a diet in which the percentage of sugar is relatively low.

Although an infant fed on whole milk without addition of any sort is likely to be free from any very stormy attacks of diarrhoea and vomiting, it is not to be supposed that the results will invariably be entirely satisfactory. In such infants the want of sugar often leads to constipation, to want of growth, and to backward development generally. We can therefore draw a sharp contrast between the baby fed only on cow's milk—pale, undersized, backward in development, with subnormal temperature and cold blue feet and hands, with alkaline, formed, clay-coloured stools and a tendency to constipation—and the infant fed upon a diet rich in sugar, whether milk dilutions to which sugar has been freely added or one of the numerous proprietary foods, in nearly all of which the sugar is present in great excess, an infant perhaps larger and better grown but with a troublesome tendency at the least provocation to suffer from explosive attacks of diarrhoea and vomiting. With each attack the tolerance for sugar tends to be lowered, sometimes only temporarily, sometimes permanently, so that a second attack supervenes more readily than in the first instance. In bad cases the tolerance for sugar may fall so low that dyspepsia is produced upon an amount less than that necessary for the maintenance of the body weight. In such a case a condition of true marasmus is produced in which the usual paradoxical reaction to food is seen. By the paradoxical reaction is meant that the child loses weight slowly when almost starved and loses weight with terrible rapidity when an attempt is made to increase the amount of food, because of the dyspepsia which results.

I do not mean that all infants fed on cow's milk will develop the one set of symptoms or that all infants fed on mixtures rich in sugar the other set of symptoms as an invariable rule; but if unsatisfactory results do follow they will in most cases be of the type described. We have, indeed, always to remember how great is the tolerance of infants living under good hygienic surroundings for even the most unsuitable forms of diet, provided only that no sudden changes are introduced. If infants invariably responded to an excess of any one constituent by developing the appropriate and expected symptom we should have a much clearer idea of the results of excess than we have at present. Because one sturdy infant has successfully accustomed itself to thrive upon a diet consisting largely of starch and sugar we must not conclude that to adopt a similar diet will therefore bring salvation to a weakling already in difficulties with its digestion. Yet this is the procedure again and again adopted by mothers and nurses, and it is the argument constantly reiterated by proprietors of special foods.

Proprietary foods have a distinct field of utility among a community which is not skilled in the difficult art of cookery for young children. We find in them an easily available and perfectly successful means of combating the ill effects which I have tried to describe as resulting from an exclusive milk diet. If we remember that most of them are composed preponderatingly of carbohydrate of one or other

* An address delivered before the Camberwell Division of the British Medical Association.

sort and that therefore they have the drawback that they are liable, in those infants whose carbohydrate tolerance is small, to produce fermentative dyspepsia, diarrhoea, vomiting, colic, and excoriation of the buttocks, we shall be in a position to make use of them to attain good results without endangering the stability of digestion.

We may divide the foods into seven groups:

1. *Condensed Milk with a High Percentage of added Cane Sugar.*

Sweetened condensed milk is enormously popular among the poorer classes; it is cheap, it keeps for a long time, and it is easy to prepare. If one heaped teaspoonful is mixed with 3 oz. of water, a mixture containing approximately 1 per cent. fat, 1 per cent. protein, and 5 per cent. sugar results. During the first two months of life infants often show a marked intolerance for cow's milk, occasioned by their inability to digest the comparatively high percentage of fat, with the result that vomiting of curd is extremely common. On the other hand, upon a mixture with a low percentage of fat and a high percentage of sugar, such as sweetened condensed milk, they often thrive well. The danger lies in the increasing tendency which the child shows to develop fermentative dyspepsia as its growth calls for an increased concentration and larger amounts of food. I find, too, that mothers frequently add to the risk by adding still further amounts of cane sugar. In children over 6 months the extremely low fat content is very liable to produce rickets.

2. *Condensed Milk without added Sugar.*

This consists of milk condensed in a vacuum to a third of its bulk. By the addition of water a mixture of approximately the same composition as milk can be obtained. For some reason or other, probably because it does not keep so long as the sweetened variety, it has never been popular, and it is sometimes difficult to get shopkeepers to stock it. There may, however, be a further explanation for this unpopularity in that unsweetened condensed milk does not differ sufficiently in its composition from fresh milk to make its substitution haphazard a procedure likely to bring about improvement. The not infrequent good results achieved by the sweetened variety are, as I have said, due to the accident that in many young infants there is an idiosyncrasy against fat, while the power of digesting sugar remains good. Such infants are, therefore, well suited by the change from cow's milk to a sugar-rich diet such as sweetened condensed milk. Unsweetened condensed milk, on the other hand, is nearly as rich in fat as fresh milk, and contains no more sugar. It is very useful when a supply of pure milk cannot be obtained, as in times of great heat or when travelling.

3. *Dried Milks.*

These are prepared by spreading a very thin sheet of milk over a heated metal plate, so hot that the milk is rapidly dried and converted into a powder. The composition of these milks does not differ materially from fresh milk, and in consequence their prescription does not as a rule show very marked therapeutic effects. I do not believe that dried milk is possessed of advantages over fresh milk, except, of course, in its relatively low bacterial content. If good fresh milk can be obtained its use is always to be preferred. In proprietary foods we are not seeking for a permanent substitute for cow's milk, but are prescribing for the time being a change in the diet with a definite therapeutic object. From this point of view foods under the headings 2 and 3 are of little service.

4. *Dried Milks with added Malted Sugar.*

Such preparations are undoubtedly very valuable because of the high percentage of malted sugar which they contain. All sugars are not equally liable to undergo fermentative changes, and to give rise in consequence to diarrhoea and vomiting. Undoubtedly the least liable is maltose, just as cane sugar is at the other extreme and is the worst offender in this respect. While comparatively poor in fat, these foods have a high carbohydrate percentage, while at the same time they are free from added cane sugar. They are therefore often very useful in the dyspepsias produced in very young infants fed upon cow's milk with its relatively high percentage of

fats. In older children they are too poor in fats unless used in a concentration which raises the percentage of sugar to a dangerous height. They have the further drawbacks of being relatively expensive and of permitting the development of scurvy.

5. *Pure Malted Sugar.*

If a child is convalescent from an attack of fermentative dyspepsia, or if it is known that its tolerance for sugar is permanently low, we should choose a malted sugar in preference to lactose or cane sugar.

6. *Foods consisting almost entirely of Unaltered Starch.*

Such preparations are specially useful for children over 7 months of age. In the later months of infancy it is often wise to make use of the growing power of the child to digest starch rather than to run the risk of producing diarrhoea by giving large amounts of saccharine matter. After 9 months of age a second form of carbohydrate in the form of starch should always be given. For young infants these foods are quite unsuitable.

7. *Foods consisting of Mixtures of Unaltered Starch and Malted Sugar.*

Many of these foods contain a ferment which is capable of converting starch into sugar, and the amount of this conversion to some extent depends on the length of time during which the milk mixture is allowed to simmer by the fireside. By diminishing this gradually we can attempt to train the infant's powers of starch digestion.

These are the classes of food at our disposal, and by an intelligent use of them much can be accomplished. Unfortunately mothers and nurses, relying on the extravagant claims of proprietors, are apt to prescribe them absolutely at random without the least appreciation of their composition or properties. Often each is tried in turn, in the hope, too often fallacious, that one will eventually be found to suit. Before this happy result is reached, if it ever be reached, very often an enormous amount of harm and suffering is caused. To give a young infant suffering from the effects of sugar excess a proprietary food in which this particular fault is accentuated, is often to cause a serious danger to life itself.

TREATMENT AND DIET.

The infant with green watery stools, vomiting, colic, ulceration of the buttocks, and a slightly raised irregular temperature benefits almost always by a change to a whole-milk diet. Such infants are commonly fed on proprietary foods containing a gross excess of sugar or starch, or upon a milk mixture to which large amounts of cane sugar have been added. One attack predisposes to another because the tolerance for sugar is lowered long after convalescence is established. In hot weather, because his food and drink are bound up in the same fluid, the child, rendered thirsty by diarrhoea, vomiting, and perspiration, is apt to take excessive amounts of his sugary diet.

Treatment should be instituted by a purge and by twenty-four hours' starvation. During this time boiled water sweetened by saccharine alone is allowed. In severe cases the stomach and bowel may be washed out with a weak solution of sodium bicarbonate. A few drops of hydrochloric acid—*acidi hydrochlor. dil. mxxx-xl, mucilag. ʒss, syrup. simplicis ʒss, aquam ad ʒiv*, two teaspoonfuls every four hours—are extremely useful in controlling the fermentative process in the stomach. In all these cases the absence of free hydrochloric acid from the stomach plays an important part in the production of the excessive fermentation. When the symptoms improve, feeding may be begun again by giving small amounts of boiled milk undiluted except in the case of the very youngest infants. One ounce of this may be given at first every four hours. If the infant, used to the taste of the much sweetened food, will not take the plain milk, it may be sweetened with saccharine. About $\frac{1}{10}$ grain of saccharine is equivalent in sweetening power to a teaspoonful of cane sugar. During these days of underfeeding the needs of the child for fluid must be met by the provision of a plentiful supply of

water, and care should be taken to see that he is kept very warm. Gradually the amount of milk taken may be increased, but any diminution in the interval between the feeds should be avoided for some time, because the treatment aims at allowing the stomach to empty itself completely between meals. Only in this way can the fermentation be controlled. In very severe cases the cream should be removed from the milk. Sometimes further amounts of proteid may be given by the addition of somatose or plasmon. The principle underlying all these prescriptions is that no acid fermentation is possible on a purely protein diet. After recovery from the attack of diarrhoea, the child may sometimes be kept for a long time upon this diet of whole milk and continue to thrive. In other cases the addition of some carbohydrate feeding becomes necessary.

The troubles which manifest themselves on a diet of pure cow's milk are of two sorts. In the first place, very many young infants manifest a complete inability to digest the fat of cow's milk, even in great dilution. Such babies suffer from profuse vomiting, often of curdled milk, and are either constipated or pass bulky white, greasy, foul-smelling stools. Upon a change to a fat-poor, sugar-rich diet the symptoms usually cease at once. A similar fat indigestion, with vomiting, colic, and constipation, is usual with very young infants nursed every two hours at a freely flowing breast, with abundance of rich milk. Less frequent nursing and the provision of a little sugar will usually cure the vomiting and constipation.

In the second place, many babies fed on cow's milk, although they are free from diarrhoea and vomiting, remain small and ill developed. I have seen infants who for months showed no gain in weight, although they were daily taking enormous amounts of milk of good quality. These children are pale, flabby, and constipated because the volatile acids present in such excess in the sugar-fed child, and which form the natural stimulus to peristalsis, are reduced to a minimum. The stools are large, bulky, and pale when the percentage of fat is high, or hard and pellet-like when the milk is poor in fat, and are always alkaline to litmus. In such cases the addition of carbohydrate produces immediate improvement. In young infants the use of a malted sugar or of a dried milk with added malt is indicated. At 6 months one or more feeds made with the addition of some starch-containing food may be advisable, and substituted for a similar number of pure milk feeds. After 6 months it is found over and over again that infants who immediately react to increase in the amount of sugar with diarrhoea will tolerate starchy forms of carbohydrate perfectly well. Finally, it may be said that extract of malt agrees well with the milk-fed baby, but aggravates the disturbances of sugar-fed children, while cod-liver oil has properties just the reverse.

The disorders of sugar over-feeding are much more common among the poor than among the well-to-do. There are few infants in the hospital class who do not at some time or other suffer in this way, and we have here, I think, the explanation of the undoubted success of whole-milk feeding among them. Among the upper classes fat over-feeding from the use of a milk rich in cream is more common, and there is a distinct tendency at present to adopt the principle of giving undiluted milk without diminishing the bulk of the feeds and increasing the intervals between meals proportionately. Among these children the substitution of a suitable form of carbohydrate for the large amounts of fat consumed is sure to produce benefit in more rapid growth and in the disappearance of constipation. In infants habitual constipation, like habitual diarrhoea, is seldom to be treated by drugs, but is often to be looked upon as a symptom indicating a faulty composition of the food calling for the prescription of a change in the diet upon the lines indicated. The use of large doses of castor oil and of opium in young infants is generally to be avoided because such drugs mask the very symptoms which should guide our prescriptions, and introduce factors disturbing to our observations.

THE first meeting of the Swiss Surgical Society, founded last year, was held at Berne on March 8th. Professor Kocher, of Berne, was elected president; Professor Girard, of Geneva, vice-president; Dr. Steinmann, of Berne, secretary.

PREVENTION VERSUS CURE IN MODERN PRACTICE.

By CHARLES J. WHITBY, M.D. (CANTAB.),

BATH.

THE President of the British Medical Association, in the address which he delivered at Liverpool on the occasion of the annual meeting, foretold the coming of a new era, in which the practice of medicine will be devoted largely and increasingly to the prevention rather than the cure of disease. I mention this in order to emphasize the fact that it is not necessary to be an admirer of the National Insurance Act—of which, indeed, Sir James Barr has been one of the most outspoken opponents—in order to realize the proximity and inevitableness of this new era. Still, it remains true, and is not without significance, that the Act does provide for the payment of medical men for attendance on a large section of the community upon what is intended to be a preventive basis. I confess to grave misgivings as to whether the intention will be fully realized, because it does not seem to me that the conditions of genuinely preventive practice are met by the provisions of the Act. But the intention is there, and may be taken for what it is worth as a sign of the times and, we will hope, of better things to come. It seems to me, therefore, a timely proceeding to consider what are, as a matter of fact, the main conditions of success in the translation of medical practice from the mainly curative to the mainly preventive sphere, and to what extent these conditions already are or are in a fair way to be met.

To begin with such conditions as affect the profession as a whole, not as mere individuals, it seems indispensable that it should be functionally organized throughout in such a way that its ultimate resources of science and art shall be available at need for each and every case that may arise. This, I need scarcely say, is at present very far from being so; and in so far as it is so, the credit belongs in the main not to the State or the community but to the profession itself. We have done our best to arrange that the wisdom and skill of our wisest and most skilful shall be at the free disposal of those who cannot afford to pay for them. But there is a limit to the possibilities of charity, and, since those whose need is the sorest must be conceded the first claim, it inevitably happens that the resources of general and special hospitals are exhausted in the task of patching up more or less hopelessly damaged organisms rather than in the detection and stamping out of the insidious beginnings of disease. So far as charity is concerned, all the time and knowledge and skill that we can afford to give away are fully occupied at present in the curative sphere; of the attempt at prevention it is as yet futile even to dream. Yet it is, at all events, a hopeful sign that during the past three years the organization of the profession has advanced by leaps and bounds. It is as yet merely an economic and defensive organization, analogous to that of the trade unions; but I do not believe that it will stop there. Functional organization is bound to follow, and, if we are wise, will proceed upon lines governed by the preventive ideal. By functional organization I mean an arrangement by which every malady shall be recognized in its incipient stage by the regular attendant, and, if it be of a nature whose treatment falls without his province, referred to the proper quarter, where State-aided or other provision shall be made for its needs. The germ of such an arrangement may be recognized in recent suggestions that the out-patient department of hospitals, as at present constituted, be abolished, and that only consultative work and special forms of treatment be undertaken in its place. But the subject is too large for detailed discussion in a short paper—it is a matter for collective investigation, and one which the Association itself will probably have to take seriously in hand before very long.

To come now a little more to close quarters with our subject, it is obvious that the transition from the mainly curative to the mainly preventive aim in medical practice involves not merely a shifting of the general and individual points of view, but also a new standard of values as regards the theoretic basis of our work. Physiology

and hygiene must be elevated to the seats of honour; pathology and therapeutics must be content with lower places in medical esteem. This may seem a hard saying, but it is beyond question the logical consequence of the admission that prevention is better than cure. It does not necessarily, I think, involve the paramountcy of the public health service. That is concerned mainly with such minimum requirements as good housing, pure water, an uncontaminated milk supply, the notification and isolation of infective diseases—all highly important matters, but matters upon which all enlightened minds are practically agreed. There can be no health without the conditions for whose maintenance the public health service is responsible; it does not follow, however, that there will be satisfactory health when its task is done.

A community is made up not of average or typical units but of infinitely diverse individuals with infinitely diverse requirements from the health point of view. The average citizen considered and legislated for by the framers of health laws is no less mythical than the "producer" and "consumer" of political economy. The physiology and hygiene upon which preventive practice will be based will have to take account of idiosyncrasy just as curative practice takes account of it now. Generalizations may be unavoidable, but they must not be rash or premature, and must be based on the natural history of genuine types. By anthropometrical methods, aided by psychological acumen, we shall probably arrive in time at some sort of a classification, which may have important practical effects from the sociological point of view. For instance, it would not surprise me greatly if research along these lines were to result in a scientific vindication of the ancient caste idea, leading possibly to its re-establishment in a suitably modified form. For I confess to the belief that individuals fall naturally into distinct groups or strata, differentiated by inborn temperaments and capacities; and that, from the health point of view—to say nothing of happiness—it is indispensable that such matters be very much more seriously taken into account in the choice of a given individual's vocation than is at present the case. Here, then, is one among many matters in relation to which the preventive practitioner of tomorrow may find ample scope for his erudition and insight, however great these may be. Wherever he finds a round peg in a square hole, it will be his duty to call the attention of the powers that be to the danger of disease and breakdown that such a predicament, at least in extreme cases, undoubtedly involves. The economy of life and ability is a matter of vital concern to every civilized commonwealth. Unfortunately this obvious truth is far from being realized to any adequate extent as yet; it is for us, therefore, to make it known.

But these remarks are a digression from the subject of the theoretical basis of preventive practice, to which I wish for a few moments to return. It is a curious example of the way in which, during transition periods, all things work together for a common revolutionary end that the boundary line severing physiology from pathology seems to be rapidly becoming invisible. It is impossible, or soon will be, to say where one ends and the other begins. The time has long passed when it was customary to think of disease as a something extra-natural—a visitation of the invisible—to be combated by amulets and spells. But the traces of this conception have lingered until quite recently in the minds of even the most enlightened. Now they are well-nigh obliterated; pathologist and physiologist, tunnelling in opposite directions, have met on common ground. We think of disease in terms of health, and of health in terms of disease. Health seems to be in the main conditioned by the functional equilibrium of various glands; and since now one, now another of these glands takes the lead and evokes the antagonism of the others as the rhythm of growth and development proceeds, it is hardly too much to say that, from the chemico-vital aspect, a series of antitoxications, followed by slowly acquired immunities—that is to say, of illnesses and recoveries—is the normal course of events. Dentition, puberty, adolescence, menstruation, sex life, the climacteric, afford, even in the healthiest individuals, common ground for the physiologist and the pathologist. There is a pathological factor in all health, and a physiological in all disease; the two conditions

overlap, and merge into one another by imperceptible gradations.

So preventive and curative medicine meet when a disease due to functional inhibition of a given set of glands is treated by the administration of full doses of the missing internal secretion, thus affording immediate relief of symptoms as well as the interval of rest required by the damaged organs. Much of modern surgery belongs equally to the preventive and curative spheres. Metchnikoff has gone so far, I believe, as to advocate the systematic removal of the large intestine, which he regards as a retrograde, functionally useless structure, and a source of real danger to its possessor. Professor Keith declines to follow him all the way in this drastic proposal, so that I think we may not promise our surgeons this fine field of adventure in the near future. But obviously such common procedures as the removal of adenoids from the nasopharynx, of a chronically inflamed appendix, even of an early malignant growth, are items of preventive practice. And the scope and possibilities of such preventive surgery are extending yearly.

A very important branch of preventive practice, in regard to which a satisfactory theoretical basis is, however, still mainly to seek, is the regulation of diet. We all have our notions about diet; we all accept, because we cannot do otherwise, the responsibility of forbidding this or that to our gouty, rheumatic, rheumatoid, pyrexial, or diabetic patients, and permitting other things. But how many of us are prepared to justify on scientific grounds either our sanctions or prohibitions? The voice of the food reformer is loud in our midst; his proposals become every year more iconoclastic. There is hardly a single article of common food, not excepting the "staff of life" itself, which has not been condemned as deleterious to health by one or another section of lay opinion. But so far as we as a profession are concerned, with the exception of one or two individuals like Dr. Haig and Dr. Campbell, there are no signs of any live interest in this very important and indeed urgent subject. Surely it is high time that an organized effort were made to grapple with some of the many problems connected with dietetics and to solve them satisfactorily. It seems to me pre-eminently a matter for collective investigation; and now that our Association is to some extent relieved from the uncongenial task of a quasi-political campaign, I hope that it will take up this kind of work in earnest. It is probable that, not merely for every kind of work, but also for every constitutional type, there is a diet conducive to maximum health and efficiency. Some kinds of food may be conducive to mere longevity, others to mental or muscular energy, others again to reproductive or combative power. Such generalizations, if they could be arrived at and justified, would be of the greatest possible aid to every practitioner, and of real national utility.

No paper dealing with the preventive aspect of medicine could omit mention of the all-important problems connoted by the term "Eugenics." For prevention begins too late if it begins only at birth; it must aim at the eradication and replacement of those morbid inborn tendencies of which actual disease is the issue. The term "Eugenics" is at present used to designate both the scientific study of heredity and the application of its principles to the improvement of a given stock. It would be better to apply the term "Genetics" to the purely scientific branch of such investigations. "Eugenics" is the name proposed by Galton for the systematic attempt at the betterment of the human stock. Genetics is a science; Eugenics is, or may become, an art based thereupon. And Eugenics may be subdivided into two forms, negative or positive, according as it aims merely at the prevention of unfit or the promotion of desirable births. Into the subject of Genetics it is impossible for me to enter here, but those interested therein will find an excellent account of some typical research work in a volume entitled *Heredity and Eugenics*, recently published by five investigators connected with the University of Chicago. It was reviewed in the BRITISH MEDICAL JOURNAL for November 30th, 1912. With regard to the eugenic ideal, the first desideratum, according to Sir James Barr, is the frank recognition of the need of a new racial morality and of the responsibility of medicine for the interests of the race, as well as and in precedence of those of the individual. Galton went even further, insisting that the task of

deliberately and systematically furthering human evolution should be regarded as a religious duty; and, in my opinion, rightly; for where the control and guidance of so powerful an instinct as that of reproduction is in question nothing short of an appeal to the deepest of all motives is likely to prove effectual. Morality is based upon religion; and the first cannot be changed unless and until the second has been modified. In the sphere of negative eugenics something may no doubt be done by legislation, by prohibiting reproduction in cases of sheer imbecility and idiocy. In fact this is already being attempted. But this is a rudimentary matter; on the other hand, the new racial morality advocated by Sir James Barr will, if I be not greatly mistaken, prove a much more formidable proposition. It will winnow the community, and in particular our profession, from top to bottom, severing the husk from the grain.

That the transition from the curative to the preventive aim in medicine will be a slow and gradual one goes without saying; so far, then, as the immediate future is concerned it admits of no laxity in regard to matters therapeutic, but, on the contrary, demands from the practitioner, in addition to all past requirements, a new alertness as to the possibilities of personal hygiene, mental and emotional as well as physical, an intelligent interest in sociology, and the cultivation of an evolutionary conscience, based on study of the conditions that will make or mar the future of the race. Preventive practice is not likely to prove easier than curative practice, nor less attractive to a high type of personality.

A CASE OF CHRONIC PLUMBISM IN WHICH MULTIPLE ANEURYSMS OCCURRED.

By R. GODWIN CHASE, M.B., B.C. CANTAB.,

HONORARY SURGEON TO THE CHESTERFIELD AND NORTH DERBY
HOSPITAL.

THE following notes of an interesting case that died in the Chesterfield and North Derbyshire Hospital bring out in a very remarkable way the close association between the occupation of painter, attacks of colic, chronic interstitial nephritis, atheroma, aneurysm, and the simulation of intestinal obstruction.

I am indebted to the house-surgeon, Mr. F. C. Pridam, for the following facts, which he obtained from the patient and his friends upon admission and subsequently, and also for making of the *post-mortem* examination, at which I was present.

The patient was a man 44 years old, whose occupation for thirty years had been that of a painter. He stated that he had had several attacks of lead colic, evidenced by severe headache, constipation, and abdominal pain of a colicky nature, relieved by pressure. He thought he was healthy except for the fact that micturition was frequent during night time.

On February 18th, 1912, he was attacked with severe pain in the head and abdomen. He vomited and became giddy. Two days later he had a slight attack of haematemesis, and later on melaena was present. The bowels had previously not acted since February 18th. This pain and constipation continued until his admission into hospital on February 25th as a case of subacute intestinal obstruction.

He was a pale, anaemic-looking man. He was apathetic, lying on his back listlessly, and appeared indisposed to answer questions, though he did answer when spoken to.

The apex beat was in the fifth space just external to the nipple line; it was forcible. The exact area of cardiac dullness was not noted. There was a loud systolic murmur at the apex traceable outwards towards the axilla, and a loud systolic murmur heard best at the aortic cartilage, but traceable down the sternum. Capillary pulsation was absent; there was no dullness over the second and third cartilage. There was evidence of emphysema, but no other pulmonary abnormality.

The pulse was high in tension and poor in volume. The walls were not felt to be thick. The tension of the left posterior tibial artery was thought to be greater than the tension in the right.

The abdomen was thin; the skin on its surface was easily picked up and lacking in elasticity. A tumour, which was thought to pulsate, was felt below and just to the right side of the umbilicus; marked pulsation could be felt above the umbilicus. Mr. Pridam was of opinion that both these pulsations were expansile. The intestinal coils were slightly distended; nothing abnormal could be detected on percussion; the liver and spleen were not felt. On auscultation a loud systolic murmur, traceable upwards and downwards on the abdominal wall, was heard over the tumour.

The nervous system, as far as it was examined, was normal; Argyll Robertson pupil was not present; the teeth were absent from the upper jaw, and there was pyorrhoea in the lower. There was no blue line. Urine: specific gravity 1015, acid, no sugar, no albumen, and no incontinence. There was no sign of specific disease nor any history thereof.

We had to decide whether the patient was suffering from some slow-growing neoplasm, causing abdominal pain for some time, and then producing more obstruction, leading to vomiting, blood in the motions, and afterwards to constipation, with distended small intestine. The lump in the region of the caecum, if not the neoplasm itself, might have been due to the secondary enlargement of glands, the pulsation of the right common iliac artery being transmitted through it.

If this diagnosis were accepted, immediate laparotomy would be called for. The alternative diagnosis was an aneurysm of the right common iliac artery. The man's occupation was one which predisposes to arterial degeneration; the aortic murmur suggested much atheroma of the aortic orifice, and he was, therefore, a likely subject for aneurysm. Mr. Pridam was quite certain the tumour was expansile, as an aneurysm would be, and though I could not myself be quite definite on this point, there was no mistaking the systolic bruit over it, nor the difference in the pulsations of the two posterior tibial arteries. Melaena may occur in patients with abdominal aneurysm, and hence this symptom did not necessarily weigh in favour of growth. As the bowels were moved twice as a result of two enemata soon after admission (the motions contained a little mucus) I decided on the diagnosis of aneurysm of the right common iliac artery.

He was kept at rest in bed and given potassium iodide gr. x three times a day. This produced a rash which cleared up when the dose was doubled, leaving a little erythema.

He lay in bed, taking very little interest in anything, until March 1st, when it became more difficult to induce him to answer questions. Next day he was still more drowsy and apathetic; he fainted on sitting up, and showed a tendency to mental wandering. The iodide was stopped.

On March 5th hiccup commenced and he was much more drowsy. The rate of the pulse was increased but its volume diminished. The abdominal tumour still felt and the amount of urine passed was scanty. On the next day the abdomen became tender and swollen. The pulse at times was scarcely perceptible. The heart sounds were as before except that the aortic systolic murmur was more difficult to hear. Urine 1015, acid; no reduction of lead salts with potassium iodide. The patient had had incontinence for several days.

On March 7th, at 3 a.m., after a feed the pulse disappeared and respiration, which had been slow, stopped. After about ten minutes the pulse started again for one or two beats, but death then ensued.

Post-mortem Examination.

The lungs were emphysematous. Pleura very adherent at bases and posteriorly. Apices free.

Heart.—Left ventricle thickened; muscle wall very hard. Right ventricle large and flabby. Very little blood in any part of heart. The aortic, tricuspid, and pulmonary valves were competent. Mitral regurgitation was present. The aorta was markedly atheromatous, and there was present a large dissecting aneurysm extending the whole length of the ascending arch, which was itself much elongated. Vessels were filled with old and new clot. There was an aneurysm of each common iliac artery filled with clot. The left external iliac artery was very much thickened and hard. The inferior vena cava contained recent blood clot past the renal veins to the common iliac veins.

The liver was large and fatty; the spleen was small.

Kidneys.—Soft capsule, stripping fairly easily; cortex diminished in size.

Intestine.—Bluish-black. The large intestine was distended up to the splenic flexure, where there were a few adhesions. There was no growth and no obstruction.

Specimens of intestine and kidney were sent to the Clinical Research Association, which reported on them as follows:

"A minute trace of lead was found present both in portion of kidney and of intestine. Histologically, the kidney shows a very marked condition of chronic interstitial nephritis. There is a great increase of intertubular fibrous tissue. The glomeruli show typical changes and some minute cysts are formed. These appearances are consistent with those seen in the kidney of those suffering from chronic plumbism."

This patient was therefore proved by *post-mortem* examination to have suffered from: Chronic plumbism, chronic interstitial nephritis, mitral regurgitation, marked atheroma of the aorta, dissecting aneurysm of the arch of the aorta containing old and new clot, two aneurysms of the common iliac artery, thrombosed inferior vena cava, fatty liver, and a trace of metallic lead in kidney and intestinal tissues.

The explanation of what happened whilst he was alive in hospital was, I think, that the complete rest in bed, possibly together with the iodide, promoted the formation of blood clot in the thoracic aneurysm. This would have the effect of making the lumen smaller and so decrease the blood supply to the rest of the body; urinary secretion would therefore be diminished with consequent early uraemic symptoms; apathy and drowsiness, inclination to easily faint, would correspond to a low blood pressure, consequently a diminished pressure of blood in his brain. Then suddenly a piece of the clot totally obliterated the aneurysm, stopping the passage of blood, with consequent arrest of the heart.

Abdominal aneurysm is rare, but a case in which two are present is rarer still. This rarity, together with the occurrence of thoracic aneurysm, as well as the numerous other morbid conditions, most, if not all of them, traceable to his occupation, is my reason for publishing these notes and observations.

UNUSUAL FERTILITY IN SYPHILITIC PARENTS, ASSOCIATED WITH ANOMALOUS INVOLVE- MENT OF THE CHILDREN.

By H. FERGUSON WATSON, M.B., Ch.B.,
L.F.P.S. GLASG., L.R.C.P. EDIN.,

LATE MEDICAL OFFICER, ROYAL HOSPITAL FOR SICK CHILDREN'S
DISPENSARY, GLASGOW.

(From the Pathological Laboratories of the University and Western
Infirmary, Glasgow.)

It has been suggested by Wassermann¹ that the serum of every woman admitted to a lying-in hospital should be tested. Mott² suggests that a Wassermann reaction should be done on all infants born of parents who are syphilitic or who are suspect, whether the infants present symptoms or not. If these suggestions were adopted probably a large proportion of positive results would be obtained in cases which presented no other evidence of syphilis.

So far there are few records in which an examination of children who did not present syphilis has been carried out. We find, however, that Churchill³ has investigated 102 cases of infants and children in an American children's hospital—cases in which syphilis was not suspected—and obtained a positive Wassermann reaction in 39 cases. Findlay and Watson have shown the importance of recurrent eczema oris in cases of congenital syphilis.⁴

Since the discovery of the reaction introduced by Wassermann, Neisser, and Bruck over five years ago, it has been shown that a positive result is practically specific for syphilitic infection. It is known, however, that positive results are obtained in framboesia and leprosy, and perhaps in malaria and trypanosomiasis. Such diseases are tropical, hence a positive result in this country is taken to mean infection with the *Treponema pallidum*. The value of the reaction cannot be overestimated in latent syphilis and in cases of paroxysmal haemoglobinuria.⁵ In mild cases of congenital syphilis the disease soon passes into a latent stage, and for a time there may be no other evidence of syphilis; the symptoms have been regarded as "hives" by the mother and medical opinion has been passed over.

I have had the opportunity of examining a large number of children in which there were no stigmata of syphilis at the Royal Hospital for Sick Children, Glasgow, yet among such I have found a large number who gave a positive result. It has been the custom to examine, whenever possible, the parents and other members of the family, as the examination of such groups of related cases has been found to yield results of very great clinical interest. Where a positive result has occurred in a child it has rarely happened that every other member of the family was negative.

In all cases the family history and physical condition have been carefully investigated, and the Wassermann reaction has been carried out according to the method of Browning, Cruickshank, and Mackenzie.⁶ In the investigation of the family history there are certain difficulties. Some mothers are not at all anxious to lay bare facts which happened before or even after marriage. Others have had such slight manifestations of disease that they did not regard them as of a venereal character. It is

always important, in my opinion, to ascertain if the parent had any irregular habits before marriage. In the case of either parent a history of taking alcohol to excess before marriage suggests other irregular habits.⁷ A neurotic condition is always suggestive, as I have found a large percentage of positive results in that class where there was nothing further to suggest syphilis.

At present I wish to put on record an investigation into the condition of a single family. There are various points of interest, and I shall give details of each member in turn. The family was that of a wandering gipsy found in the slums. The mother brought up one of her children for examination. The child had multiple dactylitis. Examination of the condition led to the conclusion that the child was suffering from syphilis, though there was no other evidence, the mother being apparently healthy and denying that she had ever had venereal disease. Each member of the family was then examined and the blood of each drawn off for a Wassermann reaction.

The mother, aged 21, a woman of average height, intelligent, well nourished, but very dirty, was born and brought up in Russia, but had been in this country since her marriage in 1910. She gave a negative history, stating that her health had always been good; she had never suffered from any eruption, loss of hair, or sore throat. On physical examination, her teeth seemed normal and in a good state of preservation. There were no scars on the body and the superficial glands were not palpable. On the right labium majus, however, there was a definite scar. Questioned about this, she said she thought there was a "pimple" there soon after marriage, but she did not associate it with venereal disease, and still was firm in her belief that she never had had venereal disease. Since her marriage in 1910 she has been thrice pregnant, and each time has given birth to twins. There have been no miscarriages. The first children were born seven months after her marriage; she stated spontaneously that their birth was two months premature. The second children were born eleven and a half months afterwards at the eighth month, while the youngest children were born ten months after the second pair, they also being born at the eighth month. The youngest children were born in Ireland on September 14th, 1912. Thus the mother has given birth to six children in twenty-two months—the first being born in November, 1910, and the last in September, 1912.

It is of interest to note that all the children, according to the mother's statement, which appeared to be accurate, were born prematurely. Owing to the fact that a multiple pregnancy frequently ends in premature expulsion, it is difficult to form an opinion as to whether syphilis had anything to do with premature labour; but, nevertheless, it will be observed that the first pregnancy resulted in expulsion of the twins at the seventh month, whereas her succeeding pregnancies ended one month later. On the other hand, it should be observed that the first twins were of normal size, while the other four children, born one month later, were small as compared with the first children.

The father, aged 29, was born in Russia, and, like his wife, lived there till his marriage. Since then he has been all over the British Isles. He makes tin cooking utensils. He denies ever having had venereal disease. He denied ever having had any eruption, any sore throat, or that his hair ever fell out. His general appearance caused one to doubt his truthfulness, and as he gave a history of alcoholic excess we subjected him to a most minute physical examination. His teeth were well preserved and appeared normal. All superficial glands were indurated and readily palpable, especially those in the groin. There was a small scar on the penis, but no scars in the groin. Questioned minutely about the scar on the corona glandis, he said it was not venereal, though he "skinned" the organ two years before marriage, and it "festered" and took some time to heal. However, he maintained that it was not a venereal sore. At that time also he had sore eyes, but never any headache. At the time of examination the pupils were small, equal but irregular in outline, and reacted sluggishly to light. Knee-jerks were in excess. Babinski's sign was negative. His speech was slow and hesitating. There was a tremor of the lips and he was easily excited. His ideas seemed slightly exaggerated. Indeed, though not certifiable, he seemed a case

of very early general paralysis of the insane. From the history it would appear that he was infected before marriage, and this we consider of importance in view of what will be found in the history of the first twins.

First Twins.—B. (girl) and S. (boy), aged 1 year and 11 months. Both children seem in perfect health, being well nourished and free from evidence of syphilitic stigmata. Both parents state that these children never had any eruptions after birth.

Second Twins.—W. and M., aged 11 months, both females. The former was the child brought to me with multiple dactylitis of phalanges of second right and third left fingers; third right and third and fourth left toes. There is no evidence of suppuration and no evidence of thickening of the metacarpals or metatarsals. The other child has thickening of both humeri and of the right femur and left fibula (it being thicker than the tibia of that side). The thickenings are more nodular than spindle-shaped and are multiple. The parents state that both these children had slight eruptions on the buttocks at six weeks, but no peeling of skin of palms or soles. The former had difficulty in breathing by the nose.

Third Twins.—A. and J., aged six weeks, both males. Both children have condylomata of anus, sore eyes, peeling of skin of hands and feet. The former has marked fissuring of the lips, an eczematous patch at the right side of the nose, and marked snuffles. The latter has a marked coppery eruption on the nates and the line of junction of mucous membrane and skin of lower lip is very irregular. He also has snuffles.

I examined the serum of the parents and children, and in each case obtained a very marked positive result.

TABLE SHOWING RESULT OF EXAMINATION OF SERUM OF PARENTS AND CHILDREN.

Date of Wassermann Reaction, October 30th, 1912.

v.m. = Very

marked.

a.c. = Almost complete.

j.e. = Just complete.

c. = Complete.

SUMMARY.

There are various points of interest in these cases:

1. Both parents deny specific disease.
2. Both show evidence of syphilis which is only revealed on very minute physical examination.
3. Parents and children all give a positive Wassermann reaction.

4. Manifestations of syphilis appear to be more severe with successive pregnancies.
5. There have been no abortions.
6. Successive multiple pregnancies.
7. Six children born in twenty-two months.

GONOCOCCAL URETHRITIS IN A BOY AGED SEVENTEEN MONTHS.

BY

ARCHIBALD SMITH, CH.M.MANCH., F.R.C.S.ENG.

AND

C. S. MCKEE, M.D.TORONTO, M.C.P. and S.ONTARIO,
VANCOUVER, B.C.

F. P., aged 17 months, the child of parents in comfortable circumstances, was first seen on December 5th, 1912. The complaint was that he could not pass urine. On examination there was some redness at the end of the foreskin, which could, however, be retracted completely. A hot bath soon relieved his disability, and he was ordered local boracic fomentations and a dusting powder.

Circumcision was suggested, and approved by the father but objected to by the mother, and for the time refused.

Ten days later similar trouble caused another summons to the child. The local condition was now much aggravated, a typical balanitis being present, and the foreskin would not retract. Circumcision was now insisted upon, and performed next morning. Four days later a discharge from the urethra was noticed. A specimen was taken for bacteriological examination, treatment being delayed until the report was received and until the circumcision wound was more nearly healed.

A verdict from the bacteriologist of colon bacillus or staphylococcus infection was anticipated, but a verdict of gonococcus was almost incredible. A report by Dr. C. S. McKee on the bacteriological findings is appended.

The subsequent history of the case was uneventful. At first a mild lotion of zinc sulphocarbolate was used, but after a few days, as very little improvement was manifest, 1 per cent. carentosol, a colloidal silver preparation recently put on the market, was substituted. After five days discharge ceased, and treatment was continued a further five days; eight days later a slight recurrence of the discharge took place and treatment was resumed. All discharge ceased again in four days, but treatment was continued for a further seven days, with complete cure and no complications.

The rarity of this case makes it worth recording. The difficulty was to trace the source of the infection. No one but the mother and nurse had had access to the child. The parents were certainly not infected. The nurse is a respectable woman, but is a widow of about three years' standing, her husband having died six months after marriage of "rheumatism." She admitted having taken the child into her own bed when restless. The remaining links in the chain of infection can only be surmised, but it would appear as though the source had been traced. Moreover, there seems no doubt that it was a case of gonorrhoea from the beginning, the balanitis being secondary to the gonorrhoea, and not of urethritis consequent upon balanitis—a possible but unusual sequence.

BACTERIOLOGICAL REPORT BY DR. MCKEE.

On examination of a smear of pus from the above case stained by Gram's method, I expressed the opinion that it was gonorrhoeal. The picture was typical of that disease in grouping of the organisms in the pus cells, their shape and staining qualities.

Doubt of the correctness of this opinion by the attending surgeon made cultures necessary, and these were made on various media, including a rather rich ascitic fluid agar to

which haemoglobin had been added, a medium I use altogether for the isolation of the gonococcus.

No gonococcus-like organisms grew on any of the media except the latter, and on this there developed a number of characteristic colonies, which on staining showed the usual characters of this organism. Subcultures of the pure growth were made on the aseptic media, as well as on various others; only on the aseptic agar did any growth occur, and only a limited number of the colonies showed ability or desire to grow in subculture. Even those which did grow in subculture were very sensitive to their surroundings, and the one pure culture which I kept for stock, now in its sixty-fifth transfer, needs to be transferred every day or it will die. I have not been able to make it grow on any modification, even, of the original medium.

TETANY IN ACUTE SUPPURATIVE APPENDICITIS IN AN ADULT.

BY

BASIL HUGHES, M.A., M.B., B.C., B.Sc., F.R.C.S.,
BRADFORD.

THE condition of tetany occurring in adults is not altogether common. Perhaps the commonest conditions with which it is associated are gastro-intestinal disorders (gastritis, dilatation of the stomach, and intestinal parasites), pregnancy, and operations upon the thyroid gland; sometimes it complicates the infectious fevers, notably typhoid. Less rarely still is it associated with certain poisons taken into the system, such poisons being lead, alcohol, and ergot. It is said to complicate cerebral and cerebellar tumour, but this must be extremely rare. Tetany associated with surgical operation upon the thyroid gland is a very rare condition, and I cannot recall a case out of a large number I have seen operated upon. It has been said that tetany occurring in this last named condition is due to removal of the parathyroid bodies, and experimental work seems to lend support to this statement. The following is a case of tetany associated with acute suppurative appendicitis.

A. C., aged 35, married, was admitted to the Bradford Royal Infirmary on December 19th, 1912, complaining of acute abdominal pain. The onset was very sudden, and she had vomited once a bile-stained fluid. She was admitted thirty-six hours after the onset of the pain.

History.

We found out that four years ago she had been seized suddenly with acute abdominal pain, not so severe as the present attack, but she gradually got better without operation. She was seen two years later by Dr. Manknell, of Bradford, and her symptoms resembled those of gastric ulcer. She had another attack between this last and her present one, and again her symptoms suggested a gastric origin. She had suffered pain after food, constipation, and lassitude, and she was never well for any length of time. She had never had haematemesis, jaundice, or malaena. The urine was dark, but contained no extraneous matter.

Condition on Admission.

The temperature was 100°, pulse 112 and regular, respirations 24. The abdomen moved only slightly on respiration, and this on the left side only. There was a rigidity and general tenderness all over the right upper and lower abdominal quadrants. Pain was noticed on deep pressure in the right loin. The right flank was dull, the liver dullness was normal. On rectal examination, thickening and tenderness was found high up on the right side. The condition of acute appendicitis was diagnosed.

Two hours after admission the patient developed marked and typical tetany in both hands, and the pulse rose to 120. Her general condition suddenly became grave, and an immediate laparotomy was performed. She had never had tetany before.

Operation.

By means of the right rectus incision the abdomen was opened, and an appendix abscess containing about 2 oz. of stinking pus was evacuated. The appendix was retrocaecal, and its tip was bound down to the lower pole of the right kidney. There was a perforation about 1 in. from the end, and a concretion had escaped. The appendix was removed with some difficulty, and a large drainage tube inserted.

After-History.

The patient made an uneventful recovery, and left the hospital on January 5th, 1913. She had no return of the tetany while in hospital, and I hear from Dr. Manknell that she is now very well, and has been bothered in no way since the operation.

This case is interesting, as it is the only one I have been able to find in which tetany was associated with acute

appendicitis. When the tetany developed I was naturally prompted to reconsider the diagnosis and to think that after all it might be some gastric lesion. Unfortunately, owing to the nature of the operation; I was unable to look at the stomach; but seeing that this patient has had no gastric symptoms since, that she has very much improved on her condition prior to operation, and has put on weight and enjoyed and felt ready for food, it is possible that the stomach itself was never at any time at fault. In view of the excellent exposition of this truth by Sir Berkeley Moynihan, whose words on appendix dyspepsia we are all acquainted with, and which surgeons must by now have confirmed, I think it is quite reasonable to attribute the condition of tetany in this case to a diseased appendix. How the tetany was produced, whether it was toxic or reflex, I am not prepared to say.

This case may perchance shed some light on other cases of tetany which may have been attributed to dyspepsia, gastritis, or other gastro-intestinal conditions, and in such cases a careful inquiry into the history and an examination to exclude the presence of a diseased appendix should be thought about.

ADRENALIN IN CHLOROFORM ANAESTHESIA.

BY

H. T. DEPREE, M.B., B.C. CANTAB.,

RESIDENT ANAESTHETIST, ST. MARY'S HOSPITAL, LONDON.

THE following case seems to be worth publishing if only to emphasize a very real danger which is perhaps not as widely recognized as it should be.

The patient was a male aged 26, a well-developed and healthy man. The heart sounds were normal; the urine contained nothing abnormal. Operation for deflected nasal septum was decided upon.

Anaesthesia was induced by chloroform given upon a Skinner's mask, the induction taking about seven minutes and being unaccompanied by struggling. The patient was transferred to the operating table, and it was decided to inject some adrenalin into the nose subcutaneously. At the time of the injection anaesthesia was light (a brisk corneal reflex being obtainable), the pulse strong, and the patient's colour good. No more chloroform was given.

About one minute after the injection the pulse suddenly became very rapid and then imperceptible; at the same time the patient's colour became leaden grey and the pupils widely dilated. About three deep gasps were taken after the pulse had failed, and then respiration ceased.

The head was at once lowered, artificial respiration performed, and 1 c.cm. of pituitary extract injected hypodermically, and oxygen administered. Finally, an incision was made along the left costal margin and the heart was massaged through the diaphragm, but to no purpose; 5 minims of a 1 in 1,000 solution of adrenalin was used for the injection.

The nostrils had been plugged ten minutes before the induction of anaesthesia with a solution containing cocaine (10 per cent.) and adrenalin.

At the *post-mortem* examination nothing abnormal was found in any of the organs.

In the BRITISH MEDICAL JOURNAL (September 14th, 1912) Dr. A. Goodman Levy published the results of experiments he had made upon cats under chloroform anaesthesia with injections of adrenalin. He found that when the anaesthesia was light after the injection of small doses of adrenalin into a vein, a definite series of events followed: the heart first beat more rapidly and forcibly, but then inco-ordinately, and finally ceased, the effect of the injection being to bring about fibrillation of the ventricles. Under deep chloroform anaesthesia the effect was much less marked, and passed off after a few moments, the heart again beating regularly. Under ether anaesthesia no effect was produced. The case quoted above seems to correspond exactly clinically with Dr. Levy's experimental work.

In the *Proceedings of the Royal Society of Medicine* (February 3rd, 1911) Dr. J. Blumfeld describes a case of sudden collapse following the injection of 6 minims of a 1 in 4,000 solution of adrenalin in a patient anaesthetized with C.E. mixture. In this case, however, the patient recovered after the employment of remedial measures.

If an injection of adrenalin be made just before an anaesthetic is given, no bad results occur. It is difficult to understand the fact that when chloroform anaesthesia is deep the danger of injecting adrenalin is less than when light; unfortunately, in those operations in which adrenalin is most often used for haemostatic purposes—those about the nose and throat—it is a light anaesthesia that is desirable, and the anaesthetic chosen is usually chloroform.

MEDICAL, SURGICAL, OBSTETRICAL.

LONG INTERVAL BETWEEN BIRTH OF TWINS.

A somewhat unusual case of twins occurred in the practice of Dr. Macklin and myself, and seems of sufficient interest to record.

A multipara had a living male child on February 24th, the labour being quite straightforward. Another child could be felt with the vertex on the left and the child's back to the mother's left front. She had severe after-pains at half-hourly intervals for ten hours, and after that at longer intervals, until they ceased in twenty-four hours after the birth of the first child. The lochia was almost absent. She was allowed up at the end of a fortnight, and went about performing her household duties until April 4th, when labour pains came on again and she was delivered of a living female child. The first child weighed 6 lb. and the second 6½ lb., both being small but well nourished, and both are doing well now.

The point of interest is the long interval between the two births, nearly six weeks, and the fact that though the pains after the birth of the first child were strong and fairly frequent they failed to dislodge the second.

She has had four other children, single births, and one miscarriage.

Whalley.

J. M. POSTLETHWAITE.

STRANGULATED HERNIA IN AN INFANT.

The cases recorded last November by Dr. Nichols and Mr. Dent induce me to record a case that occurred in my own practice some two years ago.

The patient was an infant aged 6 weeks at the Jenny Lind Children's Hospital, and I was summoned to it late one evening because the hernia—one of the strangulated inguinal variety—had resisted all attempts at reduction.

Chloroform having been administered, I found that the gut could not be reduced by gentle taxis, and as previous attempts had been made, I operated at once. On opening the sac, about a teaspoonful of turbid serum escaped. The bowel was intensely injected and of a purple colour. The neck of the sac being divided, the gut was easily reduced, and the opportunity was taken to do a radical cure, two buried sutures being used. The child made a good recovery.

I had never previously seen a case of strangulation in so young an infant. During nearly twenty years' work on the staff of the Children's Hospital here I had never seen a case of strangulated hernia in so young an infant, nor did I while house-surgeon at the Manchester Children's Hospital under Professor G. A. Wright. The latter in his book *Diseases of Children* (Ashby and Wright) does, however, mention cases as young as 3 weeks (Halsewood) and 4 weeks (Maunder), and Mr. Rushton Parker, in the *BRITISH MEDICAL JOURNAL* of October 26th, 1912, quoting from Mr. Howard Marsh's article, gives cases as young as 8 days and upwards to 13 years.

I note that Mr. Parker, in his case of an infant 28 days old, used the original strict Listerian dressing, which I also adopted in my case, deeming it safer, but have latterly regularly used the "open" method of Mr. Stiles—that is, no dressings. I have never punctured the scrotal swelling, as Mr. Parker did, although I have on several occasions thought of doing so, the swelling having eventually subsided.

Consulting Surgeon, Jenny Lind Hospital for
Sick Children.

Norwich.

SUGGESTED OPERATION FOR RELIEF OF PROSTATIC HYPERTROPHY.

A CORRESPONDENT (p. 804) has raised a point which has interested me much during the last few years, although I have not had the opportunity to put it to a practical test.

In 1900 I devised and practised an operation for the cure of cystocele in the female, which is mentioned in Dr. Inglis Parson's book on the treatment of *Uterine Prolapse* (page 52). I have since performed the operation in many cases, and always with success.

The results have been so good that I have often wished to put to the test the effect of a similar operation in an early case of enlargement of the prostate gland. The conditions are very similar, for how much of the abnormal growth of the prostate may be due to the infiltration of its substance from the decomposing urine in the residual sac which lies behind and below it? Could an arrest be effected by the obliteration of this sac and its load of bacteria?

The operation for cystocele in the female is simple and safe. The recti are divided in the middle line until the distended bladder is exposed, as in the suprapubic operation for calculus. The finger is then gently swept round the upper surface of the bladder, and detaches it from its abdominal relations until the upper surface of the distended bladder is freed. The contents of the bladder are then allowed to escape, and the loose upper part is drawn down and puckered with a stitch which is lightly tied, the ends being left long. Each long end is threaded in a needle, and is passed through its corresponding rectus as near as possible to its insertion on the pubis, and is then made to serve in closing the lower end of the divided muscles. Other stitches close the upper part of the muscle and the skin wound. For some days afterwards the urine is drawn off by the catheter every three hours. At the end of a fortnight it will be found that the residual urine is almost *nil*. I distend the bladder with a boric acid solution, and give an assistant the charge of the meatus urinarius, which he controls with his finger until he is told to release it, after the upper portion of the bladder has been freed from its former site.

It would be more easy to control the escape of the fluid used to distend the bladder in the male.

Guernsey.

J. AIKMAN, M.D., C.M. Glasg.

A BIMANUAL METHOD OF RECTIFYING A FACE PRESENTATION.

ON March 11th I was called to a woman in labour with her fourth child. Previous labours had been difficult, the pelvis being small and the children rather large.

The face was presenting, the chin being left anterior. The membranes were ruptured and the os uteri partly dilated, but though the face had just engaged the brim, the head was not coming down into the pelvis. It seemed quite obviously a case for podalic version as recommended by the books. As, however, the nearest help was five miles away and I did not at all relish the prospect of failing to deliver an after-coming head, I decided first to make what effort I could to turn the presentation into a vertex.

The patient being in the left lateral position across the bed, I inserted the left hand into the uterus, grasped the head, and rotated the chin well to the right so as to bring the occiput to the left, in order to enable me to make use of both hands to advantage. The left thumb was then pressed upwards on the chin, and with the fingers hooked over the occiput I tried to draw it down; the palm steadied the head, whilst with the right fist pressure was made downwards on the occiput through the abdominal wall. The manoeuvre proved quite successful, adequate flexion being quickly secured. The occiput was then rotated back again and round to the front, the blades of the forceps were accurately adjusted to the sides of the head, and delivery was effected after much pulling.

I am quite satisfied that I should have found very much greater difficulty if I had performed version, and I shall not hesitate to use this method of rectification again if and when occasion serves.

Harston, Cambridge.

W. J. YOUNG, M.R.C.S., L.R.C.P.

Reports

ON MEDICAL AND SURGICAL PRACTICE IN HOSPITALS AND ASYLUMS.

KIDDERMINSTER INFIRMARY AND CHILDREN'S HOSPITAL.

AN UNUSUAL CASE OF HENOCH'S PURPURA.

(Under the care of Mr. J. LIONEL STRETTON.)

[Reported by JAMES R. CRAIG, M.B., Ch.B., House-Surgeon.]

TAKEN in conjunction with recently reported cases of Henoch's purpura, the following presents some unusual features:

A woman, aged 39, was admitted on January 18th with the diagnosis of acute "gastric ulcer." She had been seized during the night previous with epigastric pain and had vomited blood. For three months prior to this attack she had been suffering from severe paroxysmal crises of pain in the back and abdomen. The remissions were fairly complete. She lost flesh, became short of breath and very anaemic, so that she was quite unable to carry on her household duties. She had never previously vomited blood, but stated that once or twice when the pain had been very severe she had strained very much at stool and the motion had been very black. There was a family history of tuberculosis. On admission, the patient was blanched and weak, complained of pain in the stomach and between the shoulders. There was general tenderness over the abdomen, but no definitely painful spot and no rigidity. The temperature was normal, pulse soft and 130. For the first two weeks after admission her condition somewhat improved, she took milk well, had little pain, and complained of nothing but extreme weakness. There was no more vomiting, no albumen or blood in the urine, and none in the stools.

On February 5th the right knee and ankle became painful and swollen, mostly from periarticular oedema. In a few days the other leg became similarly affected, and continued so for about a week. Then the pain left the lower limbs, and she began to suffer from intense crises of pain across the back and the lower part of the abdomen. The pains were most severe, and necessitated the use of morphine. The abdomen was very tender to pressure, but no blood was passed per rectum. The liver was enlarged, reaching to 1½ in. below the costal margin, and tender on palpation. The spleen was enlarged and tender. The urine occasionally showed a trace of albumen, but no blood nor tube-casts.

On February 25th, that is about three weeks after the onset of the joint pains, there appeared a purpuric rash, first on the lower limbs and later upon the sides of the chest and abdomen. The spots came out in scanty crops generally where the pain had been most intense, and were heralded by a sharp stinging sensation, like the sting of a nettle. They were mostly of small size, but several about as large as half a crown were noted on the hips.

The general condition of the patient became gradually worse, and in spite of taking food fairly well and actually gaining in weight, she became progressively more anaemic and enfeebled. Her pallor was intense and the mucous membranes blanched. She continued to have the crises of pain, sometimes across the epigastrium, sometimes across the lower part of the abdomen, and at other times in the legs. On March 25th, after being sick for a day or two, she vomited copiously of "coffee-ground vomit," and died a few hours later.

Unfortunately, a *post-mortem* examination was refused.

The main points of interest in this case are:

1. The age and sex of the patient. The large proportion of recorded cases have been in boys under 10 years of age, where the abdominal crises are so apt to simulate intussusception.

2. The long time before the purpura developed. It was just over five weeks after admission before the first crops appeared.

3. The attacks of haematemesis, leading to the diagnosis of gastric ulcer, and ultimately to a fatal issue.

4. The marked enlargement of liver and spleen.

I am indebted to Mr. J. Lionel Stretton for permission to publish this case.

British Medical Association.

CLINICAL AND SCIENTIFIC PROCEEDINGS.

STAFFORDSHIRE BRANCH.

The second general meeting of the session was held at Stafford on February 27th, under the chairmanship of Mr. E. C. STACK, F.R.C.S.I., President.

Exhibition of Living Cases.

Dr. COOKSON showed: (1) The patient upon whom he had operated for cancer of the sigmoid colon, referred to in his paper which followed. (2) A boy who, on October 26th, 1912, put his arm through a glass door. Later trophic ulcers and other typical symptoms of section of the ulnar nerve appeared. After an operation to freshen and unite the ends of the divided nerve the ulcers at once began rapidly to heal and sensation to return.

Mouth Breathers and Deafness.

Mr. PRIESTLEY discussed the question of mouth breathing and enlarged tonsils in relation to deafness, and illustrated his statements by reference to the data brought to light at school medical inspections. If the deaf cases among children generally were enumerated, it would, he said, be found year after year that they were about 6 per cent.; but if those children who breathe through the mouth were investigated it would be found that 38 or 40 per cent. of them were deaf. If, however, the children with enlarged tonsils were taken and all those rejected who, in addition to having large tonsils, breathed through the mouth, the proportion of deaf cases among the remainder was again only about 6 per cent., the same as that of children generally. This showed that enlarged tonsils as such did not entail any danger of deafness. Moreover, as many, if not most, cases of enlarged tonsils had adenoid growths in the naso-pharynx also, it might further be inferred that even adenoid growths at the back of the nose, unless large enough to cause mouth breathing, did not entail any particular danger of deafness. It was mouth breathing which entailed the danger. Mr. Priestley's paper was discussed by Mr. STACK, Mr. CHOLMELEY, Mr. DICKSON, and Drs. CODD and RIDLEY BAILEY; and Mr. PRIESTLEY replied.

Specimens from Cases of Abdominal Section.

Dr. NESFIELD COOKSON read a paper on three pathological specimens recently removed by abdominal section. The specimens, which were shown with microscopical sections of the two carcinomata, were:

1. A uterus much enlarged; the cavity was opened by a central incision through the anterior and posterior walls, showing a large single submucous myoma about the size of two closed fists; about half its circumference projected into the cavity of the uterus. This was removed on January 3rd, 1913, from a woman 42 years of age, married, with no children. Progress was uneventful; she got up on January 17th, and on February 16th resumed her ordinary housework, including looking after four boarders. Though not in attendance, he had been personally acquainted with the clinical history of the patient for some seventeen years. Always pale, she required little medical attendance till some eight years ago, when she was treated for menorrhagia. Since then her appearances for treatment had been at gradually diminishing intervals, always with similar symptoms—great loss and increasingly severe pain. Menstruation began at 13 years of age; it was always excessive but regular and without pain until eight years ago. Since then the intervals grew less till the flow recurred every fourteen days, and the pain was increasingly severe, lasting twenty-four or more hours and preventing sleep. When seen in December, 1912, she was very markedly anaemic, with fairly general oedema. The enlarged uterus was felt, and removal recommended. Dr. Cookson said that the specimen and the history indicated that this myoma was in process of being extruded; he had met with two cases in which this had occurred. The first, a single woman with a large knobby uterus to be felt in the abdomen, had a large fibroid polypus in the vagina. She had had continuous haemorrhage for eighteen

months, and carcinoma had been diagnosed. When seen she was in a condition of general anasarca, absolutely blanched, and could not turn over in bed without severe dyspnoea. As she was obviously too ill to be given an anaesthetic the mass was seized with two vulsella and twisted round and round in the vagina till free; a mass the size of a large fetal head was then delivered with midwifery forceps. The patient made a good recovery, and was still well with the other fibroids still *in situ*. The other, a half-witted single woman, a servant in an out-of-the-way farmhouse, presented no symptoms until, because of offensive odour and the dropping of blood on the floor, medical aid was sought for. A large gangrenous fibroid was found hanging between the legs, showing incisions where attempts to remove it with scissors had been made by the patient. Simple removal was followed by recovery without symptoms of importance.

2. Uterus and appendages removed by Wertheim's method, showing a fungating epithelioma of the cervix extending on to the vaginal wall. This was removed on January 6th, 1913, from a woman 28 years of age. In July, 1912, she gave birth to her third child. The confinement was non-instrumental. She noticed a discharge a month after, which gradually became more profuse and offensive. When seen on December 7th, 1912, there was a large fungating mass; the uterus was small and freely movable; there was a very offensive discharge. A piece removed for section was reported to be a squamous-celled carcinoma. The growth was curetted and regular douching employed to try and clean the vagina, but the discharge was still offensive when the operation was performed. Suppuration followed the operation in the pelvis, and although the edges of the wound were protected by rubber sheeting after five days, the skin looking quite normal, because of discharge from one part, the wound was opened to its full length and the deeper parts found to have a peculiar greenish sloughy appearance. Beyond requiring regular catheterization for seven or eight days very little bladder trouble followed. With peroxide fomentations and douching all septic sequelae cleared up, and she went home well on February 9th.

3. A portion of sigmoid flexure showing an annular carcinoma in the centre, with a colotomy opening in the part of bowel above the growth. The bowel was infiltrated by a malignant growth having the structure of a carcinoma, composed of irregular alveoli lined by cubical epithelium and infiltrating the muscle coats. This was removed on January 27th, 1913, from a woman 28 years of age. Dr. Cookson operated first on January 21st for intestinal obstruction. The woman was four months pregnant and complete obstruction had occurred for a week, though she passed flatus shortly before operation. A median incision was made, as the site of obstruction was not apparent, and a growth found in the centre of the sigmoid flexure, which had a long meso-sigmoid. The sigmoid, with the growth, was fixed at the upper end of the incision, outside the abdomen, opened, and a Paul's tube fixed in on January 23rd. The bowels were thoroughly cleared during the next few days, and on January 27th the wound opened up again and the sigmoid, with a V-shaped portion of meso-sigmoid, removed and end-to-end anastomosis done, using two continuous sutures, the first through the muscular and mucous coats, the second a continuous Lembert, and an interrupted Lembert outside. A drain was placed down to the bowel through a hole made in the side, and the median incision closed. She miscarried on the fifth day after, without pain; the placenta was removed manually; the bowels acted naturally the same day, and were thoroughly cleared with aperients on the ninth day. She never felt ill, and went home on February 19th feeling very well, the bowels acting regularly without aperients.

The main interest in these two cases was, Dr. Cookson said, the early age for the appearance of carcinoma and the question of prognosis. Dr. Cookson said he looked upon a fungating squamous carcinoma as a favourable form but had not met with one in so young a patient, nor had he seen a similar bowel growth to this at this age. A considerable portion of bowel having been removed, the permanency of the "cure" depended probably on the presence or absence of glandular infection, of which he did not see any signs. Dr. Cookson's paper was illustrated by sections shown under the microscope, and was discussed

by Mr. STACK, and Drs. ELIZABETH MOFFETT and LOWE. Dr. COOKSON replied.

Exhibition of Pathological Specimens.

Mr. CHOLMELEY showed (1) a large stone from the bladder of a girl of 18, whose only complaint had been of profuse haematuria; (2) an aneurysmal varix of the internal saphenous vein of a man of 21—removed entire.

HONG KONG AND CHINA BRANCH.

A MEETING of the Hong Kong and China Branch was held on March 7th. Colonel J. M. IRWIN, President, was in the chair, and twenty other members were present.

Scarlet Fever.—Dr. MCKINNEY read notes of a case of scarlet fever, which had been under his care in the Tung Wah Hospital. The symptoms were typical, and albuminuria was present. The patient had resided in Hong Kong for the previous six months. Dr. McKinney referred to the rarity of scarlet fever in Hong Kong, and stated that the cases which had been reported had generally been imported. Dr. CLARK asked the President if he had any knowledge of cases of scarlet fever in Tientsin and North China; there was a virulent form in Shanghai some years ago. Dr. MARRIOTT asked if scarlet fever existed in the tropics otherwise than as imported cases. Colonel IRWIN replied that he had not seen or heard of cases in Tientsin.

Dry Gangrene.—Dr. MCKINNEY also related the case of a man, aged 55, admitted for enlargement of the liver and ascites who suddenly developed dry gangrene of fingers and toes. Fruitless inquiry was made as to what Chinese drugs he had taken.

Typhoid Fever.—Dr. MCKINNEY discussed the types of typhoid fever met with in Hong Kong. The rash, he said, was frequently absent; the pulse was accelerated, but rarely dicrotic. The pyrexia was either typical or of "septic type," or after starting typically fell to normal in the first five or seven days. The stools were rarely typical.

Fractures.—Captain HODGE read a paper dealing with the older and more recent methods of treatment of fractures. He said that the modern method of operation and fixation by plates, etc., presented great risks, and was only satisfactory in the hands of a few experts, and frequently left depressed cicatrices or damaged soft parts. He dealt with the importance of properly padded splints to avoid pressure, and dwelt on the necessity of using anaesthetics in the reduction of difficult cases of fracture. Greater importance should be attached to the study of clinical symptoms rather than to *x-ray* photographs; a single such photograph was useless unless followed by a second in a different plane. He also instanced numerous cases in which there had been free movement for some time after the occurrence of fracture. Fleet Surgeon STALKARTT disagreed with the sweeping condemnation of operative treatment of fractures, and thought that many operations were most successful and necessary for a good result. Dr. LOBB disagreed with the arguments against operation; it was neither very difficult nor dangerous, even in compound fractures. He instanced many cases in which infection had been escaped, even in very dirty cases.

Specimens.—Captain ARTHUR demonstrated a specimen, sent by Dr. GIBSON, of a case of sarcoma of the foot. Dr. MOORE showed a seven months fetus from a case of ectopic gestation; the viscera were extruded from the abdominal cavity and there was apparently only one orifice for the bowel and genito-urinary purposes.

On April 1st the House of Representatives of the Minnesota State Legislature passed, by a vote of 61 to 45, a bill providing for the sterilization of defectives, habitual criminals, and degenerates.

At the last meeting of the Royal Meteorological Society a report was presented on observations, chiefly made at the Meteorological Office, South Kensington, and Kew Observatory, which showed that the temperature fell nearly 3° during the solar eclipse of April 17th, 1912, the minimum occurring ten minutes after the maximum phase. At stations in the south of England the loss of recorded sunshine due to the eclipse varied from about twenty to twenty-five minutes.

Reports of Societies.

ROYAL SOCIETY OF MEDICINE.

SECTION OF LARYNGOLOGY.

At a meeting on April 4th, Mr. HERBERT TILLEY, President, in the chair, the following were among the exhibits:—The PRESIDENT: A foreign body removed from the bronchus of a woman aged 42. It was a shawl pin, the point of which was directed towards the observer, and appeared only as a thread of mucus. Twice it slipped from the forceps, but was eventually drawn out with the bronchoscope. Morphine, atropin, and chloroform narcosis were employed, while the trachea and larynx were painted with 20 per cent. cocaine. Mr. G. N. BRIGGS: (1) An almost complete *Cyst of the epithelial lining of the oesophagus*. It consisted of the epithelial lining and was vomited up three days after the patient had swallowed 1 oz. of chloroform. Rectal feeding was employed and bismuth lanolin and parolin given every four hours by the mouth. An oesophagoscopy three months later gave no indication of contraction. (2) A specimen of *Lympho-sarcoma* from the throat of a child aged 13. The glands of the neck and mediastinum were extensively involved. Dr. E. A. PETERS: A case of *Cyst of the aryteno-epiglottidean fold*, which burst spontaneously with a rent in the upper surface. In such cases some of these cysts, he observed, disappeared rapidly on puncture, while others required removal of a considerable part of the wall. In this case the cyst appeared to be re-forming. The PRESIDENT said he had experienced redistension with some cysts and had found it necessary to remove a considerable part of the wall; he considered that a multilocular character explained this fact in some cases. Dr. FITZGERALD POWELL recommended the opening of the cyst by the caudery and its subsequent application to the lining. Dr. WILLIAM HILL advised puncture. Mr. E. B. WAGGETT would use suspension laryngoscopy and remove part of the cyst wall. Mr. G. W. BADGEROW had noticed the frequent disappearance of these cysts on mere puncture. Dr. J. DONELAN: A case of *Cyst on the epiglottis*, with symptoms suggestive of oesophageal stricture. The cyst was small and associated with a scarred condition, characteristic of healed syphilis or lupus. Dr. FITZGERALD POWELL contended that the symptoms were due to a growth, and not to the small cyst. Dr. E. D. DAVIS exhibited a healthy looking man with *Tuberculous disease of the epiglottis* and tubercle bacilli in the sputum. It was found impossible to remove the whole of the disease with punch forceps, but with Killian's suspension laryngoscopy apparatus the epiglottis was readily trimmed with forceps and scissors. Mr. F. A. MUECKE: A patient on whom *Tracheotomy* was performed six years ago for tertiary obstruction of the larynx, and who was still carrying a tracheotomy tube; there appeared to be a mass of granulations, though the patient could breathe through the larynx. Mr. SECCOMBE HETT exhibited a man who was able to speak after removal, two and a half years ago, of the whole of one cord and of the anterior part of the other for malignant disease. A discussion followed on the question of nasal feeding. Dr. WILLIAM HILL was in favour of feeding *per os*. It was suggested that the nasal route was unsatisfactory when the nasal passages were either irritable or diminished by vasomotor rhinitis or other obstructions.

SECTION OF OTOLOGY.

At a meeting on April 18th, Dr. DUNDAS GRANT, President, in the chair, Mr. MARK HOWELL, in introducing a discussion on *Functional and simulated affections of the auditory apparatus*, objected to the term "functional deafness," because the function of the ear was to hear, and deafness was, therefore, a loss of function. Deafness was frequently simulated from various motives, and there were also cases of apparent suppression of hearing power as the result of a violent emotional influence. There were others in which deafness was simulated without an apparent object, or in which deafness was due to a temporary want of the necessary nerve power, the latter being found among persons who masturbated. In dealing with a case of deafness which was said to be simulated, care

should be taken not to be prejudiced by statements made by persons associated with the patient; and where there was no apparent motive for loss of hearing, it was desirable to remove the patient from uncongenial surroundings. The object of the examination should be the discovery of diseased conditions if present. In many cases of simulated deafness the onset was sudden, the modulations of the voice remained unaltered, and there was an absence of the quick movement of the eyes exhibited by most deaf persons to obtain the knowledge which normally they would derive by the sense of hearing. No tests should be employed which could harm the patient, such as firing a pistol close to the ear. Where there was no apparent reason for the simulation, recovery was sometimes hastened by the medical attendant behaving as though he considered the case genuine. In some cases, while making an examination of the patient and conversing with the friends, a simple request to the patient to put out his tongue would sometimes lead to his doing so, he having been thrown off his guard. The PRESIDENT showed a case of apparently functional deafness in an unmarried woman, aged 29, who complained of deafness, which was worse on the left side, and which came on suddenly after a fit three and a half weeks before, probably vertiginous in character, though he considered it had a hysterical element. The tuning-fork test showed Rinne positive on both sides. After a somewhat exhaustive examination she seemed to hear better than at the beginning. The voice-raising test was only slightly positive. The patient suffered from a cardiac condition, and was nervously weak, and her syncope attack had no doubt frightened her. Dr. Grant proceeded to detail tests by placing the tuning-fork on the vertex to detect malingersers simulating caisson disease when working at the Blackwall tunnel, some of whom had obtained generous compensation. Some forms of functional deafness he attributed to self-hypnosis, and such cases were often considered to have been cured by some unorthodox and fanciful form of treatment. Dr. W. MILLIGAN (Manchester) pointed to the vestibular reactions as important tests of hearing power or its absence; in hysteria they differed from those found in organic disease. This matter had been worked out very thoroughly by Dr. Dan McKenzie, and the point was that the vestibular reactions and the vertiginous symptoms in hysteria were all "up and down," and there was lack of uniformity in result on testing at different times. Dr. H. MACNAUGHTON-JONES said that in testing soldiers in the south of Ireland he had met with a certain amount of malingering. He objected to the term "hysterical deafness," and did not believe he had ever come across a case which could rightly be thus described. Dr. DAN MCKENZIE pointed out that a form of functional deafness occurred in old cases of organic deafness; the nerve centres, not being exposed to the usual stimuli, fell asleep, and this factor intensified the degree of deafness. Mr. HUGH JONES (Liverpool) said he had often thought there was a functional element in the chronic deafness of a degenerate child, perhaps a functional or epithelial change comparable with that in the crystalline lens.

MEDICAL SOCIETY OF LONDON.

At a meeting on April 14th, Sir W. WATSON CHEYNE, President, in the chair, the following were among the exhibits: Dr. F. PARKES WEBER: (1) *Primary tumour of bone* (? endothelioma). It was removed from a woman aged 54. The bones were very friable. The ribs could be broken like rotten twigs, and the laminae of the vertebrae cut through with scissors. The right lobe of the liver was also infiltrated with new growth. Mr. E. H. SHAW, in discussion, thought that the growth was primarily one of the liver, with secondary metastases in bones. (2) *Large Asymmetrical cervical ribs* in an old man without any symptoms. The cervical ribs were jointed, the left one articulating with the first rib, that on the right probably with the second rib. Dr. J. L. BUNEN: Two cases of *Hereditary Dupuytren's contracture*. The patients were father and son, and the condition was said to have affected the male members of the family for 300 years. Mr. E. H. SHAW: Two cases of *Carcinoma of the breast*: (1) A small irregular radiating growth with deeply retracted nipple, from a middle-aged woman. (2) An

ulcerating and fungating growth from a woman aged 50. Also *Carcinoma of the gall bladder, cystic ducts, and main bile ducts*. It was a columnar-celled growth, papillomatous for the most part, removed from a middle-aged woman. Also *Hydronephrosis* from a boy aged 6. It was produced by a sharp kink at the upper end of a very small ureter, probably congenital in origin. Dr. R. C. JEWESBURY: *Acromegaly* in a woman aged 36. The appearance was typical. The thyroid gland was definitely and uniformly enlarged; the x rays showed great expansion of the sella turcica. Also a case of *Pneumothorax* in a boy aged 5; it was of doubtful origin. The heart was displaced very much to the left, and x rays showed the whole of the thoracic spine bared from mediastinal structures. Mr. A. E. BARKER: *Remnant tumour of the umbilicus*, probably derived from the wachus or Villine duct. Mr. L. E. C. NORBURY: *Malformations*. The patient, aged 3 months, showed: (1) Accessory auricles; (2) macrostomia; (3) occlusion of the anterior fontanelle with excessive bone formation in this region; (4) deformity of the nose; (5) corneal opacity in the left eye.

LIVERPOOL MEDICAL INSTITUTION.

At a meeting on April 10th, Mr. ROBERT JONES, President, in the chair, Mr. R. W. MURRAY, speaking of undescended testicle, said that at least ten different methods of treating the condition had been described by various authorities; there was always much difficulty in keeping the organ in the scrotum. It was the practice now to open the canal and expose the testicle, hernial sac, and vas deferens at the level of the external ring; the sac was transfixed and cut across, but the lower part was left attached to the testicle. Then all the structures attaching the testicle were cut across between two ligatures, and the testicle and sac were placed in the scrotal bed. The immediate result was satisfactory, the testicle lived though its blood supply was cut off; it possibly supplied an internal secretion. Mr. F. T. PAUL said he had treated these cases by suturing the tissues in the canal across the cord to prevent it from being drawn up. He did not sacrifice the duct. Dr. SYDNEY WHITAKER showed a woman who had suffered from rheumatoid arthritis for fifteen years. All treatment proved useless except a fourteen-day fast, during which all pain left the joints. A coliform autogenous vaccine also produced slight benefit. As x rays showed intestinal stasis an ilco-colo-stomy was performed, with marked improvement in the joints and general condition. Dr. WALTER C. ORAM, in a paper on *X rays as therapeutic agents*, laid down three essentials: The rays must reach the tissue to be treated in sufficient quantity; they must be absorbed by the tissue; and the tissue must be susceptible to their action. The denser tissues of the body—the spleen, the thyroid, and the ovary—were far more susceptible to x -ray treatment than those of less density, such as the muscles, the kidney, and the brain. Even quite small variations in density caused considerable differences in the absorptive power for the rays. Tissues varied much in their susceptibility; thus x -ray exposures over the ovarian regions could bring about the suspension of activity of the ovaries, while the overlying skin, which had in the interval received a considerable dose, was not affected. Dr. F. H. BARENDT considered the x rays to be a valuable adjunct to treatment of skin diseases. In some cases of tuberculous disease good results were obtained, while in others the results were not satisfactory; the knowledge of the susceptibility of the tissues was wanting. Mr. THURSTAN HOLLAND thought the methods of measurement should be more accurate. In the treatment of malignant disease the method was of use if started early after a surgical removal; it then prevented recurrence, and secondary malignant nodules often disappeared. In menorrhagia the loss could be checked without risk. Pruritus was in many cases cured very rapidly. Dr. MA KENNA also spoke of the rapid action in cases of pruritus. He did not think the expectations with regard to malignant disease had been fulfilled. Sir JAMES BARR had used x -ray treatment in cases of leukaemia, and had had rapid and striking improvement. Unfortunately this had not been maintained, and when symptoms again appeared the x rays had no effect, and all his cases had died.

HUNTERIAN SOCIETY.

At a meeting on April 9th, Mr. A. H. TUBBY, President, in the chair, Dr. NATHAN RAW resumed a discussion on *Tuberculin treatment*, commenced at the meeting on March 26th. Dr. Raw's experience in 1,056 cases of various forms of tuberculosis had left on him a favourable impression. Undoubtedly localized forms of tuberculosis responded more readily to tuberculin than cases of pulmonary tuberculosis with a general systemic infection. He invariably treated his cases by cross-vaccination. Pulmonary tuberculosis, being most frequently an infection by human tubercle bacilli, was best treated by a tuberculin prepared from bovine bacilli, and the localized forms of tuberculosis, being very frequently infections by bovine bacilli, were best treated and gave better results by treatment with human tuberculin. With regard to dosage, he was firmly of the opinion that immunity should be established very slowly, and with only moderate doses of tuberculin. Tuberculin was a remedy of the greatest value, especially in early cases, and where the deposit of tubercle was localized, as in one apex or a lymph gland or single joint, but where the tuberculosis was disseminated and complicated by secondary infections the use of it could not be expected to be of much avail. It certainly limited the spread of the disease in the body. Tuberculin was not going to revolutionize the treatment of tuberculosis, but it was a valuable aid to the other methods of treatment. He agreed that bovine tuberculin gave the best results in pulmonary tuberculosis, and vice versa. He had treated lupus by tuberculin, and had found the results of diagnosis by von Pirquet's reaction pretty good in this disease. He had had good results of treatment in early cases of pulmonary disease. Dr. HUNSTON FOX had found the results of oral administration to be uncertain. He submitted that the inoculation test, on account of its risks, should be used only in exceptional and obscure cases. Dr. R. A. O'BRIEN pointed out that the outcome of a severe reaction was really to desensitize. There were three great problems facing the clinician. First, could one immunize against tuberculosis? The answer was in the negative. The second question, whether one could diagnose the existence of tuberculous disease by specific tuberculin tests alone, must also be answered in the negative, for in comparatively insensitive animals, such as the horse or man, a reaction only meant that the subject had, or had had, tuberculosis. Finally came the question whether one could prevent or forestall the existence of hypersensitiveness in a patient under treatment; this, again, he feared was impossible. Dr. BUTLER HARRIS dismissed the treatment of tuberculous joints by tuberculin. He believed that in an early case, if the joint be put at rest, the tuberculin treatment helped. Dr. LATHAM agreed that the method of dispensary treatment with intensive doses was overdone, but he thought that every method should be tried adequately, so that under the sanatorium benefit sufficient data could be obtained for the purposes of comparison. He was not convinced by Dr. Raw that human tuberculin should be used for infections with the bovine bacillus, and vice versa. Neither could he share Dr. Raw's view that tuberculin often diminished the length of time during which treatment was necessary, although in a few cases that appeared to be merely holding their own and marking time it certainly gave the necessary stimulus. He would again emphasize the fact that it was of no value in cases where autoinoculation was frequent, irregular, and uncontrollable. Mr. FRANK CURRY gave a demonstration illustrating the preparation of the various tuberculins and their characteristics. The President, after thanking those who had taken part in the debate, spoke of cases of tuberculous spine treated by tuberculin, pointing out that he now knew that the reason why this treatment was unsuccessful was that these cases were purulent and caseous from the very first.

MIDLAND OBSTETRICAL AND GYNAECOLOGICAL SOCIETY.

At a meeting at Birmingham on April 8th, Dr. MALINS, President, in the chair, Dr. PURSLOW showed a large *Cystic tumour of the kidney* removed by abdominal section from

a single woman aged 35, who presented a cystic swelling the size of a seven months gravid uterus. The tumour, which was lobulated, was freely movable, and extended across the middle line, and could be felt from the vagina and not from the loin; in fact, it showed all the characters of an ovarian cyst, and was diagnosed as such. As soon as the abdomen was opened the tumour was seen to be renal in origin; the outer layer of the ascending meso-colon was incised and the tumour removed, after tying off its attachments. The peritoneum of the meso-colon was closed with sutures and the abdominal wall closed without drainage. The patient made an uninterrupted recovery. Even after operation the most careful questioning failed to elicit anything in the previous history which would have given a clue to the condition. Dr. WALTER SWAYNE observed that he had had precisely a similar experience to that recorded by Dr. Purslow. In his case it was quite impossible to say before operation from which side of the abdomen the tumour had arisen. Even when the abdomen was opened the organ was only diagnosed as being kidney by reason of the loose peritoneum over it. Dr. T. CLARE recorded an instance of an enormously dilated kidney becoming manifest immediately after labour. In this case the condition had in no way interfered with pregnancy or labour. Dr. THOMAS WILSON remarked that two or three years ago he had diagnosed a tumour as an axial rotation of an ovarian cyst complicating pregnancy, but it proved to be a suppurating hydronephrosis which had become infected from the ascending colon. Dr. PARDY thought that in these difficult cases the diagnosis frequently depended upon whether a general surgeon or gynaecologist saw the patient. He had seen more than one instance where a tumour was diagnosed by a general surgeon as a movable or cystic kidney, which proved at operation to be a cyst of ovarian origin. Dr. PURSLOW, in reply, mentioned two diagnostic points which had been cited as useful by a general surgeon, namely, if pain were produced upon pushing the tumour down into the pelvis it was likely to be of renal origin; if the tumour projected markedly forwards it was probably connected with the ovary. Dr. THOMAS WILSON showed the fetus and sac from a case of *Full-term intraligamentary gestation*. The patient had never shown any signs of pregnancy and was unaware of the nature of her condition. Menstruation had been quite regular throughout. The fetus had undergone "aseptic skeletonization." Dr. F. EDGE remarked on the extreme difficulty that might arise in the diagnosis of a fetus enclosed in a sac even after the abdomen had been opened. Dr. LEWIS GRAHAM said that in a case of full-term ectopic gestation under the care of Dr. Copeland Savage the uterine sound could be passed for 9½ in. In this case fetal movements were quite evident. Dr. WILLIAM SMITH showed: (1) A uterus, the seat of *Multiple fibromyomata complicating a two and a half months gestation*. The patient had had no pressure symptoms, and was in good health. Hysterectomy was performed instead of awaiting events, because of the extraordinarily rapid development of the mass whilst under observation. The growths were both interstitial and subperitoneal. The patient made a good recovery. (2) The right uterine appendages from a case of *Tubal abortion with extensive pelvic hæmatocele*. The course of the case and other phenomena had led to a diagnosis first of pyosalpinx secondary to early uterine abortion, and then of ectopic gestation. Laparotomy was performed, and the patient made a good recovery. Dr. T. CLARE having read a paper on the pathology and treatment of a case of *Dysmenorrhœa and sterility*. Dr. THOMAS WILSON recalled the fact that at the annual meeting of the British Medical Association in 1911 he had read a short paper upon small fibroids at the level of the os internum as a cause of dysmenorrhœa; probably the underlying factor was disturbance in the polarity of the uterus. Dr. WALTER SWAYNE said he had had a small experience in altering the position of the cervix as suggested by Dudley of Chicago, and had found that the operation relieved the sterility but not the dysmenorrhœa. Dr. K. M. PARDY having shown some fibromyomata of the uterus from a patient who first recognized the tumour at the age of 20. Dr. PURSLOW said that 24 was the earliest age at which he had himself seen fibroids of the uterus develop.

Rebuelus.

SURGERY OF THE STOMACH.

Of all the modern exploits of surgery, perhaps there is no enterprise so attractive and fascinating as the bold invasion of the stomach region. The reasons are at least twofold. The manipulative dexterity demanded in the performance of all operations on the stomach and the mental exercise of planning the best procedure are a real intellectual delight to a skillful man, while the results frequently achieved are brilliant. Mr. HERBERT PATERSON has been prominent for some years as an authority on gastric surgery. His former works have won for him a well-merited place, and his most recent book, *The Surgery of the Stomach*,¹ establishes his position more soundly than ever. This work is concerned with the diagnosis and treatment of those affections of the stomach which are amenable to direct surgical interference. The advances in diagnosis of abdominal diseases have not kept pace with the researches in pathology and with the variety and boldness of operations. It would probably be well were test-meal investigations more freely undertaken by the family practitioner. Mr. Paterson thinks that the doctor would be amply repaid if he carried out ordinary qualitative tests and estimated the total acidity of the gastric contents even if he did nothing else. The cry of the operating surgeon in all cancers, and especially in stomach cancer, is for the cases to be sent early. The examination of test meals in every case of persistent dyspepsia which does not yield in a reasonable number of weeks to medical treatment would, Mr. Paterson urges, be the best means of making early diagnosis in gastric cancer. The chapters dealing with this department of stomach surgery are exceedingly thorough, and support admirably the author's earnest advocacy of the universal early adoption of methods of chemical investigation.

Gastro-jejunostomy is, of course, the favourite among the surgical operations on the stomach, and Mr. Paterson has much to say of it in all its phases, applications, results, and complications. We are interested and surprised to note that although the posterior operation is that usually performed, in his opinion "it is immaterial which method be adopted; either operation, in suitable cases, gives excellent results." The grounds upon which this opinion is founded might have been more fully stated, for we believe that owing to the appeal which the posterior operation makes to so many surgeons as anatomically sound, the performance of the anterior mode is exceptional. The technique described in the text is exceedingly clear and simple, and no small assistance is afforded by a very good series of photographs. We note that after the hæmostatic suture encircling the stoma is completed, the edges of the gastric and jejunal mucosa are everted, and so are still visible; these edges are buried by the last suture, which is a single serous suture, and the anastomosis is complete. Many surgeons, we believe, hold that a stitch which inverts the edges of the two mucosae will be more secure. Such a stitch is adopted by the Mayos; it is a through-and-through stitch, which they call the "in and out and over"—that is, it passes from the serous side through the whole thickness of the bowel wall, emerges at a quarter of an inch distance parallel with the visceral incision, and then crosses over to repeat the manœuvre in the stomach wall, and so on. Mr. Paterson does not consider gastro-jejunostomy purely a drainage operation, but that it is physiological, in so far as its immediate consequence is diminution of hyperacidity with maintenance of motility. The discussion on jejunal and gastro-jejunal ulcers forms a very interesting chapter, as also does that on appendicular gastralgia, a subject which is already associated with Mr. Paterson's name.

This book is a most excellent and thorough and complete work, and Mr. Paterson deserves hearty congratulations on its production. It is a full statement of all the modern work, much of which has been done by the writer himself, and we feel assured that it will meet with a cordial reception from surgeons. We venture to suggest that the style

¹ *The Surgery of the Stomach: A Handbook of Diagnosis and Treatment*. By Herbert J. Paterson, M.A., M.C., M.B., Capt. R.F.C.S. Eng. London: James Nisbet and Co., Limited. 1913. (Med. 8vo, pp. 326; figs. 74. 12s. 6d. net.)

of writing might well be more impersonal in some parts, and we think, too, that it is hardly fair to gird at some old-fashioned methods as "superstitions," for after all, these "superstitions" were stages in the journey towards the goal to which we all are striving.

TREATMENT OF SKIN DISEASES.

Dr. BULKLEY has long been known as the apostle of the simple life in the treatment of skin disease, and he is particularly zealous in his advocacy of a vegetarian diet in psoriasis. He has embodied his ideas on these subjects in a series of lectures on *Diet and Hygiene in Diseases of the Skin*.² These were originally delivered as clinical lectures at the New York Skin and Cancer Hospital, and make very interesting reading, and although one may not be able to follow the author to the end of the path which he has elected to travel, deference must undoubtedly be paid to a physician of such great experience. The French and American dermatologists are inclined to lay more stress than their British brethren on the internal medication and the dietetics of skin disease, and it is possible that they underrate the powers of local treatment, aided only by the avoidance of obvious excesses in food and drink. The contrast between the two schools is especially brought out in the way in which they regard psoriasis and infantile eczema. In the former case few British writers do more than inculcate abstinence from alcohol, while in the latter it is customary merely to see that digestion is properly carried out. Dr. Bulkley, on the other hand, always finds in patients suffering from psoriasis, by means of minute volumetric analyses of the urine (of which, however, no details are given in the present volume), evidences of disordered metabolism, and he is very careful in prescribing an exact diet for the eczematous infant, usually including a special "wheat-jelly" of his own invention. Dr. Bulkley also claims excellent results with his system of giving in acute dermatoses a diet consisting only of boiled rice, white bread, and water for several days. He is fortified in his opinion by the fact that he himself is liable to attacks of acute erythema, accompanied by bullae, which he was unable easily to control until he adopted this system. Those who wish to make trial of Dr. Bulkley's methods—and they are undoubtedly worthy of consideration in many instances, if not in all those in which the author advocates them—will find the appendix very useful. Here are given numerous vegetarian dietaries, with indications for their employment, and in some cases directions for the preparation of the dishes recommended. Some, however, of the articles mentioned are peculiar to America. For these the English physician must find appropriate substitutes.

We have also received a copy of Dr. BULKLEY'S *Compendium of Diseases of the Skin*,³ which is really the fifth edition of his manual of skin diseases. The number of editions is sufficient testimony of the success of the book. It is essentially based upon lectures delivered by the author, and, although the whole art of dermatology is compressed into fewer than 300 pages, it makes quite good reading. Very wisely most of the space is occupied with the consideration of the commoner diseases and their treatment. Here the author again lays great stress upon the importance of dietary measures. There is also a very good therapeutic formulary included. Almost alone among books upon skin disease, it has no illustrations.

HOSPITAL REPORTS.

St. Bartholomew's Hospital.

THE steady increase in the development of scientific medicine and surgery is well exemplified in this forty-eighth volume of the *St. Bartholomew's Hospital Reports*,⁴ if compared with the earlier volumes of the archives of that venerable institution. In the medical series of contributions is one by Dr. Woodwark on the line of treat-

ment in mental and physical deficiency, based upon the therapeutic action of the internal secretions; in it there is mention of the pituitary gland, till lately held to be insignificant, yet of recent years wonderfully prominent in works on physiology, therapeutics, and scientific anatomy. We all know its relations to gigantism, ably demonstrated by Professor Arthur Keith in respect to O'Brian and other interesting but pathological sons of Anak. A distinct sign of the times in the volume under review is the truly scientific consideration given to venereal disease, till lately associated with empiricism and rule-of-thumb clinical and therapeutical routine work. For not only does Dr. A. W. D. Coventon contribute a paper on syphilis and parasyphilis of the nervous system in childhood, in which we hear much of the now familiar Wassermann's reaction, but there is also a highly interesting analysis of 131 cases of blood infection in gonorrhoea and an inquiry into the value of vaccines in their treatment by Mr. R. Foster Moore. The summaries of Dr. Coventon's and Mr. Moore's articles are in themselves worth study, the more so as the text is devoted to matter which only those who are more or less experts can judge correctly. As the result of scientific clinical investigation Dr. Coventon expresses the opinion that syphilitic and parasyphilitic disease of the nervous system is not very rare in childhood, and is liable to be overlooked; but the tests now at our disposal show that certain well-known nerve symptoms by no means prove that the child's malady is due to syphilis. Mr. Moore dwells on gonorrhoeal arthritis and iritis. Turning to the surgical department, Mr. Neon and Mr. Moreton's critical examination of six complete cases of acute pneumococcal peritonitis is a short but good and well tabulated article. The results of operative and expectant treatment shown in the tables will interest the surgeon. All the patients were female children except one, a man aged 57. Mr. Neon adds a further series of cases of general peritonitis of appendicular origin, with notes on the after-treatment, and in association with this contribution, Mr. Vick's investigation of 100 cases of appendicitis may be mentioned. Both Mr. Neon and Mr. Vick supply us with instructive tables. This volume of the *Reports* is decidedly superior in quality to quantity. For its original article department is limited to 166 pages, twenty less than those allowed to the "statistical tables," whilst the museum report takes up forty pages. Of the other original contributions, not mentioned above, there is a paper on the age incidence of intracerebral haemorrhage by Dr. Andrewes, a case of intermittent glycosuria by Mr. Mackenzie Wallis and Dr. F. A. Roper, and a good surgical report by Mr. Gask on a case of thrombosis of the axillary artery, in which an operation was undertaken for the removal of the clot and suture of the vessel; the author gives abstracts of 9 cases already published. Mr. E. Anslie contributes a paper on the diagnosis of endosteal tumour, Mr. Harold Wilson one on 2 cases of muscular paresis of the bladder, and Mr. C. D. Kerr an account of a case of lateral sinus thrombosis followed by hernia of the cerebellum in which recovery ensued. The reports are headed by a graceful obituary notice of Sir Henry Butlin with a portrait.

Guy's Hospital.

Dr. Spriggs contributes to the new volume of the *Guy's Hospital Reports*⁵ a very substantial paper on congenital intestinal occlusion. He had two cases under his own observation a few years ago, and has studied numerous museum preparations. The table of references is most copious, old writers as well as current authorities being freely quoted. Congenital occlusion, it is shown, is generally single, and most often occurs in the lower ileum. The next most frequent site is in the duodenum near the biliary papilla. When occlusions are multiple they are usually situated in the jejunum-ileum. Such cases are very unfavourable for treatment, but early abdominal section, followed by dilatation of the contracted gut by water pressure and lateral anastomosis, may save the patient. Mr. Alan Todd, in a paper on the results of operation for glaucoma, gives an instructive account of the examination of nearly

³ *Compendium of Diseases of the Skin*. By L. Duncan Bulkley, A.M., M.D. New York: Paul Hoeber, 1913. (Med. 8vo, pp. 296, 2 dols.)

⁴ *St. Bartholomew's Hospital Reports*. Edited by H. M. Fletcher, M.D., and W. McAdam Eccles, M.S., F.R.C.S. Vol. xlviii. London: Smith, Elder and Co. 1913. (Med. 8vo, pp. 216; illustrations 6.)

⁵ *Guy's Hospital Reports*. Edited by F. J. Steward, M.S., and Herbert French, M.D. Vol. lxi, being the fifty-first of the Third Series. London: J. and A. Churchill. 1912. (Med. 8vo, pp. 451.)

80 cases. Dr. Frederick Taylor's cases of poisoning by opium will interest the toxicologist and physician, especially those who have studied his writings on the faradic current as a therapeutic agent. The volume contains reports from the throat and aural department, and also a remarkable note, illustrated by a photograph and a drawing, on carcinoma of the left kidney, in which a continuous clot extended from the kidney along the left renal vein and up the inferior vena cava into the right auricle, producing an intercardiac polypoid mass, which led to tricuspid stenosis of the ball-and-socket type; the clot was infiltrated with carcinoma of the same type as that in the kidney itself. This communication is written by Dr. Herbert French, who also reports a case of adrenal hypernephroma in a girl 6 years of age. Signs of precocious puberty, as in cases previously recorded, were irregularly developed; pubic hair had been noted when the child was 8 months old, but there was no abnormal hair in the axillae or on the face. The clitoris had been hypertrophied since infancy. Dr. Arthur Hertz, who edits a series of "Neurological Studies," writes notes on cases of hereditary intention tremor, epilepsy with remarkable aura, and lead neuritis involving the circumflex nerves, and, in conjunction with Dr. W. Johnson, an analysis of fifty cases of disseminated sclerosis; Dr. Johnson himself contributes as a separate paper some observations on the influence of congenital syphilis on mental deficiency in children; and Mr. J. L. M. Symms a paper on the vibratory sense in peripheral neuritis. As there are altogether twenty-three original articles in this volume of the *Reports*, want of space precludes notice of all of them. The first paper is a good obituary notice of Dr. Pavy, written by Dr. Frederick Taylor.

HEPATIC DISEASE.

ALTHOUGH not so designated on the title page, Dr. ROLLESTON'S book on *Diseases of the Liver, Gall Bladder, and Bile Ducts*⁶ is really a second edition of his work of the same name published in 1905 and noticed by us in that year (see BRITISH MEDICAL JOURNAL, April 15th, 1905, p. 827), and the author indeed prints a "preface to the second edition." In our former notice we wrote "this is the most considerable work on diseases of the liver which has appeared since the classical treatise of Murchison. It fully deserves to take a high place among modern textbooks, and we heartily congratulate Dr. Rolleston on his success." There is, therefore, no need for us to add anything beyond an endorsement of the author's claim to have thoroughly revised his work, added much new matter, made many alterations, and carried out condensation so far as compatible with a full consideration of the subject. The present volume contains a few more pages than the earlier, but owing to the use of a lighter paper is not so heavy to hold in the hand.

DEGREES FOR LONDON STUDENTS.

DR. ELLIOT-BLAKE, who has already challenged opinion as an advocate of certain changes in the Royal Colleges of Physicians and Surgeons in London, has recently issued another volume on the same subject, with additional matter of more general appeal.⁷ In the first place, he urges those responsible for the governance of the Royal Colleges to take steps, either by agreement with the university authorities, or, failing that, by an Act of Parliament, to convert their licences to degrees. And, as a natural consequence of this line of action, he desires the present courses of study for diplomates to be conformed to the university type. In order that present holders of the conjoint diplomas may not suffer by the change, he further advocates the granting to them of retrospective degrees, perhaps after the reading of a thesis. On behalf of these changes he argues that the present system, with its multiplication of medical class distinctions, is confusing to the public, unjust to a deserving body of practitioners, and provocative of bad blood. He claims that "every public report and medical

leader who has examined the subject has declared that no practical difference exists between the pass diploma licence and a pass degree." And, in support of this contention, he calculates that candidates holding the London diplomas obtained in eighteen competitive examinations 69.1 per cent. of successes, as compared with 48.5 obtained by graduates of Scottish and Irish universities. The Senate of the University was, he states, enjoined by the Act of 1898 to ratify extensions of higher education, and to organize them within the London radius, while the Royal Colleges were singled out by specific reference as worthy of incorporation. He therefore considers that the representatives of the Colleges upon the Senate of the University have been remiss in failing to press for the reforms which he advocates. To the passive resistance of the Senate he attributes the failure of the collegiate representatives to avail themselves of Section 123 of the Statutes, which in his opinion entitle the Colleges to examine for degrees and to claim university ratification. The inclusion of a Royal Colleges Board in the University Faculty of Medicine in London would, he argues, be in accordance with traditional usage as exemplified in the development of other universities, for example, those of Paris and Bologna. He appeals for the financial aid of wealthy philanthropists, failing which, he is of opinion that some part of the huge sums at present devoted to the primary education of the masses would be more usefully employed in the endowment of a reformed system of medical teaching. For, as he justly pleads, the standard of efficiency demanded of the modern practitioner is constantly rising, and can only be generally attained by a method of teaching which is based upon a cultural rather than a merely utilitarian ideal. He considers the suggested "one portal" system objectionable in several ways. For one thing, it is based upon French and German models, and inapplicable, he thinks, to the English educational situation. In the second place, it would have the result of bolstering up "the bad old licensing system." And, thirdly, he objects, it would involve the addition of one more burden to the present examination incubus. For these and other reasons, into which space does not permit us to enter—all picturesquely phrased and forcibly expounded—Dr. Elliot-Blake maintains that it was incumbent upon the Royal Colleges to prepare and submit to the Royal Commissioners a definite scheme claiming on behalf of their students participation in the privileges of the University on condition of their passing a suitable arts examination and undergoing a curriculum modified in the direction of the university system. In an appendix dealing with the earlier reports of the Royal Commission on University Education in London, Dr. Elliot-Blake strongly supports the recommendation of Sir William Ramsay that the teachers' records of work done *in statu pupillari* should be taken account of in the granting or withholding of degrees. As his book was published before the final report of the Commission was issued, he was unable to note its recommendations on this and other subjects.

The second part of the book opens with a musical setting of Raleigh's reform song, "The Soule's Arrant," which we must resign to more competent criticism. Then follows an anthology of "reformed adages" and miscellaneous aphorisms, as to which we own to some apprehension that the bulk of them will prove caviare to the general. But they reveal a mind whose originality goes to atone for harshness and obscurity of expression.

NOTES ON BOOKS.

*Every Man His Own Builder*⁸ is a most practical book addressed by a professional man to an amateur. It is not often that in a well settled country it can be worth a man's while to give his own time and labour to the actual work of building his own dwelling house; but Mr. G. GORDON SAMSON has an eye also for countries in the process of being opened up, and is at pains to discuss colonial conditions and to suggest means of meeting difficulties due to want of skilled labour and distance from sources of supply. But even in this country the information the book contains will be useful to most dwellers in rural districts, who, if they have not to build houses to

⁶ *Diseases of the Liver, Gall Bladder, and Bile Ducts*. By Humphry Davy Rolleston, M.A., M.D. Cantab., F.R.C.P. London: Macmillan and Co., Ltd., 1912. (Roy. 8vo, pp. 826, figs. 108, plates 7. 25s. net.)

⁷ *University Reform for the Royal Medical Colleges, and Reformed Adages*. By H. Elliot-Blake, M.R.C.S., L.R.C.P., etc. Free Path Series, Vol. ii. London: John Bale, Sons, and Danielsson, Ltd. (Fcap. 4to, pp. 198. 11s. net.)

⁸ *Every Man His Own Builder*. By G. Gordon Samson, Architect. A book for every one who owns a piece of land. London: Crosby, Lockwood and Son, 1913. (Demy 8vo, pp. 360. 5s. net.)

dwelling in, are constantly having to meet interminable demands for repairs and often wish to erect outhouses. There are a good many books which give plans and suggestions for plans, but Mr. Gordon Samson is concerned rather with the details of construction: how to lay out foundations, to make and lay concrete, to make mortar, to choose timber and adjust it, to build a wall, to make a ceiling, to lay a floor, to build flues, to fix grates, and so on to all the hundred and one details which have to be met in even quite small building operations. He even tells his reader how to make and burn bricks, and also how to thatch—a most difficult operation requiring much skill and practice. To the city householder also the book will be useful, for it will help him to understand the true significance of the mysterious terms in the builder's estimate for repairs. There is a glossary constructed on the simple principle of quoting the page on which the meaning of the technical term is explained; it might have been made much fuller with advantage. The volume has an index also and is very fully illustrated by diagrams and drawings of details. It has a plan for a small farmhouse and outhouses, and a chapter on drawing a plan and elevation.

A special feature of the *City of London Year Book*⁹ is that, appearing as it does in the fourth month of each year, it contains information not to be found in any of its compeers. Thus in the edition for the present year, we find a list of members of the London County Council after its reconstitution at the recent election. Equally up to date is the information as to the membership of other large bodies closely connected with work in London, such as the committees of the Corporation of the City, Lloyds, and the Stock Exchange. Not less useful at times is the accurate information supplied as to miscellaneous points, such as the history of the City Guilds and the schools and charities supported by them.

The Far Eastern Association of Tropical Medicine appears to have obtained a very good grip on qualified medical men of all nationalities in Eastern Asia and its surroundings, and the second congress at Hong Kong in January, 1912, was very well attended. The papers then read and reports of the discussions on them have been brought together by Dr. FRANCIS CLARK, the general secretary of the association, and form a volume¹⁰ which is especially strong on the subject of beri-beri and of general interest to all those at work in tropical areas. As already announced, the next congress will take place at Saigon on the invitation of the Government of French Indo-China.

Some of the wild blood of his Viking forbears must still flow in the veins of Dr. SVEN HEDIN, for the account of his wanderings *From Pole to Pole*,¹¹ of which an abridged translation has recently been published for the use of English-speaking children, is full of adventures such as would have delighted the hearts of those early explorers. Dr. Hedin has penetrated into places where a white man had never before set foot; and his story is a record of perilous journeys and hairbreadth escapes, which he relates with as little emotion as though he were describing a trip to Paris and back. The great Swedish explorer writes very modestly of those feats of daring that have made his name famous far beyond the confines of his own country. His chief aim seems to have been to describe what he has seen in the course of his travels rather than what he has endured; and his book is therefore more a vivid panoramic view of the different countries of the world than a record of his own personal experiences. The latter, needless to say, form the most interesting portion of a book in which there is not a single dull page. Dr. Hedin possesses a keen sense of humour and a wide sympathy with all sorts and conditions of men; and the child must be hard indeed to please who is not thrilled and fascinated by this simple manly narrative of one of the greatest of modern explorers. The interest of the book is increased by the numerous photographs and maps with which it is illustrated.

a mind in harmony with nature, keenly sensitive to all her moods—bright, or sombre, or mysterious. He has, for example, felt the sense of other-worldliness which may come over the wayfarer on a moor when a sea mist sweeps up to him and seems to wrap him away from his fellow men and all the worries and struggles of workaday life. Filley possesses a charm not quite easy to define; it resides, no doubt, primarily in the unsurpassed variety of the coast scenery and the ever-changing sea which beats about the Brigg even on the calmest day, but in it the well-marked characteristics of the race of fishermen, who combine daring with prudence, and shrewdness with simplicity to no common degree, have a share. To both influences "Carr Point"—a pen name which veils the identity of Dr. Herbert J. Robson of Leeds—gives graceful expression.

MEDICAL AND SURGICAL APPLIANCES.

Intratracheal Insufflation of Ether.

MR. EDMUND BOYLE (Assistant Anaesthetist, St. Bartholomew's Hospital) writes: The accompanying illustration shows an apparatus that has been devised by Mr. G. E. Gask and myself for the intratracheal insufflation of ether. Air is driven from the bellows A through hot water in the bottle C (the tap B is for air, and B₁ is a reserve tap for oxygen if necessary). The air then passes through E over the surface of the ether in the smaller bottle, and so on to the gum-elastic catheter F. When it is desirable to give air without ether E E₁ are turned off and G is turned on. By regulating these taps it is quite easy to have either the whole or part of the air laden with ether vapour. The manometer D registers the pressure under which the air is driven into the trachea. The apparatus and the method of maintaining anaesthesia are mainly intended for intrathoracic operations, which in

the past were only possible with the aid of negative pressure cabinets. But now, thanks to the work of Meltzer, Auer, and Elsberg, these intrathoracic operations can be performed and anaesthesia maintained with safety by means of the intratracheal insufflation of ether. The method of administration is as follows: The patient is first anaesthetized, and then the catheter is passed through the vocal cords down to the bifurcation of the trachea. Air laden with ether vapour is then pumped in at varying pressures according to the necessities of the case. By this means it is possible to produce an excellent type of anaesthesia which has the great advantage of being quite safe, since by pumping in pure air we can easily and rapidly restore the patient to consciousness. Indeed it is held that when once the catheter is in position we have a perfect form of artificial respiration, for we are able to aerate the lungs at will. Although this method is mainly intended for use in intrathoracic operations where it may be necessary to allow the lungs to collapse during the operation, and then subsequently, at the end of the operation, to reinflate them when the pleura is being sewn up, I think that the method is quite likely to be of great service for the removal of goitres. My experience in this type of case is at present limited, but yet sufficient to lead me to think that the method is well worth an extensive trial. The apparatus can be obtained from Messrs. Mayer and Meltzer.

THE twenty-third Congress of Alienists and Neurologists of France and French-speaking countries will be held at Le Puy in August (1st to 6th).

THE CORONERS ACT AND THE NEED FOR ITS AMENDMENT.

As the law relating to coroners and coroners' inquests at present stands, many difficult questions present themselves for consideration—questions which directly affect the public welfare on the one hand, and which have also a bearing upon the good name, and to a lesser degree upon the material interests, of the medical profession upon the other. The general question has been considered both by a Select Committee of the House of Commons and also by a Departmental Committee. Both issued reports full of valuable recommendations, but, as is so often the case, these reports have so far been fruitless, and the question seems to have fallen completely into abeyance. It may therefore be of interest to review the position as it is at present with especial reference to some of the more important points involved. The British Medical Association has for a very long time realized the need for amendment of the law in this matter, and has devoted great consideration to the question, and as long ago as 1905 was prepared with a bill to amend the law relating to coroners, but owing to changes of Government, busy sessions, and the usual causes that so often prevail in such matters, it disappeared. The Association was very active in the matter in 1908, and a Departmental Committee was appointed by the Home Office to inquire into the whole question of coroners and their practice, an additional reference being made to the Committee as to deaths under anaesthetics, and the dangers arising from the use of flannolette. The Association was prepared to offer evidence to the Committee, and presented a carefully considered memorandum of its views and suggestions, receiving a promise from the Committee that the memorandum should be circulated to all its members, and that it should be printed as an appendix to the report when it was issued, but, owing to the sudden closing of the taking of evidence, the witnesses for the Association were not heard. The most important point advocated by the Association was the need for amendment of the present system of death certification and registration. As the law at present stands, a registrar can register a death only on receipt of certain kinds of information: (a) if a registered medical practitioner has been in attendance upon the deceased, upon the statement of a qualified informant (in accordance with Sections 10 and 11 of the Act), accompanied by a certificate from such practitioner; (b) if no registered practitioner has been in attendance, upon the statement of the qualified informant only; (c) on the certificate of a coroner that after inquiry he does not consider an inquest necessary; (d) if an inquest has been held, upon a certificate of the finding of a coroner's jury.

As the law at present stands, a medical practitioner who has been in attendance is required (under penalty) to give (without fee) a certificate as to the cause of death "to the best of his knowledge and ability." Forms for the purpose are issued by the Registrar-General, but there is no statutory or legal obligation upon the practitioner to give all the particulars indicated upon the form, or even to use the form at all. Under the Regulations, the registrar is directed in every case of violent or sudden death, or where the cause of death is suspicious or unknown, to report the same to the coroner before registering it, in order that the coroner may decide as to the necessity for an inquest. The coroner has, of course, other sources of information, such as the police, but, as was pointed out as long ago as 1893, the only official responsible for deciding whether or not there is a suspicious element in a case is the registrar, for the only statutory obligation upon the medical practitioner in this matter is that if he has been in attendance he shall give a certificate as to the cause of death to the best of his knowledge and belief. He is under no statutory obligation to use the form of certificate supplied and is not obliged to certify as to the fact of death, and the words "as I am informed" in the form safeguard the practitioner from being required to certify that the person in question is in fact dead, rendering it thus possible that the person whom he attended and to whom the certificate purports to relate may not be dead—this state of the law facilitates the substitution of one body for another.

The Select Committee in 1893 made a very strong pronouncement concerning deaths registered upon the

information of a "qualified informant" (or, in other words, cases in which no medical practitioner has been in attendance), as the following extracts from the report show:

The Registrar in such cases is instructed by the Regulations to register the death and to give the best information regarding its cause that he is able to obtain from the informant. He may, therefore, legally take information on this point from a person who has no real knowledge of the matter. He cannot, however, refuse to register the death, and it is no part of his duty to make any personal investigation of the facts of the case, and unless a case be reported to the coroner there is no authority for delaying registration in order that inquiries may be made. . . . There can be little doubt that much of the information obtained in these cases is far from trustworthy. In other cases, however, it is to be feared that the information given to the Registrar is not only untrue, but known to be so by the informant. There appears to be nothing in the existing procedure to prevent a fictitious cause of death being assigned in the case of a person got rid of by foul play, and for a certificate to be issued upon registration of such information. In short, the existing procedure plays into the hands of the criminal classes. It cannot be legitimately expected that a Registrar of Births and Deaths, whatever his education and intelligence may be, should be able to form a satisfactory opinion as to the trustworthiness of the information tendered to him by the informant of a death, and your Committee is convinced that a system which permits registration to take place upon information so obtained, cannot be other than dangerously defective. . . . Your Committee is much impressed with the serious possibilities implied in a system which permits death and burial to take place without the production of satisfactory medical evidence of the cause of death. . . . Your Committee, fortified with the weighty opinions of the witnesses who have appeared before them, has arrived at the conclusion that uncertified deaths should as a class cease to exist, and that means should be devised whereby a medical certificate should be obtained in every case not certified by a registered practitioner in attendance.

This impressive statement was made twenty years ago, and no advance has yet been made. The British Medical Association drafted a comprehensive bill, printed in 1904, designed to overcome the various weaknesses and anomalies of the existing law; the main points regarding this particular matter were as follows:

1. Every death, if possible, to be certified by a registered practitioner who has been in attendance.
2. The body to be viewed after death by a registered practitioner prior to certification. The certificate to be a confidential document subject to the discretion of the Registrar-General.
3. All deaths not certified by a registered practitioner to be referred to the coroner, or, in the case of Scotland, the Procurator-Fiscal.
4. That a special medical officer be appointed in every coroner's district to visit and examine the body and report to the coroner in all cases of death where no registered practitioner is able to give a certificate, such medical officer to be associated in his investigation with the usual medical attendant of the deceased, or any registered practitioner who may have been called in.

These various points were all included in the memorandum placed by the Association before the Departmental Committee in 1908, and it is interesting to note the report of the Committee, which takes the same serious view of this question as did the Select Committee of 1893. The report states:

The general question of the certification of death is outside the scope of our inquiry, but we would venture earnestly to call attention to the report of the Select Committee of 1893, to the representations made by the London County Council, and to the evidence given by the Registrar-General. . . . It is no fault of the law if premature burial does not take place. The present law of death certification offers every opportunity for premature burial and every facility for the concealment of crime.

Although the Committee considered this question outside the scope of its reference it did not hesitate to express the above emphatic opinion, and what is more, to make two most important recommendations upon the matter—namely, that no certificate should be accepted from a practitioner unless it states that he has by personal inspection satisfied himself as to the fact of death, and that in every case in which no such certificate is forthcoming it should be made a statutory duty for the registrar to report the death to the coroner, who would then exercise his discretion, and, if the amendment of the law suggested by the Association were adopted, would be fortified in the exercise of that discretion by the skilled medical advice of competent persons appointed for his assistance.

The existing law makes cremation difficult in the case

of bodies brought from abroad, as at present no body so brought can be cremated unless the coroner considers himself justified in holding an inquest and giving a certificate in the prescribed form. Cremation is becoming more and more common; it is a practice much to be commended, and under proper safeguards no unnecessary obstacles should be placed in its way.

With regard to the fees payable to medical men several questions arise. One that is very constantly cropping up has reference to inquests held upon persons dying in public institutions; the medical officers of such institutions are not entitled to receive any fees from the coroner either for giving evidence at the inquest or for making a *post-mortem* examination when directed to do so. The legal anomaly which compels the coroner to withhold fees from those engaged in such work must continue until the law is altered, for Section 22 of the Coroners Act of 1887, which deals with the fees payable to medical men, especially excludes from participation in the fees enumerated the medical officers of public institutions, and proceeds at some length to specify such institutions. It is difficult to imagine the reasons that could have induced the Legislature to impose such a restriction, as the net result is that a penalty is imposed upon a very hard worked and by no means highly paid section of the medical profession, without any advantage accruing either to the public welfare or to the particular institution concerned. It seems difficult logically to justify the practice of paying fees to the medical officers when persons are brought dead to the institution, and of withholding them when they die within its walls.

The practice of withholding fees in such cases is in England almost universal with regard to hospitals, although some county councils do allow such fees to be paid to medical officers of workhouses, workhouse infirmaries, and cottage hospitals. In countries with modern legal enactments, such as the Commonwealth of Australia and New Zealand, the fees are payable in all cases. In this matter the medical profession has the sympathetic support of the coroners of the country, who fully recognize but have no power to remedy this curious anomaly. The Departmental Committee expressed the opinion that there could be no good reason for withholding fees in such cases, and that the restriction should be removed.

The Departmental Committee also recognized the necessity for the provision of adequate fees for the services of expert pathologists.

With regard to the employment of pathologists, the question as to the position of the ordinary medical attendant in such cases arises. The Association has long contended that in the elucidation of the cause of death it is in the public interest to make use of all available clinical evidence in addition to that of the pathologist, and that the practitioner who has been in attendance should be summoned to attend the *post-mortem* examination in order that his clinical knowledge of the case may be available for the assistance of the pathologist. It has never been contended that the practitioner who has been in attendance is necessarily the most suitable person to give evidence or to make the *post-mortem* examination, or that the coroner is legally bound to direct him to do so; but it has been contended, and rightly, that in cases in which he is not summoned he should be invited to be present both at the inquiry and the examination.

This point was accepted by the Departmental Committee, which, however, recognized that the coroner might be placed in a difficulty, inasmuch as on a strict interpretation of the existing law he is prevented from paying both the medical witness who gives clinical evidence and the pathologist who makes the examination. The Committee recommended that the coroner should be empowered to summon and pay such medical witnesses as might be necessary for the proper determination of the case.

The adoption of this recommendation would dispose of the vexed question of the unsatisfactory position occupied by medical practitioners with regard to furnishing coroners with information which may determine the necessity for an inquest. It has long been the custom for medical practitioners in this country to supply coroners (without fee) with any information that can assist in determining

the necessity, or otherwise, for the holding of an inquest, with the result that what was originally an act of grace on the part of the profession has come to be regarded more or less as an obligation by certain coroners, who upon occasion have made unfair use of information so received and have held inquests without taking the medical evidence of which they have, so to speak, obtained private information from the practitioner concerned, or who have decided when placed in possession of such information that it is unnecessary to hold an inquest. In contingencies such as these it is quite exceptional for the practitioner concerned to receive any fee, although the course decided upon has been determined by the information obtained from him—information which he is under no statutory obligation to supply, although he has upon occasion been accused of neglect of duty when it has not been forthcoming.

A very large number of medical practitioners appear to be in ignorance of their true position in the matter, and to believe that they are bound to assist the coroner in this way; but it is quite clear that there is no legal obligation upon a medical practitioner to render any assistance to coroners in investigating the cause of death other than that of making a *post-mortem* examination, when so ordered in writing by the coroner, or to attend and give evidence at an inquest when duly summoned to do so.

It therefore seems to be very desirable that, if the preliminary inquiry made by a coroner is to be regarded as an integral portion of State procedure in the elucidation of the cause of death, and there is much to be said in favour of the adoption of such a course, it should be regularized by legislation which would definitely determine the obligations and duties of coroners, medical practitioners, and public, and which would in addition define the fees to be paid for services rendered by the various parties concerned.

The Committee pointed out that in Scotland the Procurator-Fiscal has a much freer hand, and recommended that certain features of the Scottish system might with advantage be adopted in England and Wales with the view of preventing the holding of unnecessary inquests. The report of the Committee states:

There is great, and we think justifiable, dissatisfaction in the medical profession with the scale of fees in coroners' courts and the methods of their allocation. We think that the whole matter should be dealt with by regulations and not by the iron-bound provisions of an old statute.

Strong representations were made with regard to the holding of inquests upon persons dying under an anaesthetic. It was contended by the Association that a lay body could hardly be considered efficient to deal with such questions, and recommended that inquiry in such cases should in the first instance be privately made by a medical authority appointed by the Home Office. If it were then found that a public inquiry was desirable it should be held by a High Court tribunal with medical assessors. This point was also recognized to some extent by the Committee, which was of opinion that every death under an anaesthetic should be reported to the coroner, who should make inquiry, but that if he were satisfied that all due care and skill had been exercised, it was undesirable that an inquest should be held.

The coroner's officer of to-day occupies an important but anomalous position. He has no legal status, there are no necessary qualifications for the office, and any information given him is given purely as an act of grace by the informant. His duties are, notwithstanding, very important, as he, under direction of the coroner, makes those preliminary inquiries upon the result of which the coroner decides whether or not an inquest shall be held.

The Committee fully recognized this curious position, and expressed the euphatic opinion that he should always be an acting member of the police force, for the reason that the fees paid were inadequate to obtain the services of a good man who was dependent upon them for his livelihood, whereas if a police officer were appointed they would be paid to the police fund and not to the officer, and there would then be no temptation to make illegitimate profits.

With regard to coroners' juries, it was contended that they were of no real value for the purpose of investigating the cause of death. If twelve members of a jury agree, it

would appear that the coroner is bound to accept their verdict no matter how insensate it may be; if he alters it he may be guilty of forgery! Two verdicts were quoted before the Select Committee in 1893, and appear in the report:

1. The man died from stone in the kidney, which stone he swallowed while laying in a gravel path in a state of intoxication.

2. A child three months old found dead, but "no evidence to show whether born alive."

No suggestion was made by the Committee as to replacing the jury by some other machinery, but it was recommended that in cases of perverse or foolish verdicts the coroner should take the verdict, and that as the question of delay is one of great importance, he should be empowered to apply immediately to a judge in chambers, who would authorize him to summon a new jury. It was further recommended that any riders passed by the jury should be separate from the verdict and endorsed upon the back of the inquisition, and that the coroner should be at liberty to record his dissent and give his reason for so doing.

This, in the opinion of the Association, did not go far enough, for it would not prevent juries from reflecting upon the conduct of individuals who had not been afforded an opportunity of giving evidence on their own behalf, and this we know to be a far from unusual occurrence.

Recommendations were made by the Committee with regard to many other important points, and it is satisfactory to notice that these recommendations were largely in accord with the views put forward in the memorandum submitted by the British Medical Association, and it is much to be desired that they shall not be lost sight of. This comparative statement of some of the principal points that affect the profession and the public welfare clearly shows the need of reform, and it is a matter of importance that the question of reform should not be allowed to fall into abeyance for long. It is much to be hoped that, when the present crisis that has overtaken the profession has passed away, the Association will once more put its shoulder to the wheel in order to prevent the work it has done from being wasted, and will agitate until the whole subject is rescued from that limbo of forgotten things to which it seems to be at present consigned.

YELLOW FEVER COMMISSION (WEST AFRICA), 1913.

The Secretary of State for the Colonies has appointed a Commission to study the nature and the relative frequency of the fevers occurring amongst the Europeans, natives, and others in West Africa, especially with regard to yellow fever and its minor manifestations.

The funds for the investigation will be provided by the West African dependencies. The members of the Commission are:

Sir James Kingston Fowler, K.C.V.O., M.D., D.Sc., F.R.C.P. (Chairman), Major Sir Ronald Ross, K.C.B., F.R.S., M.D., F.R.C.S., D.P.H., I.M.S. (ret.), Colonel Sir William Leishman, F.R.S., M.B., K.H.P., R.A.M.C., Professor W. J. R. Simpson, C.M.G., M.D., F.R.C.P., D.P.H.

Secretary.—Mr. A. Fiddian, of the Colonial Office.
Assistant Secretary.—Mr. T. F. G. Mayer, M.R.C.S., L.R.C.P., West African Medical Staff.

In the absence of special reasons, the Commission will not proceed to West Africa, but local investigators will work under its direction at certain centres. As at present arranged, those centres will be Freetown in Sierra Leone, and Sekondi and Accra on the Gold Coast. The investigators will be:

Freetown.—Major J. C. B. Satham, R.A.M.C., Sanitary Officer of the Command, and Mr. G. G. Butler, B.A., M.B., B.C. Cantab., M.R.C.S., L.R.C.P., of the West African Medical Staff.

Sekondi.—Mr. H. S. Coghill, M.B., B.Ch. Edin., D.T.M. and H. Cantab., Assistant at the Medical Research Institute, Lagos, and Mr. H. M. Hänschell, M.R.C.S., L.R.C.P., D.T.M. and H. Cantab., Senior Demonstrator at the London School of Tropical Medicine.

Accra.—Mr. G. E. H. Le Fanu, M.B., C.M. Aberd., D.T.M. Liverpl., of the West African Medical Staff, and another.

The investigation will be set on foot towards the end of April or early in May. Endeavours have been made to

enlist the co-operation of all medical men practising in the British dependencies in West Africa, whether as Government medical officers or otherwise.

THE PARLIAMENTARY COMMITTEE ON PROPRIETARY MEDICINES.

THE MEDICAL PROFESSION AND PROPRIETARY PREPARATIONS.

ON April 17th the examination of Mr. E. J. Parry, analytical chemist retained for the purposes of the inquiry by the Proprietary Articles Section of the London Chamber of Commerce, was resumed.*

In reply to Mr. Glyn-Jones, the witness said that his main objection to the volumes, *Secret Remedies* and *Mors Secret Remedies*, was with regard to the inferences drawn from what was found by analysis. In certain instances he would expect any analyst to come to the same conclusions, but he objected to the inferences drawn.

Mr. Glyn-Jones: You put in, for the private information of the Committee, certain testimonials given by members of the medical profession in regard to a proprietary medicine. Can you explain in any way why medical men, apparently of high standing, should write testimonials for proprietary and secret medicines?

The Witness: This particular proprietary remedy contains a most valuable drug, recognized by the medical profession.

Is it within your knowledge that it is not an uncommon thing for the medical profession to write testimonials of this kind?—It is a very common thing indeed.

Can you offer any explanation? Are they paid for it?—Oh, no. That would be a grave breach of professional etiquette; I should say that would hardly ever be done.

You think medical men genuinely believe, though they do not know what the article contains, that it is a good thing?—I am confident of it.

In this particular case have you any knowledge whether the doctors when they wrote the testimonials knew of this special ingredient to which the article owes its merit?—I should say certainly not; they were speaking from the results of their own trials.

Mr. Newton: It seems difficult to believe that a doctor would give a testimonial to a medicine which promised to do practically everything.

The Witness: It is only rarely they promise that; in the majority of cases the claims are limited.

Asked by Mr. Newton how he proposed to deal with the cancer and consumption cures which he condemned, the witness said that since the remedy already at hand—an action at common law—was never set on foot, these preparations should be suppressed altogether. The diseases mentioned were known to every intelligent person to be incurable by mere drugs; it was a question of treatment rather than drugs. As this was an admitted fact it was not fair that the public should be defrauded by them.

In reply to Dr. Chapple, the witness said that a preparation claiming to do the impossible should be prohibited. In the case of the preparation as to which he had put in testimonials from medical men, the important constituent was a well-known drug in constant use under another name.

Dr. Chapple: Do you think it right that any one who likes can take a well-known drug, give it a new name, and advertise it as though it was something unknown to the profession?

The Witness: That is a question of ethics. In this case I should say "Yes." A really excellent remedy is to hand which a limited number of the profession know. In order to make it more widely known, and so to bring relief to a larger number of people, a large amount of money must be spent on advertising. You will not get a philanthropist to do that; you must give him some trade rights or it will never be done.

Are there not sufficient facilities in the medical profession for spreading this knowledge without the assistance of lay persons? Does the education of the profession depend on the proprietary medicine vendor?—I will say that the education of a very large number of practitioners depends on the firms who make or pack

* BRITISH MEDICAL JOURNAL, APRIL 19th, 1913.

drugs, and not on the textbooks. The amount of money spent on travellers who call upon doctors to induce them to prescribe nothing but a given firm's remedies is enormous. The ingredients of compressed tablets, for instance, are known, but it requires the expenditure of an enormous amount of money to ensure that the medical man will add the initials that will secure that a particular firm's compressed tablets are used.

What is the inducement to use a particular drug when it does not differ from any one else's?—With the greatest respect to the medical profession, it is because they are exceedingly prejudiced with regard to drugs. There can be no reason why a doctor should prescribe a given brand except that doctors are susceptible to being talked over by travellers who can talk.

Is not the appeal to the medical man based on the ground that the maker has managed to combine the ingredients in such a way that they are simple, elegant, and easily dispensed?—Yes, but only in the same way that twenty other makers have done.

But you do not instruct the doctor in the therapeutic value of the drugs?—You persuade him that your substances, which are identical, are better than other people's.

But you would not presume to tell the doctor the value of the drugs?—I think you will find that that is just what you do tell doctors. In support of this remark the witness quoted an advertisement in the *BRITISH MEDICAL JOURNAL* in which the diseases that a given remedy was claimed to cure were mentioned.

Dr. Chapple: But these synthetic remedies are quite different from secret ones. Suppose some one comes to the doctor with a preparation called "Cureit," and asks him to try it for this and that disease?

The Witness: The doctor does it.

Upon no evidence except that a layman tells him these things?—They do.

Dr. Chapple: That is not my experience, and I am surprised that it should be yours.

In reply to Mr. Bathurst, the witness said he thought the practice under the Pharmacy Acts of putting the word "poison" on the bottle was preferable from the public point of view to the disclosure of the name of the poison that the preparation contained. As to making it an offence to advertise remedies for incurable diseases, Mr. Bathurst asked the witness whether he would advocate a public prosecution rather than a civil action in dealing with this.—The witness replied in the affirmative, and said he would make it a penal offence. He added that there should be sufficient power under the Indecent Advertisements Act to deal with remedies of an undesirable character in connexion with sexual diseases.

Mr. Bathurst: Various witnesses have suggested that a doctor's chemical knowledge is lacking?

The Witness: The curriculum is too short.

Dr. Chapple: Is it not carried on by the study of medical literature?

The Witness: Yes, but also by literature emanating from private firms.

Mr. Bathurst: Are you of the opinion that a sufficient education of the doctors in chemistry and therapeutics would put a stop to what, to my mind, is an undesirable way of educating the profession?

The Witness: No. The average doctor is a very busy man, and he will prescribe something that is easy to obtain.

Dr. Chapple: Do not these firms depend upon doctors for their information in the first instance?—I think not.

At the request of the Chairman (Sir Henry Norman), the witness made a general statement of what he regarded to be the possibilities of analysis. He said that in the case of purely organic drugs the difficulty of analysis increased enormously as the number of ingredients present increased. The vast majority of organic drugs—important ones—did not contain such identifiable principles as a glucoside or an alkali, and when they were alone, more certainly when they were in mixtures, the analyst had to rely on some other method than chemical means. In the case of a liquid the microscope was useless, and the analyst had to fall back on taste and smell. Broadly speaking, he could only get analytical results consistent with about twenty different formulæ.

The Chairman put it to the witness that, according to his statement of the limits of analysis, any person, having

made up a preparation of no real medicinal value, could protect himself by adding to the preparation six familiar drugs in very small quantities and then claim that the formula was totally undiscoverable by analysis.

The witness replied that the average vendor did not need to put in fictitious drugs for the purpose of "fogging" the analyst because the ordinary formulæ of such remedies presented sufficient difficulties. He did not think such an action was at all usual, although it was possible. In analysing proprietary remedies, he had never found drugs which gave any evidence of having been included for such a purpose as the Chairman had indicated.

The witness said, in reply to other questions, that he had no suggestion to make as to the way in which exaggerated statements in proprietary medicine advertisements could be supervised. He thought the difficulty would be met in a great measure by prohibiting the advertisement of remedies for a specified list of diseases.

The Chairman: What is the ethical position of a doctor who prescribes remedies of whose composition he knows nothing, and who does so in the way you have described, at the suggestion of an advertising firm?

The Witness: I think he knows generally that when people spend money and time advertising a preparation there is reason to believe that the remedy may do good.

Would you be content with that?—That is the doctor's standpoint; he does it.

The Chairman: Do you realize that your series of criticisms of the medical profession, added together, really make a grave charge? You have told us that doctors are widely ignorant, that they do not know of the existence of a great many drugs, that they are very credulous, that they are easily talked over—I presume by glib salesmen—and that they are inadequately equipped from an educational point of view.

The witness objected that some of these expressions had been put in his mouth by questioners. He did say that the time at doctors' disposal was short for instruction in pharmacy, chemistry, and materia medica. That was acknowledged by every medical man.

The Chairman: You also said in effect that their education was incomplete until the proprietary medicine vendor had rounded it off.

The Witness: Words were put in my mouth to force me to that. I do say that their education in these matters is not adequate; there is not sufficient time. That is borne out by the fact that the General Medical Council is prolonging the curriculum by fifteen months. In support of his view that doctors prescribed proprietary medicines to a considerable extent, and also that they were ignorant of the composition of many of these preparations, the witness declared that medical men "rushed" for anti-kamnia, whereas under the name of Daisy Powder they condemned it. The ingredient of both, he said, was acetanilide. The medical profession to a limited extent prescribed medicines of which they knew nothing, and to an enormous extent those of which they had only a very little knowledge. In conclusion, the witness remarked that nearly every case of death from self medication had been due, not to a proprietary medicine but to poisonous drugs sold under their own names. More people had been killed in one year by veronal before it was put on the poisons list than had been killed in a hundred years by proprietary medicines.

In thanking the witness as he withdrew, the Chairman remarked, "I hope you will not get into trouble with any of your medical friends."

ASSOCIATION OF WHOLESALE DRUGGISTS.

Mr. R. C. WREN gave evidence as Secretary of the Association of Wholesale Druggists, which, he said, was composed of firms supplying packed medicines to the working classes through the channel of shopkeepers who were not registered chemists and druggists. The articles dealt in were mainly well-known drugs and medicines or simple compounds intended for use in minor and common ailments. The association asked that in any fresh legislation the right should be preserved of referring to the human body and its organs, and to the names of illnesses, on the labels of the preparations he had alluded to, without liability for stamp duty being incurred.

UNIVERSITY OF LONDON.

FINAL REPORT OF THE ROYAL COMMISSION.

[SECOND NOTICE.]*

NO MEDICAL FACULTY.

THE strict application of the principles laid down by the Commissioners with regard to what constitutes University education, or perhaps it would be better to say the strict terms in which those principles are defined, has led to at least one surprising result, which is that the new University of London as they conceive it would start, and it seems probable would long remain, without a Faculty of Medicine. This recommendation must seem to many so much of the nature of a step backward, that the arguments of the report and all its conclusions are at once laid under some suspicion; this suspicion will not be allayed when it is remembered that, though the commission had the advantage of hearing many competent medical witnesses, no member of it has had any practical experience of medical education, its methods or its needs.

DEFECTS IN CLINICAL LECTURES.

THE conclusion rests on what may seem a rather sandy foundation—an opinion that the clinical lecture or demonstration in London is insufficient and ill-prepared, because the clinical teacher is hampered by the demands of private practice, the want of an adequate staff of highly trained and skilled assistants, and time and laboratory facilities for research. To the London-trained practitioner of medicine who remembers the important part the clinical lecture or demonstration played in his own education the conclusion will, when first presented, probably seem wholly untenable. But a more careful consideration of the grounds upon which the conclusion is based may show that there is a good deal of truth in the assertion that, though the clinical lecture, founded on French models and greatly developed by some great teachers, was long one of the two chief means of clinical education, it has not in recent years undergone in London the development necessary to fulfil the more complicated requirements of modern medicine.

THE Commissioners appreciate the high value of the British system of clerkships and dresserships by which the student is brought at an early stage into direct relation with patients, and indeed of the whole system of progression from clinical clerk to house-physician or house-surgeon by which his responsibilities are gradually increased. They would retain this system and combine it with the German professorial system of the hospital unit, as Sir William Osler retained and combined it at Johns Hopkins Hospital. There would be no difficulty about this; it would, in fact, be in the line of the natural evolution of medical education in this country. But the Commissioners have been so strongly impressed by the arguments of the advocates of the hospital unit system as to be induced to conclude that there is no hope for medical education in this country save through it.

IT will not be disputed that the complete clinical study of many types of cases in the wards demands a much greater expenditure of time, a stronger body of assistants, and a much more complete armamentarium than thirty or forty years ago. The recognition of this fact is essential to progress, and the Commissioners are to be thanked for putting it so clearly before us; but to propose on that ground to refuse to the medical schools and medical teachers their place in the sun, and to seek to deprive them of their proper share in the direction and administration of the University, is to ride a hobby to death.

MEDICAL SCHOOLS OF THE UNIVERSITY.

AS stated in the first notice of the report, the Commissioners propose that the existing medical schools in London should be recognized as University Schools in Medicine. The definition of "School" is that it is a public educational institution, or a group of departments in a larger educational institution, which is not under the educational and financial control of the University, but complies with certain conditions set out in the existing statutes of the University. Of these the most important are that in deciding on the claim of an institution to be

admitted in whole or in part as a school of the university the Senate shall have regard to the following matters: (a) The general character and financial position of the institution; (b) the adequacy in number and qualifications of the teaching staff; (c) the University standard of the teaching; (d) the adequate provision of laboratories and other appliances necessary for giving instruction in the subjects in respect of which the institution seeks to be admitted; (e) the conditions as to age and attainments on which students are admitted; (f) the number of students proceeding or likely to proceed to degrees in the University; (g) the relation of the institution to any other University.

BOARD OF MEDICAL STUDIES.

THE principal teachers in the Schools of the University would be grouped into Boards of Studies. Each such board, the Board of Medical Studies, for example, would prepare the curriculums and syllabuses of examinations for students in the Schools of the University, and would report these curriculums and syllabuses for approval to the Senate. The examinations would be conducted by boards of examiners consisting in the main, as at present, of teachers in the schools, together with at least one external examiner in each subject appointed by the Senate. The Commissioners, while prepared to recommend that candidates who have not studied in schools of the universities should be admitted to the general examinations in all cases in which exclusion might involve individual hardship or injustice, are of opinion that no such hardship could arise in the case of medicine and engineering. Upon this they make the following observations:

THE courses of study for these degrees are professional in their aim, they are of necessity very largely practical in character, and they are intended to fit their holders to follow occupations which closely affect the safety of the public. This combination of characteristics differentiates them from all other degrees awarded by the University. We are convinced that the University should grant its first degrees in medicine and in technology only to those who have undergone a course extending over at least three years, which is under the control of the University itself, and given either in a constituent College, a university department, or in a School of the University. The medical evidence we have received on this subject strongly supports this view. The Faculty of Medicine unanimously adopted the following resolution:

That the Medical Degrees of the University of London should be open only to those students who are students in the Schools of the University.

MOREOVER, with the exception of the witnesses from St. Mary's Hospital Medical School, all the witnesses from the London medical schools who referred to this matter and a number of other witnesses, urged the abolition of the external degree in medicine. We admit the argument of several witnesses that it is an injustice to doctors who studied in London and obtained the London degree, that the same qualification should be open to students who have never had any connexion with the University beyond sitting in its examination halls. Every school of medicine in the kingdom is now connected with a university, and no hardship would be imposed by requiring that medical students should graduate in the university in which they have studied.

INSTITUTIONS which refuse, or cannot qualify themselves, to accept these conditions would still be allowed to present their students for general examinations for degrees, provided they comply with the conditions laid down for the recognition of Schools of the University, and their teachers would be members of a Board of Medical Studies (with power to appoint committees), which would advise the Senate through the faculties on the syllabuses and courses of study for the general examinations; but the institutions themselves cannot be included as constituent colleges or departments of the University into which they do not come, and their teachers cannot constitute the faculty of the University, which, so far as is consistent with the academic interests of the University as a whole, will have the direction and control of the medical education provided by the University. The question whether an institution does or does not form an integral part of the University, one with it in interest, in spirit, in educational standard and aims and ideals, is a question of fact, and there is no room for compromise. The financial and educational control, direction, and

* The first notice was published on April 19th, p. 836.

administration must belong to the University, otherwise it is impossible to establish within it the academic freedom and autonomy which we are convinced are essential to its existence and development.

POSSIBLE ORGANIZATION OF MEDICAL COLLEGES IN THE FUTURE.

When eventually, as it is hoped, the medical schools or some of them qualify to be admitted as Constituent Colleges of the University, it would be the medical school and not the hospital which would be incorporated, and arrangements would have to be made between the University and the governing body of the hospital with respect to the use of the hospital for the purposes of medical education and research, and with respect also to the appointment of those teachers in the medical school who from the nature of their work must also be members of the staff of the hospital. In further reference to this matter the Commissioners, after stating that Constituent Colleges, or University Departments, in the Medical Faculty of the future would have the same control over the University examination of their students as Constituent Colleges or Departments of other faculties, continue as follows:

The difficulty about the medical schools is that if they were all to agree to come into the University in the sense we have described, it would probably be found impossible, even on their present financial basis, to continue them all as institutions for the instruction of undergraduate students. The great defect of the present system in London is that it dissipates its strength upon unnecessary multiplication of undergraduate teaching on identical lines without providing opportunity for extensive study of particular subjects, while resources unrivalled in variety and extent are either neglected altogether, or are largely wasted for want of time and training on the part of those through whose hands the materials pass. In a great University Faculty of Medicine, developed in an indefinite number of directions, there would not only be a large increase of post-graduate work and research, but there ought to be a much wider range of undergraduate study than there is at present. This does not mean that undergraduate work would be separated from more advanced work by any hard and fast line. We think more freedom for the student is desirable than the English system provides. If his general education is good and his scientific training is what we hope to see, he ought not to be treated as under authority through his whole course to the same extent as at present. The matter is not free from difficulty and even danger. Regulations of the University would be necessary, but in proper cases the student ought to be able to arrest almost at any stage the general course of his necessary medical training in order to pursue further than is required of him any subject which fascinates his attention and appeals to his mind. There is no difficulty for such a man in returning to his regular course and completing it with increased power, greater self-confidence, and more of the initiative which should come from the side of the learner. There would be some risk of the unstable and the incompetent going astray, but there are methods of guidance by counsel and criticism well known to the teacher and very freely exercised by fellow students which should restrain him. In any case, we think it is a risk which must be run in the interest of the competent men of original mind. The university student is not a schoolboy, and the best results for the best men should not be made difficult or impossible.

But although in these and other ways there is ample scope for the development of medical education in London, the fact remains that it would be impossible for the University to absorb and continue the whole of the London Medical Schools to do their present work. They are kept alive partly by traditional loyalty and partly by the other causes to which we have already referred—the desire to maintain the status and efficiency of the hospitals, the desire to teach and do hospital work, and the professional advantages which usually accompany the holding of hospital appointments.

FIRST STEPS.

The Commissioners recommend that a Faculty of Medicine should be constituted when funds are available for the payment of the Professors and Readers they deem necessary, and when the University obtains financial and educational control of one or more medical schools attached to a general hospital.

They recommend that the proper course for the University would be to endeavour in the first instance to enter into an agreement with the executive authority of one or more of the London hospitals with regard to the future of the hospital medical school. As was stated in the first notice of this report the Commissioners have in mind the establishment of hospital units for medicine, surgery, and gynaecology respectively. Each unit would consist of

a professor with the control of wards; an out-patient department; assistants nominated by the professor with a view to complementing his own knowledge and affording him the special assistance he requires to carry on research in the direction in which he is interested; and, finally, laboratory accommodation in close proximity to the wards, not only for the service of the wards and the examinations and procedures connected with the diagnosis and treatment of the cases, but also for the purposes of research.

On this suggestion they make the following observation:

For scientific instruction in medicine the kind of teaching known as the clinical demonstration or lecture appears to us of great value, and we think in some form or other it ought to be systematically given. The time and knowledge required for this kind of teaching cannot be expected from the man in large practice. It needs a man who is devoting his life to the pursuit of science in his subject, and who is aided by a competent staff of assistants.

APPOINTMENT OF TEACHERS.

With reference to future appointments it is recommended that the appointment to the staff should be made by the governing body of the hospital, and to the teaching post by the University, both bodies being advised by a joint committee consisting of representatives of each. In connexion with the higher appointments the joint committee would ask for a report from a board of advisers and would eventually report to the Senate. It is believed that in this way the staff of the hospital and college would gradually be organized and co-ordinated in accordance with university ideals, and the whole course of the students' education from the time they enter the college rendered thoroughly scientific in principle. It is calculated that the complete organization of the hospital staff on university lines would thus be brought about in a period not exceeding twenty years at the most. When this result had been achieved the Faculty of Medicine would consist mainly of university professors and other teachers of standing in the university medical colleges, together with professors of subjects such as public health, forensic medicine, and mental diseases comprised in the Faculty but not necessarily taught within the medical colleges themselves, with perhaps, in addition, some eminent members of the medical profession who were not teachers of the University.

In entering into negotiation with a London hospital and its medical school the University would propose to appoint three professors—of medicine, surgery, and gynaecology respectively—in connexion with the hospital, together with the assistants above mentioned, and to undertake to pay both the professors and assistants, provided they were appointed to the staff of the hospital and had an adequate number of beds assigned to them. The Commissioners' suggestion of the way in which this proposal might be worked out in practice is as follows:

This would have to be arranged either by the retirement of some members of the existing staff, or by the transfer of beds from them all, or, in all probability, by a combination of both methods. It would certainly make things easier if the senior physician and surgeon on the staff whose terms of office would, in any event, be near completion, were to retire. For the present no other change would be necessary in the existing staff of the hospital. The professors would confine their instructions during the period of transition to the final year of the curriculum, and the present physicians and surgeons of the hospital would continue their teaching as before, and would be members of the Faculty of Medicine of the University. It is, of course, necessary that the University, together with the governing body of the hospital, should have a free hand in selecting and appointing the professors, but it is by no means impossible that in some cases the best man for the post would be found on the existing staff of the hospital, and would be willing to accept the appointment. It must be borne in mind that one important reason for proceeding slowly is that there would be a

difficulty in finding at present any large number of men fitted for the position of clinical professors, and willing to accept the chairs.

FINANCE.

As was stated in the previous notice, the estimate for the cost of the maintenance of a medical unit is £4,000, so that for the three units recommended each college would have to be provided with £12,000 a year, or for the three colleges deemed necessary, if all the London University and Oxford and Cambridge students are to be provided for, a total of £36,000 a year. This estimate proposes that the professors in the Faculty should receive not less than £1,000 a year, and a reader not less than £300. The professor would not be wholly debarred from private consulting practice, and it seems to be contemplated that an assistant, after serving in that capacity for seven years, should give up his university work and take to private practice, but remain eligible for promotion to the professoriate when a vacancy occurred.

(To be continued.)

LITERARY NOTES.

PROFESSOR JAMES STUART relates in his *Reminiscences* (1912) that at Cambridge he knew Professor Willis, whose death some eight years later led to his own appointment as a professor. Willis, he says, was a very interesting man, of extraordinary ability as a handicraftsman. He was a son, or grandson, of the Dr. Willis who attended George III when he was insane. Professor Stuart says he heard that George III had to affix a stamp for his signature to death warrants, because when allowed to sign with a pen he always wrote, "Hang Willis!" This is not unlikely, for Willis was said to have treated his royal patient with great harshness.

Another anecdote told by Professor Stuart shows Sir George Humphry's ingenuity in getting out of what to many doctors would have been a tight place. At a dinner at Cambridge, the conversation having turned on some medical matters, W. G. Clark, then public orator, said to him: "Take care now, Humphry, what you say, for I am going to tell you a story. Before you knew who I was I came to you, and said I was not feeling very well, and having described my symptoms you said, 'What do you take for your lunch?' and I said, 'A glass of sherry and a biscuit.' 'That is the cause,' you said, 'take a glass of beer and a mutton chop.' I did so, and after some time, the symptoms recurring, I came to you again. You had forgotten all about me, and when you heard them you said, 'What do you take for your lunch?' I said, 'A glass of beer and a mutton chop,' and you said, 'That is the cause of it; take a glass of sherry and a biscuit.'" To which Humphry replied, "I believe I was right in both cases. It was a change you wanted."

The phrase, "Who shall decide when doctors disagree?" which has become a part of the language, is constantly quoted as if it referred to doctors of medicine. It is held, indeed, to enshrine the proverbial tendency to disagreement among medical authorities. The reference is, however, to "doctors" or authorities in general. It is the opening line of the third of Pope's Moral Essays, which is addressed to Lord Bathurst, and deals with the abuse of riches. The poet asks:

Who shall decide when Doctors disagree,
And sondest Casuists doubt like you and me?

After summarizing his own views and those of the nobleman to whom the epistle was addressed, he says:

Like Doctors then, when much dispute has past,
We find our tenets just the same at last.

Doctors of medicine, as a matter of fact, probably disagree less than men of other professions. It may be said to be the business of lawyers to disagree, and from the warmth of theological controversy, even in these days of large tolerance, it is easy to understand how ready divines in days of more fervent faith were to use the stake as an argument against those who differed from them in opinion. The quarrels of literary men are proverbial; and, although a modern philologist would probably not say to a rival, like Dr. Cherubino in the *Golden Legend*:

May he send your soul to eternal perdition
For your treatise on the irregular verbs,

his unexpressed thought is doubtless often very much to the same purpose.

That Latin as written by many journalists and authors is a dead language is sufficiently shown by the corrupt fragments so freely strewn about certain kinds of current literature. A few specimens were given in the *JOURNAL* of April 12th. Since then we have come across another sample which proves that, even when Latin was the common tongue of educated men, learned doctors sometimes used it as barbarously as the least classical of moderns. In a passage on the death of Gabrielle d'Estrées, quoted from the *Mémoires* of Pierre de l'Estoile by a writer in the *Chronique Médicale*, La Rivière, physician to Henry IV, is said to have left the king's mistress in her last agony with the edifying but ungrammatical exclamation, "*Hic est manus divinum!*" We hope that the blunder is that of the historian, not of the physician!

We have received a copy of the first number of the *Hungarian Spectator*, a periodical published under the auspices of the British American Literary Society in Hungary. It is hoped to convert it into a monthly devoted to spreading a knowledge of Hungary and its institutions and literature among English-speaking people, and to encourage the study of English literature in Hungary. The editor is Dr. Arthur B. Yolland, chairman of the society. The number before us contains articles on the mission of Hungary, by Count Albert Apponyi; interesting reminiscences of Hungary in Great Britain by Professor Arminius Vámbéry, and an essay on Shakespeare in Hungary—a brief review of Hungarian contributions to the world-wide literature that has gathered round the author of Hamlet. Mr. Desider Rozsa writes on the English psychological novel, taking the works of George Eliot, Meredith, and Thomas Hardy as his text. Other articles deal with modern Hungarian drama, and the conquest of Hungary. One object of the *Hungarian Spectator* is to bring prominently before British and American readers the health resorts and the wealth of healing and other natural springs for which Hungary is already famous. Our contemporary is very optimistic as to the future of Hungary as a place for visitors when its attractions come to be known, and goes so far as to say that Hungary will undoubtedly one day receive due appreciation as the Et Dorado of tourists. Our new contemporary is excellently printed, without any of the distortions of our English speech that make English periodicals and books printed abroad so irritating. We wish its founders and promoters success in the object at which they aim.

Our American contemporary, *Surgery, Gynecology, and Obstetrics*, has added a new and very valuable feature to its contents. This is an *International Abstract of Surgery*, which is published in collaboration with the *Journal de Chirurgie* (Paris), the *Zentralblatt für die gesamte Chirurgie und ihre Grenzgebiete* (Berlin), and the *Zentralblatt für die gesamte Gynäkologie und Geburtshilfe sowie deren Grenzgebiete* (Berlin). The *International Abstract of Surgery* is intended to be: (1) A comprehensive index of surgical literature from all sources, arranged anatomically under departments, giving the author's name, subject of communication, and the name and date of the journal in which the article appeared; (2) an abstract of the surgical literature of all countries, prepared by the combined efforts of the German and French journals that have been mentioned, and a special staff for America and the British Empire. This will include abstracts and reviews of (a) original articles, (b) monographs, (c) books, and (d) clinics. It is stated by the managing editor, Dr. Franklin H. Martin of Chicago, to be the first journal in the English language "devoted exclusively and comprehensively to indexing and abstracting the surgery of the world." The *International Abstract of Surgery* is, in fact, a distinct journal supplementary to *Surgery, Gynecology, and Obstetrics*. It is excellently arranged and beautifully printed, and the illustrations are admirably reproduced. To specialists in the various provinces of practice which it covers it will be invaluable. The English editor is Sir Berkeley Moynihan.

M. Chacornac, of Paris, will publish a French translation of the complete works of Paracelsus. The first volume has already appeared, and there will be thirty in all. The translator is M. Grillot de Givry. The translation has been made from the Latin and collated with German editions of the works of Paracelsus.

British Medical Journal.

SATURDAY, APRIL 26TH, 1913.

HOUSING OF THE WORKING CLASSES.

THE time of the House of Commons on Friday, April 18th, was devoted to a second reading debate on the Housing of the Working Classes Bill, introduced by Sir Randolph Baker. It is commonly known as the Boscawen Bill, for it is practically identical with the bill introduced by Sir Arthur Griffith-Boscawen last year as it was amended in Committee. The bill secured a second reading by a majority of 140, the minority against it being only 41. As was the case last year, the bill had to encounter the opposition of the President of the Local Government Board; but he did not divide the House against it, and, as Mr. Burns failed to put forward any constructive proposals of his own to deal with what was recognized to be an urgent need, it was evident that his attitude of opposition met with little sympathy in any part of the House.

A private member, however, cannot secure the passing of legislation which involves a charge on the Exchequer unless the Government of the day brings forward a resolution in the House authorizing the Treasury to supply the money required. The Boscawen bill would require a Treasury grant of £1,000,000—that is to say, £500,000 in respect of rural housing, and £500,000 in respect of urban housing; and, if Mr. Burns adheres to his expressed intention not to submit such a resolution, it is evident that the operative part of the bill in respect of making grants to local authorities to aid them in building schemes cannot be passed into law. Other parts of the bill which would secure amendment of other Acts and additional provisions may perhaps secure passage through the House as a shorter bill.

Sir Randolph Baker introduced, and Sir A. Griffith-Boscawen seconded, the bill, which was opposed by Mr. Neitson and Mr. Dundas White. Colonel Kyffin-Taylor, Chairman of the Housing Committee of Liverpool, supported the bill, as did Mr. G. Roberts of the Labour Party, Lord Henry Cavendish Bentinck, and others. Mr. J. Samuel opposed it, mainly on the ground that it was inadequate to deal with the needs of the case. Mr. Walter Long, whilst severely critical of the measure, gave it his general support, stating that he had come to recognize that State help was essential if local authorities were to deal with the question in any adequate manner.

The bill is founded mainly upon the Housing of the Working Classes Act, 1900, which is cited as the principal Act. The main alterations proposed with a view to enforcing the existing Acts are the provision of a special Housing Department of the Local Government Board and the appointment of three Housing Commissioners, one of whom must possess the qualifications of a medical officer of health; another must have had large experience, in rural areas, of the practical development and administra-

tion of working-class dwellings, and another, similar experience in urban areas. The Commissioners would be required to ascertain the needs and conditions of various districts, to co-ordinate the work of the various officers of the Board already employed in this work, and to assist local authorities by advice and information. They would annually make a report to Parliament on housing matters.

If it were shown that a local authority was culpably neglecting its housing duties, the Local Government Board, after application to the court, would be empowered to deal with slums and to provide the housing accommodation itself in place of and at the cost of the local authority. The bill would provide (Clause 6) for the relaxation of certain existing by-laws as applied to the new buildings erected, but it would be necessary that they should be constructed in accordance with plans approved by the Local Government Board. It further (Clause 10) would seek to prevent a slum owner from deriving additional compensation because the property to be dealt with was overcrowded, and yielded extra rental on that account. The bill proposes also that the Local Government Board should have power to make grants to a local authority to meet the deficiency arising out of any housing scheme up to, but not exceeding, four-fifths of the deficiency.

Though the bill as a whole cannot become law unless the Government alters its attitude and undertakes to provide the necessary funds, and though in the other event the prospects of the bill, even in a truncated form, are not very bright, yet the debate has shown a current of opinion in favour of legislation on these lines so strong and general that no Government will desire to disregard it. The debate has therefore served a very useful purpose, and marks a distinct step forward.

FRANCIS BACON ON MEDICINE.

In his *Treatise on the Advancement of Learning* Bacon has some remarks on the practice of medicine which are well worth attention even at the present day. He says the "variable composition of man's body hath made it as an instrument easy to dis-temper." The variability of the subject has, he goes on, made "the art by consequent more conjectural; and the art being conjectural hath made so much the more place to be left for imposture." He meets the gibes, so common even now, as to the fallibility of medicine with the following excellent argument: "The lawyer is judged by the virtue of his pleading and not by the issue of the cause. The master in the ship is judged by the directing his course aright and not by the fortune of the voyage." On the other hand, the physician, and perhaps the politician, has no particular acts demonstrative of his ability, but is judged most by the event, "which is ever but as it is taken; for who can tell if a patient die or recover, or if a state be preserved or ruined, whether it be art or accident?" By reason of this imposture often triumphs over knowledge. How little human nature has been changed by the greater enlightenment of which we are so ready to boast at the present day is shown by the following passage: "Nay, we see the weakness and credulity of men is such as they will often prefer a mountebank or a witch before a learned physician. . . . For in all times in the opinion of the multitude witches and old women and impostors have had a competition with physicians. And what followeth? Even this, that physicians say to themselves, as Solomon expresseth it upon a higher

occasion, 'if it befall to me as befall to the fools, why should I labour to be more wise?'"

Bacon noted in his day a feature of the medical character which is still conspicuous in many doctors—that is, versatility of mind and corresponding variety of interests. He says: "You shall have of them antiquaries, poets, humanists, statesmen, merchants, divines." Sir Henry Thompson, himself an artist of no mean skill, used to say that he had been struck by the number of collectors and connoisseurs in various lines that he met with among his professional brethren. We do not accept Bacon's further statement, that physicians are "in every of these better seen than in their profession, and no doubt upon this ground that they find that mediocrity and excellency in their art maketh no difference in profit or reputation towards their fortune; for the weakness of patients and sweetness of life and nature of hope maketh men depend upon physicians with all their defects." With all respect to the author of *The Advancement of Learning*, we venture to think that this is something more than paradox; it is perilously near nonsense. The public is a bad judge of a doctor's quality, and even when medicine was as conjectural an art as it was in Bacon's day a reputation for skill must have profited a practitioner, while a name for incompetence must have led patients to seek counsel elsewhere.

Among the "deficiencies" of the medical profession he particularly mentions what we not long ago called the waste of medical experience. He condemns "the discontinuance of the ancient and serious diligence of Hippocrates, which used to set down a narrative of the special cases of his patients, and how they proceeded and how they were judged by recovery or death. . . . This continuance of Medicinal History I find deficient; which I understand neither to be so infinite as to extend to every common case nor so reserved as to admit none but wonders; for many things are new in the manner which are not new in the kind; and if men will intend to observe they shall find much worthy to observe."

With Celsus he reprobates the vivisection of human beings, but goes on: "Yet in regard of the great use of this observation the inquiry needed not by him so slightly to have been relinquished altogether or referred to the casual practices of surgery; but might have been well diverted upon the dissection of beasts alive which notwithstanding the dissimilitude of their parts may sufficiently satisfy this inquiry." On the strength of a passage in *Cymbeline*, in which experiments with poisons are denounced, Shakespeare is often cited by the antivivisectionists as sharing their views on the subject. The contradiction on this point between him and Bacon, when speaking in his own name, may supply a new argument to those who think it worth while to spend time in a foolish controversy. Bacon further insists on the necessity of a multitude of *post-mortem* examinations and on the contribution of each practitioner's experience to the general sum of knowledge, with exact references to the diseases and symptoms shown by the appearances seen in the bodies of the dead, "whereas now upon opening of bodies they are passed over slightly and in silence."

Under the heading *Inquisitio ulterior de Morbis insanabilibus*, Bacon reproaches doctors with declining to treat many diseases as in their nature incurable and others as past the period of cure. In this way, he says, they "do enact a law of neglect and exempt ignorance from discredit." There is perhaps still some ground for imputing this to doctors as a

"deficiency." There is a suggestive passage in Sir James Paget's *Clinical Essays*—we cannot give the reference as we have not the book at hand—in which he urges practitioners to continue the fight against death even when the disease is by all the rules of art incurable. Bacon held that in certain cases euthanasia was not only justifiable but a duty to the patient. He says that doctors "ought both to inquire the skill and to give the attendances for the facilitating and assuaging of the pains and agonies of death."

Another "deficiency" which Bacon found in physicians was that they "have not partly out of their own practice, partly out of the constant probations reported in books, and partly out of the traditions of empirics, set down and delivered over certain experimental medicines for the cure of particular diseases besides their own conjectural and magistral descriptions. For as they were men of the best composition in the State of Rome which either being consuls inclined to the people or being tribunes inclined to the Senate: so in the matter we now handle they be the best physicians which being learned incline to the traditions of experience or being empirics incline to the methods of learning." He further complains that the "prescripts" in use are too compendious to attain their end. For he says, "it is a vain and flattering opinion to think any medicine can be so sovereign or so happy as that the receipt or use of it can work any great effect upon the body of man." In view of the amazing illustrations of polypharmacy presented by the prescriptions of the doctors of Bacon's own day and for some three centuries after his time, this complaint is not a little remarkable. One gathers that the doctors of his time very frequently changed their treatment, for he says: "And although a man would think by the daily visitations of the physicians that there were a pursuance in the cure; yet let a man look into their prescripts and ministrations and he shall find them but inconstancies and every day's devices without any settled providence or project. Not that every scrupulous or superstitious prescript is effectual, no more than every straight way is the way to Heaven; but the truth of the direction must precede severity of observance." Not a word is said of the horrible substances then in common use in therapeutics. It is curious also that there is no mention of surgery; Bacon had evidently not the faintest prevision that the art of healing would be so greatly advanced as it has been by the gradual reclamation by the surgeon's knife of the waste land which not long ago formed so large a part of the "conjectural art" of medicine.

THE ETIOLOGY OF MINER'S NYSTAGMUS.

MINER'S nystagmus, according to Llewellyn, causes an annual loss to the State of over £100,000, as well as an immense amount of suffering to the afflicted miners. The number affected appears to be increasing rapidly, and constitutes a serious charge upon the colliery owners for compensation and loss of labour, and a large loss of wages to the miners. The time is, perhaps, ripe for the appointment of a Royal Commission to investigate the etiology and methods of prevention of the disease.

The exact cause still remains a matter of opinion. At the Oxford Ophthalmological Congress last July miner's nystagmus formed the topic of a formal

discussion which was opened by Mr. Harrison Butler, who expressed the opinion that the prime factor in the etiology was the defective illumination of mines. This view was supported by Drs. Court, Coulter, Cridland, Elworthy, Jameson Evans, Folker, Llewellyn, McMurray, Norman, Ridley, Riseley, and Tomlin, and at the end of the discussion the opinion was unanimously expressed that defective illumination was the prime factor in the causation of the disease. The Congress also asked the Government to appoint a Royal Commission. It is obvious, therefore, that practically all the English medical men who have studied the subject are unanimously of the opinion that bad light causes the disease. The view was expressed that, were the use of an electric lamp made compulsory, miner's nystagmus would soon become a historical disease.

The facts which have led to this opinion are, briefly, that the disease is practically absent from candle mines, even in those in which the seams are as low as 18 in., and in which the coal getters have to work in exceedingly cramped positions; and that it is exceedingly prevalent in mines lighted by safety lamps, even in those with seams so high that the holers stand to their work, and do not labour in the cramped position which the late Mr. Simeon Snell believed to be the cause of the disease. These two facts seem to prove conclusively that illumination is the determining factor. They also logically exclude strain of the eye muscles as a prime cause, because the disease is common in mines where the colliers work standing up in comfortable and natural positions.

These views are not universally accepted upon the Continent. At the thirty-fourth Congress of the Belgian Ophthalmological Society, held last November, Dr. Dransart read a paper in which he strongly supported the theory that muscle fatigue was the prime factor, and he stated that all cases showed paresis of the external or internal rectus muscle, but generally, in fact almost always, of the internal. This has been pointed out by Ohm and others, and requires further investigation. In any case, paresis is the wrong word to employ; it would be better to speak of exophoria with Ohm, who has on three occasions advanced the internal recti with some measure of success. Coppez supported the same view, and stated that the graphic record of the nystagmus showed the same type of undulation as was obtained from a fatigued muscle with the myograph (incomplete tetanus). Benoit thought the disease was caused by the effect of the increased atmospheric pressure upon the labyrinth, causing hyperexcitability and labyrinthine nystagmus. Two vital objections can be offered to this hypothesis: the first is that miner's nystagmus gives an undulatory graph, *nystagmus à pendule*, whereas labyrinthine nystagmus is *à ressort*; and the second, that workers in deep metal or diamond mines never develop nystagmus. The question has often been asked, Why do some miners develop nystagmus whereas others escape? Dransart boldly says all the miners who develop the disease have exophoria—that is, insufficiency of the rectus internus. McMurray and many other English surgeons believe that a large number of nystagmic miners have errors of refraction. Some have gone so far as to say that all have some error of refraction. It appears to be a fact that an error of refraction is more frequently discovered among nystagmic miners than among non-nystagmics, but the investigations of Harrison Butler, Cridland, and others show that 100 per cent. is a very excessive estimate. A nervous temperament has been invoked

to explain the question, and probably with a considerable degree of truth.

The conclusion would seem to be that the disease is primarily caused by defective illumination, and that errors of refraction and muscle balance, associated in some cases or in all with a neuropathic diathesis, are the determining factors in the incidence of the disease. When it is borne in mind that Llewellyn has shown that the effective illumination of the ordinary safety lamp under service conditions is only one-tenth of that given by the miner's candle with spread-out wick, the importance of illumination will be better appreciated. The probable reason why Dransart and so many of the Belgian ophthalmic surgeons still cling to the myopathic theory is that there are no candle mines in Belgium, so that they have no personal proof of the fact that no matter how confined the seams nystagmus does not arise spontaneously in candle mines.

Since Dransart's paper was published an opportunity has been taken to examine three cases of miner's nystagmus. Tested with the Maddox rod at 20 ft., one of them had 6° of esophoria, and two of them orthophoria. Not one of the three had the paresis of the internal recti which Dransart says is practically always present. It would be well if all surgeons who see these cases were to make a special investigation of the muscle balance.

CHANGES OF DOCTOR BY INSURANCE PATIENTS.

It has been assumed by many practitioners that as the arrangements made between Insurance Committees and medical practitioners were for a provisional period of three months, insured persons at the end of that time would be allowed to make a fresh choice of doctor. In areas in which many doctors went on the panels before the abrogation of the pledge of the Association many insured persons, urged by the Local Insurance Committees, put their names down on the list of some doctor who had already joined the panel, although had there been time they would have preferred their own doctor whose name did not then appear there. These latter practitioners looked forward to an opportunity on April 15th to redress a grievance in which they have the entire sympathy of the Association. It appears, however, that the Insurance Committees are averse from approving any wholesale change, and, looked at from their point of view, and indeed from that of a large number of practitioners, the mere idea of what happened in the middle of January last coming over again even on a diminished scale would be most unwelcome. Some other means of redressing this grievance should be found, and we believe can be found.

Apart from the discomfort and extra work which it would entail, there is another reason why such a general reshuffle should not be lightly entertained by the medical profession. In many areas serious difficulties have arisen with regard to the treatment of uninsured persons, and various organizations have advertised for, and we are sorry to say, obtained, the services of practitioners who are willing to take the place of and undersell the practitioners of the area.

Attempts to introduce outsiders have in some areas failed because it was not possible to offer the imported practitioner the cards of a large number of insured persons who, if they had not already chosen their doctor, would, in their desire to defeat

the profession and get attendance for their dependants on cheaper terms, have been willing to select the imported practitioner as their insurance service doctor. In other districts where practitioners have been introduced, their financial position is rendered precarious by the difficulty just mentioned. It is probable that in such areas the profession would in self defence strongly object to a general fresh choice of doctor, and in considering the question this danger—a very real one in some districts—must be kept carefully in mind.

Wherever members of the profession in any area so desire it, however, it will not be difficult for them effectively to meet the case of those practitioners who declined to go on the panel until after the pledge was abrogated. This can be done by allowing them to place upon their lists at once all those patients who, had the delay been longer, would have placed their names there in the first instance. Regulation 26 (a) allows of a simple transference of any patient from one practitioner to another by mutual consent, and with no more trouble than the signing of a document by the patient and the two doctors concerned. This method has the merit of being entirely within the control of the profession itself, and for this reason it seems worthy of the serious consideration of the Local Medical Committees in every area when they have to deal with the position of members of the profession who, by their steadfastness and loyalty to the pledge of the Association, have suffered the loss from their lists of insured persons previously among their patients. This suggestion is made in full knowledge of the fact that the London Insurance Committee has thought fit to issue to persons who wish to be transferred from one practitioner to another a circular, in which it not only asks, as is provided by the regulation, for the written consent of the insured person and the two doctors concerned, but also that the insured person shall state his reasons for wishing to change. The natural inference from this demand is that the reason given must be approved by the Insurance Committee. There is nothing in Regulation 26 which gives an Insurance Committee a right to make any such demand. It looks almost as if the London Insurance Committee were trying to discourage changes in the medical list, and thus drive a coach and horses through the Act and Regulations. Not only is it illegal and unnecessary to impose on the insured person the obligation to state in a document of this kind the reasons for desiring a change, but it would be a most invidious proceeding for him, and he might quite conceivably fear that it might lead to difficulties not unconnected with the law of libel. The provision in Regulation 26 is a perfectly straightforward method of approximating the conditions of insurance practice so far as change of doctor is concerned to those of general practice, and it seems to be altogether improper for any Insurance Committee to seek to put unnecessary difficulties in the way. The State Sickness Insurance Committee so soon as the circular of the London Insurance Committee was brought to its notice decided to send a protest both to the Insurance Committee for the County of London and to the Insurance Commissioners. The terms of this protest are given in the report of the proceedings of the Committee published in the SUPPLEMENT this week. It is to be hoped that the Commissioners will at once require the London Insurance Committee to withdraw a circular which is not only mischievous, but, as we submit, clearly *ultra vires*.

THE ROYAL MEDICAL BENEVOLENT FUND.

THAT life is extremely uncertain even in the case of the young and apparently healthy is a very trite saying; but few observations of the sort become trite unless they are in essence both true and useful. Of the truth of this particular observation there is constant evidence even in our own obituary columns. In this week's issue, indeed, there is a notable instance in point. It is also a trite saying that virtue is often its own and only reward, and this, too, is not seldom demonstrably true. It is, indeed, again a truth to which our obituary columns this week bear testimony, recording as they do the death of a man who lived a life of utility both to his colleagues and the general public, before he had had an opportunity of making adequate provision for his family. At first sight it would seem as if members of the medical profession least of all men needed reminding of facts of this kind. Practical experience, however, suggests that either familiarity with accidents and death, and financial and other calamities due to sickness and ill health, produce in them a certain contempt, or that the circumstances of their lives prevent them paying due heed to such matters. However this may be, it remains true that medical men habitually take risks about their health such as in their patients they would utterly condemn; and that while many medical men make nothing more than just enough to cover the daily outgoings of a family, practically all are so occupied in looking after other people as to have little time to devote to their own private affairs. The net result is that it is by no means rare for members of the medical profession either to die leaving behind them wives and children for whom they have been unable to make any adequate provision, if indeed any provision at all, or practically to complete their professional career without having been able to set aside anything for the time of age and natural infirmity. Instances of such events are by no means rare in our own columns, and occur with lamentable iteration in the lists of those whom the Royal Medical Benevolent Fund has been able to assist during the previous few weeks or months. The position which that fund has attained has been recognized by His Majesty the King, who has recently accorded it the right to substitute the present for its original title, the British Medical Benevolent Fund. Further testimony has also been forthcoming from Prince Arthur of Connaught, who has agreed to take the chair at a dinner in furtherance of the objects of the fund at the Hotel Cecil next Wednesday, April 30th. It is a fund which grants assistance, so far as circumstances permit, to all medical men who are in distress from age or illness, as also to the widows and children of deceased medical men. It is therefore fully entitled to the support of British medical men wherever they practise, and should receive it plentifully, since the annual reports leave no doubt whatever that it is admirably managed by its committee, and more especially its officers—the president, Sir John Tweedy; the treasurer, Dr. Samuel West, of 15, Wimpole Street; the chairman, Dr. Parker Young; and the honorary secretary, Mr. W. E. Sargant, of St. Bartholomew's Hospital. On the financial side there is conclusive evidence to this effect in the fact that, despite the number of private inquiries which have to be made before assistance is given, the working expenses barely exceed 5 per cent. of the gross income. Those conversant with the administration of charitable enterprises need scarcely be told that this is a somewhat notable record. In regard to income, the authorities of the fund look to the medical profession itself in the first instance; but they also consider that the fund has a claim upon the public, which can never pretend that it acquits its full debt to the medical profession by payment of the fees demanded by individual medical men. This is a point worth bearing in mind, for, besides assisting the fund by

donations and subscriptions, small or large, medical men can also attempt to assist it by mentioning its existence to their wealthier patients. Sundry items in the accounts furnished in the annual reports suffice to prove that when such attempts are made the members of the public approached often prove glad that a form of charity in which they can take a real interest has been brought to their notice. To recur once more to the dinner next Wednesday, it should be noted that, of the many ladies expected, some will be present in a kind of official capacity. This is due to the fact that the experience of the fund convinced it some three years ago that personal service by ladies would be of great advantage in its work. A guild was brought into existence, which now has branches scattered all over the United Kingdom, and conducts its highly successful work on a semi-independent basis. On its general council, which has as president the Dowager Lady Broudbent, are the wives of many well-known medical men; while its executive committee has as chairman Lady Tweedy, other officers being Mrs. H. D. Rolleston, Mrs. Liveing, and Mrs. Garrod. The honorary treasurer is Mrs. Scharlieb, and the visiting secretary Mrs. Fuller. The members of this guild, apart from collecting funds, make a regular practice of visiting and assisting in many practical ways those who are beneficiaries of the fund. They do such excellent work that the foundation of the Royal Medical Benevolent Fund Guild must be regarded as one of the happiest thoughts that have ever occurred to the authorities of the parent body.

THE TITLE OF DOCTOR.

By long use and wont the title of "doctor" has come to be almost universally applied by the public to all practitioners of the healing art whether their qualification to practise be derived from a university or a chartered corporation. The same custom exists in other countries, but nowhere else, perhaps, is the word so generally used, both in a collective and particular sense—both for the members of the profession as a body, and for individuals. The Royal College of Physicians of London, by the alteration recently made in its by-laws, has recognized this fact. Formerly it forbade a diplomate to make use of the title of "Doctor"—to call himself "Dr. —" on a door-plate or visiting card—unless, of course, he possessed a doctor's degree from a university. Many Licentiates have been at a good deal of pains to carry out the spirit of the regulation by trying to induce the public not to apply the title to them. The effort has for the most part left the public puzzled and indifferent, and the use of the title by it has become more rather than less common. Under its amended regulation, the Royal College of Physicians will no longer require its diplomates to refrain from the use of the title of "Doctor," recognizing that it has acquired an occupational significance. It will, of course, not countenance the use of the letters "M.D." or of any locution, such as Doctor of Medicine, which has an academic or university signification, for it does not under its charters possess the right of conferring a degree. The by-law, as it was finally adopted at the meeting of the College on December 12th, 1912, was published in the *JOURNAL* of December 21st, p. 1734. The alteration is shown by the words in italics which have now been omitted: "No Fellow, Member, Extra-Licentiate, or Licentiate of the College shall *assume the title of Doctor, or append to his name the title of Doctor of Medicine, or the letters M.D., or any other letters indicating that he is a graduate of a university, unless he has obtained a degree entitling him so to do.*"

TOWN PLANNING ACT AT WORK.

To those who are concerned with the improvement of the housing conditions of many of our towns it is provoking to reflect that many of their difficulties have been caused by

the haphazard manner in which, within quite recent years, streets have been laid out and houses have been erected. Existing highways, whatever their width or however tortuous they may have been, have been built upon without any thought of the effect to be produced in the future. The result has been that whole streets have had to be widened and dangerous corners rounded off at very considerable cost. One of the objects of the Housing, Town Planning, etc., Act, 1909, was to prevent a repetition of the errors of past years, and by enabling local authorities to prepare anticipatory schemes with respect to "any land which is in course of development, or appears likely to be used for building purposes, to secure proper sanitary conditions, amenity, and convenience in connexion with the laying out and use of the land and of any neighbouring lands." When a local authority desires to carry out this provision of the Act, the first step is to obtain the consent of the Local Government Board to the preparation of a suitable scheme: and, the scheme having been prepared, it must receive the approval of the Board, who may either modify it, or impose such conditions with respect to it as may be considered desirable. Several local authorities have already been authorized to prepare schemes, including the corporations of Birmingham, Bournemouth, Chesterfield, and Rochdale, and the urban district councils of North Bromsgrove, Oldbury, and Ruislip-Northwood. The scheme of the last-named authority has, we believe, reached a more advanced stage than that of the others, and a local inquiry on behalf of the Local Government Board was opened on April 17th. The area concerned surrounds the Ruislip Manor estate, which is to be laid out on garden city lines by a company whose dividends are limited to 5 per cent.; any surplus profits, after making provision for proper reserves, must be devoted to the purchase, provision, and maintenance of parks, pleasure grounds, open spaces, and public buildings. The entire area to be covered by the two schemes is nearly ten square miles in extent. The district is served by no fewer than six railway stations, from which London may be reached in from eighteen to forty minutes, so that there is a good prospect of the development schemes being successful. The main features of the district council's scheme include new and improved lines of road connecting the estate with the railway stations, main roads, and other approaches to the neighbouring towns and villages and towards London; the allocation of certain areas for special purposes or different classes of buildings, such as shops, private dwelling houses, factories, etc., in order to protect the residential amenities; the provision of open spaces, both public and private, and the limitation over the whole district of the number of houses to be placed on a given area. It is anticipated that the maximum number of houses to the acre will be twenty, and that in many instances there will not be more than eight or ten. It is thought that while the indiscriminate mixing of large and small houses is not desirable, a judicious proportion of medium-sized houses may be distributed among the larger ones without depreciating the value of the latter, and that provision should be made in special areas for housing the working classes employed in connexion with the larger houses. The housing accommodation for the working classes at present existing is quite inadequate, and an effort at improvement is being made by the formation of the Ruislip Manor Cottage Society, which as a public utility society can obtain two-thirds of the cost of erecting houses from the Public Works Loan Commissioners. This society has already approved schemes for building 150 small houses, which can be let at rents varying from 6s. to 15s. a week. The tenants will be entitled to share in the surplus profits in addition to interest on any moneys they may invest in the society. Unlike many other similar profit-sharing schemes, there is provision for the acquirement of his house by a tenant, who will be required

to make an initial payment of from £25 to £100 and an annual payment equal to the rental.

THE PROFESSION OF THE FUTURE.

THE philosopher Descartes said that if the human race is to be perfected it is in medicine that the means to that end are to be found. Diderot, who, though not a member of the profession, took a great interest in the science, and wrote much about it and physiology, was even more persuaded of the truth of Descartes's maxim than that philosopher himself. He found the means of perfection in disinterested medicine. Here we may be allowed to say that, although of course there have been rapacious doctors, the profession as a whole, especially in modern times, has shown the world the unique spectacle of a body of men actually working against their own interests. Sanitary science, whose aim is the protection of the health of the community and the steady diminution and ultimate abolition of infectious diseases, is the result of medical research. If doctors consulted only their own selfish interests, they would not strive so earnestly as they do to suppress diseases that are so abundant a source of profit. People of the intellectual calibre of Viscount Harberton, better known as the Hon. Ernest Pomeroy, call doctors "fee hunters" because they advocate vaccination. Has this ornament of our hereditary legislature attempted to estimate how much more medical practitioners would benefit financially if small-pox were as prevalent as it used to be in pre-Jennerian days? To return to Diderot, he was probably inspired by the great physician Borden. He said there were no books that he read more willingly than those treating of medicine, no men whose conversation was more interesting to him than that of doctors. He had grasped the importance of the experimental method and had by scientific second sight seen the shadows cast before by physiological discoveries which were to be made by that method long after his death. Mr. Stephen Paget in the *Letters and Memoirs* of his distinguished father relates that Sir James Paget one evening at Grillon's sat between Mr. Gladstone and Mr. Matthew Arnold. The talk turned on professions. Arnold said that he had been much impressed in America by the superiority of the doctors over the clergy and the lawyers. Mr. Gladstone said that the medical profession, steadily developing and improving, was the profession of the future. This is not the only time that Mr. Gladstone expressed his belief in the great destiny of the medical profession. At the opening of the Medical College of Guy's Hospital on March 26th, 1890, he said that now, both from social considerations and likewise from the immense and steady advance in knowledge of his great science, the doctor was from year to year, from generation to generation, becoming a more powerful and important person as a portion of the social machine. Nor was this a mere outburst of enthusiasm inspired by the occasion. Many years before, at the dinner held in connexion with the Annual Meeting of the British Medical Association in London in 1873, Mr. Gladstone spoke of the change that increase of knowledge had made in the medical profession. It was impossible, he said, even to an observer from without, not to see the doctor's greater and more sustained earnestness of purpose; the elevated sense of his professional dignity; the desire to make it subservient to the good of humanity; the general exaltation of his aims. He added that the course of affairs tended in every way to show that this process was continuous. The position of the profession had long been, and he thought must continue to be, one of constantly increasing influence and power. Mr. Gladstone's testimony to the growing importance of the profession is all the more striking in view of the fact that he never seems to have realized that the public health was any concern of the politician; even his intimate friend,

Sir Henry Acland, could not arouse in the man whose intellectual curiosity was of the most encyclopaedic range any interest in a thing which should be among the first cares of a statesman. But, although his prophecy has not yet been fulfilled, we think that in his vision of the profession of the future Mr. Gladstone showed a surer appreciation of the truth than some of the politicians into whose hands the divine lyre of his oratory has degenerated.

SALVARSAN AND EPILEPTIFORM CONVULSIONS.

LAST year there was an important discussion in the Berlin Dermatological Society¹ on a paper by Dr. Fritz Lesser entitled "Epileptiform Convulsions following the Administration of Salvarsan." A number of instructive points were raised by various speakers with regard to the complications, and in some instances the fatal results, following salvarsan, and the general trend of the discussion was critical. In his concluding remarks Lesser said that he had collected 18 cases of epileptiform convulsions which he had divided into two groups: 12 in which the attacks occurred from three to five days after the intravenous injections, and 6 in which the attacks were observed nine weeks or more after the injection. He has since reported that the cases in which acute attacks had followed salvarsan have doubled in number, and has expressed the opinion that they are more common than was thought. Some cases of this kind must pass unrecognized. In those instances in which the attacks occurred suddenly three to five days after the intravenous injection, and were similar in character, they could only be referred to a single toxic agent. He pointed out, too, that of the 18 cases mentioned in his paper recovery occurred in 2 only. Necropsies revealed mostly a lepto-meningitis, less commonly of a haemorrhagic nature. This may be compared with the experimental results of Marschalko, who observed meningeal haemorrhages after injecting salvarsan in animals. Nor did F. Lesser accept the Herxheimer reaction as an explanation of the convulsions. The fact that in half his cases the attacks only occurred after the second intravenous injection was greatly against such an explanation. How to avoid complications was, he considered, difficult to decide. If small doses were injected nervous symptoms might occur, and if the doses were too large epileptiform convulsions might result. Nor could he accept Ehrlich's view that in cases presenting malaise, headache, and so forth, small doses only of salvarsan should be injected, as such symptoms indicated the presence of spirochaetes in the brain. Lesser had shown, on the other hand, that epileptiform convulsions had occurred in patients who had not presented any such symptoms before the injection. In conclusion he pointed out that it was necessary not to be hasty in employing salvarsan. A complication or accident following the exhibition of salvarsan in the primary and early stages of syphilis might be justified by the fact that an attempt at a *therapia sterilisans magna* had been made. He insisted on the value of salvarsan when used in such circumstances, but it was quite another matter to employ the drug in other stages merely because the Wassermann reaction happened to be positive.

OFFENSIVE DRINKING WATER.

RECENTLY in certain districts the water supplied by the Metropolitan Water Board has not been up to the usual high standard so far as taste and smell are concerned. About the middle of February isolated complaints were made as to the taste and smell of the water. These complaints would seem to have been dealt with effectively, and all went well for some three weeks, but then a large crop of complaints, much more widespread and serious, arose. All sorts of allegations were made about the water: it was said to taste oily, or like paraffin, or to

¹ *Verhandlungen der Berliner dermatologischen Gesellschaft* (1911-1912). Berlin: Karger, 1913.

smell fishy. No doubt there was just cause for complaint and some reason for fear lest the cause of the disagreeable odour and nasty taste might be injurious to health. There was a feeling of relief when the Water Board authorities were able publicly to state that the water, although disagreeable, was not dangerous to health. The Board's officers grappled with the question energetically and decisively, and soon the scare was over. For the last month the water has flowed as clear and sweet as of old. We understand that the source of all the trouble was the water from the Staines reservoir. This great reservoir, which has a site-area of 500 acres and a total capacity of 3,338 million gallons, was constructed by the water companies interested, and the inlets and outlets were placed in the same tower. The circulation of the water throughout the vast area was thus rendered physically impossible. Moreover, the water began to be taken in on May 16th, 1902, and was allowed to lie without being drawn until December, 1904. This stagnation gave the various forms of algae a splendid opportunity to grow, decay, and sow the seed of future trouble. Even public bodies learn by experience, and we believe that not only have steps been taken to ensure circulation of the water in the Staines reservoir, but in all the new reservoirs devised by the Water Board the utmost care is taken to have a full and free circulation throughout their whole extent. Staines under the circumstances afforded a habitat favourable to the growth of algae, and water from this reservoir carrying these plants found its way to the filters. There these organisms formed a skin on the surface of the sand, decomposed, and gave rise to the odour and taste complained of. The particular algae which have been detected are tabellaria and asterionella, the former being in larger number. Both of these growths produce taste and smell in water, and their presence would account for the condition of the water during the period of which we speak. In America these algae, flowerless plants of simple cellular structure, have given a great deal of trouble, and the scientists in that country have fought these insignificant but disagreeable organisms energetically and with considerable success. There can be no doubt that those who have the charge of caring for the quality of the water supplied to London, as well as those in a like position throughout the country, are quite up to date with the best methods of dealing successfully with these growths, so that we may hope that this somewhat exceptional experience will not recur. It is also a matter for thankfulness that, so far as we know, algae or their products do not give rise to disease; indeed, it is highly probable that if those who drank the water and justly complained of it had not been endowed with taste and smell, they would have drunk the water without being a penny the worse.

SCHOOL DENTAL CLINICS.

THE term "school dental clinic," though still comparatively novel, has been used so frequently in connexion with medical inspection of elementary schools during the last year or two that probably many people are under the impression that institutions of the class to which the phrase is now commonly applied came into existence for the first time as a consequence of the Elementary Education (Administrative Provisions) Act, 1907. This, however, is not really the case; there were school dental clinics in existence long before the passage of that Act. As far back as 1897 the Local Government Board issued a formal Order authorizing the appointment by boards of guardians of dental officers to attend to the teeth of the children in Poor Law schools, and laid down the main principles on which the work should be done. Over ninety boards of guardians in London and the provinces sooner or later took advantage of the permission granted, and still maintain the school dental clinics established by them. Even before this date the Local Government

Board had agreed to sundry boards of guardians undertaking work of the same order on behalf of the children under their charge, and some of these have had dental clinics at work ever since 1892. Such clinics have also been maintained for a good many years at practically all the reformatory and industrial schools under the control of the Home Office. A complete list of these, as also a good deal of information on the whole subject, may be found in the second edition of a pamphlet¹ published by the School Dentists' Society. The latter, which came into existence some fourteen years ago and had as first president Mr. Sidney Spokes, was the offspring of a committee appointed by the British Dental Association in 1890 to investigate the dental condition of the elementary school population. This committee in its turn was largely indebted for its existence to the energies of Mr. W. MacPherson Fisher of Dundee, who, we believe, should be credited with being the first person publicly to recognize the importance of the whole question and to endeavour to direct attention to it. At the annual meeting of the British Dental Association in 1885 he read a paper contending that the teeth of a child required, and should receive, precisely the same degree of care as any other part of its body. Every child's mouth, he argued, should be examined and treated at the beginning of school life, and subsequently at least once a year, or oftener. At further annual meetings Mr. Fisher returned to the subject, and in 1888 secured the passage of a resolution by which the association agreed to make a grant for the purpose of providing case-books wherein any of its members willing to take the trouble could record their observations of the teeth of school children, and thus either corroborate or refute the statements made by Mr. Fisher in regard to the disastrous condition of the teeth of the children of the nation. The net outcome was the appointment in 1890 of the committee which has been mentioned.

NOGUCHI'S CUTANEOUS LUETIN REACTION.

WHEN Noguchi found that the *Spirochaeta pallida* could be grown in pure culture it was an easy step to develop a skin reaction for syphilis analogous to von Pirquet's test for tuberculosis. Noguchi's test emulsion is called luetin. It is an extract of the cultivated *Spirochaetae pallidae* killed by heat and carbolized with 0.5 per cent. phenol. The control emulsion is similar, but has not been inoculated. In the *Archives of Ophthalmology*, January, 1912, Dr. Cohen of New York describes the method of using luetin and the nature of the reaction. The emulsion is drawn into a syringe with a fine sharp needle, and one drop is injected not under, but into, the skin of the arm. A drop of control is injected into the opposite limb at a corresponding spot. In *non-syphilitic* cases the results are as follows: on both sides there is no inflammatory reaction, and all signs disappear in forty-eight hours. In *syphilitic* cases a characteristic series of changes occur at the site of the luetin injection. There first appears in from six to twenty-four hours, or even later, a papule surrounded by a bluish-red halo. The papule grows, and the halo vanishes. The papule, which is from 5 to 10 mm. in diameter, develops in the majority of cases a central area of suppuration which eventually ruptures. A sero-purulent fluid escapes, and there is denudation of the contiguous epidermis, and a hypertrophic condition of the skin supervenes, which may last for some months. Noguchi finds that this pus is uniformly sterile. The control injection generally causes no reaction, but in a small number of cases the appearances resemble the luetin reaction, except that no hypertrophy of the skin follows. Cohen, as the result of the application of the test to 60 cases, found that in 76.6 per cent. the luetin reaction corresponded either

¹ *The School Dentists' Society: Objects and Aims*. Second edition, 1913. Watford: Published for the Society by W. Michael and Son. (Crown 8vo. pp. 113. Price 1s. net.)

with clinical evidence or with the result of a Wassermann test, and in 23.5 per cent. it did not so correspond. The cases which did not correspond fall into two categories: in the one, despite the old infection of syphilis, the clinical and serological evidence could not be found at the time of making the luetin injection. These are latent cases of syphilis, and the detection of the disease is highly desirable and yet difficult. In the other group the activity of the disease is so strong that the patient is incapable of acquiring the anaphylactic condition necessary for the reaction. The test will probably be greatly improved, and may become a valuable aid to diagnosis. It has in 170 cases proved harmless.

TREATMENT OF THE TYPHOID CARRIER.

A CASE of chronic typhoid intestinal carrier cured by the administration of an autogenous vaccine is reported by Drs. Donald H. Currie and F. H. McKeon.¹ A somewhat similar case was reported in 1911 by Major R. W. Clements and Captain A. Dawson, R.A.M.C.² In this case the man had been inoculated against typhoid fever in April, 1909. In September, 1909, he was admitted for typhoid fever, which proved to be a mild attack, but left some pain over the region of the gall bladder. At the Enteric Convalescent Dépôt he was found to be a chronic "intestinal carrier." In February, 1910, an autogenous vaccine was prepared; six injections were given, beginning with a dose of 125 million, increased later to 600 million. The last injection apparently produced an acute attack of cholecystitis, which, including a relapse, lasted over a month, but afterwards the bacilli could not be isolated from the stools. Owing to the grave risk of carriers spreading disease among the troops a subcommittee of the Army Medical Advisory Board was appointed to investigate the treatment of typhoid carriers; but unfortunately, in spite of a great deal of work, no satisfactory solution was found. The Army Council has ordered that unless a "carrier" elects to remain in hospital for further treatment he is to be invalided out of the service after a period of three months' observation in England. The subcommittee classified carriers into four groups: (1) Pure intestinal carriers; typhoid bacilli are only excreted in the faeces. (2) Urinary cases; typhoid bacilli are only excreted in the urine. (3) Intestinal cases with symptoms of inflammation of the gall bladder; typhoid bacilli are excreted in the faeces, but obviously have a focus in the gall bladder. (4) Mixed intestinal and urinary cases; typhoid bacilli are excreted in both urine and faeces. Cases belonging to this last group are apparently exceptional. There is a good deal of evidence to show that the typhoid bacilli are discharged from some necrotic patch or abscess cavity which may be situated in the liver, gall bladder, intestine, kidney, or urinary passages. This explains the difficulty of effecting a cure, since any remedial agent introduced into the circulation is prevented from coming into contact with the growing typhoid bacilli by the surrounding mass of necrosed tissue. Various forms of treatment have been tried.³ Two intestinal carriers were treated with cultures of the Bulgarian lactic acid bacillus grown in sterile diluted malt extract. The daily dose was at first only 25 c.cm., but in the course of three months it was raised to 300 c.cm. daily. In one case the effect was to reduce temporarily the number of typhoid bacilli excreted in the stools; in the other the typhoid bacilli disappeared, apparently permanently. Experiments *in vitro* showed that the resistance of the strain of typhoid bacilli excreted by the first man to lactic acid bacilli was much greater than of that excreted by the second man. In other cases antityphoid vaccine was used. The treatment was begun with the ordinary prophylactic vaccine, using a dose of 400 to 500 million, which was very soon increased to

1,000 million; the injections were given at intervals of a week to ten days. After some five to six injections, as there were no signs of improvement, an autogenous vaccine was prepared and used for each case. Unfortunately, this did not have any effect in reducing the excretion of typhoid bacilli. Antiseptic treatment has also been used. In one case a reduced diet was tried, together with the administration of urotropine and castor oil. It reduced the number of bacilli from 470 million per gram of faeces to 2 million in the course of a week, but the man's general health suffered, and he refused to continue the treatment. Two days after his return to ordinary diet the typhoid bacilli had increased to 212 million per gram of faeces. Capsules containing cyllin were tried, but did not influence the excretion of bacilli. Medical izar oil (six minims in two ounces of an emulsion four times a day) seemed to exert a favourable influence, but the patients objected strongly to the drug and refused to continue the treatment. In one instance, an intestinal carrier, the area of the gall bladder was x-rayed three times a week, ten exposures altogether being given. During the treatment and for three weeks after it no typhoid bacilli were found in the stools. The bacilli then appeared again; after a fourth course of x rays no more bacilli could be found. It must, however, be noted that this patient was an intermittent carrier, his stools having been on one occasion free from typhoid bacilli for six weeks. The application of x rays over the kidneys was tried in a urinary carrier, but without effecting any permanent benefit. It has been determined by experiment that the typhoid bacilli cannot grow in a medium the acidity of which is +50; an attempt was therefore made to increase the acidity of the urine of two urinary carriers artificially by administering benzoate and acid phosphate of soda. It was found impossible to maintain the high acidity of the urine. Urotropine also failed to influence the excretion of typhoid bacilli in a urinary carrier. Niepratsek⁴ reported an instance in which a chronic urinary carrier was apparently cured by borovertin, 1 to 1.5 grams, six times a day. This drug is hexamethylenetetramine trihydrate, urotropine being hexamethylenetetramine. Irwin and Heuston in a chronic female urinary carrier tried urinary antiseptics, and then autogenous vaccination; finally, under sodium lactate the urine became clear and the excretion of typhoid bacilli finally ceased.

THE TROPICAL DISEASES RESEARCH FUND.

THE report of the Advisory Committee for the Tropical Diseases Research Fund for the year 1912 has been issued. In noticing the report for 1911 we gave some account of the constitution, objects, and resources of this fund, and it will be sufficient now to recall that the income of the committee consists of grants from the Imperial Government, the Government of India, and from the governments of certain dominions and colonies. The total amounted last year to £3,245. The fund was expended in grants to the London and Liverpool Schools of Tropical Medicine and the Universities of London and Cambridge. The amount so expended exceeded receipts by £588, and the schools of tropical medicine are warned that the grants for this year must be reduced. The report has seven appendices. The first contains reports of antimalarial measures in the Crown colonies and protectorates; the second and third are reports from the Professor of Protozoology in the University of London, and from the Director of the Quick Laboratory, Cambridge; the fourth and fifth are reports from the London and Liverpool Schools of Tropical Medicine respectively; the sixth consists of reports of work done in the colonial laboratories, and the committee expresses regret that these are not so numerous nor so complete as in former years, but at the same time

it is satisfied that excellent work is being carried out in these laboratories, and trusts that it may be found possible in future to increase the opportunities afforded for research work in the colonies. Among these reports are two on the work done at the Institute of Medical Research, Kuala Lumpur, Malay States, covering the period from October, 1911, to September, 1912, and dealing, among other matters, with the causation of beri-beri by polished rice. The importance of the matter to the States is shown by the statement of Dr. Fraser, the director of the laboratory, that in 1911 there were admitted into the Government hospitals of the Federated Malay States 5,340 cases of beri-beri, of whom 695 died. The patients were almost all Chinese, of whom there are 433,244 in the Straits Settlements. The deaths from this disease in 1911 numbered 2,056, as against 1,737 in the previous year. An alcoholic extract prepared from "polishings"—that is to say, material rejected in the process of polishing rice—was prepared, and it was found valuable both as a curative and prophylactic agent in fowls. The seventh appendix is a report by Captain Potter, R.A.M.C., on vomiting sickness in Jamaica. The general conclusion is that the term "vomiting sickness" should be abandoned, as the majority of deaths ascribed to it are due to yellow fever.

A HUMAN AQUARIUM.

AN interesting though somewhat nauseating account is given by Dr. W. Sternberg¹ of a French circus artiste named Norton, whose gastronomic feats were discussed by Dr. Paul Farez in the *Revue de Psychothérapie*. One of Norton's performances is the swallowing of 5 to 7 litres of water at one draught, and the expulsion of the fluid by the mouth, either in a fine jet or in a torrent, as the showman may direct. The performer experiences no discomfort or nausea while playing the part of an ornamental fountain, nor does he mind retaining the water for an indefinite period. This performance alone is worthy of our close attention and of the pennies of side-show patrons; though it is merely the starting-point for yet more wondrous feats. Having taken some water, Norton swallows five to ten living frogs, and reproduces them still alive after a short sojourn in his belly. The disappearance of a live frog down the artiste's gullet, and the reappearance of the frog's legs between his lips before it is finally removed in triumph from his mouth, produce those thrills and sensations among the spectators which it is the aim of the successful showman to evoke. Another successful "turn" is the swallowing of ten frogs, followed by as many goldfish, whose susceptibility to changes in their environment is well known. Yet, at the showman's command, they reappear none the worse for their pilgrimage. It is a curious fact that, though the frogs are swallowed first, they are also the first to reappear. The goldfish must consequently have passed them somewhere in the stomach. The fluid ejected at will is perfectly clear and contains no mucus. In this fluid the artiste washes the frogs before they and the goldfish start on their downward journey; and in it, too, he washes his hands at the end of a performance. By swallowing a couple of electric lamps he is able to display the frogs and goldfish swimming about in their unfamiliar lodgings; and, this, we take it, is the culmination of a performance evidently warranted to draw. Norton is a healthy, powerfully built man of 35, whose organs, apart from his stomach, are said to be normal. No dilatation of the oesophagus or stomach is demonstrable by the *x* rays, and except for its wonderful elasticity and capacity for voluntary contractions the stomach itself presents no abnormalities. Norton's father and grandfather could also drink large quantities of fluid and expel it at will; but only in the third generation does this heirloom appear to have been converted into a source of revenue.

MEDICAL OFFICERS OF HEALTH SUPERANNUATION BILL.

At the sitting of the House on Friday, April 18th, the second reading of this bill was deferred, as the whole time of the House was occupied in discussion of the Housing Bill. Some of the promoters of this measure do not perhaps fully realize the procedure of the House in connexion with bills of this character. The supporters of the bill were unfortunately not successful in obtaining a place in the ballot which insures discussion of the measure on one of the available Fridays, and without this opportunity it is open to any member of the House, by simply saying "I object," to prevent the second reading of such a bill if Government time has not been allotted to it. The only way to secure a second reading for the bill is for its supporters regularly to note those who object and seek to remove the ground of their opposition by personal explanation and by a systematic campaign for its support amongst members. Unless this kind of thing is regularly done, private bills which are unfortunate at the ballot have very little chance of securing a second reading.

SOME HEATING AND VENTILATING PROBLEMS.
